Results: BNT162b2 mRNA vaccine-received 289 RD patients {mean age 66.9 [standard deviation (SD), 12.6] years; 241 females and 48 males} and 33 controls (mean age 70.7 [SD, 7.8] years; 22 females and 11 males) were mainly analyzed. Anti-S IgG values markedly increased in both groups at M1 [CG; 9751.5 (2385.3 – 21506.1), RD; 2300.8 (188.5 – 7671.7) AU/mL, expressed as median (25th to 75th percentiles)], subsequently decreased, and were significantly lower in the RD group than in the CG at all time points [CG; 5012.2 (2933.3 – 6628.4), RD; 1505.0 (459.0 – 3229.0) at M3, CG; 1353.6 (505.8 – 1910.3), RD; 402.0 (130.5 – 836.2) at M6]. Regarding antibody positivity, all patients in the CG tested positive at all time points. The antibody positivity rate was significantly lower in the RD group (85.0% at M1, 92% at M3, 86.4% at M6). In comparisons by disease, anti-S IgG values were significantly lower in patients with rheumatoid arthritis, systemic lupus erythematosus, vasculitis and dermatomyositis/polymyositis. In comparisons by treatment, anti-S IgG values were significantly lower in patients receiving rituximab [8.9 (5.8 – 68.2) at M1, 51.7 (26.4 – 144.0) at M3, 45.3 (23.1 – 67.4) at M6], mycophenolate mofetil [258.4 (1.1 – 713.7), 395.1 (18.0 – 2096.1), 212.3 (14.2 – 458.9)], cytotoxic T lymphocyte-associated antigen 4-immunoglobulin (CTLA4-Ig) [336.8 (33.5 – 1166.7), 324.9 (111.2 – 480.6), 84.0 (37.9 – 118.7)],

and prednisolone (PSL) [449.4 (26.3 – 2920.1), 709.6 (135.3 – 2008.5), 201.4 (44.7 – 602.5)]. A multivariate analysis with a linear mixed model indicated that there was a significant inverse association between age and the extent of changes in anti-S IgG values from M1, indicating greater decreases in antibody values at an older age from M1 [-75 (-133 – -18), expressed as regression coefficient (95% confidence interval)]. The extent of the decrease in anti-S IgG values was also significantly greater in males [-1873 (-3604 – -142)] and patients treated with PSL [-2071 (-3590 – -551)], CTLA4-Ig [-4018 (-6606 – -1429)], TNF inhibitors [-2009 (-3861 – -157)], and IL-6 inhibitors [-2422 (-4488 – -355)]. Adverse reactions were similar in both the CG and RD group.

Conclusion: These results showed that SARS-CoV-2 mRNA vaccination is effective and safe in patients with RD treated with a variety of immunosuppressants. However, even following the ACR guidance on withholding dugs, anti-S IgG values were lower and significantly decreased over time depending on disease and immunosuppressive drugs. Therefore, relative short-term repetitive vaccination might be warranted in patients with RD receiving immunosuppressive drugs.

CLINICAL CHARACTERISTICS OF SARS-COV-2 INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN ARGENTINA: DATA FROM THE SAR-COVID NATIONAL REGISTRY

Keywords: COVID, Systemic lupus erythematosus

C. A. Isnardi[1], K. Roberts[1], Y. Tissera[2], I. Petkovic[2], G. Berbotto[2], C. Gobbi[2], R. Tanten[2], A. K. Cogo[2], C. Asnal[2], A. R. Baños[2], F. Vivero[2], M. Schmid[2], M. A. Lazaro[2], N. German[2], L. Takashima[2], J. Scafati[2], M. L. Werner[2], L. Casalla[2], S. S. De la Vega Fernandez[2], D. Castrillon Bustamante[2], F. Rodriguez[2], S. Moyano[2], M. L. Martin[2], V. Cosentino[2], N. Herscovich[2], E. R. Tralice[2], T. Barbich[2], D. L. Vasquez[2], E. Buschiazzo[2], P. Maid[2], C. Ledesma[2], V. Yohena[2], G. Gómez[1], R. Quintana[1], G. Pons-Estel[1]. [1]*Argentina Society of Rheumatology, Research Unit, Buenos Aires, Argentina*; [2]*Argentina Society of Rheumatology, On behalf of the SAR-COVID Registry, Buenos Aires, Argentina*

Background: Patients with systemic lupus erythematosus (SLE) present greater severity of SARS-CoV-2 infection compared to the general population, particularly those with glomerulonephritis and who are treated with glucocorticoids. Likewise, high disease activity and some immunosuppressants have been associated with worse outcomes.

Objectives: To describe the characteristics of SARS-CoV-2 infection in patients with SLE in Argentina from the SAR-COVID registry and to establish factors associated with a worse outcome.

Methods: Observational study. Patients diagnosed with SLE with confirmed SARS-CoV-2 infection (RT-PCR and/or positive serology) from the SAR-COVID registry were included. Data was collected from August 2020 to March 2022. The outcome of the infection was measured using the World Health Organization - ordinal scale (WHO-OS). Severe COVID-19 was defined as an WHO-OS value ≥5. Descriptive analysis, Student's T test, Mann Whitney U, ANOVA, Chi2 and Fisher. Multiple logistic regression.

Results: A total of 399 patients were included, 93% female, with a mean age of 40.9 years (SD 12.2), 39.6% had at least one comorbidity. At the time of infection, 54.9% were receiving glucocorticoids, 30.8% immunosuppressants, and 3.3% biological agents. SARS-CoV-2 infection was mild in most cases, while 4.6% had a severe course and/or died. The latter had comorbidities, used glucocorticoids and had antiphospholipid syndrome (APS) more frequently and higher disease activity at the time of infection. In the multivariate analysis, high blood pressure (OR 5.1, 95%CI 1.8-15.0), the diagnosis of APS (4.7, 95%CI 1.2-15.8), and the use of glucocorticoids (10 mg/day or more: OR 5.5, 95%CI 1.6-20.5) were associated with severe hospitalization and/or death from COVID-19 (WHO-EO≥5).

Conclusion: In this cohort of SLE patients with confirmed SARS-CoV-2 infection, most had a symptomatic course, 22.1% were hospitalized, and 5% required mechanical ventilation. Mortality was close to 3%. The diagnosis of APS, having high blood pressure, and the use of glucocorticoids were significantly associated with severe COVID-19.

FREQUENCY OF DISEASE FLARE AND ITS RISK FACTORS FOLLOWING TWO-DOSE OF COVID-19 VACCINATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Vaccination/immunization, Rheumatoid arthritis, Safety

S. Kojima[1], Y. Kondo[1], Y. Sakai[1], S. Kasai[1], J. Kikuchi[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Tokyo, Japan*

Background: Amid the coronavirus disease 2019 (COVID-19) crisis, two messenger RNA (mRNA) vaccines against severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) have benefitted most people worldwide. However, the safety of vaccine has not been established in patients with rheumatic arthritis (RA). Previous studies reported that flares of underlying RA following SARS–CoV-2 vaccination were not so frequent, and there was no report of severe flare. However, those reports did not assess patients' disease activity with validated disease activity measures and described only simple self-reported questionnaires. Hence, the effect of vaccination on disease activity in patients with RA is still unclear. Understanding the association between arthritis flare in patients in RA and vaccination is important to overcome vaccine hesitancy.

Objectives: To clarify the effect of SARS-CoV-2 vaccination on disease activity in patients with RA and identify risk factors associated with RA flares following the vaccination.

Methods: This is a prospective cohort study in patients with rheumatic musculoskeletal disease including RA who received the SARS-CoV-2 mRNA vaccines BNT162b2 or mRNA-1273 from March 16, 2021, at Keio University Hospital. The disease activity was evaluated with disease activity score for 28 joints using C-reactive protein (DAS28), simplified disease activity index (SDAI), and clinical disease activity index (CDAI) before vaccination and after second vaccination (within two months). RA flare was defined as ΔDAS28-CRP>0.6with requirement of treatment intensification. All analysis in this study was carried out with JMP.

Results: We enrolled 318 patients with RA in this analysis. The mean age was 61 years old, and 283 (89%) were female. The mean DAS28-CRP before vaccination and after 2nd dose of vaccination were 1.70±0.71 and 1.78±0.81, respectively (p=0.84). The increase in DAS28-CPR after vaccination > 0.6 was observed in 53 patients (16.7%), and among them, 23 patients (8.2%) needed treatment intensification. The types of SARS-CoV-2 vaccine, humoral immunogenicity including neutralizing antibody titer and its adverse effects including systemic reaction (fever or general fatigue) were not different between the flare and non-flare groups (9.8 vs 9.1 IU/mL, p=0.88; 31.2% vs 18.7%, p=0.32, respectively). In the flare group, swollen joint counts (SJC), hourly erythrocyte sedimentation rates, DAS28-CRP, and SDAI were significantly higher than those in the non-flare group (0.5 vs 0.0, p<0.000; 13 vs 11 mm/h, p=0.01; 1.57 vs 1.45, p<0.001; 3.9 vs 2.4, p=0.02, respectively). Multivariable logistic regression analysis revealed that the number of swollen joints before vaccination contributed RA exacerbation after SARS-CoV-2 vaccination significantly (odds ratio 1.3, 95% confidence interval 1.06-1.65, p=0.01). The receiver operating curve analysis identified that having two or more swollen joint counts predicts RA flares after vaccination with an area under the curve of 0.64, a sensitivity of 42.3%, and a specificity of 86.9%.

Conclusion: Disease flare with requirement of treatment intensification is observed in 8.2% of patients with RA. Patients with higher disease activity, especially having two or more swollen joint counts are at high risk of flare following mRNA SARS-CoV-2 vaccination.

AB1331 COVID VACCINATION AND ADVERSE REACTIONS AMONG PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: WHAT IS THE RHEUMATOLOGIST'S ROLE?

Keywords: Vaccination/immunization, Myositis, COVID

A. Valle[1], S. Mahmood[2]. [1]*Montefiore Medical Center, Medicine, Bronx, United States of America*; [2]*Montefiore Medical Center: Einstein Campus, Division of Rheumatology, Bronx, United States of America*

Background: Since 2021, EULAR has advocated for the vaccination of patients with rheumatic and musculoskeletal diseases [1]. However, there is significant patient hesitancy, and it is often attributed to concern regarding vaccine adverse events (AEs) [2]. Idiopathic inflammatory myopathies (IIMs) are an example of rare rheumatic conditions in which population-specific data is limited and rheumatologists may play vital role in a vaccine discussion.
Objectives: Our aim was to evaluate COVID vaccination and AEs rates in patients with IIM and determine whether rheumatologist-initiated vaccine discussions correlated with patient vaccination rates.
Methods: The Montefiore Medical Center Myositis registry was created from patients that met 2017 EULAR/ACR classification criteria for IIM. Patients without a history of rheumatology care at our hospital or those who had died prior to COVID vaccines availability were excluded. Demographics and IIM subtype were documented. Vaccination details, including vaccination type and number, were recorded. Medical records were reviewed for minor and major vaccine AEs and documentation by a rheumatologist of COVID vaccine discussion. The presence of fever, headache, fatigue, or pain at injection site within 2 weeks of vaccine administration was considered a minor vaccine AE. The presence of anaphylaxis, Guillen Barre Syndrome, myocarditis, pericarditis, death or IIM flare within 3 months of vaccination administration was defined as a major AE. Statistical analyses included two-sample t-test, Chi-square tests or Fisher's exact tests.
Results: Of 153 within the registry, 116 met inclusion criteria. 81 of 116 (70%) of patients had received at least one COVID vaccination. Demographics (age, sex, race, ethnicity) were similar between vaccinated and unvaccinated patients. Of the vaccinated patients, all had received the primary series, 69% (56/81) had received a booster, and only 7% had received the primary, booster, and bivalent series. Overall, the rates of minor and major AEs were 17% and 2%, respectively. There were no differences in AEs based on the vaccine type (Pfizer, Moderna, or Janssen). However, it was more likely for patients to have minor AEs after receiving a booster vaccine in comparison to the primary or bivalent series, regardless of vaccine type (p=0.02). 7% (6/81) patients experienced a flare within 3 months of vaccination. In total, 38/116 (33%) of IIM patients had a documented COVID vaccine discussion with their rheumatologist. Of those patients who discussed the vaccine, 34 (89%) received at least one COVID vaccine while only 60% (47/78) of the patients who had not discussed vaccination were vaccinated (Figure 1).
Conclusion: While majority of IIM patients have received the primary series, the booster and bivalent series are much less prevalent. IIM patients whose rheumatologist discussed vaccination were more likely to be vaccinated. This signifies the importance of rheumatologist-initiated vaccine discussions. We reported less minor AEs and the same frequency of major AEs as larger, self-reported IIM studies. The low prevalence of AEs and IIM flares may be a tool in the rheumatologist-led vaccination discussion.

AB1332 CLINICAL OUTCOMES AND RISK FACTORS OF COVID-19 IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES: A LARGE REAL-WORLD SURVEY IN CHINA

Keywords: COVID, Vaccination/immunization

Y. Geng[1], Y. Fan[1], Z. Zhang[1]. [1]*Peking University First Hospital, Rheumatology and Clinical Immunology Department, Beijing, China*

Background: The impact of COVID-19 on vulnerable populations with autoimmune inflammatory rheumatic diseases (AIIRDs) has been of great concern.
Objectives: The aim is to report the clinical features, outcomes as well as risk factors of infection and hospitalization in Chinese AIIRDs patients during the big wave of infection last month.
Methods: A real-world survey was conducted during the peak of severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) (8 December 2022 to 13 January 2023) in China. All patients completed the survey via internet or at the rheumatology inpatient and outpatient clinic of a tertiary hospital in Beijing with a medical diagnosis of AIIRDs. Clinical features, outcomes and risk factors of COVID-19 in AIIRDs were analyzed. The main outcome were SARS-CoV2 infection and hospital admission related to COVID-19. We apply the multivariable logistic regression model to assess risk factors for the infection and hospitalization.
Results: Totally 2005 patients with AIIRDs completed the survey. The leading AIIDs were systemic lupus erythematosus (SLE) (1039, 51.8%), rheumatoid arthritis (RA) (290, 14.5%) and Behcet's disease (BD) (231, 11.5%). There were 1690 (84.3%) patients who were infected and 315 (15.7%) patients not infected. The independent factors protecting patients from COVID-19 infection were the time interval of less than 3 months from last vaccination (OR: 0.53; p=0.037) and RA as the underlying AIIRDs (OR: 0.62; p=0.041). 57 out of 1690 patients (3.4%) were hospitalized. 46 (80.7%) of them experienced severe/critical course. In multivariable logistic regression analysis, independent risk factors for hospitalisation with COVID-19 were age over 60 years (OR: 11.5; p<0.001), with comorbidity (OR: 1.83; p=0.045) and SLE as the underlying AIIRDs (OR: 2.59; p=0.036).
Conclusion: Our study suggested that time from last vaccination of less than 3 months and having RA decreased the risk of COVID-19 in AIIRDs. Among the infected patients, older age, having previous comorbidity and having SLE increased the risk of hospitalization.

COVID-19

AB1333 **THE IMPACT OF IMMUNOCOMPROMISE ON OUTCOMES OF COVID-19 IN CHILDREN AND YOUNG PEOPLE - A SYSTEMATIC REVIEW AND META-ANALYSIS**

Keywords: Outcome measures, COVID

C. Ciurtin[1], J. Greenan- Barett[1], S. Aston[1], C. Deakin[1]. [1]*University College London, Centre for Adolescent Rheumatology, London, United Kingdom*

Background: Despite children and young people (CYP) having a low risk for severe Coronavirus disease 2019 (COVID-19) outcomes, there is still a degree of uncertainty related to their risk in the context of immunodeficiency or immunosuppression, primarily due to significant reporting bias in most studies, as CYP characteristically experience milder or asymptomatic COVID-19 infection and the severe outcomes tend to be overestimated.
Objectives: To systematically evaluate the impact of immunosuppression on severe COVID-19 infection outcomes in CYP and perform a meta-analysis to estimate differences in outcomes compared to general population.
Methods: A comprehensive systematic review to identify globally relevant studies in immunosuppressed CYP and CYP in general population (defined as younger than 25 years of age) up to 31st October 2021 (to exclude vaccinated populations), was performed. Studies were included if they reported the two primary outcomes of our study, admission to intensive therapy unit (ITU) and mortality, while data on other outcomes, such as hospitalisation and need for mechanical ventilation were also collected. A meta-analysis estimated the pooled proportion for each severe COVID-19 outcome, using the inverse variance method. Random effects models were used to account for interstudy heterogeneity.
Results: The systematic review identified 30 eligible studies for each of the two populations investigated: immunosuppressed CYP (n=793) and CYP in general population (n=102,022). Our meta-analysis found higher estimated prevalence for hospitalization (46% vs. 16%), ITU admission (12% vs. 2%), mechanical ventilation (8% vs. 1%) and increased mortality due to severe COVID-19 infection (6.5% vs. 0.2%) in immunocompromised CYP compared to CYP in general population (Figure 1A-D depicts the pooled estimates for the above outcomes in immunocompromised CYP). This analysis shows an overall trend for more severe outcomes of COVID-19 infection in immunocompromised CYP, similar to adult studies.
Conclusion: This is the only up to date meta-analysis in immunocompromised CYP with high global relevance, which excluded reports from hospitalised cohorts alone and included 35% studies from low- and medium-income countries. Future research is required to characterise individual subgroups of immunocompromised patients, as well as impact of vaccination on severe COVID-19 outcomes.

AB1335 **INTAKE OF ACETAMINOPHEN SUPPRESSES ANTIVIRAL HUMORAL IMMUNE RESPONSES IN PATIENTS WITH RA FOLLOWING VACCINATION WITH ANTI SARS-COV-2 MRNA BASED VACCINES**

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Vaccination/immunization

K. Schmiedeberg[1,2], J. Beyer[3], I. Abela[4,5], N. Vuilleumier[6], M. Schwarzmueller[5], S. Pagano[6], J. Von Kempis[1], A. Rubbert-Roth[1]. [1]*Kantonsspital St.Gallen, Department of Rheumatology, St. Gallen, Switzerland*; [2]*University Hospital Bern, Department of Rheumatology and Immunology, Bern, Switzerland*; [3]*Institute of Forensic Medicine, Kantonsspital St.Gallen, Department of Forensic Toxicology, St. Gallen, Switzerland*; [4]*University Hospital of Zürich, Department of Infectious Diseases and Hospital Epidemiology, Zürich, Switzerland*; [5]*University of Zurich, Institute of Medical Virology, Zürich, Switzerland*; [6]*Hôpitaux Universitaires de Genève (HUG), Laboratory Medicine Division Geneva, Genève, Switzerland*

Background: Acetaminophen (APAP = paracetamol) may potentially impact vaccine-associated immune responses as the intake of APAP has been associated with a worse outcome in tumor patients receiving checkpoint inhibitors.[1] Different DMARD regimen have been shown to impair the humoral immune response to mRNA SARS-CoV-2 vaccines in patients with rheumatoid arthritis but the effect of paracetamol has not been explored thus far.
Objectives: To analyse whether the intake of APAP may interfere with antiviral humoral immune responses following two doses of an anti-SARS-CoV-2 mRNA based vaccine in patients with rheumatoid arthritis (RA) on DMARD therapy.
Methods: The RECOVER trial (**R**heumatoid **C**ovid-19 **V**accin**e** Immune **R**esponse) was a non-randomised, prospective observational control group trial and enrolled 77 RA patients on DMARD therapy and 21 healthy controls (HC). We performed a posthoc analysis of blood samples taken before the first vaccine dose (T0), two (T1) and three (T2) weeks after the first and second vaccine dose, and at 12 (T3) weeks. APAP intake was measured using ELISA. The antibody response (anti-S) to the receptor binding domain (RBD) within the SARS-CoV-2 S1 protein was measured with the Elecsys Anti-SARS-CoV-2-S (Roche Diagnostics GmbH) test. The neutralizing activity NT50 at week 12 was assessed using an HIV-based pseudovirus neutralization assay against Wuhan-Hu-1.
Results: Baseline characteristics of participants are detailed in Table 1. The immunogenicity analyses were based on 73 RA patients after exclusion of 4 patients with previously unnoticed SARS-CoV-2 infection (positive for anti-nucleoprotein at baseline). APAP was detected in serum samples from 34/73 (25%) RA patients and in 7/21 (33%) HC (least at one timepoint T0, T1 and/or T2). APAP intake in HC did not affect levels of anti-S at any timepoint and all HC developed potent neutralizing activity (NT50 ≥ 250) at week 12. RA patients, who tested positive for APAP at T1, showed comparable anti-S levels at T1, T2 and T3 compared to RA patients not exposed to APAP. The detection of APAP at T2 corresponded to lower anti-S levels at T2 (Figure 1 A, B). The detection of APAP at T2 was associated with a significantly lower SARS-CoV-2 neutralizing activity at week 12 compared to patients without perivaccination APAP exposure (p =0.04) (Figure 1 C).
Conclusion: A decrease of antiviral humoral immune responses was observed in RA patients (but not in HC) who were exposed to APAP at the time of the second mRNA vaccine dose compared to patients in whom APAP was not detected. Our data suggest that the use of paracetamol within the time period around vaccination may impair vaccine-induced immune responses in patients with an already higher risk for blunted immune responses.

AB1336

EVALUATION OF THE IMMUNOGENICITY AND EFFICACY OF THE SARS-COV-2 VACCINE IN PATIENTS WITH CHRONIC INFLAMMATORY DISEASES TREATED WITH BIOLOGICAL THERAPY

Keywords: COVID, Vaccination/immunization, bDMARD

J. Calvo Gutierrez[1], M. C. Ábalos-Aguilera[2], D. Ruíz-Vilchez[2], E. Iglesias[3], R. Ortega Castro[1], A. Escudero Contreras[1], C. López-Medina[1]. [1]*Reina Sofía University Hospital, Maimónides Institute of Biomedical Research of Córdoba (IMIBIC). University of Cordoba (UCO), Rheumatology, Córdoba, Spain*; [2]*Maimónides Institute of Biomedical Research of Córdoba (IMIBIC)., GC05 group, Córdoba, Spain*; [3]*Reina Sofía University Hospital, Maimónides Institute of Biomedical Research of Córdoba (IMIBIC)., Digestive, Córdoba, Spain*

Background: Data on the immunogenicity and efficacy of vaccines against COVID-19 in patients with chronic inflammatory diseases (CID) are uncertain and possibly lower than those observed in the general population, but the potential for severe COVID-19 in this population warrants their use.
Objectives: To determine the seroconversion rate and efficacy after the complete vaccination regimen against SARSCoV-2 in patients with CID on bDMARD treatment, as well as to evaluate the infection rate after vaccination and adherence to vaccination regimens.
Methods: Single-center, prospective observational study of 114 patients with CID from the HURS of Córdoba, who have received full vaccination for SARS-CoV-2 in 2021 (without having previously suffered from COVID-19 disease) according to national guidelines with a 12-month follow-up after vaccination. All of them underwent two determinations of specific IgG antibodies against the trimeric spike protein of SARS-Cov2 (2021 and 2022). It has been established that an Ab titer of less than 260 BAU/ml can be considered indicative and indicative of a poor response to vaccination. Information was collected for each patient regarding IHD, type of bDMARD, vaccine administered, concomitant treatments, adverse effects, and infection after vaccination.
Results: 114 patients were included (mean age 50 years, 67.5% women). 36% of the patients had RA, 12.3% SpA, 9.6% PSO, 28.9% IBD, and 13.2% other CID. 16.7% were receiving treatment with Rituximab, 36.8% anti-TNF, 9.6% Tocilizumab, 7% abatacept, 4.5% anti-JAK, and 6.1% other treatments. 19.3% only with synthetic Fame. Anti-SARS-CoV-2 antibodies and neutralizing activity were detected in 80% of study participants. Rituximab-treated patients showed significantly higher non-seroconversion (73.7% vs. 5.3%, p<0.001) (Figure 1) as well as a 58-fold higher risk of non-seroconversion compared to patients without bDMARDs (OR: 58.80 CI (8.86 - 120.4) p<0.001. Interestingly, we found that methotrexate alone also decreased seroconversion significantly (mean Ab titer reduction -654.6 (95%CI -1127.7 to -181.4, p=0.007). Furthermore, we observed a significant interaction between the type of biologic and the concomitant use of methotrexate, such that the reduction in the antibody titer is enhanced by the combination of methotrexate and anti-TNF, anti-IL 6, Rituximab, and other DMARDsb (Figure 2). 18.9% presented mild adverse effects after the administration of the vaccine.17.5% presented covid-19 infection during the last year of follow-up, being more frequent in the group vaccinated with Astrazéneca, although without statistically significant differences. No patient experienced a disease flare. In relation to adherence to vaccination, slightly more than half (56.14%) have administered at least 4 doses.
Conclusion: Our results show that mRNA vaccines against SARSCoV-2 produce seroconversion in the majority of patients with CID, except in the case of patients with rituximab. No serious adverse effects or ICD reactivation were found. Despite the small number of patients included, this study suggests the need for revaccination and the use of other vaccination strategies in the group of patients treated with rituximab and in the group of patients taking methotrexate. Efforts should be made to improve adherence to covid 19 vaccination in this group of patients.

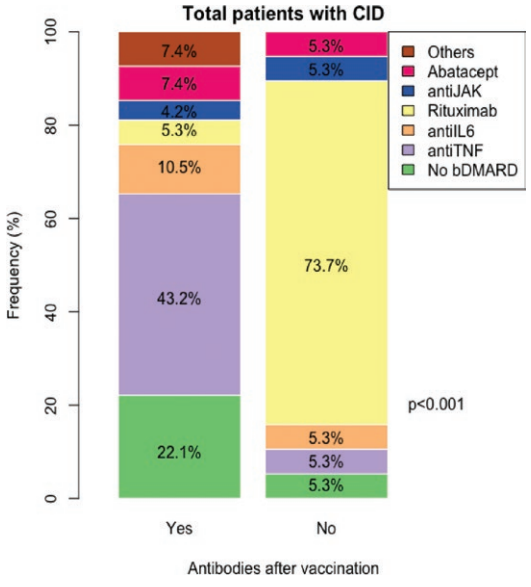

Figure 1. Shows how the use of rituximab is significantly associated with not developing antibodies.

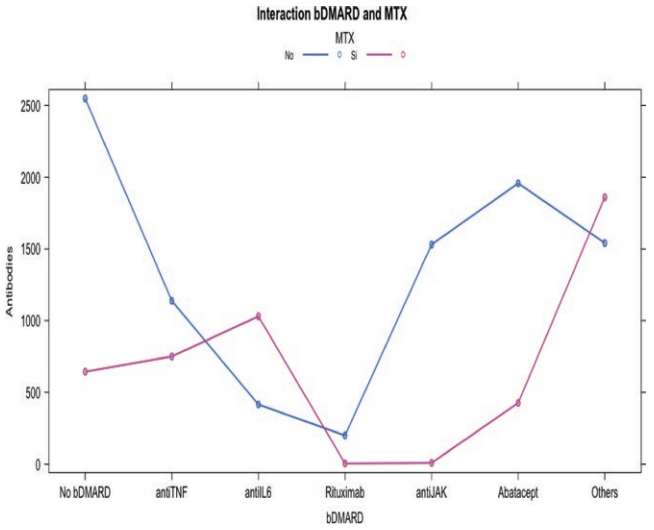

Figure 2. Represents the interaction between the biological drug and the use of methotrexate in relation to the level of Antibodies.

COVID-19 AND JAKI: ANALYSIS AFTER THREE-YEAR PANDEMIC AT A SPANISH TERTIARY CARE HOSPITAL

Keywords: Targeted synthetic drugs, COVID

P. Muñoz Martinez[1], L. Mas Sanchez[1], E. Grau García[1], A. M. Torrat Noves[1], D. Ramos Castro[1], C. Riesco Barcena[1], A. V. Huaylla Quispe[1], S. Leal Rodriguez[1], I. Cánovas Olmos[1], H. Charia[1], L. Gonzalez Puig[1], J. Ivorra Cortés[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J. E. Oller Rodríguez[1], F. Ortiz-Sanjuán[1], E. Tovar-Sugrañes[1], E. Vicens Bernabeu[1], J. A. Román Ivorra[1]. [1]HUP La Fe, Rheumatology Department, Valencia, Spain

Background: The Coronavirus disease (COVID-19) is caused by the SARS-CoV-2 virus, which has led to a world revolution in many spheres, especially in the field of health, for more than three years. It is important to take into account that patients who are immunocompromised, such as those treated with JAK inhibitors (JAKi) are at higher risk to get sick with COVID-19 and have a worse prognosis.
Objectives: To analyze the impact after a three-year pandemic in those patients treated with JAKi in a Rheumatology Department at a Spanish tertiary care Hospital.
Methods: Retrospective longitudinal observational study of patients treated with JAKi from December 2019 to December 2022. Demographic and clinical variables were collected from the electronical medical record. Incidence of COVID-19 was considered as adverse event. Those infections which required hospitalization or were a threat to the patient's life were categorized as serious adverse event. The proportion of COVID-19 vaccinated patients was analyzed.
Results: 209 patients treated with JAKi were included. Rheumatoid Arthritis was the most frequent disease (n=162) and tofacitinib the most used JAKi (n=89). 193 (92,34%) patients received at least 1 dose of the vaccine against COVID-19. 17 infections were observed as adverse event. 3 of them were seriously ill and required hospitalization, none of them were vaccinated at that moment. Out of the 14 patients with minor infection, 7 were vaccinated. One death was registered but it was not caused by infection. Baricitinib (n=7) was the most related JAKi with minor infection. Upadacitinib (n=2) was the most associated JAKi with serious infection.
Conclusion: In our series of patients, we observed an incidence of 17 infections from COVID-19, 3 of them serious. The 92,34% of the patients were vaccinated. We didn't notice any infection in patients treated with Filgotinib, probably because of the short time of commercialization and few patients treated. The scarce number of infections reported is remarkable, especially in the second part of the pandemic. This is probably due to the effectivity of the vaccine, the success of vaccination campaigns and the normalization of the disease, with the consequent infradiagnosis.

AB1338

CLINICAL COURSE IN COVID 19 DISEASE IN IMMUNOSUPRESSED PATIENTS DIAGNOSED WITH RHEUMATIC DISEASES

Keywords: Comorbidities, COVID, Vaccination/immunization

M. Migkos[1], E. Kaltsonoudis[1], T. Zoi[1], E. Pelechas[1], N. Kougkas[2], A. Garyfallos[2], P. Voulgari[1], A. Drosos[1]. [1]*University of Ioannina, Medical School, Department of Rheumatology, Ioannina, Greece*; [2]*Aristotle University of Thessaloniki, Department of Internal Medicine, Hippokration Hospital,Thessaloniki, Greece*

Background: Patients with pre-existing rheumatic diseases may be exacerbated during SARS-CoV-2 infection, or may develop new autoimmune features. Furthermore, immunosuppressive agents used to treat autoimmunity-inflammation as well as comorbidities can also affect the disease outcome.
Objectives: To evaluate the outcome of rheumatic diseases after Covid 19 infection in patients diagnosed with rheumatic diseases, under various immunosuppressive treatment, as well as the effects of vaccines against Covid or antiviral treatment in this sensitive population group.
Methods: During the pandemic, 1493 patients with autoimmune or autoinflammatory disease who were continuously followed up in two tertiaries hospitals in northern and northwestern Greece were included in the current study. The patients were compared with 769 controls after adjustment for age, sex, weight, vaccination status and comorbidities. Of the 1493 patients, 648 had rheumatoid arthritis, 282 psoriatic arthritis, 173 ankylosing spondylitis, 122 systemic lupus erythematosus, 98 Sjogren's syndrome, 43 polymyalgia rheumatica, 34 mixed connective tissue disease or overlapping syndromes, 31 vasculitis, 27 systemic sclerosis, 18 myositis, 10 Behcet syndrome, 5 primary antiphospholipid syndrome and 2 had Familial Mediterranean Fever. The vast majority of patients and controls were fully vaccinated (82%) and 397 patients received antiviral treatment, 94% of them were fully vaccinated.
Results: Covid 19 disease in vaccinated patients with rheumatic diseases was shown to perform the same or about the same as those in the control group after adjustment for risk factors for severe disease. 19 of our patients required admission in the intensive care unit (62% full vaccinated) while a total of 12 died (66% non vaccinated). Major risk factors for severe disease were previous respiratory failure, chronic renal impairment, obesity, and failure to receive antiviral therapy. It was also shown that infection with Covid led to an exacerbation or induction of autoimmune disorders in 25 of the participants.

Table 1.

	Total of patients n=209
Age - years (SD)	62 (8.20)
Female - n (%)	165(78.94%)
Diagnosis – n (%)	
Rheumatoid Arthritis	162 (77.51%)
Psoriatic Arthritis	23 (11%)
Axial Spondyloarthritis	12 (5.74%)
Juvenile Idiopathic Arthritis	2 (0.95%)
Others	10 (4.78%)
Comorbidities - n (%)	
Dyslipidemia	64 (30.62%)
Hypertension	56 (26.79%)
Diabetes Mellitus	20 (9.56%)
Tobacco use	38 (18.18%)
Type of JAKi - n (%)	
Tofacitinib	89 (42.58%)
Baricitinib	56 (26.79%)
Upadacitinib	60 (28.70%)
Filgotinib	4 (1.91%)
Concomitant treatment – n (%)	
DMARD	107 (51.19%)
Corticosteroids	110 (52.63%)
COVID-19 Vaccination – n (%)	193 (92.34%)
COVID-19 Infections – n	
Minor	14
Serious	3

Conclusion: In this large cohort, Covid 19 disease was shown to affect patients with autoimmune rheumatic diseases the same or approximately the same way as the general population if they are fully vaccinated and if they start timely antiviral treatment where indicated. Further research and monitoring of the results after the multiple mutations of the virus is advisable.

AB1339 EFFICACY AND SAFETY OF THE SARS-COV-2 VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Vaccination/immunization, Rheumatoid arthritis, COVID

E. F. Vicente-Rabaneda[1], M. Torres[2], M. Uriarte3, P. Quiroga Colino3, F. Gutiérrez-Rodríguez3, A. Triguero-Martinez[4], A. Gutiérrez[5], N. García Castañeda3, A. Romero3, L. Cardeñoso[5], S. Castañeda3. [1]*Hospital de La Princesa, Rheumatology, Madrid, Spain*; [2]*Hospital de La Princesa, Universidad Autónoma de Madrid, Madrid, Spain*; [1]*Hospital de La Princesa, Rheumatology, Madrid, Spain*; [4]*Hospital de La Princesa, Immunology, Madrid, Spain*; [5]*Hospital de La Princesa, Microbiology, Madrid, Spain*

Background: Rheumatoid arthritis (RA) and DMARDs are associated with a dysfunction of the cellular and humoral immune system that increases their susceptibility to infection, with vaccinations being one of the main infection prevention measures in these patients.

Objectives: To describe the efficacy and safety of the SARS-CoV-2 vaccine in a series of patients with RA.

Methods: Retrospective observational study of RA patients, fulfilling the ACR/EULAR 2010 classification criteria, vaccinated against the SARS-CoV-2 virus from December 2020 to October 2021, who had post-vaccination serology and subsequent follow-up for a minimum of 6 months in a university hospital. The efficacy and effectiveness of the vaccine was evaluated by analyzing the serological response (anti-SARS-CoV-2 IgG antibodies) and the incidence of post-vaccination SARS-CoV-2 infection. Vaccine safety was investigated recording adverse events and RA flares. Logistic and linear multivariate regression analyzes adjusted for age, sex, and time elapsed from vaccination to serological determination were used to identify factors associated with vaccine response. Statistical analysis was carried out with Stata® and significance was set at p<0.05.

Results: We included 118 patients with RA (87.2% women, mean age 65.4±11.6 years, mean evolution 12.0±9.6 years) vaccinated against SARS-CoV-2 (95.76% received the complete vaccination schedule). Patient characteristics regarding socio-demographic, clinical and laboratory RA related variables, as well as prior Covid infection are shown in Table 1.

Table 1.

	POPULATION CHARACTERISTICS	SEROLOGICAL RESPONSE TO VACCINE			GRADE OF SEROLOGICAL RESPONSE
		YES	NO	p	p
Age (years)	65.47±11.69	65.25±11.67	67.14±12.10	0.233	0.498
Sex (male/female)	15 (12.71)/ 103 (87.29)	12 (11.54)/ 92 (88.46)	3 (21.43)/ 11 (78.57)	0.385	**0.019**
Smoking (pack-year index)	8.79±18.55	6.87±15.23	23.01±31.83	**<0.001**	0.387
Comorbility	68 (57.63)	58 (55.77)	10 (71.43)	0.389	0.498
RA duration	12.08±9.63	11.57±8.59	15.93±15.28	0.994	0.815

ESR	19.88±18.64	20.00±19.04	19.00±15.94	0.855	**0.020**
CRP	0.51±0.78	0.47±0.64	0.82±1.44	0.239	**0.006**
HAQ	0.575 (0.66)	0.59±0.67	0.43±0.59	0.810	0.561
DAS28	2.39±1.07	2.37±1.12	2.53±0.60	0.110	0.603
Prior COVID-19	21 (17.8)	22 (20.19)	0 (0)	0.072	**<0.001**

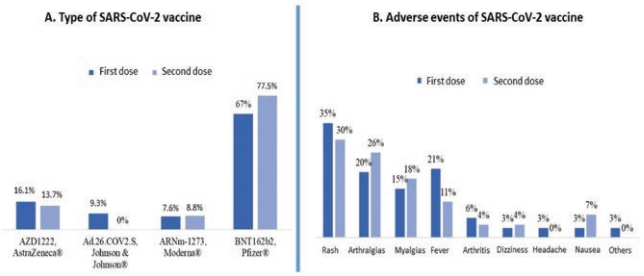

Figure 1.

57.6% of the patients had associated comorbidity, especially dyslipidemia 41.5%, arterial hypertension 31.4% and diabetes mellitus 10.2%. Almost all patients received csDMARDs, especially MTX (83.9%), and 46.6% had biologic therapy or JAK inhibitors, with a predominance of TNF antagonists (20,3%) and RTX (16,1%). Types of vaccines and schedule are shown in Figure 1A. Most patients (88.1%) developed humoral immunogenicity. Univariate analysis of factors associates with humoral response and grade of response to the vaccine are shown in Table 1. Multivariate analysis found that smoking (OR 0.96, 95%CI: 0.94-0.99, p=0.034) was the only variable significantly associated with humoral response to the vaccine. The degree of serological response was significantly related to younger age (coefficient -16.11, 95%CI: -31.84 to -0.39, p=0.045) and previous COVID-19 infection (coefficient 4.496, IC 95%: 3.604-5.388, p<0.001), which had occurred in 17.8% (5% severe) and was associated with male gender (p=0.016). After vaccination, 18.6% presented SARS-CoV-2 infection, although mild. Vaccine adverse events (19.5%) were mostly mild (Figure 1B) and associated with age (OR 0.95, 95%CI: 0.91–0.99, p=0.042). RA flares were anecdotal (1.7%), being inversely related to age (OR 0.95, 95%CI: 0.91-0.99, p=0.042).

Conclusion: Our results, with a limited sample, suggest that the SARS-CoV-2 vaccine induces adequate humoral immunogenicity, with an acceptable safety profile in RA patients, reducing the severity of SARS-CoV-2 infection.

AB1340 CRYOFIBRINOGENEMIA IN PRECOVID-19 AND COVID-19 ERA: A COMPARATIVE STUDY IN A SINGLE UNIVERSITY HOSPITAL

Keywords: Descriptive studies, Skin, COVID

C. Lasa[1], M. E. Peiró Callizo[2], J. Irure-Ventura[3], M. Lopez-Hoyos[3], M. Renuncio García[3], A. Martínez Gutiérrez[2], C. Secada-Gómez[2], A. Sanchez-López[1],

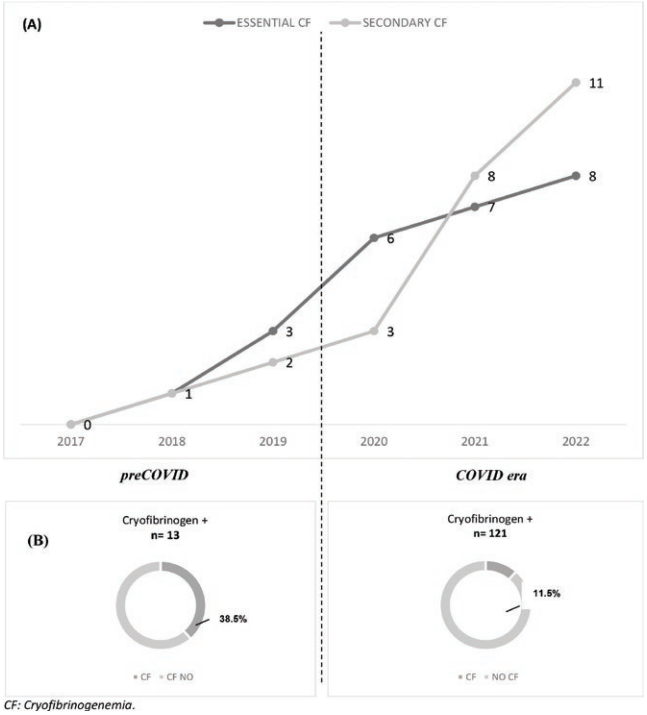
R. Blanco[2]. [1]*Marqués de Valdecilla University Hospital, Division of Rheumatology, Santander, Spain*; [2]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; [3]*Marqués de Valdecilla University Hospital, Immonology, Santander, Spain*

Background: Cryofibrinogenemia (CF) is an under-recognized syndrome due to the lack of definitive criteria and the rarity of disease. CF may be essential or secondary to autoimmune, neoplastic or infections conditions **[1]**. Skin manifestations, mainly ulceration, are the most common and may be a pseudovasculitic syndrome. During COVID-19 era the number of cases with skin lesions get increased. Further studies are needed to characterize this association between CF and SARS-CoV-2 **[2].**

Objectives: A) To evaluate the frequency of CF during preCOVID era and COVID era. **B)** To describe the clinical profile of CF and the mainly characteristics of patients in both study groups.

Methods: Observational single-center study in northern Spain University Hospital of 134 patients with at least one positive cryofibrinogen determination, between January 2017 and March 2020 (preCOVID era) and March 2020 and December 2022 (COVID era). CF diagnosis was confirmed accordingly to reported criteria **[3].** Clinical conditions, laboratory parameters, including immunological and serological analysis were collected from all patients. Blood was collected in citrated tubes for cryofibrinogen detection. Stadistical analysis was performed using SPSS software. Quantitative variables were expressed as mean±SD. Qualitative variables were compared using chi-squared test. Quantitative variables were compared using the student's *t*.

Results: CF was confirmed in 19/134 (14.2%) patients with at least one positive cryofibrinogen test determination (5 in preCOVID era; 14 in COVID era). Patients of COVID-19 era were more frequently male (64.3% to 40%) and younger (43.6 to 60.6 years). Main features are shown in **Table 1**. In preCOVID era most of cases were essential CF (60%) and in COVID era most of them were secondary ones (64.3%). The 33.3% of secondary CF were mainly due to COVID. Cutaneous manifestations were similar in both subgroups, especially as purpuric macules (perniosis-like) in acral distributions. Antiaggregant drugs and corticosteroids were used more frequently in preCOVID era. The comparative incidence after and before COVID is shown in **Figure 1.** From patients with positive cryofibrinogen test, a greater proportion in preCOVID had a CF.



Conclusion: CF is a rare disorder with a low prevalence. This study showed the change in the trend of CF subtypes, probably due to the influence of the COVID infection. In COVID era the number of positive cryofibrinogen test had envolved due to SARS-CoV2 infection, CF cases were not increased. Clinical expression of the disease has not changed in both groups.

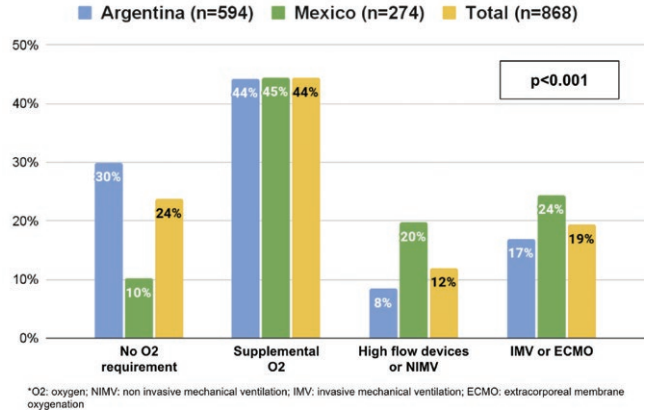
[1]*Argentina Society of Rheumatology, Research Unit, Buenos Aires, Argentina*; [2]*Argentina Society of Rheumatology, SAR-COVID Registry, Buenos Aires, Argentina*; [3]*Colegio Mexicano de Reumatologia, Mexican Study Group of COVID-19 in Rheumatic Diseases, Ciudad de México, Mexico*

Background: Patients with immune-mediated rheumatic diseases (IRD) have poorer outcomes of SARS-CoV-2 infection compared to the general population.

Objectives: To assess and compare clinical course, severity and complications of SARS-CoV-2 infection in patients with rheumatic immune-mediated inflammatory diseases (IMIDs) from Mexico and Argentina.



Methods: Data from both national registries, CMR-COVID (Mexico) and SAR-COVID (Argentina), were combined. Briefly, adult IRD patients with SARS-CoV-2 infection were recruited between 08.2020 and 09.2022 in SAR-COVID

and between 04.2020 and 06.2022 in CMR-COVID. Sociodemographic data, comorbidities, and DMARDs were recorded, as well as clinical characteristics, complications, and treatment for SARS-CoV-2 infection. Descriptive analysis. Chi square, Fisher, Student T, Mann Whitney U tests and multiple logistic regression analyses were performed.

Results: A total of 3709 patients were included, 1167 (31.5%) from the CMR-COVID registry and 2542 (68.5%) from the SAR-COVID registry. The majority (82.3%) were women, with a mean age of 50.4 years (SD 14.4). The most frequent IRD were rheumatoid arthritis (47.5%) and systemic lupus erythematosus (18.9%). Mexican patients were significantly older, had a higher female predominance and had higher prevalence of rheumatoid arthritis, antiphospholipid syndrome, and axial spondyloarthritis, while the Argentine patients had more frequently psoriatic arthritis and ANCA-associated vasculitis. In both cohorts, approximately 80% were in remission or low disease activity at the time of infection. Mexicans took glucocorticoids (43% vs 37%, p<0.001) and rituximab (6% vs 3%, p<0.001) more frequently. They also reported more comorbidities (48% vs 43%, p=0.012). More than 90% of patients presented symptoms related to SARS-CoV-2 infection. The frequency of hospitalization was comparable between the groups (23.4%), however, the Mexicans had more severe disease (Figure 1) and a higher mortality rate (9.4% vs 4.0%, p<0.0001). After adjusting for risk factors, Mexicans were more likely to die due to COVID-19 (OR 2.2, 95%CI 1.5-3.1).

Conclusion: In this cohort of patients with IRD from Mexico and Argentina with SARS-CoV-2 infection, the majority presented symptoms, a quarter were hospitalized and 6% died due to COVID-19. Mexicans presented more severe disease, and after considering risk factors they were two times more likely to die.

AB1342 THE EMERGENCE OF FIBROMYALGIA FOLLOWING ACUTE COVID-19 INFECTION

Keywords: Pain, COVID, Fibromyalgia

E. Savin[1], A. M Tsur[1], G. Rosenn[1], O. Gendelman[1], D. Buskila[2], G. Halpert[1], D. Amital[3], H. Amital[1]. [1]*Sheba Medical Center, Department of Medicine 'B', Ramat Gan, Israel*; [2]*Ben-Gurion University of the Negev, Rheumatology, Beer Sheva, Israel*; [3]*Barzilai Medical Center, Psychiatry, Ashkelon, Israel*

Background: The exact pathogenesis of fibromyalgia (FM) syndrome is unclear. However, different infections including hepatitis C virus, Human immunodeficiency virus and Lyme disease have already been implicated with the development of FM after their acute phase[1]. Imbalance between pro-inflammatory and anti-inflammatory cytokines has been suggested as a possible mechanism that facilitates the neuropathic pain[2].

Objectives: To investigate the incidence of FM syndrome among convalesced individuals following hospitalization for Acute Coronavirus Disease-2019 (COVID-19) and to identify possible risk factors.

Methods: We performed a cross-sectional study on patients who were discharged after COVID-19 hospitalization from the Sheba Medical Center, Israel, between July 2020 to November 2020. A phone interview was performed consisting of the following questionnaires: the Fibromyalgia Survey Diagnostic Criteria Questionnaire, Sense of Coherence Questionnaire to evaluate resilience, and the Subjective Traumatic Outlook Questionnaire to assess the associated psychological aspects of the trauma. The incidence of post-COVID FM was calculated and regression models were performed to identify predictors.

Results: The study population consisted of 198 eligible patients who completed the phone interview. The median age was 64 (52-72) and 37% were women. The median follow-up was 5.2 months (IQR 4.4-5.8). The incidence of FM was 15% (30 patients) and 87% (172 patients) had at least one FM-related symptom. Female gender was significantly associated with post-COVID FM (OR 3.65, p=0.002). In addition, high median Subjective Traumatic Outlook scores and low median Sense of Coherence scores were both significantly associated with post-COVID FM (OR 1.19, p<0.001 and OR 0.92, p<0.001, respectively).

Conclusion: FM is highly prevalent among COVID-19 convalescent patients. Our finding suggests that a significant subjective traumatic experience and a low resilience are highly associated with post-COVID FM.

AB1343 PERSISTENCE OF SYMPTOMS AFTER SARS-COV-2 INFECTION IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A RETROSPECTIVE STUDY

Keywords: Spondyloarthritis, COVID, Rheumatoid arthritis

C. Castellani[1], E. Molteni[1], G. Sciarra[1], L. Di Sanzo[1], G. Bevignani[1], M. Di Franco[1], V. Riccieri[1], C. Alessandri[1], A. Sili Scavalli[1], R. Priori[1,2], R. Scrivo[1], F. Conti[1]. [1]*Sapienza University of Rome, UOC Reumatologia - Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari, Roma, Italy*; [2]*Università UniCamillus | Saint Camillus International University of Health Sciences, Saint Camillus International University of Health Science, Roma, Italy*

Background: The World Health Organization defined long-COVID or post-COVID-19 condition as "the continuation or development of new symptoms 3 months after the initial SARS-CoV-2 infection, with these symptoms lasting for at least 2 months with no other explanation" [1]. Data on long-COVID in patients with inflammatory arthritis are very limited. The prevalence of this condition is 45% in the general population affected by COVID-19 who still experience symptoms after 4 months from the infection [2].

Objectives: To investigate the persistence of symptoms after SARS-CoV-2 infection in a cohort of patients with inflammatory arthritis and the most common clinical manifestations.

Methods: We enrolled adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) classified according to standard criteria that received a diagnosis of COVID-19 through molecular, rapid or quantitative antigen swab tests between September 2020 and September 2022. Demographic and clinical data including age, body mass index (BMI), smoking habit, comorbidities, rheumatic treatment at diagnosis of COVID-19, date of COVID-19 diagnosis and clinical manifestations were collected through a questionnaire and recorded in a database.

Results: Thirty-eight (40%) patients with RA, 49 (51.6%) with PsA, and 8 (8.4%) with AS [total: 95 patients; F:M=65:30, median age 56 years (IQR

15), median BMI 25.54 kg/m^2 (IQR 5.58), active smokers 21 (22.1%), median rheumatic disease duration 96 months (IQR 120), median COVID-19 duration 13 days (IQR 7)] were recruited. Eighteen (19%) were only treated with csDMARDs, 38 (40%) only with bDMARDs, 29 (30.5%) with csDMARDs and bDMARDs, 8 (8.4%) were not taking any treatment and 2 (1%) were only taking glucocorticoids. Six (6.3%) patients were hospitalized (either in Day Hospital facilities for monoclonal antibodies infusion or in the emergency room). Twenty-six (27.3%) and 7 (7.3%) patients reported pre-existing cardiovascular or respiratory comorbidities, respectively. Ninety patients (94.7%) had a symptomatic SARS-CoV-2 infection. Seventy-five (79%) patients reported the persistence of symptoms after the end of the infection (negative swab), while 20 (21%) patients reported no symptoms. Among the former, 38 (50.7%) patients were symptomatic for ≤3 months and 37 (49.3%) were symptomatic for >3 months. In the hospitalized subgroup, 6 (100%) patients reported the persistence of COVID-19 symptoms, while this was reported by 69 (77.5%) patients in the non-hospitalized subgroup (p=ns). The clinical manifestations and their persistence after the infection are reported inFigure 1. The most common were cough and fatigue, which both lasted ≤3 months in 38 (42.2%) patients and >3 months in 3 (3.33%) and 21 (23.3%) patients, respectively. Headache (32 patients - 35.5%), arthralgias (28 patients - 31.1%), myalgias (27 patients - 30%) and shortness of breath (25 patients - 27.7%) were the most common symptoms that persisted in the first 3 months after the infection. Symptoms that persisted for >3 months in more than 20% of the patients were arthralgias (24 patients - 26.6%) and sleep disturbances (19 patients - 21.1%). However, it is difficult to assess whether arthralgias and myalgias were consequences of COVID-19 or secondary to the rheumatic disease. No COVID-19-related deaths were recorded.

Conclusion: Our data show the persistence of symptoms of COVID-19 after recovery in 79% of patients with chronic inflammatory arthritis. 49.3% of patients were symptomatic for >3 months. Cough, fatigue, headache, arthralgias, myalgias and shortness of breath were the most represented symptoms in the first 3 months after the infection, while arthralgias, fatigue, and sleep disturbances were the most reported after 3 months from SARS-CoV-2 infection.

AB1344

DO PATIENTS ON SUPPRESSIVE THERAPY HAVE A DECREASED HUMORAL RESPONSE TO SARS-COV2 VACCINATION?

Keywords: bDMARD, Vaccination/immunization, COVID

R. Bourguiba[1], K. Dridi[2], M. Ayari[3], M. Boudokhane[1], I. Abdelaali[3], T. Jomni[3], S. Bellakhal[1], M. H. Douggui[1]. [1]*Hopital des Forces de sécurité de l'intérieur, Internal Medecine, La Marsa, Tunisia*; [2]*Hopital des Forces de sécurité de l'intérieur, Laboratory, La Marsa, Tunisia*; [3]*Hopital des Forces de sécurité de l'intérieur, Internal Medecine and Gastroenerology, La Marsa, Tunisia*

Background: SARS-Cov2 vaccination has been shown to be effective against severe forms of SARS-Cov2 infection. Several studies investigated the humoral and cellular response to SARS-Cov2 vaccines in patients followed for autoimmune and inflammatory diseases under immunosuppressive or immunomodulatory treatments. It has been shown that patients on immunosuppressive or immunomodulatory therapies have a poor humoral response to the vaccine[1]

Objectives: The aim of our study was to investigate the humoral response in patients under conventional immunosuppressive and biotherapies compared to healthy controls.

Methods: Patients followed for immuno-inflammatory diseases under immunosuppressive or immunomodulatory drugs who received at least one dose of anti-SARS-Cov2 vaccines were included. Quantitative Anti- SARS-Cov2 antibodies (IgM and IgG assay) VIDAS ® were assessed for all patients. Patients were then compared with healthy controls.

Results: We enrolled 93 blood samples (63 patients with autoimmune and inflammatory disease and 30 healthy controls), the median age was 52 years [Q1 43, Q3 56]. The immuno-inflammatory diseases were: Crohn's disease (n=28), Rheumatoid arthritis (n=9), Hemorrhagic rectocolitis (n=5), Behçet's disease (n=5), Systemic lupus erythematosus (n=4), Sjogren's syndrome (n=3), Sarcoidosis (n=2), Takayasu disease (n=1). All patients continued their treatment during and after vaccination. Nineteen patients were on biotherapies: Infliximab (n=12), Adalimumab (n=3), etanercept (n=2), Ustekinumab (n=1), tocilizimab (n=1). Forty-three patients were on conventional immunosuppressive: azathioprine (n=18), methotrexate (n=16), corticosteroids > 10 mg/d (n=12). All patients had received at least one dose of vaccine: the median number of doses in both groups was 2[1-4] with no statistically significant difference between the 2 groups (p=0.2). The vaccines received in the group of patients were mRNA vaccine (n=35) and other type of vaccine (n=28). In the healthy control group, type of vaccine were mRNA (n=13) other type vaccine (n=17). The patient had a lower mean level of Ig G against SARS-Cov2 antibodies (24.64 IU +/- 16.65) comparing to healthy controls (33.05+/-10) with statically significant difference (p= 0.014). No difference between the 2 groups was noted in Ig G levels according to the history of SARS-Cov2 infection. No difference was found between conventional immunosuppressive drugs and biotherapies regarding to the level of antibodies.

Conclusion: Our study highlights that patients with autoimmune disease and under immunosuppressive therapy displayed a decrease of humoral response comparing to healthy controls. This finding was reported in several studies, Geisen et al[2] reported that patients with chronic inflammatory condition and receiving TNF alfa blockers had a decreased protection and a low level Ig A against spike. Based on these data, patients with autoimmune and inflammatory diseases have decreased humoral immunity to SARS-Cov2 and should be encouraged to receive a booster dose of SARS-COv2 vaccine.

COVID-19 AND ADVERSE MENTAL HEALTH OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Mental health, COVID

M. Ghali[1], M. Ardhaoui[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, University of Monastir, Rheumatology, Monastir, Tunisia*

Background: The COVID-19 outbreak is known to increase the fear level of most patients with chronic diseases. Patients with rheumatoid arthritis (RA) are very vulnerable to environmental stress. During this pandemic, the psychological pressure may be further increased due to the perplexing nature of information about the risk of infection in RA patients.
Objectives: The objective of this study was to determine the impact of the COVID-19 pandemic on the mental health of RA patients and to investigate associated factors.
Methods: This is a cross-sectional study of 190 patients with RA who met the ACR/EULAR 2010 criteria. For each patient, we collected sociodemographic, clinical, and biological data. Depression and anxiety were assessed by the Hospital Anxiety and Depression scale (HADs) and disease activity by the DAS-28 score.
Results: The average age of our patients was 55 years with a female predominance (86.3%). The average duration of the disease was 8 years. The mean DAS 28 score was 4.1 ±1.03. The disease was deforming in 52.9% of cases. All of us patients were on disease-modifying therapy, 87.1% were on methotrexate and 12.9% were on biotherapy. Sixty patients (31.57%) had contracted SARS-CoV-2. During the pandemic, depression was present in 38.4% of patients. It was mild in 33.1% of cases, moderate in 4.1%, and severe in 1.2% with a mean HADs depression score of 4.4 ± 3.1. This score was significantly higher in patients with a history of SARS-COV-2 infection in a family member (p=0,002), comorbidities (p<0.001), joint deformities (p=0.008), and high disease activity (p<0.001). Anxiety was present in 55.6% of patients. It was mild in 32.6% of cases, moderate in 20.6%, and severe in 2.4% of cases with a mean HADs anxiety of 6.4 ± 3.9. The presence of anxiety was correlated with fear of COVID-19, higher disease activity, the presence of comorbidities, and the presence of deformities (p<0.001 for all cases). This score was also significantly higher in the illiterate (p<0.001) and unemployed patients (p=0.001).
Conclusion: In our study, depression and anxiety were frequent in RA patients during the COVID-19 pandemic. These psychological disorders were more common in patients with active and disabling RA associated with comorbidities. As the pandemic continues, more patients are susceptible to experience anxiety and depression. Therefore, rheumatologists must remain vigilant to these psychological alterations and provide the necessary support.

AB1346 ASSOCIATION OF URIC ACID LEVELS WITH COVID-19 SEVERITY DURING 2020 AND 2021 YEARS

Keywords: Prognostic factors, COVID, Lungs

A. Sydorova[1], O. Iaremenko[1]. [1]*Bogomolets National Medical University, Department of Internal Medicine №3, Kyiv, Ukraine*

Background: The decrease in uric acid levels attracts more and more attention from clinicians every year [1]. In particular, a factor such as Covid-19 can cause a significant decrease in uric acid due to its increased excretion by the kidneys [2]. This retrospective study aimed to determine changes in the level of uric acid in different years, which allows us to assume the influence of different strains of Covid-19 on uric acid.
Objectives: To analyze the relationship between uric acid levels through admission to the hospital and Covid-19 severity during 2020 and 2021 years.
Methods: Our retrospective study includes 127 hospitalized patients with confirmed Covid-19 in 2021 and 63 patients in 2020 (only patients who didn't receive urate-lowering therapy). Most patients were over 45 years old (84,2% vs 90,5%), women and men almost equally. The severity of Covid-19 we determined by the type and presence of oxygen support ((1) without O2, (2) O2 by mask or nasal cannula, (3) continuous positive airway pressure, (4) positive bi-pressure in the airways or high-flow oxygen, (5) invasive ventilation). A chi-squared test and comparison of means were used.
Results: We cannot establish the dependence of the uric acid level on the severity of the course of the Covid-19 disease, which is determined by the type of oxygen support in both 2020 and 2021. For example, in 2021, the difference between the least severe type (without O2) and the most severe (invasive ventilation) was almost the same (246.2 vs 277.12 μmol/L), as between O2 by mask or nasal cannula and positive bi-pressure in the airways or high-flow oxygen (257 vs 239.1 μmol/L). However, it was established that in 2020, higher indicators of the level of uric acid were observed for all types of oxygen support. For example, for patients who were without O2, it is higher by 72.95 μmol/L, which is statistically significant. In addition, we analyzed the dependence of the uric acid level on such indicators as the patient's age, the level of lymphocytes, C-reactive protein, and LDH at admission to the hospital. As a result of the analysis, it was found that the dependence is present for the LDH indicator (the lower the LDH, the higher the uric acid: chi-square at the level of 0.05), and for all other indicators, it was absent in 2021. In 2020, a positive relationship between CRP, LDH, and uric acid levels was also observed.
Conclusion: Although there is a trend towards lower uric acid levels in the background of Covid-19, it is not a marker of a severe disease course. The lower uric acid levels in 2021 are likely due to a feature of the strains circulating in 2021 that caused more significant renal excretion of uric acid.

AB1347 LABORATORY PARAMETERS ASSOCIATED WITH CODIV-19 CYTOKINE STORM DEVELOPMENT

Keywords: COVID, Prognostic factors

A. Gherasim[1], R. Ionescu[1], T. Horia[2], T. Cristian[2], G. Teodora[1]. [1]*Colentina Clinical Hospital, Internal Medicine 3, Bucuresti, Romania*; [2]*UMFCD, UMFCD, Bucharest, Romania*

Background: Since the end of 2019, physicians became more and more familiar with SARS-CoV-2 infection and the variety of forms in which it may present and evolve. There have been a lot of studies trying to understand and predict why some patients develop a dysregulation of the immune response, with an exaggerated release of pro-inflammatory cytokines, called cytokine storm (1–4). There is scarce evidence in Romania regarding this aspect.
Objectives: This study aims to verify the correlation between some laboratory parameters and the development of cytokine storm in SARS-CoV-2 infection in a cohort of over 200 patients admitted in a tertiary hospital from Romania, hoping that early identification of these risk factors of progression to a severe form of the disease can bring considerable benefit to patient care.
Methods: This is an analytical, observational, case-control study which includes 219 patients (all COVID-19 hospitalized patients on the Internal Medicine 3 department of Colentina Clinical Hospital, Bucharest, from 01 March 2020 to 1 April 2021). A series of data were collected, the laboratory parameters being the most important, including: albumin, lymphocyte (percentage), neutrophil (absolute value), aspartate aminotransferase, alanine aminotransferase, D-dimers, lactate dehydrogenase (LDH), anionic gap, chloremia, potassium and the BUN:creatinine ratio (BUN - blood urea nitrogen). The laboratory parameters used for the statistical analysis represent the average values of the first 7 days of hospitalization for those who did not develop cytokine storm, respectively until the day of its development, for the others. Patients were classified into these groups, those who developed cytokine storm, respectively those who did not have this complication taking into account the clinical and paraclinical criteria (impairment of respiratory function, elevations of certain markers 2-3 times above the upper limit of normal, those who died as a result of SARS-CoV-2 infection). Then Binary Univariate Logistic Regression was applied in order to verify the individual impact of every laboratory parameter on cytokine storm development. Furthermore, all laboratory parameters were subsequently included in the multivariate analysis, using the backward selection technique to achieve a model as predictive as possible.
Results: We mention that the analysis of demographic data was previously performed, showing no statistically significant relationship between patient gender, age or comorbidities (history of neoplasm, lung diseases, cardiac pathology, obesity, type II diabetes and hypertension) and their evolution to cytokine storm. After performing binary univariate logistic regression we concluded that 8 of the 13 laboratory analyzes have had a significant change between groups (ferritin, PCR, albumin, Lymphocyte, Neutrophils, TGO, LDH, BUN:creatinine ratio). Only 150 patients were then included in the multivariate analysis. After the analysis, some of the variables lost their statistical significance, the final model including C-reactive protein, neutrophilia, LDH, ferritin and the BUN:creatinine ratio. This model correctly predicts the development of cytokine storm in 88% of cases.
Conclusion: High C-reactive protein, neutrophilia, LDH, ferritin and the BUN:creatinine ratio are risk factors for cytokine storm development and should be monitored in all COVID-19 patients in order to predict their evolution.

AB1348 PERICARDITIS AFTER COVID-19 VACCINATION: A CASE SERIES

Keywords: Heart, COVID, Vaccination/immunization

F. Casarin[1], C. Carollo[1], R. Mascolo[1], A. Pedroli[1], G. Faraci[1], E. Bizzi[1], M. Pancrazi[1], L. Trotta[1], C. Lorentino[1], A. M. Pisacreta[1], A. Brucato[1]. [1]*Fatebenefratelli Hospital, Milan, Internal Medicine, Milan, Italy*

Background: COVID-19 vaccination campaigns successfully impacted on viral spreading and in particular on clinical course of the disease. However, secondary to a highly extended vaccination program, several local and systemic adverse events associated with mRNA COVID-19 vaccines have been reported. Pericarditis and myocarditis are examples of cardiac complications related to these vaccines. In particular, cases of pericarditis have occurred after mRNA COVID-19 vaccination (mostly secondary to vaccination with Moderna than Pfizer-BioNTech), especially in male adolescents and young adults, more often after the second dose. The incidence is approximately of 1-2 cases/100.000.
Objectives: Aim of our study was to study the clinical profile of pericarditis occurred within 30 days after COVID-19 vaccines in our clinic.
Methods: We present a case series of patients who developed pericarditis after COVID-19 vaccination in the Department of Internal Medicine at Fatebenefratelli Hospital in Milan, followed from December 1, 2021 to April 15, 2022.
Results: Twenty-five individuals, of which 18 (72%) were women and 7 (28%) were males, had vaccine related pericarditis. Two patients were vaccinated with AstraZeneca, 2 with Moderna, the remaining with Pfizer-BioNTech. Median age was of 42 years. Of all patients, one subject was affected by constrictive effusive pericarditis, while another required treatment of pericarditis with Anakinra, switched to Canakinumab after severe skin reactions, because of failure of therapeutic response to first-line treatments. Two patients required hospital admission, in one case for a transient constrictive pericarditis. In the remaining cases clinical symptoms associated with post-vaccines pericarditis were mild and didn't require hospitalization. Chest pain was reported in 100% of cases, whereas pericardial effusion (in one case larger than 10 mm) was evidenced in 30% of subjects. Eighty percent of patients experienced tachycardia, whereas 90% reported asthenia. An increase in indices of inflammation (CRP) was documented in 50% of patients, usually mild. With regard to therapy, 90% of patients were treated with NSAIDs, 95% with colchicine, while 50% of cases required treatment with low-dose steroids.
Conclusion: COVID-19 vaccination induces a particular form of pericarditis, often insidious and very troublesome, but with good prognosis. The clinical phenotype showed less typical chest pain, often normal indices of inflammation and little or no instrumental changes, but patients often experimented tachycardia and functional limitation. With regard to therapy, we used NSAIDs at adequate dosages to control the clinical condition, or low-dose colchicine. Low doses of cortisone (e.g., prednisone 5-10 mg a day) were useful in the presence of marked asthenia or systemic symptoms. Beta-blockers or ivabradine were used in the presence of tachycardia.

AB1349 D-DIMER AND FIBRINOGEN TRENDS IN PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES INFECTED WITH SEVERE ACUTE RESPIRATORY SYNDROME CORONAVIRUS 2: A RETROSPECTIVE COMPARATIVE STUDY

Keywords: COVID, Infection-related RMDs, Biomarkers

O. Alsaed[1], S. Al Emadi[1], K. Becetti[1], R. Saleh[1], H. Ashour[1], E. Elsayed[1], M. Hamed[1], F. Alam[1], Y. A. Y. Alrimawi[1], M. A. Al Kahlout[1], B. Awadh[1], M. Hammoudeh[1]. [1]*Hamad Medical Corporation, Medicine/Rheumatology, Doha, Qatar*

Background: D-dimer and fibrinogen elevation has been observed in severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) infection which is associated with higher incidence of venous thromboembolism (VTE) and higher mortality rates. [1-3]. Autoimmune Rheumatic Diseases (ARDs) are associated with higher rates of VTE compared to general population [4]. Whether patients with ARDs infected with SARS-CoV2 have similar D-dimer and fibrinogen trends compared to patients without ARDs is unknown.
Objectives: Compare D-dimer and fibrinogen levels in patients with ARDs infected with SARS-CoV2 to patients without ARDs.
Methods: Patients with ARDs infected with SARS-CoV2 were identified retrospectively from the electronic medical records (EMR) of Hamad Medical Corporation and matched (age and sex) to controls (1:3). D-dimer and fibrinogen levels were extracted electronically from EMR and stratified into six-time intervals defined in table 1. Day 0 was defined as the date of positive nasopharyngeal polymerase chain reaction swab test. 2 Independent Samples test (Mann-Whitney U) was used to compare the median (25th - 75th interquartile range [IQR]) level of D-dimer and fibrinogen between both study groups at the defined intervals.
Results: The study included 203 cases and 551 controls with a mean (SD) age of 45.3 (11.7) and 44 (12.5) years, females were (122 [60.1%] vs. 297 [53.9%], p = 0.129), respectively. Distribution of ARDs was rheumatoid arthritis 86 (42.4%), spondyloarthropathy 33 (16.1%) and systemic lupus erythematosus 31 (15.7%) cases. 67% were on conventional synthetic disease modifying anti-rheumatic drugs (Cs-DMARDs), 15.8% on biological DMARDs and 4.9% on rituximab. About 83% of the ARDs group were in remission or low disease activity and 13% were in moderate or high disease activity. The median (25^{th} - 75^{th} IQR) level of D-dimer and fibrinogen were comparable between study groups in all defined intervals with insignificant p values except at interval 4, fibrinogen was significantly higher in the cases, p 0.006. Table 1
Conclusion: There was no significant difference in the trend of D-dimer and fibrinogen levels during SARS-CoV2 infection between patients with ARDs and those without ARDs. Additional studies are needed to quantify the actual risk of VTE in patients with ARDs during SARS-CoV2 in correlation with serum markers of VTE.

AB1350 THE KINETICS OF HUMORAL AND CELLULAR RESPONSES AFTER THE BOOSTER DOSE OF COVID-19 VACCINE IN INFLAMMATORY ARTHRITIS PATIENTS

Keywords: COVID, Vaccination/immunization

J. Wroński[1], B. Jaszczyk[2], L. Roszkowski[2], A. Felis-Giemza[3], K. Bonek[1], A. Kornatka[4], M. Plebanczyk[4], T. Burakowski[4], B. Lisowska[5], B. Kwiatkowska[6], W. Maśliński[4], M. Wisłowska[1], M. Massalska[4], E. Kuca-Warnawin[4], M. Ciechomska[4]. [1]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Rheumatology, Warszawa, Poland*; [2]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Outpatient Clinics, Warsaw, Poland*; [3]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Biologic Therapy Center, Warsaw, Poland*; [4]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Pathophysiology and Immunology, Warsaw, Poland*; [5]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Anesthesiology, Warsaw, Poland*; [6]*National Institute of Geriatrics, Rheumatology and Rehabilitation, Department of Early Arthritis, Warsaw, Poland*

Background: Impaired immunogenicity of COVID-19 vaccinations in inflammatory arthritis (IA) patients results in diminished immunity. However, optimal booster vaccination regimens are still unknown, due to unstudied kinetics of the immune response after booster vaccinations.
Objectives: This study aimed to assess the kinetics of humoral and cellular responses in IA patients after the COVID-19 booster.
Methods: In 29 IA patients and 16 healthy controls (HC) humoral responses (level of IgG antibodies) and cellular responses (IFN-γ production) were assessed before (T0), after 4 weeks (T1), and after more than 6 months (T2) from the booster vaccination with BNT162b2.
Results: IA patients, but not HC, showed lower anti-S-IgG concentration and IGRA fold change at T2 compared to T1 (p=0.026 and p=0.031). Furthermore, in IA patients the level of cellular response at T2 returned to the pre-booster level (T0). All immunomodulatory drugs, except IL-6 and IL-17 inhibitors for the humoral and IL-17 inhibitors for the cellular response, impaired the immunogenicity of the booster dose at T2. However, none of the immunomodulatory drugs affected the kinetics of both humoral and cellular responses (measured as the difference between response rates at T1 and T2).
Conclusion: Our study showed impaired kinetics of both humoral and cellular responses after the booster dose of the COVID-19 vaccine in IA patients, which, in the case of cellular response, did not allow the vaccination effect to be maintained for more than 6 months. Repetitive vaccination with subsequent booster doses seems to be necessary for IA patients.

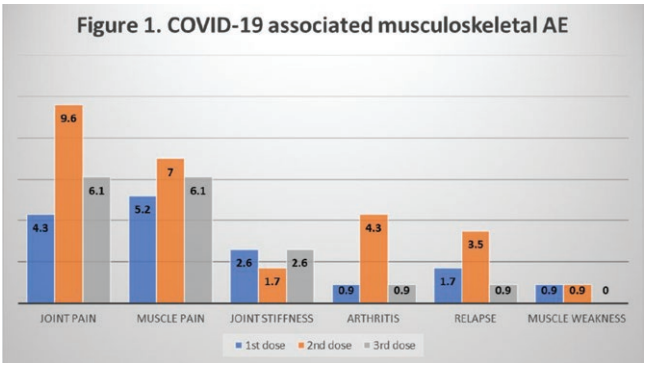
AB1351 FREQUENCY OF VACCINE-RELATED ADVERSE EVENTS IN PATIENTS WITH RHEUMATIC DISEASE



Keywords: COVID, Rheumatoid arthritis, Vaccination/immunization

D. X. Xibille Friedmann[1], V. Balderas Reyes[2], M. Olvera[2], M. Alcocer León[2], A. A. Reyes Salinas[2], M. Rodríguez Falcón[2], S. M. Carrillo Vazquez[2]. [1]*Cuernavaca General Hospital Dr. José G. Parres., Rheumatology, Cuernavaca, Mexico*; [2]*ISSSTE Regional Hospital October 1, Rheumatology, Ciudad de México, Mexico*

Background: Patients with rheumatic diseases are at greater risk of developing serious infections due to dysregulation of the immune system and the use of immunosuppressants1. Therefore, preventing infection is crucial, with vaccination being the most important primary prevention intervention, leading to a lower rate of hospital admissions due to infections. However, vaccine hesitancy among persons with rheumatic diseases is widespread due to concerns regarding the safety of vaccines2.
Objectives: Describe the frequency of adverse events associated with vaccination in patients with rheumatic diseases.
Methods: Observational, descriptive, cross-sectional and retrospective study was carried out in patients with rheumatic diseases from the Rheumatology Department of the Hospital Regional 1° de Octubre ISSSTE, from February to May 2022; it included patients over 18 years of age with an established diagnosis of rheumatic disease who had received a vaccine; the researcher applied the vaccine-associated adverse events survey to those patients who agreed to participate by signing the informed consent. The sample size was of 95 patients. Descriptive statistics and summary measures were employed for analysis. We used the chi-square test or Fisher's exact test (when <5) for the comparative analysis of the frequencies of nominal qualitative variables. P<0.05 was considered significant.
Results: The survey was applied to 115 patients. 85.2% were women; mean age 57.9 years; 61.7% had rheumatoid arthritis (RA), followed by systemic lupus erythematosus (SLE) in 13.9%. 55.6% of the patients were treated with steroids, 52.2% received bDMARDs and 48.7% csDMARDs. Patients received various vaccines, of which the most frequent was the one for COVID-19, with 99.1% of included patients having received at least one dose, followed by influenza in 30.4%. 78% of the patients who received at least one dose of a vaccine against COVID-19 presented ≥1 adverse events. The disease in which the highest frequency of adverse events occurred was RA, without this difference being statistically significant (Table 1). The adverse events according to the type of COVID-19 vaccine were the following: Sputnik-V 80%, Pfizer 76.6% and AstraZeneca 76.1%, without statistically significant difference between vaccine types. The most frequently occurring adverse events were injection site pain (80.1%), headache (30.7%), and fatigue (30.7%); In addition, the main vaccine-associated musculoskeletal symptoms were joint pain, myalgia, and morning joint stiffness (Figure 1), which on most cases improved after a NSAID use. Joint pain was more frequent after the second dose of certain vaccine types.

Table 1. Frequency of AE after COVID-19 vaccination in patients according to disease.

	AE (%)	p
RA	56	0.790
SLE	14	0.326
Spondyloarthritis	4	0.068
Osteoarthritis	6	0.614

Conclusion: Vaccination-associated AE occurred more frequently than reported in international studies; however, they were not more serious. Providing this information to patients is important to improve vaccine acceptance. In addition, the administration of NSAID after the application of the vaccine could be proposed to reduce the presence of side effects.

Background: The disease modifying antirheumatic drugs (DMARD) impair the immune response of patients with immune-mediated inflammatory diseases (IMID).

Objectives: To analyze the seroprevalence of SARS-CoV-2 in patients with IMID treated with biological disease modifying antirheumatic drugs (bDMARD) or targeted synthetic (tsDMARD).

Methods: An ambispective cross-sectional study was performed in patients with IMID treated with bDMARD or tsDMARD. Seroprevalence was compared by measuring IgG against SARS-CoV-2 between October 2020 and May 2021.

Results: A total of 550 patients with IMID were studied, all of them on bDMARD or tsDMARD therapy, none of them vaccinated at that time against SARS-CoV-2. Patients receiving anti-TNFα therapy had a higher seroprevalence than other biologic and synthetic targeted therapies (OR= 1.792; 95% CI 1.088-2.951; p= 0.021). Patients with bDMARD or tsDMARD treated concomitantly with some type of conventional synthetic DMARD (csDMARD) presented a lower seroprevalence compared to patients treated in monotherapy, 10.7 vs. 19.9% (p= 0.003). When analyzing the treatments with the different csDMARD separately (methotrexate, leflunomide, sulfasalazine, azathioprine, hydroxychloroquine and the others), methotrexate was determined to influence in a lower seroprevalence, compared to those who did not receive any csDMARD, 9.8 vs 19.9% (OR= 0.439, 95% CI 0.232-0.828; p= 0.011). When evaluating the influence of methotrexate on seroprevalence among the different groups of bDMARD or tsDMARD, a lower seroprevalence was demonstrated in the group of patients receiving anti-TNFα and methotrexate in combination, versus patients on this bDMARD in monotherapy, 10.1 vs 24.1% (OR= 0.355, 95% CI 0.165 - 0.764; p=0.006). No significant differences were identified with the other bDMARD. Regarding the patients' IMIDs, no differences in seroprevalence were observed when compared by disease groups with each other.

Conclusion: Seroprevalence in the group of patients with IMID is influenced according to the therapy received, being higher in patients receiving anti-TNFα monotherapy, but significantly lower if concomitant to this drug they receive methotrexate. These differences are not seen with the other b/tsDMARD and csDMARD.

AB1353 RHEUMATOLOGICAL PAIN CONDITIONS ARE NOT RISK FACTORS FOR THE DEVELOPMENT OF WIDESPREAD POST-COVID PAIN IN COVID-19 SURVIVORS

Keywords: COVID, Epidemiology

L. Arendt-Nielsen[1], B. D. Ebbesen[1], R. Giordano[1], J. A. Valera-Calero[2], C. Fernández-de-Las-Peñas[3]. *[1]Aalborg University & Aalborg University Hospital, School of Medicine, Center for Neuroplasticity and Pain/SMI, Gistrup, Denmark*; *[2]Universidad Camilo José Cela, Department of Health, Madrid, Spain*; *[3]Universidad Rey Juan Carlos, Department of Physical Therapy, Occupational Therapy, Physical Medicine and Rehabilitation, Madrid, Spain*

Background: Up to 60% of COVID-19 survivors develop long-COVID symptoms[1]. Musculoskeletal pain is also a common (~11%) symptom of long-COVID.[2] Current theories hypothesize that post-COVID pain can be widespread as in other chronic pain conditions. The presence of previous rheumatological diseases could act as a risk factor for the development of persistent widespread post-COVID pain due to a potentiation of pro-inflammatory responses seen during the infection or due to a less robust immune response. A previous pilot study investigated if rheumatological diseases were associated with post-COVID symptoms in a specific population of hospitalised COVID-19 survivors.[3]

Objectives: The aim of this study was to identify if the presence of previous specific rheumatological diseases are risk factors for the development of widespread post-COVID pain in previously hospitalised and non-hospitalised COVID-19 survivors.

Methods: We conducted a nation-wide, cross-sectional exploratory study with a pain-related questionnaire collecting demographics, pre-existing rheumatological conditions and the development of widespread pain symptoms after SARS-CoV-2 infection from a Denmark-based population.

Results: Data from 1.000 randomly previously hospitalised (51.2% males; 60.4±15.2 years; 85.6±18.5kg) and 1.000 randomly previously non-hospitalised COVID-19 survivors (43.5% males; 50.4±15.9 years; 79.2±16.6 kg) were analyzed. Distribution of gender ($p<0.001$), age ($p<0.001$), and weight ($p<0.001$) was different between groups. The presence of widespread pain symptoms six months after infection was higher ($P<0.001$) in hospitalised survivors (20%) as compared to non-hospitalised patients (4.2%). The presence of previous rheumatological conditions such as arthritis, osteoarthritis or joint pain were not associated with the development of widespread post-COVID pain in either group (all, $P>0.1$).

Conclusion: This exploratory study shows that the presence of previous rheumatological conditions before SARS-CoV-2 infection was not a risk factor associated with development of widespread post-COVID pain symptomatology. Other risk factors e.g., female sex or the presence of musculoskeletal pain, could be more relevant for widespread post-COVID pain-related research.[4]

AB1355 EFFECT OF COVID-19 VACCINES ON ACTIVITY OF AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Vaccination/immunization

M. A. Mahmoud Besar[1], A. Abd El Salam[1]. [1]*Faculty of Medicine, Mansoura University, Rheumatology, Immunology, Internal Medicine, Mansoura, Egypt*

Background: The SARS-CoV-2 pandemic has paralyzed the world, Patients with autoimmune rheumatic diseases (AIRDs) are at high risk for SARS-CoV-2 infection[1]. Worldwide vaccination campaigns, which have increasingly built up immunity in this populations. Studies on the efficacy and safety of the vaccines have shown rapid and strong development of immunity in healthy populations and AIRDs [2].
Objectives: To evaluate COVID-19 vaccination status in patients with autoimmune rheumatic diseases (AIRDs) whether receiving primary and booster vaccination and its relation to disease activity.
Methods: An observational cross section study conducted on a total number of 282 subjects divided into 2 groups: group (I): 179 vaccinated AIRD patients and group (II): 103 non-vaccinated AIRDs patients where Complete COVID-19 vaccination history. Disease activity scores of AIRDs were measured pre to post vaccination.
Results: Most of studied group 63% were vaccinated, Pfizer vaccine was the most common 33%, Asterzinca 19%, Sinpharm/Sinovac 10%, while Moderna was the least the least type of vaccine 1%, Figure 1. Pfizer vaccine 46% was the most common booster type, Asterzinc 39%, Sinopharm/Sinovac 8% and Moderna vaccine 3% and 4% of studied group not received booster vaccination, Figure 2. Most of Rheumatic disease were vaccinated; 46.4% Rheumatoid arthritis 39.7% Systemic Lupus Erythematosus, 5% Bechet's disease 3.9% Ankylosing Spondylitis and 2.8% Vasculitis. In vaccinated group, severity of disease activity was statistically significantly higher in post-vaccination than pre -vaccination, Table 1.
Conclusion: Pfizer vaccine was the most common vaccine in AIRDs.
COVID-19 vaccination may induce flare of disease activity in AIRDs.

COVID-19 VACCINE PERCEPTION AND HESITANCY AMONG PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASE (AIRD) IN MALAYSIA

Keywords: Vaccination/immunization, COVID, Comorbidities

S. S. Shaharir[1], L. Kamaruzaman[1], T. N. Mariamutu[1], M. S. Mohamed Said[1], A. Mohammed Nawi[2], W. S. Wan Ghazali[3], M. Mohd Noh[4]. [1]*Universiti Kebangsaan Malaysia, Faculty of Medicine, Internal Medicine, Kuala Lumpur, Malaysia*; [2]*Universiti Kebangsaan Malaysia, Faculty of Medicine, Public Health, Kuala Lumpur, Malaysia*; [3]*Universiti Putra Malaysia, Faculty of Medicine And Health Sciences, Internal Medicine, Serdang, Malaysia*; [4]*Universiti Malaysia Sabah, Faculty of Medicine and Health Sciences, Medicine, Kota Kinabalu, Malaysia*

Background: Patients with autoimmune rheumatic disease (AIRD) are at risk of severe COVID-19 infection and vaccine has been demonstrated to be able to reduce the severity of infection. Malaysia has a low flu vaccination coverage rate (approximately 3%) and hence it is important to assess the perception and hesitancy of COVID-19 vaccine especially among the vulnerable group.
Objectives: To study the perception of COVID-19 vaccine and to determine the prevalence of vaccine hesitancy among AIRD patients in Malaysia.
Methods: This was a cross-sectional survey using online Google Forms® that was conducted among adult AIRD patients (18 years and older) from August 2021 until February 2022. Patients were recruited from the outpatient clinics as well as distribution of the survey through social medias. The survey was in English and Malay language. The survey collected data on the socio-demographic background, prior history of other vaccination after the age of 18 and COVID-19 vaccination with reasons of hesitancy, defined as being unsure or unwilling to be vaccinated. The survey also assessed the patients' perception by specifying the level of agreement to COVID-19 vaccine statements using the Likert response scale: 1-Strongly disagree; 2- Disagree; 3-Neither agree nor disagree; 4-Agree; 5-Strongly agree.
Results: A total of 162 patients participated in the survey and majority of them were females (87.7%). Our multi-racial cohort consisted of Malay (n=103, 63.5%), followed by Chinese (n=38, 23.5%), Sabahan Bumiputra (n=12, 7.4%) and Indian (n=7, 4.3%). More than half (n=107,66.6%) have not had any history of other vaccination after the age of 18. Only 16.7% (n=27) agreed/strongly agreed that COVID-19 vaccine can be given to patients with co-morbidities and 24.1 (n=39) agreed/strongly agreed that COVID-19 vaccine can be given to patients who have history of allergy to other drugs or food. At the time of the survey, vast majority of the respondents have received at least the 1st dose of Covid-19 vaccine (n=148, 91.4%). A total of 9 (5.6%) patients were hesitant to be vaccinated (6 were unsure and 3 patients were not willing to be vaccinated). The commonest reasons of being unsure or not willing to be vaccinated was worried of the vaccine's adverse effects (66.7%), worried of the blood clot complication (33,3%), worried of disease flare post-vaccine (33,3%), worried of allergic reaction (22.2%), lack of information on the safety of the vaccine in patients with AIRD from government and media (22.2%), face mask and social distancing measures were adequate (22.2%). Statistical analysis revealed that more patients who had vaccine hesitancy were from the lower socioeconomic status (income <1066 Euro/month), 88.9% vs 11.1%, p=0.03 but no association with ethnicity, education status, marital status or place of residence (urban vs rural).
Conclusion: COVID-19 vaccine hesitancy is low in Malaysian patients with AIRD but patients with a low socioeconomic status are prone to have vaccine hesitancy. More education on the vaccine's efficacy and safety especially among patients with co-morbidities are warranted.

AB1357 RISK OF APS AND APLS POSITIVE PATIENTS FOR THROMBOSIS WITH COVID-19

Keywords: COVID, Autoantibodies, Anti-phospholipid syndrome

F. Berianu[1], R. Butendieck[1], B. Wang[1]. [1]*Mayo Clinic, Rheumatology, Jacksonville, United States of America*

Background: Coagulopathy, thromboembolic events and DIC during COVID-19 infection has been reported. Antiphospholipid antibodies (aPLs), present in 1–5 % of healthy individuals. aPLs are associated with the risk of antiphospholipid syndrome (APS) which is associated with higher risk of thrombosis.

Objectives: We wanted to see if patients with known APS or aPLs only are at higher risk of a thrombotic event compared to control when developed COVID-19. We retrospectively review EMR for over a year for thrombotic events in patients with COVID and prior history of APS or aPLs only and matched them to control.

Methods: Patient characteristics and laboratory testing were summarized according to the following groups: APS, aPLs detected or control. The control were matched according to age and gender for each group. Continuous variable were summarized as median (range) and mean (standard deviation), while categorical variables were reported as frequency (percentage). The binary patient outcome of thrombotic event, hospitalization for COVID, death, and composite event (the combined occurrence of thrombotic events, hospitalization, death) were calculated and interpreted as the multiplicative increase in odds of the given outcome for aPL group compared to control group. Multivariable logistic regression models were adjusted for potential risk factors (immobilization, hypertension, coronary artery disease, diabetes mellitus, and smoking) one at a time due to the rare occurrences of events studied.

Results: In single variable analysis (unadjusted) the odds of the patient having a thrombotic event was approximately 27 times higher in patients with aPL only compared to Controls (P<0.001). We see similar results in multivariable analyses (adjusted) adjusting for the following variables one at a time: immobilization, hypertension, coronary artery disease, diabetes mellitus, and smoking. In each of the multivariable analyses, the adjusted odds of a thrombotic event was between approximately 24 and 29 times higher in patients with aPL Antibody Only compared to Controls (all P<0.001) indicating that association of aPL Antibody Only with thrombotic event was independent of immobilization, hypertension, coronary artery disease, diabetes, and smoking. There was no statistically significant risk of thrombosis in APS group vs control. Majority of patients with APS were on chronic anticoagulation.

Conclusion: We found a statistical significantly difference in patient with aPLs only versus control regarding risk of thrombosis when developed COVID-19. No statistically significant risk was noted in patients with APS. While chronic anticoagulation in APS patients is protective it seemed that patient with aPLs only do carry a high risk of thrombosis if any inciting factors like COVID-19.

Table 1. Patients baseline characteristics

	Patients that did not suspended bDMARD during pandemic (n = 689)	Patients that suspendedp bDMARD during pandemic (n = 143)	
Female gender, n(%)	549 (79.7)	125 (87.4)	0.02
Age, median (IQR)	55 (45 – 63)	52 (42 – 60)	0.04

Background: The COVID-19 pandemic triggered serious challenges in the treatment of chronic diseases due to the lack of access to medical attention. Patients with rheumatic diseases (RD) must have adequate treatment compliance in order to reach and maintain remission or low activity of their diseases.

Treatment suspension because of non-medical reasons might lead to disease activation and organ damage.
Objectives: Identify the frequency of biologic treatment (bDMARD) suspension in patients with RD during the COVID-19 pandemic and determine the associated factors for suspension.
Methods: In this study we included all patients registered in the Mexican Biologics Adverse Events Registry (BIOBADAMEX), that started bDMARD before March 2019 and suspended treatment during the COVID-19 pandemic. We used descriptive statistic to analyze baseline characteristics and main treatment suspension causes. We used Chi[2] and Kruskal Wallis tests to analyze differences between groups.
Results: A total of 832 patients patients registered in BIOBADAMEX were included in this study, 143 (17%) suspended bDMARD during the COVID-19 pandemic. The main causes of suspension were inefficacy in 54 (38%) patients, followed by *other* motives in 49 (34%) patients from which 7 (5%) was loss of medical coverage. Adverse events and loss of patients to follow up were the motive in 16 (11%) and 15 (11%) patients respectively. When we compared the group that suspended bDMARD with the non-suspenders (Table 1), we found statistical differences in patient gender, with 125 (87%) female patients that suspended bDMARD, with a median age of 52 (42-60) years, and a treatment duration of 3.8 years.
Conclusion: In our study we found that 17% of patients with RD suspended bDMARD treatment during the COVID-19 pandemic and that non-medical motives such as lack of patients follow up and loss of medical coverage due to unemployment were important motives. These results are related to the effect of the pandemic on other chronic diseases.

AB1359 CLINICAL FEATURES OF COVID-19 IN PATIENTS WITH CONNECTIVE TISSUE DISEASES DURING THE RECENT PANDEMIC IN GUANGZHOU, CHINA

Keywords: Real-world evidence, Health services research, COVID

Y. Jiang[1], X. Zheng[1], X. Wu[1], S. Zhong[1], Y. Liang[1], Q. Wei[1], J. Gu[1], Y. Pan[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: Patients with connective tissue diseases (CTD) are vulnerable to SARS-COV-2 infection, given that a proportion of CTD patients suffer from interstitial lung diseases (ILD). Moreover, the use of glucocorticoids and immunosuppressive agents could affect the outcome of lung diseases. The impact of coronavirus disease 2019 (COVID-19) infection on rheumatic diseases remains poorly investigated as the pandemic has recently occurred in Southern China.
Objectives: The study aimed to describe the clinical features and hospitalisation costs of COVID-19 in CTD patients, especially those with COVID-19 pneumonia.
Methods: It was a cross-sectional case series study. Demographic data, symptoms, signs, medical history, laboratory, radiological findings and costs were collected from 86 CTD patients from the inpatient department in a tertiary hospital during the COVID-19 pandemic in Guangzhou, China.
Results: Of all the 86 CTD patients, 67 (77.9%) were females, and 24 (27.9%) had CTD-ILD before admission. 54 (62.8%) of them had SARS-COV-2 infection dected by nucleic acid or antigen tests for SARS-COV-2. Patients with SARS-COV-2 infection had older age, higher WBC, neutrophil/lymphocyte ratio and CEA. Moreover, 325 (29.1%) of the participants had COVID-19 pneumonia confirmed by the HRCT. Noticeably, 15 CTD patients without ILD presents with COVID-19 pneumonia. Patients with COVID-19 pneumonia had older age, higher serum ferritin, CEA, and C-reactive protein ($p<0.05$). According to the rheumatologists' assessment, 6 (41.9%) of the patients had worsened CTD disease activity. 14 (16.3%) of the patients had confirmed infections involving the lung (6), skin (3), urinary tract (2), gastrointestinal tract (1), blood (1), and vagina [1]. The pathogens isolated included staphylococcus aureus, candida albicans, escherichia coli, cytomegalovirus, Epstein-Barr virus and herpes zoster virus. Among all the symptoms related to COVID-19, coughing was the most frequent symptom, followed by sputum, fatigue and fever. 27 (31.4%) of the patients required a nasal cannula for oxygen administration; 7 (8.1%) needed high-flow humidification therapy. 24 of the CTD patients were given higher doses of glucocorticoids. Five patients were given anti-virus medication, 4 were using baricitinib or tocilizumab, and 10 were taking intravenous immunoglobulin. There was no difference in the hospitalisation costs between the patients with or without SARS-COV-2 infection; however, patients with COVID-19 pneumonia had significantly higher costs with a mean of 24083 RMB (≈3318 Euros). All the patients got improved before the discharge.
Conclusion: Disease flare and COVID-19 pneumonia should be noticed in patients with CTD during the pandemic.

AB1360 AUTOANTIBODIES RELATED TO RHEUMATIC DISEASES AFTER COVID-19 INFECTION

Keywords: Real-world evidence, COVID, Autoantibodies

X. Zheng[1], X. Wu[1], Y. Jiang[1], Y. Liang[1], S. Zhong[1], J. Gu[1], Z. Liao[1]. [1]*Third Affiliated Hospital of Sun Yat-sen University, Department of Rheumatology and Immunology, Guangzhou, China*

Background: SARS-CoV-2(Severe acute respiratory syndrome coronavirus 2) has been circulating worldwide for three years. It mainly causes upper respiratory tract infection, which can manifest as pulmonary infection and even respiratory distress syndrome in severe cases. Different autoantibodies can be detected in patients infected with COVID-19.
Objectives: To explore autoantibodies related to rheumatic diseases after COVID-19 infection.
Methods: Ninety-eight inpatients were tested for antinuclear antibodies (ANA), antibodies to extractable nuclear antigens(ENA), anti-neutrophil cytoplasmic antibodies (ANCA), anticardiolipin antibodies,a-β2GPI (IgG/IgM). They were from a tertiary hospital in Guangzhou during the COVID-19 epidemic. Data were described statistically.
Results: Ninety-eight hospitalized patients were tested for relevant antibodies. The average age was 50.64±19.54; 67 (68.4%) were male, 64 (65.3%) were COVID-19 positive, 90 (90.9%) had rheumatic diseases, and 56 of them were COVID-19 positive patients with rheumatic diseases. There were 76 patients tested for antinuclear antibodies;29 (38.16%) were negative, 18 (23.68%) had a 1/80 titre, and 29 (28.16%) had a titre greater than 1:80. The 31 covid patients were positive for ANA. In the high-titer group, 19 patients with rheumatic diseases were positive for COVID-19, and 12 patients had an exacerbation of the rheumatic diseases (6 of whom had previously had pulmonary fibrosis). Of 31 covid patients, only two were non-rheumatic patients, and both were elderly, aged 85 and 100, respectively. Fifty-six patients had ENA results, and 29 for positive antibodies, 8 for ds-DNA antibodies, 2 for anti-Sm antibodies, 6 for anti-nucleosome antibodies, 12 for anti-U1RNP antibodies, 2 for anti-Scl-70 antibodies, 12 for anti-SS-A antibodies, 3 for anti-mitochondrial M2 antibodies, 2 for anti-centromere antibodies, 1 for anti-Po antibodies, and one for anti-Jo-1 antibody. All 56 patients had rheumatic diseases, and no new patients were found. There were 62 patients with ANCA data. P-ANCA was positive in 12 cases(19.35%), and MPO-ANCA was positive in 2 cases. An 85-year-old non-rheumatic COVID-19 patient was P-ANCA positive. She had a history of hypertension, colon cancer, CKD3, coronary heart disease, and atrial flutter. In the anticardiolipin antibodies group, there were 62 patients; only 6 were positive, and 2 were rheumatic patients infected with COVID-19. Antiphospholipid antibodies were detected in 33 patients, and a-β2GPI was tested in one patient, an 82-year-old COVID-19 patient with gout, diabetes, and cerebral infarction in the past. We did not find a statistical difference in the above results.
Conclusion: We have not found a correlation between SARS-CoV-2 and serum autoantibodies of rheumatic immune diseases. It needs large samples and an extended follow-up to research.

AB1361

COVID-19 IN PATIENTS WITH INFLAMMATORY ARTHRITIS IN THE VINSCHGAU VALLEY IN SOUTH TYROL

Keywords: COVID, Inflammatory arthritides

P. Matznellerˡ, A. Mulrenin[1,2], M. Wierer[1,2], C. Duftner[2], C. Dejaco[1]. [1]*South Tyrol Health System ASDAA-SABES, Service of Rheumatology, Bruneck, Italy*; [2]*Medical University of Innsbruck, Department of Internal Medicine, Clinical Division of Internal Medicine II, Innsbruck, Austria*

Background: For patients with autoimmune rheumatic diseases, the Covid-19 pandemic carried some implications in addition to those faced by the general population. In particular, the question whether these patients are at increased risk of contracting Covid-19 or have an unfavourable disease course has been and is a matter of concern. In autumn 2020, the population of the Vinschgau valley in South Tyrol, northern Italy was still largely spared from infection with SARS-CoV-2. Accordingly, incidence of the disease in the upcoming winter was anticipated to be high.
Objectives: This prospective observational study aimed at characterizing Covid-19 infections in a population of patients with inflammatory arthritis (IA) residing in the Vinschgau valley. The study was conceived as companion project to an analogously designed prospective cohort study in the general population of the Vinschgau valley, the CHRIS Covid-19 study.
Methods: Between september and december 2020, IA patients (i.e. previously diagnosed rheumatoid arthritis [RA], psoriatic arthritis [PsA] or peripheral spondyloarthritis [SpA]) residing in the Vinschgau valley (n=394 based on national healthcare system database) were contacted. Those who consented to participate in the study underwent a clinical baseline visit including TJC, SJC, VAS and assessment of RAID, PsAID9 or BASDAI (range 0-10, respectively). In addition, a Covid-19 screening questionnaire was administered. Then, active and/or past infection with SARS-CoV-2 were determined by nasopharyneal swab (PCR) and serum antibody test. In positively tested subjects, Covid-19 disease severity was graded according to WHO criteria (range 0-8, with 0 = no evidence of infection and 8 = death). Patients were followed-up with regular telephone interviews including Covid-19 screening questionnaire and RAID/PsAID/BASDAI for up to 12 months.
Results: 111 patients (72 RA, 29 PsA, 10 SpA) were enrolled (see Table 1 for demographics and comorbidities). A total number of 19 PCR-confirmed SARS-CoV-2 infections in 17 patients (10 RA, 7 PsA) were observed. Mean ± standard deviation 7-day incidence (incident cases/study population) was 0.003 ± 0.007. Fatigue, fever, anosmia and sore throat (present in 57.9%, 47.4%, 42.1% and 36.8% of infections, respectively) were the most frequent symptoms. Median (min-max) disease severity was 2 [1-4]. Two infections led to hospitalization, in one case oxygen supply was necessary. Four infections were asymptomatic (Figure 1). One patient died during follow-up due to pre-existing non-small cell lung cancer. Median absolute difference between post- and pre-infection disease activity was 0.4 and -0.8 for RAID and PsAID, respectively (both markedly below the minimal clinically important difference of 3 and 3.6 points, respectively).
Conclusion: Incidence of Covid-19 in the analysed cohort of patients with IA was low. Symptoms and comorbidities of SARS-CoV-2-positive IA patients reflected those known from the general population. Covid-19 seemed to have no relevant impact on IA disease activity. Comparison of these preliminary data with those of the general population is planned.

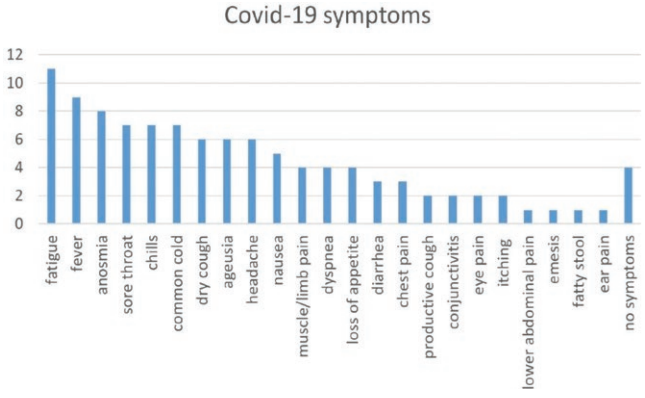

Figure 1. Spectrum of clinical symptoms reported by study patients during infection with SARS-CoV-2

Table 1. Demographic data and selected comorbidities of study patients. Age and body mass index (BMI) are given in means ± standard deviation, female sex and comorbidities are given in n (% of column totals).

	Total	SARS-CoV-2 positive	Hospitalized
	111	17	2
Age at inclusion (years)	59.7 ± 9.4	62.5 ± 10.0	76.3 ± 9.0
BMI at inclusion (kg/m^2)	27.9 ± 17.1	26.1 ± 3.3	30.5 ± 1.6
Female sex	76 (68.5)	10 (58.8)	1 (50)
Active smokers	22 (19.8)	1 (5.9)	0 (0)
Arterial hypertension	44 (39.6)	8 (47.1)	2 (50)
Diabetes mellitus	4 (3.6)	1 (5.9)	1 (50)
Hyperlipidemia	27 (24.3)	2 (11.8)	1 (50)
Cardiac arrhythmias	12 (10.8)	2 (11.8)	1 (50)
History of cancer	5 (4.5)	1 (5.9)	0 (0)
Chronic bronchitis	4 (3.6)	1 (5.9)	0 (0)
Asthma	3 (2.7%)	0 (0)	0 (0)
Hospitalized in previous 12 months	21 (18.9)	3 (17.6)	0 (0)
Surgery with general anaesthesia in previous 12 months	11 (9.9)	2 (11.8)	0 (0)

AB1362

STUDY OF ADVERSE REACTIONS TO COVID-19 VACCINATION IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Vaccination/immunization, COVID

Y. Akiyama[1,2,3], M. Matsuda[4,5]. [1]*Tochin Yoshida Internal Medicien & Rheumatology, Rheumatolory, Nagano, Japan*; [2]*Setagaya Rheumatology Clinic, Rheumatolory, Tokyo, Japan*; [3]*Meiyo Immunology & Rheumatology Clinic, Rheumatolory, Tokyo, Japan*; [4]*Setagaya Rheumatology Clinic, Nurse, Tokyo, Japan*; [5]*Meiyo Immunology & Rheumatology Clinic, Nurse, Tokyo, Japan*

Background: Vaccination has been recommended in the midst of the COVID-19 pandemic, but some patients are not vaccinated due to concerns about adverse reactions.
Objectives: The purpose of this study is to investigate the adverse reactions in rheumatic diseases and to guide the decision-making of patients and physicians.
Methods: A questionnaire was sent to patients with rheumatic diseases, and patients who could be counted as of September 2021, when they consented to this study, were surveyed.
Results: The subjects were 123 (male:female=10:113), 84 with rheumatoid arthritis and 39 with other immune diseases. The therapeutic agents used were PSL 31(25.2%), MTX 65(52.8%), NSAID/COX inhibitors 28(22.8%), bDMARDs 42(34.1%). adverse reactions after the first and second vaccination were fever 17(13.8%)/50(40.7%), joint symptoms 7(5.7%)/22(17.9%), local injection reactions (pain/irritation) 22(17.9%), local injection reactions (pain/erythema) 93(75.6)/98(79.7), systemic skin symptoms 0(0%)/2(1.6%), other symptoms (malaise, myalgia, etc.) 59(48.0%)/85(69.1%), and treatment intensification 5(4.1%)/12(9.7%). These responses differed in occurrence only for fever with and without PSL medication (22.5%: 47.3% (p=0.02)). The odds ratio for disease worsening after the first dose of vaccine and again after the second dose was 33.5 (p<0.01).
Conclusion: No specific adverse reactions other than the commonly known ones were observed, but some patients experienced worsening of symptoms after vaccination, requiring intensified treatment. Based on the results of this study, we believe that adverse reactions to vaccination are acceptable. We plan to accumulate more cases and analyze them in the future. The exacerbation of disease after the first vaccination would predict the exacerbation after the second vaccination.

FIRST PRESENTATION OF AUTOIMMUNE RHEUMATIC DISEASES AFTER COVID-19 VACCINATION: A SYSTEMATIC REVIEW

Keywords: COVID, Epidemiology, Vaccination/immunization

C. Soto[1], A. Peña[1], F. Gonzalez[1], P. Flores[1], A. C. Medina-Garcia[1], A. Bernal[1], O. L. Vera Lastra[2], C. Pineda[1], L. J. Jara[1]. [1]*Instituto Nacional de Rehabilitacion, Rheumatology, Mexico City, Mexico*; [2]*Centro Medico Nacional La Raza, Medicina Interna, Mexico City, Mexico*

Background: Covid-19 vaccination prevents 52% of expected infections, 56% of expected hospitalizations, and 58% of expected deaths in adults 18 years or

older [1]. Nevertheless, some case reports and series have demonstrated the new-onset rheumatologic syndromes after vaccination.
Objectives: The aim of this systematic review is to establish the frequency, clinical features, and treatment response of new onset autoimmune rheumatic diseases after COVID-19 vaccination.
Methods: Systematic search for original research articles published between January 2021 and January 2023 was formulated. The search process was carried out following the PRISMA guidelines. Electronic searches were performed in Medline, EMBASE, Cochrane, Scopus, EBSCO, WoS and LILACS using the following key terms in all possible combinations: "Rheumatic diseases", "Systemic Vasculitis", "Myositis", "Polymyositis", "Systemic Lupus Erythematosus", "Antiphospholipid Syndrome", "Adult onset Still disease", "Rheumatoid arthritis", "ANCA-associated vasculitis", "Spondyloarthritis", "Reactive arthritis", "Sjogren's syndrome", "Systemic sclerosis", "Covid-19 vaccine" and "SARS-CoV-2 vaccine". Cohort studies, case reports or case series were included if the patients fulfilled the specific diagnostic/classification criteria and/or nomenclature for each rheumatic autoimmune disease. Publications were excluded if they did not fulfill the above criteria.
Results: The electronic search yielded 280 publications. A total of 163 articles were evaluated and 59 reports with 108 patients (GCA 10, IgA vasculitis 9, SLE 14, ANCA vasculitis 24, adult-onset Still's disease 12, reactive arthritis 2, Rheumatoid Arthritis 5, Sjögren's syndrome 3, Systemic Sclerosis 2, Takayasu's arteritis 2, cryoglobulinemic vasculitis 1, Kawasaki disease 3, Polymyalgia rheumatica 16, PAN 1, SpA 2, Overlap syndrome 1, and Antisynthetase syndrome 1) were included. 44.4% were men and 43.5% were women with a median age of 60 years (IQR 40-74 y/o), 47.2% developed rheumatic disease after the first dose and 35.2% after the second dose, with a median of 10 days (IQR 5.5-14.5 days). 67.6% received corticosteroids (16.7% High-dose and 15.7% Pulse), 31.5% received immunosuppressant (cyclophosphamide 7.4%, rituximab 2.8, hydroxychloroquine 4.6, methotrexate 6.5, tocilizumab 2.8, mycophenolate 2.8, immunoglobulin 8.3 y 4.6% others). The 55.6% had complete remission, 24.1% partial and 6.5% non-response.
Conclusion: 1. After Covid 19 vaccine, a minority of patients may develop for the first time an autoimmune rheumatic disease. Despite the increasing number of documented cases, the incidence remains low compared to the benefits of vaccination. 2. Patients present a high variability of clinical manifestations and most patients respond favorably to treatment. 3. The complex interaction between the vaccine component and the immune system must be studied.

AB1364 **VACCINATION AGAINST COVID-19 IN PARAGUAYAN PATIENTS WITH RHEUMATOID ARTHRITIS**

Keywords: COVID, Rheumatoid arthritis, Vaccination/immunization

S. Cabrera-Villalba[1,2], G. Avila[1,2], A. Amarilla[1], M. Zarza[1], E. Leiva[2], P. Pusineri[2], L. Roman[3], V. Valinotti[1], P. DE Abreu Trigueros[3]. [1]*Hospital Central del Instituto de Previsión Social, Rheumatology, Asunción, Paraguay*; [2]*Hospital de Clínicas, Universidad Nacional de Asunción, Rheumatology, Asunción, Paraguay*; [3]*Sociedad Paraguaya de Reumatología, Rheumatology, Asunción, Paraguay*

Background: In February 2021, the first doses of COVID-19 vaccines were received in Paraguay, and rheumatic patients were the preferred population to get these vaccines. Up to December 2022 the vaccination coverage in Paraguay was 59.4%, with at least one vaccine dose. 52.4% accessed the primary scheme (two doses), while 28.6% had at least one booster dose. Only 7.1% completed the COVID-19 immunization scheme.
Objectives: To describe vaccination against COVID-19 in Paraguayan patients with Rheumatoid Arthritis (RA).
Methods: Descriptive, cross sectional, observational study, in a Paraguayan cohort of RA patients meeting ACR/EULAR2010 criteria, under follow-up in two Rheumatology reference centers, from October to December 2022. A standardized questionnaire according to the variables included (clinical, vaccination, vaccine type, number of doses) was made. Quantitative variables were presented as means and qualitative as frequencies.
Results: 568 patients with RA were included, 84.1% were female, mean age 55.48±13.94 years old. 23.9% patients were from Hospital de Clínicas and 76.1% from Hospital Central del Instituto de Previsión Social. The average number of received vaccinations doses was 2.54±1.19. 88.7% of patients acquired at least one dose of COVID-19 vaccine, 85% obtained two doses; and, while 60.9% of patients received the first booster, 21.2% had the second one.
Conclusion: In this series of Paraguayan RA patients, vaccination against COVID-19 is higher than the general population, perhaps due to priority of patients with rheumatic diseases receiving immunization, and frequent access to medical care with physician's prompt to receive vaccinations. While over 80% of patients have a complete primary schedule, and more than 60% received the first booster; only 21% have a complete immunization schedule, which is still much higher than the general population in Paraguay.

Table 1. Vaccines in Paraguayan patients with Reumatoid Arthritis

Vaccines against COVID-19	First Dose n: 504	Second Dose n: 483	First booster n: 344	Second booster n: 122
Sputnik V(Gam--COVID-Vac) n (%)	149 (26.2)	137 (24.1)	10 (1.8)	0
Astrazeneca (ChAdOx1 nCoV-19) n (%)	172 (30.3)	171 (30.1)	110 (19.4)	36 (29.5)
Pfizer n (BNT162b2) (%)	81 (14.3)	80 (14.1)	198 (34.9)	68 (55.7)
Moderna (mRNA-1273) n (%)	41 (7.2)	38 (6.7)	22 (3.9)	18 (14.8)
Hayat Vax n (%)	29 (5.1)	28 (4.9)	1 (0.2)	0
Sinopharm BBIBP n (%)	2 (0.4)	1 (0.2)	0	0
Covaxin n (%)	28 (4.9)	26 (4.6)	3 (0.5)	0
CoronaVac n (%)	2 (0.4)	2 (0.4)	0	0

AB1365 **COMPARISON OF HOMOLOGOUS AND HETEROLOGOUS BOOSTER SARS-COV-2 VACCINATION IN AUTOIMMUNE RHEUMATIC AND MUSCULOSKELETAL PATIENTS**

Keywords: COVID

D. Honfi[1], G. Szebeni[2], A. Balog[1]. [1]*University of Szeged, Rheumatology and Immunology, Szeged, Hungary*; [2]*University of Szeged, Biological Research Centre, Szeged, Hungary*

Background: Vaccine-induced immunity is very important for controlling the COVID-19 infection. The vaccination supports humoral and cellular immunity, and this is one of the main strategy for us. Various vaccines approved in the countries have been shown to reduce infection rates, severity, and mortality.
Objectives: We aimed to compare humoral and cellular immune responses after homologous or heterologous vaccination among patients with aiRMDs at their third vaccination with BNT162b2 or with two vaccinations followed by COVID-19 infection. We detected the anti-SARS-CoV2 antibody levels and measured the SARS-CoV-2 reactive B-, or T-cell mediated immunity in aiRMDs receiving homologous (Hom.), heterologous (Het.) vaccines or became infected (Inf.).
Methods: A single center observational study evaluated immunogenicity and safety of the third dose vaccines or after two-dose regimen of vaccine and COVID infection in patients with aiRMDs. Neutralizing anti-RBD antibodies and specific T-cell response were measured.
Results: We showed that following 4 months of the booster vaccination with the third dose of mRNA-based vaccine or after COVID infection, the positive (>21.8 BAU/mL) neutralizing anti-RBD IgG antibody response was outstanding in all three patient groups, 95.5%, 100% and 100% of the homologous and heterologous as well as the SARS-CoV-2 infected groups. Taken together booster vaccinations or SARS-CoV-2 infection after completing 2 doses of the vaccination can lead to the production of neutralizing antibodies still protective in RMD cases after 4 months of the third antigen exposition. The booster vaccination reduces the frequency of hospital admissions and mortality with ai RMDs. The vaccinations are effective independently from the type of vaccine, the SARS-CoV-2 specific memory B-cell populations showed a statistically not significant but lower frequency in the infection group. Clinical activity of aiRMDs was not increased following booster vaccination.
Conclusion: Patients, who received a heterologous booster vaccine had a higher level of peripheral memory B-cells compared to those who had COVID-19 infection. Biologic therapy decreased the level of B-cells. Patients with a disease duration of more than 10 years had higher level of CD8+TNF-α+ and CD8+IFN-γ+ T-cells compared to patients who were diagnosed less than 10 years ago. The third booster mRNA-based vaccine was as much effective as in the homologous and heterologous patients groups compared who had COVID infection.

Pain in rheumatic diseases, including fibromyalgia_

AB1366

A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE PREVALENCE OF PAIN SENSITISATION AND NEUROPATHIC LIKE PAIN IN INFLAMMATORY ARTHRITIS, USING QUESTIONNAIRES

Keywords: Systematic review, Pain, Inflammatory arthritides

Z. Rutter-Locher[1], N. Arumalla[1], S. Norton[2], L. Taams[3], L. B. Kirkham[1], K. Bannister[4]. *[1]Guy's Hospital, Rheumatology, London, United Kingdom*; *[2]King's College Hospital, Psychology Department, Insitute of Psychiatry, London, United Kingdom*; *[3]King's College London Guy's Campus, Centre for Inflammation Biology & Cancer Immunology, London, United Kingdom*; *[4]King's College London Guy's Campus, Wolfson Centre for Age-Related Diseases, London, United Kingdom*

Background: Targeted pain relief is a major unmet medical need for patients with inflammatory arthritis (IA), where approximately 40% of patients experience persistent pain[1]. Self-reported questionnaires which report on pain sensitivity and neuropathic like pain may provide an insight into certain pain types to guide targeted treatment.

Objectives: In this systematic review and meta-analysis we evaluated self-reported pain sensitivity and neuropathic like pain in subjects with IA, as defined by questionnaires.

Methods: MEDLINE, Embase, Web of Science, PsycINFO and google scholar were searched for publications and conference abstracts, reporting on pain sensitivity and neuropathic pain using painDETECT, DN4, LANSS, CSI, PSQ and McGill pain questionnaire in adult patients with IA. Risk of bias was assessed using National Institute of Health Quality Assessment Tool. Meta-analysis according to individual questionnaire criteria, was undertaken.

Results: 63 studies (38 full text and 25 conference abstracts) were included in the review, reporting on a total of 13,035 patients. On meta-analysis, prevalence of pain sensitivity/neuropathic pain in IA was 36% (95% CI 31-42%) according to painDETECT, 31% (95% CI 26-37%) according to the DN4, 32% (95% CI 32-49%) according to the LANSS and 42% (95% CI 34-50%) according to the CSI. On meta-regression, prevalence of pain sensitivity/neuropathic pain in RA was significantly lower than SpA (p=0.01) and PsA (p=0.002) using the painDETECT questionnaire. Across all questionnaires, pain sensitivity and neuropathic like pain were significantly associated with pain severity, disease activity, disability, quality of life and anxiety and depression measures. Studies reporting on whether neuropathic like pain is a predictor of treatment outcome were inconsistent.

Conclusion: Pain sensitivity and neuropathic like pain contributes to pain perception in up to 42% of patients with IA. Despite substantial heterogeneity between studies on meta-analysis, this review highlights the large proportion of patients with IA who may experience pain due to underlying mechanisms other than/in addition to synovial inflammation.

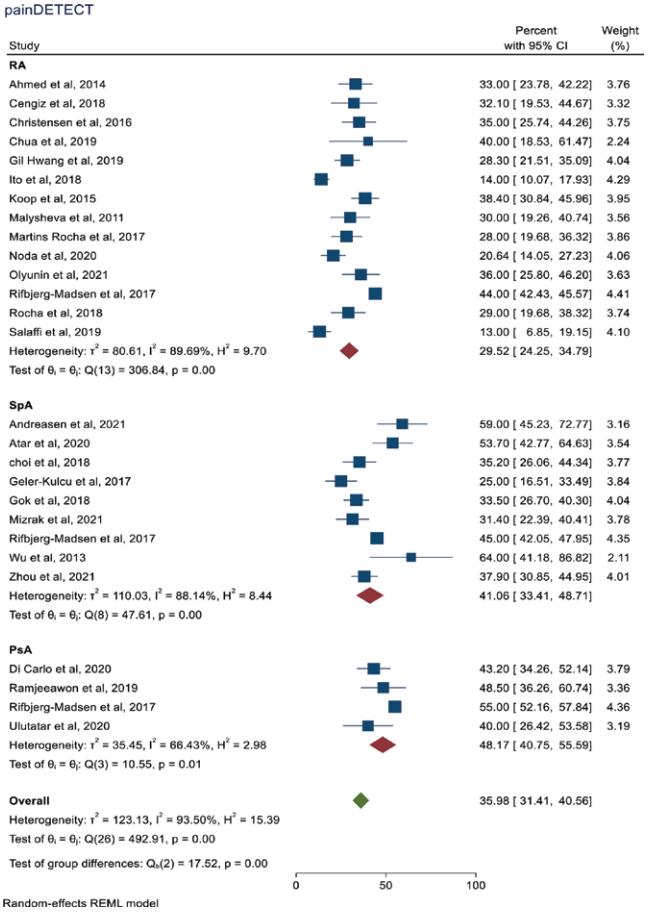

Figure 1. Prevalence of neuropathic like pain or pain sensitization according to painDETECT in RA, SpA and PsA.

Conclusion: All rehabilitation strategies were effective for pain and HRQOL, and has marginal effect on depression, sleep, and fatigue but efficacy was not maintained at the time of post-trial follow-up. However, in this review we could not

EFFECTIVENESS OF REHABILITATION STRATEGIES IN PRIMARY FIBROMYALGIA SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Rehabilitation, Fibromyalgia, Non-pharmacological interventions

A. Pathak[1], J. Rai[1], N. Rai[2], R. Singh3, G. Bhatt[4]. *[1]AIIMS Bhopal, Physiology Department, Bhopal, India*; *[2]Neurocity Centre for Neuro Excellence, Neurology, Bhopal, India*; *[1]AIIMS Bhopal, Physiology Department, Bhopal, India*; *[4]AIIMS Bhopal, Pediatrics Department, Bhopal, India*

Background: Fibromyalgia is characterized by chronic inconsistent widespread pain and tenderness. It is also associated with other comorbid symptoms like sleep disturbances, fatigue, cognitive impairments (memory and mood disturbances), and/or irritable bowel syndrome. [1] Prevalence of fibromyalgia is 2.7% globally, being slightly higher in middle aged women (4-9%). 75 to 100 % patients with fibromyalgia face depression, anxiety and/or stress. The probability of occurrence of depression is almost 40% at any stage in the course of fibromyalgia. [2] Patients usually report physical symptoms of depression (e.g. appetite, sleep, and sexual dysfunction) rather than mood-related psychological symptoms (e.g. suicidal ideation, low self-esteem), however depression is affective expression of chronic pain and neuromarkers of both cannot be isolate. [3] Reviews done till date are either oriented toward specific form of exercise or towards specific outcome. We could not come across any review which included all form of exercise with measurement of multiple outcomes.

Objectives: The aim of this review was to 1) summarize evidence on the effectiveness of rehabilitation strategies in Fibromyalgia syndrome (FMS) and 2) determine the most effective rehabilitation strategy for reducing pain and depression in people with FMS.

Methods: PubMed, Ovid (Sp), and Cochrane search engines were used for identifying the studies done till 1 July 2022. Randomized control trials (RCTs) that have passive control group and active control group were included in this review for primary and secondary aim respectively. The primary outcome measures were Pain and depression. Secondary outcome was one from the sleep or fatigue or healthy related quality of life (HRQOL).

Results: A total of 25 RCTs were included. Separate random effect model meta-analysis is performed for randomised control trial with active and passive control group. Mean difference or Standard Mean difference with 95% confidence interval used to assess the effect size. Studies with passive control group showed moderate to large positive effects on pain (SMD -0.65, 95% CI -0.93 to -0.38; I2 = 72%) and HRQOL(MD -5.40, 95% CI -10.17 to -0.62; I2 = 74%) but non-significant for sleep, fatigue, and depression. Furthermore, on subgroup analysis studies with short term protocol showed significant effect on pain only, whereas studies with long term protocols showed positive effect on pain and HRQOL only but non-significant at the time of post-trial follow-up. Studies with active control group represent non- significant results except mixed exercises which showed positive effect (MD -4.78, 95% CI -7.98 to -1.57; I2 = 0%) for HRQOL.

differentiate any rehabilitation strategies for the best among those used in the included studies.

AB1368 PROBLEMATIC USE OF OPIOIDS IN MUSCULOSKELETAL CHRONIC NON-CANCER PAIN: A PROSPECTIVE REAL LIFE STUDY

Keywords: Descriptive studies, Epidemiology, Pain

A. Loret[1], V. Sophie[2], P. Anne[2], G. Carvajal Alegria[1], P. Goupille[1], I. Griffoul[1], D. Mulleman[1], D. Chu Miow Lin[1]. *[1]University Hospital Center of Tours, Rheumatology, Tours, France*; *[2]University Hospital Center of Tours, Pain Center, Tours, France*

Background: Musculoskeletal chronic non-cancer pain (CNCP) has a multidimensional impact. Opioid treatments have a key role in their management but expose to risks of serious adverse effects and in particular to opioid use disorder and misuse. There is a lack of data on this topic in France. This work assesses the proportion of patients with problematic use of their opioid treatment in the rheumatology department and in the pain center of the University Hospital of Tours.

Objectives: This work assesses the proportion of patients with problematic use of their opioid treatment in the rheumatology department and in the pain center of the University Hospital of Tours.

Methods: We carried out a prospective monocentric observational study in routine care in patients followed for musculoskeletal CNCP and treated in this indication with weak or strong opioid treatment at the time of inclusion between January and December 2021. We collected demographic, clinical and opioid prescribing data. The primary endpoint was the percentage of problematic use of opioid treatment defined by overconsumption and/or misuse according to the Prescribed Opioid Misuse Index (POMI) and/or opioid use disorder according to DSM V criteria.

Results: 97 patients were included (68% women, median age 55 years); 37% of patients were treated with strong opioids. The median duration of opioid treatment was 4.5 years; 30% of patients had problematic use of their opioid treatment. There was overconsumption in 20% of patients, misuse in 22% and opioid use disorder in 15%. The group of patients with problematic use of opioid treatment had a higher body mass index and reported significantly more history of psychotrauma.

Conclusion: The problematic use of opioids in patients with musculoskeletal CNCP is frequent. These data are in agreement with those in the literature in other indications. The interest of therapeutic education programs or other preventive interventions remains to be defined.

Keywords: opioids, chronic non-cancer pain, opioid use disorder, misuse.

AB1369 FIBROMYALGIA AND INFORMATION SOURCES, THE EXAMPLE OF YOUTUBE: A CROSS-SECTIONAL ANALYSIS

Keywords: Patient information and education, Patient-led research, Fibromyalgia

A. Mouamnia[1], A. Desvages[2]. *[1]Armentières Hospital Center, Rheumatology, Armentières, France*; *[2]Lille University Hospital, Rheumatology, Lille, France*

Background: Fibromyalgia is a chronic condition affecting 2 to 8% of the population. Like any chronic disease, there is a need for information. More than one in two patients use the Internet as a source of health information. YouTube is an online video-sharing website that is consulted daily by both patients and healthcare professionals. This is the second most visited website in the world after Google. Usually, users view the top 60 most relevant videos.

Objectives: The aim of our study was therefore to analyse the scientific quality of fibromyalgia videos on YouTube.

Methods: We performed an analysis by using the French version of youtube (www.youtube.fr) using the keyword "fibromyalgia". Search parameters were left as default (i.e. ranking videos by relevance as most users do). Only videos in French were included. The Global Quality Scale (GQS) was used to assess the quality of the content.

Results: 60 videos were selected. Four videos were excluded: 2 duplicates and 2 videos containing only music. The main results are presented in Table 1. 37.5% (n=21) of the videos were published by academic institutions and healthcare professionals. The mean duration of the videos was 12min34. The median GQS was 4. 75% (n=42) were scientifically relevant. 62.5% (n=35) of the videos demonstrated high quality, followed by intermediate quality (19.6% (n=11)). According to the GQS, 17.0% (n=10) of the videos were of low-quality.

Conclusion: To the best of our knowledge, we have conducted the first study examining the scientific quality of fibromyalgia-related content on YouTube. Most of the content on YouTube relating to fibromyalgia provide useful information. Nevertheless, physicians should remind their patients to be cautious about using such a source of information.

Table 1. Baseline features of the analyzed videos

Variables	Videos (n=56)
Number of comments	13 (0-227)
Number of likes	201 (0-2400)
Number of views	9676.5 (241-99618)

AB1370 DEMOGRAPHICAL, SOCIOPROFESSIONAL FACTORS AND HABITS ASSOCIATED WITH CHRONIC WIDESPREAD PAIN IN A LARGE GENERAL POPULATION COHORT

Keywords: Epidemiology, Pain, Fibromyalgia

F. Bailly[1,2], A. Petit[3], S. Kab[4], V. Foltz[5], M. Badard[5], B. Fautrel[1,5]. *[1]INSERM UMRS 1136, Pierre Louis Institute of Epidemiology and Public Health, Paris, France*; *[2]Assistance Publique - Hôpitaux de Paris, Pain Department, Paris, France*; *[3]CHU Angers, Centre de consultations de pathologie professionnelle, Angers, France*; *[4]INSERM IMS011, Constances Department, Paris, France*; *[5]Assistance Publique - Hôpitaux de Paris, Rheumatology Department, Paris, France*

Background: Clinical and demographic characteristics associated with chronic widespread pain (CWP) are well known, contrary to the social and professional characteristics in general population.

Objectives: To evaluate the set of characteristics associated with CWP.

Methods: The Constances cohort consisting of randomly selected volunteers aged 18 to 69 years, between 2013 and 2020 in France (ref). An ancillary study from this cohort aims to identify musculoskeletal pain using the Nordic Questionnaire. Chronic pain was defined as pain in at least 4 of the 6 areas, during at least 30 days during the previous year. Individuals diagnosed with a cancer were excluded. Demographic, clinical, social, and occupational data at inclusion were collected. Missing data were imputed. Multivariate analysis was performed.

Results: 193,436 people were included, of whom 7% (13,447 people) suffered from CWP. Female gender, age, higher BMI, depression, medium or high physical activity at work, current or past smoking, less sleep duration, and low socio-professional category were associated with CWP. Diploma was a protective factor, as well as leisure physical activity, while job search, household income, alcohol or cannabis were not or poorly associated with CWP.

Conclusion: CWP remains frequent in the French general population and is significantly associated with specific socioeconomic factors.

AB1371 CENTRAL SENSITIZATION AS A PREDICTOR OF FUNCTIONAL DISABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Diagnostic tests, Pain, Rheumatoid arthritis

V. Bombela[1], I. Shapoval[1], M. Stanislavchuk[1]. *[1]National Pirogov Memorial Medical University, Vinnytsya, Department of Internal Medicine №1, Vinnytsya, Ukraine*

Background: Rheumatoid arthritis (RA) is a common systemic inflammatory autoimmune disease. Patients with rheumatoid arthritis suffer from chronic pain, restricted function and reduction of daily activities [1]. Recent evidence reveals that central sensitization (CS) is associated with the development and maintenance of chronic pain. [2].

Objectives: The aim of this study was to determine the functional status of RA patients in the presence of CS.

Methods: The study involved patients diagnosed with RA according to the ACR/EULAR criteria (2010). The presence of the CS phenomenon was established according to the Central Sensitization Inventory (CSI) (Mayer, T. G. Et al., 2012). The Health Assessment Questionnaire-Disability Index (HAQ-DI) was used to assess the functional status of patients. RA activity was determined by DAS-28, SDAI, CDAI. Pain intensity was assessed by Visual Analog Scale (VAS). Statistical analysis was performed using MS Excel and SPSS22 software (©SPSS Inc.). Odds ratios (OR) and their corresponding 95% confidence interval (CI) were calculated. A descriptive analysis of the variables was carried out using mean and standard deviation (M±SD).

Results: A total of 168 RA patients (female 78%) were included. The median age of patients was 52.7±14.1 years, and the median duration of disease was 8.7±7.9 years. The examined patients showed mainly moderate and high activity of the disease (DAS-28 – 4.9±0.9; SDAI – 34,9±9,6; CDAI – 32,0±9,3). The presence of central sensitization (CSI≥40) was revealed in 59 (35%) of patients. The group of patients with CS had greater functional impairment compared to patients without CS: HAQ - 1.9±0.7 versus 1.0±0.6 ($p<0.05$). Also, patients with CS reported a higher intensity of pain (VAS pain - 7.8±1.2 versus 6.4±1.4; $p<0.05$). Mild functional disability (HAQ-DI value up to 1) was observed in 41% of patients with RA, moderate (HAQ-DI from 1 to 2) – in 38%, severe (HAQ-DI more than 2) – in 21%. The group of RA patients with CS had significant differences from the group without CS regarding HAQ-DI (Table 1.).

Table 1. Characteristics of the RA patients with and without CS regarding HAQ-DI.

	CSI<40 (n=109)	CSI>40 (n=59)	p
HAQ-DI (M±SD)	1.0 ± 0.6	1.9 ± 0.7	p<0.01
HAQ-DI ≤ 1, (n/ %)	61/ 55.9 %	8/ 13.6 %	
HAQ-DI 1 ≤ 2, (n/ %)	44/ 40.4 %	19/ 32.2 %	
HAQ-DI > 2, (n/ %)	4/ 3.7 %	32/ 54.2 %	

Notes: HAQ-DI - Health Assessment Questionnaire, CSI - Central Sensitization Inventory, P – the significance of differences between groups.

Finally, the strong correlation was determined between CSI and HAQ-DI (r=0,745; p≤0,01). Significant moderate correlations were also found between CSI and VAS pain (r=0,532; p≤0,01). We found that the presence of CS in patients with RA was associated with an increased risk of functional disability. Odds ratios are used to identify the risk of functional disorders in patients with CS. RA patients with CSI score ≥ 40 had an odds ratio of 6,97 [95% CI: 3,02 – 16,1] ($p < 0.0001$) for moderate functional disability and 21,3 [95% CI: 8,07 – 56,4] ($p< 0.0001$) for severe functional disability.

Conclusion: Central sensitization is common in RA patients. The phenomenon of central sensitization is associated with high level of functional disability of patients with RA and severity of pain. The phenomenon of central sensitization should be considered as a predictor of functional disability.

AB1372 PREDICTING ACUPUNCTURE EFFICACY IN FIBROMYALGIA: RESULTS OF A PRAGMATIC OPEN-LABEL STUDY

Keywords: Fibromyalgia

M. Di Carlo[1], G. Beci2, E. Cipolletta2, F. Salaffi2. *[1]Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy*; *[1]Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy*

Background: Fibromyalgia (FM) is a condition mainly characterized by the presence of chronic widespread musculoskeletal pain that affects a large proportion of the general population. Acupuncture, like other complementary and alternative medicines, is a patient-centered treatment and is generally well tolerated and appreciated by patients and the latest EUropean League Against Rheumatism (EULAR) recommendations on the management of FM made a weak recommendation for acupuncture in FM. To date, there is no study that indicates which variables predict response to acupuncture treatment in FM, either in terms of immediate response or persistence of response, and thus can enable the implementation of personalized treatment a prevention of therapeutic failure.

Objectives: The aim of this study is to identify the predictive factors of failure to acupuncture in patients with FM.
Methods: FM patients refractory to standard drug therapy (defining as standard drug theraphy the association of duloxetine and pregabalin) underwent eight weekly acupuncture sessions. Significant improvement, defined as a reduction of at least 30% of the FIQR, was assessed at the end of the eight weeks (T1) of treatment and three months after the end of treatment (T2). Univariate analysis was conducted to identify predictors of significant improvement at T1 and T2. Variables, which resulted significantly associated with clinical improvement at univariate analysis, were included in multivariate models.
Results: Analyses were conducted on 77 patients (9 males, 11.7%). At T1, significant improvement in FIQR was recorded in 44.2% of patients. At T2, significant improvement in FIQR persisted in 20.8% of patients. In multivariate analysis, predictive variables of treatment failure were tender point count (TPC) (odds ratio [OR] = 0.49, 95% confidence interval [95% CI]: 0.28 – 0.86, p = 0.01) and pain magnification (OR = 0.68, 95% CI: 0.47 – 0.99, p = 0.04) assessed with Pain Catastrophizing Scale, at T1. At T2, the only predictive variable of treatment failure was concomitant duloxetine use (OR = 0.21, 95% CI: 0.05 – 0.95, p = 0.04) (Table 1).

Table 1. Multivariate analyses considering the significant clinical improvement at the end of treatment (T1) and 3 months after the end of the treatment (T2) as dependent variable, independent variables the parameters that achieved statistical significance at univariate analyses.

T1			
Independent variables	Odds Ratio	95% CI	p
FIQR	1.00	0.96 - 1.05	0.88
PHQ15	0.95	0.83 - 1.09	0.47
PCS helplessness	0.92	0.76 - 1.13	0.43
PCS rumination	1.07	0.86 - 1.32	0.54
PCS magnification	0.68	0.47 - 0.99	0.04
PDQ VAS highest pain	0.91	0.53 - 1.55	0.72
PDQ VAS mean pain	1.06	0.64 - 1.77	0.81
TPC	0.49	0.28 - 0.86	0.01
T2			
Independent variables	Odds Ratio	95% CI	p
Duloxetin use	0.21	0.05 - 0.95	0.04
FIQR physical function	0.94	0.82 - 1.06	0.31
PCS helplessness	0.98	0.83 - 1.15	0.76
PCS magnification	0.75	0.50 - 1.12	0.16
TPC	0.69	0.40 - 1.19	0.18

Abbreviations. CI = confidence interval; BMI = Body Mass Index; FIQR = Revised Fibromyalgia Impact Questionnaire; PCS = Pain Catastrophizing Scale; PDQ = PainDetect Questionnaire; VAS = Visual Analogue Scale; TPC = Tender Point Count.

Conclusion: High TPC and a tendency for pain magnification predict immediate treatment failure, while duloxetine therapy predicts it three months after completion of the acupuncture course. The identification of clinical characteristics of unfavorable response to acupuncture could help to implement a cost-effective prevention of treatment failure in FM. The results of this study can provide a reference for the integration of a non-drug treatment such as acupuncture into the complex FM scenario.

AB1373 ARE FIBROMYALGIA AND/OR DEPRESSION THE MOST COMMON DIAGNOSES SEEN IN ROUTINE RHEUMATOLOGY CARE, ALBEIT AS SECONDARY DIAGNOSES, BUT WHICH MAY COMPLICATE CLINICAL ASSESSMENT, PROGNOSIS AND MANAGEMENT?

Keywords: Outcome measures, Fibromyalgia

T. Pincus[1], J. Schmukler[1], T. Li[2], J. Block[1]. [1]*RUSH University Medical Center, Medicine, Division of Rheumatology, Chicago, United States of America*; [2]*Georgetown University, Biostatistics, Bioinformatics & Biomathematics, Washington, United States of America*

Background: Fibromyalgia (FM) and depression (DEP) are common comorbidities in all primary rheumatic diagnoses, easily recognized in many patients, but often underestimated, particularly in patients who meet criteria for a primary rheumatic disease. Two screening indices to recognize FM and/or DEP are found within a 2-page multidimensional health assessment questionnaire (MDHAQ), FAST4 (fibromyalgia assessment screening tool) and MDS2 (MDHAQ depression screen) [1]. FAST4 agrees 90% with 2011 revised FM criteria, and MDS2 agrees 80% with reference HADS-D (hospital anxiety and depression scale–DEP).
Objectives: To analyze patients with different rheumatic diagnoses according to FAST4 and MDS2 as well as reference 2011 FM Criteria and HADS-D, to recognize those who screen positive for FM and/or depression.
Methods: The MDHAQ is a 2-page patient self-report questionnaire designed for routine care, completed by most patients with any diagnosis in 5-10 minutes at all visits to 2 academic rheumatology sites. The MDHAQ includes scores to calculate FAST4 and MDS2: the FM screen is positive (FAST4+) if 3/4 are present of: pain 0-10 visual numeric scale (VNS) ≥6/10, fatigue VNS ≥6/10, patient self-report 0-54 RADAI painful joint score ≥16/54, 60-symptom checklist (ROS) ≥16/60. The DEP screen is positive (MDS2+) if 0-3.3 DEP in the patient-friendly HAQ format is ≥2.2 OR DEP is + on ROS. The % of patients with various primary diagnoses, and % who screened positive or negative by FAST4, MDS2, 2011 revised FM criteria, or HADS-D was computed.
Results: Among 1,038 routine rheumatology care patients at 2 settings, 307 were FM+ by FAST4, 297 by 2011 FM criteria,295 DEP+ by MDS2, and 364 DEP+ by HADS-D. These prevalences were ≥28.0% according to FAST4 and MDS2 in all patients, as high as most prevalent primary ICD-10 diagnosis of 291 for rheumatoid arthritis (RA) (Table 1). Percentages of FM+ and DEP+ patients were within 12% for all diagnosis categories except for 6.3% of patients with primary FM (Table 1).
Conclusion: Non-somatic problems of FM and DEP are as common as any diagnosis seen in routine rheumatology care at 2 academic sites, albeit as secondary diagnoses in most patients. FM and/or DEP may complicate assessment, prognosis, and management of clinical status and explain poor responses to treatment in some patients. It is feasible to screen for FM and DEP on a single MDHAQ, completed by most patients in 5-10 minutes, as FAST4 and MDS2 indices, at any rheumatology site.

AB1374 ADVERSE EVENTS AFTER VACCINATION FOR SARS-COV2 IN A CASE SERIES OF FIBROMYALGIA PATIENTS VERSUS HEALTHY CONTROLS

Keywords: Fibromyalgia, Vaccination/immunization, COVID

M. L. Aprile[1,2], L. Cutore[1,2], D. Sambataro[3], G. Sambataro[3], M. Colaci[1,2]. [1]*University of Catania, Clinical and Experimental Medicine, Catania, Italy*; [2]*Ospedale Cannizzaro, Rheumatology Unit, Catania, Italy*; [3]*Artroreuma S.R.L., Rheumatology Outpatient Clinic, Mascalucia, CT, Italy*

Background: Fibromyalgia (FM) is a chronic widespread pain syndrome of unknown origin that leads to hypersensitivity for physical, chemical and/or psychic triggers. Vaccination, as an inflammatory stimulus and as a psychologically stressful act, could represent a challenge for these patients.
Objectives: We aimed to investigate the incidence of adverse reactions after vaccination for Sars-Cov2 in a series of FM patients versus healthy controls.

Methods: We recruited 65 consecutive FM patients classified according to the 2016 ACR diagnostic criteria[1] (M/F: 5/60; mean age 53.6 +/-12.5 years), without other associated rheumatologic conditions, and 65 age/sex-matched healthy controls. All patients filled a questionnaire in order to investigate eventual adverse events occurring up to 6 months after administration of a Sars-Cov2 vaccine. The questionnaire was divided into two parts: the first part included the patient's demographic information, the vaccine type performed and the anamnestic data. In the second part, the individuals described all new symptoms or signs occurred after the first, the second or the third dose of Sars-Cov2 vaccine.
Results: Overall, FM patients reported a higher frequency of adverse events after Sars-Cov2 vaccination in comparison with healthy controls. In particular, 44/65 FM patients vs. 11/65 controls complained of exacerbation of diffuse pain ($p<0.001$). Fatigue, diarrhea, sweating, tingles, headache, dizziness, transient respiratory discomfort, and paroxysmal vision blurring were also more frequent in FM patients than controls (47/65 vs. 30/65, $p=0.004$; 6/65 vs. 0/65, $p=0.028$; 18/65 vs. 8/65, $p=0.047$; 20/65 vs. 0/65, $p<0.001$; 22/65 vs. 9/65, $p=0.013$; 21/65 vs. 5/65, $p<0.001$; 10/65 vs 1/65, $p=0.009$; 17/65 vs. 2/65, $p< 0.001$, respectively). No significant difference between FM and the control group as regards fever was reported (24/65 vs. 30/65; $p=0.7$). Interestingly, swelling at the injection vaccine site was more commonly reported in controls (9/65 vs. 20/65; $p=0.034$). Finally, one case of Bell's palsy was registered in the FM series while one case of myocarditis in the control group.
Conclusion: FM patients showed an increased frequency of adverse events to Sars-Cov2 vaccination compared to healthy controls. In particular, all the symptoms reported seemed to be associated with the functional hypersensitivity that characterizes FM.

AB1375 SHORT-TERM EFFECTIVENESS OF A MULTIMODAL TREATMENT PROGRAM FOR REFRACTORY CHRONIC PAIN SYNDROMES INCLUDING PRIMARY AND SECONDARY FIBROMYALGIA

Keywords: Fibromyalgia, Pain

T. Pretat[1], T. Hügle[1], P. Ming Azevedo[1]. [1]*Lausanne University Hospital, Rheumatology, Lausanne, Switzerland*

Background: Treatment-refractory Chronic Pain Syndromes (CPS) are highly heterogenous entities with a high socio-economic burden. Multimodal treatment programs combining physical and cognitive-behavioral interventions have shown promising results but definition of clinically relevant response remains challenging.
Objectives: To identify clinical endpoints and predictive factors for effectiveness of a multimodal CPS program.
Methods: Retrospective observational study with 201 patients (22 to 72 years old) with refractory CPS with or without concomitant inflammatory rheumatic disease participating in a 2-week inpatient program in a tertiary rheumatology center in Lausanne, Switzerland. The approach included: Intensive physiotherapy, chiropractic and osteopathy treatment, peripheral or spine infiltration (if appropriate), rheumatological assessment, occupational therapy, psychiatric assessment, group-based education, sleep assessment by actigraphy and virtual reality sessions. Patients with psychiatric or physical conditions affecting ability to follow the program were excluded. BPI (primary endpoint) plus 6 other standardized questionnaires were executed before and after program. Multivariable regression was performed between delta BPI and clinical and demographical characteristics.
Results: The descriptive analysis is compatible with patients with severe refractory CPS patients. 73.3% are women (48% > 50 years old), 33.8% are overweight, 30.6% are obese, 73.2% describe pain in childhood or adolescence, 14% have had multiple surgeries (≥ 3) related to pain, 89% report back pain (86% lumbar), 27.1% have a present or past clinical diagnosis of hyperlaxity, 78% met the 2010 ACR criteria for FM, 81% had FiRST>4, 73.8% received concomitant psychiatric diagnosis, alexithymia was diagnosed in 34%, 50.2% presented reduced sleep efficacy and 78.4% showed hyper-fragmented sleep. After the program, the majority of patients improved scores for ODI (51%), FABQ-P (57%), POAM-A (48,5%), BPI-S (51.5%), BPI-I (65.6%), HAS (55%), HDS (59%) and PCS (63.7%). 48.5% of patients improved POAM-P and 34% improved FABQ-W scores. Interesting, patients who improved in HDS often improved also in PCS and HAS (measures of affective stress). The same correlated variation did not occur between ODI and BPI impact (measures of function). TAMPA variation was slightly correlated with PCS.
Several variables associated with BPI in univariable analysis were excluded in the multivariable due to excess of missing data. Clinical and demographic variables associated with BPI-S in multivariable analysis were age ($p=0.007$), disability allowance ($p=0.062$) and post-traumatic stress disorder ($p=0.44$). For BPI-I the association were with clinically significant peripheric arthrosis ($p=0.001$), patient origin ($p=0.008$) and the diagnosis of a biomechanical disorder ($p=0.002$).
Conclusion: The present work suggests that multimodal pain programs should have other goals besides pain reduction, such as improving function, reducing fear of movement, reducing affective stress, and changing cognition and behavior associated with the persistence of pain. The above-mentioned questionnaires target these aspects and may be utilized as endpoints. Questionnaires addressing affective stress had interrelated variations so that composite scores can be proposed and should be tested in long-term. AB1376 CENTRAL SENSITIZATION IN AUTOIMMUNE CONNECTIVE TISSUE DISEASES: IS IT RELATED TO DISEASE ACTIVITY, COEXISTING FIBROMYALGIA, AND LABORATORY FINDINGS?

Keywords: Systemic lupus erythematosus, Sjögren syndrome, Pain

Z. Bazancİr Apaydİn[1], H. Apaydın[2], B. Armagan[2], K. Gok[2], S. Erten[2]. [1]*Ankara Medipol University, Physical Therapy and Rehabilitation, Ankara, Turkey*; [2]*Ankara City Hospital, Rheumatology, Ankara, Turkey*

Background: Central sensitization (CS) is a phenomenon associated with chronic pain disorders and may be seen in several rheumatic diseases with chronic musculoskeletal pain such as osteoarthritis, spondyloarthropathy, and fibromyalgia, but little is known about CS in patients with autoimmune connective tissue diseases (ACTDs).
Objectives: The purpose of the study was to investigate the role of CS in patients with ACTDs and how it relates to disease activity, coexisting fibromyalgia, and laboratory findings.
Methods: A total of 82 patients (mean age 49.2±13.1 years) with ACTDs were included and were divided into three groups in terms of their diseases: Sjögren's syndrome (SS), rheumatoid arthritis (RA), and systemic lupus erythematosus (SLE). The CS was assessed using the central sensitization inventory (CSI-A and CSI-B scores). The disease activity (using Sjögren's syndrome disease activity index, ESSDAI, for SS; Disease Activity Score-28 C-reactive protein, DAS28-CRP, for RA; and Systemic Lupus Erythematosus Disease Activity Index, SLEDAI, for SLE), pain intensity (using visual analog scale), coexisting fibromyalgia, and laboratory findings (erythrocyte sedimentation rate-ESR and C-reactive protein-CRP) of all patients were evaluated.
Results: CS were present in 39% of all ACTDs patients (57.1% in SS, 36.8% in RA, and 26.1% in SLE). No significant differences were found in the CSI-A score ($p = 0.161$) and CSI-B score ($p = 0.809$) among the groups. There was a significant correlation between disease activity and the CSI-A scores in patients with RA ($p = 0.027$, $r = 0.360$), but no significant relationship between disease activity and the CSI-A scores in SS ($p = 0.390$) or SLE patients ($p = 0.179$). CSI-A and CSI-B scores were higher in the coexisting fibromyalgia in patients with ACTDs ($p = 0.002$, $p < 0.001$, respectively). There is no significant relationship between CSI-A scores and laboratory findings (ESR, CRP) in patients with ACTDs ($p > 0.05$).
Conclusion: CS is seen as a common condition in patients with ACTDs who also have fibromyalgia and is related to the disease activity in patients with RA. In addition to specific pharmacological treatments, pain-coping strategies may reduce pain and increase the quality of life of patients with these conditions. It is essential to increase awareness about the important role played by CS pain in patients with ACTDs.

AB1377 **FELDENKRAIS AWARENESS THOUGH MOVEMENT INTERVENTION FOR FIBROMYALGIA SYNDROME: A PROOF-OF-CONCEPT STUDY**

Keywords: Physical therapy/physiotherapy, Fibromyalgia, Non-pharmacological interventions

V. Giorgi[1], S. Farah[2], F. Salaffi[2], P. Sarzi-Puttini[1]. *[1]IRCCS Istituto Galeazzi - Sant'Ambrogio, Rheumatology Department, Milan, Italy*; *[2]Polytechnic University of Marche, Rheumatology Department, Jesi (AN), Italy*

Background: The Feldenkrais Method is a form of awareness through movement (ATM) which aims at increasing awareness about spatial and kinesthetic relationships among body segments and the environment thought verbally guided movements [1]. Fibromyalgia syndrome (FM) is a form of chronic widespread pain associated to a variety of ancillary symptoms, among which fatigue, sleep disturbances and regional pain syndromes are preponderant. Lately, increasingly more attention has been drawn on mind-body interventions and meditative movement therapies for FM treatment [2]. ATM application for chronic pain has been promising but with low quality studies [3,4].
Objectives: The aim of this study was to explore the effectiveness of ATM for FM patients after 4 months of ATM activity; in particular, the proof-of-concept design aims at determining the domains for which an ATM-based intervention may be effective for FM patients.
Methods: This is a proof-of-concept, observational, non-controlled prospective study which lasted 6 months. Participants were recruited by the Italian Fibromyalgia Syndrome Association (AISFOdv), a non-profit patient organization, through social media advertising. After signing the informed consent, they were divided into eleven groups of eleven/twelve patients each. Two Feldenkrais teachers were assigned to each group. All patients attended an ATM course lasting 15 lessons, with a lesson every week, 1.5 h long (from January to May, 2021). The sessions were entirely virtual platform- based and live. Clinimetric tests and patient-reported outcome tests were administered at baseline and at the end of the intervention.
Results: One hundred twenty-eight FM patients (mean age 54 years old, 2% males) participated in the study. A statistically significant improvement was found in FM-specific measures (Polysymptomatic Distress Scale, PDS) (p=0.003) and the Pain Catastrophization Scale (PCS) (p=0.020); coherently, the amelioration in the Revised Fibromyalgia Impact Questionnaire (FIQR) almost reached statistical significance (p=0.08). The logistic regression analysis found a correlation between PDS, fatigue and anxiety measures; PCS, years from diagnosis and anxiety.
Conclusion: In conclusion, ATM could improve FM-specific measures and pain-related catastrophizing. Improving awareness about one's one body and movements through ATM sessions may have helped FM patients to improve their cognitive attitude towards their pain condition, embracing a more positive, hence less catastrophizing attitude; furthermore, ATM could benefit FM patients because of its induction of muscular relaxation [5]. Further studies are needed to identify FM subgroups in order to find personalized targets that can be used to guide treatments.

AB1378 **TITLE: BENEFIT OF GROUP MEDICAL VISITS IN THE MANAGEMENT OF FIBROMYALGIA**

Keywords: Fibromyalgia, Diet and nutrition, Non-pharmacological interventions

J. A. Pando[1,2], C. Welton[2], S. Griffith[2], O. Pando[3]. *[1]DelawareArthritis, Rheumatology, Lewes, United States of America*; *[2]Delaware Arthritis, Rheumatology, Lewes, United States of America*; *[3]Sidney Kimmel Medical College, Medicine, Philadelphia, United States of America*

Background: Fibromyalgia (FM) is a chronic condition characterized by widespread pain, fatigue, sleep disturbances and mood disorders (depression and anxiety)[1]. While there is no cure for Fibromyalgia, non-pharmacologic integrative modalities have been demonstrated to be effective improving clinical outcomes[3]. Group medical visits (GMV) have been used to integrate self-management skills and to deliver education to improve outcomes in patients with chronic diseases.[4-5] There are scant reports of the use of GMV in the management of patients with rheumatic diseases. The goal was to assess the benefit of GMV in patients diagnosed with Fibromyalgia (FM).
Objectives: We conducted a pilot study to assess the benefits of group medical visits (GMV) among patients with Fibromyalgia. Our primary objective was to improve outcomes by educating patients and demonstrating five integrative techniques: breath work, journaling, mindfulness, movement, and nutrition.
Methods: Patients diagnosed with Fibromyalgia participated in a series of group appointments. The four consecutive monthly sessions included: (1) an introduction to the series and demonstration of breathing techniques and journaling; (2) a presentation of the benefits of movement and participation in Tai Chi session; (3) an overview to mindfulness and guided meditation; (4) a discussion regarding the biosome, nutrition, and elimination diets. Our clinical outcome measures included: The Fibromyalgia Impact Questionnaire (FIQ score), Personal Health Questionnaire Depression Scale (PHQ8) and Multi-Dimensional Health Assessment (MDHAQ). We took measurements at baseline and following completion of the last appointment. Our analysis consisted of a paired t-test to determine whether the mean difference between the baseline and follow-up outcomes was statistically significant.
Results: The average baseline and follow up measures were as follows: FIQ 61.5 to 50.3(CI -15.8 - 4.3, p-value 0.0011), PHQ8 10.7 to 6.5 (CI -5.8 - -2.1, p-value 0.0001) and MDHAQ 16.4 to 13.59(CI -4.9 - -1.5, p-value 0.0006), respectively. All measurements were statistically significant.
Conclusion: Our findings suggest that group medical visits are a valuable, beneficial, efficacious and cost-effective way to deliver care and information to patients with fibromyalgia. GMV's facilitate education, provide social support and most importantly, improved clinical outcomes.

AB1379 MICROBIOTA AND MITOCHONDRIAL IMBALANCE IN FIBROMYALGIA: A PILOT STUDY

Keywords: Fibromyalgia, Biomarkers

E. Duran Gonzalez[1,2], J. A. Ramirez Tejero[2], A. Martínez Lara[1,2], I. Sepulveda[2], A. Huancas Díaz[3], M. Carvajal[3], D. Cotán[1,2], J. A. Sánchez Alcázar[1]. *[1]Pablo de Olavide University Sevilla, Department of Physiology, Anatomy and Cell Biology., Sevilla, Spain*; *[2]Pronacera Therapeutics S.L., I+D, Sevilla, Spain*; *[3]Instituto de Medicina Funcional e Integral, Instituto de Medicina Funcional e Integral de Perú, Miraflores, Peru*

Background: Fibromyalgia (FM) is a widespread chronic disease characterized by chronic pain and fatigue that has a strong impact on the quality of life of patients, who represent the 6% of the world population. There is no molecular analysis FM condition, being currently diagnosed through clinical self-questionnaires. Since FM patients present a strong lack of energy and several gastrointestinal disturbances, the relationship between the microbiota-mitochondrial axis could be a relevant mechanism [1]. The intestinal microbiota has a great impact on health and energy balances. When the distribution is altered, intestinal dysbiosis appears and the majority of the dysbiosis-related conditions are strongly related to FM [2]. As a result, some authors have pointed to the intestinal microbiota as the main player in FM [3]. The intestinal microbiota works as an intermediary in the final goal of provide energy to cells through the production of ATP, the core task of mitochondria. This organelle is especially abundant in tissues such as muscle and brain, both affected by the etiology of FM [4]. In addition, many studies have highlighted the involvement of mitochondrial imbalances and oxidative stress in patients with FM [5]. Interestingly, crosstalk between mitochondria and microbiota is implicated in inflammation [6], a hallmark of FM.

Objectives: To characterize intestinal microbiota composition and mitochondrial balance in a cohort of FM patients.

Methods: A group of 26 patients (7 men and 19 women) diagnosed with primary FM according to the ACR criteria where selected. Intestinal microbiota composition was determined by qPCR of some central genera as well as secretory IgA levels. Mitochondrial mass was determined by western blot in peripheral blood mononuclear cells protein (PBMC) to detect mitochondrial mass and mitophagy biomarkers. Additionally, Total Antioxidant Capacity (TAC) was measured with e-BQC lab (Bioquochem, Asturias, Spain), an electronic device that oxidizes the samples by applying an electrochemical current.

Results: *Roseburia* spp./*Eubacterium* spp. ratio is shifted to *Roseburia* species, and *Akkermansia muciniphila* has lost its representativeness. Additionally, more than half of the patients presented sIgA values below the reference range. Lastly, the mitochondrial ratio showed a mitochondrial imbalance in most of the patients, which had higher mitochondrial mass.

Conclusion: The results suggested an imbalanced intestinal microbiota and mitochondrial ratio in FM. These results open up a wide range of possibilities, both to develop treatments and diagnostic techniques for the disease.

AB1380 ASSESSMENT OF OPTIC NERVE AND MACULA FINDINGS WITH OPTIC COHERENCE ANGIOGRAPHY IN FEMALE PATIENTS WITH FIBROMYALGIA AND ITS RELATION WITH DISEASE SEVERITY

Keywords: Fibromyalgia

Ş. Koldaş Doğan[1], M. Bulut[2], G. Çelik[1], H. Büber[3], D. Durmaz[3]. *[1]University of Health Sciences, Antalya Training and Research Hospital, Physical Medicine and Rehabilitation, Antalya, Turkey*; *[2]Private Lara Anatolia Hospital, Opthalmology, Antalya, Turkey*; *[3]University of Health Sciences, Antalya Training and Research Hospital, Opthalmology, Antalya, Turkey*

Background: Fibromyalgia syndrome is a chronic disorder characterized by widespread pain, fatigue, sleep disturbances and cognitive dysfunction. The pathophysiology is still unknown, however, sympathetic dysfunction, central and peripheral sensitization, neuroendocrine anomalies, psychosocial factors can be counted as possible mechanisms. In recent years vascular changes and perfusion anomalies of brain, neuroretina changes have been reported.

Objectives: To evaluate the optic nerve and macula findings in female fibromyalgia patients compared with healthy controls and investigate the relations with disease severity.

Methods: Sixty-two female fibromyalgia (FMS) patients with a mean age of 43.11±7.94 years and sixty female healthy controls with a mean age of 40±12.26 years were included. Fibromyalgia was diagnosed according to the American College of Rheumatology Criteria. Schirmer and tear break up time (BUT) test were recorded. Choroidal thickness, optic nerve head blood flow area, retinal nerve fiber layer was measured with optic coherence tomography angiography (OCTA). Widespread pain index (WPI), symptom severity scale (SSS), tender point count, Fibromyalgia impact questionnaire (FIQ) were recorded.

Results: BUT test findings were lower in FMS patients compared to healthy controls and the differences were statistically significant ($p<0.0001$). There were no significant differences in Schirmer test and intraocular pressure findings between FMS patients and healthy controls ($p>0.05$). Optic disc total and peripapillary densities of FMS patients were found to be higher than healthy controls ($p<0.05$). Choroidal thickness, inner retina perifoveal thickness values of FMS patients were higher than healthy controls ($p<0.05$) but in outer retina foveal thickness values of patients were lower than healthy controls ($p<0.05$). In addition, foveal avascular zone (FAZ) and nonflow area were found to be enlarged in FMS patients compared to the healthy controls ($p<0.05$). There were weak positive correlations between fibromyalgia severity scale and choroidal thickness values, optic disc total and peripapillary densities and FAZ area. In addition, there were weak negative correlations between fibromyalgia severity scale and BUT test values.

Conclusion: Due to the known increase in inflammation in FMS patients, we found choroidal thickness and vascular density values around the optic disc to be higher than in the healthy control group. In addition, we found that FAZ and nonflow area values were enlarged compared to the control group, consistent with ischemia due to vascular damage in FMS patients. We found a significant correlation between all these values and the fibromyalgia severity scale values. In conclusion, we think that the results we evaluated with OCTA measurements are useful in detecting damage to retinal and optic disc vascular structures in FMS patients.

AB1381 **SLEEP QUALITY AND PAIN CHARACTERISTICS IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS, AND OSTEOARTHRITIS**

Keywords: Rheumatoid arthritis, Pain, Spondyloarthritis

M. A. Burlui[1,2], L. Macovei[1,2], A. Cardoneanu[1,2], D. M. Stincescu[2], A. Codrianu[2], I. Bratoiu[1,2], P. Richter[1,2], E. Rezus[1,2]. [1]*"Grigore T. Popa" University of Medicine and Pharmacy, Rheumatology, Iași, Romania*; [2]*Clinical Rehabilitation Hospital, Rheumatology, Iasi, Romania*

Background: Pain is a cardinal symptom of chronic rheumatic conditions and can involve nociceptive and non-nociceptive (neuropathic) components that may be linked to central sensitization. Poor sleep quality has been connected to central sensitization and the appearance of neuropathic pain in patients with chronic rheumatic conditions.
Objectives: We aimed to investigate pain characteristics and sleep quality in adult patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), and osteoarthritis (OA).
Methods: We conducted a prospective observational study including patients with RA, AS and OA who were evaluated in the Rheumatology Department of the Clinical Rehabilitation Hospital of Iasi between July-December 2022. We excluded patients with diabetes mellitus, neoplasia, and comorbid neurological conditions. We evaluated pain intensity using the visual analog scale (VAS) and pain characteristics using the PainDETECT questionnaire (PD-Q). Sleep quality was assessed using the Pittsburg Sleep Quality Index (PSQI).
Results: The final study group included 152 patients (50 RA, 52 AS, and 50 OA) with a mean age of 59 years. PD-Q scores did not differ significantly in the three subgroups. In patients with RA, PD-Q scores correlated with disease activity (DAS28 and CDAI; p=0.008 and p=0.036), whereas the relationship between BASDAI and PD-Q scores approached statistical significance (p=0.056). PD-Q scores were correlated with pain intensity in AS (p=0.037), but not RA or OA (p=0.421, p=0.393). In RA patients, nociceptive pain was significantly more prevalent compared to AS and OA (p<0.001) and was associated with a higher consumption of symptomatic medication during hospitalization. Neuropathic pain was notably more frequent in AS compared to RA (p<0.001) and OA (p<0.001). Neuropathic pain did not lead to significantly higher medication expenses in our study group. In the RA subgroup, PD-Q scores were significantly correlated to total PSQI (p<0.001), as well as the values for each of the PSQI domains. Moreover, in these patients, pain intensity was connected to poor subjective sleep quality, low sleep efficiency, and sleep disturbance. Total PSQI scores were also correlated with DAS28 (p=0.011). In AS patients, total PSQI was linked to PD-Q scores (p<0.001), but not pain intensity. PD-Q was significantly connected to subjective sleep quality, sleep latency, sleep duration, sleep efficiency, and sleep disturbance in AS. In the OA subgroup, pain intensity was associated with total PSQI (p=0.007), subjective sleep quality, sleep latency, sleep duration, and sleep efficiency. Nevertheless, poor sleep quality was not significantly linked to neuropathic pain in the OA group.
Conclusion: Non-nociceptive pain is frequent in patients with chronic rheumatic conditions. Moreover, non-nociceptive pain may impact activity score values in AS and RA. Poor sleep quality is connected to pain intensity and non-nociceptive pain in patients with RA and AS. Sleep quality was not linked to neuropathic pain in OA patients. Pain remains a key symptom in rheumatic diseases and its management remains a challenge for the clinician, especially in the context of central sensitization.

AB1382 **IMPACT OF CENTRAL SENSITIZATION ON PAIN IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES**

Keywords: Inflammatory arthritides, Pain

I. Berrichi[1], F. Z. Taik[1], H. Fouzia[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. [1]*Abdelmalek Essaadi University,Faculty of Medicine of Tangier-Tetouan-Al Houceima,University Hospital Mohammed VI, Rheumatology,Tangier, Morocco*; [2]*Abdelmalek Essaadi University,Faculty of Medicine of Tangier-Tetouan-Al Houceima,University Hospital Mohammed VI, Physical Medicine and Rehabilitation,Tangier, Morocco*

Background: Pain in chronic inflammatory rheumatism (CIR) is polymorphic; nociceptive, neuropathic and central sensitization (CS) may be involved. The International Association for the Study of Pain (IASP) defines central sensitisation as « Increased responsiveness of nociceptive neurones in the central nervous system to their normal or sub-threshold afferent input » (1) Chronic inflammation can play an important role in this CNS hyperexcitability. During CIR pain may persist, despite objective control of inflammation suggesting the involvement of SC phenomena.
Objectives: The objective of this study is to detect the impact of central hypersensitivity phenomena on pain in patients suffering from CIR. A second objectif is to look for other factors associated with this central sensitization.
Methods: This is a cross-sectional study that included all patients aged ≥ 18 years followed up for chronic inflammatory arthritis (SPA, RA, undifferentiated CIR) presenting to the rheumatology department.Patients with psychiatric or memory disorders or who refused to participate in the study were excluded. Sociodemographic data, comorbidities and treatments received were collected.Nociceptive pain was assessed by visual analogue scale (VAS),disease activity by DAS-28 and ASDAS and central sensitization by the validated Moroccan version of the Central Sensitization Inventory part A (CSI-A). This inventory has 2 parts: Part A measures a range of 25 somatic and emotional symptoms associated with central sensitization, scored from 0 (never) to 4 (always), for a possible total score of 100. Part B concerns the recording of previous diagnoses related to central sensitization (not used in our study). A CSI-A score ≥ 40 was the threshold considered for the definition of CS. The Pain catastrophizing scale (PCS) was used to assess pain-related catastrophic thoughts and the PHQ-9 (Pain Health Questionnaire) to assess the severity of depressive symptoms.
Results: We included a total of 189 patients, 107 (56.61%) had rheumatoid arthritis, 67 (35.45%) spondyloarthritis and 15 (7.94%) undifferentiated inflammatory arthritis. The median duration of the disease course was 8 years [4-17], the mean age was 47.49 ± 13.70 years [14.74], 75.7% were women. The mean pain VAS was 4.77+-2.76 and 50.8% had a strong or moderate activity. The mean central sensitization score was 37.42+- 16.75, with 44.9% having a CSI score≥40.For treatments 38.2%of patients were on corticosteroids and 6.3%were using biological treatment. In uni and multivariate analysis,the parameters associated with CS were pain severity (0.039) and depression (≤0.001) A statistically significant correlation was found between the CSI-A score and pain VAS (r=0.32 p <0.001)
Conclusion: Pain in patients with CIR has often been attributed to peripheral inflammation. However, our study suggests that central sensitization may increase pain intensity independent of disease activity. Screening for central sensitization mechanisms in patients followed for CIR seems necessary to guide management by targeting central pain in order to avoid useless therapeutic switches and escalations, sometimes even harmful for our patients.

AB1383 **A STUDY ON THE CLINICAL PROFILE OF PATIENTS WITH HYPERMOBILE JOINTS**

Keywords: Pain

V. Viswanath[1], A. G. Varier[1], H. Sreekumar[1], L. Sreekumari Ramachandran[1]. [1]*Dr Vishad Viswanath's IRIS Centre for Arthritis & Rheumatology, Rheumatology, Thiruvananthapuram, India*

Background: Hypermobile joints are a common yet under-recognized cause of noninflammatory joint pains. Patients with Hypermobile joints display a range of movement that is considered excessive, considering their age, gender, and ethnic background [1]. Hypermobile joints may be asymptomatic or associated with pain, fatigue, multisystemic complaints, and significant disability. In this study, we look at the clinical profile of patients with hypermobile joints who presented to our clinic.
Objectives: To study the clinical profile of patients with Hypermobile joints.
Methods: This is a prospective observational study. Patients who presented to our clinic (from 2018 to 2022) with musculoskeletal complaints with a Beighton score of 4 without concomitant inflammatory arthritis were selected. Clinical data were collected by doctors/trained nursing professionals using a proforma, and demographic and relevant clinical data were collected and analyzed.

Results: 236 patients were studied(203 females and 33 males).The mean age of patients was 41.6 years (±12.7 SD). The median duration of symptoms was 48 months (1 540 months) Median Beighton score was 7. The mean global VAS was 4(± 2 SD). Associated clinical features were as in Table 1. Criteria for Fibromyalgia(2016 revised criteria) were satisfied by 31% of patients. Total Beighton score showed a negative correlation with age (r= 0.334, p<0.05)

Conclusion: People with joint hypermobility-related disorders present a wide range of symptoms that extend across multiple body sites. Symptomatic hypermobile joints are present across all age groups. In our study, most patients presented with pains, especially in the form of dragging pains and cramps. An increase in joint stiffness with age leads to a decrease in the Beighton score, which should be considered to not miss hypermobility in the elderly. Extraarticular features of hypermobility give a clue to diagnoses of hypermobility in those with low Beighton scores. Often these patients are labeled as having fibromyalgia. In our study, 31% of patients satisfied the criteria for fibromyalgia. Hypermobile Joint Syndrome should be considered in patients presenting with nonspecific noninflammatory pains across multiple body sites in all age groups.

AB1384 BENEFITS OF PHYSIOTHERAPY RESOURCES IN FIBROMYALGIA

Keywords: Fibromyalgia, Non-pharmacological interventions, Physical therapy/physiotherapy

M. Antunes[1], A. Pasqual Marques[1]. [1]*University of São Paulo, Department of Physiotherapy, Speech Therapy and Occupational Therapy (FOFITO), São Paulo, Brazil*

Background: In patients with fibromyalgia, the physiotherapist is essential in the treatment. He will act throughout the patient's rehabilitation process, from the application of initial assessment instruments to full recovery.

Objectives: Check the performance and benefits of physiotherapy resources in the current scientific literature for patients with fibromyalgia.

Methods: A literature review was carried out in the databases Scientific Electronic Library Online (SciELO), Latin American and Caribbean Literature in Health Sciences (LILACS), Medical Literature Analysis and Retrieval System Online (MEDLINE), Scopus, Web of Knowledge ISI, Physiotherapy Evidence Database (PEDro), Excerpt Medical Database (Embase), Cumulative Index to Nursing and Allied Health Literature (CINAHL), Cochrane Library, and SPORTDiscus for articles dated March 2012 to March 2022. The terms fibromyalgia AND (physiotherapy OR "physiotherapy" OR rehabilitation) were used as keywords in English, Portuguese and Spanish. The searches were not limited to titles and abstracts, we chose to leave them free, appearing in all fields of the articles. In addition, some specific physiotherapy interventions were manually searched. The articles were searched in all indicated databases and then the main information was read and collected and then analyzed descriptively.

Results: Physical therapy interventions have shown positive therapeutic effects on fibromyalgia. Among the different interventions, aerobic and resisted physical exercises are the most indicated and widely used. With regard to manual therapy, myofascial release, connective tissue massage, manual lymphatic drainage and Shiatsu produce good results. Electrophysical agents are also used in the clinical practice of physiotherapists who assist individuals with this disease. The use of complementary therapies has increased and evidence shows that acupuncture, diet, herbal medicine, homeopathy, massage and supplements show promise for managing pain associated with various musculoskeletal conditions. Health education is essential and recommended for individuals with fibromyalgia. This type of intervention should promote the optimization of care through the physiotherapist's guidance to the individual, guiding him on how to control pain and deal with problems associated with his lifestyle. As such, combining multiple therapies (including exercise) to devise an optimal treatment plan for different individuals would be an important developmental step for treating fibromyalgia in the future.

Conclusion: There are several physiotherapeutic interventions that can be chosen to improve the health and quality of life of patients with fibromyalgia. Something very important is to always associate rehabilitative techniques with the patient's health education. In Brazil there is a program that was created called "Amigos de Fibro", an interdisciplinary educational program that seeks to promote the health of individuals with fibromyalgia and has shown promising results.

AB1385 SUBOPTIMAL IDENTIFICATION AND MANAGEMENT OF NON-NOCICEPTIVE TYPES OF PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS REGARDLESS THE ACTIVITY STATUS

Keywords: Rheumatoid arthritis, Fibromyalgia, Pain

F. Berghea[1], R. Bratu[2], N. Cristina[2], A. M. Spoeala[2], T. Dogaru[2], A. Dinoiu[2], A. Mihailescu[2], C. Boromiz[2], E. Juganaru[2], A. Constantinescu[2], V. Zanfir[2], D. Mardale[2], A. Doran[2], M. Duna[2], V. Vlad[2], M. Abobului[2], M. M. Negru[1], I. Saulescu[1], C. Cobilinschi[1], C. Constantinescu[1], D. Mazilu[1], A. Borangiu[1], S. Daia-Iliescu[1], L. Groseanu[1], D. Opris-Belinski[1], D. Predeteanu[2], V. Bojinca[1], D. Zaharia[2], A. Trandafir[2], A. Balanescu[1]. [1]*Carol Davila University of Medicine, Rheumatology, Bucharest, Romania*; [2]*Saint Mary Clinical Hospital, Rheumatology, Bucharest, Romania*

Background: Pain represents one of the main clinical symptoms of Rheumatoid Arthritis (RA) being used as an indicator of disease activity. However, many RA patients reports clinically significant levels of pain even in the periods of remission. Recent studies [1] revealed that biological treatments are inequal in terms of how they manage inflammation and pain. The concept of Post-Remission Syndrome was defined in the context presence of residual pain in RA patients that are in clinical remission but still present clinical symptoms that impairs their quality of life [2]; the syndrome might be a reason for decreased work productivity [3,4]. Apart of the nociceptive pain previous works identified neuropathic and nociplastic pain in the composition of residual pain. In order to better understand and manage this situation is paramount important to identify and explain the exact nature of pain present during and after the periods of activity in RA.

Objectives: The present study intended to explore the quality of pain assessment and management in subjects with RA in a major tertiary clinic.

Methods: In a major tertiary clinic of rheumatology consecutive subjects with RA have been questioned about the history, evolution and management of their disease; separately the level of nociceptive, neuropathic and nociplastic (fibromyalgic) pain was evaluated by using validated instruments. For a better understanding of the differences, we included and compared subjects with osteoarthritis and other inflammatory rheumatic diseases.

Results: 43 subjects have been evaluated in a 6 months interval with a 2:1 F:M ratio; 22 of them received biological therapy (8 different molecules have been

identified). Although 32 subjects did not present any sign of inflammation 21 of them declared significant level of pain (VAS>4), 12 have identified with neuropathic pain and 11 with nociplastic pain. Both in case of neuropathic and nociplastic pain groups less than 50% have been previously actively evaluated for non-nociceptive pain. Non-nociceptive pain was poorly treated and prolonged anti-nociceptive pain treatment was used despite evident lack of effect. The variable ability of pain reduction of biological DMARDs has not been previously discussed with any subject; the subject of residual pain was also poorly covered during biological drug selection.

Conclusion: Non-nociceptive pain has the potential to be considered a major reason of residual pain in RA and non-RA subjects. Rheumatologists seems to be captured in the paradigm of nociplastic = inflammatory pain with little interest in other types of pain that results in suboptimal diagnostic and management of pain.

AB1386 THE ROLE OF OBSESSIVE-COMPULSIVE TRAITS IN FIBROMYALGIA: ARE OBSESSIVE THOUGHTS OF PAIN CORRELATED WITH PAIN INTENSITY AND ASSOCIATED WITH FUNCTIONAL IMPAIRMENT?

Keywords: Fibromyalgia, Pain, Mental health

M. Amital[1], D. Buskila[2], H. Amital[3,4], D. Amital[2,5]. [1]*Ariel University, The Adelson School of Medicine, Ariel, Israel*; [2]*Ben Gurion University of the Negev, Medical School for International Health, Beer Sheva, Israel*; [3]*Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel*; [4]*Sheba Medical Center, Department of Medicine B & The Center for Autoimmune Diseases, Tel-Hashomer, Israel*; [5]*Barzilai Medical Center, Head of Division of Psychiatry, Ashkeon, Israel*

Background: Fibromyalgia syndrome (FMS) is defined as a chronic pain syndrome that is characterized by widespread pain, tenderness, and diffuse stiffness. In addition, neuropsychological symptoms such as fatigue, sleep disorders, poor mood, cognitive impairment, and headaches are often reported. Many researches had demonstrated the coexistence of affective disorders and anxiety with FMS, yet few focused on its association with obsessive-compulsive disorder (OCD).

Objectives: We investigated the occurrence of classical patterns of OCD in patients with FMS and assessed their effect on pain perception and functional impairment.

Methods: The research population included 37 patients diagnosed with FMS, and treated at the Rheumatology Clinic in the Sheba Medical Center, Tel-Hashomer, Israel. We used validated questionnaires including a demographic questionnaire, assessment of average and maximal pain intensity, the Eysenck Personality Questionnaire – Revised (EPQ-R(, the Perceived Stress Scale, the Pain Catastrophizing Scale, the Pain Obsessive questionnaire, and the Yale–Brown Obsessive Compulsive Scale (Y-BOCS).

Results: Patients with FMS were found to have intrusive and obsessive thoughts regarding pain for several hours every day, causing a high degree of anxiety and high levels of pain, catastrophizing, and magnification, leading to helplessness and functional impairment. Twenty-seven percent of the patients reported severe malfunction due to pain and pain ideation, and 49% demonstrated mild obsessive-compulsive symptoms that were strongly correlated with pain intensity and functional impairment.

Conclusion: Obsessive-compulsive thinking patterns contribute to pain magnification and to the cognitive aspects of Fibromyalgia syndrome.

AB1387 A RARE CAUSE OF PES ANSERINE BURSITIS: TIBIAL EXOSTOSIS: THREE CASE REPORTS

Keywords: Imaging, Bone diseases, Pain

C. Mülkoğlu[1], İ. Taka[2], B. Ordahan[3]. [1]*University of Health Sciences, Ankara Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey*; [2]*Ankara Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey*; [3]*Meram Medical School, Necmettin Erbakan University, Physical Medicine and Rehabilitation, Konya, Turkey*

Background: Pes anserine bursitis is a syndrome causing pain at the medial knee and the proximal medial tibia [1]. Sartorius, gracilis, and semitendinous tendons attach 5 cm distal to the medial knee joint line taking a shape is called pes anserinus. It is more common obese females with knee osteoarthritis between 50-80 years of age [1]. Rarely, tibial bone spurs present as rose thorns and cause pes anserinus bursitis and knee pain [2].

Objectives: In this case report, we presented proximal tibial exostosis which randomly detected and resulting to pes anserinus syndrome in three patients.

Methods: Case 1 (NB): A 58-years-old female patient was admitted to our outpatient clinic with right knee pain. She had pain for 2 months, increasing with standing and walking. In the physical examination, she did not describe any trauma, the area where the pes anserinus tendons attached to medial proximal tibia was painful. There was no swelling and redness on the skin. A bone spur from the proximal tibial metaphysis was seen in the right knee on direct radiography (Figure 1). Case 2 (BE): A female who 22 years-old, was admitted to our outpatient clinic with left knee pain, which was for 5 months. The skin appearance above the knee was normal. There was no swelling. Medial left proximal tibia was tender with palpation. Physical examination was normal. The blood tests of the patient were completely normal. A spur like as a rose thorn forming from the proximal tibial region was observed in the left knee, similar to the first case, on the direct radiography (Figure 2). Case 3 (GB): A 64-year-old female patient was admitted to our outpatient clinic with pain in the medial left knee. Her complaint was present for 6 months. There was no history of trauma. Knee joint range of motion was normal. There was no effusion in knees. Mc-Murray test was negative. There was a minimal sweelling and tenderness on pes anserine region. A bone exostosis was observed in the left medial tibia on the direct radiography requested from the patient.

Results: The Case 1 was told to rest for two weeks and not to walk much. Non-steroidal anti-inflammatory drug therapy and 10 minutes cold application to the knee per 6 hours were recommended. At the follow-up one month later, the visual analog scale (VAS) score was regressed from 7 to 2. Non-steroidal anti-inflammatory drug was started to Case 2 and activity restriction was recommended. At the follow-up two weeks later, VAS score decreased from 6 to 4. 1 ml of methylprednisolone was injected locally to the pes anserinus region of Case 3. One month later, the patient's VAS score decreased from 7 to 1.

Conclusion: Rarely, pes anserine bursitis may be accompanied by medial tibial exostosis. The clinicians must be keep in mind proximal tibial spurs in patients presenting with knee pain and pes anserinus bursitis.

SEVERE FIBROMYALGIA: DO CENTRAL SENSITIVITY MECHANISMS WORK TOGETHER?

Keywords: Fibromyalgia, Pain, Patient reported outcomes

A. Capacci[1], A. Ortolan[1], G. Calabrese[1], P. Rubortone[1], A. Zoli[1], M. A. D'agostino[1,2]. [1]*Agostino Gemelli General Hospital Foundation - IRCCS, Rome, Italy, Division of Rheumatology, Rome, Italy*; [2]*Catholic University of Sacred Heart, Rome, Italy, Rheumatology, Rome, Italy*

Background: Fibromyalgia (FM) is among the most common causes of diffuse chronic pain and falls into the category of central sensitivity syndrome which may be associated with other symptoms such as asthenia, sleep disturbance, bowel and memory disorders, anxiety and depression.
Objectives: We aimed at evaluating in a hospital based setting which of these symptoms were more commonly associated with disease severity.
Methods: cross-sectional evaluation of consecutive patients with a diagnosis of FM according to the ACR criteria [1] who attended the dedicated outpatient clinic between 2020 and 2022. Clinical symptoms including disease duration, demographic characteristics, education level, lifestyle, clinical and laboratory parameters and therapeutic regiment were collected for each patient as well as Pros Questionnaires-"*Italian-Fibromyalgia impact questionnaire (FIQR), Widespread Pain Index (WPI), Symptom Severity Scale (SSS)*- [2][3] Disease severity was defined as FIOR>64. Categorical and continuous variables were compared between patients with FIQR ≤ 64 and those with FIQR>64, using descriptive statistics (Chi squared test/ Fisher test and Mann-Whitney test). Thereafter, a logistic regression having as dependent variable FIQR>64 was carried out.
Results: 187 patients were included. Patients with FIQR >64 (severe disease), had a higher frequency of bowel symptoms/irritable bowel syndrome, menstrual cycle alteration or endometriosis, headache and depression, compared to those with FIQR≤ 64, (Table 1). At univariate analysis, the variables statistically associated with FIQR > 64 were: male gender (OR 0.38; 95%CI 0.13-1.08), active smoking (OR 1.97; 95%CI 0.92- 4.25), depression (OR 4.95; 95%CI 2.32-8.76), bowel symptoms (OR 1.96; 95%CI 1.09-3.53), sicca syndrome (1.71; 95%CI 0.92-3.20), and more than 4 episodes of headache each month (OR 2.22; 95%CI 1.21-4.08). In the multivariate model, the variables independently associated to FIQR >64 were depression (OR 4.95; 95%CI 2.36- 10.39) and more than 4 episodes of headache/month (OR 2.28; 95%CI 1.11-4.70).
Conclusion: Patients with severe FM more frequently present with headache, depression, irritable bowel syndrome and dysmenorrhea. All those symptoms belong to the family of central sensitivity syndromes, suggesting that some central sensitivity mechanisms play a key role in disease activity and severity.

DO PATIENTS WITH LOW BACK PAIN AND CENTRAL SENSITIZATION SHOW DIFFERENCES IN PHYSICAL PERFORMANCE?

Keywords: Pain

I. Berrichi[1], F. Z. Taik[1], H. Fouzia[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. [1]*Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Houceima, University Hospital Mohammed VI, Rheumatology, Tangier, Morocco*; [2]*Abdelmalek Essaadi University, Faculty of Medicine of Tangier-Tetouan-Al Houceima, University Hospital Mohammed VI, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Common low back pain is a common reason for rheumatology consultation. Advances in neuroscience concerning pain have advanced its understanding in chronic musculoskeletal pathologies, in particular low back pain, The role of central sensitization (CS) on physical activity remains understudied.
Objectives: The objective of our study is to investigate the role of central sensitization in patients with low back pain and its impact on their physical performance.
Methods: This is a cross-sectional study that included any patient ≥ 18 years with low back pain presenting to the rheumatology department. Patients with psychiatric or memory disorders or who refused to participate in the study were excluded. Functional capacity was assessed by the Oswestry score (Oswestry Disability Index); a 10-item self-assessing questionnaire, each item contains 6 levels of answers that can be scored from 0 to 5. A total score is calculated, percentage of disability ranges from 0% (no disability) to 100% (complete disability). The interpretation of this scale is based on the scores: from 0 to 20%: minimal disability; from 20 to 40% moderate disability; from 40 to 60%: severe disability; from 60 to 80% crippling low back pain and beyond 80% the person is confined to bed.

The physical performance of the patients was assessed by the 6-minute walk test (6MWT), catastrophizing by the PCS (Pain Catastrophizing Scale) and the CS by the validated Moroccan version of the Central Sensitization Inventory Part A (CSI-A). This inventory has 2 parts: Part A measures a range of 25 somatic and emotional symptoms associated with central sensitization, scored from 0 (never) to 4 (always), for a possible total score of 100. Part B concerns the recording of previous diagnoses related to central sensitization (not used in our study). A CSI-A score ≥ 40 was the threshold considered for the definition of CS.
Results: We included 118 patients. The average age was 53.01+-14.09, 86.4% of the patients were women and 88.7% had comorbidities. The median duration of evolution was 8 [2-10] years. The mean pain VAS was 5.75+-2.07 and 71.5% of patients had an Oswestry score >20.The average score of CS was 42.16+-17.67 while 53.4% had a CSI-A ≥ 40 The average walk test result was 377.64+-154.15 meters. There was no statistically significant difference between patients with CSI-A ≥40 and CSI-A <40 with regard to the performance of the 6MWT (362.67 Vs 394.87, p=0.094). On the other hand, there was a statistically significant difference between the two groups with regard to the pain VAS (6.00 Vs 5.47), p=0.017) and PCS score (33.03Vs 22.08, p=0.001)
Conclusion: Central sensitization does not seem to affect the physical performance of Moroccan patients with low back pain.

AB1390 MULTICOMPONENT NATURE OF PAIN SYNDROME IN PATIENTS WITH RHEUMATIC DISEASES AND ITS RELATIONSHIP WITH CLINICAL CHARACTERISTICS

Keywords: Spondyloarthritis, Pain, Rheumatoid arthritis

N. Tileubek[1], A. Garaeva[2], K. Shaporeva[2], S. Lapshina[2], Z. Gabdullina[3], D. Abdulganieva[2]. [1]*Institute of Gastroenterology, Hepatology and Metabolism "Interna Clinic", Rheumatology, Almaty, Kazakhstan*; [2]*Kazan State Medical University, Department of Hospital Therapy, Kazan, Russian Federation*; [3]*Republican Clinical Hospital, Rheumatology, Kazan, Russian Federation*

Background: Pain is one of the leading clinical manifestations and a criterion of severity in most patients with rheumatic diseases. However, pain is not always inflammatory, and its intensity does not correlate with disease activity and dysfunction.
Objectives: To study the specifics of pain syndrome in patients with rheumatoid arthritis and ankylosing spondylitis.
Methods: 78 patients with immunoinflammatory diseases were studied, 30.8% with rheumatoid arthritis (RA) and 68.2% with ankylosing spondylitis (AS). The average age was 42 [34.5; 59.5]. Among AS patients 80.8% were men and 19.2% were women, while 100% of RA patients were women. DAS28 and ASDAS were used to rate activity in patients with RA and AS, respectively. High activity was observed in 69.3% of patients, moderate activity in 23.1%, and low activity in 7.6% of the cases; 23.1% of patients had functional class I, 34.6 – class II, 34.6% - class III, and 7.7% - class IV. The mean disease duration was 194.6±103.2 months, with a median of 192 [114;258] months. A neurological examination was performed to detect neuropathic pain (NP), and its severity was assessed using the pain DETECT questionnaire (PD); the relationship between pain and central sensitization (CS) was determined using the Central Sensitization Inventory (CSI); quality of life was assessed using the questionnaire EQ-5D. The collected data were analyzed with the IBM SPSS Statistic 26.0 program. Spearman correlation analysis was used to assess the relationship between the studied indicators; differences were considered statistically significant at p<0.05.
Results: All of the patients in the study had chronic inflammatory pain in their joints and/or back, and 69.3% of them also had non-inflammatory pain: 38.4% had NP, and 50% had pain typical of CS. There was no significant correlation between the presence and severity of NB and/or CS and the patient's age, disease duration, indices of RA and AS activity, or patient's gender. In the group of patients with RA, NB prevailed, while CS prevailed in the group of patients with AS. The PD questionnaire yielded a positive result in 53.9% of all patients, 41.2% in AS, and 87.5% in RA. A positive moderate correlation was found between the PD and laboratory indicators of inflammation (ESR and CRP) (rSp=0.445; p=0.026), pain intensity according to VAS (rSp=0.470; p=0.018), however, there was no correlation with global functional status. According to CSI, a positive result was observed in 50% of all patients, 52.9% in AS and 44.4% in RA. CSI results positively correlated to pain intensity according to VAS (rSp=0.699; p=0.001), and a negative moderate correlation was found with EQ-5D index (rSp=-0.659; p=0.001). Comorbidities were observed in 61.5% of patients: osteoporosis – in 38.5%, arterial hypertension (AH) – in 30.8%, anemia – in 38.5% of patients. Comorbidities were present in 41.7% of patients with CS and 71.4% with a positive PD index. AH occurred in 46.2% with CS and in 16.7% without CS. Anemia correlated to PD and CSI indices (rSp=-0.536; p=0.006 and rSp=-0.692; p=0.001, respectively); a negative correlation between hemoglobin levels and the VAS scale was also observed (rSp=-0.541; p=0.005). The presence of CS was found to have a negative correlation with the use of anti-inflammatory therapy (NSAIDs, DMARDS and corticosteroids).
Conclusion: The majority of patients (69.3%) with immunoinflammatory diseases have pain of mixed origin; additionally, in RA, it is more due to the neuropathic component, whereas in AS, it is CS. Pain intensity as measured by VAS was significantly higher in patients with neuropathic and central pain components, as expected. In patients with NB and CS, laboratory activity is higher, and comorbid pathology, anemia, and AH are more common. Patients with a concomitant central component of pain have a significantly lower quality of life. Thus, when examining patients with RA and AS, a detailed description of the pain syndrome is required, followed by a differentiated approach to analgesic therapy.

AB1391 RELATIONSHIP BETWEEN BODY MASS INDEX AND FIBROMYALGIA

Keywords: Fibromyalgia

L. Riccio[1], A. Ruggiero[1], V. Marino[1], F. Riccio[1], F. Ciccia[1], R. Tirri[1]. [1]*University of Campania L. Vanvitelli, Department of Precision Medicine, Naples, Italy*

Background: Fibromyalgia (FM) is a clinical condition characterized by chronic widespread pain associated with symptoms such as fatigue, waking unrefreshed, depression. Several studies reported a relationship between high body mass index (BMI) and painful syndromes such as FM, but the real impact of a high BMI on clinical severity in patients with FM is still unclear. Furthermore, FM is characterized by a neuropathic component of pain. Obesity and overweight seem to get worse the intensity of neuropathic pain.
Objectives: The aim of this study was to evaluate the relationships between BMI categories and FM related symptoms, investigating fatigue, neuropathic pain, depression and sleep disorders.
Methods: We analyzed a cohort of 419 patients (M 15/ F 404, median age 56), with a diagnosis of FM according to the 2016 ACR criteria. The participants were consecutively recruited from the Fibromyalgia clinic of the University of Campania "Luigi Vanvitelli". All patients were stratified into three groups according to BMI categories: normal weight (18,5-24,9), overweight (25,0-29,9) and obesity (>30,0). We assessed fatigue by Functional Assessment of Chronic Illness Therapy-Fatigue Subscale (FACIT-F), neuropathic pain by PainDETECT Questionnaire (PDQ), depression by Patient Health Questionnaire-9 (PHQ-9) and sleep disorders by Pittsburgh Sleep Quality Index (PSQI).
Prism GraphPad software was used; the level of significance was set at $p < 0.05$.
Results: Total patient population (n=419) had a mean BMI 26,64 (SD 5,768); all patients showed fatigue (100%) with a mean FACIT-F score 23,01 (SD 10,15); we found neuropathic pain (PDQ>20) in 301 patients (71,83%) with a mean PDQ score 22,95 (SD 8,935); 52 patients (12,41%) had no depression (PHQ-9 <4), 68 patients (16,23%) showed a mild depression (PHQ-9 10-14), 121 patients (28,88%) a moderate depression (PHQ-9 15-19) and 140 patients (33,41%) a severe depression (PHQ-9 ≥20) with a mean PHQ-9 score 15,53 (SD 7,704); sleep disorders were found in 360 patients (85,91%) with a mean PSQI score 11,28 (SD 6,117). 155 (37%) normal weight patients (mean BMI 22,13) (SD 1,672) had a mean FACIT-F score 20,14 (SD 10,52), a mean PDQ score 17,93 (SD 9,740), a mean PHQ-9 score 11,62 (SD 8,266) and a mean PSQI score 8 (SD 6,330); 161 overweight patients (38,4%) (mean BMI 27,15) (SD 1,400) had a mean FACIT-F score 22,64 (SD 9,983), a mean PDQ score 24,33 (SD 7,831), a mean PHQ-9 score 15,54 (SD 6,809) and a mean PSQI score 11,57 (SD 4,978); 103 obese patients (24,6%) (mean BMI 34,80) (SD 5,320) had a mean FACIT-F score 27,96 (SD 7,808), a mean PDQ score 28,34 (SD 4,136), a mean PHQ-9 score 21,43 (SD 2,953) and a mean PSQI score 15,76 (SD 4,150). For each of the FM symptoms investigated the results were statistically significant (p *value* < 0.0001) between the category of obese and both normal weight and overweight patients, but not statistically significant (p *value* > 0,05) between the category of normal weight and overweight patients.
Conclusion: Our study suggests that obesity is a risk factor for Fibromyalgia severity. Obese patients had higher FACIT-F, PDQ, PHQ-9, PSQI scores than normal weight patients. Therefore, according to these findings, a Fibromyalgia treatment program should include weight loss strategies. Anyway further studies are needed to investigate the association between BMI and Fibromyalgia.

AB1392 **GENETICALLY PREDICTED APOLIPOPROTEIN B IN RELATION TO SYSTEMIC SCLEROSIS**

Keywords: Systemic sclerosis, Diet and Nutrition, Genetics/Epigenetics

X. Yang[1,2], Q. Dong[1,2], D. Wu[1,2], Q. Feng[1,2], J. Y. Chen[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. *[1]Shanxi Medical University, Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Taiyuan, China*; *[2]Shanxi Medical University, Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, China*; *[3]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*; *[4]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by progressive skin and internal organ fibrosis and has significant clinical sequelae [1]. Apolipoprotein B and E are found in two major subgroups of LDL [2]. Apolipoprotein E can be used as a predictor of SSc.[3] Apolipoprotein B is involved in autoimmunity [4]. However, whether apolipoprotein B is associated with SSc remains unestablished.
Objectives: We performed a two-sample Mendelian randomization (MR) analysis to investigate the causal relationship between apolipoprotein B and SSc.
Methods: Statistics on apolipoprotein B were obtained from a genome-wide association study (GWAS) from the UK Biobank, which included 349,376 samples of European ancestry. A total of 182 single nucleotide polymorphisms (SNPs) were selected as genetic instruments, which satisfied linkage disequilibrium ($r2 < 0.001$ and clump window > 10,000 kb) and related to apolipoprotein B ($P<5\times10\text{-}8$). Summary-level data for SSc (107 cases and 218,499 controls) were derived from the FinnGen consortium. The inverse-variance weighted (IVW) method was used as the primary statistical model. The weighted median and MR-Egger regression were used as supplementary analyses to supplement the validation of IVW results. The Cochran Q-test was applied to check SNPs' statistical heterogeneity using MR-Egger estimates, with $P < 0.05$ deemed significantly heterogeneous. The leave-one-out method was used to evaluate the effect of a single SNP on the causal association by excluding each SNP in turn.
Results: Genetically predicted apolipoprotein B was inversely associated with SSc risk (odds ratio (OR):0.51, 95% confidence interval (95% CI):0.26-0.98, P=0.04). MR-Egger also confirmed that apolipoprotein B was inversely associated with SSc risk (P=0.02). No heterogeneity was detected in Cochran's Q statistic. The intercept in the MR-Egger regression indicated no pleiotropy in any analysis (all P values>0.05), suggesting this finding was reliable. Details of the results are shown in Fig. 1.

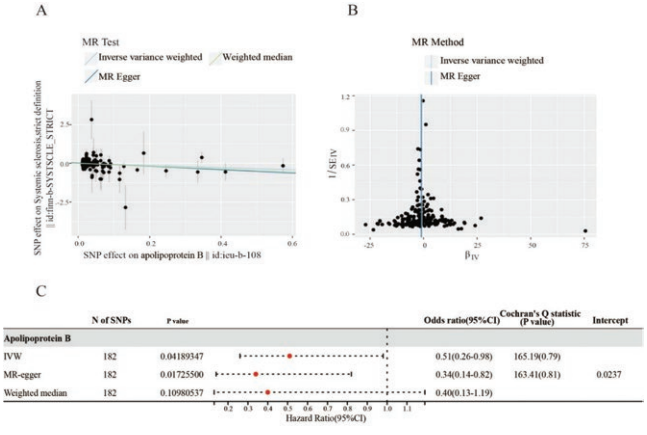

Figure 1. Scatter plots (A) and funnel plots (B) show the estimated effect of each SNP on the result. Forest plot (C) of the relationship between apolipoprotein B and SSc.

Conclusion: Apolipoprotein B is a protective factor for SSc, indicating that apolipoprotein B may be used as a component of drugs to treat SSc and slow down the development of SSc.

AB1393 **CLINICAL AND MRI PREDICTIVE FACTORS OF SIGNIFICANT RESPONSE TO A TREATMENT COUPLING CAPSULAR DISTENSION AND INTENSIVE REHABILITATION IN PATIENTS WITH SEVERE ADHESIVE CAPSULITIS**

Keywords: Rehabilitation, Imaging, Real-world evidence

S. Hamroun[1], V. Cinotti[2], F. Mihoubi-Bouvier[3], R. Garofoli[2], G. Couraud[2], M. Boisson[2], A. Roren[2], C. Nguyen[2], A. Feydy[3], H. Guérini[3], F. Rannou[2], J. L. Drapé[3], M. M. Lefevre Colau[2]. *[1]Cochin University Hospital, Rheumatology, Paris, France*; *[2]Cochin University Hospital, Physical Medicine and Rehabilitation, Paris, France*; *[3]Cochin University Hospital, Radiology, Paris, France*

Background: Adhesive capsulitis (AC) is a frequent shoulder affection[1] and is responsible of a significant impact on daily life. However, its management is not codified, with contradictory results in the literature on the effectiveness of capsular distension (CD), probably due to the lack of selection of patients in the studies. Furthermore, MRI has shown interest in the positive diagnosis of AC in difficult cases and to determine the stage of the disease[2].
Objectives: The aim of the study was to determine clinical and MRI predictive factors of good response to CD in patients with severe AC.
Methods: Patients addressed to physical medicine and rehabilitation unit in Cochin Hospital with a severe AC were prospectively included in the study between May 2017 and June 2021. Severe AC was defined by presence of intense shoulder pain (Numerical Analog Scale of maximal pain in daily activities ≥ 5/10) lasting for at least 3 months, with failure of first-line treatment – including NSAIDs, analgesics corticosteroid injection and physiotherapy. Participants had before treatment protocol a shoulder MRI with and without gadolinium intravenous injection. All participants then underwent 1 to 3 CD with injection of betamethasone at the same time at weekly intervals, each followed by intensive rehabilitation. Patients were evaluated 1 month after the 1st CD by a physiotherapist, who collected information on pain and range of motion and self-reported patient questionnaire. Primary outcome was the reduction of more than 50% of pain in daily activities evaluated by NAS at 1 month, by a multivariate logistic regression model. Secondary outcomes were the modification of NAS nocturnal pain, NAS incapacity, active and passive range of motion, SPADI, quick DASH, HAD and FABQ scores, and return to work at 1 month.
Results: 97 patients were included in the study. Of these, 72 (74.2%) were women, mean age was 51.2 (+/- 7.29) years, median disease duration was 8 [6-12] months and was greater than 9 months in 41 (42.3%) of patients and 62 (63.9%) had a secondary form of AC. Mean NAS pain in daily activities was 7.88 (+/- 1.47) at baseline and 4.32 (+-/ 2.68) at 1 month. 46 (47.4%) filled out the primary outcome and were considered as treatment responders. The multivariate model adjusted for age, sex, work interruption because of AC, initial shoulder traumatism, disease duration greater than 9 months, DASH score, NAS pain at baseline, and MRI thickness of the rotator interval (millimeters) found an association between response to treatment and disease duration < 9 months (OR 2.27 95% CI [1.00-5.26] p = 0.05), DASH score at baseline (OR 0.96 (per point) 95% CI [0.93-0.98] p = 0.03) and MRI thickness of the rotator interval (OR 1.65 (per millimeter) 95% CI [1.04-2.62] p = 0.04). No association was found with the injected MRI criteria.
Conclusion: This study provides original results on predictive factors of response to CD associated with intensive rehabilitation in patients with AC. It found an association of response to treatment and lower DASH score at baseline, shorter disease duration and MRI thickness of the rotator interval and offers suggestions for better patient selection to CD.

AB1394 INTRADISCAL CUTIBACTERIUM ACNES DECIDE ON INNATE AND ADAPTIVE IMMUNE PATHWAYS IN MODIC TYPE 1 CHANGES

Keywords: Adaptive immunity, Innate immunity, -omics

I. Heggli[1], T. Mengis[1], L. Opitz[2], N. Herger[1], C. Laux[3], F. Wanivenhaus[3], J. M. Spirig[3], M. Betz[3], B. Aradi-Vegh[1], M. Farshad[3], O. Distler[1], S. Dudli[1].
[1]University of Zurich, Center of Experimental Rheumatology, Balgrist Campus, University Hospital Zurich and Balgrist University Hospital, University of Zurich, Switzerland, Zurich, Switzerland; *[2]University and ETH Zurich, Functional Functional Genomics Center Zurich, University and ETH Zurich, Zurich, Switzerland, Zurich, Switzerland*; *[3]University of Zurich, Department of Orthopedics, Balgrist University Hospital, University of Zurich, Switzerland, Zurich, Switzerland*

Background: Modic type 1 changes (MC1) are painful vertebral bone marrow (BM) edema of unclear etiology. Besides mechanical aspects, animal studies show the plausibility for two biological etiologies. In the bacterial etiology, *Cutibacterium acnes* (*C. acnes*) invades damaged intervertebral discs (IVDs) resulting in IVD infection and endplate damage. IVD-derived pro-inflammatory cytokines and virulence factors can consequently drain into the adjacent BM and induce an inflammatory response. In the autoimmune etiology, IVD and endplate damage expose immune privileged IVD cells and matrix to BM leukocytes, which react with an autoimmune response.
Objectives: To show that intradiscal *C. acnes* load is decisive for the pathomechnisms in MC1 bone marrow.
Methods: In a first study population, degenerated IVDs adjacent to a MC1 and not adjacent to a MC1 lesion were collected and *C. acnes* copy numbers/gram tissue (CCN) were quantified. The upper 99 % confidence interval (CI) limit in the control group was defined as threshold that distinguishes the two etiologies. From a second study population of MC1 patients, a MC1 and an intra-patient control BM aspirate, and the MC1 adjacent IVD was obtained from each patient. IVD CCN were determined, the etiology was assigned, and bulk RNA sequencing from total BM cells was performed. MC1 gene expression was normalized to intra-patient control and then compared between etiologies. Differentially expressed genes (DEGs) ($p < 0.01$, log2 fold-change > |0.5|) were identified and gene set enrichment analysis (GSEA) was performed. From a third study population, BM aspirates and IVDs were obtained. IVD CCN were quantified, ten pro- and anti-inflammatory and pro-fibrotic BM plasma proteins were quantified with ELISA, and RNA sequencing of $CD45^+CD66b^+$ sorted BM neutrophils was performed. BM plasma protein concentrations were clustered and compared between cluster with Mann-Whitney test, and overrepresentation analysis (ORA) of DEGs between MC1 and intra-patient control BM neutrophils was determined.
Results: Of the first study population, the median CCN of control IVDs (n = 10) was 388 (interquartile range (IQR): 118-685)) and the upper 99 % CI limit was 870. MC1 IVDs (n = 30) had similar median CCN overall (Mann-Whitney: p = 0.29, 464 (229-1614)), but eleven samples (36 %) had > 870 CCN (2659, (899-12900)), which was unique to MC1 IVDs and indicated a bacterial etiology (**Fig. 1a**). From a second study population, three MC1 patients from the bacterial (the three with the lowest CCN) and three from the autoimmune (the three with highest CCN) etiology were selected. Bulk RNA sequencing revealed 222 DEGs between the bacterial and the autoimmune etiology. GSEA showed enriched "neutrophil mediated immunity" and "granulocyte activation" in the bacterial and "adaptive immune response", "B- and T-cell activation" in the autoinflammatory etiology, pointing towards innate immune system contribution in the bacterial, and adaptive immunity in the autoimmune MC1 etiology (**Fig. 1b**). In the third population, MC1 to intra-patient control normalized BM plasma protein concentrations of the ten measured proteins were visualized using UMAP dimensionality reduction technique. Thereby, two patient clusters could clearly be distinguished (**Fig. 1c**). To identify whether clusters represented patients of different etiologies, CCN were compared between clusters and found to differ strongly (cluster 1: 351, (325, 387) vs. cluster 2: 2848, (1355, 3339)). Cytokine analysis between clusters showed upregulated neutrophil associated cytokines in cluster 1 vs. cluster 2 (IL-8: 16 pg/ml, (1, 54) vs. -15 pg/ml, (-21, -11), p = 0.004; ENA-78: 91 pg/ml (-5, 456) vs. -25 pg/ml, (-137, -21), p = 0.048), and a BM neutrophil "defense response to bacterium" in cluster 1, but not in cluster 2, further supporting that clusters represent different etiologies.

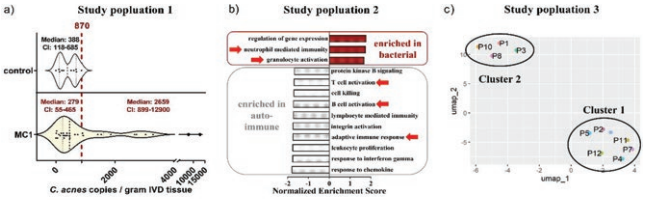

Figure 1: a) *C. acnes* copy number distribution. b) GSEA between etiologies of total cells. c) Cytokine clustering.

Conclusion: We show that IVD *C. acnes* load is decisive for the etiology-specific MC1 pathomechanisms. This has important clinical implications, as different MC1 etiologies might require different treatment strategies.

AB1395 UROLITHIN A AND B ACCELERATE MYOCYTE FUSION INTO MYOTUBES

Keywords: -omics, Sarcopenia, Cell biology

Y. Henrotin[1,2,3,4], C. Lambert[1,4], A. Florin[1,4], J. Zappia[1,4], P. Centonze[1,4], C. Sanchez[1,4]. *[1]ULiege, MusculoSKeletal Innovative Research Lab (mSKIL), Liege, Belgium*; *[2]Artialis, SA, Liege, Belgium*; *[3]Princess Paola Hospital, Physical Therapy and Rehabilitation, Marche-en-Famenne, Belgium*; *[4]ULiege, Center for Interdisciplinary Research on Medicines, Liege, Belgium*

Background: Urolithins are intestinal bacterial metabolites of ellagic acid, from pomegranate and nuts. They modulate oxidative-regulated pathways and display anti-inflammatory, antioxidative properties. Several studies indicate that they could be inducers of muscle strengthening.
Objectives: The aim of this in vitro study was to investigate their mechanisms of action at plasma concentrations on primary human myotubes.
Methods: Urolithin A and B (UA and UB) were evaluated separately on primary human muscle CD56+ cells, isolated from the vastus lateralis of 6 men and 3 women (aged range 55 to 96-y) and differentiated in myotubes. 24h-treatment mRNA-sequencing of these 9 patients was studied by DESeq2 analysis (R software). Modulation of several target genes was then validated in several concentrations (1-5 or 10 µM) by RT-qPCR and ELISA on 4 different patients. Organelles and cell morphology changes were observed by NanoLive CX-A live cell imaging during 72h.
Results: After 24h of treatment at 5 µM, UA and UB significantly modified the expression of 1779 and 319 genes, respectively (adjusted p-value of 0.01 and Log2FoldChange |>0.32|). Among the most regulated genes, we found genes involved in myoblasts to myotubes differentiation. UA increased the expression of MYMX (+70%), PANX1 (+50%), MSTN (+64%), MYH2 (+28%) and conversely decreased FGF9 (-75%), MRLN (-33%), ICAM5 (-52%) and TGFBI (-55%). Regarding UB, it decreased IGFN1 (-75%), TGFBI (-60%) and increased MYH2 (+34%) and TGM2 (+59%). However, UA, but not UB, decreased DMD gene expression (-86%), a key factor in muscle strength, and MEF2C (-45%), a regulator of skeletal myogenesis. We also have observed the modulation of genes involved in the inflammatory process. They both induced a important decrease

of CYP1B1 expression (-95%). Further, LIF was increased by 80% by UA and PTGS1 was decreased by 41% by UA and 43% by UB. UA and UB had the opposite effect on IL17B, a cytokine involved in tissue repair but its role in muscle is still to be defined. IL17B was decreased by 49% by UA and conversely upregulated by 45% by UB. In a second step, we confirmed the modulation of MYMX, PANX1, FGF9, ICAM5, PTGS1-PGE2, IL17B and TGFBI following UA and/or UB treatment at 1, 5 and 10 µM by RT-qPCR and ELISA. Finally, we also observed with live cell imaging that UA and UB increased myocyte fusion in myotubes, already after 6h of treatment.

Conclusion: UA and UB promote the differentiation process of myoblasts to myotubes. In parallel, urolithins present anti-inflammatory properties, mainly by reducing CYP1B1 expression and the PGE2 synthesis via PTGS1, but also for UA by increasing LIF. Our data provide a better understanding of urolithin activities and highlight their potential in the treatment of muscle disorders such as sarcopenia.

AB1396 FUTURE OF HIP CARTILAGE PRESERVATION: A ANGLE ENDPOINTS OPTIMIZE INDICATIONS FOR CONSERVATIVE CARE

Keywords: Cartilage, Prognostic factors, Imaging

E. Campos Martins[1], D. Almeida Gomes[1], H. De Brito Fontana[2], T. Martins Teixeira[3], D. Araujo Fernandes[1]. [1]*Federal University of Santa Catarina, Department of Surgery, Florianópolis, Brazil*; [2]*Federal University of Santa Catarina, Department of Morphological Sciences, Florianópolis, Brazil*; [3]*Fractures Institute, Fractures Institute, Florianópolis, Brazil*

Background: In the context of osteoarthritis (OA) prevention, great attention is given to hip preservation surgery [1]. Patients with femoroacetabular impingement (FAI), a highly prevalent painful condition, are at increased risk of developing OA [2]. However, an undefined fraction of these patients manage to get rid of clinically significant OA with conservative care [3]. Recently, we realized that α angle can be a key to define which patients would benefit from conservative care and which of these should undergo surgery to prevent clinically significant OA.

Objectives: This meta-analysis aimed to answer: i) "does α angle predict the degree of hip chondral health in FAI?" and ii) "what are the α angle endpoints that correspond to each group of degree of chondral health?."

Methods: We followed the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA). Two independent reviewers performed the study selection and data extraction steps. Databases were screened: Embase, MEDLINE/PubMed, SCOPUS, SPORTDiscuss and The Cochrane Library. Good quality primary studies that, by using regressions and other similar statistical tests, assessed the capability of α angle values in predicting the degree of hip chondral health for patients with FAI were considered eligible. Risk of bias was assessed through the QUIPS tool. We conducted a pooled linear regression in order to establish α angle endpoints correlated to each chondral health group.

Results: Twelve studies were considered eligible for bias assessment. We found a high risk of bias due to misreporting and the presence of confounders in 2 studies, which were then excluded from analysis. A summary of the included studies' reported findings is in the Table 1. All 10 included studies demonstrated that α angle predicts the degree of chondral health, with good to excellent effect sizes. For the pooled analysis, 447 patients were enrolled. As the severity of chondral deterioration increases from 1 to 4 in an Outerbridge scale, the corresponding α angle endpoints are 56°, 61°, 65° and 72°- respectively (R^2 = 0,987; p <.001) (Figure 1).

Conclusion: The α angle is a good tool to identify FAI patients who are at higher risk of developing clinically significant OA without surgical intervention. In order to prevent clinically significant OA, we recommend that patients with an α angle greater than 65° should undergo surgery - since they are at high risk of developing significant chondral damage associated with OA progression.

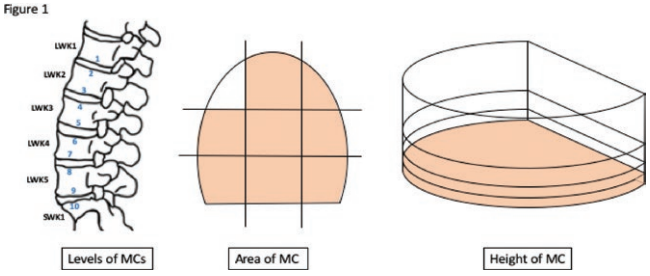
AB1397 SERUM MASS SPECTROMETRY IDENTIFIES APOLIPOPROTEIN D AS POTENTIAL BIOMARKER FOR MODIC TYPE I CHANGES

Keywords: Pain, Diagnostic Tests, Biomarkers



F. Schulze[1], J. Määttä[2], I. Heggli[1], F. Brunner[3], O. Distler[1], J. Karppinen[2], J. Lotz[4], S. Dudli[1]. [1]*University Hospital Zurich and Balgrist University Hospital, Center of experimental Rheumatology, Zürich, Switzerland*; [2]*Oulu University Hospital and University of Oulu, Medical Research Center Oulu, Oulu, Finland*; [3]*Balgrist University Hospital, Department of Physical Medicine and Rheumatology, Zürich, Switzerland*; [4]*University of California San Francisco, Department of Orthopaedic Surgery, San Francisco, United States of America*

Background: Modic changes (MC) are inflammatory vertebral bone marrow lesions adjacent to degenerative intervertebral discs [1]. On MRI, three types can be distinguished: Modic types 1 – 3 changes (MC1, MC2, MC3). Especially MC1 are associated with low back pain (LBP), and the larger the lesion, the stronger is the association with pain [3]. However, in clinics, MC is often a binary (present/absent) observation with insufficient inter-observer reliability in identifying and classifying MC.
Objectives: The aim of our study was to find potential serum biomarkers for the presence or the extent of MC using data of the Northern Finland Birth cohort of 1966 (NFBC1966) [2].
Methods: We selected 103 participants of the NFBC1966 to form 4 groups: With and without MC, and with and without LBP. For each participant with MC, we had information about the type, number, location, height, and transverse area (TA) of the MC. Height was given in 4 groups: "along the endplate", "> 25%," "25-50%" and "<50% of the height of the vertebral body". TA was measured in 1/9 parts of the vertebral endplate surface of a fictitious 3x3 grid (Fig. 1). We defined the MC load for each person and MC type as the sum of the product of height and TA of each MC. The serum samples were subjected to a sequential window acquisition of all theoretical mass spectra (SWATH-MS) analysis. To find a potential biomarker for the presence of each MC type we compared serum concentrations of proteins identified by mass spectrometry between participants with and without MC using Mann-Whitney-U tests. Performance to predict MC was calculated with Receiver Operating Characteristics (ROC). A covariate analysis for significantly different proteins was done with a ANCOVA. To find a potential biomarker for the extent of MC, we searched for associations between serum concentration and MC-load with Spearman's logistic regression. We corrected for multiple comparisons with False Discovery Rate (FDR).
Results: Of the 103 participants, 49 had MC, 54 had no MC (noMC). Of the participants with MC, 5 (10.2%) had only MC1, the others had multiple types of MC. 30 (61.2%) had MC1, 43 (87.7%) had MC2 and 40 (81.6%) had MC3. The average number of MC per person was 3.0 (1 – 9). The MC load, calculated from number, area, and height of the MC-lesions, was on average highest for MC2 (12.33, 95% CI: 9.0 – 15.6) followed by MC3 (11.26, 95% CI: 8.0 –14.5) and MC1 (7.0, 95% CI: 3.5 – 10.6). Serum Mass Spectrometry identified 1087 proteins. Of these, only the concentration of Apolipoprotein D (APOD) was significantly different between MC1 and noMC (Mann-Whitney-U-Test, FDR-adjusted p= 0.034). A covariate analysis with ANCOVA showed that this was independent of LBP. There was no significant result for MC2 or MC3 after correction for multiple comparisons. The ROC for APOD in MC1 had an Area under the curve (AUC) of 0.79. As APOD is part of lipoproteins and involved in lipid transport, we hypothesised a disturbed lipid transport in patients with MC1 and tested if adding other proteins involved in lipid transport to the model could increase the AUC of the ROC. Adding Apolipoprotein C3 (APOC3) to the linear model increased AUC of the ROC to 0.83 despite not associating with MC1. Additionally, linear regression showed a correlation between serum APOD and MC1 load (ρ=0.46, FDR adjusted p-value = 0.002).
Conclusion: The serum concentration of APOD is associated with the presence of MC1 and correlates with the load of MC1. Especially in combination with the serum concentration of APOC3, it is a potential biomarker for the presence of MC1.

AB1398 **STROMAL CELLS IN MODIC TYPE 1 CHANGE BONE MARROW PROMOTE NEURITE OUTGROWTH**

Keywords: Pain, Bone diseases

T. Mengis[1], I. Heggli[1], N. Herger[1], B. Aradi-Vegh[1], F. Brunner[2], M. Farshad[3], O. Distler[4,5], S. Dudli4. [1]*University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland*; [2]*Balgrist University Hospital, Department of Physical Medicine and Rheumatology, Zurich, Switzerland*; [3]*Balgrist University Hospital, Department of Orthopedics, Zurich, Switzerland*; [1]*University of Zurich, Center of Experimental Rheumatology, Zurich, Switzerland*; [5]*University Hospital Zurich, Department of Rheumatology, Zurich, Switzerland*

Background: Vertebral bone marrow lesions known as Modic type 1 changes (MC1) are a major contributor to unspecific lower back pain. Pain may relate to the higher innervation of MC1 endplates. Blocking neo-innervation in MC1 could be a promising treatment approach for MC1. Bone marrow stromal cells (BMSC) can produce neurotrophic factors and are dysregulated in MC1.
Objectives: The aim of the study was to identify if BMSC in MC1 support neo-innervation through release of neurotrophic factors.
Methods: The RNA sequencing data set (ENA PRJEB39993) of MC1 BMSC vs. intra-patient control vertebral BMSC (n=3 MC1 + 3 intra-patient control) was used to investigate enriched gene sets. From additional patients, BMSC were isolated from vertebral bone marrow aspirates (n=4 MC1 + 4 intra-patient control) and were co-cultured with the neuroblastoma cell line SH-SY5Y for 8 days. Neurite outgrowth from SH-SY5Y was quantified as a measure for neurotrophic activity using microscopy. Thirty neurotrophic cytokines were analyzed in the supernatant of the co-culture using C-Series Human Neuro Discovery Array C2.
Results: Gene set enrichment analysis of MC1 vs. intra-patient control BMSC identified gene sets associated with BDNF signaling such as "BDNF TRKB signaling" (normalized enrichment score (NES) = 1.71, p<0.001) and "mBDNF and proBDNF regulation of GABA neurotransmission" (NES = 1.61, p<0.001) amongst the top enriched gene sets. SH-SY5Y cells co-cultured with MC1 BMSC compared to intra-patient control showed significantly increased neurite outgrowth after 4 days (p = 0.045), 6 days (p = 0.027), and 8 days (p = 0.031). (Fig. 1a). Cytokine array analysis revealed significantly more mature brain-derived neurotrophic factor (mBDNF) (p = 0.021) and ciliary neurotrophic factor (CNTF) (p = 0.030) in supernatant of MC1 vs. control BMSC (Fig. 1b).
Conclusion: Neurotrophic activity of MC1 BMSC is increased. This might be mediated by BDNF and CNTF. Therefore, BDNF and CNTF may represent interesting novel treatment approaches for MC1 that directly target pain mechanisms.

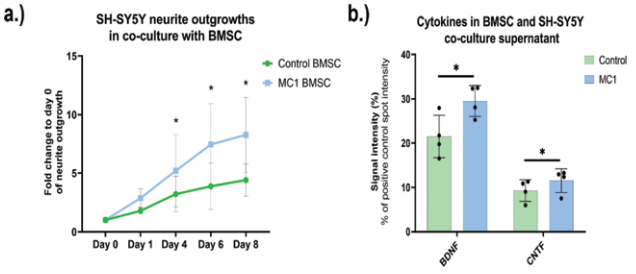

Fig. 1: a.) Effect of BMSC on neurite outgrowth of co-cultured SH-SY5Y normalized to day 0 (n=4). b.) Cytokine array spot intensities of BMSC and SH-SY5Y co-culture media (n=4) calculated as perecentage of positive control spot. Analysis for significance with paired t-tests. Asteriks indicate significance: *p < 0.05.

AB1399 **INVESTIGATING THE USE OF VERTEBRAL HEIGHT MORPHOMETRY DATA AS A PREDICTOR OF FRACTURE: AN OBSERVATIONAL COHORT STUDY**

Keywords: Bone diseases, Epidemiology

H. Amin[1], M. Bukhari[2], A. Khan[2]. [1]*Lancaster University, Faculty of Health and Medicine, Bailrigg, United Kingdom*; [2]*University Hospitals of Morecambe Bay NHS Foundation Trust, Rheumatology, Lancaster, United Kingdom*

Background: Dual energy x-ray absorptiometry (DEXA) has an established place in the diagnosis of osteoporosis and fracture risk estimation using the FRAX® tool. DEXA is also useful in producing morphometry data on bones including the vertebrae at low radiation doses during appointments. Currently there exists limited clinical use for vertebral height measurement, with no data published on the use of vertebral height as a useful clinical measurement. FRAX currently uses bone mineral density from the hip to calculate the risk of either hip fracture or major osteoporotic fracture, however, previous literature has identified that BMD as a predictor of fracture is specific but not sensitive [1]. Moreover, it may not be possible to get such value in certain patient demographics such as patients with hip replacements. Therefore, further data and predictors of fractures are needed to better allow fracture risk estimation.
Objectives: The aims of this study is to assess the use of vertebral height data measured during routine DEXA appointments as a predictor of fracture in an observational cohort.
Methods: We analysed data on 31546 patients referred to a district BMD scanner in the northwest of England between 2004-2019. Data collected at attendance include site of fragility fracture and the vertebral height at lumbar vertebrae L1-L4. Logistic models reporting odds ratio were used to examine the predictive value of vertebral height at L1-L4 in different types of fragility fracture.
Results: The mean age at the time of the first scan was 65 +/- 12.9 (SD). Our dataset comprised 26,156 (82.9%) female and 5390 (17.1%) male patients. A total of 11875 fractures occurred in our population. The mean height at L1 was 3.117 (95% CI 3.117-3.12), L2: 3.239 (95% CI 3.236-3.242), L3:3.78 (95% CI:3.75-3.381) and L4: 3.424 (95% CI: 3.420-3.428). Patients with average vertebral height at these spinal levels were less likely to experience any type of fracture. Interestingly when running the analysis individually at each fracture site, different spinal levels were associated with fractures at different sites. L1 had the highest predictive value while L2 had the least.

Table 1.

vertebral level AVG_height	L1	95 CI	L2	95 CI	L3	95 CI	L4	95 CI
tibfib fracture	1.07	(.90-1.23)	0.95	(.80-1.13)	1.04	(.89-1.23)	0.76	(.67-86)
wrist fracture	0.042	(.02-.94)	1.78	(.172-18.31)	0.68	(.0.19-25.20)	95.98	(7.35-1253.48)
spine fracture	0.32	(.27-.38)	0.52	(.44-.62)	0.83	(.70-.97)	0.92	(.80-1.05)
rib fracture	1.02	(.78-1.36)	0.85	(.65-1.12)	0.93	(.72-1.21)	1.11	(.91-1.37)
pelvis	0.5	(.32-.79)	0.81	(.51-1.29)	0.61	(.40-.94)	0.75	(.53-1.06)
humerus	0.69	(.54-.88)	0.8	(.62-1.022)	0.75	(.60-.94)	0.82	(.68-.98)
forearm	0.84	(.73-.96)	0.89	(.78-1.01)	0.77	(.68-.87)	0.78	(.71-.85)
femur	0.78	(.61-.98)	0.82	(.64-1.03)	0.72	(.56-.89)	0.79	(.66-.94)
elbow	1.4	(.36-5.5)	0.89	(.23-3.43)	0.82	(.24-2.8)	0.77	(.29-2.01)
ankle	0.02	(.00-.38)	1.7	(.05-54.3)	3.4	(.03-422.14)	2.57	(.03-249.87)
all fractures	0.45	(.42-.50)	0.49	(.45-.53)	0.52	(.48-.56)	0.57	(.54-.61)
key:								
green = p<0.05								
blue = p<0.001								

Conclusion: This study is the first to analyse the use of vertebral height data. We found that average vertebral height at spinal level L1-L4 is protective for fragility fractures however specific spinal levels were protective for certain types of fracture. While the link between BMD and fracture has been known for some time and consequently has been integrated into risk estimation tool such as FRAX®, the use of morphometry data to predict fracture is novel. Further research is needed to compare the predictive power of BMD to morphometry data as predictors of fracture, as well as understanding the role of morphometry data in future iterations of fracture risk estimation tools.

SPINE AND SACROILIAC JOINTS FINDINGS IN YOUNG MALES AND FEMALES WITH CHRONIC BACK PAIN UNDERGOING MAGNETIC RESONANCE IMAGING IN CLINICAL PRACTICE: RESULTS FROM THE SHERPAS STUDY

Keywords: Health Services Research, Spondyloarthritis, Imaging

D. Benavent[1], M. Tapia-Viñé[2], D. Bernabeu[2], V. Muley[2], C. Plasencia[1], A. Balsa[1], V. Navarro-Compán[1]. [1]*Hospital La Paz, Department of Rheumatology, Madrid, Spain*; [2]*Hospital La Paz, Department of Radiology, Madrid, Spain*

Background: Magnetic resonance imaging (MRI) is frequently used in patients with chronic back pain (CBP) to diagnose mechanical and inflammatory diseases, including axial spondyloarthritis (axSpA). Recent data suggest sacroiliac joints (SIJ) MRI findings in axSpA may differ according to sex[1]. Whether this holds true for spinal MRI and other causes of CBP is currently unknown.
Objectives: To analyze spinal and SIJ MRI findings in young male and female patients with CBP.
Methods: The "Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis" (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with CBP asked to undergo an MRI of the spine by other specialists different than rheumatologists in a tertiary hospital, starting in September 2021. After inclusion, an additional MRI of the SIJ, followed by a rheumatology visit and eligible blood tests were performed. Dataset for this interim analysis was locked in October 2022. The protocol for MRI of the spine used a 1.5T scanner to acquire sagittal T1-weighted turbo spin echo (TSE) and T2-weighted TSE, both for the lateral sides of vertebral bodies, and T2-Multistack. On top of this, an MRI of the SIJ, which involved T1-TSE, T2- weighted SPAIR and short-tau inversion recovery (STIR) sequences, was performed. MRI findings were assessed according to clinical practice by one of the four musculoskeletal radiologists working in the centre, describing the presence of mechanical lesions (spondylolisthesis, spondylolysis, disc herniation, disc protrusion, facet joints abnormalities), inflammatory findings (both SIJ and spine), and SIJ structural findings. For this analysis, results were stratified by sex.
Results: Among 152 recruited patients, 85 (55.9%) were female; mean age was 34.2 (5.3) years. Spinal MRI findings were reported in 130 (87.2%) patients, with no differences between sexes (male 90.8% vs female 84.5%, p=0.3). As shown in **Table**, the most frequent diagnosis in both sexes were disc protrusion, followed by disc herniation. Inflammatory spinal findings were detected only in one male patient. No differences were found for any of the spinal lesions. SIJ MRI findings were reported in 49 (33.1%) patients, being numerically more frequently observed in males than females (41.5% vs 26.5%; p=0.08). Concurrence of both structural and inflammatory lesions was more frequently in males (9.2% vs 1.2%, p<0.05), while no differences in isolate SIJ MRI findings were found between sexes. Overall, 45 (29.6%) patients presented findings both in the spine and SIJ (**Figure 1**).
Conclusion: In young patients who are requested a spinal MRI by other specialists different than rheumatologists, spinal lesions are reported in most patients, and similarly in males and females. Remarkably, SIJ MRI findings are reported in one out of three patients in this population, being more frequently in males.

AB1401 HEALTH LITERACY AND OUTCOMES IN PATIENTS UNDERGOING TOTAL KNEE ARTHROPLASTY

Keywords: Outcome measures, Education

L. Yue[1], H. Do[1], J. A. Gibbons[2], D. Sun[1], D. Jannat-Khah[1], A. Bass[1], B. Mehta[1], L. Russell[1], M. Figgie[3], M. Parks[3], S. Goodman[1]. [1]*Hospital for Special Surgery Main Hospital, Rheumatology, New York, United States of America*; [2]*Columbia University Vagelos College of Physicians and Surgeons, Medicine, New York, United States of America*; [3]*Hospital for Special Surgery, Orthopedics, New York, United States of America*

Background: Health literacy is the ability to read and gain an understanding of health-related information, and make treatment and behavior choices accordingly. Poor health literacy is a main driver of health disparities in chronic medical conditions. Little is known about literacy in orthopedic surgery patients, which may be critical for post-surgical recovery.
Objectives: This study assessed health literacy in patients undergoing total knee arthroplasty (TKA) and its association with individual and community demographics, surgical length of stay (LOS), and discharge disposition.
Methods: The study population consisted of TKA patients at a single urban orthopedic specialty hospital from 2018-2021 who completed the health literacy screen. Health literacy, patient demographics and clinical variables were extracted from a data warehouse. Patient health literacy was defined by a validated single question tool (Morris et al. 2006) administered pre-operatively: *"How often do you have someone like a family member, friend, hospital or clinic worker or caregiver help you read health plan materials, such as written information about your health or care you are offered?"*. Answers were "Always," "Often," "Sometimes," "Occasionally" or "Never." "Always," "Often," or "Sometimes" answers reflect low health literacy and "Occasionally" or "Never" reflect adequate health literacy. Census-tract level measures of community poverty and education were obtained from the 2020 American Community Survey 5-year estimates. Variable comparisons were analyzed by $\chi 2$ and one-way analysis of variance (ANOVA), with $p < 0.05$ considered statistically significant.
Results: 7,875 TKA patients were included. 81.3% had adequate health literacy and 18.7% had poor health literacy (**Table 1**). Poor health literacy patients were older (71 vs 69, p<0.0001) and spoke a non-English preferred language (7.2% vs 1.9%, p<0.0001). These patients had more comorbidities (Charlson score 2+, 92.1% vs 11.5%, p=0.001), longer LOS (hours, 58 vs 56, p<0.001), and were less often discharged to home (84.3% vs 87.8%, p=0.002). Multiple linear regression analysis using backwards elimination showed that LOS was associated with sex, comorbidity and discharge disposition, factors themselves also shown to be linked with health literacy. There were no differences in health literacy by ethnicity, insurance, community poverty or education levels.
Conclusion: We found that patients in our population with low health literacy were older, non-English speaking, of Asian/other race, had higher comorbidity scores and a lower proportion of home discharges than those with adequate health literacy. Thus health literacy screening can identify patient groups for whom interventions during the pre-surgical process can be targeted. Based on results, further study can examine whether tools to support health literacy may lead to impact on important measures such as LOS and discharge disposition in orthopedic surgery patients.

AB1402 THE EFFECTS OF SPINAL STABILIZATION EXERCISES VIA TELEREHABILITATION ON INDIVIDUALS WITH CHRONIC LOW BACK PAIN: A RANDOMIZED CONTROLLED STUDY

Keywords: Physical therapy/Physiotherapy, Telemedicine, Rehabilitation

A. Fanuscu[1], M. Öz[1], O. Ulger[1]. [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: Chronic low back pain is a very common problem worldwide. Reasons such as repetitive problems and lack of a clear treatment cause low back pain to be a serious burden for society [1]. Telerehabilitation provides remote application of rehabilitation services with the developing technology. Especially in the COVID-19 pandemic, the problems experienced in health services have increased the popularity of telerehabilitation services [2].
Objectives: Aim in this study is to investigate the effects of spinal stabilization exercises performed remotely with asynchronous video clips on pain, disability, quality of life, trunk flexion range of motion and gait parameters.
Methods: A total of 20 individuals with chronic low back pain were included in the study. After recording demographic information, pain levels were evaluated with the Visual Analogue Scale (VAS), disability levels were evaluated with the Oswestry Disability Index (ODI), and quality of life was evaluated with the Nottingham Health Profile (NHP). Trunk flexion range of motion was evaluated with

the Valedo ® system (Hocoma, Switzerland), and the spatiotemporal parameters of the gait (step time, cadance) were evaluated with the OPTOGAIT system (OPTOGait, Microgate, Italy). After the evaluation, the individuals were divided into 2 groups. One group did face-to-face progressive spinal stabilization exercises in the clinic, while the other group did the same exercise program remotely with asynchronous videos. The exercise program was 8 weeks, 3 days a week.

Results: The mean age of the telerehabilitation group (4 M, 5 F) was 41.44 ± 9.74, and their body mass index (BMI) was 26.34 ± 3.1. The mean age of the clinical group (1 M, 8 F) was 41.0 ± 13.0, and their BMI was 27.64 ± 3.55. All parameters were similar in the two groups before treatment. There was a significant difference in parameters except gait parameters in both groups after treatment ($p<0.05$). In the evaluation between the groups after treatment, the results of the two groups were similar in all parameters ($p>0.05$) (Table 1).

Table 1. Baseline and after treatment characteristics of telerehabilitation and face to face group and comparison of with-in group and between group

	Telerehabilitation			Face to Face			
	Baseline	After Treatment	p value	Baseline	After Treatment	p value	Between Group
VAS	6.51±1.61	2.41±1.17	0.00*	6.62±0.95	2.33±1.98	0.00*	0.79
ODI	20.66±9.94	13.55±10	0.00*	30.22±15.5	17.11±12	0.02*	0.54
NHP	131.51±121.29	34.0±29.61	0.01*	203.55±60.07	63.08±76.24	0.00*	0.66
Trunk Flexion Range of Motion	99.55±12.24	106.55±7.51	0.04*	88.11±15.26	94.11±15.18	0.00*	0.09
Step length (cm)	60.67±9.07	64.35±9.58	0.51	53.82±21	65.95±9.41	0.17	0.54
Step Time (sec)	0.55±0.04	0.51±0.08	0.26	0.40±0.12	0.34±0.18	0.13	0.06
Cadance	105.67±9.17	106.13±17.46	0.44	103.37±8.64	105.31±9.45	0.67	0.73

Conclusion: According to the results of our study, it is seen that both methods did not provide any change in gait parameters. However, it has similar effects in reducing pain and disability, improving quality of life, and increasing trunk range of motion. For individuals with chronic low back pain, it seems that remote exercise with asynchronous videos can be as effective a treatment as face-to-face exercise. There is a need for studies to be conducted in a larger population with longer follow-up.

AB1403 IS MUSCLE STRENGTH ASSOCIATED WITH SPATIOTEMPORAL GAIT PARAMETERS IN PATIENTS WITH NON-SPECIFIC CHRONIC LOW BACK PAIN? THE BACKFIT PROJECT

Keywords: Pain, Motor function, Rehabilitation

G. Tsiarleston[1], Y. M. Gil-Gutiérrez[2], B. Donoso[3], E. Ruíz-Malagón[1], J. M. Chicano-Gutiérrez[4], V. Segura-Jiménez[2]. *[1]Univesity of Granada, Physical Education and Sport, Granada, Spain*; *[2]Instituto de Investigación Biosanitaria ibs.GRANADA, UGC Neurotraumatología y Rehabilitación, Hospital Universitario Virgen de las Nieves of Granada, Granada, Spain*; *[3]University of Cordoba, Psychology, Cordoba, Spain*; *[4]Sport and Health Research Institute (iMUDS), Physical Education and Sport, Granada, Spain*

Background: Non-specific chronic low back pain (NSCLBP) is one of the most common musculoskeletal disorders globally, as approximately 10-40% of individuals experience it[1]. Chronic pain is characterized when persists more than 12 weeks, and non-specific when causes of pain are of unknown origin[2]. People with NSCLBP present weakness of multifidus, transversus abdominis, internal oblique and gluteus maximus muscles and present difficulties to maintain a coherent walking due to the lack of strength and control[3].

Objectives: To explore the association of back flexor, back extensor, lower- and upper-body muscle strength with spatiotemporal gait parameters in patients with NSCLBP.

Methods: A total of 105 patients with NSCLBP, 69 women (mean ± standard deviation= 50.9±9.9 years) participated in this cross-sectional study. Back flexor, back extensor, upper- and lower-body muscle strength were measured with reliable and valid tests (prone bridging, Biering-Sørensen, hand dynamometry (TKK 5101) and 30-second chair-stand test, respectively). Global muscle strength was calculated with normalized index (z-score) procedure from each muscle strength test. Spatiotemporal gait parameters (contact time, gait speed, stride length, stride cycle/time, double support and load respond) were obtained with an Optogait™ platform, where patients were informed to walk comfortably until 150 to 200 steps were registered in 5 meters closed circuit. Linear regression analysis was used to study the association between muscle strength and spatiotemporal gait parameters. Age, medication for pain, relaxation and depression, and fat percentage were used as covariates using the 'stepwise' method. These variables were administered via interview, except fat percentage which was measured with 8 tactile polar electrode bioimpedance system (InBody R20).

Results: In women, greater back flexor muscle strength was associated with lower contact time (β=-0.328), stride cycle/time (β=-0.382), double support (β=-0.313) and load respond (β=-0.302), higher gait speed (β=0.341), and longer stride length (β=0.272) (all $p\leq0.013$). Greater lower-body muscle strength was associated with less contact time (β=-0.160) and double support (β=-0.237), higher gait speed (β=0.365) and longer stride length (β=0.415) (all $p\leq0.031$). Greater upper-body muscle strength was associated with higher gait speed (β=0.380) and longer stride length (β=0.476) (all $p\leq0.001$). Greater global muscle strength was associated with less contact time (β=-0.370), stride cycle/time (β=-0.468), double support (β= -0.324) and lower load respond (β=-0.320), higher gait speed (β=0.431) and longer stride length (β=0.491) (all $p\leq0.03$). In men, greater back extensor muscle strength was associated with higher gait speed (β=0.353), and lower double support (β=-0.387) and load respond (β=-0.365) (all $p\leq0.038$). Greater lower-body muscle strength was associated with lower stride cycle/time (β=-0.342) ($p=0.044$). Greater global muscle strength was associated with higher gait speed (β= 0.414), longer stride length (β=0.410), and lower double support (β=-0.373) and load respond (β=-0.354) (all $p\leq0.037$).

Conclusion: Our findings suggest that greater muscle strength was consistently associated with better spatiotemporal gait parameters in females and males patients with NSCLBP. Future studies might determine whether randomized control trial focused on strengthening global musculature might contribute to improve gait abnormalities in patients with NSCLBP.

AB1404 THE ASSOCIATION OF PAIN INTENSITY AND MUSCULOSKELETAL FACTORS, PHYSICAL ACTIVITY, AND QUALITY OF LIFE IN PREGNANT WOMEN WITH LOW BACK PAIN: A CROSS-SECTIONAL STUDY

Keywords: Pregnancy and reproduction, Quality of life, Pain

E. Üzelpasacı[1], T. Akbayrak[2]. *[1]Eskisehir Osmangazi University, Physical Therapy and Rehabilitation, Eskisehir, Turkey*; *[2]Hacettepe University, Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: Low back pain (LBP) is one of the most common musculoskeletal problems affecting pregnant women. While the etiology/pathogenesis of pregnancy-related LBP (PR-LBP) has not been fully explained, it is thought to stem from several biological/physical factors including hormonal, vascular, and biomechanical changes, trauma, metabolic factors, insufficient muscle control, stress, weight gain, sedentary lifestyle, muscle function loss [1,2]. As such, risk factors need to be assessed comprehensively during pregnancy and those women who are at risk should be given preventive recommendations.

Objectives: The aim of this study was to determine the association between musculoskeletal factors (abdominal muscle thickness and diastasis recti), physical activity, quality of life and self-reported LBP intensity during different trimesters of pregnancy.

Methods: A total of 107 pregnant women who were between 11 and 37 weeks of gestation, without obstetric and medical complications were included in this study. Detailed, sociodemographic and obstetric characteristics were recorded. The pregnant women were shown the region of LBP on a figure and they were asked to mark the relevant average pain intensity on a 10 cm Visual Analogue Scale (VAS). Disability was evaluated using the Oswestry Disability Index (ODI) to evaluate the degree of loss of functionality. Abdominal muscle thicknesses and diastasis recti were measured by ultrasonography. Pregnancy Physical Activity Questionnaire (PPAQ) and Short Form-36 (SF-36) were used to assess physical activity and quality of life. Univariate regression was used to analyse associations between each plausible independent variable and low back pain severity.

Results: Among 107 primiparous women, 43 were in the 1st trimester (mean age: 31.18±4.58 years, mean body mass index (BMI): 24.15±4.26 kg/m^2), 33 in the 2nd trimester (mean age: 30.62±4.53 years, BMI: 25.65±3.77 kg/m^2), and 32 were in the 3rd trimester (mean age: 30.58±4.60 years, BMI: 27.08±3.70 kg/m^2).

The mean LBP intensity was 3.09±2.37 and they were 2.68±2.09, 2.73 ±1.98, 2.16± 2.01 for the 1st, 2nd and 3rd trimesters, respectively. Demographic and medical variables in pre-pregnancy and pregnancy periods were not associated with PR-LBP intensity. On the contrary, ODI score was associated with LBP intensity during pregnancy. Higher ODI score shows severe low back pain (coef=0.05, R2=0.11, p=0.03) and ODI scores explain 11%, 13% and 26% of LBP severity during 1st, 2nd and 3rd trimester, respectively. Musculoskeletal variables (abdominal muscle thickness and diastasis recti) were not associated with PR-LBP intensity. SF-36 emotional role limitation (coef=-0.03, R2=0.20, p=0.01) in the 3rd trimester and SF-36 pain in the 1st (coef=-0.04, R2=0.12, p=0.02) and 3rd (coef=-0.05, R2=0.26, p=0.004) trimesters were associated with PR-LBP intensity. Rest of the SF-36 subscales were not associated with LBP intensity during any trimester. Physical activity were not associated with PR-LBP intensity, except of the PPAQ-sedentary during the 2nd trimester (coef=0.17, R2=0.17, p=0.02).

Conclusion: Increased PR-LBP intensity can be associated with different factors in different trimesters of pregnancy. Clinicians should comprehensively assess pregnant women, taking into account the relevant risk factors according to trimester, and make preventive/therapeutic recommendations for pregnant women.

AB1405 POSTOPERATIVE RESULTS OF JOINT-PRESERVING SURGERY WITH MITCHELL'S OSTEOTOMY FOR HALLUX VALGUS DEFORMITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Bone diseases, Rheumatoid arthritis

C. Yoshimura[1], T. Okano[1], S. Anno[2], Y. Yamada[1], K. Orita[2], K. Mamoto[1], Y. Sugioka[3], M. Tada[4], K. Inui[5], T. Koike[3], H. Nakamura[1]. *[1]Osaka Metropolitan University Graduate School of Medicine, Department of Orthopedic Surgery, Osaka, Japan*; *[2]Yodogawa Christian Hospital, Department of Orthopedic Surgery, Osaka, Japan*; *[3]Osaka Metropolitan University Graduate School of Medicine, Center for Senile Degenerative Disorders (CSDD), Osaka, Japan*; *[4]Osaka City General Hospital, Department of Orthopedic Surgery, Osaka, Japan*; *[5]Osaka Saiseikai Nakatsu Hospital, Department of Orthopedic Surgery, Osaka, Japan*

Background: In recent years, joint-preserving surgery has become common surgical procedure for forefoot deformities in Japanese patients with rheumatoid arthritis (RA). Since arthritis contributes to hallux valgus deformity in patients with RA, the postoperative outcome may differ from that in patients with idiopathic hallux valgus (IHV) patients.

Objectives: In this study, we compared the postoperative results of Mitchell's osteotomy in patients with RA and IHV.

Methods: We evaluated 181 feet in 111 patients (52 feet in 34 patients with RA, 129 feet in 77 patients with IHV) who performed Mitchell's osteotomy surgery between January 2006 and September 2021 and followed-up more than one year. The hallux valgus angle (HVA) and intermetatarsal angle (IMA) were measured from standing X-ray images of the foot, before and after surgery and one year later, and the postoperative course of RA and IHV patients was compared.

Results: Preoperative HVA was 42° [20-73] in patients with RA and 40° [17-62] in patients with IHV, with no significant differences. Preoperative IMA was 14° [6-22] in patients with RA and 15° [7-23] in IHV patients, significantly smaller in the RA group (p<0.01). HVA at 1 year was 7° [-21-34] in patients with RA and 9° [-24-38] in patients with IHV, with no significant differences. IMA at 1 year was 7° [0-18] in patients with RA and 8° [1-21] in patients with IHV, with no significant differences. The recurrence rate at 1 year postoperatively was 17.3% in patients with RA and 16.3% in patients with IHV, with no difference. Traditionally, metatarsal head resection has been performed for rheumatoid forefoot deformities. However, joint-preserving surgery is recently performed due to the improvement of anti-rheumatic drugs such as biological disease modifying drugs and Janus kinase inhibitors. Mitchell's osteotomy has been recommended for IHV as a joint-preserving surgery, as has Chevron osteotomy. The results of this study showed that Mitchell's osteotomy is useful treatment method for patients with RA as well as for patients with IHV. In addition, preoperative IMA in patients with rheumatoid forefoot deformity was significantly smaller than patients with IHV, but there was no difference in HVA. This suggests joint inflammation leads to lateral dislocation of proximal phalanx without metatarsal bone medialization.

Conclusion: Joint-preserving surgery with Mitchell's osteotomy was useful method for hallux valgus deformity in patients with RA.

AB1406 COMPARISON OF FOOT POSTURE, PAIN, FUNCTION AND QUALITY OF LIFE IN PATIENTS WITH PES PLANUS AND HALLUX VALGUS: A PILOT STUDY

Keywords: Quality of life, Pain

G. Aydin Yağcioğlu[1], M. Karapinar[1]. *[1]Süleyman Demirel University, Department of Physiotherapy and Rehabilitation, Isparta, Turkey*

Background: Hallux valgus is a common deformity characterized by abnormal rotation, lateral deviation, angulation of the great toe at the first metatarsophalangeal joint. Pes planus is known as the loss of the medial longitudinal arch. While some studies have suggested that pes planus plays an important role in the development of hallux valgus [1, 2], others reported that no correlation between these disorders [3, 4]. Thus, the differences in the problems caused by these disorders should be clarified.

Objectives: The aim of this study was to compare individuals with hallux valgus and pes planus in terms of foot posture, function, pain, and quality of life.

Methods: Thirty-one (13-hallux valgus, 18-pes planus) individuals of both sexes, who were determined to have pes planus or hallux valgus by clinical evaluation, were included in the study. The dominant foot of the patients was evaluated by the Foot Posture Index (FPI-6), Foot Function Index (FFI), The American Orthopedic Foot and Ankle Society (AOFAS), and their quality of life was evaluated by the Short Form-36 (SF-36). FPI-6 evaluates foot posture with 6 items in the range of (-12) - (+12). According to FPI-6, negative values indicate the foot is in supination, and positive values indicate that the foot is in pronation. The FFI scores for the domains of pain, disability, and activity limitations. A higher score indicates greater impairment. AOFAS, also consists of pain, function, and alignment subscales, and the total score ranges from 0-100, and higher scores indicate better outcome. SF-36 is a scale that evaluates health-related quality of life with 8 subscales, and physical function and general health subscales of SF-36 were used in this study, and higher scores also demonstrate a better quality of life. Mann Whitney-U test was used to investigate the differences between patients with hallux valgus and pes planus.

Results: Individuals with pes planus and hallux valgus were homogenous in terms of physical characteristics (p>0.05). It was determined that patients with pes planus had worse foot postures according to FPI-6 and more foot pain according to FFI and AOFAS compared to patients with hallux valgus (p<0.05). Other results were similar between patients with pes planus and hallux valgus (p>0.05) (Table 1).

Conclusion: To the best of our knowledge, this study was the first to compare between patients with hallux valgus and pes planus. Current findings revealed that pes planus caused more pain and foot posture disorders compared to hallux valgus. A comparative study on a large sample is ongoing to assess the difference between these foot disorders.

AB1407 EFFECTIVENESS OF TREATMENT OF FACET SYNDROME BY THE METHOD OF BLOCKADE OF INTERVERTEBRAL JOINTS UNDER ULTRASOUND CONTROL

Keywords: Pain

T. Tarasenko[1,2], O. Tarasenko[3]. [1]*Kherson State University, Medical Faculty, Dnipro, Ukraine*; [2]*Rheumatology Clinic of Professor Rekalov, Rheumatology, Dnipro, Ukraine*; [3]*Kherson State University, Medical Faculty, Dnipro, Ukraine*

Background: recently there has been an increase in the prevalence of facet syndrome (spondyloarthrosis) in back pain syndromes. This is due to hypodynamia, increased body weight, and the increase in the specific gravity of the so-called "sedentary" professions. With hypertrophy of the intervertebral joints, there is chronic compression of the Lyushka nerve (return nerve), which directly causes pain, as well as constant spasm of the innervating muscles. In the treatment of facet syndromes, many methods are used - drug treatment, massage, various physical methods of influence, etc., but none of these methods provides quick relief from the pain syndrome. The blockade method has been used for a long time with considerable success, but even more works are appearing that show much better efficiency of these manipulations with high-precision introduction of drugs under ultrasound or X-ray control.
Objectives: to determine the effectiveness of blockades of intervertebral joints under ultrasound control in facet syndrome.
Methods: we conducted a study of patients in whom the clinical manifestations of the facets of the lumbosacral spine syndrome were confirmed by radiological research methods (radiographic or MRI). The level of pain syndrome was assessed according to the VAS scale before the start of treatment and after 1 and 7 days after the start of treatment. Along with traditional treatment (NSAIDs, muscle relaxants, etc.), facet blockade was performed under ultrasound control.
Results: 50 patients (22 women and 28 men) were included. The average age was 43.28 years±0.80 years. 56.42% of patients were overweight. The average body mass index was 28.18±0.43 kg/m2. 80% of patients had multilevel facet syndrome L3-S1. 20% of patients had a monofacet syndrome at the level of L4-L5 or L5-S1. Patients were divided into 2 groups of 25 people. Patients of both groups were prescribed drug therapy with NSAIDs and muscle relaxants. The patients of the first group were additionally subjected to facet blockade under ultrasound control, and a solution of corticosteroid and local anesthetic was injected into the affected areas. Depending on the number of lesion levels, a multilevel procedure was performed. Before the procedure, the average pain level according to VAS in patients of the 1st group was 84±1.7 mm, in the 2nd group - 82±2.3 mm. After 1 day, the pain level in patients of the 1st group was 31±4.2 mm, while in the 2nd - 72±2.8 mm. 7 days after the start of treatment and manipulation, the pain level was 28±2.9 mm in the 1st group and 51±3.7 mm in the second group of patients (who were not manipulated).
Conclusion: the method of facet blockade under ultrasound control is a modern, low-traumatic, highly effective method in the complex treatment of facet syndrome.

AB1408 INVESTIGATION OF GAIT SYMMETRY, CERVICAL PROPRIOCEPTION AND FUNCTIONALITY IN INDIVIDUALS WITH CHRONIC IDIOPATHIC NECK PAIN

Keywords: Pain, Outcome measures

H. Ayan[1,2], B. Kara[3], R. Erbayraktar[4]. [1]*Dokuz Eylul University, Institute of Health Sciences, Izmir, Turkey*; [2]*Izmir Katip Çelebi University Vocational School of Health Services, Department of Medical Services and Techniques, Physiotherapy Program, Izmir, Turkey*; [3]*Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, Izmir, Turkey*; [4]*Dokuz Eylul University, Department of Neurosurgery, Faculty of Medicine, Izmir, Turkey*

Background: Previous studies have shown that persons with chronic idiopathic neck pain (CINP) have gait disturbances [1]. However, it has not been clarified whether they have gait asymmetries. Cervical proprioception is important to maintain gait function [2]. However the association between gait symmetry and cervical proprioception in CINP is not known.
Objectives: The first aim was to investigate gait symmetry, cervical proprioception, cervical range of motion, and functional disability in persons with CINP and compare them with healthy controls (HC). The second aim was to investigate the relationship between gait symmetry and cervical proprioception and functional disability in persons with CINP.
Methods: This study included 35 persons with CINP (27 females, 8 males, mean age 25.48 ± 8.69 years), and 34 HC (25 females, 9 males, mean age 25.76 ± 7.96 years). Gait symmetry was assessed with a wearable sensor device. The device, which can provide real-time data transfer in determining gait symmetry, allows the patient to move freely without laboratory conditions with its wireless sensor feature. Joint position error (JPE) was assessed for proprioceptive ability. The cervical range of motion (flexion, extension, lateral flexion, rotation) and cervical JPE (flexion, extension, lateral flexion, rotation) were evaluated with an easy-to-use device (Cervical Range of Motion; CROM) containing 3 head-mounted inclinometers. Neck Disability Index (NDI) was used to assess functional disability in the CINP group.
Results: Persons with CINP had significantly worse gait symmetry than HC ($p<0.001$). There were significant differences between the CINP and HC in all directions of cervical JPE and all directions of cervical range of motion ($p<0.01$). In the CINP group, gait symmetry was significantly correlated with the cervical JPE (flexion, extension, right lateral flexion, $r = -0.387, -0.459, -0.443$, $p<0.05$) and NDI ($r = -0.493$, $p<0.05$). There were not significant correlation between gait symmetry and cervical left lateral flexion ($r = -0.237$, $p=0.171$), and right cervical rotation ($r = -0.187$, $p=0.171$) and left cervical rotation ($r = -0.102$, $p=0.561$) JPE.
Conclusion: In our study persons with CINP had significantly more asymmetrical gait, worse cervical proprioception and worse cervical range of motion compared to the healthy controls. It has been shown that gait symmetry is related to cervical proprioception (flexion, extension, right lateral flexion) and functional disability in CINP.

AB1409 EFFICACY AND SAFETY OF SODIUM THIOSULFATE IN CALCIFIC TENDINITIS OF THE ROTATOR CUFF – ANALYSIS OF AN ONGOING RANDOMIZED CLINICAL TRIAL

Keywords: Patient reported outcomes, Randomized control trial, Outcome measures

H. Parente[1], S. Azevedo[1], F. Guimarães[1], C. Dantas Soares[1], M. Pontes Ferreira[1], D. Faria[1], D. Peixoto[1], J. Tavares-Costa[1], C. Afonso[1], F. Teixeira[1]. [1]*Centro Hospitalar do Alto Minho, Rheumatology, Ponte de Lima, Portugal*

Background: Calcific tendinitis of the rotator cuff is a major cause of omalgia. [1] Ultrasound guided percutaneous lavage (UGPL) is indicated when conservative treatments fail. [2] Recent reports interested the use of topical sodium thiosulfate (STS) in the treatment of other diseases with ectopic calcifications [3, 4, 5].
Objectives: To assess the efficacy and safety of UGPL with STS versus with saline solution (standard of care - SOC) in calcific tendinitis.
Methods: Double-blinded randomized clinical trial including adult patients with calcific tendinitis, omalgia ≥3 months and ≥1 positive shoulder impingement test. Only dense type A calcifications (Molé Classification) >5 mm in diameter were included. Patients were randomized in two groups: STS and SOC lavage. Informed consents were collected. Both groups were reevaluated at week 1, month 1 and 3 after UGPL. Pain Visual Analogue Scale (VAS) at rest and during activities, shoulder range of motion and strength, impingement tests, Disabilities of the Arm, Shoulder and Hand (DASH), DASH-Work, EuroQol five-dimensional (EQ5D) and University of California at Los Angeles (UCLA) scores, ultrasound (US) and radiographic evaluations were performed on all follow up visits. SPSS was used for statistical analysis with a significance level of 2-sided $p<0.05$.
Results: We included 32 patients, where 78.1% (25) were women, with a mean age of 51.0 (SD=8.5) years old. Pain's mean duration before the procedure was 16.3 months (SD=22.3). We randomized 18 patients (56.3%) to the control group (SOC) and performed a saline UGPL; the other 14 patients (43.8%) to the treatment group (STS). Baseline characteristics are shown in table 1. Since patient inclusion is dynamic, our sample met 28 patients at week 1 (SOC=15

and STS=13), 26 patients at month 1 (SOC=14 and STS=12) and 21 patients at month 3 (SOC=10 and STS=11). Both procedures numerically improved pain, range of motion, functionality and calcification size, but only SOC lavage was statistically significant for calcification size reduction (p=0.005), EQ5D, DASH work and UCLA improvements (p=0.021, 0.042 and 0.03, respectively), while both STS and SOC lavage statistically reduced the DASH score (p=0.014 and 0.06, respectively). No adverse effects/complications were reported.

Conclusion: Although well tolerated with no side effects, STS UGPL has failed to uphold the SOC benefits for calcific tendinopathy. Further studies using STS are needed to ascertain its interest in this disease. This on-going work will be reevaluated with a larger sample.

Table 1. Demographic and baseline clinical characteristics.

AB1410

ASSOCIATION BETWEEN MUSCLE MASS PERCENTAGE WITH PAIN AND DISABILITY IN PATIENTS WITH NON-SPECIFIC CHRONIC LOW BACK PAIN: THE BACKFIT PROJECT

Keywords: Motor function, Rehabilitation, Pain

Y. M. Gil-Gutiérrez[1], G. Tsiarleston[2], B. Donoso[3], M. Delgado-Fernández[2], M. Y. Castellote-Caballero[4], V. Segura-Jiménez[1]. *[1]Instituto de Investigación Biosanitaria ibs.GRANADA, UGC Neurotraumatología y Rehabilitación, Hospital Universitario Virgen de las Nieves of Granada, Granada, Spain*; *[2]Univesity of Granada, Physical Education and Sport, Granada, Spain*; *[3]University of Cordoba, Psychology, Cordoba, Spain*; *[4]University of Jaén, Health Sciences, Jaén, Spain*

Background: Non-specific chronic low back pain (NSCLBP) is one of the most common musculoskeletal disorders worldwide[1]. Recent studies have shown higher levels of pain[2,3] and disability[4] in patients with NSCLBP who presented higher body mass index. However, the relationship between body muscle mass and these two variables is unknown.

Objectives: To determine if there is an association of body muscle mass percentage with pain and disability in patients with NSCLBP.

Methods: 105 patients (70 women, 50.59 ± 9.95 years) participated in this cross-sectional study. Body muscle mass percentage was evaluated using portable bioimpedance of eight tactile polar electrodes (InBody R20). Pain sensitivity threshold was assessed using manual pressure algometry (FPK 20, Wagner Instruments, Greenwich, CT, USA). Pain intensity was evaluated using two instruments, on the one hand a visual analogue scale (VAS) and on the other hand the pain dimension of the Short-Form Health Survey-36 (SF-36) questionnaire. The Oswestry Low Back Pain Disability questionnaire was used to assess disability due to pain. To study the association between the main variables, a linear regression analysis was carried out, controlling for age, sex, marital and educational status, time since clinical diagnosis and waist circumference as covariates using the 'stepwise' method. As there was no interaction in terms of sex, the analyses were carried out jointly (women and men).

Results: Higher levels of body muscle mass percentage were associated with higher pain sensitivity threshold (b=0.071; 95% confidence interval (CI)= 0.017,0.130; p=0.017, lower VAS-pain (b=-0.095; 95% CI= -0.184, -0.007; p=0.03) and higher score in the SF-36 pain dimension (b=1.038; 95% CI= 0.376, 1.701 p=0.002), and lower disability due to pain (b= -1.028; 95% CI= -1.513, -0.542; p<0.001).

Conclusion: Patients with NSCLBP presenting higher body muscle mass percentage showed lower pain and disability due to pain, and higher pain sensitivity threshold. Further intervention studies are necessaries to check the effects on pain and disability of programs focused on improving muscle mass in this population.

AB1411

THE EFFECTS OF YOGA AND AEROBIC EXERCISE ON PAIN, FUNCTION, METABOLIC CAPACITY, QUALITY OF LIFE AND COGNITIVE VARIABLES IN INDIVIDUALS WITH CHRONIC LOW BACK PAIN: PRELIMINARY RESULTS

Keywords: Rehabilitation, Cognitive Function, Pain

M. Öz[1], O. Ulger[1]. *[1]Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: It is known in the literature that exercise is effective on pain and function in the treatment of chronic low back pain (CLBP). However, it is emphasized that there is insufficient evidence about which type of exercise is more effective and the effect of exercises on cognitive parameters associated with chronic pain.

Objectives: The study aims to determine the effects of yoga and aerobic exercise on pain, function, metabolic capacity, quality of life (QoL), and cognitive variables in individuals with CLBP.

Methods: Thirty individuals with LBP for 3 months or longer were included in the study. Individuals were randomly divided into 2 groups. The first group was given aerobic exercise training, and the second group was given a yoga program. Both programs were applied for 8 weeks, 2 days a week, for 1 hour, accompanied by a physiotherapist. Individuals were evaluated at baseline and after 8 weeks of treatment. Pain intensity was assessed with a visual analog scale (VAS), metabolic capacity with 6 Minute Walking Test, kinesiophobia with Fear Avoidance Beliefs Questionnaire (FABQ), pain perception with a pain catastrophizing scale (PCS), cognitive function with Montreal Cognitive Assessment Scale (MoCA), back awareness with Fremantle Back Awareness Questionnaire (FreBAQ) and QoL with the Nottingham Health Profile (NHP).

Results: In the study, it was shown that both exercises approach reduced pain and improved function, metabolic capacity, and cognitive parameters (p<0.05). The effects of both exercises on pain, function, cognitive level, metabolic capacity, and NHP total score were similar (p>0.05). However, kinesiophobia and back awareness improved only in the yoga group; pain catastrophizing, NHP-sleep, and NSP-emotional reaction sub-parameters improved only in the aerobic exercise group (p<0.05).

Conclusion: It has been shown that yoga and aerobic exercise, whose effects on pain and function are well known, are also effective on metabolic capacity, QoL, and cognitive parameters. These results may help physiotherapists to comprehensively evaluate individuals according to the multidimensional nature of CLBP and to organize the content of treatment programs for the identified needs.

Paediatric rheumatology

AB1412 THE DAMAGE OF JUVENILE IDIOPATHIC ARTHRITIS IN ADULT PATIENTS

Keywords: Outcome measures, bDMARD, Disease-modifying Drugs (DMARDs)

K. Kern[1], D. Kaudewitz[1], H. M. Lorenz[1], J. P. Haas[2], N. Blank[1]. [1]*Division of Rheumatology, Department of Internal Medicine V, Heidelberg, Germany*; [2]*Kinderklinik Garmisch-Partenkirchen, Deutsches Zentrum für Kinder- und Jugendrheumatologie, Garmisch-Partenkirchen, Germany*

Background: Juvenile idiopathic arthritis (JIA) is the most common disease in pediatric rheumatology. After transition, chronic active JIA requires continuing treatment. Little is yet known about the JIA activity in adult patients.
Objectives: To assess disease activity, treatment and comorbidities in adult patients with JIA between 2000 and 2022 at the University Hospital of Heidelberg.
Methods: This is a monocentric, retrospective analysis of adult patients with onset as JIA. The electronic medical records were analyzed from the first to the last documented visit in our center. Prognostic factors for disease activity in adults were determined using Fisher's exact test, chi-square test and cross tables.
Results: Until March 2022, 172 JIA patients with a median age of 27.7 years (range 18.1 to 78.4) and a median disease duration of 19.4 years (range 1.3 to 68.8) at their last visit were identified. Oligoarticular (oligo-) (n=36, 20.9%), extended-oligo (ext-oligo-) (n=28, 16.3%) and polyarticular (poly-) (n=61, 35.5%) were the largest JIA subgroups. Females (n=134, 77.9%) were more prevalent than males (n=38, 22.1%) (p<0,001). The prevalence of uveitis was 27.9% (n=48). Patients with RF+ poly-JIA (n=17, p<0,001) or initiation of MTX after 2 years (n=41, p=0,006) or bDMARD after 3 years (n=44, p<0,001) of disease onset were associated with significantly more erosive joint damage. Patients with late MTX and/or bDMARD initiation (n=190) had more frequently osteoporosis (n=48, p=0,011, p=0,012) and required more frequently total joint replacement (n=41, p=0,012, p=0,04). Radiological joint damage was more prevalent in patients with a disease onset before the year 2000. At the last documented visit 51.8% of patients (n=72) were in SDAI and DAS28 remission.
Conclusion: The delay of MTX and bDMARD therapy in patients with active JIA was associated with erosive joint damage, total joint replacement and osteoporosis. The JIA onset before the year 2000 was associated with significantly more joint damage and a lower prevalence of remission.

AB1413 ASSESSMENT OF FATIGUE IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Osteoporosis, Sarcopenia, Mental health

M. Kulyk[1], T. Karasevska[1], M. Dzhus[1]. [1]*Bogomolets National Medical University, Internal Medicine Department No 2, Kyiv, Ukraine*

Background: Fatigue is a common and frustrating symptom in many chronic inflammatory diseases, including juvenile idiopathic arthritis (JIA), impacting all parts of daily life.
Objectives: This study aims to determine the prevalence of fatigue in young patients with JIA and to analyze its correlation with clinical characteristics of the disease, body mineral content (BMC), and bone mass density (BMD).
Methods: Cross-sectional study included young adults with JIA according to ILAR criteria, disease duration ≥3 years. Exclusion criteria: age<18 and >44 years, the presence of any comorbidity that could be accompanied by fatigue (diabetes, chronic kidney disease, neuropathy, obesity, chronic obstructive pulmonary disease, infections, malignancy). Demographic data and the following clinical parameters were collected: pain Visual Analog Scale (VAS) measured by patients and doctors, tender joint count (TJC), swollen joint count (SJC), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), Disease Activity Score 28 (DAS28), Juvenile Arthritis Disease Activity Score (JADAS27), health assessment questionnaire (HAQ), Juvenile Arthritis Damage Index-articular (JADI-A) and Juvenile Arthritis Damage Index-extra-articular (JADI-E). BMC and BMD were determined using dual photon X-ray absorptiometry (DXA). Fatigue was assessed using the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) short 13-item questionnaire validated in RA. Fatigue was considered mild if the FACIT-F score was ≥40, moderate if 20≤FACIT-F<40, and severe if 0≤FACIT-F<20. A p-value lower than 0.05 was considered significant.
Results: We included 40 patients with JIA (24 women and 16 men) with a mean age of 24.4±5. The mean disease duration was 13,8±8,1 years. The mean pain VAS measured by the patient was 38,8±3,4; the mean pain VAS measured by the doctor was 33,6±4,1; the mean TJC and SJC were 4,2±4,9 and 1,9±3,2, respectively. The mean levels of ESR and CRP were 20,2±2,7 mm/h and 26,1±7,0 mg/l, respectively. The mean DAS28-ESR was 3,6±1,5, the mean JADAS27 was 13,3±8,7, and the mean HAQ score was 0.60±0.6. The mean FACIT-F score was 30.1±12.4. Fatigue was mild in 37.5% (15 patients), moderate in 35% (14 patients), and severe in 27.5% (11) of patients. A significant negative correlation was noted between the FACIT-F score and the following parameters in JIA patients: disease duration (r=-0.436, p<0.001), articular and extra-articular damage obtained by JADI-A and JADI-E indices (r=-0.393, p=0.01, r=-0.440, p=0.05, respectively), pain VAS obtained by a doctor (r=-0.358, p=0.02), but not with pain VAS obtained by the patient (r=-0.167, p=0.3), ESR (r=-0.503, p<0.001), but not with CRP (r=-0.157, p=0.3), DAS28-ESR (r=-0.414, p<0.05), JADAS27 (r=-0.391, p<0.01) but not with TJC (r=-0.080, p=0.8), and SJC (r=-0.239, p=0.2). FACIT-F score was positively associated with total BMD (r=0.364, p=0.2), femoral neck BMD (r=0.519, p=0.007), appendicular lean mass (r=0.666, p<0.001), total lean mass (r=0.622, p<0.001), and skeletal mass index (r=0.703, p<0.001), but not with HAQ (r=0.035, p=0.8).
Conclusion: In our study, moderate and severe fatigue among young patients with JIA was 35% and 27.5%, respectively. The fatigue was associated with disease activity, duration of disease, articular and extra-articular damage, total and femoral neck BMD, and lean mass.

AB1414 PREDICTIVE FACTORS OF BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (BDMARD) USE IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS

Keywords: bDMARD

A. Martins[1,2], S. Ganhão[3], F. Oliveira Pinheiro[1,2], C. Morais[4], M. Leuzinger-Dias[5], M. Rodrigues[3], L. Figueira[5], I. Brito[2,3]. [1]*São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; [2]*Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal*; [3]*São João Universitary Hospital Center, Pediatric and Young Adult Rheumatology Unit, Porto, Portugal*; [4]*São João Universitary Hospital Center, Pediatrics, Porto, Portugal*; [5]*São João Universitary Hospital Center, Ophthalmology, Porto, Portugal*

Background: The advent of disease-modifying antirheumatic drugs (DMARDs), in the past two decades has been revolutionary in the treatment and prognostic outcomes of patients with Juvenile Idiopathic Arthritis (JIA). Since some patients have inadequate responses to conventional DMARDs, biologic DMARDs (bDMARDs) must be prescribed to guarantee the achievement of complete remission. Early and appropriate treatment can prevent joint destruction, loss of joint function and extraarticular manifestations, with subsequent less morbidity and mortality.
Objectives: To identify the JIA patients with a higher probability of requiring treatment with bDMARDs and to investigate the predictive factors.
Methods: A retrospective single-center study of patients with JIA followed in a tertiary Hospital was conducted. Sociodemographic, clinical, laboratory and treatment characteristics were collected from Portuguese Rheumatic Diseases Register and medical records. Statistic was performed with independent samples t-test, Mann-Whitney U test, chi-square test and Fisher's exact test. Statistical significance was set up at a p-value <0.05. A multivariate logistic regression analysis was performed to identify possible predictive factors for bDMARD use. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated.
Results: A total of 165 patients with JIA (107 females, 64.8%) were included. Seventy-five patients had oligoarthritis (45.6%, 62 had persistent oligoarthritis and 13 had extended oligoarthritis), 17 psoriatic arthritis (10.3%), 30 rheumatoid factor (RF)-negative polyarthritis (18.1%), 6 RF-positive polyarthritis (3.6%), 14 systemic arthritis (8.5%) and 23 enthesitis related arthritis-juvenile spondyloarthritis (13.9%). Fourty-five patients were treated with bDMARD (27.3%). Males were treated more frequently with bDMARDs than females (p=0.058). Regarding JIA subtype, more RF-positive polyarthritis patients needed bDMARDs to achieve remission (p=0.027). Likewise, concerning disease activity, JIA patients with higher C-reactive protein (CRP) values were more frequent treated with bDMARDs (p=0.032), which was not verified for erythrocyte sedimentation rate (ESR). Uveitis was significantly more frequent in the bDMARD group (p=0.006). Moreover, more patients with bilateral involvement were treated with bDMARDs, compared with patients with unilateral uveitis (n=0.032). Nevertheless, no differences were found concerning age and number of joints involved at onset, disease duration and ANA positivity. In a multivariate regression model adjusted for gender, the presence of uveitis (OR 4.42, 95% CI 1.43 to 13.60, p=0.010) and polyarticular involvement (OR 6.62, 95% CI 2.05-21.43, p=0.002) remained statistically significant predictive factors for bDMARD use in patients with JIA.

Conclusion: Male patients, polyarticular involvement (with negative or positive RF) and bilateral uveitis were more frequently treated with bDMARDs. In addition, CRP values at onset of JIA were higher in the bDMARD group. Thereby, the presence of uveitis and polyarticular involvement seem to predict the need of bDMARD treatment in JIA patients. Prompt treatment with these agents, early in the disease course, especially in JIA patients with more articular involvement and extraarticular manifestations like uveitis, refractory to conventional DMARDs, should be strongly recommended, in order to avoid irreversible damage and to achieve complete and long-term remission.

AB1415 INVESTIGATION OF THE EFFECTS OF HEALTH LITERACY LEVELS OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS AND THEIR FAMILIES ON THE GENERAL HEALTH STATUS, QUALITY OF LIFE AND PHYSICAL FUNCTION CAPACITY OF THE PATIENTS

Keywords: Inflammatory arthritides, Patient information and education, Quality of life

Y. Doğan[1], N. B. Karaca[2], S. Buran[2], E. N. Atabey Gerlegiz[2], E. Aliyev[3], Y. Bayındır[3], Y. Bilginer[3], E. Ünal[2], S. Ozen[3]. *[1]Hacettepe University Medical School, Physcial Medicine and Rehabilitation, Ankara, Turkey*; *[2]Hacettepe University Faculty of Physical Therapy and Rehabilitation, Physiotherapy and Rehabilitation, Ankara, Turkey*; *[3]Hacettepe University Medical School, Pediatric Rheumatology, Ankara, Turkey*

Background: Juvenile idiopathic arthritis is a chronic rheumatological disease characterized by persistent joint inflammation [1, 2]. This disease, which we can consider to be relatively rare, causes pediatric patients to encounter health problems at an early age and therefore struggle with more questions and problems than their peers [3]. At this point, it is important that both children and their families have access to adequate and accurate information about health and that they can use this information [4]. Access to health-related information has brought the concept of "health literacy", which has become more important in recent years, to the agenda [5].

Objectives: Our primary aim is to reveal the health literacy levels of children with JIA and their caregivers by using the Turkish Health Literacy-32 (THL-32), Adult Health Literacy Scale (AHLS) and Turkish version of the Health Literacy for School-Aged Children (HLSAC-T) the validity and reliability studies of which have been done before [6-8]. In addition, revealing the relationship between health literacy and the health status and quality of life of children with JIA is the secondary main aim of the study. Another secondary aim is to evaluate the physical limitations and functional capacity caused by JIA.

Methods: This cross-sectional study was conducted between September and December 2022 at Hacettepe University. Inclusion criteria were a confirmed JIA diagnosis according to the International League Against Rheumatism (ILAR) criteria, aged between 9–18 years. Children and one of their parents were invited to study. Demographic data, clinical findings, laboratory findings, and previous treatment information were recorded retrospectively from patient files and by asking the participants themselves. THL-32, AHLS, and HLSAC-T questionnaires were used to assess health literacy. Functional ability was assessed with the Turkish version of the Childhood Health Assessment Questionnaire (CHAQ) [9]. The Juvenile Arthritis Biopsychosocial Questionnaire (JAB-Q) was used to evaluate the problems experienced by both the child and the parent from a biopsychosocial perspective [10]. The 6-minute walk test (6MWT), 10-meter walking test (10-MWT) and 10-stair climbing test (10-SCT) were used to evaluate the physical and exercise capacity of children [11, 12].

Results: Seventy-nine patients with JIA and one of their parents were included in the study. The patients' mean age was 13.67 ± 2.80 years, and 60.8% of them were female. The mean disease duration was 6.75 ± 4.28 years. The JIA subtypes were as follows: 39 (49.4%) had oligoarticular JIA; 15 (19.0%) had polyarticular JIA; 19 (24.1%) had enthesitis-related arthritis; and 6 (7%) had systemic JIA. Following the THL-32 scale scoring, level of parents' health literacy resulted in the following percentages: inadequate, 3.8%; problematic, 22.8%; sufficient, 34.2%; and excellent, 39.2%. From a total of 79 patients with JIA, 16.5% had low HL, %55.7 had moderate HL, and 27.8% had high HL. The mean age of children with high health literacy was statistically older than the group with medium health literacy ($p < 0.017$). There was no statistically significant relationship between the children's health literacy and parent health literacy.

Conclusion: According to the results of our study, children's health literacy levels show a positive increase as they get older, and there is no significant relationship between parents' health literacy levels. Parents' health literacy levels and education levels are compatible with the AHLS, which includes objective questions. As the education level of the families increases, positive changes are observed in the CHAQ, JAB-Q parameters and 10-SCT test results. Our study shows that the education level of the families is positively related to the quality of life and physical condition of the children, but health literacy is not statistically related to other parameters other than the age of the children.

AB1416 INTERFERON SIGNALIZATION IN CHILDREN WITH JUVENILE SCLERODERMA

Keywords: Skin, Vasculitis, Myositis

S. S. Kilic[1], H. Kose[2], A. Simsek[3], M. A. Kizmaz[3], T. Bozkurt[3], F. Ozturk[4], H. Sarıcaoglu[4], F. Budak[3]. *[1]Uludag University Medical Faculty, Pediatric Immunology and Rheumatology, Bursa, Turkey*; *[2]Uludag University Medical Faculty, Pediatric Immunology and Rheumatology, 16, Bursa, Turkey*; *[3]Uludag University Medical Faculty, İmmunology, 16, Bursa, Turkey*; *[4]Uludag University Medical Faculty, Dermatology, 16, Bursa, Turkey*

Background:

Interferon Signalization in children with Juvenile Scleroderma: Hulya Kose[1], Abdurrahman Simsek[2], Muhammed Ali Kizmaz[2], Tugce Bozkurt, [2] Ferdi Ozturk[3], Ferah Budak [2], Hayriye Sarıcaoglu[3] Sara Sebnem Kilic [1]

1.Uludag University Faculty of Medicine, Department of Pediatric Immunology and Rheumatology

2.Uludag University Faculty of Medicine, Department of Immunology

3.Uludag University Faculty of Medicine, Department of Dermatology

Juvenile dermatomyositis (JDM) is an inflammatory disease of the muscle, which is characterized by skin involvement, vasculitis, and progressive muscle weakness. Increased interferon signaling is thought to play a role in the pathogenesis of JDM and is associated with disease severity and activation, as well as the development of calcinosis. Juvenile scleroderma (JSc) is a heterogeneous group of diseases associated with sclerotic skin lesions, grouped together as systemic sclerosis and localized scleroderma (morphea). Although JSc has a different types of skin involvement than JDM, some similarities in their pathogenesis can be identified.

Objectives: The aim of this study is to measure the levels of cytokines and chemokines involved in interferon signaling in patients with JDM and JSc and to determine their correlation with disease severity.

Methods: Thirty-one JSc, 5 JDM, and 13 healthy controls were included in the study. Patients with morphea were scored according to the LoSCAT (activity index) and LoSDI (damage index) indices. Cytokines and chemokines involved in interferon gene signaling (IL -8, IL -1, IP-10, MCP1, TNF-α, CXCL-10, IFN-α, IFN-β, IFN-γ) and interferon signalizing genes including IFI27, IFI44, ISIG15, IFIT1, OAS1, RSAD2 were measured by ELISA and RT_PCR method respectively.

Results: The ratio of female to male patients was 24/12, the median age was 14 years (min 4, max 18), and the median follow-up time was 36 months (min 12, max 108). According to LoSCAT assessment of patients with JSc, the scores were mild 36% (n=13), moderate 25% (n=9), and severe 11% (n=4). Similarly, LoSDI assessment revealed mild 38% (n=14), moderate 22% (n=8), and severe 11% (n=4). It was found that IL-8, IFN-β, IP-10, and MCP-1 were significantly decreased in patients with JSc compared with the healthy control group. TNF-α and IFN-γ were found to tend to decrease in patients with JSc, whereas IFN-α tended to increase in patients with JDM. The correlation of LoSCAT and LoSDI indices with cytokine and chemokine levels in patients with JSc is summarized in Figure 1. In RT_PCR analysis of the interferon signaling genes, including IFI27, IFI44, ISIG15, IFIT1, OAS1, RSAD2, we found no statistically meaningful expressions of the genes compared with the healthy group. However, we identified the fold changes in RSAD2, IFI27, and IFIT1 in JDM and JSc patients compared with the healthy controls in the related genes. The fold changes of the interferon signaling genes are depicted in Figure 2.

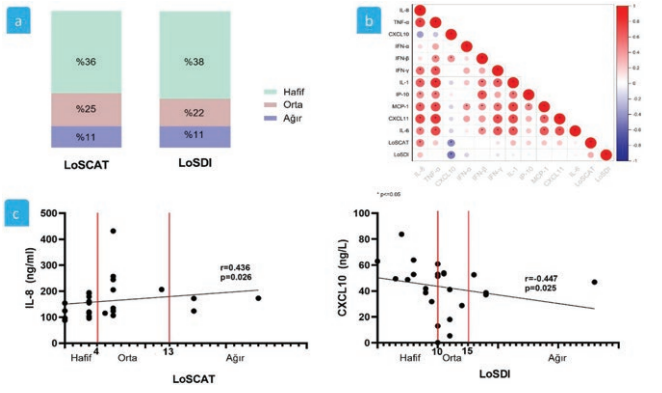

Figure 1. Correlation of LoSCAT/LoSDI Scores with cytokines and chemokines in patients with Localized Sclerodermaa. LoSCAT/LoSDI asssesment. b. Cytokine and chemokine correlation map, c. Statistically significant correlations

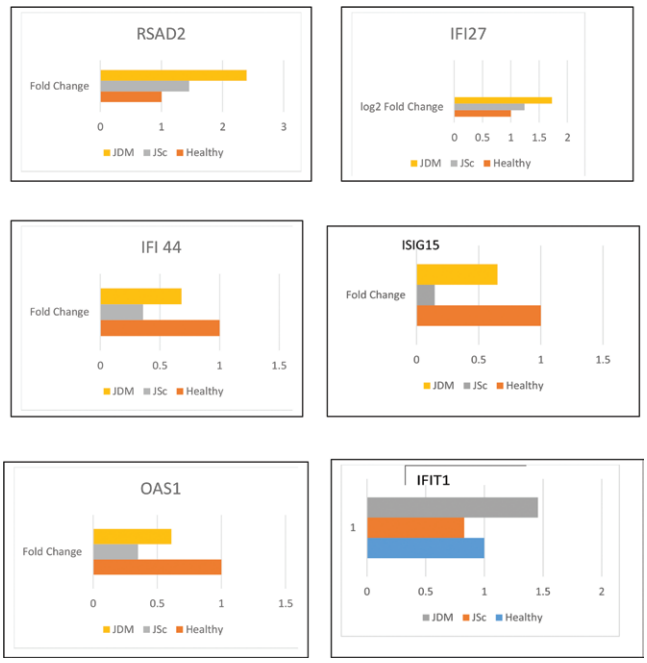

Figure 2. The diagrams of the interferon signaling genes

Conclusion: The results suggest that interferon signaling may be impaired in patients with JDM and JSc, and that cytokines and genes whose significant changes were observed in this study may play a key role in monitoring disease activity. Repeating these studies with larger numbers of patients may shed light on the clinical pathogenesis.

Background: Juvenile psoriatic artritis (JPSA), a subtype of juvenile idiopathic arthritis (JIA), constitutes 5% of JIA. The literature is inconsistent regarding features of JPSA, and physicians debate whether it is a distinct entity within JA. Moreover, the criteria diagnosis for JPsA is currently in debate.There are two pediatric diagnostic classifications based on clinical criteria: ILAR classification criteria and Vancouver classification criteria. Classification of JIA has been a great debate since this entity disappeared. [1] The CASPAR criteria are standard in adults. These criteria have a specificity of 91.4% and a sensitivity of 98.7%, makingdiagnostic classification easier. However, the peculiarities of childhood cause some differences to consider.

Objectives: To compare 3 diagnostic criteria for JPSA ILAR, Vancouver and CASPAR.

Methods: Multicenter, cross-sectional study of data from children with JPsA (diagnosis by prescritor physician) who consecutivelly attended in ped-rheumatology outpatient clinic and enrolled from 9 centers within the last 1.5 years. Sociodemographic, clinical characteristics and family history of Psoriasis were collected to assess compliance with diagnostic classification criteria using using the Cohen's Kappa statistic index.

Results: Forty eight children were included with the following sociodemographics characteristics;(table1) Thirty eight children who met the VANCOUVER criteria (80,9%) while thirty two children met the ILAR criteria (68.1%). As for the CASPAR criteria, thirty eight children were diagnosed (80.9%). The diagnostic agreement between the ILAR and CASPAR criteria and ILAR and Vancouver criteria (diagnosed defined) was weak (K=0.67 and K=0.67). In contrast, the agreement was total (K=1 between the CASPAR and Vancouver criteria.

Conclusion: Despite minimal changes between the Vancouver and ILAR criteria, the ILAR exclusion criteria limit the diagnosis of PsA in childhood. Given that the CASPAR and Vancouver were able to detect a significant number of patients with PsA in our series (predominantly adolescents), the application of the CASPAR criteria in the subgroup of children with late onset could be considered.

AB1418 SYSTEMIC JUVENILE ARTHRITIS: EPIDEMIOLOGY AND LONG-TERM OUTCOME IN WESTERN AUSTRALIA.

Keywords: Epidemiology, Registries

J. Nossent[1], E. Kelty[2], H. Keen[1], D. Preen[2], C. Inderjeeth[1]. [1]*The University of Western Australia, Rheumatology section, Medical School, Crawley, Australia*; [2]*The University of Western Australia, School of Population and Global Health, Crawley, Australia*

Background: Systemic juvenile arthritis (S-JIA) is a rare but serious multiorgan autoinflammatory condition of childhood with an unpredictable disease course [1]. There is no data on disease frequency and outcome of S-JIA from the Pacific region.

Objectives: To investigate the epidemiological characteristics and long-term disease outcome in patients hospitalised with S-JIA in Western Australia (WA).

Methods: This population-level observational study includes children under the age of 16 with a recorded diagnosis of S-JIA (ICD-10-AM M08.20-M08.29) residing in WA between January 1999 and December 2014. Individual longitudinal health data regarding hospital admissions, ED visits, cancer and death were derived from the WA Rheumatic Disease Epidemiological Registry (WARDER) that contains routinely collected health data from public and private health care organisations for the entire state of WA.

Results: Based on 46 incident cases (71.7 % girls, median age 6.5 years) the average annual S-JIA incidence rate was 0.61/100,000 (CI 0.28-1.25), which did

not no change significantly over time. Two thirds of incident cases were diagnosed in winter/spring and point prevalence for S-JIA reached 7.15/100,000 (CI 5.29-7.45) in 2014. Disease course was monocyclic in 42% of patients with MAS findings recorded in 4.4% and no case fatality observed during median follow up of 8years. Twenty-seven patients (58%) were readmitted for S-JIA with higher rates per 100 person years in boys (58.3/100, CI 44.5-74.9 vs 14.7 CI 9.9-20.9) (p<0.001). Girls had significantly higher admissions rates for conditions not directly related to S-JIA (rate 103.3 vs 54.4, P<0.001). At last follow-up, arthroplasty had been performed in 4% of patients and there was a high rate of ED visits (72.3/100 person years) after initial s-JIA admission.

Conclusion: The epidemiology of S-JIA in Australia is not unlike other countries [2]. While s-JIA incurred no deaths in the biologic era, S-JIA admission was followed by significant morbidity and health care usage over a lengthy period suggesting the need for extended care for s-JIA patients.

Nuruzzaman[3], S. Opsahl Hetlevik[3], Y. Uziel[3], N. Helmus[1]. *[1]Hamburg Centre for Pediatric and Adolescence Rheumatology,An der Schön Klinik Hamburg Eilbek, Hamburg, Germany*; *[2]German Rheumatism Research Center, German Rheumatism Research Center, Berlin, Germany*; *[3]jSSc collaborative group, Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany*

Background: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1 000 000 children. In adult patients decreased body mass index (BMI) correlates with higher mortality. We hypothesized that jSSc patients with lower BMI at presentation have more severe organ involvement.

Objectives: To compare the organ involvement pattern at inclusion into the cohort of jSSc patients with BMI ≤ -2 z score with the patients with higher BMI.

Methods: We reviewed the clinical characteristics of patients who were recruited to the juvenile jSScC till 1st of December 2022. We compared patients with BMI ≤ -2 z score with patients (lwgroup) with higher BMI (nlwgroup). jSScC is a prospective cohort of jSSc patients, who developed the first non-Raynaud´s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion.

Results: At the time of the evaluation, we had 232 patients in the cohort and 217 of them had BMI data to include in the evaluation. Thirty-three patients were in the lwgroup (15%) and 88% (n=29/33) of them diffuse subtype and in the nlwgroup 64% (113/177). The median age at onset of Raynaud phenomenon in the whole group was 10.6 years and the median age at the first non-Raynaud symptom in the whole group was 11.0 years. Median disease duration in the whole group was 2.4 years at the time of inclusion. Approximately 95% of the patients were treated with a DMARD. There were no statistically significant differences between the lwgroup compared to nlwgroup regarding antibody pattern, inflammatory marker or organ involvement pattern, except higher number of patients with Gottron papules (41% lwgroup vs 25% nlwgroup; p=0.01) and sclerodactylia (84% lwgroup vs 73 % nlwgroup; p=0.049). Regarding the patient related outcomes at inclusion in the cohort, the global disease activity by VAS 0-100 was 40 in both groups (p=0.032), but the patient global disease damage by VAS 0-100 was 50 in the lwgroup which was significantly higher compared to 30 nlwgroup (p=0.014).

Table 1. Comparison of patients with different BMI z-scores at time of inclusion in the cohort

	Z-Score ≤ -2 N=33	Z-Score > -2 to < 2 N=177	P value
Gottron Papules	41% (13/32)	25% (44/175)	0.001
Puffy Fingers	13% (4/30)	38% (61/159)	0.049
Sclerodactylie	84% (27/32)	73% (121/166)	0.049
Patient global disease damage	50 (30 – 75) n=27	30 (10 – 55) n=133	0.014

Conclusion: In our jSSc cohort, currently the largest of the world, we could not find any differences regarding major internal organ involvement in patients with lower BMI at time of inclusion in the cohort. Nevertheless, there is a significant difference in patient related outcomes regarding global organ damage between the two groups. The long-term prognosis of these patients should be addressed in future studies.

AB1420 PAEDIATRIC PRESENTATION OF ANTIPHOSPHOLIPID SYNDROME: A REVIEW OF RECENT LITERATURE WITH ESTIMATION OF LOCAL PREVALENCE

Keywords: Anti-phospholipid syndrome, Systemic lupus erythematosus, Epidemiology

M. Radin[1], I. Cecchi[1], M. Arbrile[1], D. Montin[2], L. Farinasso[2], M. Cioffi[1], S. G. Foddai[1], A. Barinotti[1], E. Menegatti[1], S. Baldovino[1], S. Sciascia[1], D. Roccatello[1]. *[1]University of Turin, Clinical and Biological Sciences, Turin, Italy*; *[2]University of Turin, Department of Public Health and Pediatrics, Turin, Italy*

Background: No evidence exists on any study investigating the prevalence of paediatric Antiphospholipid Syndrome (APS) in the general population (1) and most of the available recommendations on how to manage these patients come from observational studies and physicians' experience.

Objectives: We aimed to investigate the epidemiology, the clinical and laboratory characteristics of the paediatric involvement of Antiphospholipid syndrome (APS), by performing a systematic review of the current evidence and reviewing local experience in the Northwest Italy.

Methods: We performed a detailed literature search to identify articles describing clinical and laboratory characteristics of paediatric APS patients. In concomitance, we conducted a registry-study collecting data from the Piedmont and Aosta Valley Rare Disease Registry including paediatric patients diagnosed with APS in the last ten years.

Results: The systematic review included nine articles with a total of 386 paediatric patients [65% females, 50% with Systemic Lupus Erythematosus (SLE) as concomitant diagnosis]. Rate of venous and arterial thrombosis were 57% and 35% respectively. "Extra-criteria manifestations" of APS included mostly hematological and neurological involvement (91 thrombocytopenia, 32 haemolyticanaemia, 19 chorea, 8 multiple sclerosis-like lesions, 9 migraines and one transverse myelitis). Almost one quarter of patients (19%) reported recurrent events and 13% manifested as CAPS. Further details of the included studies are detailed in Table 1. A total of 17 paediatric patients (mean age 15.1 ±2.8, 76% female) developed APS in the Northwest of Italy. In 29% of cases SLE was a concomitant diagnosis. Deep vein thrombosis was the most frequent manifestation (28%) followed by Catastrophic APS (CAPS) (6%). Taking into account that the paediatric population of the Piedmont and Aosta Valley Region is around 680,000 persons, the calculated estimated prevalence of paediatric APS in Piedmont and Aosta Valley Region is 2.5 cases per 100,000 people. When analyzing the data of the register in an eleven year period (from January 2011 to December 2021), the estimated mean annual incidence was 0.2 cases per 100,000 inhabitants.

Conclusion: Clinical manifestations of paediatric APS seem to be more severe and with a high prevalence of non-criteria manifestations. International efforts are needed to better characterize this condition and to develop new specific diagnostic criteria to avoid missed/delayed diagnosis in children with APS.

DOES THE SACROILIAC JOINT MAGNETIC RESONANCE IMAGING ENHANCE THE ENTHESITIS-RELATED ARTHRITIS DIAGNOSIS?

Keywords: Imaging

H. Ferjani[1], L. Kharrat[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1].
[1]Kassab Orthopedics Institute, Ksar Sa'id, Rheumatology, Tunis, Tunisia

Background: Magnetic Resonance Imaging (MRI) is the gold standard in the diagnosis of adult spondyloarthritis [1]. MRI sensitivity and specificity seem to be less studied in juvenile spondyloarthritis, especially in Enthsitis-related Arthritis (ERA).
Objectives: We aimed to determine the sensitivity and specificity of MRI in the diagnosis of ERA.
Methods: We conducted a retrospective study including 44 patients with Juvenile Idiopathic Arthritis (JIA) meeting the International League of Associations for Rheumatology (ILAR) 2001 criteria. For each patient, we collected the following data: age, age at the onset of JIA, JIA subtype, disease duration, C-reactive protein (CRP), HLA-B27 typing, and Erythrocyte sedimentation rate (ERS) levels. Each patient had a sacroiliac joint MRI. Sacroiliitis was defined using the OMERACT JAMARIS scoring system [1]. Disease activity was assessed using the JSpADA score for ERA and JADAS-CRP-10 for the rest of the JIA subtypes. We divided patients into two groups: Group 1 (G1) patients with ERA and Group 2 (G2) patients with non-ERA subtype. Statistical analysis was performed using SPSS software.
Results: We included 28 boys and 16 girls. The mean age was 13.65 ± 4.62 years. The mean age at the onset of the disease 9.57 was ± 3.97 years. The mean disease duration was 4.34 ± 3.09 years. There was enthesitis-related arthritis in 61% of the cases (n=27), oligoarticular JIA in 14% of the cases (n=6), polyarticular JIA in 11% of the cases (n=5), and psoriatic arthritis in 7% of the cases (n=3). JIA was undifferentiated in 7% of the cases (n=3). Sacroiliac joints were painful in 15 patients (34%). The mean CRP and ESR were 14.42 ± 19.67mg/L and 26.56 ± 20.87mm, respectively. The mean JADAS and JSpADA were 6.6 ± 4.7 and 3.09 ± 1.55, respectively. HLA-B27 was performed in 22 patients and was positive only in five patients. IRM was normal in 25 patients (57%) (G1: 11 versus G2:14) and showed bone marrow in the sacroiliac joints in 19 patients (34%) (G1=16 versus G2=3, p=0.005). The sensitivity and specificity of the sacroiliac joints MRI in the diagnosis of ERA were 61.54% and 82.35%, respectively. Positive predictive value and negative predictive value were 84.21% and 58.33%, respectively. Furthermore, sacroiliac joint pain in the clinical examination was able to predict sacroiliac bone edema in MRI with an odds ratio of 6.8 (95% confidence interval 1.68 to 28.09; p=0.006).
Conclusion: According to other studies, ours showed that MRI inflammatory lesions could be observed in JIA regardless of JIA sub-types [2]. Interestingly, we found that MRI abnormalities were not sensitive but had a good specificity in the diagnosis of ERA. Thus, MRI could guide the diagnosis of ERA but could not be the gold standard in this disease.

CLINICAL MANIFESTATIONS AT THE ONSET OF PEDIATRIC MIXED CONNECTIVE TISSUE DISEASE (PMCTD): A SYSTEMATIC REVIEW.

Keywords: Systematic review, Mixed connective tissue disease, Rare/orphan diseases

A. Terminiello[1], E. Marrani[2], I. Pagnini[2], I. Maccora[2], M. V. Mastrolia[2], A. Alletto[2], G. Simonini[2]. *[1]Meyer Children's Hospital IRCCS, ERN-ReCONNET full member, Pediatric Unit, Florence, Italy*; *[2]Meyer Children's Hospital IRCCS, ERN-ReCONNET full member, Rheumatology Unit, Florence, Italy*

Background: pMCTD is a rare disorder that includes features of systemic lupus erythematosus, polymyositis/dermatomyositis, juvenile idiopathic arthritis, and systemic sclerosis. Fifty years have passed since Sharp identified MCTD in 1972, and diagnosis of this disorder remains challenging.
Objectives: The aim of this review is to identify any clinical features at the diagnosis of pMCTD and manifestations that are not currently part of the available diagnostic criteria.
Methods: A systematic literature review was performed in accordance with PRISMA guidelines using electronic bibliographic databases: MEDLINE via PubMed and EMBASE. Data obtained were extracted using a dedicated database containing clinical data that best categorize patient characteristics. Criteria for inclusion: studies including patients with a pMCTD diagnosis with onset before 18 years of age and reporting a description of initial clinical features.
Results: The search returned a total of 1372 results: 409 articles were excluded as duplicates and 790 based on title/abstract, 133 because of publication type (n = 4) or because the full text was not available (n = 65) or not in English (n = 64). One (n=1) eligible article resulted from manual screening of references cited in the selected publications and in the reviews. Finally, 41 articles were included: 23 case reports, 9 case series, 5 prospective, and 4 retrospective studies from 1973 to 2019, with a total number of 218 patients. They were predominantly female (81.56%, n=167), and the mean age at onset was 147 months (median 126 months, 10.5 years). When indicated, the most commonly used criteria for diagnosis were Kasukawa criteria (50%, 11 studies), then Alarcon-Segovia criteria (31%, 7 studies), then Sharp criteria (23%, 5 studies); no Khan criteria were used. Clinical features are listed in Figure 1.

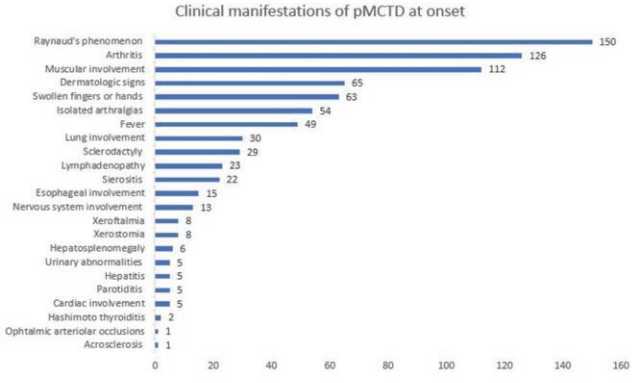

Figure 1. Number of patients for clinical feature at onset.

Joint involvement, Raynaud's phenomenon, myositis, and swollen fingers/hands are the most common clinical features at diagnosis according to the data reported in the literature, although with slightly lower percentages than in other reviews. Dermatologic signs are very heterogeneous, but were found to be a very present feature at disease onset, affecting 1/3 of patients. Fever, not covered by any of the diagnostic criteria, was noted in 1/4 of cases. Pulmonary and esophageal involvement are reported in a lower percentage at the onset of the disease, indicating a more developmental nature of these conditions.

Conclusion: The data from this systematic review suggest greater clinical heterogeneity of the disease in the pediatric population, for which there are no validated diagnostic criteria. Typical features appear to be less common when case reports are included, suggesting a less characteristic initial presentation than an advanced stage; therefore, the absence of typical features at baseline should not preclude a diagnosis of pMCTD. Fever often occurs early in the disease and is not included in the diagnostic criteria. This systematic review may provide useful insights for future research to better assess the clinical features of pMCTD and the potential development of scores/algorithms for diagnosis in the pediatric population.

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. The emergence of new biological drugs has changed the prognosis and therapeutic approach to these patients, and costs are reduced with the use of biosimilar disease modifying antirheumatic drugs (bsDMARD).

Objectives: Our aim was to describe the use of bsDMARD therapies in JIA.

Methods: Data was obtained from the nationwide prospective registry BIOBADASER. All patients diagnosed before age 16 in our database between 2000 and 2022 were included in the analysis. JIA is classified into 7 subgroups: systemic, persistent or extended oligoarthritis, RF positive polyarthritis, RF negative polyarthritis, enthesitis-related arthritis, psoriatic arthritis, and undifferentiated arthritis. Due to the registry design, it was not possible to identify each of the JIA subgroups; thus, we classified them into oligo/polyarticular JIA, JIA related to enthesitis, and psoriatic JIA. Proportions, means and standard deviations (SD) were used to describe our population and the utilization of treatments. Drug persistence was calculated using Kaplan-Meier survival curves until termination of treatment due to any reason.

Results: From a total of 313 patients, 130 patients (41.5%) received 151 treatments with bsDMRAD, 60.8% of which were women (n= 79). Mean age at diagnosis was 11.2 years (SD= 6.1) and mean age at the beginning of treatment was 25.1 (SD= 13.4). Patients were classified as oligo/polyarticular JIA (79.2%), JIA related to enthesitis (16.2%) and psoriatic JIA (4.6%). Methotrexate was used in combination in 39.1% of the biosimilar treatments. The most commonly used drug was Adalimumab (56.8%), followed by Etanercept (28.7%). Table 1 shows the biologic therapies used in our sample and the reasons for discontinuation. The median survival rate with the biosimilar drug and original was similar.

Conclusion: Adalimumab were the most commonly used biosimilar therapy in JIA. Ineffectiveness was the main reason for discontinuation. There were no differences on 5 years survival rates, which is a crucial endpoint in JIA.

AB1424 CLINICAL VARIABILITY IN PATIENTS DIAGNOSED OF JUVENILE IDIOPATHIC ARTHRITIS WITH POSITIVE AND NEGATIVE ANTINUCLEAR ANTIBODIES (ANA)

Keywords: Autoantibodies

A. M. Torrat Noves[1], J. Ivorra Cortés[1], E. Grau García[1], D. Ramos Castro[1], L. Mas Sanchez[1], C. Riesco Barcena[1], P. Muñoz Martinez[1], A. V. Huaylla Quispe[1], S. Leal Rodriguez[1], J. E. Oller Rodríguez[1], E. Vicens Bernabeu[1], F. Ortiz-Sanjuán[1], I. Martínez Cordellat[1], L. Gonzalez Puig[1], R. Negueroles Albuixech[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], E. Tovar-Sugrañes[1], H. Charia[1], I. Calvo[2], B. Lopez-Montesinos[2], J. A. Román Ivorra[1]. *[1]HUP La Fe, Rheumatology Department, Valencia, Spain*; *[2]HUP La Fe, Paediatric Rheumatology Department, Valencia, Spain*

Background: Juvenile Idiopathic Arthritis (JIA) involves a set of chronic arthritis of onset in childhood. JIA can be splitted into 7 categories based on the classification of the International League of Associations for Rheumatology (ILAR):

systemic arthritis, oligoarthritis, rheumatoid factor (RF) negative polyarthritis, RF positive polyarthritis, enthesitis related arthritis, psoriatic arthritis, undifferentiated arthritis. In addition to this classification, some authors propose differentiating between patients who have positive (+) and negative (-) ANA in serum because there could be differences between these two subgroups, raising the possibility of homogenizing subtypes based on this [1].

Objectives: To describe the variability of extra-articular manifestations, treatment and prevalence of the different JIA subtypes between patients who have positive and negative ANA in serum.

Methods: Cross-sectional descriptive study in 68 patients with JIA according to ILAR criteria visited in the transitional consultation of a Spanish tertiary-level hospital. Clinical features, analytical and treatment data were collected, and patients were divided according to ANA+ or ANA- in serum. A >1/80 title of ANA determined by IFI on at least 2 occasions was considered positive. Subsequently, the qualitative data was analyzed using Chi-Square test, and the means were compared using ANOVA analysis.

Results: 68 patients were included in the study. 33 were grouped in ANA- and 35 in ANA+. The ANA+ group was composed with 28 women (80%) and the ANA- group was made up with 18 women (54.44%) (p= n.s.). The mean age of diagnosis was 11 years old in the ANA- group and 9 years old in the ANA+ group.

Variable (n)	*ANA-*	*ANA+*	*P-value*
	N=33	*N=35*	
	n(%)	n(%)	
Subtype			
Oligoarthritis (20)	3 (9.09%)	17 (48.57%)	<0.001
RF(-) polyarthritis (14)	8 (24.24%)	6 (17.14%)	0.6719
RF(+) polyarthritis (4)	0 (0%)	4 (11.43%)	0.1372
Enthesitis related arthritis (14)	11 (33.33%)	3 (8.57%)	0.0216
Systemic arthritis (6)	6 (18.18%)	0 (0%)	0.0268
Psoriatic arthritis (4)	2 (6.06%)	2 (5.71%)	0.9999
Undifferentiated arthritis (6)	3 (9.09%)	3 (8.57%)	0.9999
Clinical features			
Psoriasis (8)	2 (6.06%)	6 (17.14%)	0.2979
Uveitis (10)	3 (9.09%)	7 (20%)	0.354
Enthesitis (9)	3 (9.09%)	6 (17.14%)	0.5344
Oral and genital thrush (14)	7 (21.21%)	7 (20%)	0.9999
Raynaud (6)	3 (9.09%)	3 (8.57%)	0.9999
Analytical			
HLAB27+ (20)	12 (42.86%)	8 (27.59%)	0.3523
RF+ (7)	1 (3.57%)	6 (18.18%)	0.1673
CCP- antibodies+ (9)	2 (6.06%)	7 (20%)	0.1811
Treatment			
sDMARD (31)	12 (36.36%)	19 (55.88%)	0.1748
bDMARD (30)	13 (39.39%)	17 (48.57%)	0.6049
Corticosteroids (6)	5 (15.15%)	1 (2.86%)	0.1742

Oligoarticular JIA was more frequent in the ANA+ group (48.57%) than in the ANA- (9.09%), being this difference statistically significant. Enthesitis related arthritis was more frequent in the ANA- group (33.33%) than in the ANA+ (8.57%), as it was systemic arthritis (18.18% in ANA- and 0% in ANA+), both differences being statistically significant. Uveitis, psoriasis and the use of sDMARD were more frequent in the ANA+ and corticosteroid use was more frequent in ANA- patients, but without reaching statistical significance.

Conclusion: In our study, as in the literature, the oligoarticular JIA type occurred more frequently in the ANA+ group, while enthesitis related arthritis and systemic arthritis were more frequent in the ANA- group. Although the treatment patterns and the prevalence of psoriasis and uveitis appear to differ between the two groups we did not find statistically significant difference. This could be due to the small number of patients included, with the possibility that it could be corrected if the sample was expanded.

Background: Systemic autoinflammatory diseases (SAIDs) are rare inherited disorders characterized by periodic or chronic multisystemic inflammation. The diagnosis is based on typical phenotypes and often supported by genetic testing. However, a distinct diagnosis cannot be met in half of these patients, being classified as undefined SAIDs (uSAIDs) [1].

Objectives: To analyse the clinical and genetic characteristics of a portuguese cohort of uSAID.

Methods: Patients followed up in 2 SAIDs clinics with recurrent or persistent episodes of systemic inflammation associated with serum acute phase reactants elevation who do not meet the PRINTO diagnosis criteria for any well-defined SAIDs [2] were classified as having uSAID. Patients who do not have any pathogenic gene mutation or have 1 variant of uncertain significance of a gene related to a well-known autosomal dominant SAID were included, as well as patients with pending genetic analysis. Categorical variables are described as frequencies and percentages and continuous variables as median (IQR1, IQR3).

Results: This study included 24 patients, of which 12 (50.0%) were female and 12 (50.0%) were male. The median age at disease onset was 2.4 (IQR: 1.4, 8.2) years old, the median age at diagnosis was 6.5 (IQR: 2.4, 9.9) years old and the median time of disease duration was 6.8 (IQR: 9, 12.4) years. The majority of the patients (n=14, 58.3%) had episodes of recurrent systemic inflammation lasting 2 to 5 days. Two patients exhibited persistent inflammation. Regarding patients with recurrent inflammation, 10 (41.7%) had more than 12 episodes per year, 7 (29.2%) had 2 to 6 episodes per year and 4 (16.6%) had 7 to 12 episodes per year. The remaining patient had an episode every 2 years. In 13 (54.2%) the intercritical interval was regular, with a median of 21 days. Besides fever, the most commonly reported clinical manifestations were mucocutaneous lesions (n=24) including mouth ulcers (n=11), abdominal pain (n=12), lymphadenopathy (n=10) and arthralgia (n=10). C-reactive protein was elevated in all patients during attacks, erythrocyte rate sedimentation in 20 (83.3%) and amyloid A protein in 10 (41.7%). In 14 (63.6%) patients, acute phase reactants normalized during the intercritical phase. Genetic analysis was performed in 22 patients of this cohort – 8 patients were found to have a variant of uncertain significance in genes associated with hereditary SAIDs or mutations in genes that are not known to be associated with SAIDs and results are pending in the remaining 4. The most frequently used therapy was oral steroids (n=18, 75.0%) and half of these patients were treated with a single dose of 1 mg/kg of oral prednisolone on demand with shortening/resolution of the episode in 8 patients. Colchicine was used in 14 patients decreasing the number of episodes in 9 (64.2%). Anakinra led to complete remission in 3 of the 5 treated patients. Two patients were treated with canakinumab achieving complete remission. Infliximab, in association with azathioprine, resulted in disease remission in the only patient in which this therapy was used. None of the 3 patients submitted to tonsillectomy achieved remission.

Conclusion: Similarly to other uSAIDs' cohorts, mucocutaneus manifestations, abdominal pain and arthralgia were frequently reported. A third exhibited acute phase reactants elevation in the intercritical phase. Most of our patients had a favourable response to colchicine and IL-1 inhibitors. It is worth noting the high frequency of mouth ulcers, lymphadenopathy and pharyngitis and the high response rate to oral steroids and colchicine. These features resemble PFAPA syndrome, highlighting the challenges in the differential diagnosis of both conditions.

CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS AND BOWEL INFLAMMATION: A MONOCENTRIC COHORT

Keywords: Rare/orphan diseases, Gastrointestinal tract, Remission

S. Costi[1], S. Germinario[2,3], M. R. Pellico[2,3], A. Amati[2,3], M. Gattinara[1], C. Chighizola[1,2], A. Marino[1], R. Caporali[1,2,3]. [1]*ASST G.Pini-CTO, Unit of Pediatric Rheumatology, Milan, Italy*; [2]*University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; [3]*ASST G.Pini-CTO, Department of Rheumatology and Medical Science, Milan, Italy*

Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare autoinflammatory disease of bone primarily affecting children and adolescents. Although CRMO can be associated with inflammatory bowel disease (IBD)[1], the prevalence of subclinical bowel inflammation and its relationship with other autoimmune bowel disorders remains uncertain.
Objectives: This study aims to evaluate the prevalence of subclinical bowel inflammation in CRMO patients and the potential association with celiac disease.
Methods: Clinical records of patients diagnosed with CRMO attending the Unit of Pediatric Rheumatology of Gaetano Pini Hospital were retrospectively reviewed. Fecal calprotectin and screening for celiac disease were performed in all patients within 2 years after diagnosis.
Results: Complete data from 24 patients were collected (83% female). The mean age at diagnosis was 10.1 (DS ± 2.7) and the median follow-up time was 68.5 months (IQR 97.5). The first symptom at onset was bone pain (100%), while only 4 patients (17%) complained of gastrointestinal symptoms (abdominal pain, weight loss, diarrhea). The patients in our cohort had no specific comorbidity, except for two patients suffering from hemophilia and pyoderma gangrenosum, respectively. 96% (23/24) of patients had polyostotic disease. During the follow-up period, 9 patients (38 %) received only non-steroidal anti-inflammatory drugs therapy, 10 patients (42%) received conventional disease-modifying antirheumatic drugs (methotrexate), 4 (17%) received anti-tumor necrosis factor (TNF) agents and 12 (50%) received intravenous bisphosphonates. Cumulative treatments are summarized in Figure 1. Two patients, both in clinical remission off medication, were lost to follow-up. Calprotectin levels were normal in 100% of patients, while 3 patients (13%) presented positive screening test for celiac disease with a positive test for IgA anti-tissue transglutaminase antibodies (Table 1). In one of these patients, the diagnosis of celiac disease was confirmed by duodenal biopsy. After a gluten-free diet, the patient, who was off medication, achieved complete clinical remission and a remarkable improvement in radiological lesions.
Conclusion: The link between autoinflammatory bone disease and intestinal inflammation should be further investigated since it might open insight into bone inflammation and new therapeutic options. In our experience, controlling bowel disease may promote a better response to CRMO treatments. On the other hand, the percentage of unexplained bone pain in celiac disease is high, and, in this scenario, a possible inflammatory bone disorder should be ruled out.

AB1427

HIP DAMAGE ASSESSED BY CARSH SCORE WAS MORE SEVERE IN ENTHESITIS-RELATED ARTHRITIS SUBTYPES

Keywords: Imaging, Validation

A. Dghaies[1], H. Ferjani[1], D. Ben Nessib[1], D. Kaffel[1], K. Maatallah[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, Manouba, Tunisia*

Background: Juvenile idiopathic arthritis is a heterogeneous group of diseases characterized by unknown origin arthritis under 16 years. Compared to other juvenile idiopathic arthritis subtypes, enthesitis-related arthritis has a poor prognosis with a higher disability. Moreover, the frequency of hip involvement contributes to poorer outcomes and higher disease activity in this form. The childhood Arthritis Radiographic Score of the Hip (CARSH), a valid score of hip damage, is used to quantify and monitor hip osteochondritis changes such as space narrowing, erosions, malalignment, sclerosis, flattening of the femoral head, and growth abnormalities [1].
Objectives: This study aimed to assess hip damage using the CARSH in children suffering from different subtypes of JIA.
Methods: We conducted a cross-sectional study including patients with JIA according to the ILAR criteria with hip involvement in the rheumatology department at Kassab Institute of orthopedics. The hip involvement was defined as the presence of hip pain and/or limping and range motion limitation, and/or abnormal hip findings in pelvic radiography, ultrasound, or MRI. We collected demographic data, juvenile arthritis subtypes, hip pain and limitation, presence of antigen HLA, and extra-articular manifestations. Experimented and blinded pediatric rheumatologists read the pelvic radiograph using the Childhood Arthritis Radiographic Score of the Hip (CARSH).
Results: Twenty-two children with a median age of 13 years [5-22] were included. The gender ratio was 1.4 (13 Males/9 Females). The median age of disease onset was 9.5 years [4-14]. The frequency of each JIA subset was as follows: enthesitis-related arthritis (n=13), psoriatic arthritis (n= 3), oligoarthritis (n= 4), polyarticular with rheumatoid factor (n= 1), and polyarticular without rheumatoid factor (n=1). Antigen HLA was positive in two patients. One patient had anterior uveitis, and one patient had personal psoriasis. Eight patients had bilateral hip pain, 6 patients had unilateral hip pain and 8 patients didn't have hip pain. Six patients had limitations of both hips, 6 patients had only one limited hip and 10 patients had normal mobility of the hip. MRI showed inflammatory signal abnormality of the hip joint in 12 patients and ultrasound showed synovitis in 6 patients. Forty-four hips were assessed by the radiographic score. The median CARSH was 1.8±2.2 [0-7]. Statistical analysis showed a higher CARSH score in enthesitis-related arthritis patients compared to other JIA subtypes (p = 0.04) (Figure1).
Conclusion: This study showed that the radiographic score CARSH was higher in enthesitis-related arthritis patients. This finding prompts the escalating of the treatment approach in this JIA subtype to prevent damage and joint replacement surgery.

PSORIATIC ARTHRITIS: CLINICAL FEATURES IN CHILDHOOD

Keywords: Psoriatic arthritis

S. Dahmani[1], N. Zhuravleva[2], T. Smirnova3, V. Diomidova3, A. Arkhipova3. [1]*"Rahmani" Pharmacy,"Rahmani" Pharmacy, Casablanca, Morocco*; [2]*"Chuvash State University named after I. N. Ulyanov","Chuvash State University named after I. N. Ulyanov", Cheboksary, Russian Federation*; [2]*"Chuvash State University named after I. N. Ulyanov","Chuvash State University named after I. N. Ulyanov", Cheboksary, Russian Federation*

Background: Diagnosis and treatment of psoriatic arthritis require attention from specialists. Clinical manifestations of psoriatic arthritis in children are variable.
Objectives: The purpose of the study: to evaluate the clinical picture of psoriatic arthritis (PsA) in children.
Methods: The case histories of 23 children with psoriatic arthritis aged 3 to 17 years who were treated by a rheumatologist from 2019 to 2022 were analyzed.
Results: Probable psoriatic arthritis was diagnosed in 7 (29%) patients, definite psoriatic arthritis was diagnosed in 16 (71%) patients. At the same time, 12 (53%) children fell ill at the age of up to 7.5 years. In 7 (29%) patients, the disease began with skin lesions, in 16 (71%) patients immediately with articular syndrome. In the group of patients with certain psoriasis, plaque psoriasis was noted, it was detected in 17 (76.3%) children, guttate psoriasis was in 3 (13.5%), isolated psoriasis of the nails in 3 (10.2%) children. In 5 (21.7%) children, lesions of the skin and nail plates were observed. It was noted that psoriatic onychodystrophy was represented by onycholysis, an "oil spot" in the area of fingers and toes in 5 (23%) patients, and thimble symptom was diagnosed in 4 (18.1%) patients. At the onset of the disease, oligoarticular or asymmetric articular syndrome was noted in 65.6% of cases, a symmetrical rheumatoid-like variant in 20.2% of cases, and psoriatic spondylitis in 14.2% of cases. The dynamics of the articular syndrome after 3 years of observation and treatment indicated the development of symmetrical rheumatoid-like arthritis in 41.2% of patients, asymmetric oligoarthritis in 24.1% of children, and spondyloarthritis in 22.1%.
Conclusion: The clinical picture of psoriatic arthritis in children is variable. Skin lesions preceded the development of arthritis in children. At the onset of the disease, asymmetric oligoarthritis predominated, followed by transformation into symmetrical rheumatoid-like arthritis.

EMAPALUMAB TREATMENT FOLLOWED BY HEMATOPOIETIC STEM CELL TRANSPLANTATION IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS COMPLICATED BY RECURRENT MACROPHAGE ACTIVATION SYNDROME

Keywords: Cytokines and chemokines, Innate immunity

C. Bracaglia[1], M. Pardeo[1], G. Marucci[1], S. Riccio[1], F. Quagliarella[2], I. Caiello[1], G. Prencipe[1], P. Merli[2], F. Locatelli[2], F. De Benedetti[1]. [1]*IRCCS Bambino Gesù Children's Hospital, Division of Rheumatology, Rome, Italy*; [2]*IRCCS Bambino Gesù Children's Hospital, Department of Hematology/Oncology, Cell and Gene Therapy, Rome, Italy*

Background: Macrophage activation syndrome (MAS) is a life-threatening complication of different rheumatic diseases, particularly of systemic juvenile idiopathic arthritis (sJIA).
Objectives: We report the case of 17-year-old girl with sJIA complicated by recurrent severe MAS episodes.
Methods: Patient received emapalumab (anti-IFNg antibody) in two subsequent MAS episodes, then underwent an uncomplicated hematopoietic stem cell transplantation (HSCT) from a haploidentical donor, while receiving emapalaumab and anakinra granting complete control of inflammatory activity of the underlying disease. One year after transplant she is in complete disease remission.
Results: A 13-year-old Caucasian girl presented with fever, rash and hepato-splenomegaly. Laboratory parameters were consistent with full-blown MAS (tab 1). In the absence of clear evidence of an underlining condition, a diagnosis of secondary HLH was made. Treatment with high dose of intravenous (IV) methylprednisolone (mPDN) and oral cyclosporine (CYC) was started with progressive improvement. After one year, still on CYC, she presented with fever, rash and arthritis with laboratory parameters consistent with MAS (table 1), diagnosis of sJIA complicated by MAS was made. In 24 hours, her general condition rapidly worsened and she was admitted to the ICU. High dose of IV mPDN (7 pulses of 30 mg/kg/day) as well as IV CYC (5 mg/kg/day) did not yield a response. Emapalumab was started, in the NI-0501-06 trial, (6 mg/kg initial dose followed by 3 mg/kg every 3 days) for 11 infusions. Conditions progressively improved. In order to prevent flares of the underlining sJIA, anakinra (2 mg/kg/day) was started. After 2 years in clinical remission, while she receiving anakinra every other day, she presented with fever, vomiting and diarrhea. Anakinra was immediately increased to daily dosing. Stool analysis showed Salmonella infection and antibiotic therapy was started. Her condition rapidly worsened, laboratory parameters were again consistent with full-blown MAS (tab 1). She required ICU admission for multiorgan failure. Anakinra was administered IV and the dose increased up to 12 mg/kg/day. IV MPDs (8 pulses of 30 mg/kg/day) as well as IV CYC (5 mg/kg/day) were started with partial response. Based on her previous response, emapalumab was started again (compassionate use) with marked and rapid improvement. Because of recurrent MAS episodes, particularly for their rapidly progressive evolution, the patient underwent an ex-vivo T cell-depleted haploidentical HSCT from her mother. The conditioning regimen was based on a Thiotepa-Treosulfan-Fludarabine scheme. Emapalumab was continued 1 month after HSCT together with anakinra. The patient developed mild complication, achieved full donor engraftment with complete donor-derived immune reconstitution after 3 months. One year after HSCT, the patient is in excellent clinical condition on anakinra every other day, with complete remission of sJIA/MAS, also confirmed by persistently normal levels of IL-18 and CXCL9 (tab 1).

Table 1. Laboratory parameters and cytokine levels during disease course.

Laboratory parameters	Range	First MAS	Second MAS	Third MAS	HSCT	1 year after HSCT
GB (10^3/uL)	5.5-15	10.87	8.87	3.41	1.87	8.54
PLT (10^3/uL)	150-450	80	195	147	184	327
Ferritin (ng/ml)	13-150	13.088	27.396	5.921	230	26
ALT (UI/L)	<33	50	81	505	12	13
AST (UI/L)	<32	89	125	865	24	22
LDH (UI/L)	135-225	1717	1623	941	175	234
Fibrinogen (mg/dl)	190-430	400	500	193	341	428
TGL (mg/dl)	<170	197	208	220	148	106
IL-18 (pg/ml)	<300	189764	27761	36606	995	341
CXCL9 (pg/ml)	<612	112895	22488	29403	50	50

Conclusion: This case provides further evidence of the efficacy of emapalumab in MAS [1], of the potential benefit of HSCT in difficult sJIA patients [2]. Notably, full control of inflammatory activity with emapalumab and anakinra may help to obtain a successful HSCT and reduce the risk of rejection.

AB1430 THE EXPERIENCE OF YOUNG PEOPLE WITH RHEUMATIC DISEASES TRANSFERRING THEIR CARE FROM PAEDIATRIC TO ADULT SERVICES AND THEIR SUGGESTED AREAS FOR IMPROVEMENT

Keywords: Health Services Research, Real-world evidence, Patient information and education

L. Williamson[1,2,3,4], A. Bouraoui[2,3], E. Williams[2], S. Meyer[2], S. Mavrommatis[2,3], M. J. Leandro[2,3,5], C. Ciurtin[2,3,5], D. Sen[3,5], C. Fisher[2,3]. [1]*Great Ormond Street Hospital for Children, Paediatric Rheumatology, London, United Kingdom*; [2]*University College Hospital, Adolescent Rheumatology, London, United Kingdom*; [3]*Centre for Adolescent Rheumatology, Adolescent Rheumatology, London, United Kingdom*; [4]*Arthritis Australia, Arthritis Australia, Glebe, Australia*; [5]*University College London, Department of Rheumatology, London, United Kingdom*

Background: Transition of care from paediatric to adult services is a critical time period for patients with rheumatic diseases. A seamless transition process can aid young people in their development to adulthood, whilst also allowing them to gain independence in managing their rheumatic condition. Young people and their caregivers often express concerns to their paediatric rheumatology teams about the transition to adult services.
Objectives: This study seeks to explore the experience of transition from the perspective of young people with rheumatic diseases, and their suggestions for areas to address in improving the transition process. The second aim of the study is to find out whether young people want to fill out information about themselves in advance of their appointment at the adult rheumatology service, in order to help staff to get to know them better, and if so, what information they felt was important to know.
Methods: Anonymised survey questionnaires were given to young people with rheumatic diseases, via a scannable QR code, to be filled in prior to their rheumatology outpatient visit. All patients surveyed had transferred their care from paediatric to adult services. Further responses were sought by sending the survey questionnaire to young people with rheumatic diseases who had consented to be on a patient and public involvement and engagement (PPIE) mailing list. Survey data were analysed in Microsoft Excel.
Results: Average age of respondents: 18 (median), range 16-26. The majority of respondents were female (76%). 52% of patients had juvenile idiopathic arthritis (JIA), 12% had juvenile dermatomyositis, 12% had juvenile systemic lupus erythematosus, and 18% did not disclose their diagnosis. Most young people were satisfied with the transition process (satisfaction score rated 8 out of 10 (mean)). Young people perceived the following aspects of transition to have been done well: "Communication about the change", having a "named transition coordinator", having a "personal tour of [the adult hospital]", and having a "smooth process". Aspects of the transition process that young people suggested could be improved included: "more transparent and understandable medical talk", "more follow-up [appointments]", "knowing how to contact [a] named transition coordinator", feeling as though the healthcare professional was "talking to my mum rather than me", and "the general feeling of… care not being as personal". Overall, 60% of young people stated that they would be willing to fill out an electronic form prior to their appointment at the adult rheumatology service to give information that would allow staff at the adult hospital to get to know them better. When stratified by age, only 50% of 16–18-year-olds would be willing to fill out a form, whereas 80% of 19–26-year-olds would. The most commonly suggested pieces of information were: hobbies, sports, favourite school subject, goals, and career aspirations.
Conclusion: Most young people were satisfied with the transition process and had helpful suggestions about how this might be improved in the future.
The majority of young people were willing to fill in a form to provide information about themselves in order to help adult rheumatology staff to get to know them better, especially those who were aged 19-26 years. At a critical time in young people's development, enabling them to provide information about themselves that they feel is important, may help to improve their perception of the transition process and reduce their anxiety about transferring care to adult services.

Background: New outcome measures are needed to optimize personalized tailored treatment and to predict response in patients with juvenile idiopathic arthritis (JIA).
Objectives: Aim of this multicenter, longitudinal study is to identify biomarker (clinical examination of the joints, ultrasound and inflammatory biomarkers) for the evaluation of disease activity in children with JIA.
Methods: DAISY study planned to recruit 120 patients with JIA polyarticular and at least 30 patients with JIA oligoarticular disease course according to International League of Association for Rheumatology (ILAR) classification criteria, with active disease calculated by JADAS 10 and 27 and treated according to current recommendations[1,2]. At enrollment, 3, 6 and 12 months patients were simultaneously evaluated for disease activity status (JADAS 10 and 27), examined by musculoskeletal ultrasound (MSUS) gray-scale (GS) and power-doppler (PD) in 44 joints using OMERACT synovitis scoring system by an expert in pediatric MSUS. At each visit blood samples are collected for evaluation of inflammatory biomarkers (cytokines, chemokines, S100A8, S100A9 and S100A12). In case of disease worsening, the same parameters were performed as unscheduled visit. Experienced sonographers in pediatric MSUS were blinded from clinical examination as well as pediatric rheumatologist performing clinical examination were blinded from the MSUS finding. Prior to the patient enrollment it was mandatory that all sonographers access the study educational material on DAISY web-portal and perform test for sonographers that represents calibration web-based reliability exercise on still images, presenting different grades of synovitis using OMERACT synovitis scoring in order to optimize interrater reliability.
Results: Study is conducted in 9 participating centers in 8 different countries after Ethics Committee Approvals and Informed Consents/assents were obtained. A total of 52 JIA patients were enrolled: 15 (28.8%) males and 37(71.2%) females; median age at enrollment 11.25 years, interquartile range (IQR) 8.06-14.19 years and median disease duration 1.67 years, IQR 0.97-5.26 years. Of the JIA patients, 18 (34.6%) had oligoarticular JIA, 21(40.4%) had rheumatoid factor negative polyarthritis, 5 (9.6%) had rheumatoid factor positive polyarthritis, 7 (13.5 %) had enthesitis related arthritis while only one (1.9%) had psoriatic arthritis. Two patients (3.8%) had uveitis, while eight (15.4%) of them had a family history of autoimmune diseases. In total, 42 (80.8%) were treated with synthetic disease modifying antirheumatic drugs (methotrexate) while 31(59.6%) of JIA patients were receiving biologics.
Conclusion: Study results are expected to enable definition of the new more sensitive clinical tool to predict response in JIA and achieve optimized personalized tailored treatment of our patients.

AB1432 BODY MASS INDEX AND INFLAMMATORY LESIONS IN MAGNETIC RESONANCE IMAGING IN JUVENILE IDIOPATHIC ARTHRITIS: IS THERE A LINK?

Keywords: Imaging

L. Kharrat[1], H. Ferjani[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1].
[1]Kassab Orthopedics Institute, Ksar Sa'id, Rheumatology, Tunis, Tunisia

Background: Obesity is usually associated with low-grade inflammation in the general population. However, several studies have noted that high body mass index (BMI) in rheumatoid arthritis patients was associated with less structural damage in X-rays and in Magnetic Resonance Imaging (MRI) [1,2]. The impact of BMI on inflammatory MRI lesions in Juvenile Idiopathic Arthritis (JIA) is less studied.

Objectives: We aimed to determine the link between BMI and inflammatory MRI lesions of sacroiliac joints in JIA.

Methods: We conducted a retrospective study including 44 patients followed for JIA meeting the International League of Associations for Rheumatology (ILAR) 2001 criteria. For each patient we collected the following data: age, age at the onset of JIA, JIA subtype, disease duration, BMI, C-reactive protein (CRP) and Erythrocyte sedimentation rate (ERS) levels, and MRI data. Disease activity was assessed using the JADAS score. Statistical analysis was performed using SPSS software.

Results: We included 28 boys and 16 girls. The mean age was 13.65 ± 4.62 years. The mean age at the onset of the disease 9.57 ± 3.97 years. The mean disease duration was 4.34 ± 3.09 years. There was enthesitis-related arthritis in 61% of the cases (n=27), oligoarticular JIA in 14% of the cases (n=6), polyarticular JIA in 11% of the cases (n=5), and psoriatic arthritis in 7% of the cases (n=3). JIA was undifferentiated in 7% of the cases (n=3). The mean BMI was 20.22 ± 5.6kg/m². Four patients had overweight (9%). The mean CRP and ESR were 14.42 ± 19.67mg/L and 26.56 ± 20.87mm, respectively. The mean JADAS was 6.6 ± 4.7. Sacroiliac joints IRM showed bone marrow edema in 43% of the cases (n=19) and irregularities in iliac edges in 9% of the cases (n=4). Inflammatory lesions in sacroiliac joints MRI was associated with lower BMI (19.15 ± 4.28 vs 21.33 ± 6.4kg/m², p=0.036). However, there were no correlations between BMI and the following parameters: CRP, ESR, or JADAS.

Conclusion: Our results are consistent with other studies conducted in rheumatoid arthritis patients, which noted that high BMI was associated with less severe synovitis and bone marrow edema, and thus less severe radiologic progression [1-3]. Baker et al. suggested that patients with greater BMI have a beneficial adipokine effect on bone remodeling [3]. In addition, it seems that JIA patients with severe disease activity suffer from early weight loss. Thus, a greater BMI may stipulate a less severe JIA phenotype.

AB1433 FACTORS ASSOCIATED WITH DIAGNOSIS DELAY IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Descriptive Studies

L. Kharrat[1], H. Ferjani[1], D. Ben Nessib[1], K. Maatallah[1], D. Kaffel[1], W. Hamdi[1].
[1]Kassab Orthopedics Institute, Ksar Sa'id, Rheumatology, Tunis, Tunisia

Background: The diagnosis delay is very variable in Juvenile Idiopathic Arthritis (JIA). The duration between the occurrence of symptoms, the diagnosis time, and the establishment of the treatment is very important in disease progression.

Objectives: To determine the diagnosis delay in JIA and study the factors affecting this delay.

Methods: We conducted a retrospective study including patients with Juvenile Idiopathic Arthritis (JIA) meeting the International League of Associations for Rheumatology (ILAR) 2001 criteria. For each patient, we collected the following data: age, gender, age at the onset of JIA, JIA subtype, diagnosis delay, clinical examination data, extra-articular manifestations, C-reactive protein (CRP) and Erythrocyte sedimentation rate (ERS) levels. Disease activity was assessed using the JADAS score. Statistical analysis was performed using SPSS software.

Results: We included 44 patients. They were 28 boys and 16 girls. The mean age was 13.65 ± 4.62 years. The mean age at the onset of the disease was 9.57 ± 3.97 years. The mean diagnosis delay was 4.34 ± 3.09 years. There was enthesitis-related arthritis in 61% of the cases (n=27), oligoarticular JIA in 14% of the cases (n=6), polyarticular JIA in 11% of the cases (n=5), and psoriatic arthritis in 7% of the cases (n=3). JIA was undifferentiated in 7% of the cases (n=3). The mean tender and swollen joint counts were 1.46 ± 2.33 and 0.17 ± 0.54, respectively. Fourteen patients had clinical enthesitis (32%). Sacroiliac joints were painful in 15 patients (34%). Fifteen patients had low back pain (34%). Only 4 patients had extra-articular manifestations (2 psoriasis and 2 uveitis). The mean CRP and ESR were 14.42 ± 19.67mg/L and 26.56 ± 20.87mm, respectively. The mean JADAS was 6.6 ± 4.7, respectively. The diagnosis delay was positively correlated to the patient's age ($r=0.561$, $p<10^{-3}$) and negatively correlated to the ESR level ($r=-0.331$, $p=0.037$). Besides, diagnosis delay was associated with extra-articular manifestations (4.45 ± 3.12 versus 2±0.1 years, $p<10^{-3}$). Besides, ERA patients had longer diagnosis delay compared to other JIA subtypes but the difference was not significant (p=0.061). However, diagnosis delay was not associated with low back pain, enthesitis, or sacroiliac joint pain.

Conclusion: Our results are consistent with Kurt et al. study [1]. Older age, the occurrence of extra-articular manifestations, and low ESR level could lead to diagnosis impediment.

AB1434 CLINICAL PROFILE OF JUVENILE IDIOPATHIC ARTHRITIS: ABOUT 55 CASES

Keywords: Inflammatory arthritides, Descriptive Studies

M. Ardhaoui[1], D. Khalifa[1], R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], E. Bouajina[1]. *[1]Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children with wide variety in its clinical profile.

Objectives: The aim of our study was to describe the epidemiological, clinical, paraclinical and management aspects of JIA among Tunisian children.

Methods: This is a monocentric retrospective and observational study including children who met the ILAR criteria for the diagnosis of JIA. They were collected from the rheumatology department of Farhat Hached Hospital of Sousse in Tunisia.

Results: Out of the 55 included children, 27 (49.1%) were boys and 28 (50.9%) were girls. The mean age was 13.6 years. The mean age of onset of JIA was 6.4

years [3 months-16 years]. The mean duration of JIA progression was 4.4 years. The predominant subtypes of JIA were the seronegative polyarticular form (21 cases, 38.2%), the seronegative oligoarticular form and juvenile spondyloarthritis (9 cases, 16.4% each). The other forms were: seropositive polyarthritis (7 cases, 12.7%), systemic onset JIA (SOJIA) and psoriatic arthritis (4 cases, 7.3% for each) and arthritis with enthesitis (1 case, 1.8%). Arthritis was present in all patients. Wrist followed by knee were the most affected joints in all subtypes. Fever, lymphadenopathy, hepatosplenomegaly and rash were exclusive to patients with SOJIA. Uveitis (2 cases, 3.6%) and anti-nuclear antibodies (ANA) positivity (1 case, 1.8%) were rare. Biological inflammatory syndrome was found in 65.5% of cases. The means of ESR and CRP were 42.4 mm/h and 28.8 mg/L respectively. Anemia was found in 56.4% of cases. Standard X rays revealed carpitis in 4 cases (7.2%) and bone erosions in 9 cases (16.4%). Coxitis was present in 30.9% of the patients. Concerning treatment, our patients received non steroidal anti-inflammatory drugs (61.8%), oral corticosteroids (67.3%), and pulse steroid therapy in 47.3% of cases. Methotrexate was used for 65.5% of patients. Twenty-four patients (41.8%) were treated with biologics. Delayed growth as a complication of the JIA was observed in 8 cases (14.5%). Twenty-three patients (41.8%) developed joint deformities.
Conclusion: JIA has heterogeneous presentations with a challenging diagnosis in rheumatology practice. In our study, the seronegative polyarticular form was the most common subtype of JIA. Inflammatory syndrome, coxitis and deformities were frequent whereas uveitis and ANA positivity were rare findings in our population.

AB1435 RELEVANCE OF AUTO-ANTIBODIES AGAINST CARBAMYLATED PROTEINS IN JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Autoantibodies, Inflammatory arthritides, Biomarkers

M. Thomas[1], G. Martinroche[2], A. Combier[1], J. Wipff[1], G. Touanga[1], P. Quartier[3], C. Bordes[2,4], M. E. Truchetet[4,5], Y. Allanore[1]. [1]*Cochin Hospital, Rheumatology, Paris, France*; [2]*Hospital Center University De Bordeaux, Immunology and Immunogenetic Department, Bordeaux, France*; [3]*Necker Hospital, Reference Centre for Rare Diseases, Paediatric Immunology-Haematology and Rheumatology Unit, Paris, France*; [4]*Bordeaux University - Campus Carreire, ImmunoConcEpt, CNRS, UMR 5164, Bordeaux, France*; [5]*Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France*

Background: Auto-antibodies against carbamylated proteins (anti-CarP) are emerging biomarkers in rheumatoid arthritis with relevant prognostic value. Juvenile idiopathic arthritis (JIA) is characterized by high heterogeneity and risk-stratification could be improved.
Objectives: We aim at determining whether anti-CarP in J IA's patient, at the time of transition, could help to predict patients' outcomes.
Methods: We conducted a monocentric retrospective study at the Cochin Hospital in Paris on a cohort of JIA patients in transition to adult rheumatology for whom serum has been collected and stored in a biobank between 2011 and 2013 with the approval of research ethic committee (EUDRACT 2010-A01386-33, reference S.C.2852). Demographic data, diagnosis, biological and radiological results, and treatments were collected retrospectively thanks to computerized files. Samples of serum available in the biobank were analyzed to measure anti-CarP and anti-CCP by ELISA in the department of Immunology and Immunogenetic from the Bordeaux University Hospital.
Results: Twenty-eight (20%) patients were anti-CarP positive. The median age was 21.6 (18.6-23.1) years in anti-CarP positive as compared to 19 (17-21.1) in anti-CarP negative group (p=0.02). In anti-CarP positive group, 41% were polyarticular-JIA, 26% oligoarticular, 15% had enthesitis related arthritis and 15% were systemic, but this was not different as compared to anti-CarP negative patients. Structural radiographic damages were identified in 44% of anti-CarP positive such as in 50% in anti-CarP negative group (p=0.6). Concerning treatment, 28% of anti-CarP positive patients were treated with synthetic DMARD and 72% with biologic DMARD as compared to 44% (p=0.1) and 65% (p=0.5) for anti-CarP negative. Among anti-CarP positive patients, 10 (7.4%) were also anti-CCP positive. These double-positive patients were polyarticular-JIA for 90% and 9 (90%) received a biotherapy at the last available follow-up as compared to 16% of polyarticular-JIA (p=0.002) and 44 (46%) on biotherapy (p=0.03) for double negative.
Conclusion: Anti-CarP antibodies were observed in 20% of JIA's patients at transition but could not help for risk-stratification of the patients. The respective value of anti-CarP and anti-CCP for structural damages and treatment intensification will require larger cohort but double positive patients appeared to be the most severe polyarticular-JIA patients.

AB1436 BIOLOGIC THERAPY IN JUVENILE IDIOPATHIC ARTHRITIS TUNISIAN PATIENTS

Keywords: bDMARD, Inflammatory arthritides

M. Ardhaoui[1], D. Khalifa[1], O. Farhat[1], R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children under the age of 16. Biologic therapy significantly improved the management and prognosis of this disease.
Objectives: We aimed to evaluate the indications, clinical efficacy and safety of biotherapy for the treatment of JIA in a tunisian population.
Methods: This is a monocentric retrospective and observational study including patients followed for JIA (ILAR criteria) in the Rheumatology department of Sousse in Tunisia.
Results: Fifty-five children (28 girls and 27 boys) were included. The mean age was 13.6 years. The predominant subtypes of JIA were the seronegative polyarticular JIA (38.2%), and the seronegative oligoarticular form and juvenile spondyloarthritis (16.4% each). Besides biologics, our patients received non steroidal anti-inflammatory drugs (61.8%), oral corticosteroids (67.3%), and pulse steroid therapy in 47.3% of cases. Methotrexate was used for 65.5% of patients. Twenty-four patients were treated with biologics, with a prevalence of 41.8%. The mean age at the beginning of biotherapy was 12 years, with a mean time for initiation of 5 years. The main indications were the first and second-line treatments failure (29.1%) and their side effects (12.7%). The most frequently used biologics were TNF alpha blockers: Etanercept (9 patients), Infliximab (6 patients), Certolizumab and Adalimumab (2 patients each). Anti-Interleukin-6 (Tocilizumab) was used in the systemic JIA form for 4 patients. The mean duration of treatment with biologics was 3.55 years. A trend towards lower disease activity was observed with steroid therapy stopped in 25%. Five patients switched biologics. The overall safety profile was good. No serious adverse drug events occurred except anaphylaxis in 2 cases: 1 with Tocilizumab and one with Infliximab. The other side effects were hepatic toxicity with elevated transaminases (2 patients) and moderate cutaneous infection (1 patient).
Conclusion: Biologics have provided interesting new therapeutic alternatives in Tunisian patients with JIA, despite the delay of their initiation. However, the long-term side effects of modulating the immune system are not yet fully understood in this young population.

AB1437 NAILFOLD CAPILLAROSCOPY IN DEFICIENCY OF ADENOSINE DEAMINASE 2 (DADA2): A CASE-CONTROL STUDY

Keywords: Genetics/Epigenetics, Vasculitis

P. F. Bica[1], C. Matucci-Cerinic[2,3], E. Hysa[1], A. Cere[1], E. Gotelli[1], S. Volpi[2,3], R. Caorsi[2,3], A. Sulli[1], C. Pizzorni[1], S. Paolino[1], M. Cutolo[1], M. Gattorno[2]. [1]*University of Genova, IRCCS San Martino Polyclinic Hospital, Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties (DIMI), Genova, Italy*; [2]*I.R.C.C.S. Giannina Gaslini, Center for Autoinflammatory Diseases and Immunodeficiencies, Genoa, Italy*; [3]*I.R.C.C.S. Giannina Gaslini, DINOGMI, University of Genoa, Genoa, Italy*

Background: Deficiency of adenosine deaminase 2 (DADA2) is a rare monogenic autoinflammatory disease characterized by the presence of systemic inflammation, vasculitis, early-onset stroke, and hematologic manifestations such as cytopenia and immunodeficiency. Mucocutaneous and peripheral microvascular manifestations, such as livedo racemosa, cutaneous ulcers and Raynaud's phenomenon (RP), can occur, in up to 50%, 22% and 8 % of DADA2 patients respectively [1].
Objectives: To investigate the microvascular architecture in nailfold capillaries of DADA2 patients comparing them with adequate healthy controls (HCs) and primary RP individuals.
Methods: The data of 9 patients with DADA2 followed at Istituto Gaslini were retrospectively retrieved and compared to 11 HCs and 7 RP. Clinical and genetic data were collected for DADA2 patients. Nailfold videocapillaroscopy (NVC) findings were collected in the whole cohort, independently from their current treatment. The capillaroscopic parameters were classified according to the Fast Track Algorithm and distinguished between scleroderma-pattern (encompassing specific NVC alteration, such as the presence of giant capillaries and/or loss of capillaries combined with abnormally shaped capillaries) and non-scleroderma

patterns (non-specific NVC alterations) [2]. A validated semiquantitative scale (score 0–3 for each NVC parameter) was used to compare microvascular findings in the three groups [3]

Results: The patients with DADA2 were diagnosed according to genetic testing. The disease onset was in early infancy, while the mean age at NVC was of 18.8 years. Livedo racemosa was present in 7 patients (78%), digital ulcers in 1 patient, and an ischemic stroke was reported in 5 patients (55%). None of the patients had RP (0%). The NVC showed the presence of non-specific alterations in all DADA2 patients (capillary dilations in 100%, abnormally shaped capillaries and haemorrages in 23% of patients). The capillary density was normal (median = 9) and no scleroderma-like pattern was found. No significant differences in the rates of each microvascular finding were detected between DADA2, RP patients and HCs.

Conclusion: This is the first report investigating the NVC findings in DADA2 patients. Microvascular damage in DADA2 does not show a specific capillaroscopic alteration but the presence of non-specific findings might suggest a disease-related endothelial damage.

Background: GVHD is a significant complication of allogenic stem cell transplant, mediated by donor T cell activation and proliferation and affecting 30%-70% of patients. Clinical manifestations often have overlapping features with auto-immune diseases such as scleroderma, Sjogren's syndrome, eosinophilic fasciitis, primary biliary cirrhosis and immune cytopenia. Clinical myositis with muscle tenderness and elevated muscle enzymes is recognized as a distinctive and uncommon manifestation of GVHD with estimated frequency of 3.5–7.6%. In addition to corticosteroids, various immunosuppressive agents are being used for treatment, however, the optimal therapeutic strategy has not yet been defined.

Objectives: To describe a case of GVHD related myositis in a 4 years old female, successfully treated with Rituximab and to increase awareness for this rare condition and the role of Rituximab for its treatment.

Methods: Two years old female underwent a successful bone marrow transplantation from matched unrelated donor for Juvenile myelomonocytic leukemia (JMML). Four months post BMT she developed severe GVHD, primarily involving her skin and oral mucosa, GI and liver. She was treated with mycophenolate, cyclosporine, prednisolone, ruxolitinib and tacrolimus in different combinations. Almost two years post BMT she developed fever, general weakness and severe respiratory distress which required mechanical ventilation. After a comprehensive diagnostic work-up, she was diagnosed with inflammatory myositis based on elevated CPK, characterized EMG and muscle biopsy (Fig 1, 2). She was treated with steroid pulses and IVIG with no significant improvement and therefore Rituximab was added to her regimen. Two weeks following the first dose of Rituximab, clinical and laboratory improvement were noted, and the patient could get off ventilator.

Results: Patient remained in remission with monthly IVIG and decreasing doses of prednisone.

Conclusion: Myositis is a rare complication of GVHD. High index of suspicion is recommended for early diagnosis. Rituximab should be considered as a treatment option.

AB1439 ASSESSMENT OF HEALTH-RELATED QUALITY OF LIFE IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Inflammatory arthritides, Patient reported outcomes, Quality of life

M. Ghali[1], D. Khalifa[1], M. Cheour[1], R. Fakhfakh[1], N. El Amri[1], K. Baccouch[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease that causes physical and psychological disability. Considering the young age of patients and the potential long-lasting disability, the consequences of JIA on health-related quality of life (HRQoL) may be significant.

Objectives: This study aimed to measure HRQoL and identify associated factors.

Methods: This is a cross-sectional monocentric study including children with JIA diagnosed according to the International League of Associations of Rheumatology (ILAR) classification criteria. To evaluate disease activity we used the Disease activity score (DAS-28) for oligoarticular and polyarticular forms, and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score for axial forms. The Childhood Health Assessment Questionnaire (C-HAQ) was used to assess functional disability. The HRQOL was evaluated by the Pediatric Quality of Life Inventory 4.0 (PedsQL4) which is a questionnaire composed of 23 items. The higher scores indicate a better quality of life.

Results: Thirty-six patients were enrolled. The average age was 13.5 ± 5.9 with a female percentage of 55.6 %. The polyarticular form was the most frequent (52.8%) meanly seronegative, followed by the Oligoarticular form (13.9%), then the enthesitis-related form (12.4%). The mean disease duration was 5.5±4.7 years. The median of the C-HAQ was 1 (IQR=0- 2). The median of PedsQL4 was 65.8 (IQR= 43.2-90.4). The physical functioning subscale had the lowest score, with a median of 60.1 (IQR= 30.4-90.7), followed by the school functioning with a median of 63.2 (IQR=41.7-90.1), then the social functioning with a median of 69.2 (IQR=45.7-91), then the emotional functioning with a median of 70.8 (IQR=47.7-92). The impairment of HRQoL was significantly associated with higher disease activity (p=0.002), the presence of joint deformities (p=0.02), higher C-HAQ score (p=0.001), and hip involvement (p=0.003). The PedsQL4 global score and its domains had no significant correlations with age, forms of JIA, or biological abnormalities.

Conclusion: The HRQoL was impaired in our population of JIA. Physical health was the most affected. Early and effective management of disease activity could improve HRQoL in children with JIA.

ASSESSMENT OF THE PREVALENCE OF SARCOPENIA IN ADULT WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Sarcopenia, Inflammatory arthritides, Diet and Nutrition

I. Slitine[1], A. Hittinger[1], I. Charlot-Lambrecht[1], B. Loïs[1], M. Geoffroy[1], J. H. Salmon[1]. *[1]Hospital Maison Blanche, Rheumatology, Reims, France*

Background: Sarcopenia is a progressive and systemic disorder of skeletal muscles responsible for an acceleration of function impairment and loss of mass muscle [1]. It is well known associated with ageing, but a new life-course approach suggests that muscle mass and function in older people also depends on the mass muscle peak in early adulthood [2]. Prevalence increasement of sarcopenia has been well described in inflammatory rheumatic diseases, particularly in rheumatoid arthritis and spondylarthritis, but has never been studied in rheumatic diseases with a juvenile onset.
Objectives: The aim of this study was therefore to investigate the prevalence of sarcopenia in juvenile idiopathic arthritis in adult life.
Methods: We performed a monocentric cross-sectional study including patients followed up in rheumatology unit of Reims hospital for juvenile idiopathic arthritis (JIA) from November 2021 to September 2022. Each patient received a measurement of muscle quantity and quality by dual-energy X-ray absorptiometry, a measurement of muscle strength by Grip test, a screening for sarcopenia by the SCARC-F score, an assessment of physical activity by the IPAQ score and of fatigue by the FACIT-F score. The diagnosis of sarcopenia was confirmed by a decrease in appendicular muscle mass (AMM) < 20 kg in men and < 15 kg in women or an ASM/height[2] < 7 kg/m^2 in men or < 5.5 kg/m^2 in women [1].
Results: Thirty-four patients were included, aged from 18 to 45 years. The prevalence of sarcopenia was 20.6% (7/34) with a majority of women (sex ratio 0.6). Type of JIA was significantly different between the 2 groups with 57.14% oligoarticular form and 28.57% systemic form in the sarcopenic group, versus 44.4% oligoarticular form and 29.6% enthesitic form in the non-sarcopenic group (p=0.043). We did not find any significant difference in disease activity nor in treatment by biotherapy or corticosteroids between the 2 groups. Proportion of patients with a BMI <18.5 kg/m² was significantly higher in the sarcopenic population (p=0.0095). The IPAQ score showed a lower energy expenditure in the sarcopenic group, although not significantly different (p=0.099). By using a variation of -2DS of appendicular skeletal mass or <ASM/height[2] compared with age- and sex-matched reference values from a Danish cohort, we have calculated a prevalence of sarcopenia of 11.76% in our population [3]. The assessment of muscle strength defined by a -2DS decrease in grip test values compared to reference values matched for age and sex showed a decrease in muscle strength in 29.4%. By using European Working Group for Sarcopenia in Older People (EWGSOP) definition, only 11.76% of our patients presented a muscle strength decrease. Moreover, the SARC-F score established in patients over 65 years of age did not allow for the detection of sarcopenia in our population.
Conclusion: This is the first study to evaluate sarcopenia in juvenile idiopathic arthritis. JIA is associated with a risk of developing sarcopenia at an early age with an impact on peak muscle mass and, thus, on long-term muscle function prognosis. In order to prevent this risk, nutritional management and regular physical activity seem to be relevant approaches. The definition of sarcopenia by the EWGSOP does not seem to be adapted to a younger population, with a low sensitivity screening of sarcopenia in this population by the SARC-F score and an underestimation of low muscle strength by the grip test. Further studies with a larger population and a control population are needed to clarify these results.

CLINICAL CHARACTERISTICS OF PEDIATRIC PATIENTS WITH RHEUMATIC DISEASES UNDER TREATMENT WITH BIOLOGICAL THERAPY: INFORMATION FROM BIOBADAMEX

Keywords: bDMARD, Registries

S. Mendieta[1], A. Torres[2], F. Irazoque-Palazuelos[3], S. Sicsik[4], I. J. Colunga-Pedraza[5], D. X. Xibille Friedmann[6], D. Alpizar-Rodriguez[7], V. Rivera Teran[7]. *[1]ISSEMYM Hospital Materno Infantil, Pediatric Rheumatology, Toluca de Lerdo, Mexico*; *[2]Centro Medico Nacional La Raza, Pediatric Rheumatology, Ciudad de México, Mexico*; *[3]Centro Medico Nacional 20 de Noviembre, Rheumatology, Ciudad de México, Mexico*; *[4]Unidad Médica de Alta Especialidad No. 71 IMSS, Rheumatology, Torreón, Mexico*; *[5]Centro Médico Conchita, Rheumatology, Monterrey, Mexico*; *[6]Centro Médico San Diego, Rheumatology, Cuautla, Mexico*; *[7]Colegio Mexicano De Reumatologia, Unidad de Investigacion, Ciudad de México, Mexico*

Background: The advent of biologic treatment (bDMARD) in childhood rheumatic diseases (RD) has changed their evolution and prognosis. Evidence is robust for diseases such as juvenile idiopathic arthritis (JIA) and systemic lupus erythematosus (SLE), but in other diseases we still have to learn which is the ideal therapy, time to discontinuation and the potential adverse events (AE) in short and long term.
Objectives: Identify the clinical and treatment characteristics of pediatric patients with rheumatic diseases with bDMARD treatment and describe the development of AE.
Methods: BIOBADAMEX is a prospective ongoing cohort of Mexican patients with RD using bDMARDs since 2016. We included all patients younger than 18 years of age registered in BIOBADAMEX. Descriptive statistics were used for the baseline characteristics and the Chi-square test to analyze the differences between the characteristics of the groups in relation to the development of AE.
Results: A total of 45 patients were included, 31 (69%) of them female, mean age of 13.3 (±3.6) years. (Table 1). The most frequent diagnosis was JIA 25 (56%), followed by SLE 9 (20%), uveitis 5 (11%), polymyositis/dermatomyositis and hidradenitis 2 (4%) respectively; systemic sclerosis and CINCA 1 patient (2%) respectively. The mean duration disease in years was 4.67 (±2.1). Nine patients (20%) used a biologic prior to the current; 23 (51%) patients had comorbidities. The most frequent bDMARDs used was Adalimumab (ADA) in 17 (38%) patients followed by Rituximab in 15 (33%) and Tocilizumab in 10 (22%), Infliximab, Abatacept and Canakinumab were used in one patient respectively. When compared by groups, ADA and Tocilizumab were the most used bDMARDs in JIA, Rituximab the only one used in SLE and PM/DM, and ADA the only one for uveitis. 15 patients discontinued biological treatment, 4 (27%) due to AE. 82% used an additional synthetic DMARD, being methotrexate the most used in 48% of patients. Steroids were

Table 1. Baseline Characteristics

Baseline characteristics (n = 45)

DMARDs use n(%):	37 82.2				
AE, n(%):	**15 33.3**				
By disease:	**AE Type**				
	Infection	**Allergy**	**Neutropenia**	**Other**	**Chi^2**
JIA	**3**	**1**	**2**	**3**	**0.95**
SLE	**1**	**1**	**0**	**1**	
Uveitis	**3**	**0**	**0**	**0**	

used by 21 (47%) of the patients with a median dose of 10mg (IQR 5 - 25). Fifteen AEs were recorded: 7 (47%) were infections, 5 of these (71%) were COVID; allergies and neutropenia in 2 (13%) patients respectively. By disease infections were more frequent in patients with JIA and Uveitis; neutropenia only occurred in patients with JIA (p 0.95). 87% of the AEs were non-serious, 1 patient with JIA presented a severe AE and one patient with SLE a fatal AE associated with COVID (p 0.93), with no statistically significant difference between groups.

Conclusion: JIA is the most frequent indication to use bDMARD as worldwide reported. The AE in this analysis are similar to previous registries in terms of the prevalence of infections, in our group the most frequent infectious complication was COVID, being fatal in one patient related with rituximab in SLE. Our study did not find statistically significant differences in the development of AE between diseases; however, they will continue to be reported and the number of patients in the registry will increase.

AB1442 OVARIAN PRESERVATION IN JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS: A MONOCENTRIC COHORT

Keywords: Systemic lupus erythematosus, Biomarkers, Pregnancy and reproduction

S. Costi[1], D. Chevenne[2], P. Ellul[3], V. Baudouin[4], T. Kwon[4], R. Caporali[1,5,6], C. Delcou[7], I. Melki[8]. *[1]ASST G.Pini-CTO, Unit of Pediatric Rheumatology, Milan, Italy*; *[2]Robert Debré Hospital, Biochemistry Hormonology, Paris, France*; *[3]Robert Debré Hospital, Child and adolescent psychiatrist service, Paris, France*; *[4]Robert Debré Hospital, Nephrology Department, Paris, France*; *[5]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; *[6]ASST G.Pini-CTO, Department of Rheumatology and Medical Science, Milan, Italy*; *[7]Robert Debré Hospital, Department of gynecology and obstetrics, Paris, France*; *[8]Robert Debré Hospital, Infectious Disease and Internal Medicine Department, Paris, France*

Background: Systemic lupus erythematosus (SLE) can impact fertility outcomes and lead to ovarian premature failure. The exact mechanism is not completely understood. Anti-ovarian antibodies have been described as a possible explanation[1] but other intrinsic and extrinsic factors are involved. Cyclophosphamide (CYC) is known to have a gonadotoxic effect, but available data are derived from adult cohorts. Anti-müllerian hormone (AMH) is a surrogate biomarker of ovarian reserve in such studies.

Objectives: This study aims to evaluate the ovarian reserve in juvenile-SLE (j-SLE) using AMH and to follow the longitudinal evolution of this biomarker at diagnosis and after the start of treatment.

Methods: Patients with a diagnosis of j-SLE followed at Robert-Debré Hospital, Paris, France, were included. AMH levels were assessed before starting therapy, at 6-10, 12-18, and after 20 months from the start of immunosuppressive therapy. AMH values are expressed in pmol/L with a normal range varying from 7.1 to 51.8, according to pubertal status/age.

Results: 21 j-SLE patients were included (100% female). Patients were divided into 2 groups: i. j-SLE who received cyclophosphamide (48%) and ii. j-SLE who received anti-CD20 treatment (rituximab or obinutuzumab), mycophenolate, or hydroxychloroquine (52%). Clinical and demographical features are summarized in Table 1. 16 patients were menstruating at the initiation of immunosuppressive therapy, while 5 patients were not; however, the first menstrual period occurred between 2 to 4 months after initiation of treatment. The median cumulative dose of CYC was 4.8 grams (IQR 2.2). No statistically significant differences were found comparing pre-treatment AMH levels between the two groups (p= 0.60). The same trend was found evaluating AMH levels at 6-10, 12-18 months, and after 20 months from the start of therapy (p=0.48, p= 0.77, and p= 0.68 respectively). At 20 months the only two patients with AMH values below the normal limits had low values even before starting treatment (0.6 vs 4.9 in group 1 and 1.9 vs 7.4 in group 2 respectively). SLEDAI at the onset of the disease seems to correlate negatively with the values of AMH, nevertheless, the small sample size does not allow to reach statistical significance (S = 1550.9, p= 0.12). In addition, patients with SLEDAI score >20 have lower levels of AMH compared to patients with SLEDAI score ≤20 after 20 months from the start of therapy (p-value = 0.05) (Figure 1), independently of their treatment.

Conclusion: Fertility preservation is a key point in the management of patients with SLE. Our study shows reassuring data regarding the use of CYC in j-SLE and suggests that AMH levels, and consequently ovarian reserve, may be primarily affected by disease severity and activity rather than treatment.

AB1443 TRIGGERING IGA VASCULITIS BY FOOD ALLERGEN EXPOSURE, VITAMIN D DEFICIENCY, AND IL-33-ACTIVATED TYPE 2 IMMUNE RESPONSES

Keywords: Vasculitis, Vitamin D

X. MA[1], J. Wang[1], H. Jiang[1], Y. Shan[2]. *[1]The First Hospital of China Medical University, Department of Pediatrics, Shen Yang, China*; *[2]University of Occupational and Environmental Health, Japan,The First Depatment of Internal Medicine, Kitakyushu, Japan*

Background: Immunoglobulin A vasculitis (IgAV) is one of the most common types of systemic vasculitis in children and usually involves the skin,

gastrointestinal tract, kidneys, and articulation[1]. The trigger of IgAV is unclear. Study elucidated that higher serum IgE levels and vitamin D deficiency existed in IgAV commonly[2, 3], while it is worth noting that T helper (Th) 2 cells increase in IgAV and are closely correlated with aberrant production of antibodies and the development of vessel vasculitis[4]. Moreover, serum IL-33 can activate many immune cell types involved in type 2 immune responses and allergic inflammatory reactions, are elevated in IgAV patients and positively correlated with the overall clinical score[5, 6]. This study aimed to further analyze their mutual relationship and reveal the mechanism underlying IgAV development.

Objectives: We investigated the levels of antigen-specific antibodies, 25-hydroxyvitamin D [25(OH)D_3], and IL-33 and the phenotypes of Th cells in the peripheral blood of IgAV patients at the early stage of disease onset. We also analyzed the correlation between each index and clinical characteristics.

Methods: Aeroallergen-specific IgE and food-specific IgE were detected by western blotting. Serum 25(OH)D_3 and total IgE levels were determined by electrochemiluminescence immunoassay. Serum IL-33 and sST2 levels were detected by enzyme-linked immunoassays. Serum IL-2, IL-4, IL-6 and IL-10 were detected using a cytometric bead array. Frequencies of T helper cell subsets were detected by flow cytometry.

Results: About half of the patients had abnormal allergic indicators and positive results in the allergen-specific IgE assay. Up to 98.25% of the patients had decreased serum 25(OH)D_3 levels, which were inversely correlated with an abnormal increase in IgE. Th2 cells were elevated and negatively correlated with the level of serum 25(OH)D_3. IL-33, a critical cytokine for the differentiation of Th2 cells, was also increased and negatively correlated with serum 25(OH)D_3 levels.

Conclusion: Food allergen exposure and 25(OH)D_3 deficiency may trigger IgAV. 25(OH)D_3 deficiency induces the activation of type 2 immune responses and a pathological increase in IgE by promoting the secretion of IL-33, which may be the underlying mechanism of IgAV pathogenesis. Monitoring vitamin D levels and administering vitamin D supplementation might play significant roles in preventing and treating IgAV.

Corominas[1,2]. *[1]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*; *[2]Universitat Autònoma de Barcelona, Medicine, Bellaterra, Spain*; *[3]Hospital de la Santa Creu i Sant Pau, Immunology, Barcelona, Spain*; *[4]Hospital de la Santa Creu i Sant Pau, Paediatrics, Barcelona, Spain*

Background: There are no specific biomarkers of disease activity in for Juvenile Idiopathic Arthritis (JIA), and therefore it is important to identify new molecules which help us in daily practice to offer individualized treatment options. Serum Calprotectin (CLP) is an emerging biomarker of inflammation. Recent studies[1] suggest that disease activity correlates better with CLP than with classic acute phase reactants such as C-reactive Protein (CRP).

Objectives: To determine the clinical characteristics of paediatric patients with Juvenile Idiopathic Arthritis (JIA) who have discrepancy between Serum Calprotectin and C-reactive Protein.

Methods: An analytical transversal study was performed including patients with JIA from a paediatric rheumatology clinic between 2017 and 2021. A total of 25 patients were included, who had at least one measurement of CLP in daily practice. Demographic, analytical and clinical data were collected. The JADAS score by physical examination and ultrasound was collected in patients with peripheral arthritis.

Results: A total of 25 patients were included, 48% were female and the mean age was 11.5 (±4.6) years. A total of 11 (44%) patients had discrepancy between CLP and CRP. Among them, 9 (81.8%) had elevated CLP and low CRP, whereas only 2 (18.2%) had low CLP with elevated CRP. At the time of performing the analysis, 44% of the patients had an active disease. The oligoarticular JIA subtype was the one that presented a larger patient's percentage (54.5%) with discrepancy and elevated CLP. The details of clinical and analytical characteristics of the patients are shown in Table 1.

	No discrepancy. Low (n=11)	Discrepancy. Low CLP (n=2)	Discrepancy. High CLP (n=9)	No discrepancy. High (n=3)
Age (years), mean (SD)	12.2 (±4.6)	8.0 (±11.1)	10.3 (±3.5)	14.4 (±3.0)
JIA subtypes, n (%)				
- ERA + juvenile EA + APs	5 (45.4)	0 (0)	2 (22.2)	0 (0)
- Oligoarticular	3 (27.3)	1 (50)	**5 (55.6)**	2 (66.7)
- Polyarticular	2 (18.2)	1 (50)	1 (11.1)	1 (33.3)
- Systemic	1 (9.1)	0 (0)	1 (11.1)	0 (0)
Biomarkers, median (IQR)				
- CRP (mg/L)	0.5 (0.6)	8.2 (5)	1.7 (2.1)	6.3 (11.8)
- ESR (mm/h)	5 (8)	28 (32)	13 (12)	21 (56)
- Calprotectin (µg/mL)	1.4 (0.8)	0.9 (1.6)	4.3 (1.7)	4 (2.3)
JIA activity according to clinical criteria, n (%)				
- Active	4 (36.3)	2 (100)	**3 (33.3)**	2 (66.7)
- Inactive	7 (63.6)	0 (0)	6 (66.7)	1 (33.3)
JIA activity according to JADAS, n (%)				
- JADAS: activity	0 (0)	2 (100)	2 (22.2)	1 (33.3)
- JADAS US: activity	0 (0)	2 (100)	1 (11.1)	1 (33.3)
Uveitis, n (%)				
- Acute uveitis	0 (0)	0 (0)	1 (11.1)	0 (0)
Treatment, n (%)				
- PDN	2 (18.2)	1 (50)	1 (11.1)	1 (33.3)
- DMARD	6 (54.5)	1 (50)	3 (33.3)	3 (100)
- bDMARD	3 (27.3)	0 (0)	2 (22.2)	1 (33.3)

In the subgroup of patients with discrepancy and elevated CLP there were 3 (33.3%) with an active disease. Among them, 66.7% were female and all of them had an oligoarticular JIA. One of them was in a flare with both an active arthritis and uveitis at the moment of the analysis. None of them were under treatment with prednisone nor DMARD (disease-modifying antirheumatic drugs).

Conclusion: There was discrepancy between CLP and CRP in 44% of the sample. Among them, most (81.8%) had high CLP without elevation of CRP. The JIA subtype that presented discrepancy with elevated CLP was the oligoarticular one. A total of 3 (33%) patients were active in the group with discrepancy and elevated CLP, one of them being in a flare with both an active arthritis and uveitis.

THE UNITED ARAB EMIRATES JUVENILE IDIOPATHIC ARTHRITIS REGISTRY PRELIMINARY RESULTS OF PATIENT DEMOGRAPHICS, SUBTYPE DISTRIBUTION, CLINICAL FEATURES, TREATMENT AND OUTCOME.

Keywords: Registries

K. Khawaja[1], M. Masalawala[2], A. Naeem[3], E. Sharif[4], I. Afrooz5, N. Aljaberi[6]. *[1]Shaikh Shakhbout Medical City, Pediatric Rheumatology, Abu Dhabi, United Arab Emirates*; *[2]Shaikh Shakhbot Medical City, Clinical Trials Unit, Abu Dhabi, United Arab Emirates*; *[3]Shaikh Shakhbout Medical City, Clinical Trials Unit, Abu Dhabi, United Arab Emirates*; *[4]Al Jalila Children Hospital, Pediatric Rheumatology, Dubai, United Arab Emirates*; *[3]Shaikh Shakhbout Medical City, Clinical Trials Unit, Abu Dhabi, United Arab Emirates*; *[6]United Arab Emirates University, Pediatrics, Al Ain, United Arab Emirates*

Background: Juvenile Idiopathic Arthritis (JIA) is a chronic inflammatory disease that affects 1 in 1000 children worldwide. Our population in the United Arab Emirates is a multiethnic diverse population. [1, 2]
Objectives: To create centralised data for JIA in the United Arab Emirates. In this abstract we describe the Demographic data, clinical features, subtype distribution as per ILAR classification, treatment received and outcome of our patients.[3]
Methods: Retrospective entry of data from all 3 participating centres (Shaikh Shakhbout Medical City, Tawam and AlJalila). Patients with the diagnosis of JIA included. Electronic clinical research form used to collect data. Data at initial diagnosis and current outcome as per Wallace and (Juvenile Arthritis Disease Activity Score) JADAS 10. Long term out come as per Juvenile Arthritis Disease Activity (JADAI) articular > 0 and extra articular JADAI > 0. All data entered and analysed through Redcap (Research Electronic Data Capture web-based application version 12.1.1 model 2022). Simple statistics used. Ethics approval obtained.
Results: 157 patients entered in to the registry so far. Male to female distribution: 39 (24.8%) to 118 (75.2%). Local Emirati patients of 107 (68.2%). Other Arabs 16 (10.2%). South Asian 12 (7.6%), Western 12 (7.6%) and African 10 6.4%). Mean age at presentation 5.3 years (1 to 15 years). Current mean age 12 (4-22 years). Family history of Rheumatoid Arthritis in 33 patients (21%). History of Consanguinity in 54 families (34.4%). Subtype distribution: Oligo articular 77 (49.4%), extended Oligo articular 5 (3.2%). Poly articular 50 (32.1%), Systemic 11 (7.1%), Enthesitis related Arthritis 1 (0.6%), Psoriatic 9 (5.8%) and other 3 (1.9%). At presentation: Joint pain in 132 patients (84.1%), Joint effusion 115 (73.2%). Affected function in 98 (63.2%). Clinical synovitis in 138 (87.9%). Joint restriction in 100 (63.7%). Uveitis in 6 (3.8%) ANA positive 35 patients (22.3%). Rheumatoid factor positive 10 (6.4%), Anti CCP positive 6 (3.8%). Low Hb less than 10 g/L in 109 (69.4%), high ESR > 20 mm/hr in 30 patients (19.1%). High CRP >5 mg/L in 48 (30.6%). Synovitis in USS 53 (33.8%). Erosions by X-ray or USS 7 patients (4.5%). Uveitis after diagnosis in 30 patients 19.1%. Dental carries at presentation in 51 patients (32.1%). COVID infection in 74 patients (47.1%). Oral systemic steroids given to 108 patients (68.8%). Intravenous methyl prednisolone to 43 patients 27.4%). Triamcinolone Acetonide/Hexa acetonide joint injections to 91 patients (58%). Synthetic Disease modifying medication methotrexate in 108 (68.8%). Biologic treatment 76 patients (49%). Etanercept 64 patients (40.8%), Adalimumab 65 patients (41.4%), Tocilizumab intra venous 32 (20.4%) and sub cut in 10 patients (6.4%). Canakinumab 9 patients (5.7%), Anakinra 8 patients (5.1%) and Infliximab in 10 patients (6.4%). Oral Tofacitinib in 2 patients (1.3%). In regards to outcome as per Wallace criteria and JADAS 10; active disease in 16 patients (10.2%). In remission 141 patients (89.8%). Out of these in remission on treatment 118 (83.7%) and in remission off treatment 23 patients (16.3%). JADAI articular >0 in 8 patients (5%) and JADAI extra articular >0 in 14 patients (8.9%)
Conclusion: We have diverse cohort and high percentage of consanguinity in our families of children with JIA (34.4%). Biologic treatment required in 49% of patients. Patients In remission 89.8%. Out of this 83.77% in remission on treatment and 8.9% in remission off treatment. Further studies needed to understand our population better with focus of effect of consanguinity.

TREATMENT PATTERNS IN A POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS POPULATION IN GERMANY; A RETROSPECTIVE OBSERVATIONAL HEALTH CLAIMS DATA STUDY

Keywords: Disease-modifying Drugs (DMARDs), Epidemiology, Real-world evidence

G. Horneff[1,2], J. Borchert[3], J. Diesing[3], P. Klaus[4], R. Heinrich[3], H. Dally[5], C. Hagemann[5], S. Kock[6], T. Schoenfelder[3,7]. *[1]Asklepios Clinic Sankt Augustin, Department of General Paediatrics, Sankt Augustin, Germany*; *[2]University Hospital of Cologne, Department of Paediatric and Adolescents Medicine, Cologne, Germany*; *[3]WIG2, Health Services Research and Health Economics, Leipzig, Germany*; *[4]Pfizer Pharma GmbH, Inflammation & Immunology, Medical Affairs, Berlin, Germany*; *[5]Pfizer Pharma GmbH, Health Technology Assessment & Outcomes Research, Berlin, Germany*; *[6]InGef, Health Services Research, Leipzig, Germany*; *[7]Technische Universität Dresden, Chair of Health Sciences - Public Health, Dresden, Germany*

Background: Treatment of polyarticular juvenile idiopathic arthritis (polyJIA) aims to ease symptoms and inflammation and reduce further damage and comorbidities[1]. Current treatment options however are not universally effective. With the first targeted synthetic disease modifying anti-rheumatic agent having recently been approved information on how many polyJIA patients may potentially benefit from newly accessible treatment options is needed.
Objectives: Describe current treatment patterns around incident polyJIA diagnosis and beyond, especially changes in medication regimes indicative of unsatisfactory response.
Methods: In a retrospective, observational analysis of two different non-overlapping longitudinal health claims databases (the WIG2, Scientific Institute for Health Economics and Health System Research GmbH, and InGef, Institute for Applied Health Research Berlin GmbH, databases), a representative sample in terms of age and gender of the statutory health insurance (SHI) population in Germany (about 3.5 and 4 million patients, respectively) was analysed. Two incident JIA cohorts were evaluated (2014 and 2015) in each databank, and followed up for 4 or 3 years, respectively. All incident JIA patients (without a JIA diagnosis during baseline, the 4 quarters prior to index) aged 2 to 15 years in the respective observation year (2014 and 2015), with continuous data throughout the observation year and minimum 3-year follow-up (or deceased) were included. Patients were considered to have polyJIA if they had at least one inpatient ICD-10 GM (German modification) diagnosis code, or two verified outpatient codes in two different quarters in the year, of M08.0 (juvenile chronic polyarthritis, adult type, includes rheumatoid factor (RF)+ polyJIA), or M08.3 (juvenile chronic arthritis (seronegative), polyarticular form, includes RF- polyJIA and extended oligoarthritis). We evaluated top-prescribed and pre-defined medications (by 4-digit ATC code) before, during, and following, incident polyJIA diagnosis. The pre-defined medication groups were non-steroidal anti-inflammatory drugs (NSAIDs), glucocorticoids (GCs), conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs), and biologic disease modifying anti-rheumatic drugs (bDMARDs).
Results: Applying the inclusion and exclusion criteria to the incident JIA populations, we identified a total of 121 and 58 polyJIA patients in both 2014 and 2015, (of which 56 and 29 belonged to the 2015 cohort) in the InGef and WIG2 databases, respectively. Among the most frequently prescribed drugs were anti-inflammatory and anti-rheumatic drugs, specific anti-rheumatic agents, and nasal decongestants, immunosuppressive agents, vitamin B12 and folic acid. Prior to diagnosis, more than half of patients of the 2015 cohort were already receiving NSAIDs, however at diagnosis the use of csDMARDs increased more than bDMARD use. From diagnosis quarter to follow-up, there was a proportionally larger increase in the use of bDMARDs than csDMARDs, however use of all medications we examined (also NSAIDs and GCs) in our population continued to increase through follow-up (fig 1). Treatment patterns were similar for both cohorts (2014 and 2015).
Conclusion: Almost all patients continued to take NSAIDs during follow-up, many had concomitant medication with glucocorticoids in addition to csDMARDs or bDMARDs. This demonstrates there was an unmet need in the past for further advanced treatment options such as targeted synthetic DMARDs.

Background: Several studies have suggested a potential role for ultrasonography (US) in detecting enthesitis in children, thus enhancing the accuracy of the classification of juvenile idiopathic arthritis (JIA) and improving the therapeutic approach. Because of no consensual definition of ultrasonographic enthesitis in children, the pediatric sub-taskforce of the OMERACT working group posed the research question of whether there are sufficient data to support the role of US in the diagnosis and follow-up of enthesitis in JIA, particularly enthesitis related arthritis (ERA).

Objectives: We performed a systematic literature review (SLR) to assess the value of US for detecting enthesitis in JIA. The main objectives were to determine: i.which elementary lesions have been evaluated by US in JIA patients; ii.which definitions and scoring systems were used; and iii.the measurement properties of US in evaluating enthesitis in JIA according to the OMERACT Filter 2.1 Instrument Selection Algorithm (OFISA).

Methods: PubMed and Embase databases were searched for articles published from January 1966 to May 2022; we selected those meeting the inclusion criteria according to the US definition of enthesitis and metric properties studied. We assessed the clinical features of the population, study design, the type and number of entheses examined, the definition and scoring system of US enthesitis and metric properties according to the OMERACT filter (truth, discrimination, feasibility). The quality of the studies was evaluated with the Quality Assessment of Diagnostic Accuracy Studies 2.

Results: Five publications met the inclusion criteria (26 to 146 patients and 1 to 10 bilaterally examined entheses)[1-5]. All studies focused on lower-limb entheses. The elementary lesions included in the definition of adult enthesitis were generally assessed. Few studies reported US reliability, and none evaluated sensitivity to change of US. US revealed entheseal abnormalities in 9.4% to 53% of JIA patients and 20% to 83% of enthesitis-related arthritis cases. No significant abnormalities were found in healthy children. US findings were poorly correlated with clinical examination. The overall quality of the studies was low, mainly because of the lack of a reference standard.

Conclusion: US could be a sensitive tool to detect entheseal abnormalities in JIA. Nevertheless, the current evidence highlights that a standardized US definition of enthesitis in children is lacking and US criteria and discriminant validity have not been established.

AB1448 BISPHOSPHONATES IN (MONA) SPECTRUM DISORDER: TWO CASE REPORTS

Keywords: Rare/orphan diseases

I. Bencharif[1], D. Bendjenna[1], Y. Kitouni[1]. *[1]Faculty of Medicine - University of Constantine, Internal Medicine, Constantine, Algeria*

Background: Multicentric osteolysis, nodulosis and arthropathy (MONA) spectrum disorder is a rare inherited progressive skeletal disorder caused by mutations in the matrix metalloproteinase 2 (MMP2) gene. It characterized by multiple peripheral osteolysis, wide metacarpals, osteoporosis, progressive joint contractures, short stature, subcutaneous nodules as well as a coarse face, skin lesions/hirsutism and ocular and cardiac manifestations. The diagnosis is based on the typical clinical features together with normal laboratory findings, which allow this disease to be distinguished from other syndromes, including fibrotic, rheumatic and lysosomal diseases. Treatment options are limited.

Objectives: Bisphosphonates in (MONA) spectrum disorder may be an alternative therapeutic approach.

Methods: We present successful bisphosphonate therapy in two affected sisters, A.N, ten-year-old and A.I, seven-year-old, presented with history of fractures of their long bones after trivial traumas with progressive painful deformities in hands and feet with limitation motion. They were treated with bisphosphonates (intravenous zoledronate every 6 months). The following outcome variables were assessed: skeletal pain, range of motion, internal medical problems as well as neurocognitive function.

Results: Skeletal pain was reduced soon after initiation of therapy. Range of motion did not significantly improve. Neurocognitive development was normal. No further low-impact fractures occurred after starting bisphosphonate therapy. Although the nature of the disease is progressive, they are still able to walk and use their hands for writing.

Conclusion: Bisphosphonate therapy was effective especially in controlling skeletal pain and reducing fractures in MONA spectrum disorder. Early initiation of treatment seems to be particularly important in order to achieve the best possible outcome.

AB1449 **THE GENETIC DIVERSITY AND FEATURES OF TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS**

Keywords: Quality of life, Genetics/Epigenetics, Disease-modifying Drugs (DMARDs)

S. Vardanyan[1], V. Vardanyan[1], A. Sargsyan[1], N. Manukyan[1], K. Ginosyan[2]. [1]*Yerevan State Medical University,"Mikaelyan" Institute of Surgery, Rheumatology, Yerevan, Armenia*; [2]*Yerevan State Medical University, Rheumatology, Yerevan, Armenia*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic arthritis of childhood. Systemic JIA has many clinical features overlapping with familial Mediterranean fever, and MEFV gene mutations play a critical role in genetic background for JIA and influence the severity of the disease.
Objectives: 1.To find out associations between different immunological abnormalities, HLA-B27-positivity, carriage of familial Mediterranean fever (FMF) mutations, and clinical polymorphism of JIA. 2.To evaluate the effectiveness of treatment with DMARDs and NSAIDs.
Methods: 94 patients with confirmed JIA (100% male, mean age 14±2 years) were included in the study. All patients corresponded to ILAR criteria. 28 (29.8%) were treated with only NSAIDs, 66 (70.2%) with NSAIDs and sDMARDs (33/50%/ methotrexate, 33/50%/ sulfasalazine), 9 (13.6%) - with bDMARDs. The data is introduced as odds ratios (OR) with 95% confidence interval (CI). The results were considered significant when p<0.05.
Results: At baseline 17 (18.1%) patients were classified as a systemic, 13 (13.8%) - oligoarticular, 3 (3.2%) - polyarticular RF-positive, 8 (8.5%) - polyarticular RF-negative, 3 (3.2%) - psoriatic, 49 (52.1%) - enthesitis-related JIA. MEFV gene mutations were observed in 38 (40.4%) patients (35/92.1%/ - one heterozygous mutation, 3/7.9%/ - more than one mutation), FMF was diagnosed in 3 (3.2%) patients. We found positive significant association between MEFV carriage and systemic JIA (OR/CI95%/=10.3/2.7-39.2, p<0.01), as well as polyarticular RF-negative JIA (OR/CI95%/=5.3/1.5-10.6 p<0.05). Despite the MEFV carriage, colchicine was prescribed to only 5 (5.3%) patients. 28(29.8%) patients were HLA B27- positive and we found positive significant association between HLA B27-positivity and olygoarticular JIA (OR/CI95%/=5.6/2.3-15.7, p<0.05), as well as enthesitis-related JIA (OR/CI95%/=13.6/3.2-19.4/, p<0.01). Sacroiliitis was diagnosed in 85 (90.4%) patients, 26 (30.6%) – non-radiographic, 59 (69.4%) - radiographic. The rise in progression from non-radiographic sacroiliitis to radiographic significantly decreased in patients on methotrexate (OR/CI95%/=0.05/0.001-0.044/, p<0.01), compared to sulfasalazine (OR/CI95%/=0.78/0.36-2.79 p>0.05). For patients on DMARDs the disease had a self-limited course, without clinical manifestation in adulthood. Total remission was mostly associated with methotrexate (OR/CI95%/=13.5/1.6-95 p<0.01), in contrast to sulfasalazine (OR/CI95%/=0.69/0.28-1.72 p>0.05).
CONCLUSION:
1.The carriage of MEFV gene mutations increase the risk of manifestation of polyarticular and systemic JIA.
2.Early appointment of DMARDs together with NSAIDS makes it possible to stop the disease and prevent its transition to adult rheumatology.
3.Despite recent ACR treatment guidelines recommending NSAIDS and sulfasalazine for the treatment of sacroileitis, early administration of methotrexate also prevents the transition of nonradiographic sacroileitis to radiographic.

AB1450 **HIP INVOLVEMENT IN TUNISIAN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS**

Keywords: Prognostic factors, Inflammatory arthritides

M. Ardhaoui[1], D. Khalifa[1], O. Farhat[1], R. Fakhfakh[1], N. El Amri[1], K. Baccouche[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is characterized by widely heterogeneous clinical course and outcomes. Hips are the most commonly affected joints in severe uncontrolled JIA.
Objectives: The aim of our study was to determine the prevalence and associated factors of hip involvement in Tunisian JIA patients.
Methods: A retrospective and observational monocentric study including children with JIA according to the ILAR was conducted in the Rheumatology department of Sousse, Tunisia. We compared the disease parameters between the two groups with and without coxitis.
Results: We included 55 children (28 girls and 27 boys). The mean age was 13.6 years. The predominant subtypes of JIA were the seronegative polyarticular JIA (38.2%), and the seronegative oligoarticular form and juvenile spondyloarthritis (16.4% each). Biological inflammatory syndrome was found in 65.5% of cases. The mean ESR and CRP was 42.4mm/h and 28.8mg/l respectively. Hip involvement concerned 30.9% of the patients (n=17) and was bilateral in 64.7% of cases (n=11). Coxitis occurred on average 10 years after the JIA onset. The mean Lequesne index was 12. Hip radiographs were normal in 40% of cases. Magnetic resonance imaging was performed in 25% of cases and revealed synovitis in 70% of cases. Overall, 61.8% of patients had medical treatment combining non steroidal anti-inflammatory drugs and rehabilitation. Only two patients had local infiltration with Hexatrione. In 12.7% of cases (7 cases), a total hip replacement was necessary. Hip involvement was significantly associated with younger age at onset (p=0.02), polyarticular subtype of JIA (p=0.04) and with the presence of biological inflammatory syndrome (p=0.03). However, coxitis was not significantly associated with gender, the duration of JIA progression, extraarticular manifestations, structural damage or the different used treatments.
Conclusion: Our study showed that hip involvement is frequent among Tunisian patients with JIA. Coxitis was associated with the polyarticular subtype, with biological inflammatory syndrome and younger age at onset of JIA.

AB1451 **THE HIP RADIOGRAPHIC SCORE IS CORRELATED WITH THE LATE-ONSET OF JUVENILE IDIOPATHIC ARTHRITIS**

Keywords: Imaging

A. Dghaies[1], H. Ferjani[1], K. Maatallah[1], D. Ben Nessib[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Rheumatology, Manouba, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease in children affecting mobility and physical function. The hip is a load-bearing joint and its damage has a significant functional impact. An appropriate scoring system is mandatory to monitor structural progression and damage over time. The childhood Arthritis Radiographic Score of the Hip (CARSH) is a valid score covering the osteoarticular changes in the hip joint as space narrowing, erosions, malalignment, sclerosis, flattening of the femoral head, and growth abnormalities [1].
Objectives: The aim of this study was to assess radiographic changes in the hip joint using the CARSH in children suffering from JIA with hip involvement and to determine the impact of disease factors in this score.
Methods: This cross-sectional study was conducted in the pediatric rheumatology department and included patients with JIA according to the ILAR criteria. We included children with hip involvement defined as the presence of hip pain and/or limping and range motion limitation, and/or abnormal hip findings in pelvic radiography, ultrasound, or MRI. We collected from the recorded data demographics, disease characteristics [symptom duration, disease presentation, JIA subtypes], and disease activity: Juvenile arthritis disease activity (JADAS10). Experimented and blinded pediatric rheumatologists read the pelvic radiograph using the Childhood Arthritis Radiographic Score of the Hip (CARSH).
Results: Twenty-two children with a mean age of 13 years [5-22] were included in the study. The gender ratio was 1.4 (13 Males/9 Females). The median age of disease onset was 9.5 years [4-14]. The mean duration of the disease was 47 months [4-156]. The diagnostic delay median was 22 months [1-120]. The patient global assessment (PGA) median was 4 [0-8]. The visual analog scale (VAS) median was 3.6 [0-8]. The sedimentation rate (SR) and the C reactive protein (CRP) median were 25 [2-65] and 10 [1-47]; respectively. The JADAS median was 6 [0-18]. Forty-four hips were analyzed. The median score of CARSH was 1.8 [0-7]. The CARSH was positively correlated to the age of disease onset (r = 0.4; p = 0.04). No other significant correlations were found between the CARSH and the gender (p= 0.3), the duration of the disease (r = 0.7; p = 0.7), the diagnostic delay (r = 0.02; p = 0.9), the PGA (r = 0.1; p = 0.5), the VAS (r = -0.4; p = 0.8), the ESR (r = -0.08; p = 0.7), the CRP (r = -0.1; p = 0.6) and the JADAS 10 (r = 0.01; p = 0.9).
Conclusion: This study showed that the radiographic score CARSH was correlated to the age of disease onset. Our findings confirm that structural damage was more important in late-onset disease whereas early hip involvement affects growth and joint development.

ABO BLOOD GROUPS AND INCREASED RISK FOR VASCULAR INVOLVEMENT IN THE PATIENTS WITH BEHÇET'S DISEASE

Keywords: Organ damage, Vasculitis, Behcet's disease

E. Bektaş[1], A. Büyükdemir[2], Y. Yalçınkaya[3], B. Artim-Esen[3], M. Inanc[3], A. Gül[3]. *[1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey*; *[2]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey*; *[3]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Behçet's disease (BD), a multisystem inflammatory disorder of unknown etiology, is classified as a variable vessel vasculitis affecting all types and sizes of blood vessels; and a tendency for thrombosis in association with inflammatory endothelial activation is an important characteristic of BD vasculitis. Recent studies suggest an association between ABO blood groups and vascular disease in particular in those carrying non-O (A, B, and AB) groups [1].
Objectives: We aimed to investigate the potential contribution of ABO blood groups to the risk of vascular involvement in patients with BD.
Methods: We retrospectively analyzed the records of BD patients followed between 1978 and 2022. Patients fulfilling the ISG Criteria for diagnosis of BD were screened, and those with information about ABO blood groups were included into the study. Presence or absence of vascular involvement and its features were recorded using a standard form. The chi-square test, t-test, Mann-Whitney U test, and logistic regression tests were used for statistical analyses.
Results: The study group consisted of 411 patients with available blood group data, and 143 (34.8%) were carrying O [58% men, mean age at diagnosis 31.4±10.1 years, median follow-up period 153 (98-219) months], and 268 (65.2%) were carrying non-O blood groups [60.1% men, mean age at diagnosis 30.7±8.4 years, median follow-up period 148 (92-204) months]. There was no statistical significance between O and non-O groups in regard to the potential confounding factors affecting the risk for vascular disease, including sex, age at diagnosis, family history, HLA-B51 positivity, smoking, comorbidities, and prothrombotic mutations. Vascular involvement was observed in 39 (27.3%) patients with blood group O [venous in 35 (24.5%), and arterial in 11 (7.7%)], whereas 109 patients (40.7%) with non-O blood groups had vascular involvement [venous in 95 (35.4%), and arterial in 38 (14.2%)]. The frequencies of total vascular and venous involvements between the two groups were significantly different (p=0.007, p=0.023, respectively). Unadjusted and adjusted ORs with different models in the multivariate logistic regression analyses are shown in **Table 1**. After adjustments for age, sex and comorbidities, the risk for arterial disease was also found to be increased in association with non-O blood groups.
Conclusion: Vascular involvement with a tendency for thrombosis is an important feature of BD, and inflammatory characteristics resulting in endothelial dysfunction have been considered as the main underlying pathology. The results of the preliminary study supports the previous reports revealing the potential contribution of ABO blood groups in the development of vascular disease and suggest an approximately two-fold increased risk for vascular involvement in BD patients.

INFLAMMATION MARKERS, SYSTEMIC INFLAMMATORY BASED SCORES (SIBS) AND CYTOKINE PROFILES IN ADULT CHRONIC NONBACTERIAL OSTEOMYELITIS (CNO)/ SAPHO SYNDROME: AN IMMUNOLOGICAL CHARACTERIZATION

Keywords: Bone diseases, Adaptive immunity, Rare/orphan diseases

A. Leerling[1,2], E. Andeweg[1,2], J. Faber[1], T. Streefland[1], O. Dekkers[1,3], N. Appelman-Dijkstra[1,2], E. Winter[1,2]. *[1]Leiden University Medical Center (LUMC), Internal Medicine, Division of Endocrinology, Leiden, Netherlands*; *[2]Leiden University Medical Center (LUMC), Center for Bone Quality, Leiden, Netherlands*; *[3]Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands*

Background: Chronic non-bacterial osteomyelitis (CNO) is a rare bone disease occurring in children and adults. Adults mainly present with osteitis and hyperostosis of the anterior chest wall, sometimes occurring in the context of synovitis, acne, pustulosis, hyperostosis, osteitis (SAPHO) syndrome [1]. CNO is hypothesized to be an auto-inflammatory disease, as studies on pediatric patients have shown raised erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), and elevated serum concentrations of interleukin (IL)-6, 8, 17A and TNF-a [2]. For adults, however, the suspected systemic immune activation is not consistently reflected by these generic markers, and data on cytokine expression are scarce and variable [3, 4].
Objectives: To provide broad immunological characterization of adult CNO/ SAPHO, including cytokine profiles, compared to controls.
Methods: Cross-sectional study in our CNO referral center including adult CNO/ SAPHO patients with active disease (n=172) and controls (n=82) referred between 1992-2022 not using immunomodulatory treatment (exempting NSAIDs) or bisphosphonates. Generic inflammation parameters and systemic inflammatory based scores (SIBS) were compared between patients and controls and between patients with and without concomitant arthritis/dermatitis, and with strong or moderate increase in isotope uptake on nuclear imaging. Serum levels of Th1/2 and Th17-derived cytokines were determined with electrochemiluminescent immunoassays, and receptor activator of nuclear factor kappa beta (RANKL) and osteoprotegerin (OPG) with ELISA in 33 patients and 8 controls.
Results: ESR, CRP, platelet, leucocyte and neutrophil count were higher in CNO/SAPHO patients than in controls, but generally remained within the reference range. ESR was also higher in patients with concomitant arthritis/dermatitis compared to isolated osteitis (24 versus 16, *p=0.009*), and in patients with strongly rather than moderately increased isotope uptake on nuclear imaging (20 versus 13, *p= 0.009*). Neutrophil-derived SIBS (neutrophil/lymphocyte ratio (NLR) and systemic immune inflammation index (product of NLR and platelet count)) were elevated in CNO patients compared to controls. Cytokine analyses revealed no differential expression for IL-6, -8, -10, -13, -17A, -22, -23, -27, TNF-a, IFN-γ, and MIP-3a, nor for the bone markers RANKL and osteoprotegerin.
Conclusion: In this adult CNO/SAPHO cohort, generic inflammation markers and neutrophil-derived SIBS NLR and SII were increased compared to controls. In contrast to previous studies, we found no differential expression of IL-6, -8, -17A and TNF-a to support systemic cytokine imbalance in adult CNO/SAPHO. Further studies are needed to evaluate whether the auto-inflammatory hypothesis in CNO/SAPHO applies as much to the adult as pediatric subtype, and if so, whether the local inflammasome is systemically reflected.

AB1454 **DIAGNOSTIC AND THERAPEUTIC PRACTICES IN ADULT CHRONIC NONBACTERIAL OSTEOMYELITIS (CNO)/SAPHO SYNDROME: AN INTERNATIONAL LANDSCAPE**

Keywords: Quality of care, Bone diseases, Rare/orphan diseases

A. Leerling[1,2], G. Clunie[3], E. Koutrouba[1,2], O. Dekkers[1,4], N. Appelman-Dijkstra[1,2], E. Winter[1,2]. [1]*Leiden University Medical Center (LUMC), Internal Medicine, Division of Endocrinology, Leiden, Netherlands*; [2]*Leiden University Medical Center (LUMC), Center for Bone Quality, Leiden, Netherlands*; [3]*Cambridge University Hospitals NHS Foundation Trust, Rheumatology, Cambridge, United Kingdom*; [4]*Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands*

Background: Chronic nonbacterial osteomyelitis (CNO) is a rare auto-inflammatory bone disease. CNO, especially the adult variant, may occur in the broader spectrum of Synovitis, Acne, Pustulosis, Hyperostosis, Osteitis (SAPHO) syndrome. Adult CNO lacks diagnostic or management guidelines in contrast to pediatric disease (1, 2).
Objectives: We mapped current diagnostic and therapeutic practices for CNO/SAPHO in adults.
Methods: A primary survey was spread among global rheumatological/bone networks and 57 experts as identified from literature (May 2022), covering terminology, diagnostic tools (clinical, radiological, biochemical) and treatment steps. A secondary survey (sent to primary survey responders in August 2022) further queried diagnostic features, treatment motivations, disease activity and treatment response monitoring.
Results: 36 and 23 physicians completed the primary and secondary survey respectively. Diagnosis was mainly based on individual physician assessment, in which the combination of chronic relapsing-remitting bone pain with radiologically-proven osteitis/osteomyelitis, sclerosis, hyperostosis and increased isotope uptake on bone scintigraphy were reported indicative of CNO. Physicians appeared more likely to refer to the condition as SAPHO syndrome in the presence of joint and skin pathology. MRI was most frequently performed as imaging diagnostic, and the preferred diagnostic test for 47%. X-rays were second-most frequently used, while considered least informative. Typical imaging features reported were hyperostosis, osteitis, osteosclerosis, bone marrow edema, while degeneration, soft tissue calcification, and ankylosis were not regarded characteristic. Inflammation markers and bone markers were generally regarded unhelpful for diagnostic and monitoring purposes, and physicians infrequently performed bone biopsies. Management strategies diverged, including indications for treatment, response monitoring and declaration of remission. Step-1 treatment generally consisted of non-steroidal anti-inflammatory drugs/COX-2 inhibitors (installed by 83%). Common step 2-3 treatment were pamidronate, methotrexate, and TNF-a-inhibition (anti-TNFα), the latter two regarded especially convenient to co-target extra-skeletal inflammation as often seen in SAPHO syndrome. Pamidronate and anti-TNFα and were considered as most effective treatments overall.
Conclusion: Adult CNO appears to be a condition embedded within a broad and insufficiently characterized disease spectrum, likely including SAPHO syndrome. MRI is the favoured imaging diagnostic, while biochemical and histopathological investigations are rated less useful. Management strategies for CNO/SAPHO vary but pamidronate and anti-TNFα are commonly regarded most successful treatments. The survey results lay out current practices for adult CNO/SAPHO, which may serve as backbone for a future consensus clinical guideline.

Background: Chronic nonbacterial osteomyelitis (CNO) is a rare bone disease characterized by sterile bone inflammation and locally increased bone turnover. CNO that occurs in the rheumatic spectrum of synovitis, acne, pustulosis, hyperostosis and osteitis is referred to as SAPHO syndrome [1, 2]. To date, there are no objective biomarkers for monitoring disease activity. Recommended imaging tools like technetium radiolabeled hydroxymethylene diphosphonate single positron emission computed tomography visualize the increased bone turnover, but fail to reflect the relapsing-remitting disease activity course due to an imprinting pattern [3]. Likewise, magnetic resonance imaging can track the fluctuation of bone marrow edema, but is inferior compared to computed tomography (CT) in capturing subtle inflammatory and accumulated structural changes that reflect disease duration. Sodium fluoride-18 positron emission tomography/CT($Na^{18}F$-PET/CT) is another imaging modality which produces quantitative data on the spatial distribution of bone turnover that also correlate with clinical disease activity in other metabolic bone diseases [4].
Objectives: We quantified ^{18}F-uptake in CNO/SAPHO patients to evaluate its capacities as a disease activity biomarker.
Methods: Cohort study including 43 CNO/SAPHO patients not using immunomodulatory or antiresorptive medications with $Na^{18}F$-PET/CT performed at our expert clinic between 2019-2022. Images were qualitatively assessed following a systematic reporting format. Maximal standardized uptake values (SUV_{max}) were determined in the following areas as defined by radiologic appearance on CT: osteitic areas (osseous lesions), inflamed ligaments or joint spaces (soft tissue lesions) and thoracic vertebrae 5 as reference bone (ref-bone).
Results: Qualitative assessment revealed sclerosis and hyperostosis of the manubrium as most prevalent radiologic features (present in 77% and 70%) and costae 1-2 (79% each). Calcification/ankylosis of the costoclavicular ligament was seen in 58%. Quantitative analyses showed higher SUV_{max} of osseous and soft tissue lesions compared to ref-bone (mean 22±6 and 26±9 vs. 11±3 g/mL, $p<0.001$ for paired difference). Stratified per location, highest SUV_{max} was found in soft tissue lesions of the costoclavicular ligament followed by the manubriosternal joint (mean SUV_{max} of 29±13 and 25±8 respectively). SUV_{max} in soft tissue lesions positively correlated with erythrocyte sedimentation rate (Spearman correlation coefficient 0.546, $p<0.01$).
Conclusion: CNO/SAPHO patients display distinctive qualitative imaging features that are well-captured on $Na^{18}F$-PET/CT, and also show higher SUV_{max} in osseous and soft tissue lesions compared to ref-bone. Diseased soft tissue lesions showed highest SUV_{max}. Considering $Na^{18}F$ precipitates in young osteoid, these high values may reflect the process of soft tissue ossification that is common in long-existing CNO/SAPHO, as also demonstrated in fibrodysplasia ossificans progressiva [5]. Further studies should evaluate the promising application of quantified uptake on $Na^{18}F$-PET/CT as a novel biomarker for disease activity and therapy response in CNO/SAPHO.

Background: A new autoinflammatory syndrome related to somatic mutations of *UBA1* was recently described and called VEXAS syndrome.
Objectives: To describe clinical characteristics, laboratory findings and outcomes of VEXAS syndrome.
Methods: Case-series. Patients referred to a French multicenter registry between November 2020 and January 2022. Frequency and median of parameters and vital status, from diagnosis to the end of the follow-up.
Results: Among 256 patients, 207/221 (94%) were males with median age at diagnosis 65 years [49-86]. Main clinical features were skin lesions (n=215; 84%), non-infectious fever (n=121; 47%), lung involvement (n=146; 57%), relapsing chondritis (n=69; 27%), venous thrombosis (n=128; 50%), lymph nodes (n=55; 21%), and arthralgia (n=65; 25%) with arthritis (n=26). Ocular inflammatory involvement was present in 119 cases (46%), mainly uveitis (n=21) and scleritis/ episcleritis (n=43). Peripheral nervous system was noted in 18 patients (7%) with peripheral neuropathy (n=11), multinevritis (n=3) and PIDC (n=5). The skin lesions were mainly neutrophilic dermatosis (n=74) and vasculitis (n=45). Hematological disease was present myelodysplastic syndrome (MDS, n= 81; 32%), monoclonal gammapathy of unknown significance (n=18), chronic myelomonocytic leukemia (n=7). AA amyloidosis was present in 2 cases. Median CRP levels were at 56 [1-423] mg/l, with abnormal somatic mutations in 44 cases (%) mostly TET2 and DNMT3. Previous immunosuppressive therapies were methotrexate (n=15; 6%), cyclophosphamide (n=6; 3%), MMF (n=5; 4%). JAK inhibitors were used in 24 cases and were stopped in 5 cases (3 for inefficacy and 2 for adverse events). IL1R inhibitors were used in 12 cases with discontinuation for inefficacy (n=7) and adverse events (n=1), and IL6R inhibitors in 12 cases with discontinuation for inefficacy in 4 cases and adverse events in 1 cases.
Conclusion: This is the largest multicenter cohort of VEXAS syndrome and which allow to compare for the first time the efficacy and tolerance of various biologics and JAK inhibitors and seem confirm the benefit of JAKi and also of tocilizumab.

MULTIDISCIPLINARY PROSPECTIVE STUDY OF PATIENTS TREATED WITH IMMUNE CHECKPOINT INHIBITORS WHO DEVELOPED RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS

Keywords: Descriptive Studies, Organ damage, Epidemiology

M. D. C. López González[1], N. Martínez Banaclocha[2], M. García Araque[2], Y. Montoyo Pujol[2], M. Andrés[1]. [1]*Hospital General Universitario Dr. Balmis-ISABIAL, Rheumatology, Alicante, Spain*; [2]*Hospital General Universitario Dr. Balmis-ISABIAL, Oncology, Alicante, Spain*

Background: Immune checkpoint inhibitors (ICIs), by activating the immune system (specifically, T-cells), foster the reaction against tumor cells. However, parallelly, autoimmune phenomena, known as immune-related adverse effects (ir-AEs) (PMID 33902919, 29442540), can be triggered and manifest in any organ or tissue. The most common rheumatic manifestations are inflammatory arthritis, polymyalgia rheumatica, and myositis, but other inflammatory cases have also been described (PMID 32403289). More data on their frequency and characterization are needed.
Objectives: To prospectively evaluate the incidence of rheumatic ir-AEs during ICIs treatment, along with clinical characterization, management required, and outcomes.
Methods: An observational, prospective study was conducted at a tertiary center in Spain, led by the oncology department with the participation of several specialties, to evaluate the occurrence of ir-AEs in patients starting ICIs between January 2019 and April 2022. Participants were routinely followed at oncology clinics to detect ir-AEs through pre-specified clinical and laboratory assessments. For rheumatic symptoms, ir-AEs were studied by records review and evaluated in person at rheumatology clinics for those with a degree of involvement of ≥2, according to the ASCO guidelines [3]. The incidence - with a 95% confidence interval (CI) - and characterization of defined rheumatic ir-AEs are presented here.
Results: Of 181 patients, 21 (11.6%, 95%CI 7.7-17.1%) developed rheumatic ir-AEs, 13 men (61.9%) with a median age of 62.3 years (p25-75 51.8-75.0). The median time from the start of ICIs to the development of rheumatic ir-AEs was 85 days (p25-75 51.5-165). Blood tests for autoimmunity were positive in 69.2% of available cases (9/13), but all at a low titer **(table 1)**. According to ASCO guidelines, most patients had a toxicity grade 1-2, but 3 (14.3%) patients presented with severe manifestations (grade 3): 1 (4.8%) case of inflammatory arthritis, 1 (4.8%) of xerostomia, and 1 (4.8%) of Raynaud's phenomenon with ulcers. 9 (42.9%) patients also presented with concurrent ir-AEs of different types. Rheumatic ir-AEs were successfully settled, though infliximab and intravenous vasodilators were required for some cases. While discontinuing ICIs was mostly due to neoplasm progression (47.6%), in 3 cases (14.3%) it was due to grade-3 rheumatic manifestations. 7 (33.3%) patients died during follow-up due to the oncological disease, no case due to rheumatic toxicity.

Table 1.

Type of tumor n (%)	Drug n (%)	Clinical presentation (%)	Antibodies n (%)	Treatment n (%)	Outcome n (%)
Lung 9 (42.9)	Pembrolizumab 8 (38.1)	Inflammatory arthritis 7 (33.3)	ANA 8 (38.1)	No rheumatological treatment 10 (47.6)	Discontinuation of ICI due to progression 10 (47.6)
Melanoma 4 (19.0)	Nivolumab 7 (33.3)	Xerostomia 5 (23.8)	Anti-centromere 1 (4.8)	Glucocorticoids 8 (38.1)	Discontinuation of ICI due to severe ir-AEs 4 (19.0)
Hodgkin's lymphoma 2 (9.5)	Nivolumab + Ipilimumab 3 (14.3)	Polymyalgia-like syndrome 5 (23.8)	Rheumatoid factor 1 (4.8)	Hydroxychloroquine 3 (14.3)	ICI is currently ongoing 4 (19.0)
Kidney 2 (9.5)	Atezolizumab 3 (14.3)	Myositis 4 (19.0)	ACPA 1 (4.8)	Pilocarpine 2 (9.5)	Completed ICI regimen 2 (9.5)
Esophagus 1 (4.8)		Raynaud's phenomenon with ulcers 1 (4.8)	Anti-TIF1γ 1 (4.8)	NSAIDs 2 (9.5)	Lost to follow-up 1 (4.8)
Bladder 1 (4.8)				Infliximab 1 (4.8)	
Mesothelioma 1 (4.8)				Vasodilators 1 (4.8)	

Conclusion: Through a prospective and multidisciplinary study, we estimated an 11.6% of occurrence of rheumatic ir-AEs in patients under ICIs. Most presented with mild or moderate involvements, though severe cases were also seen. A coordinated approach with the oncologists is thus essential for patients treated with ICIs at risk of developing ir-AEs.

TREATMENT UTILIZATION, SYMPTOMS, AND COMORBIDITIES IN DERMATOMYOSITIS: AN ANALYSIS OF ELECTRONIC MEDICAL RECORDS IN THE UNITED STATES

Keywords: Comorbidities, Myositis, Real-world evidence

A. Kielhorn[1], Z. Wang[1], K. Moy[1], L. Christopher Stine[2], I. E. Lundberg[3], H. Chinoy[4], K. Gunter[5], R. Aggarwal[6]. [1]*Alexion, AstraZeneca Rare Disease, Research and Development, Boston, United States of America*; [2]*Johns Hopkins University, Department of Medicine, Baltimore, United States of America*; [3]*Karolinska Institute, K2 Department of Medicine, Stockholm, Sweden*; [4]*University of Manchester, Department of Rheumatology, Manchester, United Kingdom*; [5]*Patient Author, N/A, Norfolk, United States of America*; [6]*University of Pittsburgh, Department of Medicine, Pittsburgh, United States of America*

Background: Dermatomyositis (DM) is a rare, chronic inflammatory disease characterized by skin manifestations and/or progressive muscle weakness and other systemic manifestations. Prior analyses have reported higher morbidity, hospitalization rates, and mortality among patients with DM compared with matched controls[1-3]; however, more recent data on the disease burden and treatments for DM are warranted.
Objectives: We conducted this analysis to provide updated data on the treatment utilization, symptoms, and comorbidities recorded for patients with myopathic DM in the United States.
Methods: This was a descriptive, retrospective cohort analysis that used TriNetX US electronic medical records (EMR) of adults who had been diagnosed myopathic DM (ICD-9 codes: 710.3/ICD-10: M33.1x, M33.9x, M36.0) between 1 January 2007 and 1 September 2020. Key inclusion criteria were: age ≥18 years at index date (i.e., date of DM diagnosis), ≥6 months of baseline data before the index date, and ≥6 months of follow-up after the index date. Assessments included utilization rates for medications of interest prior to the index date, percentage of patients who received ≥2 consecutive unique non-steroidal immunosuppressive therapies within 12 months of the index date, classification and qualification of the most common post-index symptoms and comorbidities, along with their comparison to pre-index values.
Results: The TriNetX database contained 1097 patients with DM (mean age: 54.6 years; sex: 77% female). The mean observation period was 9.7 years (6.0 years pre-index; 3.7 years post-index). Prior to the DM index date, 60% of patients

were prescribed steroids and 24% were prescribed ≥1 non-steroidal immunosuppressive therapy. Within 3, 6, and 12 months of index date, 8%, 14%, and 20% of patients, respectively, received ≥2 immunosuppressive therapies (ISTs). A 2–3-fold increase in percentage was seen post-index compared with pre-index for a wide range of symptoms and comorbidities, including gastroesophageal reflux disease (43% and 22%, respectively), anxiety (25% and 13%), interstitial lung disease (26% and 10%), and osteoporosis (21% and 6%).

Conclusion: In this analysis of TriNetX EMR data, the majority of patients who were diagnosed with myopathic DM had received immunosuppressive therapies for an extended time to treat their symptoms before they received a formal DM diagnosis, which may have contributed to the delay in DM diagnosis. One fifth of patients had received ≥2 ISTs within 12 months of DM diagnosis, suggesting that even after receiving standard of care treatments, many patients experience DM symptoms that are difficult to control and/or tolerate. A wide range of symptoms and comorbidities increased post-DM diagnosis. These results highlight the remaining unmet need for earlier diagnosis and therapies that better control symptoms for patients with myopathic DM.

Background: IgG4 immunoglobulin-related disease (IgG4-RD) is a rare, systemic immune-mediated fibro-inflammatory process with unclear etiology and pathophysiology. Can affect multiple organs that encompass common pathophysiological, serological and clinical characteristics.

Objectives: To describe the heterogeneity of the clinical presentation, evolution, and treatment of patients diagnosed with IgG4-RD and compare the performance of the last two IgG4-RD classification and diagnostic criteria.

Methods: Single-center retrospective study in which patients with a possible diagnosis of IgG4-RD from various hospital departments are studied from January 2010 to August 2022. Some exclusion criteria were applied (patients with clinical manifestations attributable to other diseases were excluded) and to those who remained with a suspected diagnosis of IgG4-RD, the Umehara-Okazaki 2011 and ACR/EULAR 2019 criteria were applied.

Results: 182 patients with elevated IgG4 and/or a suspected diagnosis of IgG4-RD were collected. Finally, after exclusion criteria, 22 possible patients with IgG4-RD remained (Table 1). The diagnostic criteria proposed by Umehara and Okazaki in 2011 are applied to these patients, including a total of 13 patients, with a mean age of 60 years, 57% women; 5 being classified with definitive disease, 3 as probable disease and 5 as possible disease. Finally, we applied the ACR/EULAR 2019 classification criteria to those patients too, establishing diagnosis in 7 patients. The mean age was 57 years, 71% were women with a mean follow-up of 5.3 years; 85.71% of the patients had elevated IgG4, with mean levels of 176.3 mg/dL. Retroperitoneal fibrosis and aortitis was the most prevalent presentation in both groups (2011 and 2019 criteria) with 38.5% and 28.6% respectively.

Conclusion: IgG4-RD is a recently described entity that is very heterogeneous in terms of its clinical, analytical and histopathological presentation. According to our series, clinical heterogeneity is the rule, being the retroperitoneal fibrosis and aortitis the most frequent. There are differences when we use the different criteria. ACR/EULAR 2019 classification criteria are stricter criteria that allows us to classify patients more accurately. In our series 6 patients fulfilled Umehara-Okazaki criteria but not ACR/EULAR due to giving more importance to histopathology, clinical manifestations and the need to reach a minimum score in which, for example, only IgG4 levels are not enough. Therefore, on many occasions, a multidisciplinary approach with experienced teams is necessary.

CHARACTERISTICS AND EARLY OUTCOMES OF PALINDROMIC RHEUMATISM: AN INCEPTION COHORT FROM INDIA

Keywords: Synovium, Inflammatory arthritides, Autoantibodies

P. Mehta[1], T. Skaria[2], M. Pai[2], G. B[2], A. Baby[2], S. Shan[2], A. Vijayan[2], S. Ahmed[3], P. Shenoy[2]. *[1]King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India*; *[2]Centre for Arthritis and Rheumatism Excellence, Clinical Immunology and Rheumatology, Kochi, India*; *[3]Kalinga Institute of Medical Sciences, Clinical Immunology and Rheumatology, Bhubhaneshwar, India*

Background: The exact pathogenesis and risk factors of Palindromic Rheumatism (PR) remain uncertain, however, a subgroup of patients with PR share a close relationship with rheumatoid arthritis (RA) in terms of etiopathogenesis, clinical features, serology, and outcomes.
Objectives: We aim to describe the characteristics of patients in an inception cohort of PR along with determinants of progression to RA.
Methods: Patients with symptoms suggestive of PR were screened by a rheumatologist and after relevant exclusions, were classified into PR and included in an inception cohort at the Centre for Arthritis and Rheumatism Excellence, India. Their demographics, clinical characteristics, serology, inflammatory markers, and progression to RA or any other autoimmune rheumatic disease(AIRD) were recorded. Statistical analysis was done using GraphPad Prism v9.4.1 and results are expressed as mean ± standard deviation.
Results: Of 706 patients screened, 685 were classified into PR (age 45.5±11.9 and male-to-female ratio of 1:2.8) with a follow-up duration of 27±20.4 months. Of those with a follow-up of greater than one year, 102 of 505 (20.2%) progressed to RA at 30± 20 months and 13 to other AIRDs. Progression to RA was positively associated with a greater number of attacks per month; severe PR or >20 attacks per month; shoulder or wrist joint involvement, absence of erythema, positive rheumatoid factor, anti-CCP antibody, and ANA on univariate analysis. Additionally, they required treatment with a higher number of cDMARDs and even anti-TNFs (Table 1). On multivariate analysis, symptom duration of <5 years, wrist involvement, and anti-CCP positivity were associated with progression to RA. The RF and anti- CCP titers showed no association with progression to RA.
Conclusion: Early outcomes of the inception cohort of PR revealed progression to RA in 20% of the cohort and was associated with symptom duration of <5 years, wrist involvement, and anti-CCP positivity. The PR group was treated predominantly with colchicine and cDMARDs with a remission rate of 60%.

COLCHICINE INTOLERANT FAMILIAL MEDITERRANEAN FEVER PATIENTS RECEIVING IL-1 ANTAGONISTS: DO THEY MISS ADVANTAGE OF COMBINATION

Keywords: Rare/orphan diseases, Prognostic factors

D. Yildirim[1], B. Özkızıltaş[1], I. Vasi[1], R. C. Kardaş[1], R. Duran[1], H. Karadeniz[1], A. Avanoglu Guler[1], H. Küçük[1], A. Erden[1], B. Goker[1], M. Ozturk[1], A. Tufan[1]. *[1]Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*

Background: Colchicine is the mainstay of Familial Mediterranean Fever treatment, whereas interleukin-1 antagonists (IL1A) are the treatment of choice in refractory or intolerant cases [1,2].
Objectives: Aim of the study was to evaluate clinical and laboratory processes and damage status of FMF patients who colchicine resistant and/or intolerant and compare them with FMF patients who got effective doses.
Methods: A total of 125 patients diagnosed as FMF and treated with IL-1 antagonists were enrolled to the study. Study population was divided into two group according to the use of colchicine group 1 was consisted of 96 patients treated with IL1A+colchicine combination and group 2 was 29 patients only treated with IL1A due to resistance and/or intolerance to colchicine. Demographic, clinical and laboratory features were compared between tretament groups.
Results: Clinical activity and damage scores were similar between groups. Damage parameters were also assesed seperately and showed significantly higher rate of disease related amenorrhea in those patients terated with IL1A alone (p=0,017).
Conclusion: We concluded that colchicine should be added to treatment but colchicine resistant or intolerant FMF patients may be effectively treated with IL-1 antagonists alone.

AB1462 EFFECTIVENESS OF THE STILL ACTIVITY SCORE IN ADULT-ONSET STILL'S DISEASE

Keywords: Rare/orphan diseases

E. Uslu Yurteri[1], M. E. Yayla[1], B. Atmaca Haktanıyan[2], N. Göveç Gıynaş3, D. Sahin Eroglu[1], A. İlbay3, R. Yılmaz3, A. Usta3, Y. Mahmutoğlu3, T. M. Turgay3, G. Kınıklı3, A. Ates3. *[1]Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[2]Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey*; *[1]Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Adults Still's disease is a rare autoinflammatory disorder with an unknown etiology, characterized by fever, arthritis, and rash. There is no method to fully evaluate the disease's activity [1].

Objectives: The Still Activity Score (SAS) is a newly defined, easy-to-use disease activity assessment score for Still disease [2]. We aimed to compare the efficacy of the Modified Pouchot Activity Score (mPouchot), Systemic Feature Score (SFS), and Still Activity Score (SAS) [2-4].

Methods: The study included 45 patients diagnosed with Still between 2010 and 2022 who met the Yamaguchi criteria. The patients were assessed using the physician global assessment (PGA) by two different physicians. Still, activity levels were computed. According to the severity of the disease, patients with PGA<6 were categorized as having low disease activity, and those with PGA>6 as having high disease activity.

Results: The demographic, clinical, and laboratory data for the patients are detailed in Table 1. There was a significant difference between the two groups in terms of mPouchot and SFS disease activity scores (low and high disease activity) (Table 1). CRP level was correlated with the SAS, SFS, and mPouchot disease activity scores (respectively; p=0.43, p=0.008, and p=0.011). Ferritin level was correlated with mPouchot and SFS disease activity score (respectively; p<0.001, p=0.007) (Figure 1). There was a correlation between each score(p<0.001).

Conclusion: SAS, a new disease activity score, correlated with previous activity scores. CRP levels were correlated with SAS. There was a correlation between the three disease activity scores.

AB1463 AVASCULAR NECROSIS BONE IN CHRONIC GRAFT-VERSUS-HOST DISEASE POST-ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

Keywords: Pain, Bone diseases

M. Ibáñez Martínez[1], S. Pastor Navarro[1], B. Miguel Ibáñez[1], C. C. Chacón Vélez[1], A. I. Turrión Nieves[1], O. Martínez González[1], S. Gómez Castro[1], C. Montila Morales[1], C. Hidalgo Calleja[1]. *[1]Salamanca University Hospital, Rheumatology, Salamanca, Spain*

Background: Graft-versus-host disease (GVHD) is the most frequent complication after allogeneic hematopoietic cell transplantation (allo-HCT). The first line of treatment for moderate-severe chronic GVHD (cGVHD) is usually high and prolonged doses of corticosteroid therapy. Avascular necrosis bone (AVN) is a complication that appears after allo-HCT with an incidence of 5% to 19%. The exact mechanism by which it occurs is unkown and probably multifactorial. However, it has been associated with the presence and treatment of cGVHD.

Objectives: To describe the prevalence of AVN and its clinical characteristics in a cohort of patients with cGVHD evaluated in a multidisciplinary practice.

Methods: Descriptive and prospective observational study to describe the prevalence and characterization of AVN in a cohort of 132 patients with steroid-refractory cGVHD in multidisciplinary consultation. Variables related to baseline disease, transplantation and clinical manifestations of cGVHC are collected.

Results: 14 (10,6%) developed AVN confirmed by magnetic resonance imaging. The transplant-related characteristics and clinical features of cGVHD are detailed in Table 1. All of them had been receiving steroids. The average time from transplantation to AVN was 2,5 years (0-5,5). The mean age of AVN diagnosis was 46 years (range 17-65). Three patients had developed the AVN before the first visit.The diagnosis of AVN was during follow-up in the rest of them, with a mean onset of 23 months (1-48). 64,3% had more than one joint affected. The head of femur was the most commonly affected area (64,3%), followed by knee (35,7%). Other sites also affected were elbow, humeral head and ankle, with one case each. 64,3% needed joint replacement.

Conclusion: AVN in our cohort is a relatively common complication and it occurs in moderate-severe cGVHD. These patients present pain and limitation in range of motion and these manifestations may also appear in the context of GVHD itself. Early recognition is a challenge to avoid misdiagnosis and the risk of overtreatment with steroids that would increase the progression of the lesion.

Background: the main cause of blindness in non-infectious uveitis is cystoid macular edema (CME). Behçet's disease (BD) is one of the most common diseases associated with CME [**1-3].**

Objectives: to compare efficacy and safety of Adalimumab (ADA), Infliximab (IFX) and Certolizumab (CZP) in refractory CME due to BD.

Methods: multicenter study of patients with CME secondary to BD refractory to glucocorticoids (GC) and at least 1 conventional immunosuppressant. All patients had CME (OCT>300μ) at baseline. From baseline up to 2 years, efficacy of ADA, IFX and CZP was assessed with the following ocular parameters: macular thickness (μm), visual acuity (BCVA), anterior chamber (AC) cells, vitritis and GC-sparing effect. Statistical analysis was performed with IBM SPSS Statistics v.23.

Results: a total of 50 patients (78 eyes) were considered. Twenty-five patients were treated with ADA, 15 patients with IFX and 10 patients were treated with CZP. No significant differences in demographic parameters were observed in the three groups. However, patients in the CZP group had a significantly longer time from diagnosis to drug initiation (75 [36-120] vs 30 [12-82] vs 15 [8-60] months; p=0.04) and received a greater median number of biological treatments (2 [0.75-3] vs 0 [0-0] vs 0 [0-0]) than the ADA and IFX groups. In CZP group, ADA and IFX were used previously in 7 patients. Combined therapy was used with ADA in 64%, with IFX in 66.7% and with CZP in 70% of CZP patients (p=0.94) (**TABLE 1**). Regarding efficacy outcomes, a rapid and maintained improvement in macular thickness was observed after 2 years of follow-up in three groups with no statistically significant differences between them (**FIGURE 1**). Improvement in BCVA, AC cells, vitritis and a GC-sparing effect was also noted. No serious adverse events were observed in IFX and CZP group. One case of pyelonephritis was reported in the ADA group.

Conclusion: ADA, IFX and CZP seem to be effective and safe in refractory CME due to BD. CZP appears effective even in patients with inadequate response to ADA and/or IFX.

AB1465 CAUSAL RELATIONSHIPS BETWEEN PHYSICAL ACTIVITIES, LEISURE SEDENTARY BEHAVIORS, AND ADULT-ONSET STILL DISEASE OUTCOMES

Keywords: Rare/orphan diseases, Self-management, Genetics/Epigenetics

J. Y. Chen[1,2], W. Li[1,2], Q. Feng[1,2], Y. Feng[1,2], Q. Yu[3], P. F. He[3], X. Li[1,2,4], S. X. Zhang[1,2,4]. [1]*Shanxi Provincial Key Laboratory of Rheumatism Immune Microecology, Shanxi Medical University, Taiyuan, Shanxi Province, China*; [2]*Key Laboratory of Cellular Physiology at Shanxi Medical University, Ministry of Education, Taiyuan, Shanxi Province, China*; [3]*Shanxi Key Laboratory of Big Data for Clinical Decision Research, Shanxi Medical University, Taiyuan, Shanxi Province, China*; [4]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, Shanxi Province, China*

Background: Adult-onset Still's disease (AOSD) is a characteristic non-familial, multi-genic systemic auto-inflammatory disorder, characterized by fever and joint pain [1]. Whether physical activities (PAs)/ leisure sedentary behaviors (LSBs) directly affect AOSD susceptibility is inconclusive.
Objectives: This study aimed to investigate the causal effects of PAs and LSBs on AOSD.
Methods: We performed a two-sample Mendelian randomization (MR) analysis to investigate the causality of 5 PAs and 4 LSBs with AOSD, of which PAs include accelerometer-base physical activity measurement (average acceleration) (n=91,084), moderate to vigorous physical activity levels (MVPA) (n=377,234), vigorous physical activity (VPA) (n=377,234), moderate physical activity 10+ minutes (n=440,266), vigorous physical exercise 10+ minutes (n=440,512) [2], and LSBs include the length of mobile phone use (n=456,972), time spent driving (n=310,555), time spent using computer (n=360,895) and time spent watching television (TV) (n=437,887). Genome-wide significant genetic instruments ($p < 5 \times 10–8$) for PAs and LSBs were extracted from European-descent genome-wide association studies (GWASs). And to satisfy the assumption that single-nucleotide polymorphisms (SNPs) were not related to outcomes, one SNP (rs2857693) was removed. The PLINK algorithm ($r2 < 0.001$) was used to clump SNPs at linkage disequilibrium (LD). AOSD data was acquired from the UK Biobank database (1,486 cases, 359,708 control samples, from Neale lab). Inverse variance weighted (IVW) was selected as the primary method for MR analysis. The MR-Egger and weighted median were considered secondarily. Moreover, sensitivity analyses were implemented with Cochran's Q test, MR-Egger intercept test, leave-one-out analysis, and the funnel plot to evaluate for heterogeneity and pleiotropy.
Results: Only spent driving time was positively correlated with AOSD in LSBs (odds ratio (OR) =1.02, 95% confidence interval (CI):0.001-0.319, p=0.0004). The Cochran's Q statistic with the IVW method revealed no heterogeneity (p=0.43), and no pleiotropy was observed (p = 0.618). However, the IVW results of PAs were not statistically significant ($p > 0.05$), so PAs were not associated with AOSD (Figure 1).

were not associated with AOSD (Figure 1).

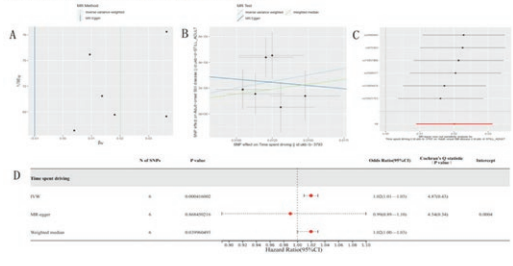

Figure 1. Mendelian randomization results for gene-level causality between physical activities (PAs), leisure sedentary behaviors (LSBs) and adult-onset Still's disease (AOSD) were evaluated by the odds ratio (OR) values of IVW, MR Egger, and Weighted median. Funnel plot (A), scatter plot (B), leave-one-out analysis (C), and forest plot (D) assessed that time spent driving increases the risk of AOSD. MR, mendelian randomization; IVW, inverse-variance weighted method; MR-Egger, Mendelian randomization-Egger; SNP, single nucleotide polymorphisms; CI, confidence interval.

Conclusion: Our findings support the hypothesis that time spent driving increases the risk of AOSD, suggesting leisurely sedentary behaviors may increase the probability of AOSD.

AB1466 CLINICAL FEATURES OF PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER OVER 50 YEARS OF AGE

Keywords: Innate immunity, Genetics/Epigenetics, Rare/orphan diseases

S. N. Baspinar[1], M. B. Yuzbasioglu[1], S. Yenigun[1], F. N. Azman[1], S. Ugurlu[2]. [1]*Cerrahpasa Medical Faculty, Department of Internal Medicine, Istanbul, Turkey*; [2]*Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Familial Mediterranean Fever (FMF) is the most common hereditary monogenic fever syndrome characterized by recurrent attacks of fever and polyserositis. Types and frquencies of attacks can change throughout the life of patients. The course of disease is affected by pathophysiological changes due to aging, increased comorbid diseases and multiple drug use.
Objectives: The objective of this study was to understand the effect of aging on clinical features and disease course in patients with Familial Mediterranean Fever.
Methods: 343 patients who were followed up with the diagnosis of FMF between 2005 to 2020 and were over 50 years old as of 2022 were included. The demographic characteristics of the patients, MEFV mutations, attack characteristics and the treatments they received were analyzed retrospectively. Attack characteristics, frequency of attacks and VAS scores of the patients were also analyzed and compared as pre-treatment, post-treatment, and most recent attacks.
Results: Female to male ratio was 1.8:1. The mean age of patients was 57.6±6.5 (50-84) years. Age of symptoms started, age at diagnosis and delay at diagnosis were compared between the female and male patients. At the age of symptoms started, no significant difference was detected between the two groups, while the age at diagnosis was later and the time of delay at diagnosis was longer in female patients (*p=0.006 and p=0.001*). Number and frequencies of attacks and VAS scores were compared as attacks before treatment, attacks after treatment and attacks in the last year, a significant decrease was found in the last attacks ($p<0.001$). The frequency of fever, abdominal pain, arthritis and chest pain was significantly lower in the most recent attacks when compared to pre-treatment and post-treatment ($p<0.001$). The last attacks of the patients were mostly in the form of abdominal pain. Patients were compared as those who did not have an attack in the last year and who had an attack, it was seen that the mean age was lower in the group that had an attack ($p<0.005$). The mean of current colchicine dose was 1.29±0.43 mg, the mean dose of colchicine at diagnosis was 1.37±0.36 mg and the mean of maximum colchicine dose was 1.6±0.43 mg.
CONCLUSION:

Demographic Status, Patients (n:343)

Male/female, n 119/224
Age of onset, mean (S.D.), years 57.6 (6.5)
Age at diagnosis, mean (S.D.), years 40.8 (10.8)
Age of symptoms started, mean (S.D), years 24 (14.4)
Delay at diagnosis, mean (S.D.), years 16.8 (14.5)

Clinical features, n (%)	Pre-Treatment n (%)	Post-Treatment n (%)	Recent Attacks n (%)	p value
Fever				
Abdominal Pain	266 (77.6)	253 (73.8)	52 (15)	**<0.001**
Arthralgia	293 (85.4)	299 (87.2)	223 (65)	**<0.001**
Arthritis	56 (16.3)	82 (23.9)	33 (9.6)	**<0.001**
Chest pain	87 (25.4)	100 (29.2)	32 (9.3)	**<0.001**
Myalgia	71 (20)	79 (23)	24 (7)	**<0.001**
Erysipelas-like	23 (6.7)	34 (9.9)	46 (13.5)	0.14
erythema	11 (3.2)	12 (3.5)	7 (2)	0.487
Number of attacks, mean (S.D.), years	15.0 (11.9)	3.04 (6.46)	2 (3.67)	**<0.001**
VAS Scores				
Pre-treatment, mean (S.D.)	8.05 (1.78)		**<0.001**	
Post-treatment, mean (S.D.)	2.91 (2.53)			
Recent, mean (S.D.)	1.75 (2.38)			

It has been shown that there is a decrease in disease activity, frequency of attacks and the dose of colchicine used in FMF with aging.

AB1467 POTENTIAL TRIGGERS OF FAMILIAL MEDITERRANEAN FEVER ATTACKS

Keywords: Rare/orphan diseases

M. B. Ates[1], K. Parlar[2], E. Bostancı[1], E. Onal[1], S. Ugurlu[1]. [1]*Cerrahpasa Medical Faculty, University of Istanbul-Cerrahpasa, Divison of Rheumatology, Department of Internal Medicine, Istanbul, Turkey*; [2]*Yeditepe Medical Faculty, University of Yeditepe, Divison of Rheumatology, Department of Internal Medicine, Istanbul, Turkey*

Background: Familial Mediterranean Fever (FMF) is an autoinflammatory disease characterized by self-limited 1 to 4 days lasting attacks. These attacks are characterized by fever, abdominal pain, chest pain, arthritis, arthralgias, myalgia, and erysipelas-like rash that is over the affected joint. Mutations of the pyrin protein which encodes by the main mutated gene of FMF, MEFV, are responsible for the inflammasome overactivation and subsequently responsible for attacks and the main underlying occurring pathophysiology of FMF[1]. The role of the factors that can contribute to and trigger this process is on a large scale unknown.
Objectives: We aimed to search for the factors that can trigger these attacks or can increase the severity of attacks. We prepared some criteria based on our clinical observations to determine the factors that can trigger pyrin protein-associated- inflammasome mechanisms that are the underlying cause of FMF[1].
Methods: We surveyed 808 patients with FMF from our adult rheumatology outpatient clinics. We used a questionnaire assessing the following: emotional stress; use of antidepressants; consumption of tea and coffee; relationship with menses; menopause and post-menauposal alleviations; seasonal changes; long-term journeys; changes of location; starvation; sleeplessness; temperature reduction; fatigue; wind and cold weather; and humidity(Table1). We also questioned some features of the attacks of patients including fever, abdominal pain, chest pain, arthritis, arthralgia, myalgia, and erysipelas-like rash.
Results: The number of patients with FMF and their potential trigger factors are given in Table 1. We performed the questionnaire to 808 patients with FMF (354 male and 454 female). 574 patients (%71) reported worsening in severity and frequency of their attacks in relation to emotional stress. Among these 574 patients, 139 patients (%24) were using antidepressants. 443 and 474 patients reported worsening and higher frequency of their attacks in relation to seasonal changes and fatigue, respectively. Among the 454 female patients, 213 patients reported worsening during their menses cycle. 96 female patients had entered menopause and 50 of them (%52) had reported obvious improvement after their menopause. In our cohort, 530 patients had experienced fever, 642 abdominal pain, 426 chest pain, 350 arthritis, 573 arthralgias, 483 myalgias, and 152 erysipelas-like rashes during their attacks.
Conclusion: The high proportion of patients who had reported worsening in their attacks in relation to emotional stress highly suggests a correlation between emotional stress and FMF attacks. Additionally, 443 and 474 patients had reported worsening in their attacks when seasonal changes occur and in times of fatigue, respectively, which is also highly suggestive of a correlation with FMF attacks. There was also an outstanding decrease in the severity of their attacks in patients who had menopause after they entered menopause. Furthermore, there were some patients who reported miscellaneous correlations in the frequency of FMF attacks and with the use of antidepressants, consumption of tea and coffee, seasonal changes, long-term journeys, changes in location, starvation, sleeplessness, temperature reduction, fatigue, wind and cold weather, and lastly, humidity.

AB1468 ENTEROPATHY IN DUTCH COMMON VARIABLE IMMUNODEFICIENCY COHORT

Keywords: Disease-modifying Drugs (DMARDs), Gastrointestinal tract, Descriptive Studies

N. Juliana[1], M. Severs[2], J. Van Montfrans[3], P. Ellerbroek[4], B. Oldenburg[2], J. Van Roon[1], H. Leavis[1]. [1]*UMC Utrecht, Rheumatology & Clinical Immunology, Utrecht, Netherlands*; [2]*UMC Utrecht, Gastroenterology, Utrecht, Netherlands*; [3]*Wilhelmina Children's Hospital, Pediatrics, Immunology and Rheumatology, Utrecht, Netherlands*; [4]*UMC Utrecht, Infectious Diseases, Utrecht, Netherlands*

Background: Common variable immunodeficiency (CVID) is the most common severe primary antibody deficiency. Although infections are the most prevalent clinical manifestations, a large amount of the patients also suffer from immune dysregulation. This results in significant morbidity [1]. Different manifestations of enteropathy can occur, yet little information is available regarding its optimal treatment.
Objectives: Here we describe clinical characteristics, endoscopy, histopathology and treatment response of CVID enteropathy (CVID-E) in a Dutch teaching hospital.
Methods: We included CVID patients from our hospital, that provided written informed consent. We collected, retrospectively, gender, age and start of enteropathy symptoms, and age at CVID diagnosis. Reports of endoscopies and histopathology, and clinical course of enteropathy related symptoms was recorded for each patient alongside the immunosuppressive medication (IS) used over time. Treatment response was defined as remission, response, need for step-up, and unknown. Descriptive statistics were used to study associations.
Results: 32 of 82 CVID patients at the UMC Utrecht had enteropathy. The average age of this group was 45.4 (13.5 standard deviation, SD) and the mean age of CVID diagnosis was 31.7 (16.7 SD). The age at first presentation of enteropathy was 30.9 years (14.6 SD). 16 of 32 patients were female. 28 (90.6%) of CVID-E patients had other complications: inflammatory, infectious and malignant. 26 (81.3%) patients had other inflammatory manifestations; the most common were lymphoproliferation (43.8%) splenomegaly (34.4%) and autoimmune disease (37.5%). Infectious complication bronchiectasis had a prevalence of 68.8% in this cohort. Two patients had a solid malignancy and one lymphoma. We compared CVID-E treated with IS to those who were not treated with IS. Autoimmune cytopenia, and bronchiectasis were significantly more prevalent in CVID-E treated with IS, than those without IS: 23.5% vs 0% ($P<0.05$) and 82.4% vs 46.7% ($p<0.01$) respectively. 30 patients underwent endoscopy, 29 (90.6%) coloscopy and 25 (78.1%) gastroscopy. The most common histopathologic findings consisted of inflammatory bowel disease-like colitis (n=10) and intra-epithelial lymphocytosis (n=9). Other findings of note were lymphocytic colitis(n=3), microscopic colitis (n=2), collagenic colitis (n=1) and apoptotic enteritis (n=1). 17 of the 32 (53.1%) patients received IS for CVID-E. 14 received local corticosteroids, 12 systemic corticosteroids, 15 DMARDs (methotrexate, azathioprine, mesalazine, baricitinib, mycophenolate, tacrolimus and sulfasalazine), 6 biologicals (adalimumab, infliximab and ustekinumab) and 6 had combined therapy. These 17 patients underwent 64 treatments. Local CS therapy did not result in remission. 9/17 (52.9%) of patients needed more than 2 systemic drugs. DMARD monotherapy achieved remission or response in 6 of 13 patients (46.2%). The best results concerning combined therapy in this cohort seemed to consist of combinations of DMARD(s) and systemic CS, and combinations of DMARD(s) and TNF-alpha inhibitors (TNFi).
Conclusion: CVID-E is strongly associated with other inflammatory complications and bronchiectasis, especially in CVID-E on IS. This cohort consists of the largest series reporting on treatment efficacy in CVID-E. We found combination treatment and DMARD monotherapy to be the most effective treatment. Additionally, TNFi seem to have a good clinical response in patients with CVID enteropathy, especially when combined with other treatments.

HEPATITIS C IN IDIOPATHIC INFLAMMATORY MYOPATHIES: DIFFERENCES IN DISEASE PRESENTATION AND PATIENT MANAGEMENT

Keywords: Comorbidities, Myositis

A. Valle[1], S. Mahmood[2]. [1]*Montefiore Hospital, Medicine, Bronx, United States of America*; [2]*Montefiore Medical Center: Einstein Campus, Division of Rheumatology, Bronx, United States of America*

Background: It is known that Hepatitis C (HCV) can cause many extra-hepatic manifestations which overlap with rheumatic diseases. New evidence is emerging that both HCV and idiopathic inflammatory myopathies (IIMs) may have a common mechanism through B cell expansion and dysfunction [1,2].

Objectives: Our aim was to describe the prevalence of HCV in patients with IIM and to compare myositis disease course, organ involvement, and rheumatologic treatment response between IIM patients with and without HCV.

Methods: A registry was created of Montefiore Medical Center patients that met 2017 EULAR/ACR classification criteria for IIM. Demographics, IIM type, antibodies, clinical manifestations, comorbidities, and rheumatologic treatment history were documented. HCV antibody, viral load, and hepatitis treatment history were noted. Rheumatic medication failure was defined by rheumatologist, discontinuation due to adverse effects, or medication change within 3 months while medication control was defined by documented clinical improvement. Statistical analyses included two-sample t-test, Chi-square tests or Fisher's exact tests were used to compare the categorical variables as appropriate and signed rank test.

Results: Of 153 patients in the registry, 130 (85%) had been screened for Hepatitis C and 11 (8.5%) had evidence of current or past HCV infection. Comparison of demographics, myositis types, presentation, and comorbidities revealed those with HCV were more likely to be male (p = 0.03) and have inclusion body myositis (IBM) (p = 0.002, Figure 1). Despite comparable numbers of dermatomyositis (DM), those with HCV were less likely to exhibit the classic dermatologic findings of DM, including Grotton's papules (p = 0.05), heliotrope (p = 0.05), or others rashes such as holster, shawl, V sign (p = 0.02). Interstitial lung disease (ILD) was less prevalent in individuals with HCV while neoplasms were more frequent in the same group (p = 0.02, p = 0.01, respectively). There were no differences in age, race, ethnicity, or treatment between IIM patients with and without HCV. Of the 11 patients that had HCV, 6 (55%) were diagnosed with HCV within 1 year of IIM diagnosis and majority (4/6) had active HCV at that time based on viral load. The others had been diagnosed with HCV for 5-10 years prior to the IIM diagnosis. For majority of HCV cases (6/11), rheumatology evaluation prompted hepatology evaluation and/or treatment.

Conclusion: Individuals with HCV may have different disease course than individuals without HCV, specifically one with a higher frequency of neoplasms and a lower frequency of ILD and dermatologic manifestations. IIM diagnosis was usually a key time to discover a concomitant HCV infection and often led to change in HCV evaluation and treatment. These findings and their immunologic basis should be further studied in larger cohorts with more power.

Background: Inflammatory ocular pathology (IOP) includes internal (uveitis) and external (mainly ocular surface pathology) involvement. IOP may be severe ocular conditions refractory to conventional and biological immunosuppressants. Janus Kinase inhibitors (JAKINIB) had shown efficacy in refractory cases of different immune-mediated diseases (IMID).
Objectives: In patients with refractory IOP treated with JAKINIB our aims were **a)** to assess the patients of Spanish referral centers, **b)** Literature review.
Methods: Multicenter study of 11 patients with refractory IOP treated with JAKINIB. For Literature review a search was conducted in PubMed, Embase and the Cochrane library from their inception to 1st January 2023. In addition, a therapeutical approach of refractory IOP is proposed.
Results: We have identified 11 cases in eight University Hospitals and 13 cases in the literature review. These 24 patients (17 women/ 7 men) (35 affected eyes), mean age 38.9±21.9 years, had different refractory IOP (uveitis=14; scleritis=5, PUK=5). Most of IOP were associated with IMID (n=19, 79.2%). The main underlying IMID were rheumatoid arthritis (n=6, 25%) and juvenile idiopathic arthritis (n=5, 20.8%) **(TABLE 1).** In addition to systemic corticosteroids, before JAKINIB, conventional (n= 23; 95.8%) and biological immunosuppressive drugs (n=18; 75%) were required. The JAKINIB most widely used was tofacitinib (n= 11; 45.8%). In one patient with Blau Syndrome and uveitis, tofacitinib was switched to baricitinib due to severe lymphopenia. In two other patients, UPA was discontinued due to anemia and skin adverse reaction. Finally, only in one patient baricitinib was withdrawn due to lack of improvement. After starting JAKINIB, 23 patients presented clinical improvement, complete (n=21, 87.5%) or partial (n= 2; 8.3%). Based on these data a therapeutical approach of refractory IOP was proposed **(FIGURE 1).**
Conclusion: JAKINIB may be an effective and safe therapy in IOP refractory to conventional or even biological immunosuppressive therapy.

PROSPECTIVE FOLLOW-UP OF THE POST-THROMBOTIC SYNDROME DEVELOPMENT RISK IN PATIENTS WITH VASCULAR BEHÇET'S DISEASE

Keywords: Behcet's disease

A. Aliyeva[1], K. Abacar[1], A. Yazici[2], S. Çelik[3], T. Ergun[4], H. Direskeneli[1], F. Alibaz-Oner[1]. [1]*Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [2]*Kocaeli University, Faculty of Medicine, Division of Rheumatology, Kocaeli, Turkey*; [3]*Educational and Research Hospital, Division of Rheumatology, Istanbul, Turkey*; [4]*Marmara University Faculty of Medicine, Department of Dermatology, Istanbul, Turkey*

Background: Deep vein thrombosis (DVT) is the most common form of vascular involvement in Behçet's disease (BD). Post-thrombotic syndrome (PTS) refers to the symptoms and signs of chronic venous insufficiency following DVT. It develops within the first 2 years in more than half of the patients after acute DVT [1].
Objectives: In this prospective study, we aimed to evaluate the risk of PTS development after DVT and the factors affecting the development and severity of PTS in BD patients.
Methods: BD patients (n=18) with acute DVT and were followed in 3 tertiary rheumatology centers were included in the study. Patients are evaluated for PTS presence during acute DVT, 6-12. months and then annually. Villalta scoring with a total score of >4 or presence of venous ulcer was defined as PTS. PTS was classified as mild if the score was between 5-9, moderate between 10-14, and presence of >14/venous ulcers as severe. Venous Damage Score (VDS) was used to evaluate the effect of venous disease on work productivity and Venous Clinical Severity Score (VCSS) for symptom severity.
Results: The clinical features of the 18 patients included in the study are shown in Table 1. Major-organ involvement was present in 12 patients (pulmonary involvement in 7 (39%), ocular involvement in 5 (28%), arthritis in 3 (13%), neurobehçet and enterobehçet each in 1 patient). Steroid and IS treatment was given to all patients after an acute DVT attack. Additional anticoagulant (AC) treatment was chosen in 16 of the patients. Patients were followed up for a median 23.2 (6-40) months after DVT. The number of patients followed for at least 1 year after an acute DVT attack was 15, and the median follow-up period was 26 (12-40) months. The median duration of AC use in patients who received AC treatment in the follow-up was 6 (0-12) months. PTS developed in 5 (33%) of 15 patients during follow-up. The baseline, 6th and 12th month course of Villalta, VCSS, and VDS scores are shown in figure 1.
Conclusion: In this prospective follow-up after an acute DVT attack 33% of BD patients developed PTS within 1 year. In our previous retrospective study, 62% of 205 patients, half of whom received AK, developed PTS during follow-up [2]. Despite the limitations of our study, such as the low number of patients and the short follow-up period, AC treatment in all patients (except 1) may have influenced a lower PTS development in the prospective follow-up compared to the retrospective data.

THE PECULIARITIES OF THE CLINICAL MANIFESTATIONS OF FAMILIAL MEDITERRANEAN FEVER ACCOMPANIED WITH LUPUS-LIKE SYNDROME

Keywords: Systemic lupus erythematosus

M. Efraimidou[1], M. Osipyan[2], L. Sevoyan[1], S. Bazeyan[1], V. Vardanyan[3], K. Ginosyan[1]. [1]*Heratsi Hospital Complex №1, Rheumatology, Yerevan, Armenia*; [2]*Erebuni Medical Center, Rheumatology, Yerevan, Armenia*; [3]*Mikaelyan Institute of Surgery, Rheumatology, Yerevan, Armenia*

Background: The most common autoinflammatory disease which occurs in Armenian ethnos is familial Mediterranean fever (FMF). FMF is a hereditary disorder characterized by recurrent attacks of fever and serosal inflammation. The main clinical manifestations of FMF are recurrent fever, abdominal, chest and joint pain, erysipelas-like skin lesion but FMF also has a lot of other rare and systemic clinical manifestations. Sometimes it is difficult to distinguish if the patient has only FMF or the overlap of FMF and other rheumatological diseases: systemic lupus erythematosus (SLE), systemic vasculitis, spondyloarthropathy, etc.
Objectives: The purpose of the study is to reveal non-classic clinical manifestations of FMF, analyze and compare the course of FMF in these cases.
Methods: 100 Armenian patients with genetically confirmed FMF, who also fulfilled Tel-Hashomer classification criteria were included in this study. Molecular-genetic detection of 26 MEFV mutations which are more common among Armenians was carried out. Only 13 patients from 100 had systemic clinical manifestations like lupus, so we continued investigation and determine ANA, anti-dsDNA antibodies, which were positive. All patients with lupus-like syndrome fulfilled diagnostic criteria of SLE by ACR. Comparison of peculiarity of course of FMF was done between 13 patients - with both lupus-like syndrome and FMF (group I) and 13 patients only with FMF (group II).
Results: There were 11 female and 2 male patients in the first group. The mean age was 40,06±2,46. The 15.4% of the patients were affected with FMF and lupus-like syndrome/SLE parallelly and in 30.8% cases the onset of SLE was prior to the clinical presentation of FMF. They all had systemic clinical manifestations such as erythema (92.3%), livedo reticularis (69.2%), photosensitivity (69.2%), Raynaud's phenomenon (23.07%). Though the frequency of FMF attacks in the I group was more than in the II group, the high temperature 39-40 C° was viewed in 23% of the I group and in 46% of the II group and the duration of attack days was respectively 1-3 and 1-5. We noticed that thoracalgia and monoarthritis were viewed less frequently in the I group than in the II, 7.7% and 15.4% respectively. The difference between the clinical manifestations is presented below (Table 1). The prevalent mutation of MEFV gene in both groups was M694V- in 19 patients (73%), from which 3 (11,5%) were homozygote and 23 (88,5%) were heterozygote.

Table 1.

Clinical manifestations	I group (FMF with coexisting SLE)%	II group (only FMF)%
Abdominalgia	92,3	76,9
Thoracalgia	69,2	76,9
Arthralgia	100	100
Monoarthritis	53,8	69,2
Pleuritis	53,8	53,8
Pericarditis	15,4	7,6

Conclusion: In conclusion, both diseases FMF and SLE have common clinical manifestations: fever, arthralgia, arthritis, skin involvement, pleuritis, pericarditis. The course of FMF with coexisting SLE is milder: these patients have lower temperature, shorter duration of attack days; thoracalgia and monoarthritis also appear less frequently. Further investigations are needed to reveal the peculiarity of duration of FMF with co-exciting of systemic rheumatic diseases.

AB1473 HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS AMONG ADULTS

Keywords: Organ damage, Systemic lupus erythematosus

M. Ben Brahim[1], S. Daada[2], S. Arfa[3], M. Wafa[4], H. Ben Brahim[4], O. Berriche[3], S. Hammami[2], M. Chakroun[4]. [1]*Taher Sfar University Hospital, Mahdia, Department of Internal Medicine, Mahdia, Tunisia*; [2]*Fattouma Bourguiba University Hospital, Monastir, Department of Internal Medicine, Monastir, Tunisia*; [3]*Taher Sfar University Hospital, Mahdia, Department of Internal Medicine, Mahdia, Tunisia*; [4]*Fattouma Bourguiba University Hospital, Monastir, Department of Infectious Disease, Monastir, Tunisia*

Background: Hemophagocytic Lymphohistiocytosis (HLH) is a rare life-threatening condition resulting from an overstimulation of the immune system leading to a multi-organ damage[1]. This condition can be either primary caused by genetic mutations or secondary triggered by infections, autoimmune diseases or malignancies[1].
Objectives: We sought to examine the clinical characteristics, underling etiologies, management and outcome of adults patients diagnosed with HLH.
Methods: We performed a multi-center retrospective study in the departments of Internal Medicine and Infectious Diseases in both Fattouma Bourguiba and Taher Sfar University hospitals in Tunisia. We identified 38 patients meeting the HLH-2004 diagnostic criteria.
Results: There were 24 women and 14 men. The male/female sex ratio was 0.58. The mean age was 38 years (range 18-80 years). Eight patients (21%) had underling auto-immune disease: 6 patients had systemic lupus erythematosus, 1 patient had rheumatoid arthritis and 1 patient had idiopathic thrombocytopenic purpura. Five patients (13.5%) had underling malignancy. Among the clinical and biological variable of the HLH criteria, the most common features were fever (100%) followed by elevated ferritin level (94.7%) and cytopenia (84.2%). Triglyceride level was elevated in 76.3% of patients. Hemophgocytosis in bone marrow was found in 35 patients (92.1%). Elevated lactatdshydrogenase was found in 76.3% of cases. The most common underlying etiologies were systemic lupus erythematosus (31%) followed by infections (24%), malignancies (16%) and adult still's disease (13%). In our study, 30 patients (78.9%) underwent intravenous immunoglobulin regimen over 2 days. Twenty-three patients (60.5%) received either intravenous and/or oral steroids. Ethoposide was prescribed in 4 cases. The overall mortality in our study was 39.5%. Twenty-three patients achieved remission with 4 relapsing later. Mean cause of relapses was infections. Patients aged above 65 years and patients with systemic lupus erythematosus had poorer prognosis (p=0.013). Patients with systemic lupus erythematosus achieved remission more likely than other patients (p= 0.021).
Conclusion: HLH is an uncommon but fatal disease. The clinical symptoms are non specific leading to misdiagnosis which is associated with a dismal prognosis. Similarly to the literature a female preponderance was found in our study[1]. Systemic lupus erythematosus was found to be the commonest underling cause of HLH in our population which disagrees with the findings of similar studies who identified malignancy or infections as the principal triggers[1,2]. A combination of intravenous steroids and immunoglobulin infusions was prescribed in 47.3% of patients. This combination was proven to be effective as first line treatment [3]. Despite treatment mortality rates remained high in our populations (39.5%) especially among elderly.

AB1474 EFFECTIVENESS AND SAFETY OF CURRENT TREATMENT STRATEGIES FOR VEXAS SYNDROME: A SYSTEMATIC REVIEW

Keywords: Rare/orphan diseases, Systematic review

Z. Boyadzhieva[1], N. Ruffer[2], I. Kötter[2], M. Krusche[2]. [1]*Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*University Medical Center Hamburg-Eppendorf, III. Department of Medicine, Hamburg, Germany*

Background: VEXAS syndrome is an adult-onset systemic autoinflammatory condition caused by an acquired deficiency of the *UBA1* gene in hematopoietic progenitor cells. Its clinical course includes relapsing and refractory inflammatory conditions with high mortality. Optimal treatment strategies remain elusive and need further investigations.
Objectives: To investigate the effectiveness and safety of treatments for VEXAS syndrome.
Methods: A systematic review of the literature in line with the PRISMA guidelines was conducted: MEDLINE, Embase and Cochrane Central Register of Controlled Trials were searched for reports on treatment strategies for VEXAS. Treatment response was recorded as complete (CR), partial (PR) or none (NR) depending on changes in clinical symptoms and laboratory parameters. Patient characteristics, safety data and previous treatments were analyzed.
Results: We identified 32 publications with a total of 83 patients. 97.6% of patients were male. Mean age at disease onset was 68 years (reported for 80/83). Mean follow up was 15.7 months (reported for 23/83). The most frequently used was azacitidine (AZA) (39.8%, 33/83): CR was reported for 9 patients (27.3%, 9/33) and PR for 11 (33.3%, 11/33) (Fig. 1). Further reports included tocilizumab (13.3%, 11/83), allogeneic stem cell transplantation (ASCT) (8.4%, 7/83), glucocorticoid

(GC) monotherapy (7.2%, 6/83), anakinra (3.6%, 3/83). Details on response are shown in **Table 1**. Data on adverse events was available for 29 patients (34.5%). Most common were infections (24.1%, 7/29), herpes zoster reactivation (6.7%, 2/29), cytopenias (13.8%, 4/29). The median number of previous treatments was 3 [IQR 2-5]. A total of 307 prior treatments were reported. In most cases (37.4%, 115/307), details on response and reasons for discontinuation were not reported. Nonresponse to therapy (30.2%, 58/192), GC dependence (22.4%, 43/192) and adverse events (11.9%, 23/192) were common triggers for therapy adjustment. Janus kinase inhibition has been reported to be beneficial in one case series (Heiblig et al., 2022). Individual patient data from this study was not available and, thus, not included in this analysis.

Conclusion: The current data on VEXAS treatment mainly stems from case reports/series and is inhomogeneous. Reporting of treatment response varies, complicating conclusions on treatment efficacy. Most patients received multiple therapies with mixed results. AZA appears promising for a subset of patients. IL-6 inhibition seems beneficial, but a risk of infections should be considered. Ciclosporine was commonly used as an add-on to IL-1 inhibitors suggesting benefits of combination therapy. In general, adverse events are scarcely reported, which hinders an objective risk-benefit assessment.

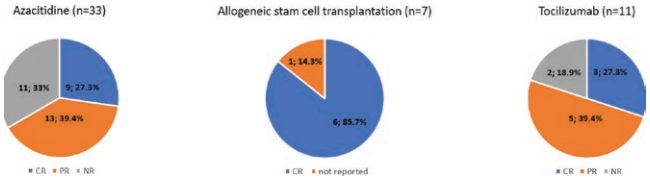

Figure 1. Summary of response

AB1475 DOES VEIN WALL THICKNESS HAVE PROGNOSTIC VALUE IN BEHÇET'S DISEASE? A PROSPECTIVE FOLLOW-UP STUDY

Keywords: Ultrasound, Behcet's disease, Diagnostic Tests

K. Abacar[1], R. Ergelen[2], F. Temiz[3], Y. Yıldız[3], T. Ergun[4], H. Direskeneli[1], F. Alibaz-Oner[1]. [1]*Marmara University, Rheumatology, Istanbul, Turkey*; [2]*Marmara University, Radiology, Istanbul, Turkey*; [3]*Marmara University, Internal Medicine, Istanbul, Turkey*; [4]*Marmara University, Dermatology, Istnabul, Turkey*

Background: We reported the first controlled doppler ultrasound study showing increased common femoral vein (CFV) thickness in Behçet's Disease (BD).[1] We also recently showed that increased CFV thickness is a distinctive feature of BD, rarely present in other inflammatory or vascular diseases with a specificity higher than 80% for the cut-off value of ≥ 0.5mm.[2] However, the association between CFV thickness and any organ involvement, disease course or treatment during disease course has not been demonstrated so far.

Objectives: This study aimed to assess the longitudinal course and prognostic value of CFV thickness measurement during a prospective follow-up BD patients.

Methods: In this study, we included 195 patients with a diagnosis of BD. The clinical, demographic, treatment data and biomarkers were recorded during routine visits. Bilateral CFV thickness was measured with ultrasonography by an experienced radiologist at the same day. Patients were started to follow up prospectively with 3-6 months intervals and in any urgent visit.

Results: At baseline, 98.6% of patients had increased CFV wall thickness above the cut-off value of ≥0.5mm. The baseline and last follow-up clinical characteristics were shown in Table 1. 139 of 195 patients had prospective clinical follow-up data with a mean of 26.5 (16.9) months. New major organ involvement or relapse leading to treatment change was seen in 39 (28%) patients. Among 22 (15.8%) patients with new major organ involvement, 12 had vascular, seven had ocular, two had neurologic and one had gastrointestinal involvement. Among 36 patients with only mucocutaneous disease at baseline, new major organ involvement developed in 9 patients during follow-up. These nine patients had higher baseline CFV thicknesses compared to patients without major organ involvement, however without reaching clinical significance (0.83mm vs 0.73mm for right CFV, 0.80mm vs 0.73mm for left CFV: p >0.05 for both) In 47 patients, the second CFV thickness measurement was done with a mean 19.8 months after the first visit. There was no statistically significant difference between the first and second CFV wall thickness measurements for both right and left CFVs (First vs. second for right CFV: 0.79 vs. 0.76mm, p=0.26; for left CFV: 0.79 vs. 0.75mm, p=0.26). We did not find any change in CFV wall thickness with the treatment modality, new organ involvement and relapses.

Conclusion: CFV wall thickness measurement with ultrasonography which is a new non-invasive diagnostic tool for BD, does not show a major change over time with treatment modality, new organ involvement or disease relapses. However, our preliminary results suggest that mucocutaneous BD patients with higher CFV thickness may have a higher risk for the development of major organ involvement during follow-up. The long term results of our prospective cohort with increased patient numbers would clarify the prognostic value of CFV thickness in BD.

Disclosures: None.

AB1476 EVALUATION OF AUTOANTIBODIES POSITIVITY IN SARCOIDOSIS PATIENTS

Keywords: Autoantibodies, Diagnostic Tests, Imaging

B. Ruaro[1], P. Confalonieri[1], M. Confalonieri[1], F. Salton[1]. [1]*Pulmonology Unit, Department of Medical Surgical and Health Sciences, Trieste, Italy*

Background: Several studies reported serum positivity for anti-nuclear (ANA), extractable nuclear antigen (ENA) and antiphospholipid antibodies in sarcoidosis patients [1,2]. However, their clinical significance is still a matter of debate.
Objectives: Several studies reported serum positivity for anti-nuclear (ANA), extractable nuclear antigen (ENA) and antiphospholipid antibodies in sarcoidosis patients [1,2]. However, their clinical significance is still a matter of debate.
Methods: We enrolled 260 sarcoidosis patients (170 females and 90 males; mean age at diagnosis 46 ± 9), after giving written informed consent. We perform clinical evaluations, laboratory tests and radiology features.
Results: 89 sarcoidosis patients were ANA positive (34%, titre ≥ 1:160), 34 patients presented ENA positivity (15%) and antiphospholipid antibodies were positive in 20 patients (8%). No statistical significant correlations were observed between ANA/ENA positivity and clinical, laboratories and imaging evaluations. However, there was a statistically significant increase of the presence of antiphospholipid antibodies in sarcoidosis patients with a diagnosis of pulmonary embolism (p-value 0.04).
Conclusion: This study demonstrated an increase of antiphospholipid antibodies positivity in sarcoidosis patients with pulmonary embolism. These results may support the screening for these antibodies in all sarcoidosis patients. Further studies are underway to confirm these preliminary data and to evaluate if the positivity of autoantibody in these patients might suggest autoimmune implications in the pathogenesis of sarcoidosis.

AB1477 **IS HYPOPHOSPHATASIA MISDIAGNOSED IN A TERTIARY RHEUMATOLOGIC CENTRE?**

Keywords: Descriptive Studies, Rare/orphan diseases, Bone diseases

Z. Boyadzhieva[1], B. Muche[1], P. Hoff[1], F. Buttgereit[1]. [1]*Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*

Background: Hypophosphatasia (HPP) is a rare disease caused by mutations of the ALPL gene leading to reduced activity of tissue non-specific alkaline phosphatase (AP). HPP can mimic other diseases clinically and be overseen, misdiagnosed or in the worst-case inadequately treated.
Objectives: To identify patients with a high likelihood of HPP, explore the frequency of HPP in our rheumatologic outpatient clinic and summarize clinical presentation of HPP patients.
Methods: Patients with measured AP levels <=45 U/l between 2013 and 2022 were identified, possible HPP symptoms and lab parameters were documented.

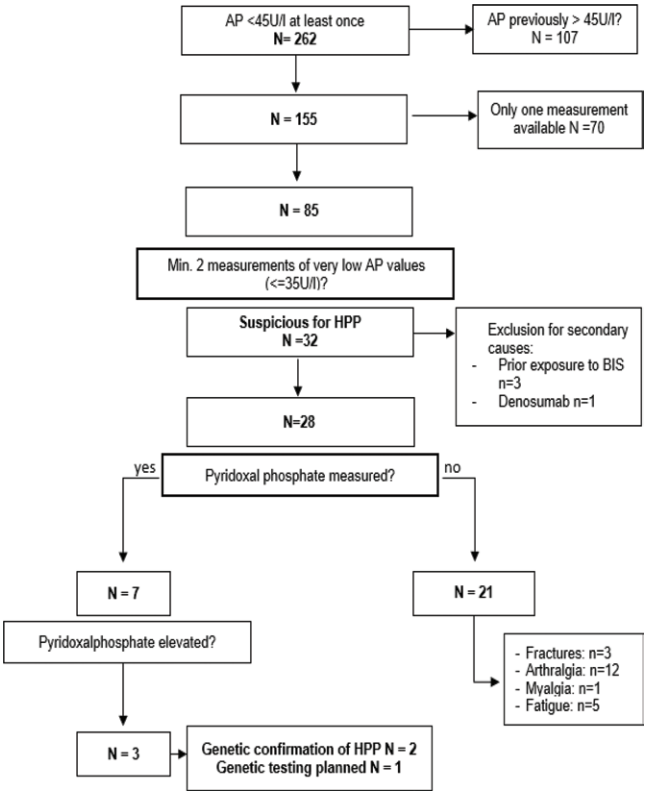

Figure 1. Workflow

Where only one measurement of AP was available, no further analysis was undertaken. All patients with AP levels>45 U/l were excluded to increase the likelihood of HPP. Those with multiple (>=2) very low AP values (<=35U/l) were defined as *suspicious for HPP*. After detailed chart review for secondary causes for low AP levels (e.g., severe hypothyroidism, exposure to bisphosphonates (BIS)) and exclusion of said cases, an analysis of the remaining ones followed. Where HPP was suspected, we aimed to initiate a measurement of pyridoxal phosphate (B6) within clinical routine. Elevated B6 levels (>50µg/l) were used as further marker suggestive of HPP.
Results: 6861 AP measurements in 3362 patients were identified. 262 (7.8%) patients had at least one low AP value. The further workflow is shown in Figure 1. 28 (10.7%) patients had AP levels <=35U/l at least twice. B6 measurements are available for 7 patients. Elevated values were seen in 3 of 7. In two cases HPP was confirmed genetically. The rest of the patients defined as *suspicious for HPP* presented unspecific symptoms (Fig. 1).

Table 1. Patient characteristics

	Age, sex	AP values	B6 value (mcg/l)	Diagnosis	ALPL mutation?	Possible HPP manifestations	Exclusion through suggested filtering strategy?
				HPP			
1	26, f	22;28	61.1	Familial mediterranean fever	No test yet	None	no
2	43, f	10;11;12	103.8	Suspected psoriatic arthritis	Heterozygous c.1343C>G	Arthralgia	no
3	74, f	33;27; 34;30;32	79	Vasculitis	Heterozygous c.1310C>T	Fracture forearm and shoulder (fall from standing height)	no
				HPP previously documented			
4	49, f	38;24;36	50 79.1	Psoriatic arthritis	Heterozygous c.526G>A	Arthralgia Myalgia Achilles tendinitis	Yes, AP>45U/l during autoimmune hepatitis
5	41, f	21;27;30; 29;36	49	Systemic sclerosis Osteoporosis	Heterozygous c.1001G>A	Calcinosis cutis universalis Arthralgia Fatigue Fracture (forearm) with delayed healing	Yes (BIS); AP values >45

During screening, 2 patients were identified with a previously confirmed HPP. However, the filtering strategy used here excluded these (for history of normal AP values and exposure to BIS). Details are shown in Table 1.

Conclusion: In our analysis of measured serum AP levels in a tertiary care centre for rheumatology we found 4 patients with definitive HPP and 1 patient with a high probability of HPP. The clinical symptoms possibly related to HPP were mild. In one case, the current diagnosis of psoriatic arthritis was documented as *suspected*; thus, the clinically leading arthralgia might be explained by HPP. All other patients had definite rheumatic diseases. Mistreatment was not found. The definitive number of patients with HPP among the cases currently defined as suspicious may be greater due to missing data on B6 in this retrospective analysis. However, only mild phenotypes were seen. Developing a universal algorithm to detect HPP remains difficult: our filtering strategy failed to identify 2 of the 4 patients with confirmed HPP. We conclude that in patients with repeatedly low serum AP levels occasionally occurring normal AP and exposure to BIS cannot rule out HPP. A further workup should include B6 levels, especially in the presence of (fragility) fractures and other symptoms not sufficiently explained by the presence of a rheumatic disease.

AB1478 THERAPEUTIC TACTICS OF IDIOPATHIC LOBULAR PANNICULITIS

Keywords: Disease-modifying Drugs (DMARDs)

G. Koilubaeva[1], O. Egorova[2], A. Bolotbekova3, A. Turatbekova3, G. Syunbai K3. *[1]3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan*; *[2]Kashirskoye Shosse, 34, Rheumatology, Moskva, Russian Federation*; *[1]3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan*

Background: Idiopathic lobular panniculitis (ILP) or Weber-Christian disease is a rare understudied disease, which manifests itself in recurrent *subcutaneous fat* necrosis often involving damage of the internals. Treatment of the disease is not standardized, and as a matter of fact it is provided empirically.

Objectives: to assess the efficiency of therapy in case of various forms of ILP.

Methods: We studied 34 patients (30 women, 4 men) with ILP, age 30-74, duration of disease 7.4±2.3 years. Besides general clinical examination we determined the level of *α1-antitrypsin,* amylase, lipase, *ferritin, creatine phosphokinase,* made chest CT scan *and carried out the pathomorphological study* of *skin biopsy specimen taken from the area of a node.* The following forms of the disease were identified: nodular form (NF) (14 patients), plaque form (PF) (9 patients), mesenteric form (MF) (5 patients) and infiltrative form (IF) (6 patients). In all cases the lobular panniculitis was verified by means of histopathological examination. All patients took glucocorticoids (GC), average daily dose of 12.8 ± 1.6mg, including 8.4± 1.7mg (for NF), 17.6± 3.2mg (for PF), 8,6 ± 1,6mg (for MF), 23.6 ± 5.3mg (for IF). In case of NF, we additionally prescribed Plaquenil, the dose of 600mg per day (8 patients), and Mycophenolate Mofetil 1.5-2g per day (6 patients); in case of PF – Cyclophosphamide (Cph), the dose of 200mg per week (4 patients) or Mycophenolate Mofetil (1.5-2g per day, 5 patients); in case of MF – Mycophenolate Mofetil (1.5-2g per day, 5 patients). Patients with IF took Cph (200mg per week). In case there was no effect after 3 months, we prescribed Mycophenolate Mofetil (1.5-2g per day). With an unsatisfactory effect, after 3 months, genetically engineered alpha-TNF antagonist drugs were used. On average, the observation period was 12 months.

Results: The treatment made it possible to achieve a significant positive dynamics in patients with NF, PF and MF: the body temperature got back to normal and there was regression of indurations (26 patients), joint pain intensity was reduced (16 patients), laboratory data on inflammatory intensity revealed decrease (24 patients). Average daily dose of GC was reduced to 4.5±0.7mg and 11.4±1.1mg, respectively. In general, a significant improvement was evident in all patients with NF and MF, in 75 % of patients with PF. In case of IF an average daily dose was increased to 25.4±1.7mg per day. In all patients of this group, an unsatisfactory effect was noted, which required discussion of the appointment of genetically engineered biological therapy. The tolerability of treatment was regarded as good, no adverse events were noted. After 14 weeks, 3 patients had a syndrome of "eluding" the effect and IL-1 inhibitor drugs were prescribed for the first time.

Conclusion: To work out dosages and treatment schedules for patients with ILP further studies are required.

AB1479 TO EACH THEIR OWN- CLASSIFICATION OF ARTHRITIS PHENOTYPE AMONG INFLAMMATORY ARTHRITIS PATIENTS WITH CANCER TREATED WITH IMMUNE CHECKPOINT INHIBITORS

Keywords: Malignancy, Inflammatory arthritides, Prognostic factors

D. Jannat-Khah[1], N. Ghosh2, L. Cappelli[3], P. Reid[4], J. Sparks[5], N. Abdel-Wahab[6], C. Calabrese[7], C. Aude2, K. K. Chan2, A. Bass[1]. *[1]Hospital for Special Surgery, Rheumatology, New York, United States of America*; *[1]Hospital for Special Surgery, Rheumatology, New York, United States of America*; *[3]Johns Hopkins University School of Medicine, Rheumatology, Baltimore,*; *[4]University of Chicago Medical School, Rheumatology, Chicago, United States of America*; *[5]Harvard Medical School, Rheumatology, Boston, United States of America*; *[6]MD Anderson, Rheumatology, Houston, United States of America*; *[7]Cleveland Clinic, Rheumatology, Cleveland, United States of America*

Background: The use of immune checkpoint inhibitors (ICIs) for the treatment of cancer can be associated with adverse events including inflammatory arthritis (ICI-IA). ICI-IA can encompass a variety of different phenotypes including: polymyalgia rheumatica (PMR)-like, spondyloarthritis-like, rheumatoid arthritis (RA)-like, and others[1]. Due to the heterogeneous clinical presentation of ICI-IA, methods are needed to find important variables and associations to describe and distinguish between clinical phenotypes.

Objectives: Use supervised machine learning techniques to find important variables associated with classification of arthritis phenotypes among patients with ICI-IA.

Methods: This study is ancillary to a retrospective observational study of patients with ICI-IA at 6 U.S sites who were treated with DMARDS (TNFi, IL6R, or methotrexate). Arthritis phenotypes was the classification target of interest. Demographics, patterns of swollen joints, medications, lab values, and concomitant irAEs were all obtained from the medical record. Descriptive statistics were computed. Classification and Regression Trees (CART) were created using the rpart and partykit packages and Random Forest (RdF) using the randomForest R package. One thousand trees were created for the forest. Variable importance scores (CART) and mean decrease in Gini scores (RdF) were created to assess the variable importance of included variables.

Results: 147 patients were included, mean age 62 years, 43% with melanoma. Arthritis phenotypes were PMR-like in 8.3%, spondylarthritis-like 19%, RA-like 48%, polyarthritis 17%, and other 8%. Two versions of the CART and RdF were performed (with and without study site) (**Table 1**). Including study site, the following were identified by both CART and RdF as important: study site was the most important variable associated with the phenotypic label, followed by cancer type, hand arthritis, age, total joint count (TJC). The CART flow diagram with study site is shown in the **Figure 1**. Excluding study site, CART and RdF identified hand arthritis, cancer type, age, TJC.

Table 1. Variable Importance (VI) from Classification and Regression Tree (CART) and mean decrease in Gini score (MDG) from Random forest (RdF) associated with Immune Checkpoint Inhibitor Inflammatory Arthritis phenotype assignment.

Characteristic	CART VI[1]	RdF MDG[2]	CART VI [1] without study site	RdF MDG[2] without study site
Study site	25	10.8	Not included	
Age	12	10.6	13	12.2
Cancer type	16	6.7	20	7.7
Maximum steroid dose of prednisone (mg)		7.3		8.7
Total Joint Count	4	5.9	6	6.2
Hand arthritis	14	3.7	25	4.0
Factors with MDG <=3		cancer stage, rash, Number of IRAEs, sex, Rheumatoid factor positive(RF+), RF+ or cyclic citrullinated peptide factor positive, arthritis affecting: shoulder, knee, ankle, hip, wrist, and knee		

[1] CART Variable importance, the higher the number the more influential the variable is in the CART[2] Mean Decrease in Gini score from RdF is a measure to rank variables; the higher the number the more important the variable.

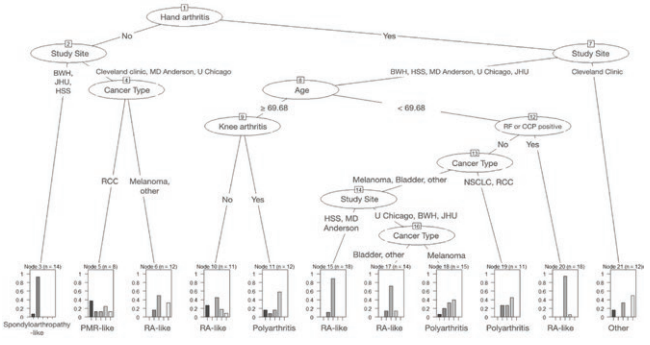

Figure 1. Classification and Regression Tree for Arthritis Phenotype with Study Site included. The bar graphs at the bottom show which arthritis phenotype is the majority for each terminal node and the y-axis shows the error rates for each group from the model.

Conclusion: We found that classification of arthritis phenotype was study site-specific in our statistical models. After excluding site, age, cancer type, TJC, maximum steroid dose, and hand arthritis were associated with phenotypic classification. The influence of study site illustrates current heterogeneity in ICI-IA phenotyping among experts and the need for formalized classification for enrollment in clinical trials. These results identify variables that could be explored by the ACR/EULAR ICI-IA classification criteria working group.

AB1480 EXPRESSION OF JAK-STAT SIGNALING PATHWAY IN HIDRADENITIS SUPPURATIVA PATHOLOGICAL BIOPSY SPECIMENS

Keywords: Cytokines and chemokines, Skin, Cell biology

T. Demirci Yildirim[1], A. Kahraman Akkalp[2], A. Köken Avşar[1], F. Onen[1], S. Akar[3], İ. Sari[1]. [1]*Dokuz Eylul University, Faculty of Medicine, Rheumatology, Izmir, Turkey*; [2]*Izmir Katip Celebi University, Pathology, Izmir, Turkey*; [3]*Izmir Katip Celebi University, Rheumatology, Izmir, Turkey*

Background: Hidradenitis suppurativa (HS) is inflammatory skin disease with an unknown etiology. JAK-STAT pathway may be implicated in its pathogenesis. Considering the unmet need in the treatment of inflammatory skin diseases, assessment of the JAK/STAT pathway could provide new understanding in the pathogenesis of these disorders. Therefore, in this study we primarily intended to investigate this pathway in patients with HS.

Objectives: Herein we aimed to investigate the JAK/STAT signaling pathway in the skin biopsies of HS patients and compared with psoriasis (PSO) and healthy subject.

Methods: This study used human tissues of healthy (n=26) and diseased skin samples obtained from the psoriatic (n=35) and HS (n=25) patients. Immunohistochemical methods were used to evaluate the expression of JAK1, JAK2, JAK3, Tyrosine Kinase 2 (TYK2), STAT1, STAT3, STAT4, STAT5, and STAT6. In the dermis, the staining intensity was recorded as 'positive' or 'negative. The epidermal part is divided into cytoplasmatic and nuclear parts and strong staining intensity recorded by staining in ≥50% of the cells.

Results: A total of 86 biopsies obtained from 25 HS (40.8 ±21.8 years, 60% male (M)), 35 PSO (46.5 ± 18.4 years, 57% M) and 26 control subjects (60.3 ± 18.3 years, 46% M) were analyzed. All JAK-STAT and TYK2 are overexpressed in dermal part of HS skin. TYK2, JAK3,STAT3 and STAT4 are strongly expressed in cytoplasmic part of epidermis in HS skin.TYK2, JAK3 and STAT1 is strongly expressed in nuclear part of epidermis in HS skin. JAK-STAT pathway is overexpressed in dermal part of psoriatic skin especially STAT2 and STAT6 but JAK1 is not expressed dermal part of psoriatic skin. All STATs and JAK1, JAK3 and TYK2 are strongly expressed in cytoplasmic part of epidermis in psoriatic skin. TYK2, JAK3 and STAT1 are strongly expressed in nuclear part of epidermis in psoriatic skin. The summary of the findings is given in Table 1. When look at the correlation analysis for TYK2 had strong correlation with HS according to control subjects in the dermal and nuclear staining. The summary of findings and the correlation analysis for HS, healty control (HC) and PSO is given in Table 1.

Conclusion: In this study, we demonstrated an increased activity in the skin biopsies of HS. When considering the unmet need in the treatment of this disease current data is significant for guiding the possible future therapies.

AB1481 EMERALD STUDY DESIGN: A TWO-COHORT, OPEN-LABEL, SINGLE-ARM STUDY OF EMAPALUMAB, AN ANTI–INTERFERON-Γ (IFNΓ) MONOCLONAL ANTIBODY, IN PATIENTS WITH MACROPHAGE ACTIVATION SYNDROME (MAS) IN RHEUMATIC DISEASES

Keywords: Systemic lupus erythematosus, Cytokines and chemokines, Inflammatory arthritides

F. De Benedetti[1], R. Krmar[2], R. Kanceva[3], A. Grom[4,5]. [1]*Ospedale Pediatrico Bambino Gesu, IRCCS, Division of Rheumatology, Rome, Italy*; [2]*Swedish Orphan Biovitrum AB, Safety Science, Stockholm, Sweden*; [3]*Swedish Orphan Biovitrum AG, Medical Science, Basel, Switzerland*; [4]*Cincinnati Children's Hospital, Division of Rheumatology, Cincinnati, United States of America*; [5]*University of Cincinnati College of Medicine, Department of Pediatrics, Cincinnati, United States of America*

Background: MAS is a severe, life-threatening form of secondary hemophagocytic lymphohistiocytosis associated with rheumatic diseases such as Still's disease (systemic juvenile idiopathic arthritis or adult-onset Still's disease) and systemic lupus erythematosus (SLE). IFNγ has been implicated in the underlying pathology of both conditions. High-dose glucocorticoids (GCs) are the standard first-line treatment for MAS; however, there is no standardized approach to treating patients who are refractory to high-dose GCs. In a pilot study of 9 patients with an inadequate response to high-dose GCs, IFNγ was rapidly neutralized, and MAS controlled, following emapalumab administration (NCT03311854). Emapalumab also had a favorable safety profile.

Objectives: To present the design of a study enrolling patients with MAS in Still's disease and SLE with the aim of evaluating the efficacy and safety of emapalumab.

Methods: EMERALD (NCT05001737) is an open-label, single-arm, multicenter, phase 2/3 interventional study enrolling pediatric and adult patients with MAS and an inadequate response to high-dose GCs into two cohorts: MAS in Still's disease (n=25) and MAS in SLE (n=16). Key eligibility criteria vary by cohort and phase (Table 1). Each cohort is a single-arm study comprising two phases: an optional run-in phase and an interventional phase. Patients are treated with high-dose GCs during the run-in phase and followed until MAS remission, inadequate response, or 12 weeks (whichever occurs first). Eligible patients enrolled in the interventional phase are treated with

emapalumab intravenously for 4 weeks (6 mg/kg on Day 1; 3 mg/kg every 3 days from Days 4–16, then 3 mg/kg twice weekly from Days 17–28) or until protocol-defined complete response (CR). Patients will be followed up for 1 year after study completion.

Key inclusion criteria	Key exclusion criteria
Run-in phase • Informed consent • Male and female patients aged 6 months to 80 years at diagnosis of MAS • MAS defined per the MAS diagnostic criteria and requiring treatment with GCs Interventional phase • Informed consent • Male and female patients aged 6 months to 80 years at diagnosis of MAS • Patients with a diagnosis of MAS having shown an inadequate response to high dose GCs as per local standard clinical practice **MAS diagnostic criteria** • Febrile patient presenting with ferritin >684 ng/mL • And any two of: – Platelet count ≤181 x10^9/L – Aspartate aminotransferase levels >48 U/L – Triglycerides >156 mg/dL – Fibrinogen levels ≤360 mg/dL	• Primary hemophagocytic lymphohistiocytosis • Confirmed malignancy • Evidence of *Leishmania* infection, clinically active mycobacteria (typical and atypical), *Histoplasma capsulatum*, salmonella infections, or latent tuberculosis • History of hypersensitivity or allergy to any component of the study drug • A bacillus Calmette-Guérin vaccine within 12 weeks prior to screening • Live or attenuated live (other than bacillus Calmette-Guérin) vaccine within 4 weeks prior to Screening • Pregnancy or lactation • At time of emapalumab initiation, treatment with: – Canakinumab, Janus kinase inhibitors, tumor necrosis factor inhibitors, tocilizumab – Anakinra at a dose >4 mg/kg • Use of etoposide for MAS within 1 month prior to treatment with emapalumab

Results: Protocol-defined CR at Week 8 after first emapalumab administration is the primary endpoint of the EMERALD study. Secondary efficacy endpoints include GC tapering, survival, time to first CR, overall response (CR and partial response), time to first overall response, MAS recurrence, pharmacokinetic/pharmacodynamic profile of emapalumab, and patient-reported outcomes. Adverse events, abnormal laboratory parameters, and anti-drug antibodies will be monitored as safety endpoints.
Conclusion: The ongoing EMERALD study is designed to address the unmet need for efficacious and safe therapies for the treatment of MAS, particularly for patients who are refractory to high-dose GCs.

AB1482 SPECIFIC BLOOD MONOCYTE DISTRIBUTION IN HISTIOCYTOSES CORRELATES WITH VASCULAR INVOLVEMENT AND DISEASE ACTIVITY

Keywords: Innate immunity

J. Razanamahery[1], M. Samson[1], J. Guy[2], J. Racine[2], C. Row[2], S. Francois[3], J. F. Emile[4], B. Nicolas[1], F. Cohen[5], S. Audia[1], J. Haroche[5], B. Bonnotte[1]. Background: Histiocytoses are rare clonal disorders characterized by the proliferation and accumulation of $CD68^+$ histiocytes in tissues[1]. During histiocytosis, circulating monocytes arising from bone marrow progenitors carry most MAP-kinase gene mutations, but only "classical" monocytes can differentiate into tissue histiocytes[2]. However, little is known about the circulating monocyte subset distribution in histiocytoses[3] and their differences from other myeloproliferative disorders.
Objectives: We aimed to evaluate the circulating monocyte subset distribution in patients with histiocytoses compared to patients with myeloproliferative disorders (Chronic myelomonocytic leukemia (CMML) and essential thrombocythemia (ET)) and healthy donors (HD).
Methods: Peripheral blood cells were obtained from patients diagnosed in Dijon University hospital between 2020 and 2021, with histiocytoses (n=17), CMML (n=7), ET (n=7), and from 21 HD at steady state. Monocytes were separated on a CD14/CD16 scattergram into $CD14^{++}/CD16^-$ (classical), $CD14^{++}/CD16^+$ (intermediate), and $CD14^+/CD16^{++}$ (non-classical) subsets after stained cell separation.
Results: During histiocytoses, an increase in "classical" monocytes was observed, compared to ET (p= 0.01) while "intermediate" (vs. ET; p= 0.02) and "non-classical" monocytes (vs. HD; p= 0.04) were decreased. The distribution of monocyte subsets in histiocytoses was close to that in CMML and homogenous among the different type of histiocytoses. Compared to CMML patients, clonal hematopoiesis in patients with histiocytoses was associated with a decrease in "classical" monocytes (87.50% vs. 97%; p= 0.002), with an increase in intermediate and "non-classical" monocytes: 5% vs. 2.5% (p= 0.03) and 4% vs. 0.5% (p= 0.01), excepted when MAP-kinase mutation was considered, as monocyte distribution was similar. Patients with vascular involvement (6 ECD including 5 $BRAF^{V600E}$, 1 RDD) had an increase in classical monocytes (96.00% [92.0-96.0] vs. 86.00% [82.5%-92.0%; p=0.008) and a decrease in "non-classical" monocytes (1.00% [1.0-2.0] vs. 5.00% [3.50-9.50]; p=0.007). The correlation between "non-classical" monocytes <4% and vascular involvement was confirmed by Pearson model (0.648; IC95%[0.25-0.86]; p=0.005). Histiocytoses patients achieving a metabolic response had a lower percentage of "intermediate" monocytes (3.5% [2.00-5.00] vs. 7.0% [4.00-13.00]; p= 0.04) and lower CRP levels (3.0 [1.1-8.75] vs. 33.65 [5.33-59.5] mg/L; p=0.04). The only factor influencing the monocytes subset repartition (for "classical" monocytes) was the presence of clonal hematopoiesis (ß coefficient: -10.78; 95%CI [-16.83 to -4.737]; p=0.002) in patients with histiocytoses.
Conclusion: The monocytes subset distribution is singular in histiocytoses compared to other myeloproliferative neoplasms and is influenced by clonal hematopoiesis. The decrease in the "non-classical" subset could represent a surrogate marker of vascular involvement, while the decrease of the intermediate fraction is associated with a metabolic response.

AB1483 CLINICAL OUTCOMES OF EXTRACORPOREAL LIFE SUPPORT AND LUNG TRANSPLANTATION IN SEVERE ANTI-MELANOMA DIFFERENTIATION-ASSOCIATED GENE 5 (MDA5)-RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE: A SYSTEMATIC REVIEW

Keywords: Systematic review, Rare/orphan diseases, Lungs

Y. Lim[1], J. Fairley[2,3], Y. Wang[1], J. Prasad[4,5,6], A. Wluka[1], R. Aggarwal[7], F. Cicuttini[1]. [1]*Monash University, School of Public Health and Preventive Medicine, Department of Epidemiology and Preventive Medicine, Melbourne, Australia*; [2]*The Alfred, Rheumatology, Melbourne, Australia*; [3]*University of Melbourne, Department of Medicine, Parkville, Australia*; [4]*The Alfred, Respiratory, Melbourne, Australia*; [5]*University of Melbourne, Senior Clinical Fellow, Parkville, Australia*; [6]*The Royal Melbourne Hospital, Respiratory, Parkville, Australia*; [7]*University of Pittsburgh, UPMC Myositis Center, Division of Rheumatology and Clinical Immunology, Pittsburgh, United States of America*

Background: Anti-melanoma-differentiation-associated gene-5 antibody (MDA5) associated dermatomyositis is associated with rapidly progressive interstitial lung disease (RP-ILD), high mortality, and progression despite aggressive immunosuppression. Extra corporeal membrane oxygenation (ECMO), as bridge to recovery or bridge to transplantation and lung transplantation offer potentially lifesaving therapy for MDA5 RP-ILD but their roles are unclear, and its use in practice is often debated[1-4].
Objectives: We systematically reviewed the clinical outcomes of patients with MDA5 RP-ILD receiving ECMO and/or lung transplantation.
Methods: Ovid Medline, Embase and CINAHL were searched (inception to Jan 2023) using keywords to identify studies of ECMO and lung transplantation in MDA5 RP-ILD. We included English language studies in adults with MDA5 RP-ILD requiring ECMO and/or lung transplantation. Review was prospectively registered on PROSPERO (CRD42022355450).
Results: The sixteen identified manuscripts reported outcomes for 33 patients with serological evidence of MDA5 (14 case reports, 2 case series). Most presented with respiratory symptoms, classic dermatomyositis cutaneous features, were amyopathic and had pulmonary radiological ground glass opacifications. Time to clinical diagnosis was usually less than 3 months from symptom onset, with rapid clinical deterioration from severe symptoms requiring hospitalisation to institution of mechanical ventilatory support within 2 weeks. Combination multi-modal aggressive induction immunosuppressants (corticosteroid, cyclophosphamide, tacrolimus, tofacitinib, rituximab and/or immunoglobulin) was used in 15/16. ECMO was used in 32 patients (Figure1): as a bridge to recovery in 16, and a bridge to transplantation in 16. ECMO used as a bridge to recovery had poor outcomes (15/16 deceased, 94%) mainly due to withdrawal of care. ECMO used as bridge to

transplantation had an 87.5% survival rate (14/16), with MDA5 disease-free remission for up to 12 years using standard induction transplant immunosuppressants.
Conclusion: In refractory MDA5 RP-ILD, early consideration of lung transplantation is essential. The findings do not support ECMO as bridge to recovery given its high mortality rate. ECMO as bridge to transplantation provided excellent patient survival and should be considered as potentially lifesaving.

ADULT-ONSET STILL'S DISEASE AND SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS: PREDICTORS OF DRUG-FREE REMISSION IN A MONOCENTRIC COHORT

Keywords: Remission, Rare/orphan diseases, Prognostic factors

G. Fontana[1], F. Crisafulli[1], M. Frassi[1], M. Cattalini[2], F. Franceschini[1], P. Airò[1].
[1]*University and Spedali Civili of Brescia, Rheumatology and Clinical Immunology, Brescia, Italy*; [2]*University and Spedali Civili of Brescia, Pediatric Clinic, Brescia, Italy*

Background: Adult-onset Still's disease (AOSD) and Systemic Juvenile Idiopathic Arthritis (SJIA, formerly termed Still's Disease), are rare polygenic autoinflammatory disorders of unknown etiology. The clinical course of AOSD/SJIA has been distinguished into different phenotypes, described on the basis of the evolution of symptoms over time. In a sizeable proportion of affected patients, disease remission can be achieved with treatments, that can be progressively tapered and stopped without relapse. Not much information is available on drug-free remission predictors.
Objectives: To look for drug-free remission predictors in a retrospective monocentric cohort of AOSD/SJIA patients.
Methods: Retrospective evaluation of AOSD/SJIA patients followed up in an Italian Rheumatology Unit between January 1997 and September 2022. All patients fulfilled the Yamaguchi criteria or PRINTO preliminary criteria. Drug-free remission was defined as the absence of clinical and laboratory markers of disease activity and absence of treatment for at least 6 months. Differences between patients who achieved drug-free remission or not were assessed using the using Mann-Whitney test, Student's t-test, Chi-squared test and Fisher test when appropriate.
Results: 57 AOSD and 7 SJIA consecutive patients were included in the study. Drug-free remission was achieved in 23 patients (35.9%) after a median period of 3,62 years (IQR 1,37 – 6). Their main baseline demographic and clinical features, as well as treatment received are summarized in Table 1. Patients in the drug-free remission group more often had white blood cells count >15.000/uL at baseline (p:0.004) than other patients. On the contrary, patients who failed drug-free remission more frequently were treated with Cyclosporine A (CyA) at disease onset (p:0.042). No significant difference was observed when analyzing if treatment with csDMARDs or bDMARDs was started within 3 months of the disease onset or not.
Conclusion: Hyperleukocytosis at baseline was identified as a potential predictor of drug-free remission in our cohort of AOSD/SJIA patients, while this was more difficult to obtain in patients treated with CyA at the disease onset. Larger and collaborative studies are needed to confirm and better define these results.

AB1485 **THE EVALUATION OF THE STATIC AND DYNAMIC BALANCE DISORDERS IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER**

Keywords: Rehabilitation, Enthesitis

H. E. Konak[1], S. C. Güven[1], K. Gok[1], E. Atalar[1], O. Küçükşahin[2], S. Erten[2]. [1]*Ankara City Hospital, Division of Rheumatology, Ankara, Turkey*; [2]*Yıldırım Beyazıt University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by self-limiting recurrent episodes/attacks of fever, serositis, arthritis, and erysipelas-like erythema[1]. Musculoskeletal manifestations such as arthralgia, enthesitis, exertional leg pain, myalgia, sacroiliitis, and lower extremity synovitis are also common in FMF [2]. The fact that the disease progresses with lifelong persistent inflammation, as well as attacks of arthritis, synovitis, and enthesitis in the lower extremities, decreased lower extremity proprioception, muscle weakness, osteopenia, and fatigue, suggests that patients with FMF may develop a balance disorder.
Objectives: The aim of this study is to examine the relationship between static and dynamic balance in patients with Familial Mediterranean fever (FMF).
Methods: FMF patients who met the modified Tel Hashomer criteria and healthy volunteers were included in the study. The demographic data,clinical characteristics, Maastricht Ankylosing Spondylitis Enthesitis Score(MASES) and International Severity Scoring System(ISSF) of FMF patients were evaluated. The balance performance was determined by the Berg Balance Scale(BBS), Functional Reach Test(FRT),Time Up and Go(TUG) tests, and Single Leg Stance(SLS) tests.
Results: When the patient and control groups were compared in terms of BBS, FRT, TUG and SLS tests, scores in the patient group were statistically worse in all evaluations. FMF patients who were at risk of falling were older with longer disease duration($p<0.001$ and $p<0.001$, respectively). VAS scores during attack, presence of arthralgia and amyloidosis were higher in patients at risk of falling($p=0.032$, $p=0.002$, $p<0.001$, respectively). ISSF and MASES scores of patients at risk of falling were significantly higher than those of patients without($p>0.001$ and $p=0.001$,respectively).
Conclusion: Our results demonstrated that the dynamic and static balance in FMF patients was worse than the healthy subjects. Longer and more severe disease, presence of enthesitis and amyloidosis may further contribute to deteriorated balance.

Background: Mucous membrane pemphigoid is a systemic, chronic, cicatricial inflammatory disease of autoimmune etiology of low incidence, characterized by the appearance of subepithelial bullous and scarring lesions that detach from the mucous membranes throughout the body. Isolated ocular involvement has classically been called Ocular Cicatrizal Pemphigoid but currently guides prefer the term Ocular Mucous Membrane Pemphigoid (OMMP). This involvement can lead to irreversible blindness if not treated early. The goal of therapy is to suppress inflammation and prevent scarring and complications, and step therapy with systemic immunomodulatory/immunosuppressive drugs is often used to achieve this. The autoimmune systemic nature of this pathology and the lack of familiarity of ophthalmologists with the use of immunosuppressive drugs motivates the referral of these patients to specialists used to their management, for interdisciplinary approach and follow-up.
Objectives: To analyze the clinical/epidemiological data and the established treatments of patients with OMMP in different Argentinian rheumatology centers.
Methods: Observational and multicenter study. Medical records of patients diagnosed and re with OMMP by an ophthalmologist, from different rheumatology centers in the Argentine Republic, were reviewed from May 2006 to July 2022.
Results: One hundred forty-seven medical records of patients diagnosed with OMMP were analyzed, mostly with confirmatory biopsy. Seventy-two percent were female. The mean age at diagnosis was 64 years (SD13). The time from the first symptoms to diagnosis was 30 months (0-300). Most of the patients (72%) were diagnosed in the last 5 years. On the analysis of 120 patients who had reported Foster's stage, 73% had stage II or less. (Foster/n: 0/9; 1/43; 2/36; 3/18; 4/14). Another associated autoimmune disease was presented in 29% and the most frequent was Sjogren's Syndrome. The most widely used treatment in 80% of patients was methotrexate and 62.5% continued with this medication until the end of the observation. In 30% of the patients the treatment had to be modified to control the disease and the most used drugs were mycophenolate, azathioprine, cyclophosphamide and rituximab. When patients were discriminated by current treatments according to Foster's stage (n: 120) patients with earlier Foster's stages used methotrexate more frequently, reaching 60% considering Foster's stages 0, I and II. Mycophenolate, azathioprine, and cyclophosphamide were used in patients with Foster's stage II or higher, while rituximab was used mainly in Foster's stage 4. Systemic steroids were used in 58% of the patients and 23% continued using it at the last visit. Adverse events that led to stopping treatment were observed in 12% of all treated patients (There were: dapsone, methotrexate, azathioprine, cyclophosphamide and mycophenolate). In Addition, one death due to sepsis secondary to cyclophosphamide was recorded. Foster's stage progressed in 31% of patients despite treatment and 8.1% (n:12) finished with blindness.
Conclusion: Most of the patients were diagnosed in recent years and three quarters present initial stages (Foster II or less). Due to the inflammatory, autoimmune, progressive and scarring nature of OMMP, early initiation of immunosuppressive/immunomodulatory therapy is essential, in order to suppress inflammation and avoid scarring and sequelae. Methotrexate seems to be a good starting alternative and treatment should be escalated according to evolution. Interdisciplinary management between rheumatologists/immunologists and ophthalmologists is essential and requires fluid communication throughout the follow-up of these patients.

Other orphan diseases

AB1487 EFFECTIVENESS OF RITUXIMAB IN IGG4-RELATED DISEASE. MULTICENTRE STUDY AND LITERATURE REVIEW

Keywords: bDMARD, Vasculitis, Organ damage

L. Sanchez-Bilbao[1], J. Loricera[1], A. Herrero-Morant[1], C. Álvarez-Reguera[1], R. Melero[2], E. Galíndez-Agirregoikoa[3], R. Blanco[1]. [1]*H.U. Marqués de Valdecilla, Rheumatology, Santander, Spain*; [2]*Complejo Hospitalario Universitario de Vigo., Rheumatology, Vigo, Spain*; [3]*Hospital de Basurto, Rheumatology, Bilbao, Spain*

Background: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory disease often associated with elevated serum IgG4 levels. High dose corticosteroids are the cornerstone of treatment, but relapses and side-effects are frequent, requiring synthetic and/or biologic immunosuppressants. Rituximab (RTX) seems to be useful.
Objectives: To assess the effectiveness of RTX in IgG4-RD refractory to conventional treatment.
Methods: Multicentre clinical practice study of IgG4-RD patients treated with biologic therapy. For the literature review, a search of PubMed, Embase and the Cochrane library was conducted from inception to 31 Dec 2022.
Results: We include 9 patients (5 women/4 men) (mean age±SD; 55.8±12.6 years) with refractory IgG4-RD, treated with RTX **(Table 1).** The affected organs were: aorta (n=5), lymph nodes (n=3), lung/pleura (n=2), retroperitoneum (n=2), lacrimal glands (n=1), salivary glands (n=1), orbit (n=1), subglotis (n=1), kidney (n=1), pericardium (n=1), biliary duct (n=1) and mesenterium (n=1). All patients had received oral corticosteroids, (mean±SD dose of 33.9±14.1 mg/day). Two patients also received corticosteroid boluses. Six of the patients received conventional cDMARDs. The cDMARDs received were: methotrexate (MTX) (n=4), azathioprine (n=1), and hydroxychloroquine (n=1). RTX schedule was of 1g x 2 (n=8), and 375 mg/m2 (n=1). After a median [IQR] follow-up of 27 [25-48] months, complete and partial clinical improvement was observed in 6 and 2 patients respectively. One patient died due to an acute myocardial infarction, while another patient developed a breast cancer. We found 3 series, in the literature review, showing RTX effectiveness **(Figure 1).** The most frequently used RTX regimen was 1g x 2.
Conclusion: RTX seems to be an effective and safe therapy in corticosteroid-refractory IgG4-RD.

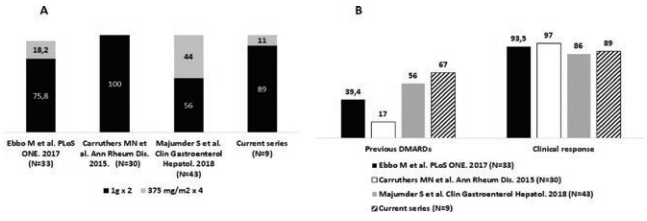

Figure 1. A) RTX regimen, **B)** previous cDMARDs and clinical response of IgG4-RD with RTX in current and other series of the literature review. All data are in %.

AB1488 GENOTYPE-PHENOTYPE CORRELATIONS OF FAMILIAL MEDITERRANEAN FEVER IN ARMENIAN POPULATION

Keywords: Geographical differences, Genetics/Epigenetics, Descriptive Studies

M. Osipyan[1], M. Efraimidou[2], K. Ginosyan[2], A. Antikyan[3]. [1]*Erebouni Medical Center, Rheumatology, Yerevan, Armenia*; [2]*1st University Hospital Complex after M. Heratsi, Rheumatology, Yerevan, Armenia*; [3]*Gyumri Medical Center, Rheumatology, Gyumri, Armenia*

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disorder that mostly affects people of Middle Eastern and Mediterranean descent, and is characterized by recurrent and self-limiting episodes of fever, serositis, arthritis and etc. Although many studies in scope of the connection of the MEFV gene variants and clinical manifestation have been carried out since the discovery of the gene, there is not yet in detail data about Armenian population peculiarities and differences in the severity of the disease between the genotypes.
Objectives: The aim of this study is to compare the severity of the disease between different FMF genotypes and propose utilization of genotype assessment as a predictor for the disease progression.
Methods: 184 Armenian patients were included in the study. All patients fulfilled Tel-Hashomer classification criteria for FMF. Patients were studied following a standard protocol. 12 most frequent mutations of MEFV gene (E148Q, P369S, F479L, M680I (G/C), M680I (G/A), I692del, M694V, M694I, K695R, V726A, A744S and R761H) were evaluated and according to the genotype patients were grouped in homozygotes, compound heterozygotes, heterozygotes and patients without mutations. Disease activity was measured by Tel-Hashomer severity score.
Results: 76,63% of examined patients were male and 23,4% -female. The mean age of the group was 41,53±18,73 years and the average duration of the disease-11,42±8,5 years. Clinical manifestation of the patients included in the study were following: episodes of fever- 124 (67,39%), abdominal pain -120 (65,2%), pleuritis - 154 (83,696%), pericarditis -11 (0,0598%) arthritis -54 (29,348%), arthralgia -101 (54,89%), erysipelas-like erythema -22(11,9565%), splenomegaly -59(32,065%), amyloidosis-6(3,26%). 118 (64,13%)of patients carried any of the MEFV examined mutations and despite the presence of clinical manifestations 66 patients (35,87%) have no mutations detected. 21 (17,8%) of patients with mutation were homozygote, 65 (55,08%)compound heterozygote and 32 (27,11 %) heterozygote. The prevalence of MEFV mutations among examined patients was 61,3%, 28,4%, 21,65%, 5,04% accordingly for M694V, M680I, V726A, E148Q exons. Patients with M694V/M694V and M694V/M680I genotype had the highest Tel-Hashomer severity score (9,8±0,6 and 8,1±1,1 accordingly). Patients with homozygote genotype have earlier onset of the disease (p=0,02), more frequent attacks (p<0,05), higher levels of ESR during the flare (P=0,009) compared with patient with other genotypes. No significant difference for the duration of the attack between different genotypes was found. Patients without any revealed mutations had the mildest disease presentations (Tel-Hashomer severity score – 3,2±1,6).
Conclusion: According to the data, age of the onset of FMF strongly correlates with the inherited genotype. Carriers of the MEFV gene mutations without any manifestations at early age should be expected to have onset years later and

Table 1. Main features of the multicentric study of 9 patients with IgG4-RD treated with rituximab.

Case	Age/ Sex	Organ involvement	Serum IgG4 (mg/ dL)/ Plasmablasts (cel/mL)	Biopsy	Diagnosis	Previous treatment	RTX regimen	Number of RTX cycles	Flollow-up (months)	Outcome

Abbreviations: F: female, GCs: glucocorticosteroids; HCQ: hydroxychloroquine, M: male, MTX: methotrexate, ND: no data, RTX: rituximab; AMI: acute myocardial infarction; CI: complete Improvement PI: Partial Improvement; ↑ PB: elevate plasmablasts counts

should be strongly monitored by clinicians. Despite the fact, that genotype is not included in Tel-Hashomer classification criteria, our study once more indicates, that not only phenotype but also genotype is very important for FMF. Further evaluation of bigger sample is required to describe the influence of the specific exons on the clinical manifestations.

AB1489 CLINICAL COURSES AND PREGNANCY OUTCOMES OF TWELVE CASES COMPLICATED WITH BEHCET'S DISEASE IN OUR INSTITUTION

Keywords: Pregnancy and reproduction, Behcet's disease

H. Shimada[1], R. Wakiya[1], S. Nakashima[1], T. Miyagi[1], Y. Ushio[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], K. Chujo[1], T. Kameda[1], H. Dobashi[1]. *[1]Kagawa University, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa, Japan*

Background: The proportion of women with Behcet's disease (BD) has increased in recent years. BD is often diagnosed at or before the time of conception, however, its impact on the clinical courses and pregnancy outcomes is not fully understood. Previous reports showed that patients with BD had a higher rate of complications such as puerperal cerebrovascular disease and gestational diabetes [1], or pregnancy outcomes like miscarriage and fetal growth restrictions [2]. Therefore, it is important to reveal the clinical course and pregnancy outcomes in patients with BD.

Objectives: The purpose of this study was to analyze the BD pregnancy cases experienced at our facility, and to idetermine the impact of disease on the course of pregnancy.

Methods: We used the data of BD patients who had been treated at planning for pregnancy and gave birth from a single center cohort of rheumatic disease pregnancy registry in our institution. The impact of BD disease activity of BD on pregnancy outocomes was examined, including therapeutic agents such as glucocorticoid (GC) and biologics.

Results: There were 12 pregnancies complicated by BD included in this analyis. The age at conception was 32.6 ± 3.6 years old, and the disease duration was 4.4 ± 3.0 years. The mean BD current activity form (BDCAF) was 0.6 ± 0.8 in 4 oral ulcers and 2 genital ulcers in the involved domain just before conception. At conception, six cases received GC, in addition, two case received adalimumab, and one case received colchicine. There were 4 cases of exacerbation of disease activity (increase of BDCAF) during pregnancy, and the active domains during pregnancy were 3 cases of oral ulcer, 2 cases of genital ulcer, and 1 case of rash and arthritis. Two cases of them needed to increase GC dose, and mean GC dose was 5.6 ± 2.1 mg per day. **Table** showed pregnancy outcomes. All cases were live births and three cases gave birth in cesarean section, two of which were emergency cesarean section due to abnormal heart rate of the infants. Mean gestational weeks was 39.2 ± 1.5 weeks, and mean birth weight was 2724.4 ± 227.1 gram. Five of the patients had had adverse pregnancy outcomes, three of which required neonatal intensive care unit (NICU) management at birth. In the cases which had exacerbation during pregnancy, three forth had these adverse pregnancy outcomes.

Table 1. Pregnancy outcomes in patients with BD

No.	outcomes	Mode of delivery	Gestational age at delivery	Birth weight of newborn	APOs	NICU administration
1	Live birth	Transvaginal delivery	38	3160		–
2	Live birth	Transvaginal delivery	41	2736		–
3	Live birth	Transvaginal delivery	38	2405	Neonatal asphyxia, LBW	+
4	Live birth	Transvaginal delivery	41	2670		–
5	Live birth	Transvaginal delivery	40	2490	LBW, LFD	–
6	Live birth	Transvaginal delivery	39	2696		–
7	Live birth	Trans vaginal delivery	39	2598		–
8	Live birth	Transvaginal delivery	39	2880		–
9	Live birth	Transvaginal delivery	40	2676	Neonatal hypervolemia	+
10	Live birth	Cesarean section	41	3108	Meconium aspiration syndrome, neonatal asphyxia	+
11	Live birth	Cesarean section	36	2714	Preterm birth, preterm PROM	–
12	Live birth	Cesarean section	38	2560		–
Mean			39.2 ± 1.5	2724.4 ± 227.1	5 (41.7)	3 (25.0)

Conclusion: In the pregnancies with BD, the disease activity was relatively stable in many cases, however, attention should be paid to the increase in disease activity, including the subsequent pregnancy outcome. It is also necessary to consider whether to continue biologics and colchicine for controlling disease activity.

AB1490 OVERLAPPING INFLAMMATORY DISEASES IN HIDRADENITIS SUPPURATIVA PATIENTS AND THEIR FAMILIES

Keywords: Skin, Comorbidities, Rare/orphan diseases

E. Er Gülbezer[1], S. Vural[2]. *[1]Koç University School of Medicine, Rheumatology, İstanbul, Turkey*; *[2]Koç University School of Medicine, Dermatology, Istanbul, Turkey*

Background: Hidradenitis suppurativa (HS) is an inflammatory disorder characterized by chronic deep-seated nodules, sinus tracts, and scars in the intertriginous areas. A significant decrease in quality of life accompanies chronic pain of active lesions.
Association with inflammatory bowel disease (IBD) and spondyloarthropathies suggest an inflammatory signature overlap with rheumatological disorders.

Objectives: Based on the idea that the association of HS and rheumatological disease is more important and frequent than previously thought, we aimed to evaluate the symptoms and findings of rheumatological diseases in our HS patients.

Methods: Consecutive HS patients presented to the dermatology outpatient clinic between 2021-2022 are included in the study. Among the HS patients who applied to dermatology between 2021 and 2022, patients with arthralgia and low back pain were referred to the rheumatology department for evaluation. Family history was taken in detail for inflammatory conditions. Acute phase reactants were analysed.

Results: The group comprised 55 HS patients, including sixteen Hurley stage I (27.2%), 24 Hurley stage II (41.8%), and 14 (23.6%) Hurley stage III patients. The mean age of onset for HS was 28.8 (min:14, max:56). 51% (N=28) were women. Family history for HS was present in 14 (25.4%) patients. Twenty-four (43.6%) of 55 HS patients who applied to the dermatology outpatient clinic had an autoinflammatory/autoimmune disease diagnosis or inflammatory symptom/finding other than HS (Table 1). Sixteen (29%) patients described arthralgia and were referred to the rheumatology outpatient clinic. Among the HS patients, 32.7% had a significant autoimmune or autoinflammatory condition other than HS in 1st or 2nd-degree relatives. Positive family history for inflammatory processes other than HS was present in 10 (41.6%) patients with an additional inflammatory condition and 8 (25.8%) patients without a different inflammatory disease. Family history of inflammatory disorders include (Familial Mediterranean fever, acne conglabata, inflammatory bowel disease, psoriasis, Takayasu arteritis, amyloidosis, ankylosing spondylitis, uveitis, erythema nodosum, Behçet's disease and vitiligo. Serum amyloid A levels (SAA) were calculated in 16 patients, and 62.5% had elevated SAA levels.

Conclusion: Autoinflammatory rheumatological diseases or rheumatological symptoms were present in a significant proportion of HS patients. Prominent family history of inflammatory diseases suggests common genetic pathways in this spectrum of diseases. In addition, detailed history taking, including rheumatological symptoms in HS patients, is valuable and crucial in determining the extent of inflammation.

Figure1: Inflammatory findings and risky family histories of hidradenitis suppurativa patients

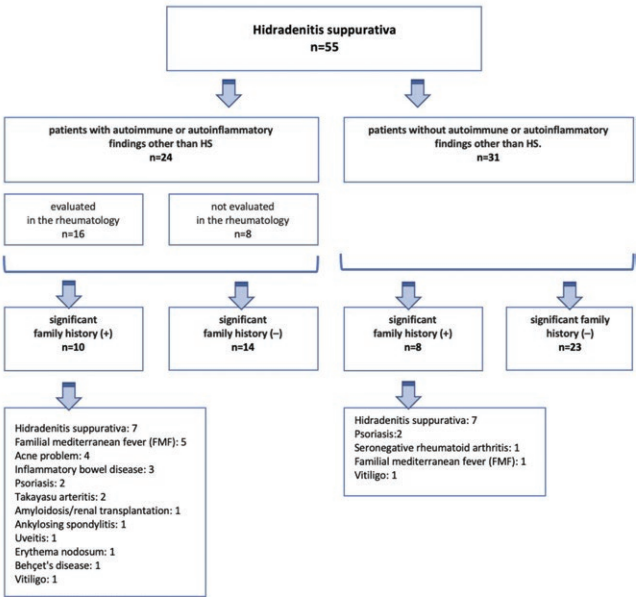

Table1: Inflammatory features of patients with autoimmune or autoinflammatory findings other than HS

Patients with autoimmune or autoinflammatory findings other than HS	n=24	%
Inflammatory joint pain or peripheral arthritis	10	41.6%
Sacroiliitis/ankylosing spondylitis	7	29.1%
Familial mediterranean fever (FMF)	5	20.8%
Oral aphtha	5	20.8%
Inflammatory low back pain	4	16.6%
Uveitis	3	12.5%
Papulopustular lesion	3	12.5%
Inflammatory bowel disease	2	8.3%
Genital aphthae	2	8.3 %
Erythema nodosum	1	4.1%
Nail psoriasis	1	4.1%
Heel pain	1	4.1%
Inflammatory neck pain	1	4.1%
Gout	1	4.1%
Sarcoidosis	1	4.1%
Autoimmune hepatitis	1	4.1%
Type1 diabetes mellitus	1	4.1%

Background: Ocular cicatricial pemphigoid (OCP) is a chronic, immune-mediated, fibrosing disease that can lead to blindness. The diagnosis is clinical and/or based on the results of the conjunctival biopsy. There are no studies that have studied the histopathological findings and the risk of clinical sequelae in this entity.
Objectives: The describe biopsies from patients with OCP and to identify characteristics of the biopsies that may be associated with a greater risk of fibrosis and sequelae.
Methods: A retrospective, multicentre study was carried out. Patients over 18 years of age with a diagnosis of OCP by pathology were selected. Medical records were reviewed and demographic, clinical, and biopsy data were collected. To assess whether histology was associated with greater or lesser fibrosis (determined by Foster's stages), the patients were divided into two groups: early stages (0 and 1) versus stages 2, 3, and 4. The variables between the two groups were compared. groups. To determine whether immunofluorescence deposits were associated with a risk of sequelae over time, a Cox multivariate analysis was performed. Sequelae were defined as a multicomponent variable consisting of queratopia, xerophthalmia, entropion, trichiasis, cataracts, glaucoma, vitreous opacity, retinal scars, synechiae, and blindness.
Results: Fifty-seven patients with POC diagnosed by pathology were included. The mean age of presentation at diagnosis was 62.7 (SD 13.2) years and 41 (71.9%) were women. The follow-up time was 1.5 years (2.9). Patients with early Foster (stages 0 and 1) were 50.9%. The presence of rounded and spindle-shaped mast cells was associated with early stages, while the presence of eosinophils was associated with later stages at the time of diagnosis. In the immunofluorescence the presence of IgM was more frequent in early stages and IgG in the later ones, with a predominant linear pattern (92%) (Table 1). During follow-up, 15 (27.3%) patients developed sequelae. In the multivariate Cox regression analysis, the presence of IgA resulted in risk during the follow-up period for the development of sequelae; IgA positive: HR 10.8, IC 95% 1.3 a 92.9 (p-value 0.03). IgG positive; HR 0.2, IC 95% 0.02 a 1.3 (p-value 0.08); IgM positive HR 0.4, IC 95% 0.1 a 2.3 (p-value 0.29) C3 positive HR 0.2, IC 95% 0.02 a 1.7 (p-value 0.14)
Conclusion: This is one of the largest rheumatologic series that has evaluated the pathology in patients with OCP and provides information on the possible role that different antibody deposits could play in the conjunctival mucosa. The presence of IgA in the biopsy may have a role in the development of sequelae. Future larger and prospective studies could help to define the detection of different clinical patterns that give us a more accurate idea of the prognosis and treatment in these patients.

Table 1. Biopsy´s characteristics according to Foster's stage.

	Total N= 57	Early Foster (0 y 1) 29 (50.9%)	Advanced Foster (2, 3 y 4) 28 (49.1%)	P value

FAMILIAL MEDITERRANEAN FEVER IN GERMANY- DOES NATIONAL ORIGIN MATTER?

Keywords: Work-related issues, Rare/orphan diseases, Geographical differences

A. Pankow[1], A. D. Wagner[2], T. Kubacki[3], A. Palmowski[1], K. Voigt[4], I. Kötter[4], M. Krusche[5]. [1]*Charité-Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany*; [2]*Hannover Medical School, Department of Nephrology, Hannover, Germany*; [3]*University of Cologne, Department II of Internal Medicine and Center for Molecular Medicine Cologne, Köln, Germany*; [4]*University Medical Center Hamburg-Eppendorf, Department of Nephrology, Rheumatology and Endocrinology, Hamburg, Germany*; [5]*University Medical Center Hamburg-Eppendorf, Department of Nephrology, Rheumatology and Endocrinology, Hamburg, Germany*

Background: Familial Mediterranean fever (FMF) is a rare hereditary, autoinflammatory disease that is characterised by recurrent episodes of fever, increased inflammatory parameters and abdominal and thoracic pain attacks.
Germany is a low- prevalence country with approximately 5800 affected patients [1]. Due to the rarity of the disease, diagnosis is difficult and time-consuming [2]. Patients often experience a long diagnostic odyssey ensuing further physical and socioeconomic damage.
Objectives: This study aimed to investigate demographical, socioeconomic and disease-associated data, in patients with FMF in a low-incidence country like Germany.
Methods: At three German tertiary centres, adult FMF patients were included in the study. Patients were asked to report data on demographic background, disease symptoms and duration, as well as the socio-economic impact of diagnostic and surgical interventions.
Results: We included 84 adult patients (female/male 35/49), the median age was 33 years (min 18- max 94) with the confirmed diagnosis of FMF. Demographic analysis showed that 52% of FMF patients were not born in Germany (country distribution see **Figure 1).** The mean age between symptom onset and diagnosis was 4 years (0-35) for patients born in Germany and 9 years (0-65) for patients not born in Germany. Furthermore, non-German-born patients reported more disease symptoms (see **Table 1**). In both groups, the number of prior diagnostic procedures and abdominal surgeries was high (53% in German FMF patients, 56% in Non-German FMF patients). Socioeconomic effects of the disease were similar in both groups: 20% of the patients born in Germany and 22% of the non-German-born patients reported that they terminated their academic education due to the disease. Furthermore, 30% of the patients born in Germany and 27% of the patients not born in Germany reported that they lost their job due to disease related problems.
Conclusion: Our data suggest that patient care for FMF in Germany is currently not optimal. A large number of patients continue to undergo a long diagnostic odyssey with unnecessary diagnostic procedures or surgeries and also experience negative effects on their education and professional careers. Furthermore, there are differences between patients born in Germany and those not born in Germany with the latter being even more negatively affected.

ADULT ONSET STILL'S DISEASE: ANALYSIS OF A MONOCENTRIC COHORT

Keywords: Rare/orphan diseases

P. Migliorini[1], D. Testa[1], S. Bilia[1], A. Tavoni[1]. [1]*University of Pisa, Clinical Immunology Unit, Dept of Clinical and Experimental Medicine, Pisa, Italy*

Background: Adult onset Still's disease (AOSD) is a systemic autoinflammatory disorder, sustained by a persistent inflammasome activation with the production of high amounts of IL-1beta and IL-18. Due to the rarity of the disorder, few multicentric cohorts of patients have been so far described.
Objectives: To analyze clinical manifestations, disease course, treatments and response to therapy in a monocentric cohort of AOSD patients.
Methods: We conducted a retrospective analysis of a cohort of consecutive patients, diagnosed as AOSD in our unit according to Yamaguchi and/or Faultrel criteria. Clinical data and therapeutic approach were analyzed; disease severity was scored by means of Pouchot score. Data were analyzed by multivariate analysis (partial least square model).
Results: We enrolled 40 patients (21 males, 19 females), mean age 63 yrs (range 21-88), age at disease onset 48 yrs. Fever and arthralgia were present in all the patients, in 77% rash, in 60% sore throat and lymphadenopathy, in 50% hepatosplenomegaly. At disease onset, 5 had intravascular disseminated coagulopathy, 4 acute respiratory distress and 2 myocarditis. In all the patients acute phase reactants were markedly increased and ferritin levels were elevated. Patients were followed for average 6,3 yrs (range 1-16 yrs): 10 patients had a monocyclic pattern, 14 polycyclic, 16 chronic articular. Mean relapses/patient

were 3,8; 26% showed >5 relapses and 7% > 25. Chronic articular pattern is the only variable that predicts the number of relapses (p=0,001). Mean Pouchot score at disease onset was 5,5 (>7 in 15 patients); it decreased to 2,2 after 6 months and was 1,2 at the last follow up visit. All the patients were treated with steroids (pulses in 18%), mean steroid dose/patient 9,6 gr. Steroids only were used in 5% of the patients, csDMARDS in 22,5% of the patients (MTX in 60%, Csa in 15%), biologicals in 72,5% (Anakinra in 62%; Tocilizumab in 28%). In 40% of the patients, steroid and one cs or bDMARD allowed to achieve disease control. In 60% one or more therapeutic switches were necessary, because of lack/loss of efficacy or adverse drug reactions. Drug retention rate was 76% at 6 months, 40% at 3 yrs and 4 yrs for Anakinra; 91% at 6 months and 36% at 5 yrs for Tocilizumab. In one patient out of 25 treated with Anakinra and in 3 out of 11 treated with Tocilizumab, the therapy was discontinued for persistent clinical remission.

Conclusion: The data we collected confirm the severity and the multisystem involvement of AOSD in a monocentric cohort with a long follow up. Among the different clinical patterns, the chronic articular one is associated with more frequent flares. Severe manifestations of the disease were present at disease onset but did not appear thereafter, suggesting the efficacy of drug therapy and close follow up. Inhibition of IL-1 and IL-6 is a safe and effective therapy. Persistent clinical remission that allows withdrawal of therapy can be obtained albeit in a small number of cases.

AB1494 SEXUAL DYSFUNCTION IN BEHÇET'S DISEASE: IS IT AN OVERLOOKED PROBLEM, ESPECIALLY IN MALE BEHÇET'S PATIENTS?

Keywords: Behcet's disease

Ö. F. Asker[1], N. Çakmak[1], S. Erdem[1], A. Öksüzer[1], E. Tufan[1], S. Kutluğ Ağaçkıran[2], H. Direskeneli[2], F. Alibaz-Oner[2], İ. Midi[3]. *[1]Marmara University Faculty of Medicine,., Istanbul, Turkey*; *[2]Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[3]Marmara University Faculty of Medicine, Department of Neurology, Istanbul, Turkey*

Background: Behçet's disease (BD) is a chronic systemic inflammatory disease characterized by oral and urogenital ulcers, ocular, musculoskeletal, vascular, and neurological involvement. Recent evidence suggests that sexual dysfunction (SD) is prevalent in BD patients.

Objectives: We aimed to determine the frequency of SD in BD and compare the rates of SD in Behçet's patients with neurological involvement (NBD), Behçet's patients without neurological involvement (BDWONI) and healthy controls (HC).

Methods: Age matched, sexually active 59 BD (17 NBD, 42 BDWONI) patients and 36 HC were recruited. All participants were questioned with Short Form-36, Beck Depression Inventory (BDI), Golombok-Rust Inventory of Sexual Satisfaction (GRISS), Female Sexual Function Index (FSFI), International Index of Erectile Function (IIEF-5), in addition, disease activity has been assessed by Behçet Disease Current Activity Form (BDCAF) in all BD patients.

Results: The rate of SD was higher in BD patients (44.2%) compared to HC (14.2%) (p= 0.003) *(Figure 1).* Male BD patients had lower sexual function scores compared to male HC. Three parameters of GRISS (premature ejaculation, noncommunication, infrequency) were observed more frequently in male BD patients compared with male HC (6.5 vs 4.7, 3.6 vs 2.0, 3.9 vs 2.4, p< 0.05 for all). The SD rates were comparable between female BD patients and HC. SD rates were similar in BDWONI (44.2%) and NBD (42.8%) groups (p> 0.05). BDCAF score was negatively correlated with IIEF scores of male BD patients (r=-0.437) and positively correlated with GRISS scores of female BD patients (r=0.748) (p< 0.05). There was no relation between SD and depression in BD patients (p= 0.284).

Conclusion: The frequency of SD is increased in BD compared to HC and affects males more frequently than females. Premature ejaculation, infrequency and noncommunication are common sexual problems in male BD patients. In conclusion, BD has a negative effect on sexuality and BD patients should be evaluated in terms of SD during follow up.

AB1495 THE RELATIONSHIP BETWEEN AMYLOIDOSIS AND ATHEROSCLEROSIS IN FAMILIAL MEDITERRANEAN FEVER

Keywords: Clinical Trials, Heart, Inflammatory arthritides

S. Gür[1], V. Yazısız[2], M. E. Terzioğlu[2], F. Erbasan[3]. *[1]Akdeniz University School of Medicine, Department of Internal Medicine, Antalya, Turkey*; *[2]Akdeniz University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Antalya, Turkey*; *[3]Akdeniz University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Antalya, Turkey*

Background: Familial Mediterranean Fever (FMF) is an autosomal recessive autoinflammatory disease characterized by recurrent fever and serosal inflammation signs [1]. The most severe complication of the disease is AA amyloidosis, with increased mortality and morbidity [2].

Objectives: To determine the relationship between amyloidosis and atherosclerosis in FMF patients.

Methods: 730 FMF patients were analyzed retrospectively for the development of amyloidosis and coroner artery disease (CAD). Cut-off values of serum amyloid A (SAA), fibrinogen, c-reactive protein (CRP), and erythrocyte sedimentation rate (ESR) variables that could predict amyloidosis and CAD were evaluated by receiver operating characteristic (ROC) analysis.

Results: The prevalences of amyloidosis and CAD were 6% and 3.7%, respectively. The incidence of CAD was higher in patients with amyloidosis (13.6%) than in patients without amyloidosis (3.1%) (p=0.004). Cut-off values that could predict amyloidosis were 44 ng/ml for SAA, 384 mg/dl for fibrinogen, 20 mm/hour for ESR, and 1.25 mg/dl for CRP (Table 1). The adjusted odds ratio for amyloidosis was 5.5-fold in patients with SSA >44 ng/ml and 3.4 in patients with ESR >20 mm/hour (Table 1). Serum AA level was significantly higher in patients with CAD (85,4±118,9) than in the group without CAD (32,4±49,5) (p=0.008). The area under the curve (AUC) values of SAA, CRP, ESR, and fibrinogen were not statistically significant for predicting CAD (Fig 1).

Conclusion: The risk of CAD is increased in amyloidosis secondary to FMF disease.

LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH HIDS (HYPER-IGD SYNDROME) – INTERIM ANALYSIS OF THE RELIANCE REGISTRY

Keywords: Rare/orphan diseases, Innate immunity, Real-world evidence

P. Oommen[1], T. Kallinich[2,3], J. Rech[4,5,6], N. Blank[7], J. Weber-Arden[8], J. B. Kuemmerle-Deschner[9]. *[1]Medical Faculty Heinrich-Heine-University Duesseldorf, Department of Pediatric Oncology, Hematology and Clinical Immunology, Center for Child and Adolescent Health, Duesseldorf, Germany*; *[2]Charité Universitätsmedizin Berlin, Department of Pediatric Respiratory Medicine, Immunology and Critical Care Medicine, Berlin, Germany*; *[3]Deutsches Rheuma-Forschungszentrum (DRFZ), an Institute of the Leibniz Association, Berlin, Berlin, Germany*; *[4]Centre for Rare Diseases Erlangen, (ZSEER), Erlangen, Germany*; *[5]Deutsches Zentrum für Immuntherapie, (DZI), Erlangen, Germany*; *[6]University Hospital Erlangen, Department of Rheumatology and Immunology, Erlangen, Germany*; *[7]Heidelberg University Hospital, Division of Rheumatology, Department of Internal Medicine, Heidelberg, Germany*; *[8]Novartis Pharma GmbH, Immunology, Nuernberg, Germany*; *[9]University Hospital Tuebingen, Division of Pediatric Rheumatology and Autoinflammation Reference Center Tuebingen, Department of Pediatrics, Tuebingen, Germany*

Background: Hyper-IgD Syndrome/Mevalonate Kinase Deficiency (HIDS/MKD) is a rare autoinflammatory disease caused by a defect in the gene encoding mevalonate kinase. Treatment with the interleukin-1β inhibitor canakinumab (CAN, approved since 2017 for HIDS/MKD) resulted in rapid remission in most patients, both in controlled trials and in clinical practice.
Objectives: The present study investigates the long-term efficacy and safety of CAN under routine clinical conditions in pediatric (age ≥2 years) and adult patients with HIDS/MKD.
Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany. Patients with clinically confirmed HIDS/MKD diagnosis who routinely receive CAN are enrolled in the study. Disease remission, disease activity, fatigue, days absent from school/work due to study indication, and inflammatory markers are assessed at baseline and at 6-monthly intervals.
Results: The present interim analysis includes baseline (N=8) as well as preliminary 18-month (N=6) and 30-month data (N=5) from HIDS/MKD patients enrolled in the study by December 2022. Of these patients, 63% were female and median age at baseline was 8 years (2–39 years). The median duration of prior CAN treatment at study entry was 1.5 years (0–5 years). The majority of patients has been treated with greater than standard dose CAN (5/8 patients at baseline, 4/6 at month 18, 3/3 at month 30). Preliminary results indicate stable remission and disease control as assessed by physicians and patients and according to laboratory parameters (**table 1**). Even though efficacy outcomes in the HIDS cohort are based on small patient numbers, data resemble outcomes in larger cohorts within the RELIANCE registry (CAPS, TRAPS, FMF). Serious adverse events occurred in N=2 patients, but none were considered as drug related.
Conclusion: The present data from baseline and preliminary interim analysis suggest good disease control in HIDS/MKD patients participating in the RELIANCE study. In addition, data analysis at 18 and 30 months revealed no unexpected safety concerns. Further interim and end-of-study data will be analyzed to assess efficacy and safety of long-term CAN treatment in HIDS/MKD patients in the course of the study.

LIVER STIFFNESS IN FAMILIAR MEDITERRANEAN FEVER: ASSOCIATION WITH ENDOCAN AND PULSE WAVE VELOCITY

Keywords: Biomarkers, Imaging

A. Lo Gullo[1], A. Toscano[2], M. Scuruchi[2], C. Morace[2], M. Cinquegrani[2], D. Sinicropi[2], G. Squadrito[2], M. Colaci[3], G. Mandraffino[2]. *[1]ARNAS "Garibaldi", Unit of Rheumatology, Catania, Italy*; *[2]The University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy*; *[3]Azienda Ospedaliera Cannizzaro, Università di Catania, Catania, Italy*

Background: Familial Mediterranean Fever (FMF) is the most common monogenic periodic fever syndrome; it is characterized by recurrent self-limited episodes of

fever, articular and serosal inflammation, and accumulation of polymorphonuclear cells into affected tissues. Recurrent inflammatory process during the attacks, and the potential chronic inflammatory status during attack-free intervals, could lead to endothelial dysfunction (ED) and atherosclerosis in FMF patients. Biomarkers could help in demonstrating ED in FMF patients. Serum endocan is a dermatan sulfate proteoglycan–structured molecule very specific for endothelium; its synthesis is stimulated by inflammatory cytokines and could be a surrogate marker of atherosclerosis.
Objectives: We designed a cross sectional study to evaluate the pulse wave velocity (PWV) as marker of arterial stiffness, carotid intima media thickness (cIMT), liver stiffness (LS, by means of FibroScan), and plasma endocan as markers of atherosclerosis process. Inflammatory markers (IM) were also evaluated.
Methods: IM, endocan plasma levels, PWV, cIMT and LS were determined in 20 FMF patients (11 men) with a median age of 36±22 years (median age at the first attack was 4 (2–7) years), and 20 matched controls (10 men) with a median age of 35±23.
Results: The body mass index 25.3±4.8 in patients was and 25.5±4.9 in controls. All subject had normal lipid profile and were not affected by diabetes or taking alcohol. All FMF patients were treated with colchicine, and 2 patients were on canakinumab. We found no differences as regards IM and cIMT in patients and controls. Endocan levels were 3-fold higher in patients as compared to controls. PWV were higher in FMF patients (8.17±2.02) with respect to controls; LS was 6.1±3.71 kPa in patients vs 5.2±2.1 kPa in controls. Hepatic Steatosis was found in 9 FMF patients (2 patients had severe steatosis, 3 moderate, and 4 mild) and 7 controls (3 moderate and 4 mild). A positive correlation was found between LS and endocan ($p<0.05$) and PWV ($p<0.05$) in FMF patients.
Conclusion: The risk of endothelial dysfunction is significantly increased in patients with FMF; moreover, a possible link between liver steatosis and CV damage could be suggested in this clinical setting.

AB1498 MANIFESTATIONS OF BONE LYMPHOMA IN A RHEUMATOLOGY DEPARTMENT

Keywords: Malignancy

O. Farhat[1], R. Fakhfakh[1], D. Khalifa[1], N. El Amri[1], K. Baccouche[1], E. Bouajina[1]. [1]*Farhat Hached Hospital, Rheumatology department, Sousse, Tunisia*

Background: Bone lymphoma is rare disease, its diagnosis is usually delayed due to the unspecefic clinical and radiological signs.
Objectives: Our objective was to describe the clinical, biological and radiological aspects of bone lymphoma to optimize diagnostic approaches.
Methods: 14 cases of bone lymphoma were collected in the Rheumatology Department of Sousse between 2001 and 2022.
Results: The mean age was 42 with a sex ratio of 1. The main symptom in 14 patients was pain associated with deterioration of general condition (10 cases), swelling of lymph glands (8 cases), fever and night sweats (6 cases), neurological signs (6 cases) with a diagnostic delay of 4 months. In biology, 13 patients had biological inflammatory syndrome, 2 of the 14 patients had hypercalcemia with a mean of 2.85, 6 patients had elevated LDH and 6 had elevated PAL. The abnormalities of the CBC were anemia in 10 cases, leukopenia in 1 case, hyperleukocytosis in 6 cases. On imaging, the lesions were single in 6 cases and multiple in 8 cases. A lytic process was found in 9 cases, osteocondensation in 3 cases and mixed lesions in 2 cases. Cortical rupture was noted in 3 cases. The soft tissues were infiltrated in 8 cases. The sites were vertebral (8 cases), sacrum (2 cases), iliac (1 case), long bone (3 cases). MRI showed a T1 hypo signal and T2 hyper signal in all cases, bone scintigraphy was performed in 6 patients and showed hyperfixation in 5 cases and a heterogeneous aspect in 1 case. A bone or lymph node biopsy was performed in all 14 patients, confirming the diagnosis and showing Hodgkin's lymphoma in 6 cases and non-Hodgkin's lymphoma in 8 cases, 7 of which were diffuse large-cell B lymphomas.
Conclusion: Due to the rarity and the various clinical and radiological presentations of bone lymphoma, the diagnosis may be difficult which is why the biopsy so important.

AB1499 TWO DISTINCT SUBSETS OF IMMUNE CHECKPOINT INHIBITOR-INDUCED INFLAMMATORY ARTHRITIS DEFINED BY LATENT CLASS ANALYSIS

Keywords: Malignancy, Inflammatory arthritides

L. Cappelli[1], J. Perin[1], C. Bingham[1], A. Shah[1]. [1]*Johns Hopkins School of Medicine, Division of Rheumatology, Baltimore, United States of America*

Background: Immune checkpoint inhibitors (ICI) can lead to immune related adverse events, including inflammatory arthritis (IA). ICI-IA is heterogeneous and can be severe, even persisting after ICI cessation. Understanding the clinical heterogeneity of ICI-IA can guide future studies of pathogenesis and identify relevant groups for clinical trials.
Objectives: To define clinically relevant subgroups within ICI-IA using a data driven approach and to examine differences between subgroups.
Methods: Participants were >=18 years old, treated with anti-PD-1, anti-PD-L1, and/or anti-CTLA-4 agents alone or in combination, and had ICI-IA diagnosed by a rheumatologist. We used information from the baseline rheumatology visit (patient reported symptoms, physical exam features, physician global arthritis rating, and laboratory studies) to cluster patients with latent class analysis. The Bayesian Information Criteria (BIC) was used to select the number of phenotypes with the lowest BIC. We then compared demographics, cancer type and treatments, and IA treatments and outcomes between the estimated phenotypes. Next, we estimated the association between these features of interest and the likelihood of being in the group with the most severe IA symptoms using logistic regression.
Results: Of the 126 patients with ICI-IA, the majority of participants were female (56%) and white (92%). Most patients had a moderate or high level of disease activity by CDAI; the mean CDAI was 16.98 (SD 10.2). Eighteen variables were used to estimate latent classes. Two distinct phenotypes were indicated by the BIC; 61 patients are estimated to be the first phenotype and 65 the second phenotype. Participants in the second phenotype were more likely to have high baseline levels of patient reported pain, stiffness, and disease activity (Figure 1). There were no significant differences in age, gender, race, ethnicity or marital status between the two phenotype groups. Patients in phenotype 2 were more likely to require steroids as compared to patients in phenotype 1 and were more likely to have persistent IA (table 1). Type of ICI therapy, type of cancer, prior chemotherapy or radiation did not differ between the groups. When adjusted for age, gender, baseline steroid use, these variables remained significantly associated with the second phenotype.
Conclusion: Two separate phenotypes of ICI-IA were determined with latent class analysis. Those in the group with more severe features at baseline were more likely to need corticosteroids and to have persistent IA, but there was no association with cancer history or treatment. Future research can interrogate underlying genetic and immunologic differences between groups.

TNF INHIBITORS ARE SAFE AND EFFECTIVE IN PATIENTS WITH SEVERE BEHÇET'S DISEASE: DATA FROM EASTERN TURKEY, INTERSECTION OF THE SILK ROAD

Keywords: Innate immunity, bDMARD, Behcet's disease

M. Bektaş[1], E. Oguz[2], M. Özer[3]. [1]*Aksaray Trainig and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Aksaray, Turkey*; [2]*Van Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Van, Turkey*; [3]*Van Training and Research Hospital, Department of Ophtalmology, Van, Turkey*

Background: Behçet's disease(BD) is a chronic inflammatory multi-systemic disease that affect skin-mucosa, joints, eye and blood vessels. Biological disease modifying anti-rheumatic drug(b-DMARD) treatment is an emerging option into the management of severe BD.

Objectives: We aimed to evaluate the clinical features and associated factors of outcome in patients with BD receiving b-DMARD treatment.

Methods: This retrospective observational study was carried out in a tertiary referral center in Van province, Eastern of Turkey.Remission was defined as no exacerbation and/or new development of clinical manifetations attributed BD at least three months. Active disease and/or relapse was defined as inadequate response to conventional treatment and/or new development of organ or system manifestations under the treatment. Ongoing mucocutaneus manifestations did not consider as active disease or relapse.

Results: We included 80 BD patients(76.3% male) who received b-DMARD therapy into the study. Mean±standard deviation(SD) of the patients was 33.3±8.8 years and median(interquartile range [IQR]) disease duration was 10(12) years. Among those patients, recurrent oral ulcer was in 98.5%, genital ulcer in 71.3%, pseudofolliculitis in 80%, erythema nodosum-like nodular lesions in 67.5%, superficial thrombophlebitis in 37.5%, uveitis in 53.8%, pathergy positivity in 66%, arthritis in 46.3%, spondylitis in 9%, gastrointestinal(GIS) involvement in 7.5%, parenchymal central nervous system(CNS) in 11.3%, parenchymal lung in 3.8%, vascular in 44%. While 28 patients(35%) had venous and 7 patients(8.8%) had arterial involvement. Overall, nearly all patients received colchicine(98.8%) and azatiopyrine (98.8%) as a background therapy, cyclophosphamide was used in 11.3%, cyclosporin in 22.5%, mycophenolate in 3.8% and interferon in 30%.Infliximab(IFX) and adalimumab(ADA) were initiated in 54(67.5%) and 26(32.5%) patients, respectively.Overall and first line retention rate were 84.7% and 92.6% for IFX and 83.3% and 80.8% for ADA, respectively(table 1).IFX was stopped in 9 patients which were in 2 patients due to allergic reaction and tuberculosis, 3 patients for inefficacy, one patient for heart failure and one patient for orbital zona.Although, no serious advers event was observed with ADA, 5 patients were switched to IFX for inefficacy.While during the follow-up, lung lobectomy were needed in one patients, no death was observed.Overall, 72 patients(90%) resumed b-DMARD end of the study;b-DMARD was stopped in 3 patients(3.8%) due to severe advers events and in 5 patients(6.2%) prolonged remission. All those patients were retained in remission after b-DMARD cessation. GIS involvement was negatively associated with b-DMARD retention in univariate(4.2% vs 33.3%;p=0.017,OR:9.8) and multivariate analysis(p=0.01,OR: 0.09,95 % confidence interval [CI]: 0.014-0.575).Higher disease duration(p=0.007,OR:5.8,95 %CI:1.6-20.8), superficial thrombophlebitis (p=0.018,OR:1.14,95%CI:1.024-1.28) were associated with corticosteroid withdrawal in multivariate analysis.

Conclusion: During the follow-up, no case of death was observed among b-DMARD receiving BD patients.Most patients were in remission, steroid-off and also retained on b-DMARD treatment.Biological treatment was safe and effective in patients with severe Behçet's disease.

AB1501 **MUSCLE BIOPSY PRACTICES: AN INTERNATIONAL SURVEY**

Keywords: Diagnostic Tests, Myositis

S. Maxwell[1], L. Ross[2,3], S. Oon[1,2], I. Wicks[1,4,5], J. Day[1,4,5]. [1]*The Royal Melbourne Hospital, Rheumatology, Parkville, Australia*; [2]*St. Vincent's Hospital Melbourne, Rheumatology, Fitzroy, Australia*; [3]*University of Melbourne, Medicine, Parkville, Australia*; [4]*WEHI - Walter and Eliza Hall Institute of Medical Research, Inflammation Division, Parkville, Australia*; [5]*University of Melbourne, Medical Biology, Parkville, Australia*

Background: Muscle biopsy is an important tool in assessment of idiopathic inflammatory myopathies (IIM), however the optimal approach is unknown. A variety of biopsy procedural techniques have been reported including open surgical biopsy, percutaneous needle biopsy and Conchotome forceps biopsy.
Objectives: This study aimed to describe current practices in obtaining a muscle biopsy amongst international experts who manage people with IIM.
Methods: An e-survey was designed and piloted to collect information regarding muscle biopsy practices. The e-survey was disseminated to members of the International Myositis Assessment and Clinical Studies (IMACS) group. Snowball sampling was used, whereby IMACS members were invited to forward the survey link to other clinicians involved in care of people with IIM. Information regarding respondent characteristics and their current practice in obtaining muscle tissue was collected. The e-survey was available for completion between 20th October 2022 and 20th of January 2023. Participants were included if they self-reported being a clinician or researcher with experience in IIM. Results were analysed using descriptive statistics.
Results: One hundred and one respondents completed the survey by 12th January 2023. Most respondents were from Europe (22.7%) and the United States (22.7%) followed by Asia (7.9%). The majority of respondents were rheumatologists (74.3%) and neurologists (20.8%) working in academic settings (73.3%). Open surgical biopsy was the most common method of muscle sampling (Table 1). Open surgical biopsies were often performed under local anaesthesia (55.6%) and without sedation (50.0%) or general anaesthesia (58.9%). Clinical examination was frequently used to guide muscle selection (85.4%), followed by MRI (50.0%) and EMG (43.8%). The influence of clinical and laboratory characteristics on decision to pursue muscle biopsy are presented in Figure 1. Many respondents were more likely to pursue diagnostic biopsy in the setting of seronegativity (65.6%), abnormal MRI (58.3%) and abnormal neurophysiology (56.3%). Conversely, many were less likely to pursue diagnostic biopsy in setting of positive myositis specific antibodies (53.2%) or classic dermatomyositis rash (70.8%). Low complication rates were reported for all muscle biopsy techniques. Non-diagnostic histopathology was reported as 'common' (observed rate between 1-10%) in 30.5% and 'very common' (observed rate ≥10%) in 14.8% of respondents.
Conclusion: Open surgical biopsy was the most common muscle biopsy approach reported by international experts who manage IIM. Clinical examination, MRI and EMG were frequently used to select a muscle to biopsy. Serology, radiographic and neurophysiological status and the presence of a classic dermatomyositis rash influence the decision to pursue diagnostic biopsy. Muscle biopsy is safe, although non-diagnostic histopathology was commonly reported regardless of technique.

AB1502 **FACTORS ASSOCIATED WITH VISION-RELATED QUALITY OF LIFE IN NON-INFECTIOUS UVEITIS PATIENTS: A LONGITUDINAL ANALYSIS**

Keywords: Uveitis, Quality of life, Patient reported outcomes

M. P. Álvarez Hernandez[1], A. Madrid García[2], L. Borrego-Sanz[3], C. Hormigos[1], B. Garcia-Tirado[1], M. Ariño-Gutierrez[3], C. Lajas[1], P. Arriola-Villalobos[3], E. Pato Cour[1], L. Rodriguez Rodriguez4. [1]*Hospital Clínico San Carlos, Rheumatology Department, Madrid, Spain*; [2]*San Carlos Health Research Institute, Musculoeskeletal Pathology Group, Madrid, Spain*; [3]*Hospital Clínico San Carlos, Ophthalmology Department, Madrid, Spain*; [2]*San Carlos Health Research Institute, Musculoeskeletal Pathology Group, Madrid, Spain*

Background: Non-infectious uveitis (NIU) are characterized by inflammation of the middle layer of the eye wall and have a significant impact on patients' visual-related quality of life (VRQoL). Objective measures of vision, such as visual acuity, do not fully account for the impact of these diseases on the patients' perceived QoL, as it includes other relevant and important aspects not evaluated in routine clinical practice. The assessment of the patient's QoL through standardized and validated questionnaires allows us to evaluate objectively the actual burden of the disease. Several cross-sectional studies have shown that the VRQoL of NIU patients is reduced. However, the evidence regarding how QoL evolves in real life clinical practice and what characteristics influence this evolution is scarce.
Objectives: To describe the evolution of the VRQoL in subjects with NIU and to identify factors associated with increased or decreased VRQoL during follow-up.
Methods: Prospective longitudinal observational study including consecutive NIU patients from a tertiary uveitis clinic from Madrid (Spain). Main outcome was the composite score of the Visual Functioning Questionnaire 25 (VFQ25), measured at baseline and after 1 and 2 years of follow-up. Influence of demographic, clinical, and treatment-related variables (assessed at the same time points) in repeated measures of VRQoL was analyzed using bivariable and multivariable generalized estimating equations (GEE) models nested by patient.
Results: One hundred and forty five patients were included in the analysis, with 422 visits. In the two years of follow up, no significant changes were observed in the evolution of the VFQ25 (Figure 1). In the multivariate analysis, lower best corrected visual acuity, presence of permanent work disability, being unemployed, cells in anterior chamber ≥2+, previous cataract surgery, previous glaucoma surgery, other intraocular surgeries, and prescription of synthetic immunosuppressive drugs were independently associated with lower VFQ25 (Table 1).
Conclusion: In the two years follow-up of our study, we did not identify significant changes in the evolution of the VRQoL in NIU patients. Nevertheless, we found some social factors that could contribute to a decreased VQ25 during follow-up. Essentially, work status and financial well-being. Clinical variables were also identified, such as lower visual acuity and factors that might reflect active disease (cells in anterior chamber ≥2+ and prescription of synthetic

immunosuppressive drugs). We also detected that previous ocular surgery might contribute to a lower VQ25 score. This preliminary data allows us to evaluate other variables that contribute to the burden of the disease and the extent of the patient's suffering regarding their vision and reflect the importance of identifying them to improve our patients' quality of life.

Table 1. Multivariate analysis to assess the influence of socio-demographic and clinical related variables in the VRQoL of a cohort of NIU patients.

AB1503 **THE IMPACT OF OBESITY ON CLINICAL COURSE AND BIOLOGIC DMARD FAILURE IN PATIENTS WITH ADULT ONSET STILL'S DISEASE**

Keywords: Rare/orphan diseases, Comorbidities, Prognostic factors

I. DI Cola[1], F. Ursini[2,3], R. Giacomelli[4], P. Cipriani[1], P. Ruscitti[1]. [1]*University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy*; [2]*Medicine & Rheumatology Unit, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy*; [3]*University of Bologna, Department of Biomedical and Neuromotor sciences (DIBINEM), Bologna, Italy*; [4]*University of Rome Campus Biomedico, Department of Medicine, Rome, Italy*

Background: Adult onset Still's disease (AOSD) is a rare inflammatory disease characterised by fever, arthritis, evanescent cutaneous rash and a typical hyperferritinemia [1]. Three clinical disease courses are usually identified: i. monocyclic, characterised by a single episode; ii. polycyclic, characterised by multiple flares, alternating with remission; iii. chronic, related to a persistent active disease [1]. AOSD may be also burdened by the occurrence of life-threatening complications. The prognosis of AOSD may be affected by the presence of comorbidities; however, the impact of obesity on these patients has not fully elucidated yet. The obesity may be considered as a negative prognostic factor in patients with rheumatic diseases. In fact, it is associated with a higher disease activity, an enhanced disability, and a less probability to achieve the clinical remission [2,3].
Objectives: We assessed the impact of obesity on clinical disease course and biologic DMARD failure in patients with AOSD. We also evaluated the influence of obesity on life-threatening complication occurrence.
Methods: An assessment of obese patients with AOSD characterised by a BMI≥30 was provided among those evaluated in Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale (GIRRCS) cohort [4]. The presence of obesity was evaluated at the time of diagnosis and defined as BMI≥30. Cox regression analyses were performed to evaluate the predictive role of obesity on predicting different disease courses and bDMARD failure in our cohort. Multivariate analyses were adjusted for age, gender, and systemic score, which was used as marker of disease severity.
Results: In this study, 139 patients were evaluated; 26 (18.7%) had a BMI≥30 and were defined as having obesity at the time of disease diagnosis (mean age of 39.3±13.6 years, 12 male gender). Obese patients did not differ in the main clinical characteristics than non-obese [fever BMI≥30: 96.2% vs BMI<30: 99.1%, p=0.340; skin rash BMI ≥ 30: 84.6% vs BMI<30: 69.0%, p=0.147; arthritis BMI≥30: 61.5% vs BMI<30: 56.6%, p=0.826]. Furthermore, obese patients showed a higher rate of bDMARD failure in the subsequent follow-up (p=0.037). In addition, obese patients with AOSD were characterized by higher values of C-reactive protein (CRP) [BMI≥30: 109.2 mg/L (IQR 117.0) vs BMI<30: 52.0 mg/L (IQR 84.3), p=0.046] than others. Obese patients with AOSD had also higher values of CRP than 2:1 age-, gender-, and BMI-matched obese patients without immune mediated inflammatory disease (IMID) (Age: 39.8 ± 13.2 years, 24 male gender out 52 patients, BMI: 32.4 ± 3.1, CRP 33.8 mg/L [IQR 34.4], p<0.001). These obese patients without IMID were recruited to fully evaluate the impact of obesity on CRP in patients with AOSD. Additionally, obesity predicted the development of a chronic disease course in patients with AOSD in both univariate (HR: 1.72, 95%CI: 1.03-2.51, p=0.038) and multivariate analyses (HR: 1.85, 95%CI: 1.45-2.89, p=0.041). Non-significant results were obtained assessing the predictive role of obesity on monocyclic and polycyclic disease courses. Furthermore, obesity resulted to be a significant predictor of failure of at least one of biologic DMARD in patients with AOSD in both univariate (HR: 3.03, 95%CI: 1.42-6.45, p=0.004) and multivariate analyses (HR: 3.59, 95%CI: 1.55-8.27, p=0.003). Conversely, obesity did not influence the development of life-threatening complications in our cohort.
Conclusion: The presence of obesity resulted to be a predictive factor for the development of a chronic disease course and biologic DMARD failure in patients with AOSD. In addition to increase the inflammatory burden, a high BMI may be indeed associated with a more rapid clearance, a higher volume of distribution, and a consequent low concentration of biologic DMARDs and their possible clinical failure.

AB1504 **CLINICAL SPECTRUM OF IGG4-RELATED DISEASE. SINGLE UNIVERSITY HOSPITAL EXPERIENCE AND LITERATURE REVIEW**

Keywords: Vasculitis, Systematic review, Organ damage

L. Sanchez-Bilbao[1], J. Loricera[1], C. Álvarez-Reguera[1], A. Herrero-Morant[1], R. Blanco[1]. [1]*H.U. Marqués de Valdecilla, Rheumatology, Santander, Spain*

Background: IgG4-related disease (IgG4-RD) is an inflammatory and fibrosing entity with very heterogeneous clinical manifestations. Its pathogenesis remains unknown, clinical features are heterogeneous and unspecific, and recently

released classification criteria are invaluable in early recognition of the disease. Therefore, regrettably IgG4 related disease continues underdiagnosed.
Objectives: a) To evaluate the clinical characteristics of patients diagnosed with IgG4-RD in a single University hospital; **b)** To compare with other large series.
Methods: Study of patients from a referral hospital and literature review of cases diagnosed with IgG4-RD. Diagnosis was made accordingly to these criteria**: a)** Okazaki; **b)** Umehara; **c)** ACR/EULAR 2020; and/or **d)** clinical, laboratory and imaging suggestive findings **(ref. 1-3)**. For the literature review, we searched PubMed and the Cochrane library from its inception until 31 December 2022, selecting the largest series.
Results: We include 11 patients (7 females/4 males) (mean±SD age; 61.2±15.6 years) diagnosed with IgG4-RD. The organs affected at diagnosis were: aorta (n=5), pleura/lung (n=4), lymph nodes (n=3), salivary glands (n=2), retroperitoneum (n=2), lacrimal glands (n=1), bile duct (n=1), kidney (n=1), orbit (n=1), subglottis (n=1), pericardium (n=1), mesentery (n=1), maxillary sinuses (n=1). IgG4 values were increase in 2 (18%) patients (median [IQR]; 250.5 [201.0-300.1] mg/dL) (normal value <135 mg/dL). Blood plasmablasts were increased in 8 (73%) patients (median; 831 [785-1218] cells/mL) (normal values <653 cells/mL). In the literature review, 6 series of more than 100 patients each were selected. The main data from the different series are listed in **table 1**. The **figure** shows the most frequently affected organs in the different series. The pancreas was one of the most frequently involved. In contrast, in our series, aortic involvement followed by lung/pleura were the most frequent.
Conclusion: IgG4-RD is a very heterogeneous disease with involvement of virtually every organ of the anatomy, usually presenting with involvement of more than one organ. Despite the name of the entity, serum IgG4 is not always elevated.

Background: Crohn's disease (CD) is a chronic inflammatory disease of unknown etiology. The IL-23/IL-17 pathway plays an essential role in the pathogenesis of CD. More and more approved IL-23 inhibitors are being used for the treatment of CD. However, no studies have systematically compared and evaluated the efficacy of these IL-23 inhibitors.
Objectives: This study aims to compare the efficacy of various IL-23 inhibitors(Brazikumab, Guselkumab, Mirikizumab, Risankizumab, and Ustekinumab) for treating Crohn's disease by conducting a Bayesian network meta-analysis (NMA).
Methods: We searched the database, including PubMed, Embase, Web of Science, Cochrane Library, MEDLINE, and Web of Science, Clinical Trials. gov, (from inception until February 5, 2023). Efficacy (Clinic response, Clinic remission, Endep remission, and C-reactive protein) were compared using a Bayesian NMA. Results were presented as the pooled estimates of odds ratios (ORs) or weighted mean difference (WMD) (95% CI). The random-effects model was selected to synthesize the data. The ranking probability for each IL-23 inhibitor was evaluated using the surface under the cumulative ranking curves (SUCRA). The larger the SUCRA value, the better the rank of the intervention. The global inconsistency was evaluated by comparing the fit of consistency and inconsistency models, where $P \leq 0.05$ indicated inconsistency. All analyses were conducted using the gemtc package of R (version 4.2.2).
Results: In terms of Clinic response, a total of 40 studies were included. The NMA showed that Brazikumab combined with Guselkumab [OR=-0.98, 95% (CI, -2.9, 0.91)], PBO(PBO) combined with Risankizumab [OR=-0.54, 95% (CI, -1.16, 0.18)], PBO combined with Ustekinumab [OR=-1.38, 95% (CI, -2.77, -0.01)], Risankizumab combined with Ustekinumab [OR=-0.84, 95% (CI, -2.43, 0.63)]. According to SUCRA, Ustekinumab (78.9%), Risankizumab (52.2%), PBO(23.6%), Mirikizumab(34%), Guselkumab (87.6%), and Brazikumab (23.6%). For clinic remission, the result of NMA showed that Brazikumab combined with Guselkumab [OR=-1.59, 95% (CI, -3.78, 0.59)], Brazikumab combined with Ustekinumab [OR=-1.37, 95% (CI, -3.57, 0.83)], PBO combined with Risankizumab [OR=-0.47, 95% (CI, -1.19, 0.34)], PBO combined with Ustekinumab [OR=-1.26, 95% (CI, -2.86, 0.33)], Risankizumab combined with Ustekinumab

[OR=-0.8, 95% (CI, -2.6, 0.93)]. According to SUCRA, Ustekinumab (79.3%), Risankizumab (53.7%), PBO(22.1%), Mirikizumab(33.4%), Guselkumab (90.3%)and Brazikumab (21.7%) (Figure 1).

Conclusion: In terms of efficacy alone, Guselkumab ranked first among all IL-23 inhibitors, followed by Ustekinumab, and all had significantly different clinical remission rates than patients in the PBO group, while the remaining drugs were less effective than PBO.

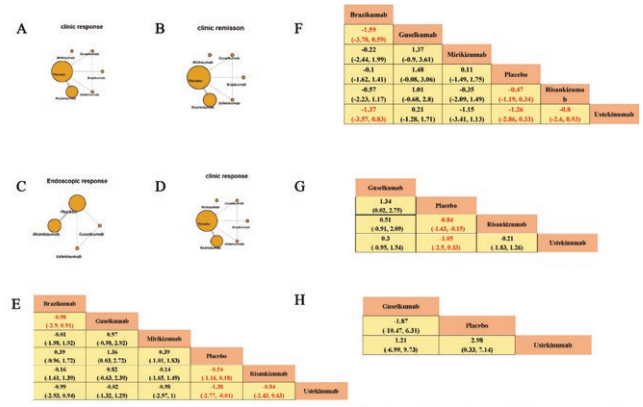

Figure 1: Network diagrams of comparisons on different outcomes of treatments of CD patients and pooled estimates of the NMA: (A, E) Clinic response; (B, F)Clinic remission; (C, G) Endep remission; (D, H)C-reactive protein. Pooled hazard ratios (95% credible intervals).

AB1506 PLASMA NEUROFILAMENT LIGHT CHAIN AND GLIAL FIBRILLARY ACIDIC PROTEIN AS BIOMARKERS IN PATIENTS WITH OCULAR SARCOIDOSIS AND NEUROSARCOIDOSIS

Keywords: Biomarkers, Rare/orphan diseases, Uveitis

K. E. Byg[1,2], J. Grauslund[2,3], T. Ellingsen[1,2], J. Wied[2,3], L. Cehofski[2,3], J. Madsen[4,5], D. Olsen[4], H. Nielsen[2,6], T. Sejbaek[5,7]. Background: Sarcoidosis is a disease characterized by non-caseating granulomatous inflammation, which can affect the eyes as ocular sarcoidosis (OS) and the central nervous system (CNS) as neurosarcoidosis (NS). Neurofilament light chain (NFL) is a structural neuronal cytoskeletal protein, and glial fibrillary acidic protein (GFAP) is part of the cytoskeleton in astrocytes and retinal Müller glial cells. Inflammation would cause leakage of NFL and GFAP. It has been demonstrated that plasma NFL is highly elevated in newly diagnosed NS patients with levels over 11.4 ng/L.

Objectives: The objectives were to compare the level of NFL and GFAP in sarcoidosis patients with or without OS and NS.

Methods: This cross-sectional study included 106 biopsy-verified chronic sarcoidosis patients examined between May and November 2019. After excluding 18 patients due to systemic comorbidity, the patients were divided according to their organ involvement over time: sarcoidosis without ocular or CNS affection (non-OS/non-NS, n=44), OS (n=14), NS (n=15), and combined OS and NS (n=15). EDTA plasma was stored at -80 ◦C until analysis. NFL and GFAP were measured blinded to clinical data by single molecule array technology (Simoa, HD-1 Analyser, Quanterix©, Billerica, MA, USA), using the commercially available 2-Plex assay. Kruskal–Wallis test, Dunn test, and Fisher's exact test were used for statistical analysis.

Results: We included 88 patients with an age median (IQR) of 52 years (41 - 60). The non-OS/non-NS group was younger than the other groups (p = 0.02) but did not differ with respect to disease duration (p=0.5). Between 67-100% of the patients received immunosuppressive treatment, most frequently in the OS group (93%) and the NS group (100%) (p = 0.02). Median NFL was 5.1, 8.4, 7.0, and 7.0 ng/L in patients with non-OS/non-NS, OS, NS, and combined OS and NS, respectively (p = 0.003), although this was only statistically significant in patients with a disease duration < 5 years (p = 0.005).

The frequency of patients with an NFL level >11.4 ng/L was lower in non-OS/non-NS group compared to the three other groups (2% vs. 14% vs. 33% vs. 20%, p = 0.004). There was a trend (p = 0.06) towards a lower median GFAP in patients with non-OS/non-NS as compared to the other groups (52 vs. 72 vs. 71 vs. 69 ng/L), which became statistically significant in patients with a disease duration < 5 years (48 vs. 67 vs. 127 vs. 52 ng/L, p = 0.02).

Conclusion: In this cross-sectional study of chronic sarcoidosis patients, we generally found a low median NFL level, including in OS and NS patients. Our results suggest that neuroaxonal damage and, thereby, active inflammation decreases in treated sarcoidosis patients. However, the median NFL levels were significantly lowest in the non-OS/non-NS group, and between 14-33% of patients in OS, NS, and combined OS and NS groups had an NFL level above 11.4 ng/l, which could indicate active CNS inflammation leading to ongoing silent neuroaxonal damage.

Table 1. Baseline characteristics and clinical findings in sarcoidosis patients

AB1507 IGG4-RELATED DISEASE – THE PORTUGUESE COHORT UNDER RHEUMATOLOGY'S CARE

Keywords: Disease-modifying Drugs (DMARDs), Geographical differences, Epidemiology

H. Parente[1], A. Carones Esteves[2], A. J. Serra Gaspar Silva[3], B. Silva[4], C. Costa[5], C. Dantas Soares[1], I. Santos[6], M. Bernardes[4], M. Silvério-António[3], R. Pinheiro Torres[7], F. Teixeira[1]. [1]*Centro Hospitalar do Alto Minho, Rheumatology, Ponte de Lima, Portugal*; [2]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [3]*Centro Hospitalar universitário Lisboa Norte, Rheumatology, Lisboa, Portugal*; [4]*Centro Hospitalar Universitário do São João, Rheumatology, Porto, Portugal*; [5]*Centro Hospitalar de Trás-Os-Montes e Alto Douro, Rheumatology, Vila Real, Portugal*; [6]*Centro Hospitalar Tondela – Viseu, Rheumatology, Viseu, Portugal*; [7]*Centro Hospitalar de Lisboa Ocidental, Rheumatology, Lisboa, Portugal*

Background: The IgG4-related disease (igG4-RD) is a rare fibro-inflammatory pseudotumoral condition, with systemic, but indolent, manifestations – pancreatic, salivary and lacrimal glands, retroperitoneal, vascular etc. It mainly occurs on middle-aged and older men[1]. It can mimic malignancies, having a complicated diagnosis. It responds favorably to corticosteroids (CCT)[2], but frequently relapses[3].

Objectives: To characterize the Portuguese sample of IgG4-RD patients followed at Rheumatology.

Methods: National multicentric observational study, including IgG4-RD patients followed on a Rheumatology consultation.

Results: Twenty-four patientes were included, with a mean present age of 59.95 years-old (SD=13.35), 56.09 (SD=14.13) at diagnosis, and 53.96 (SD=14.19) at the first symptoms. Twelve (50.0%) were men. Nine (37.5%) patients had salivary glands involvement (8 bilaterally), 6 (25.0%) had orbital, 6 (25.0%) of lacrimal glands (4 of them bilaterally), 5 (20.8%) pancreatic, 5 (20.8%) aortic, 4 (16.7%)

retroperitoneal, 4 (16.7%) of biliary ducts, 3 (12.5%) pulmonary, 3 (12.5%) renal, 2 (8.3%) of the thyroid and 1 (4.2%) of meninges. We documented a intra-ductal pancreato-biliary papillary mucinous neoplasm. Tomographically, none had a *sausage pancreas*, 3 (12.5%) had lung nodules, 1 (4.2%) a bronchovascular pattern, 1 (4.2%) an interstitial lung pattern and 4 (16.6%) had groundglass opacities. Histologically, 4 (16.6%) had *storiform* fibrosis, 20 (83.3%) lymphoplasmacytic infiltrates, and 5 (20.8%) a IgG4/IgG ratio >40%. PET scan showed inflammation in 10 (41.7%) cases. On blood analysis, 5 (20.8%) had peripheral eosinofilia, 12 (50.0%) ESR elevation and 16 (66.7%) CRP elevation, 16 (66.7%) had high levels of IgG4, 2 (8.3%) of IgG1 and 1 (4.2%) of IgE, and 4 (16.7%) had positive ANA. There was 1 (4.2%) death of unknown cause, by the age of 65. As a first line of therapy, 17 (70.8%) patients took oral CCT, with a mean dosage of 20.77mg (DP=22.98) (max=80mg/day), 1 (4.2%) took pulses of CCT, 2 (8.3%) mycophenolate mofetil (MMF), 2 (8.3%) methotrexate (MTX), and 3 (12.5%) rituximab (RTX). Presently, 1 (4.3%) patient is under pulses of CCT, due to lung and aortic disease, 16 (66.7%) are on oral CCT, with a mean dosage of 4.43mg (DP=8.59), 2 (8.3%) are on MMF, 1 (4.2%) on azathioprine, 1 (4.2%) on hydroxychloroquine, 1 (4.2%) on methotrexate, 2 (8.2%) on TNFa-inhibitor, and 7 (29.2%) on RTX. Seventeen (70.8%) patients responded well to the initial CCT; 13 (54.2%) lowered their IgG4 serum levels, and 8 (33.3%) normalized them.

Conclusion: This Portuguese cohort is heterogenous, without gender predominance, more commonly affecting middle aged people and beyond, with orbital and glandular involvement. Response to CCT was good, with a subsequent reduction in IgG4 levels, but with a frequent need to progress to other immunomodulators. Its choice relies on the affected organs – from the initial treatment, there was MTX failure, good response to MMF, and a moderate demand for RTX.

AB1508 ANXIETY AND DEPRESSION IN PATIENTS WITH FMF

Keywords: Innate immunity, Comorbidities

B. Egeli[1], O. Kilinc[2], A. Kilinc[2], F. N. Azman[2], S. Ardac[2], S. Ugurlu[2]. [1]*Children's Hospital Los Angeles, Pediatrics, Los Angeles, United States of America*; [2]*Istanbul University- Cerrahpasa, Rheumatology, Istanbul, Turkey*

Background: Familial Mediterranean Fever (FMF) is a systemic autoinflammatory disease requiring lifelong treatment, characterized by recurrent episodes of fever, arthritis, and serositis. Recent studies denote an association between FMF and behavioral disorders such as anxiety and depression[1]. Further investigations are needed to have a better understanding of the relationship of FMF to anxiety and depression.

Objectives: In this study, we aimed to assess anxiety and depression among FMF patients and their relation to different variables such as gender, age, genotype, drug compliance, biologic treatment, family history of FMF, age of first colchicine dose, age of symptom onset, degree of education, and monthly income.

Methods: We surveyed 360 (225 F, 135 M) FMF patients in our outpatient clinic between June and October 2022. Our surveys included different inventories assessing anxiety and depression which were as follows: Beck's Depression Inventory (BDI), Beck's Anxiety Inventory (BAI), and State-Trait Anxiety Inventory (STAI). We then compared the inventory scores according to different variables.

Results: The median age for the patients was 36.4 ± 11.0 (19-64). Median scores for STAI-Y1 (state), STAI-Y2 (trait), BAI, and BDI were 42.2 ± 12.0, 45.9 ± 10.6, 24.0 ± 13.9, and 13.1 ± 8.99 respectively. There was no significant difference between male and female patients on STAI-Y1, STAI-Y2, and BDI but females scored significantly higher on BAI (25.8 ± 13.7 vs 21.0 ± 13.9, p-value: 0.001). Drug compliant patients had significantly lower scores on STAI-Y1 (41.5 ± 11.4 vs 45.2 ± 14.0, p-value:0.04) compared to non-compliant patients but their scores did not significantly differ on STAI-Y2, BAI, and BDI. M694V homozygous patients got significantly lower scores from BAI and BDI (17.0 ± 12.1 vs 25.1 ± 13.9, p-value: <.001; 12.4 ±9.37 vs 13.2 ±8.93, p-value: <.001). Exon-2 mutation positive patients scored significantly higher on BAI (29.6 ± 13.3 vs 21.6 ± 13.5, p-value: <.001) but did not get significantly different scores from STAI-Y1, STAI-Y2, and BDI compared to Exon-2 mutation negative patients. The patients with Exon-10 mutation get significantly lower scores on BAI (17.9 ± 12.3 vs 27.3 ± 13.7, p-value: <.001) but positivity of Exon-10 mutation did not affect the STAI-Y1, STAI-Y2, and BDI scores significantly. Different groups of educational levels (uneducated, elementary school, secondary school, high school, university) got significantly different scores, low level groups getting higher scores, from STAI-Y2 (56.6 ± 6.80, 48.3 ± 11.6, 43.4 ± 11.0, 45.5 ± 8.63, 45.2 ± 11.2, p-value: 0.002) but all groups scored similarly on STAI-Y1, BAI, and BDI. Different groups of monthly income (<$340, $ 340-680, $ 680-1130, $ 1130+) had significantly different scores from STAI-Y2, BAI, and BDI [(46.7 ± 10.4, 45.8 ± 10.7, 40.8 ± 12.1, 41.3 ± 6.31, p-value: 0.022), (26.1 ± 13.6, 20.9 ± 13.7, 20.1 ± 13.9, 26.2 ± 16.7, p-value: 0.004), (14.0 ± 9.16, 12.2 ± 8.64, 9.88 ± 8.55, 12.3 ± 7.89, p-value: 0.034)] whereas they all had similar scores from STAI-Y1. Having a family member with FMF, biologic agent treatment, age of onset for symptoms, and the colchicine starting age did not have a significant impact on the scores taken from all four inventories.

Conclusion: Our patients had moderate anxiety according to BAI scores, and severe state and trait anxiety according to STAI-Y1, STAI-Y2 scores all of which indicates the presence of anxiety. Medication compliant patients had lower levels of anxiety. We argue that this difference was due to better disease control because of drug compliance. Furthermore, BDI scores indicated mild depression among patients. In addition, M694V homozygous patients interestingly had lower anxiety and depression levels. Further investigations are necessary to understand the effect of different variables on anxiety and depression in FMF patients.

AB1509 MUCOCUTANEOUS INVOLVEMENT IS THE MORE FREQUENT REASON FOR IMMUNOSUPPRESSIVE NEED COMPARED TO MAJOR ORGAN INVOLVEMENT IN AN EARLY MALE BEHÇET'S DISEASE PROSPECTIVE COHORT

Keywords: Behcet's disease

F. Alibaz-Oner[1], B. Aldag[2], S. Kutluğ Ağaçkıran[1], E. Karatay[3], T. Ergun[4], H. Direskeneli[1]. [1]*Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; [2]*Marmara University Faculty*

of Medicine, Department of Hematology, Istanbul, Turkey; [3]*Marmara University Faculty of Medicine, Department of Radiology, Istanbul, Turkey*; [4]*Marmara University Faculty of Medicine, Department of Dermatology, Istanbul, Turkey*

Background: Major organ involvement is one of the main causes of mortality and morbidity in Behçet's Disease (BD) [1]. However, the prognosis and predictors of major organ involvement are insufficiently studied.
Objectives: We aimed to follow young, male BD patients with only mucocutaneous symptoms who have the highest risk for new major organ involvement prospectively.
Methods: Thirty-six male patients with BD were included in the study. Patients with BD were assessed prospectively at 3-6 months intervals and in any urgent visits. New major organ involvements and reasons for immunosuppressive (IS) need were assessed during prospective follow-up.
Results: At baseline, the mean disease duration was 3.3 years. All patients were under colchicine treatment. The mean follow-up duration was 90.7 months. Overall, 13 (36.1%) patients needed IS therapy during follow-up. The reason for IS need was major organ involvement in 5 (13.9%), refractory mucocutaneous involvement in 7 (19.4%), and articular involvement in 1 (2.8%) *(Table 1, Figure 1)*. Major organ involvement was vascular in 3 patients, ocular in 1 patient, and ocular and vascular in 1 patient. In 8 of these 13 patients, step-up treatment was needed in ISs due to refractory disease or relapse.
Conclusion: Our study demonstrated a lower incidence of major vascular events in male BD patients during prospective follow-up compared to retrospective cohorts in the literature. Our results showed that refractory mucocutaneous involvement is a more frequent reason for IS need in BD than major organ involvement during prospective follow-up.

AB1510 THE RELATIONSHIP BETWEEN EMERGING NEW INFLAMMATORY MARKERS AND FAMILIAL MEDITERRANEAN FEVER SEVERITY

Keywords: Biomarkers, Rare/orphan diseases

S. Acer Kasman[1], M. E. Tezcan[1], N. Şen[1], S. Ösken[1], S. Yilmaz-Oner[1]. [1]*Kartal Dr Lutfi Kirdar City Hospital, Rheumatology, Istanbul, Turkey*

Background: Neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR) and monocyte lymphocyte ratio (MLR) are emerging inflammatory parameters. These parameters have been associated with disease activity and response to treatment in many rheumatological diseases.
Objectives: To evaluate the relation between these parameters and familial Mediterranean fever (FMF) disease severity.
Methods: We included 274 FMF patients in the study. First, we measured FMF disease severity cross-sectionally in patients with International FMF severity score (ISSF). We then divided the patients into mild disease (ISSF score ≤ 2) and moderate-severe disease (ISSF score >3) according to ISSF scores. Finally, we compared the NLR, MLR and PLR values between the two groups.
Results: Of 274 patients, 70 (25.5%) had moderate-to-severe FMF disease. More patients had amyloidosis, and the frequency of male gender was higher in the moderate-to-severe group. Other demographic and disease-related characteristics were similar between the groups. NLR, MLR, and PLR values were also similar between groups (Table 1)
Conclusion: Although emerging inflammatory markers are popular in the field of rheumatology, these parameters were unable to differentiate disease severity in patients with FMF.

AB1511 HIGHER VASCULAR INVOLVEMENT IN BEHÇET'S DISEASE AMONG KURDISH ETHNICITY: DATA FROM A SINGLE CENTER AT INTERSECTION OF SILK ROAD IN EASTERN TURKEY

Keywords: Behcet's disease, Epidemiology, Uveitis

E. Oguz[1], M. Bektaş[2]. [1]*Van Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Van, Turkey*; [2]*Aksaray Trainig and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Aksaray, Turkey*

Background: Behçet's disease (BD) is a chronic inflammatory multi-systemic disease that affect skin-mucosa, joints, eye and blood vessels. BD has some clinical differences in terms of disease manifestations and prognosis among Silk Road countries as well as various ethnicities.

Objectives: In this study, we aimed to evaluate the clinical features and course regarding cluster analysis of BD in Kurdish patients in Van provience, Eastern Turkey at the intersection of the silk road.
Methods: This retrospective observational study was carried out in a tertiarry reference center in Van province, East of Turkey. Patients data was obtained from their charts. All patients were asked about their ethnicity and patients with other ethnicities rather than Kurdish were also excluded from the study. Seven disease manifestations were included to the cluster analysis as follows; mucocutaneus findings (recurrent oral ulcer [ROU], genital ulcer [GU], pseudofolliculitis, erythema nodosum (EN)-like lesions, musculoskeletal (MSK) involvement (arthritis and spondylitis), gastrointestinal (GIS) involvement, vascular involvement (venous and/or artery), parenchymal central nervous system (CNS) involvement.
Results: We included 444 patients (of 59.2 % male) to the study. Mean±standard deviation (SD) of the patients was 35.8±10.2 years and median (Interquartile range [IQR]) disease duration was 12 [12]. Mean±SD age at initial symptom and age of diagnosis were 19.4±7 and 26.4±8.2, respectively. Fulfillment of ISG and ICBD criteria were 91.6 % and 96 %, respectively. Family history of Behçet disease and ROU were 35.4 % and 70.2 %, respectively. In cluster analysis, four clusters were observed as follow; 132 patients (31.2 %) in vascular (C1), 66 patients (15.6 %) in eye (C2), 60 patients (14.2 %) in musculoskelethal (C3) and 165 patients (39 %) in mucocutaneus (C4) clusters. Male gender (OR: 6.5, 95 % Confidence interval [CI]: 2-21.4), superficial thrombophlebitis (OR: 4.7, 95 % CI: 1.9-11.4) and uveitis (OR: 3.6, 95 % CI: 1.3-9.9) were associated with vascular involvement in multivariate analysis.
Conclusion: Among Kurdish patients with BD four disease clusters were observed. Parenchymal lung and CNS involvement were associated with vascular cluster. One third of patients had vascular involvement among Kurdish patients with BD which was quite higher compared to patients with Turkish ethnicity [1].

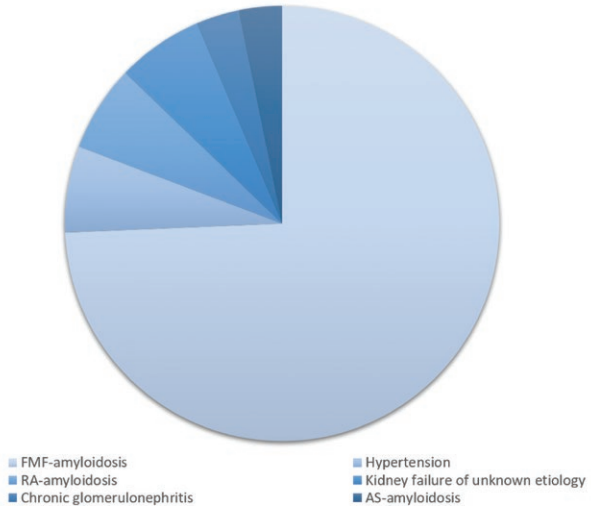
CHARACTERISTICS OF PATIENTS WHO RECEIVED BIOLOGICAL TREATMENT AFTER KIDNEY TRANSPLANTATION AND THE INCIDENCE OF SERIOUS INFECTIONS: A MULTICENTER STUDY

Keywords: bDMARD, Kidneys

T. Demirci Yildirim[1], E. Oguz Kokoglu[2], B. N. Coşkun[3], D. Yıldırım[4], S. Şenel[2], Y. Pehlivan[3], H. Küçük[4], T. Kaşifoğlu[5], İ. Sari[1]. *[1]Dokuz Eylul University, Faculty of Medicine, Rheumatology, Izmir, Turkey; [2]Erciyes University, Faculty of Medicine, Rheumatology, Kayseri, Turkey; [3]Bursa Uludag University, Faculty of Medicine, Rheumatology, Bursa, Turkey; [4]Gazi University, Faculty of Medicine, Rheumatology, Ankara, Turkey; [5]Eskisehir Osmangazi University, Faculty of Medicine, Rheumatology, Eskişehir, Turkey*



Background: Kidney transplant patients due to both primary kidney involvement of chronic/autoimmune inflammatory diseases and end-stage kidney disease related to amyloidosis are followed up in rheumatology clinics. Biological agents one of the treatment options in kidney transplant recipients with chronic/autoimmune inflammatory disease.
Objectives: However, there is insufficient data on the development of infection in kidney transplant recipients who received biological treatment. Herein, we aimed to determine the incidence of serious infections in patients with kidney transplant recipients who are received biological therapy.
Methods: Kidney transplant recipients who are received biological agents due to rheumatologic disease were included in the study. Patients' demographic features, transplantation data, biological treatment, development of infection and severity of infection were screened retrospectively. Infections that requiring hospitalization were defined as severe infections.
Results: A total of 31 patients were included in the study, 14 (45%) of whom were female and mean age was 41 ±9 years. Twenty-five patients (80%) of them were non-preemptive kidney transplant and mean duration of hemodialysis before the transplantation was 40 ±40 months. Twenty-three patients (74%) had end stage kidney failure due to FMF-amyloidosis(Figure-1-). Seventeen patients (54%) received anakinra, 11 patients (35%) received canakinumab and 3 patients (10%) received etanercept with other immunosuppressive treatment. Mean treatment duration of biological agents was 4.2±2.6 years. Two patients developed solid organ malignancy and one patient developed hematological malignancy after transplantation. Sixteen of the patients (52%) were hospitalized at least once due to infection and 4 patients (13%) died due to infection. The cause of decease in two patients was COVID-19.
Conclusion: Rheumatic diseases are an important cause of end-stage renal disease and definitive treatment is kidney transplantation. Kidney transplant recipients due to rheumatological disease also use biological agents in the post-transplantation period.

Kidney transplant recipients have higher risk for the development of infection since they receive immunosuppressive therapy and use of biologic agents may further increase the risk for development infection. Meyer et al reported that infection developed in 54 of 187 solid organ transplant recipients using biological agents.[1] Mean treatment duration of biological agents was 12 months in this study. The incidence of infection was 54% in our study. Mean treatment duration of biological agent was 4.2 year was considered main reason for higher incidence of infection in our study.

AB1513 MANAGEMENT OF RETROPERITONEAL FIBROSIS PATIENTS: A SCOTTISH COHORT OBSERVATIONAL STUDY

Keywords: Rare/orphan diseases, Descriptive Studies, Outcome measures

E. Qian[1], D. S. Sahni[2], P. Lyons[3], D. Porter[1], H. Harris[4]. *[1]NHS Greater Glasgow and Clyde, Rheumatology, Glasgow, United Kingdom*; *[2]NHS Greater Glasgow and Clyde, Urology, Glasgow, United Kingdom*; *[3]NHS Greater Glasgow and Clyde, Medicine, Glasgow, United Kingdom*; *[4]NHS Lothain, Rheumatology, Edinburgh, United Kingdom*

Background: Retroperitoneal fibrosis (RPF) is a rare condition characterised by the inflammation and fibrosis of tissues in the retroperitoneum. Often presenting non-specifically with a variable picture of abdominal pain, constipation, and systemic symptoms of malaise, fever, and weight loss. RPF may also present with severe obstructive uropathy. Initial response to steroids is usually good, but a significant proportion of patients relapse. Evidence for second line treatment is scarce, and a variety of immunosuppressive therapies, such as rituximab, have been used. Surgical intervention and interventional radiology may be useful in treating acute ureteric obstruction and preserving renal function.
Objectives: As an orphan disease without, traditionally, a clear home speciality, retroperitoneal disease is likely underdiagnosed and undertreated especially in those who do not have ureteric obstruction. We characterised patients with retroperitoneal fibrosis across West and South-East Scotland to better understand these patients and their outcomes.
Methods: Patients were previously identified in East Scotland by contacting rheumatologists and by searching the urological stent registry from 2019 to 2022. The method was replicated in the West of Scotland though was less successful as the urological stent register did not record diagnoses, and clinicians did not have an accessible database for this condition. A further avenue of patient identification was then pursued. All available radiological reports and their attached clinical data on the request from 2006 to September 2022 were searched for the term "RPF" and "retroperitoneal fibrosis". Patients were included if they were given a clinical diagnosis of retroperitoneal fibrosis. Patients were excluded if RPF was concurrent with metastatic malignancy, associated with infection or other secondary cause. Patient data was acquired from their electronic records.
Results: 78 patients were identified: 56 in the West of Scotland and 22 in the South-East. Patient demographics are shown in Table 1. The diagnosis was most often made by CT scan. The estimated annual incidence in the last 10 years 2.2 is per million population in the West and 1.6 per million population in the East, for catchment populations of 1.2 million and 0.9 million, respectively. Treatment was heterogenous in both groups. Renal outcomes for these patients were interrogated. Patients were classified as having lost renal function if there was either biochemical or radiological evidence.

Table 1. Summary of findings in the two cohorts across Scotland compared with literature.

	South-East Scotland	West Scotland	Literature
Number	22	56	
Age at diagnosis	60y (range 43-81y)	61.5y (range 45-83y)	54-64y[1]
Female: male ratio	1:2.7	1:1.9	1:1.2-3.4[1]
Lost renal function	73% (16)	75% (42)	
eGFR <60ml/min/1.73m^2	73% (16)	61% (34)	32%[2]
eGFR <30 ml/min/1.73m^2	27% (6)	18% (10)	

Conclusion: The literature suggests renal impairment is variable in retroperitoneal fibrosis with only 32% of patients with abnormal creatinine reported in one study which is much lower than our results. The current literature is sparce for alternative therapies. More work is required in determining efficacy for more recent therapies such as rituximab to further the treatment of this orphan disease and improve patient outcomes.

AB1514 EPIDEMIOLOGY OF BEHÇET'S DISEASE IN NORTHERN SPAIN

Keywords: Epidemiology, Geographical differences, Behcet's disease

C. Álvarez-Reguera[1], G. Suárez Amorín[2], A. Herrero-Morant[1], L. Sanchez-Bilbao[1], D. Martínez-López[1], J. L. Martín-Varillas[3], R. Fernández-Ramón[2], R. Demetrio-Pablo[2], R. Blanco[1]. *[1]Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; *[2]Hospital Universitario Marqués de Valdecilla, Ophthalmology, Santander, Spain*; *[3]Hospital de Laredo, Rheumatology, Laredo, Spain*

Background: The prevalence of Behçet's disease (BD) has a considerable geographical and temporal variability. Data regarding epidemiology in Spain are limited. (1,2)
Objectives: To assess the epidemiology and clinical domains of BD in a population-based cohort from northern Spain and to compare the results with other geographical areas.
Methods: We conducted a cross-sectional study of a well-defined population in Northern Spain. Cases of suspected BD between January 1980 and December 2018 were identified. The diagnosis of BD was established according to the International Study Group (ISG) for Behçet's Disease. The incidence of BD between 1999 and 2018 was estimated by sex, age, and year of diagnosis.
Results: Of 120 patients with probable BD, 59 patients met ISG criteria and were finally included in the study, with a male/female ratio of 0.97; mean age 49.7±14.7 years. Incidence during the period of study was 0.492 per 100,000 people, observing an increase from January 1999 to December 2018. Prevalence was 10.14 per 100,000 in 2018. Figure 1. Clinical manifestations were relapsing aphthous stomatitis (100%), genital ulcers (78%), skin involvement (84.7%), joint involvement (64.4%), uveitis (55.9%), central nervous system (16.9%), vascular (10.2%), and gastrointestinal manifestations (6.8%). Table 1.
Conclusion: The prevalence of BD in Cantabria is higher than in other Southern-European countries. This difference may reflect a combination of geographic, genetic, or methodological variations, as well as the free accessibility to the Spanish Public Health System. Clinical phenotypes observed are similar to those described in other world regions.

EPIDEMIOLOGY AND CLINICAL FEATURES OF MUCOCUTANEOUS LESIONS IN BEHÇET'S DISEASE: STUDY FROM A COHORT OF 120 PATIENTS IN A REGION IN NORTHERN SPAIN

Keywords: Behcet's disease, Epidemiology, Skin

C. Álvarez-Reguera[1], A. Herrero-Morant[1], L. Sanchez-Bilbao[1], D. Martínez-López[2], J. L. Martín-Varillas[3], G. Suárez Amorín[4], R. Demetrio-Pablo[4], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla, Rheumatology, Santander, Spain*; [2]*Hospital de Sierrallana, Rheumatology, Torrelavega, Spain*; [3]*Hospital de Laredo, Rheumatology, Laredo, Spain*; [4]*Hospital Universitario Marqués de Valdecilla, Ophtalmology, Santander, Spain*

Background: Mucocutaneous lesions are one of the most characteristic signs of Behçet's Disease (BD) and are included in different classification criteria [**1**].
Objectives: To describe the mucocutaneous manifestations and to assess it accordingly to age and sex.
Methods: Descriptive study of a cohort of 120 patients diagnosed with BD from January 1, 1980 to December 31, 2019. Finally, we included 92 patients following the 2014 International Criteria for Behçet's Disease (ICBD) [**2**].
Results: 92 patients (45 men/ 47 women) had mucocutaneous involvement. Mean age at diagnosis was (36.3±12.6) years. 27 (29.3%) were young adults (<30 years), 61 (66.3%) middle-aged adults (30-60) and 4 (4.3%) elderly adults (>60 years). The most frequent mucocutaneous manifestations were oral ulcers (OU) (n=92, 97.9%), genital ulcers (GU) (n=69, 73.4%), pseudofolliculitis (n=47, 50%), erythema nodosum-like lesions (EN) (n=28, 29.8%) and Raynaud's phenomenon (n=2, 2%). OU, GU, EN-like lesions and Raynaud's phenomenon were more frequent in women. GU and pseudofollicullitis were more frequent in men. No statistical differences were found between sexes (χ^2 test). Pathergy test was positive in 4 patients. Histopathology of EN-like lesions was performed in 5 patients, 3 (60%) showed septal panniculitis and 2 (40%) vasculitis with neutrophil infiltration, which is a typical pathological finding of EN-like lesion in BD [2]. **Table 1**. Mucocutaneous lesions divided by age groups are represented in **Figure 1**.
Conclusion: Identifying characteristic mucocutaneous lesions of BD, as OU, GU, pseudofollicullitis and EN-like lesions may allow early diagnosis and treatment of the disease. There were no gender differences in mucocutaneous lesions.

APREMILAST FOR TREATMENT OF ORAL APHTOSIS: REAL-WORD DATA MULTICENTER STUDY

Keywords: Real-world evidence, Rare/orphan diseases

N. De la Torre Rubio[1], N. Franco Domingo[2], I. Pérez - Sancristóbal[3], M. Pavía Pascual[1], L. F. Montaño Tapia[4], M. Machattou[1], P. Navarro Palomo[1], M. Alonso de Francisco[1], C. Navarro Joven[1], C. Merino Argumánez[1], M. Fernandez Castro[1], H. Godoy[1], C. Barbadillo Mateos[1], B. Garcia-Magallon[1], L. F. De Villa[1], C. Isasi Zaragoza[1], J. Sanz[1], J. L. Andreu Sánchez[1], J. Campos[1]. Background: The main manifestation of Behçet's disease is oral aphthae. Treatment consists of topical corticosteroids and colchicine in recurrent cases. Drugs such as azathioprine, thalidomide, interferon-alpha, tumour necrosis factor-alpha inhibitors or apremilast should be considered in selected cases[1]. A phase 3, double-blind, placebo-controlled RELIEF study suggests that apremilast is an effective agent for the management of oral aphtae in Behçet's disease and benefits were sustained up to 64 weeks. Its onset of action occurred within 2 weeks after treatment was started. Adverse events, including nausea, vomiting, and diarrhea, occurred more frequently with apremilast than with placebo[2]. It has also been shown to be effective in the treatment of psoriasis[3].
Objectives: To assess the effectiveness of apremilast in the treatment of oral aphtosis.
Methods: Retrospective descriptive multicentre study of patients treated with apremilast for oral aphtosis associated with Behçet's disease, as well as patients with oral aphtosis who have received apremilast for another indication (psoriasis) or off-label use. Four hospitals participated in the study. The following variables were collected: age, sex, diagnosis, oral aphtosis at the time of starting apremilast, aphtosis response at 3 and 6 months (partial improvement, total improvement, lack of response, discontinuation due to side effects), ESR, CRP, ferritin, 25-OH-Vitamin D, folic acid, cyanocobalamin and concomitant treatment (none, corticosteroids, methotrexate, colchicine or anti-TNF). Descriptive statistics were performed using mean and standard deviation (SD) for continuous quantitative variables.
Results: A total of 15 patients were being treated with apremilast for oral aphtosis. Ten of them were diagnosed with Behçet's disease, one with psoriasis with oral aphtosis and four with recurrent oral aphtosis. Mean age was 47.1 ± 12.4 years, 67 % were female. All patients had active oral aphtosis at the time of starting apremilast. After 3 months of treatment, 87 % of the patients had improvement of the aphtosis (61.5 % partially and 38.5 % completely resolved); 13 % of the patients had to discontinue treatment due to side effects (diarrhea), none had to discontinue treatment due to lack of response. After 6 months, all the patients maintained improvement and only two of them discontinued apremilast after 12 months due to lack of response. Results of serological data analyzed were (mean ± SD): ESR 11.4 ± 6.7, CRP 3.7 ± 6.5, ferritin 100.8 ± 167.3, 25-OH-Vitamin D 31.4 ± 18.9, folic acid 11.7 ± 9.8, cyanocobalamin 585.8 ± 527. One patient maintained concomitant treatment with an anti-TNF drug, two with corticoids and five with colchicine.
Conclusion: Treatment with apremilast seems to improve oral aphthae in over 87% of patients.

NAILFOLD CAPILLAROSCOPIC STATUS IN HYPERMOBILE EHLERS DANLOS SYNDROME PATIENTS: PILOT INVESTIGATION

Keywords: Imaging, Diagnostic tests, Rare/orphan diseases

A. Sulli[1], E. Hysa[1], A. Cere[1], F. Lalli[1], A. Pinelli[1], S. Sammorì[1], S. Balito[1], C. Pizzorni[1], S. Paolino[1], V. Smith[2], M. Cutolo[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy, Genova, Italy*; [2]*Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital;, Ghent, Belgium*

Background: Hypermobile Ehlers Danlos syndrome (hEDS) is the most common subtype among the EDS syndromes and is a rare inherited connective tissue disease characterized mostly by hyperextensible skin and generalized joint hypermobility. Microvascular assessment has been documented only by one case report in the "vascular type" of EDS, despite vascular manifestations may

occur also in other EDS subtypes [1,2]. A reduced skin thickness has been previously reported in hEDS patients [3].
Objectives: To investigate, for the first time, nailfold microvascular status in hEDS patients in comparison with healthy controls (HCs). Peripheral blood perfusion (PBP) and dermal thickness (DT) were also assessed.
Methods: Twelve hEDS patients (75% females, mean age 41±16, classified with the 2017 International Classification Criteria of EDS [4]) and twelve age- and sex-matched HCs were observed from 2018 to 2022. Beighton score was calculated for both patients and HCs. Main nailfold videocapillaroscopy (NVC) parameters (dilated capillaries, giant capillaries, microhemorrhages, abnormal shapes and number of capillaries) were analysed and compared between the two groups to assess morphological features [5]. To assess the microvascular functional status, laser speckled contrast analysis (LASCA) was used to measure PBP in several region of interests. DT was also measured by cross-sectional B-mode scans obtained by a high-frequency 22 MHz ultrasound probe in 17 different areas of the body (including upper arms, lower arms, trunk and forehead).
Results: No statistically significant differences were observed in this small cohort between hEDS and HCs concerning the microvascular findings detected by NVC, even if microhemorrages were more prevalent in hEDS patients (33% vs 0 %) (see **Table 1**). Also, PBP assessed by LASCA was found similar in hEDS patients and HCs (178.12 ± 49.76 perfusional units vs 157.81 ± 67.15 at fingertips, p = 0.43). The mean DT did not significantly differ from hEDS patients and HCs in all skin areas (mean total DT of 18.44 ± 2.21 mm in hEDS patients vs 18.49 ± 2.13 mm in HCs, p = 0.96). As expected, the mean Beighton score was significantly higher in hEDS patients than in HCs (5.54±1.75 vs 1.25±1.58), but no significant correlation was detected between DT and Beighton score (r = 0.1, p = 0.76).
Conclusion: Microhemorrages seem more prevalent in hEDS patients than in ECs, suggesting a subclinical microvascular fragilility also in this subgroup of EDS patients. Skin ultrasound and PBP findings did not detect significant differences between hEDS patients and HCs, which might be due to the small sample size. These findings will be followed by further research including cases of the vascular EDS phenotype [6].

AB1518 INCIDENTALLY FOUND INTERSTITIAL LUNG DISEASE MAY NOT BE UNCOMMON IN FAMILIAL MEDITERRANEAN FEVER

Keywords: Rare/orphan diseases, Comorbidities, Imaging

S. Acer Kasman[1], N. Şen[1], T. Baysal[2], R. Dizman[2], S. Yilmaz-Oner[1], M. E. Tezcan[1]. [1]*Kartal Dr Lutfi Kirdar City Hospital, Rheumatology, Istanbul, Turkey*; [2]*Kartal Dr Lutfi Kirdar City Hospital, Radiology, Istanbul, Turkey*

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by episodes of serositis and fever. Pleuritis is one of the common findings especially during attacks and thorax scans. However, data on other common lung findings such as interstitial lung disease (ILD) are limited in the literature.
Objectives: Here, we present the frequency of ILD and factors associated with ILD in our FMF cohort.
Methods: We included 242 patients who applied to the rheumatology outpatient clinic of a tertiary medical center within the last five years and were requested to undergo thoracic CT for any reason. The patients with a history of malignancy, active infection, active tuberculosis, or tuberculosis history, active or history of coronavirus 19 disease (COVID-19), nursing and pregnancy were excluded. An experienced radiologist blindly evaluated thoracic CT scans for ILD in accordance with relevant guidelines. We then evaluated the relationship between ILD findings and demographics and disease characteristics.
Results: Eleven (4.5%) of 242 patients had ILD. The most common ILD-related findings on thoracic CT were ground glass opacity (7/11 patients). None of the patients had honeycomb appearance. The most common reasons for requesting a thoracic CT were chest/chest pain, suspected COVID-19, and chronic cough. In addition, none of the demographic and disease-related characteristics were associated with ILD in our FMF patients (Table 1).
Conclusion: We have shown that incidentally diagnosed ILD is not uncommon in our FMF patients. In addition, FMF feature may not be associated with ILD in our patients.

AB1519 NEUTROPHIL-TO-LYMPHOCYTE RATIO AND PLATELET-TO-LYMPHOCYTE RATIO AS POTENTIAL MARKERS FOR DISEASE ACTIVITY EVALUATION IN BEHCET'S DISEASE

Keywords: Prognostic factors, Biomarkers, Behcet's disease

M. Osipyan[1], A. Haroyan[1]. [1]Erebouni medical center, Rheumatology, Yerevan, Armenia

Background: Behcet's disease (BD) is an auto-inflammatory disorder, characterized by recurrent aphthous stomatitis, genital ulcers, recurrent uveitis, erythema nodosum and other numerous mucocutaneous, gastrointestinal, neurological, vascular manifestations. Despite many biomarkers (anti-lysozyme, serum endocan, serum alpha 1-acid glycoprotein (AGP)) have been investigated for evaluating disease activity and predicting disease severity, none of mentioned above have accessibility to be used in clinical routine. During recent years neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) have been proposed as easy countable markers for severe inflammation and endothelial injury and therefor can be used in the assessment of Behcet's disease activity.
Objectives: The aim of this study is to analyze the potential role of NLR and PLR as markers of the Behcet's disease activity.
Methods: 62 patients with Behcet's disease (76,4% male and 23,6 % female) and 56 healthy controls were included in this study. Patients with Behcet disease fulfilled The International Criteria for Behcet's disease (ICBD 2006). Disease activity was assessed with Behcet's Disease Clinical Activity Form (BDCAF). All patients at the moment of the study had active Behcet's disease. Participants from the control group didn't present any history of cardiac or endocrine disease, because mentioned above conditions can also cause high levels of NLR and PLR.
Results: The mean age of patient group was 36±11,2 years. All patients had oral ulcers at any episode of the disease, 82,26% of patients had erythema nodosum, 61,29% -genital ulcers. 40,38%- eye lesions, 0,05%-entero-Behcet, 0,032%- neuro-Behcet. According to our study, levels of NLR positively correlate with the BDCAF score (r=0.401, p<0.01) and levels of CRP (r=0,571, p<0,01),

while there was no correlation found between PLR and disease activity. Levels of NLR and PLR were both significantly higher in the patient group compare to the controls (p<0,001 and p<0,05 accordingly).

Conclusion: Taking into consideration data from our study NLR could be implemented in clinical practice as a cheap and easy accessible marker of the Behcet's disease activity. On the other hand, further studies with bigger samples are required to evaluate changes of PLR in BD. Assessment of NLR and PLR among BD patient in remission is required to find out if there are any changes compared to healthy controls.

Consultorio Privado Vicente López., Rheumatology, Buenos Aires, Argentina*; *[3]Hospital Provincial del Centenario, National University of Rosario. Clínica Oftalmológica Alfa, Ophtalmology Unit. Hospital Provincial del Centenario, Rosario, Provincia de Santa Fe., Rosario, Argentina*; *[4]Hospital Provincial del Centenario, National University of Rosario., Rheumatology, Rosario, Argentina*; *[5]Hospital Luis Vernaza, Rheumatology, Guayaquil, Ecuador*; *[6]Hospital Italiano de Buenos Aires, Rheumatology, Buenos Aires, Argentina*

Background: Mucous membrane pemphigoid is a systemic, chronic, scarring inflammatory disease of autoimmune aetiology. Isolated ocular involvement has classically been called ocular cicatricial pemphigoid (OCP). Treatment is always systemic, which is why ophthalmologists seek the support of rheumatologists and guidance on autoimmunity. Given the lack of epidemiological data by region, the seriousness of this pathology, and the possible insufficient knowledge by medical professionals, it was proposed to carry out this work.

Objectives: To know the familiarity of rheumatologists and ophthalmologists with OCP and their interdisciplinary interaction in the region.

Methods: An online survey was conducted, which was accessed through a link to a Google form. This questionnaire was addressed mainly to rheumatologists and ophthalmologists belonging to similar scientific societies in America. The link was sent by email to the rheumatology societies. The questionnaire consisted of 13 questions. Questions were asked about age, sex, country, specialty, main place of work of the respondents (public or private institution, or private practice), whether or not they are familiar with the entity, how many patients they see annually, the specialties with which they work each surveyed to address these patients, diagnostic methodology (clinical vs. biopsy), the treatments used, and the difficulties in approaching these patients in daily practice.

Results: Four hundred sixty-three surveys were received and 433 were included, excluding duplications and those surveyed that did not belong to an American country. Most of the participants were from Argentina, followed by Colombia, Chile, and Mexico. Table 1 shows that, in general, doctors who work in private institutions are more aware of the disease, and rheumatologists are the primary specialty that ophthalmologists familiarized with OCP rely on their patients for multidisciplinary management. The most used treatments in the last year were: methotrexate (54.4%), azathioprine (26.8%), mycophenolate (17.4%) and rituximab (16.1%). The main difficulties reported in diagnosing and/or treating these patients were: the lack of information, knowledge, and/or transmission of the OCP in the different scientific activities and texts of the specialties involved in treating this entity; the difficulty in accessing and performing the biopsy of the ocular conjunctiva; and the difficulties in communication between specialists in order to carry out an appropriate follow-up.

Conclusion: Due to the high percentage of insufficient knowledge of this entity by rheumatologists (70%), and the great referral of these patients to rheumatology by ophthalmologists familiar with OCP (80%), it is imperative to work to expand its knowledge, transmission and joint work between both specialties, to improve and protocolize the approach to this entity, which can produce irreversible sequelae on the ocular surface.

Table 1. General characteristics

	Total, n= 433	Familiar with OCP, n=173 (39.9%)	Not familiar with OCP, n= 260 (60.1)	P value
Female, n (%)	252 (58.6)	92 (36.5)	160 (63.4)	0.06
Age, media (DS)	46.6 (11.6)	47.8 (11.2)	45.8 (11.8)	0.08

AB1521 DOES PATIENT POSITION AFFECT COMMON FEMORAL VEIN WALL THICKNESS MEASUREMENT BY DOPPLER ULTRASONOGRAPHY AS A DIAGNOSTIC TEST?

Keywords: Behcet's disease, Ultrasound

R. Ergelen[1], S. Kutluğ Ağaçkıran[2], H. Direskeneli[2], F. Alibaz-Oner[2]. *[1]Marmara University Faculty of Medicine, Department of Radiology, Istanbul, Turkey*; *[2]Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: We reported the first controlled Doppler ultrasound (US) study demonstrating increased common femoral vein (CFV) thickness in Behçet's Disease (BD) [1]. We also recently showed that this is a distinctive feature of BD, rarely present in other inflammatory diseases with a specificity higher than 80% for the cut-off value of ≥ 0.5 mm [2]. Standart lower extremity venous Doppler US is performed in erect position for venous thrombosis or insufficiency [3]. However, we measured CFV thickness in supine position in our previous studies.

Objectives: In this study, we aimed to assess CFV wall thickness measurement by Doppler US both in supine and erect positions to validate the accuracy and practicability of this diagnostic method in BD.

Methods: We included 42 patients (Male/Female:27/15, mean age:39.8 (10.04) years) with a diagnosis of BD and sex and age-matched 41 healthy controls (Male/Female:21/18, mean age: 36.5 (8.4) years). The clinical data were recorded during routine visits. Bilateral CFV thickness was measured with Doppler US both in erect and supine positions by an experienced radiologist on the same day.

Results: Clinical characteristics of BD patients were given in *Table 1.* Bilateral CFV wall thickness was significantly higher in BD than in healthy controls (0.74 vs 0.18 mm, p<0.001 for right, 0.74 vs 0.19 mm, p<0.001 for left). There was no statistically significant difference between erect and supine positioned measurements of CFV wall thickness both in BD and healthy control groups *(Figure 1).*

Conclusion: CFV measurement by Doppler US is a new, accurate and non-invasive diagnostic tool for the diagnosis of BD. Although lower extremity venous Doppler US is performed in erect position for the assessment of venous thrombosis or insufficiency, our study confirmed that patient position does not affect CFV wall thickness measurement. Both erect and supine positioned CFV wall thickness measurements can be done accurately for the diagnosis of BD.

ROLE OF BIPHOSPHONATES IN THE MANAGEMENT OF OSTEOGENESIS IMPERFECTA

Keywords: Bone diseases

F. Fhima[1], J. Mahbouba[1], M. Ardhaoui[1], M. Ghali[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*Fattouma Bourguiba Hospital, Rheumatology Department, Monastir, Tunisia*

Background: Osteogenesis imperfecta (OI), or Lobstein's disease, is a group of genetic diseases characterized by excessive bone fragility, due to a congenital defect in the elaboration of collagen fibers of the connective tissue. Bisphosphonates, with their anti-resorptive properties, are currently the reference medical treatment for this pathology, but remain a symptomatic treatment of the disease.

Objectives: This study aims to describe the addition of biphosphonates to the management of OI.

Methods: This is a retrospective descriptive study collecting patients with OI followed in the rheumatology department of the Fattouma Bourguiba Hospital of Monastir. The study period was 17 years from 2005 to 2021. We investigated the evolution of bone mineral density (BMD) under biphosphonates by evaluating the total gain in BMD with measurement of the SDD: Smallest Detectable Difference (in gr/cm2). The threshold value of the SDD in absolute value is equal to 0.030 to 0.035 g/cm2. A variation of the SDD > 0.030 g/cm2 is a significant variation whether positive or negative.

Results: We collected 16 patients. Fourteen patients had a type I of OI. Type III and type IV were found in one case each. Nine of our patients were male with a sex ratio M/F=1.3. At diagnosis, the patients were divided into 13 children and 3 adults. The mean age at diagnosis was 11 years old for children [1 year, 18 years] and 34 years old for adults [27 years, 40 years]. Fifteen patients had a history of fracture. Fractures in the lower limbs were more frequent than in the upper limbs, with a number of fractures ranging from 3 to 20. Bone deformities were found in 10 patients affecting the lower limbs in 8 cases, the spine in 4 cases, the thorax in 2 cases, and the skull in 1 case. Radiologically, all patients had bone hypertransparency. Spinal involvement was frequent and included scoliosis (2 cases), hypercyphosis (2 cases), biconcave vertebral compression (4 cases) and platyspondylia (4 cases). Osteoporosis was found in 9 cases and osteopenia in 6 cases. Therapeutically, all our patients received vitaminocalcic supplementation and biphosphonates: pamidronate, according to Glorieux's protocol: 1.5 to 3 mg/kg/cycle (i.e., 0.5 to 1 mg/kg/d 3 days in a row) for children and 90 mg (single infusion) for adults. The side effects observed with bisphosphonates were: hypocalcemia in 8 cases, flu-like syndrome in 5 cases, fever in 4 cases, and chest pain in 1 case. The evolution on biphosphonates was evaluated by the total gain in BMD. The mean SDD was: +0.105 g/cm² at the spine (significant positive change), +0.015 g/cm² at the femoral neck (non-significant positive change) and +0.014 g/cm² at the whole body (non-significant positive change).

Conclusion: The therapeutic management of patients with OI is multidisciplinary and complex. In this study, all patients were treated with pamidronate according to the protocol of Glorieux. They had a gain in bone mass that was remarkably significant in the spine.

CLINICAL SIGNS AND ACTIVITY LIMITATIONS ASSOCIATED WITH DURAL SAC ECTASIA IN INDIVIDUALS WITH MARFAN DISEASE: A CROSS-SECTIONAL CASE-CONTROL STUDY

Keywords: Cardiovascular disease, Rare/orphan diseases, Patient reported outcomes

S. Troussier[1], O. Milleron[2], L. Eliahou[2], C. Daste3, M. M. Lefevre Colau3, F. Rannou3, A. Roren3, G. Jondeau[2], C. Nguyen3. [1]*Cochin Hospital, Rehabilitation, Paris, France*; [2]*Bichat-Claude Bernard Hospital, Cardiology, Paris, France*; [1]*Cochin Hospital, Rehabilitation, Paris, France*

Background: Dural ectasia often occurs in individuals with Marfan disease. Fibrillin-1, a matrix component of microfibrils, has been hypothesized to play a role in the circulation of cerebrospinal fluid [1]. Modifications to the circulation of cerebrospinal fluid in individuals with Marfan disease may lead to an increased pressure in the lumbosacral spine and a decreased pressure in the cephalic extremity.
Objectives: We hypothesized that individuals with Marfan disease and dural ectasia, as compared to individuals with Marfan disease without dural ectasia, may display a specific pattern of painful symptoms and spine-specific activity limitations [2]. The aim of our study was to compare: the frequencies and characteristics of painful symptoms, and the intensity of back and leg pain, spine-specific activity limitations and health-related quality of life, between individuals with Marfan disease with and without dural ectasia.
Methods: We conducted a single-centred cross-sectional comparative study. All individuals with Marfan disease followed in the department of cardiology of Bichat hospital (Paris, France) and recorded in the computerized database of the department from inception to January 2022 were systematically screened. Inclusion criteria were: adults ≥ 18 and ≤ 55 years; fulfilling Ghent nosology; FBN1 mutations confirmed by genetic testing; and CT-scan or magnetic resonance imaging available. Non-inclusion criteria were: history of lumbar surgery < 1 year; specific back pain (i.e. tumor, infection, traumatism, fracture, inflammatory rheumatic disease); individuals unable to speak, read and write French. Individuals were considered to have dural ectasia or not to have dural ectasia based on CT-scan or magnetic resonance imaging, according to Ahn and colleagues' criteria [3]. All self-administered questionnaires collected between 1/28/2022 and 9/12/2022 were included in the analysis.
Results: 247 individuals were eligible to participate and were contacted by mail. 90 (36%) individuals accepted to participate and were included: 55 (61%) had dural ectasia and 45 (39%) did not **(Figure 1)**. Mean participants' age was 39.3 (9.4) years and 45 (50%) were women. 80 (89%) participants had back pain, most often located in the lower back, 65 (71%) a history of scoliosis and 8 (9%) a history of spine surgery. 15 (17%) participants had a history of high blood pressure, 84 (93%) a dilation and/or dissection of the ascending aorta, and 52 (58%) an aortic surgery. The 3 most often reported painful symptoms were increased pain in the lower back with upright posture in 53 (58%) participants, increased headache with upright posture in 36 (40%) and increased pain in the lower back when walking in 31 (34%). The frequencies of increased headache with upright posture and of increased pain in the lower back when coughing, laughing and/or sneezing were numerically higher in participants with than without dural ectasia (49% vs 26% and 13% vs 0%, respectively), without reaching statistical significance (p-value=0.030 and p-value=0.021, respectively) **(Table 1)**.
Conclusion: Individuals with Marfan disease and dural ectasia, as compared to those without dural ectasia, display a specific pattern of painful symptoms, including lower back pain and headache with upright posture. We detected too a difference in favor of a link between ectasia of the dural sac and abundance in ascending aortic surgery (64% vs 49%).

A NOVEL ACCELEROMETRY-BASED METHOD FOR EARLY DETECTION OF PERIPHERAL NEUROPATHY ASSOCIATED WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Telemedicine, Diagnostic tests, Validation

Z. Veličković[1], S. Pavlov Dolijanovic[1], N. Tomonjic[1], S. Janjić[2], B. Stojic[2], G. Radunovic[1]. [1]*Institute of Rheumatology, Internal Medicine - Rheumatology, Belgrade, Serbia*; [2]*Institute of Rheumatology, Physical Medicine and Rehabilitation, Belgrade, Serbia*

Background: Systemic autoimmune rheumatic diseases (SARDs) such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), primary Sjögren's syndrome (SS), and systemic sclerosis (SSc) occasionally affect the peripheral nervous system. Nerve conduction studies (NCS) can almost certainly confirm the diagnosis of SARD-associated neuropathy. The NCS method is usually considered the gold standard for neuropathy assessment, although this method is based on physicians' knowledge and experience. However, it is painful for patients, long-lasting, prone to errors, and can't be used for routine follow-up. There is an urgent need for potential alternative diagnostic screening methods for implementation in everyday practice. Wearable sensor devices, such as accelerometers, are instruments that can be utilized to acquire data during different activities. Their size and wirelessness, lower cost, portability, and use in home-based and real-life situations are a few of the advantages.
Objectives: To evaluate a telemedicine wearable device with a machine learning algorithm that can be used as a screening and tracking tool for SARD-related neuropathy.
Methods: A monocentric, diagnostic study was conducted at the Institute of Rheumatology in 2020. The participants were healthy volunteers and SARD patients who had suspected neuropathy. The participant started with the NCS examination; electrodes were placed on the limbs, and amplitude, latency, and conduction velocity of n. medianus, n. ulnaris, n. peroneus, n. tibialis, and n. supraspinatus (motor and sensory fibres) were measured. The novel method consists of four wearable sensors placed over the middle of the hands and feet. The subject performed six exercises with open and closed eyes. Raw data was sent through the Bluetooth connection from the sensors to the tablet and then via WiFi connection to the central server for further analysis. A wearable device uses a specific mathematical algorithm that transforms signals from the accelerometer and gyroscope into specific values. The outcome is defined as a binary variable: whether or not neuropathy exists.
Results: The study included 23 participants (9 ♂ and 14 ♀), 11 with SARDs (45.8%). Of the total number of SARD participants, 8 (72.7%) had neuropathy confirmed with the NCS examination. The features (such as acceleration or power) obtained with signal processing were examined, and only those that can be used to discriminate SARD-related neuropathy are presented (Table 1). The model for binary classification was developed and presented in Table 2. As shown, the sensitivity and specificity are satisfactory, but the confidence intervals are still wide. Positive predictive value is significantly lower compared to negative predictive value.
Conclusion: Wearable sensors represent accurate and promising technology for the diagnosis of neuropathies related to SARDs. Further studies are needed to evaluate the true accuracy of the technology.

AB1525 THE PRESENCE OF POWER DOPPLER SIGNALS IN THE DELTOID LIGAMENT, ESPECIALLY WITH A BROAD AND DEEP DISTRIBUTION, MAY PROVIDE DIAGNOSTIC CLUES FOR SPONDYLOARTHRITIS, PARTICULARLY UNDIFFERENTIATED SPONDYLOARTHRITIS

Keywords: Ultrasound, Rheumatoid arthritis, Spondyloarthritis

T. Suzuki[1], H. Shirai[1]. [1]*Japanese Red Cross Medical Center, Department of Rheumatology and Allergology, Tokyo, Japan*

Background: Power Doppler (PD) signals are occasionally detected in the deltoid ligament on musculoskeletal ultrasound (MSUS) examination of symptomatic ankles in nontraumatic inflammatory rheumatic diseases. However, it is often neglected due to its unclear clinical significance.

Objectives: To evaluate the significance of PD signals in the deltoid ligament detected by MSUS in inflammatory rheumatic diseases.

Methods: We reviewed the record of MSUS examined in Japanese Red Cross Medical Center between April 2015 and October 2022. We examined the characteristics of medical record information and images of cases in which power Doppler signals were observed in the deltoid ligament. Patients with only a few punctate signals or less were excluded. Patients with only traumatic or degenerative disorders were also excluded.

Results: PD signals more than a few punctate signals were observed in the deltoid ligament in 31 cases. The disease categories and diagnoses of the patients were as follows: 13 spondyloarthritis (SpA) patients (9 undifferentiated SpA (USpA), 2 psoriatic arthritis, 2 reactive arthritis), 10 rheumatoid arthritis (RA) patients (6 early RA, 4 established RA), 7 crystal-induced arthritis (CIA) (6 gout, 1 CPPD), and 1 primary Sjögren's syndrome. All SpA patients met the ASAS criteria for peripheral SpA and all RA patients fulfilled the 2010 ACR/EULAR classification criteria. In SpA cases, PD signals tended to distribute widely to the deep layer of the ligament (broad distribution, 10 out of 13 cases), while they tended to be predominant on the outer surface of the ligament in RA cases (superficial distribution, 7 out of 10 cases). There was a significant difference in the PD signal distribution pattern between SpA and RA by Fisher's exact test (p=0.0397). In all CIA patients, hyperechoic materials were detected in the ligament.

Conclusion: According to literature reports, SpA is considered relatively rare in Japan, where the HLA-B27 positivity rate is < 0.3%, with an estimated population prevalence of < 0.01% [1]. The estimated prevalence of patients with RA in Japan is 0.65% [2], similar to the rest of the world. Considering the prevalence of each disease, we speculate that PD signals in the deltoid ligament are more characteristic of SpA. The presence of PD signals in the deltoid ligament, especially with a broad and deep distribution, may provide diagnostic clues for SpA, particularly USpA.

AB1527 TELEDIDACTIC MUSCULOSKELETAL ULTRASOUND COURSE AND COMPARISON WITH CONVENTIONAL ON-CAMPUS TRAINING – INTERIM ANALYSIS OF THE TELMUS STUDY

Keywords: Ultrasound, Education

R. Neubauer[1], F. Recker[2], C. J. Bauer[1], S. Petzinna[1], P. Karakostas[1], P. Brossart[1], V. Schäfer[1]. [1]*University Hospital Bonn, Clinic of Internal Medicine III, Department of Oncology, Haematology, Rheumatology and Clinical Immunology, Bonn, Germany*; [2]*University Hospital Bonn, Department of Obstetrics and Prenatal Medicine, Bonn, Germany*

Background: Musculoskeletal ultrasound (MSUS) is increasingly gaining importance as an imaging tool in rheumatology. Most training programs currently address resident doctors. However, several studies have demonstrated that teaching MSUS to medical students improves their palpation skills and understanding of musculoskeletal anatomy. With the development of portable ultrasound devices, MSUS education is lately getting more flexible and location-independent. In addition, the COVID-19 pandemic raised awareness of telemedicine training as a powerful tool to ensure the teaching of practical skills under pandemic conditions.

Objectives: The purpose of our study is to establish a telemedical MSUS course for medical students and to compare its effectiveness with a conventional on-campus course as a world-wide pilot study. In doing so, we aim to expand student educational opportunities in MSUS using innovative teaching options while ensuring quality maintenance of teaching.

Methods: Thirty medical students were randomized to either a virtual group being delivered only telemedicine instructions, or an on-campus cohort receiving the course in a conventional format. Each student was provided with a hand-held ultrasound device. Prior to the start of the course, the students' skills were assessed with an Objective Clinical Structured Examination (OSCE). During the course, a DEGUM-III-certified course instructor taught the basic physics of ultrasound and standard sections of the MUDE ultrasound protocol[1]. In order to quantify the students' learning progress, a second OSCE was carried out after completion of the course. [1].

Results: At the time of this analysis, data collection within the on-campus course has already been completed, whereas the virtual course is still ongoing. While the average score of the students in the PRE-course OSCE was 21,02% (SD ±6,78), the students were able to achieve an average of 90% (SD ±6,81) in the POST-course OSCE after the intervention.

Conclusion: With the results obtained so far, it can be shown that an innovative course concept with hand-held ultrasound devices, originally developed for dermatologists to improve the detection of psoriatic arthritis, can be used very well in student teaching without major modifications and leads to a significant increase in MSUS skills among medical students. The TELMUS study thereby offers a successful example of extending an existing course concept to student teaching and thus promoting the next generation of rheumatologists.

Background: We demonstrated new bone marrow edema (BME) scoring system in X-ray (specificity 90%, sensitivity 65-70%) using deep learning with artificial intelligence (AI) reflects MRI BME in previous EULAR meeting[1].
Objectives: In this study, to ascertain whether BME score in this system by X-ray film might reflect MRI BME in Biologics therapy, we retrospectively applied this system to the rapid. radiographic progression rescue study previously reported[2].
Methods: RA patients inadequate response with MTX who have extensive BME in single or bilateral wrist joints and DAS28-ESR>3.2 were treated by enhanced group, of conventional synthetic (cs) DMARDs (26 patients) or by biologics (23 patients). X-ray film. of two groups after 3-6 months treatment applied to BME scoringsystem (cut off:0.4) and compared with MRI BME.
Results: J-PEG file of hand Xray film were uploaded to new BME scoring system(Figure 1). BME score are expressed as Positive or Negative and index [0-1]. In biologics group, number of BME score positive rate reduced from 65.3% to 15.3% after treatment in MRI BME improvement group and reduced 78.5% to 57.1% in MRI BME unchanged group(Table 1). In csDMARDs enhanced group, number of BME score positive rate reduced from 75% to 25% after treatment in MRI BME improvement group and reduced 59.7% to 53.1% in MRI BME unchanged group. In both groups, false negative (N: Figure 1, white color back) patients were observed.
Conclusion: AI-derived bone marrow edema score may reflect bone marrow edema in MRI in biologics treatment and may help early recognition of biologics efficacy during treatment.

MICROPLASTIC POLLUTION IN SYNOVIAL FLUID SAMPLES FROM SWOLLEN JOINTS ANALYZED WITH RAMAN SPECTROSCOPY

Keywords: Crystal arthritis, Diagnostic tests

T. Niessink[1,2], M. Janssen[2], T. Jansen[2], C. Otto[1]. [1]*University of Twente, Medical Cell Biophysics group, Enschede, Netherlands*; [2]*VieCuri Medical Centre, Rheumatology, Venlo, Netherlands*

Background: Microplastics (MPs) have been identified in different types of tissue, including lung, bowel, placenta and as well in human whole blood [1]. During analysis of synovial fluid samples with Raman spectroscopy with the purpose of identification of crystals related to crystallopathies, presence of multiple types of MPS have been identified. Due to the recent interest in the effect of plastic pollution on human health, the noticed presence of these particles in synovial fluid samples is concerning and worthy of our attention.
Objectives: The objective of this study was to characterize deposited MPs in samples drawn from arthritis patients presenting to our rheumatology outpatient clinic, with the aim of calculating their prevalence and estimate the significance of their presence against blank control samples as we are using a novel and highly sensitive technique of integrated Raman spectroscopy with Polarized light microscopy in routine clinical practice.
Methods: This is an analysis of Raman spectroscopic data retrieved from 156 synovial fluid samples drawn from a consecutive series of patients visiting our outpatient clinic. Data was compared against a series of blank samples of MiliQ processed in similar fashion. The number of required blank samples was calculated with the formula of Rosner (2011, [2]), the study population was compared against the controls with a Chi-Square test.
Results: A total of 96 MPs were identified, in 4 distinct types; polyethylene (PE), polystyrene (PS), polypropylene (PP), and polyethylene terephthalate (PET). A total of 44 samples (28.2%) were positive for one or more particle (Figure 1). 19 (12.2%) samples had one identified MP, 15 (9.6%) had two identified MP, and 10 (6.4%) had three or more identified MPs (Figure 3). Combinations of MPs were present in 7 of 22 samples (31.8%) with more than one MP. Most MPs were identified extracellular, although one case of intracellular polyethylene particles was identified.

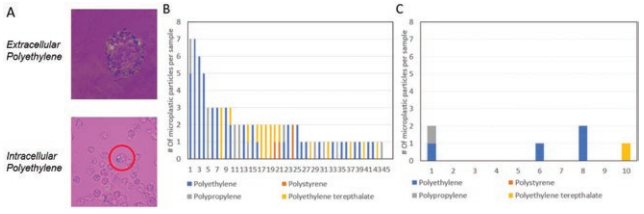

Figure 1 *: A: Compensated polarized light microscopy images of extracellularly and intracellularly found polyethylene microplastics. B: Distribution of particles over patient samples with identified microplastics. C: Microplastics found in control samples.*

The incidence in MPs in the study population was 30.8%. With an alpha (significance level) of 0.05 and a power of 90%, 10 blanks control samples would be enough to find a significant difference if in none of these samples particles are identified. However, we identified one or more microplastics in 4 (40%) of the 10 samples. Polyethylene was identified in 3 samples (30%), polypropylene in 1 (10%), and polyethylene terephthalate in 1 (10%). 1 (10%) sample had a combination of plastic types. With a threshold of 1 or more identified MPs considered positive, there is no significant difference (p = 0.542) between the blank controls and the patient sample population.
Conclusion: Due to numeric presence of extracellular microplastics in both patient material as the blank control samples we define that the presence of one or two MPs in a synovial fluid sample from a swollen joint is not significant and probably of no clinical importance. For the determination whether a higher number of extracellular MPs can be significant and of potential clinical relevance, more control samples are to be measured. The interpretation of the presence of intracellular microplastics needs further investigation.

USING MACHINE LEARNING TO ANALYZE THE FUNDOSCOPY OF ANKYLOSING SPONDYLITIS, PSORIATIC ARTHRITIS AND PSORIASIS

Keywords: Imaging, Artificial intelligence, Spondyloarthritis

Y. J. Huang[1], Y. H. Huang[2], Y. C. Kang[3], Z. Y. Liu[4], J. S. Chen[4], C. H. Lin[5], C. F. Kuo[1,5]. [1]*Chang Gung Memorial Hospital, Department of Rheumatology, Allergy and Immunology, Taoyuan City, Taiwan, Republic of China*; [2]*Chang Gung Memorial Hospital, Department of Dermatology, Taoyuan City, Taiwan, Republic of China*; [3]*Chang Gung Memorial Hospital, Department of Ophthalmology, Taoyuan City, Taiwan, Republic of China*; [4]*Chang Gung Memorial Hospital, Center for Artificial Intelligence in Medicine, Taoyuan City, Taiwan, Republic of China*; [5]*Chang Gung Memorial Hospital, Center for Artificial Intelligence in Medicine, Taoyuan City, Taiwan, Republic of China*

Background: Autoimmune diseases are associated with an increased risk of cardiovascular disease which can be preceded by microvasculature changes. The study about fundoscopy in ankylosing spondylitis is described by Bentum et al.[1] but the related study about deep learning model is insufficient.
Objectives: To validate the ability of machine learning model to verify the fundoscopy of ankylosing spondylitis, psoriatic arthritis, psoriasis and normal control.
Methods: We collected 1864 color fundus exams of 1105 patients with ankylosing spondylitis, psoriatic arthritis and psoriasis in Chang Gung Memorial Hospital in Taiwan from January 2001 to June 2022. The control group is 7122 fundoscopies of 5525 patients matched with age and gender. We separated database into training group, validation group and testing group. (7:1.5:1.5). We trained two convolutional neural networks including Vgg-11 and ResNet-18 models to perform the segmentation and capture the obscure findings of fundoscopy that human eyes cannot identify. We use the sensitivity, specificity, AUC, odds ratio and positive likelyhood ratio to evaluate the performance of machine learning to diagnose ankylosing spondylitis, psoriatic arthritis and psoriasis.
Results: The ankylosing spondylitis, psoriatic arthritis and psoriasis patients have higher body mass index, disease-modifying antirheumatic drugs and biological agent's usage, and even more comorbidities with dyslipidemia, hypertension and coronary artery disease compared with control group. In the setting of one case with solitary image of fundoscopy, the machine learning model of ResNet-18 showed AUC 0.78 with sensitivity 82% and specificity 66 %. In the setting of one case with solitary image of fundoscopy, the machine learning model of Vgg-11 showed the AUC 0.76 with sensitivity 79% and specificity 64%. The odds ratio is 8.54 and the positive likelihood ratio is 2.41 for deep learning model to predict the diagnosis of diseases.
Conclusion: The performance of machine learning model to predict the diagnosis of ankylosing spondylitis, psoriatic arthritis and psoriasis is quite acceptable. Fundoscopy analyzed with deep learning model may be a useful tool to help us to stratify the patient of ankylosing spondylitis, psoriatic arthritis and psoriasis.

HANDS-ON JOINT ASPIRATION WORKSHOP FOR INTERNAL MEDICINE RESIDENTS USING THE KNEE MODEL

Keywords: Education, Qualitative research methods, Diagnostic tests

R. Kaler[1], P. Gonzalez[1], Y. Ahmadzadeh[1], N. Sukumaran[1], Z. Y. Ll[2], K. Gilek-Seibert[2]. [1]*Roger Williams Medical Center, Internal Medicine, Providence, United States of America*; [2]*Roger Williams Medical Center, Rheumatology, Providence, United States of America*

Background: Arthrocentesis is a procedure defined as synovial fluid aspiration that has diagnostic and therapeutic value in both the outpatient and inpatient setting. As mentioned in our prior study, joint arthrocentesis is not an Accreditation Council for Graduate Medical Education (ACGME) procedural requirement for Internal Medicine (IM) residents in the United States. Thus, we started the Phase I of our study, evaluating our in-house IM residents on their confidence level in performing intra-articular injections. This study resulted in more than half of the residents not feeling comfortable in performing arthrocentesis and nearly 100% of them reporting interest in learning arthrocentesis.[1] We later designed and implemented a resident-oriented quality improvement arthrocentesis teaching series.
Objectives: To design an arthrocentesis quality improvement (QI) teaching series for IM residents at Roger Williams Medical Center (RWMC) and evaluate their hands-on procedural skills and post procedural workshop confidence level in arthrocentesis.
Methods: Pre-workshop arthrocentesis learning material, including procedural check list and video, were compiled by IM residents at RWMC. A Rheumatology fellow demonstrated a one-to-one practice session on the knee model and the IM residents were graded based on the thoroughness of the procedural checklist. Each resident completed a post-procedure survey based on this arthrocentesis workshop.
Results: A total of 20 IM residents participated in the knee arthrocentesis workshop. As noted in Table 1, 85% of the residents believed that the pre-session information was helpful in preparing them for the workshop. (Table 1) On the post-workshop survey, 100% of the residents either agreed or strongly agreed to feeling more comfortable with the knee arthrocentesis after the practice, and all (100%) were interested in participating in future knee aspirations. The overall performance on the procedural aspect was also impressive with 40% of residents being able to complete the workshop on the knee model successfully on their first attempt and 55% on their second attempt. (Figure 1) Based on the procedure checklist score in Figure 1, residents were most proficient in the post-procedure stage with 100% score meanwhile, least successful on the aspiration of synovial fluid stage with a score of 55%.
Conclusion: Our QI project has shown that a standardized lecture series on how to perform arthrocentesis has resulted in a significant improvement in the overall confidence of internal medicine residents. This should be taken into consideration and incorporated as part of the internal medicine learning curriculum.

Table 1. Post- workshop survey

Question	Responses
1.What post-graduate year are you?	PGY1: 35% PGY2: 40% PGY3: 25%
2. Prior to the session today, were you comfortable/confident with knee arthrocentesis/injection?	Not Comfortable/confident: 85% Somewhat comfortable/confident: 15% Quite comfortable/confident: 0%
3. The pre-session information was helpful in preparing me for the workshop	Strongly Agree: 85% Agree: 15% Undecided: 0% Disagree: 0% Strongly Disagree: 0%
4. After the first session, I feel more comfortable with knee arthrocentesis.	Strongly Agree: 75% Agree: 25% Undecided: 0% Disagree: 0% Strongly Disagree: 0%
5. Would you be interested in doing more knee aspirations/injections?	Yes: 100% No: 0%

A total of 20 Internal Medicine residents from Roger Williams Medical Center, a community hospital program, participated in this workshop.

Procedure Checklist and Overall Scores:

Patient Checklist (**Total score 6**)
- ☐ Identify correct patient
- ☐ Obtain consent (discuss risks and benefits)
- ☐ Allergy check (Lidocaine? Cleansing liquids? latex etc.)
- ☐ Is the patient on blood thinners? Have bleeding disorders?
- ☐ Any previous procedures? Adverse reactions?
- ☐ Confirm procedure site and mark pertinent landmarks

→ **Average for residents was score of 5.3 (88%)**

Aspiration Site Checklist (**Total Score 3**)
- ☐ Wash hands using sterile technique/use sterile gloves
- ☐ Clean area x3 with povidone-iodine, wipe with alcohol
- ☐ Spray site with ethyl chloride (optional)
- ☐ Inject lidocaine to form a wheal (optional)
- ☐ Insert neele, inject lidocaine along path of needle

→ **Average for residents was score of 2.9 (97%)**

Removal of Synovial Fluid (**Total Score 4**)
- ☐ Prepare aspirating syringe with 18-22 gauge needle
- ☐ Direct needle through weal into joint using technique discussed (lateral)
- ☐ Stabilize syringe with non dominant hand
- ☐ Gently aspirate as much fluid as possible

→ **Average for residents was score of 2.05 (51%)**
→ **40% (8/20) of residents were successful in 1st attempt of procedure, 55% (11/20) in 2nd attempt, 5% (1/20) in 3rd attempt**

Post Procedural Care (**Total Score 4**)
- ☐ Remove needle and dispose
- ☐ Cleanse and apply pressure to aspiration site
- ☐ Bandage +/- Ice
- ☐ Clean your area!

→ **Average for residents was score of 4 (100%)**

AB1532 **ULTRASOUND ASSESSMENT OF A1 AND A2 PULLEY ENTHESIS WITH ANATOMICAL AND HISTOLOGICAL CORRELATION**

Keywords: Imaging, Ultrasound, Enthesitis

L. Coronel[1], M. Miguel[2], J. Blasi[2,3], S. Marsal[1], M. A. D'agostino[4], I. Möller[5]. [1]*Hospital Universitari Vall d'Hebron: Reumatologia, Rheumatology, Barcelona, Spain*; [2]*Universitat de Barcelona - Campus Bellvitge, Unitat d'Anatomía i Embriología Humana, L'Hospitalet de Llobregat, Spain*; [3]*Universitat de Barcelona - Campus Bellvitge, Histologia, L'Hospitalet de Llobregat, Spain*; [4]*Agostino Gemelli University Policlinic, Rheumatology, Rome, Italy*; [5]*Instituto Poal de Reumatologia, Rheumatology, Barcelona, Spain*

Background: Digital entheses are of particular interest in inflammatory arthritis. The annular pulleys (A) are forms of soft connective tissue organized as transverse fibers of variable width, thickness, and configuration that overlay the synovial sheath of flexor tendons. These structures prevent the flexor tendons from bowing and maintain them in constant relationship to the joint axis of motion.
Objectives: To describe and measure the ultrasonographic, anatomical, and histological characteristics of the A1 and A2 annular pulleys entheses.
Methods: A1 and A2 annular pulleys from 15 formalin-embalmed cadavers were assessed by grey-scale ultrasound (Figure 1) and then dissected. The ultrasonographic evaluations included the identification, widths, and characterization of insertion site of the annular pulleys. For the anatomical analysis, dissection was then performed, identifying the transverse fibers of the distal region of the palmar fascia as the proximal limit and the proximal interphalangeal joint as the distal limit. Measurements of the anatomical width of the pulleys were obtained with a digital caliper. For the histological study, 2x2 cm samples were received, fixed with 4% formaldehyde, and processed to obtain paraffin blocks, then cut into 4-micron sections and stained with hematoxylin-eosin. The slides were observed and measured with a Leica DMD 108 microscope. Quantitative data were expressed as mean ± standard deviation (SD) and qualitative data as n (%). Means were analyzed using Student's t-test and frequencies using the chi-square test and Fisher test when needed. Pearson's correlation coefficient (r) was used to analyze the linear correlation between the ultrasonographic and anatomical measurements. Statistical analyses will be performed using the SPSS program version 26.0.
Results: Fifteen cadaveric hands (9 males and six females) with a mean age of 79 years were included. Regarding the ultrasonographic assessment the mean ultrasound width of the A1 pulley was 0.27 ± 0.06 mm and A2 0.11 mm ± 0.04 mm in the thumb, while A1 was 0.36 ± 0.09 mm and A2 pulley 0.46 ± 0.06 mm on the other fingers. A strong correlation between the ultrasonographic and anatomical measurements was found (r=0.82). All A1 in the thumb shows sesamoid bones (SB) in the radial and ulnar sides where the annular pulley make its proximal attachment, while SB was found in just twelve hands in the second finger (80%) and two hands (13%) in the fifth finger. The histological description of the annular pulleys shows a well-vascularized outer surface and a fibrocartilaginous component in the inner surface. The insertion points at the sesamoid or the phalangeal bones demonstrate a diverse nature of the enthesis with fibrocartilaginous and fibrous areas.
Conclusion: These preliminary results show that ultrasound is a valuable tool for identifying annular pulleys' width and entheses, with good correlation with the anatomical and histological study. The annular pulleys have a mixed fibrous and fibrocartilaginous enthesis.

AB1533 **DIAGNOSTIC VALUE AND BENEFITS OF PERFORMING A MINIMALLY INVASIVE TECHNIQUE FOR MINOR SALIVARY GLAND BIOPSY, A CASE SERIES**

Keywords: Sjögren syndrome, Diagnostic tests

M. López-Rodríguez[1], M. Freire[1], C. Cánovas[1], A. Andrade[1], L. Gómez-Suárez[1], B. Sopeña Perez Arguelles[1], A. González-Quintela[1]. [1]*Hospital Clínico Universitario de Santiago de Compostela, Unidad de Enfermedades Sistémicas e Inmunopatología, Servicio de Medicina Interna, Santiago de Compostela, Spain*

Background: Salivary gland biopsy plays an important role in the diagnosis of systemic diseases, especially Sjögren's Syndrome. Minimally invasive biopsy has a low risk of complications with respect to the classical technique, without losing its diagnostic capacity.
Objectives: To assess the utility and safety of minimally invasive technique in patients with suspected systemic disease and salivary gland involvement.
Methods: Retrospective analysis of 31 minor salivary gland biopsies performed by our Systemic Autoimmunity Disease Unit from November 1th 2020 to November 1th 2022, using a minimally invasive technique. Antibody profile and histopathological changes observed were recorded. Adverse events were registered immediately after the procedure and at the next medical visit.
Results: A total of 31 biopsies were reviewed. Mean age of patients was 60 years, most women (n=27, 87%). The success rate of obtaining glandular tissue was 94% (29/31). With respect to immunological data, 24 patients had positive ANAs (77,4%), 24 negative ENAs (77.4%) and 21 negative Rheumatoid Factor (67.7%). In histopathological evaluation 52% were normal salivary tissue (n=16), 23% had focal lymphocytic sialadenitis (n=7), 16% nonspecific chronic sialadenitis (n=5), 6% (n=2) non-existent or insufficient sample and 3% fatty infiltration (n=1). The only complication was a transient superficial lip ecchymosis in one patient (3,2%).
Conclusion: 23% of patients with immunonegative sicca syndrome are diagnosed with Sjögren´s Syndrome due to a minor salivary gland biopsy performed with a minimally invasive technique. This is a simple tool which saves time until diagnosis with low rate complications.

Hoffmann-Vold[7]. *[1]Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; *[2]Inland Norway University of Applied Sciences, Elverum, Public Health, Elverum, Norway*; *[3]Sahlgrenska University Hospital, Radiology, Gothenburg, Sweden*; *[4]University Hospital of North Norway HF, Rheumatology, Tromsø, Norway*; *[5]Revmatismesykehuset, Rheumatology, Lillehammer, Norway*; *[6]Oslo University hospital, Department of Radiology, Institute of Clinical Medicine, Oslo, Norway*; *[7]Oslo University hospital, Rheumatology, Oslo, Norway*

Background: There is a lack of knowledge concerning the validity of International classification of diseases (ICD) diagnoses extracted from health registers although this information is often used in epidemiological studies.
Objectives: To assess the validity of register derived diagnoses of interstitial lung disease (ILD) in patients with rheumatic diseases, using ILD identified on computed tomography (CT) and/or medical journal as gold standard.
Methods: The Norwegian Anti-Rheumatic Drug Register (NOR-DMARD) is a multi-centre prospective observational study that includes patients with a diagnosis of inflammatory arthritis who started treatment with disease modifying anti-rheumatic drugs. NOR-DMARD was linked to the Norwegian Patient Registry (NPR) and Cause of Death Registry. We searched both registers for ILD ICD-10 codes (J70, J84 or J99) and extracted CTs from participants at four hospitals. CTs taken three months before or within one year after the first ICD-10 diagnosis in the registries were considered relevant to the study. An expert thoracic radiologist (FA) scored all examinations according to presence of ILD and categorised the finding into; no ILD, possible ILD and confirmed ILD. Possible ILD CT images were re-examined by a second expert radiologist (TMA). In addition, medical records were searched for ILD diagnoses given by specialist clinicians on several occasions. Presence of confirmed ILD was assessed in patients with available CTs, registry ICD-code for ILD at ≥2 time points and across ILD diagnoses subgroups.
Results: We identified 80 cases with an ILD diagnosis given in a register (ICD-10 n (%); J70 10 (12.5), J84 52 (65.0) and J90 18 (22.5)). CTs were available in 72/80 (90%) patients, 60/72 (83%) within the pre-specified time-window. The ILD diagnosis was confirmed on CT in 31/80 (38.8%) and in 9/80 (11.3%) by medical records only. ILD was validated in 34 (56.7%) of 60 patients with available CT within the relevant time-period and in 28/43 (65.1%) patients who had received an ILD code at ≥2 time points and had a HRCT within the relevant time-period (Table 1). The diagnosis was confirmed in 20 (69.9%) of the 29 patients of this group who had received a J84 diagnoses. ILD diagnoses that were not validated were most frequently given under investigations for respiratory symptoms 20/38 (52.6%).
Conclusion: The validity of registry-based diagnoses of ILD must be carefully considered in epidemiological studies.

Table 1. Positive predictive value of ILD diagnoses from patient registers in cohorts with progressive selection criteria

Number of patients in cohort	Number of patients (%) with an ILD diagnosis confirmed by CT and/or medical records		
80 patients with ILD in register	42 (52.5)		
60 patients with ILD in register and available CT taken within the prespecified time-period	34 (56.7)		
43 with two or more ILD diagnoses in register and available CT taken within the prespecified time-period	28 (65.1)		
45 with two or more ILD diagnoses in register and available CT taken within the prespecified time-period across diagnoses	ICD10: J70 2 (33.3)	ICD10 J84 20 (69.0)	ICD10 J99 6 (75.0)

Footnotes: ILD: interstitial lung disease

Background: Psoriatic arthritis (PsA) is characterized by various patterns of inflammatory arthritis, enthesitis, dactylitis, and spondylitis. Apremilast is an oral immunomodulating phosphodiesterase-4 inhibitor that is indicated for treatment of PsA. Whole-body magnetic resonance imaging (WB-MRI) allows assessment of joints and entheses of the entire body in one examination when using the Outcome Measures in Rheumatology Clinical Trial (OMERACT) MRI whole-body scoring system for inflammation in peripheral joints and entheses (MRI-WIPE), which has not previously been applied in a clinical trial. Here we evaluate the efficacy of apremilast 30 mg BID (APR) on peripheral inflammation indices as measured by WB-MRI.
Objectives: To evaluate how APR affects inflammation in peripheral joints and entheses of patients with PsA as assessed by WB-MRI.
Methods: The phase 4 MOSAIC study was a multicenter, single-arm, open-label study evaluating APR (either as monotherapy or in combination with stable methotrexate) in patients with active PsA (diagnosis ≥3 months but ≤5 years, meeting the CASPAR criteria for PsA) for treatment up to 48 weeks. WB-MRI was performed at baseline, Week 24, and Week 48. Images were read and adjudicated by 2 experienced readers who were blinded to time of acquisition and clinical information. From WB-MRI, changes in the total peripheral inflammation index (83 joints and 33 entheses) were calculated using the OMERACT MRI-WIPE scoring system, as were changes in separate enthesitis and joint inflammation WB-MRI indices (WIPE-enthesitis and WIPE-joint inflammation). Changes in the heel enthesitis inflammation index (HEMRIS), the hip joint inflammation MRI index (HIMRISS), and the knee joint inflammation MRI index (KIMRISS) were explored.
Results: Overall, 122 patients were enrolled and treated with APR; 55% were women, mean age was 47 years, and patients had a mean duration of PsA of 1.9 years. The least squares mean (95% CI) change from baseline in total WIPE score based on total peripheral inflammation index (including both joint and enthesitis inflammation) as assessed by WB-MRI was -3.49 (-5.46, -1.52) at Week 24 and -4.06 (-6.39, -1.72) at Week 48, indicating significant improvement in peripheral inflammation (**Figure 1**). Significant improvements were also observed in the WIPE-joint inflammation scores at both Week 24 and 48, and in the WIPE-enthesitis scores at Week 48 (**Figure 1**). Both the heel enthesitis inflammation index (HEMRIS) and the hip joint inflammation MRI index (HIMRISS) showed little change, while the knee joint inflammation MRI index (KIMRISS) showed numerical, but not significant, improvement (**Figure 1**). No new safety signals were identified.
Conclusion: Patients with PsA treated with APR experienced a significant reduction in total peripheral inflammation, including significant improvement in peripheral joint inflammation and enthesitis, as assessed by WB-MRI. Results highlight the efficacy of APR on inflammatory manifestations of PsA as well as the benefit of using WB-MRI as a measure of inflammatory disease activity.

Figure. Inflammation Indices as Assessed by WB-MRI (FAS)[a]

	Total peripheral inflammation index[4,a]	Peripheral joint inflammation index[4,f]	Peripheral enthesitis inflammation index[4,g]	Heel enthesitis inflammation index (HEMRIS)[g]	Hip joint inflammation MRI index (HIMRISS)[g]	Knee joint inflammation MRI index (KIMRISS)[g]
Baseline Mean (SD)	28.78 (22.54)	24.06 (20.29)	4.73 (3.72)	2.22 (2.74)	0.87 (2.47)	9.93 (27.57)
Week 24[b] LS Mean Change (95% CI)	-3.49 (-5.46, -1.52)	-3.38 (-5.10, -1.66)	-0.17 (-0.65, 0.31)	0.10 (-0.21, 0.42)	0.58 (-0.23, 1.39)	-0.63 (-3.46, 2.21)
Week 48[c] LS Mean Change (95% CI)	-4.06 (-6.39, -1.72)	-3.58 (-5.66, -1.51)	-0.52 (-1.01, -0.02)	-0.01 (-0.38, 0.35)	0.34 (-0.12, 0.80)	-0.67 (-4.33, 2.99)

[a]Defined as all patients who received at least one dose of study medication.
[b]100 patients had WB-MRI assessed at Week 24.
[c]84 patients had WB-MRI assessed at Week 48.
[d]Based on mixed-effect model for repeated measures with change from baseline as the response variable and including scanner type, time as fixed effects, baseline composite score as a covariate.
[e]Sum of the peripheral joint inflammation index (BME + synovitis in 83 joints) and peripheral enthesitis inflammation index (BME and soft tissue inflammation at 33 entheses).
[f]Includes BME and synovitis in 83 joints.
[g]Includes BME and soft tissue inflammation at 33 entheses.
BME, bone marrow edema; HEMRIS, heel enthesitis MRI scoring system; HIMRISS, hip inflammation MRI scoring system; KIMRISS, knee inflammation MRI scoring system; LS, least-squares; SD, standard deviation; WB-MRI, whole-body magneticresonance imaging.

HOME SPIROMETRY AND OXIMETRY MONITORING IN PATIENTS WITH CONNECTIVE TISSUE DISEASE RELATED INTERSTITIAL LUNG DISEASE – A SINGLE CENTRE PROSPECTIVE STUDY

Keywords: Telemedicine, Lungs

W. L. Ng[1], A. Schweikert[2], D. Howard[1], L. Durcan[1], K. Hurley[2,3]. [1]*Beaumont Hospital, Rheumatology, Dublin, Ireland*; [2]*Royal College of Surgeons in Ireland, Tissue Engineering Research Group, Dublin, Ireland*; [3]*Beaumont Hospital, Medicine, Dublin, Ireland*

Background: Interstitial lung disease (ILD) is an important complication in patients with connective tissue disease causing significant impact on quality of life with a high mortality rate.
Objectives: We aim to determine the feasibility of home spirometry and oximetry reading, focusing on patients with connective tissue disease related ILD.
Methods: Patients with connective tissue disease related interstitial lung disease (CTD-ILD), idiopathic pulmonary fibrosis (IPF) and familial pulmonary fibrosis (FPF) were recruited and followed prospectively for 12 months. A handheld spirometer (MIR Spirobank Smart) and oximeter linked to a real-time electronic health journal via a smartphone app to record daily spirometry and oximetry readings were provided. Patients were asked to perform one or more spirometry manoeuvres at approximately the same time daily to reduce variability, with the best value for each day used for analysis.
Results: 62 patients with CTD-ILD, 31 IPF and 21 FPF were recruited. The median age was 66, 71 and 69 years respectively. 47.8% were males. Preliminary data on 99 patients demonstrated median forced vital capacity (FVC) predicted were 82.5% in the CTD-ILD, 84.1% in IPF and 83.7% in FPF cohorts with median follow-up of 208 days. The median oxygen saturation (SpO2) for 9501 readings was 96% in all three cohorts. 27.8% experienced Raynaud's phenomenon but only 5.6% in the CTD-ILD required an ear oximeter due to inaccurate measurement of oxygen saturation secondary to Raynaud's phenomenon.

Table 1. Forced Vital Capacity (FVC) and SpO2 readings in patients with CTD-ILD, IPF and FPF

	CTD-ILD	IPF	FPF
No. of Patients	54	28	17
Median Age (years)	66	71	69
No. of FVC Readings	5157	3384	1624
Median FVC (L)	2.35	2.66	2.06
Median FVC Predicted (%)	82.5	84.1	83.7
No. of SpO2 Readings	4475	3350	1676
Median SpO2 (%)	96	96	96

Conclusion: Home monitoring of FVC and oximetry in patients with CTD-ILD are feasible, empowers patients and generates granular data which can be useful in the detection of rapidly progressing ILD allowing early management.

CAN WE DIFFERENTIATE PATIENTS WITH DYSFERLINOPATHIES AND INFLAMMATORY MYOPATHIES BY MUSCLE ULTRASOUND? A DISCRIMINANT ANALYSIS STUDY

Keywords: Ultrasound, Myositis, Validation

C. Soto[1], S. Y. Solorzano Flores[1], F. Carranza-Enriquez[1], A. Angeles-Acuna[1], R. E. Escobar-Cedillo[2,2,2], C. Pineda[1]. [1]*Instituto Nacional de Rehabilitacion, Rheumatology, Mexico City, Mexico*; [2]*Instituto Nacional de Rehabilitacion, Electromyography and Muscular Dystrophy, Mexico City, Mexico*

Background: Immune-mediated myopathies (IMM) are a heterogeneous group of diseases characterized by inflammation and muscle weakness; among their differential diagnoses are the dysferlinopathies, which are autosomal recessive neuromuscular disorders caused by mutations in the DYSF gene that present muscle weakness and significant increase of CK, just like IMM.
Objectives: Determine the sonographic differences between dysferlinopathies and immune-mediated myopathies and whether these allow their classification.
Methods: Observational, cross-sectional, and analytical study in which we evaluated 20 muscles from 11 patients with dysferlinopathies and 11 with inflammatory myopathies according to current classification criteria. They were matched for age, sex, and time of disease evolution. Clinical and laboratory variables were analyzed. GE LOGIQ™e equipment with a 4-12 MHz linear transducer was used, and the

thickness of each muscle was measured. A semiquantitative scale evaluated elementary lesions: atrophy, edema, power Doppler, and the Heckmatt scale (0-4) was calculated. Descriptive statistics were performed using measures of central tendency and dispersion according to the distribution of the variables, followed by bivariate analysis (Student's t-test and Chi[2] test). Finally, discriminant analysis was performed to determine which ultrasound variables best predicted the diagnoses.

Results: A total of 40 muscles were evaluated, finding a greater degree of atrophy and a higher Heckmatt scale in patients with dysferlinopathies compared to MII. Discriminant analysis showed that the set of 3 muscles, Right biceps/brachialis (BB), Right quadriceps (CD), and Gastrocnemius/right soleus (GC), had a diagnostic accuracy of 100% (sensitivity 100%, specificity 100%, canonical coefficient 0.733 p=.000). We present a set of 2 formulas that allow classifying with the highest score according to the measurement of the muscles in group 1 (dysferlinopathy) or group 2 (MII). Finally, a COR analysis was performed to determine the cut-off points of each muscle to classify as dysferlinopathies.

Conclusion: The study of 3 muscle groups (BB, CD, GC) presents high diagnostic accuracy to differentiate dysferlinopathies from MII, especially when there is no genetic study or antibodies available, and there is diagnostic doubt.

AB1538 DETERMINATION OF ADENOSINE DEAMINASE (ADA) IN SYNOVIAL FLUID TO DIAGNOSE INFLAMMATORY ARTHROPATHIES

Keywords: Synovium, Inflammatory arthritides, Biomarkers

J. A. Bernal[1], J. C. Cortés-Quiroz[1], J. Ena[2], C. Raya-Santos[1], R. Gallego-Campuzano[1], A. Pons-Bas[1], L. Pons-Canet[1], M. Shalabi[3], J. M. Senabre-Gallego[1], G. Santos Soler[1], J. Rosas[1]. *[1]Hospital Marina Baixa, Rheumatology, Villajoyosa (Alicante), Spain*; *[2]Hospital Marina Baixa, Internal Medicine, Villajoyosa (Alicante), Spain*; *[3]Hospital Marina Baixa, Laboratory, Villajoyosa (Alicante), Spain*

Background: Adenosine Deaminase (ADA) determination is used to diagnose tuberculosis in several biological fluids, including synovial fluid (SF). Less known is the usefulness of ADA level in SF diagnosing other inflammatory arthropathies, and only a few reports could be found in the bibliography. In these reports ADA in SF seems higher in patients with septic arthritis, rheumatoid arthritis or crystal arthropathies compared with osteoarthritis.

Objectives: The objective is to evaluate the performance of ADA in SF in patients with joint effusion to diagnose inflammatory arthropathies.

Methods: All SF analyzed in 2022 at one center have been retrospectively reviewed. SF data have been collected (ADA levels and white blood cell) and definitive diagnosis of the treating physician -with all clinical and laboratory data- was recorded. Exclusion criteria were: bursas, prosthesis and hemarthros. Regarding the statistical analysis for the comparison of means of ADA in the different groups, the T-student test was used.

Results: There were 170 SF registered, 17 were excluded, thus finally 153 SF were included in the analysis. They were classified according to the diagnosis of the treating physician -the gold standard-: 95 inflammatory diseases (15 Spondyloarthritis, 9 Rheumatoid arthritis, 21 Gout, 10 Calcium Pyrophosphate arthropathy, 25 nonspecific arthritis, 2 Polymyalgia Rheumatica, 13 septic arthritis) and 58 non-inflammatory conditions (44 osteoarthritis, 9 meniscopathies, 2 osteonecrosis, 2 traumatic, 1 Baker cyst). ADA in SF was higher in inflammatory diseases -including septic arthritis- (mean 40.37 IU/L, SD 55.89) compared with non-inflammatory conditions (19.36, SD 12.20), and it was significant ($p<0.05$). If it is compared with inflammatory arthropathies without septic arthritis (35.28, SD 77.55) it is also statistically significant ($p<0.05$). Moreover, septic arthritis (72.43, SD 5.78) had higher levels of ADA in SF compared with other inflammatory arthritis (35.28, SD 63.66) ($p<0.05$). Furthermore, ADA in SF was higher when SF white blood cell count (WBC) was over 2000/microL – usually considered inflammatory SF- (n=104, ADA mean 40.26, SD 54.28) compared with SF WBC <2000/microL – usually considered non-inflammatory SF- (n=49, 15.72, SD 12.62) ($p<0.05$). In our center when the ADA level in SF is over 30 IU/L is considered positive. Using as gold standard the physician diagnosis, the following results were calculated to diagnose inflammatory arthropathies in patients with synovial effusion: sensitivity (Sn) 40% (30.7-50.1), Specificity (Sp) 89.7%, (79.2-95.2), positive predictive value (PPV) 86.4% (73.3-93.6) and negative predictive value 47.7% (38.6-57). And it was calculated for septic arthritis in patients with inflammatory arthropathies: Sn 69.2% (42.4-87.3), Sp 64.6% (53.8-74.1), PPV 23.75% (13-39.2%) and NPV 93% (83.3-97.2).

Conclusion: ADA in SF is higher in inflammatory arthritis -including septic or not- than non-inflammatory arthropathies. Even more, in septic arthritis SF ADA is higher than in other inflammatory arthropathies. However, comparing with the gold standard ADA test has no good results except for Sp (89.7%) and PPV (86.4%) to diagnose inflammatory arthritis and NPV (93%) to diagnose septic arthritis. The results are limited given the low number of septic arthritis (13) and the sample will be expanded to recalculate and establish a more appropriate ADA threshold for diagnosing septic arthritis and inflammatory arthropathies.

AB1539 PREVALENCE OF ANTI-CN1A ANTIBODIES AND ITS CLINICAL SIGNIFICANCE – A RETROSPECTIVE MONOCENTRIC STUDY

Keywords: Descriptive studies, Autoantibodies, Epidemiology

S. P. Silva[1,2], C. Fortes[2,3], G. Eugénio[1,2], A. Barcelos[1,2,4]. *[1]Centro Hospitalar Baixo Vouga, Aveiro, Rheumatology department, Aveiro, Portugal*; *[2]Egas Moniz Health Alliance Academic Clinical Center, Egas Moniz Health Alliance Academic Clinical Center, Aveiro, Portugal*; *[3]Centro Hospitalar Baixo Vouga, Clinical Pathology, Aveiro, Portugal*; *[4]Nova Medical School, Comprehensive Health Research Center, Lisboa, Portugal*

Background: Anti-cytosolic 5'-nucleotidase 1A (anti-cN1A) antibodies have recently been proposed as a biomarker for inclusion body myositis (IBM). With high specificity (87-100%), they can help differentiate IBM from other myositis.[1,2] Besides IBM, it has been detected in other inflammatory conditions. Recently, a higher prevalence of IBM has been associated with Sjogren Syndrome (SS), and anti-cN1A has been associated with myositis in SS, regardless of the subtype of myositis.[3] However, it can also be detected in healthy individuals and despite its high specificity in IBM, it may not be a useful biomarker for the diagnosis of autoimmune conditions.[4] Thus, the clinical relevance of anti-cN1A remains unknown.

Objectives: The aim of this study was to identify the clinical and laboratory manifestations associated with the presence of anti-cN1A.

Methods: A retrospective study of patients with anti-cN1A positivity (detected by immunoblot assay), observed from January 2021 to December 2022, in a tertiary hospital, was conducted. Demographic, clinical and immunological data were collected. A descriptive analysis was made.

Results: Sixty-five patients were positive for anti-cN1A: 53 women (81.5%) and the median age was 47.2±14.9 years. Rheumatic inflammatory diseases were diagnosed in 15 (22.7%) patients, of which 5 had systemic lupus erythematosus (SLE), 4 had SS, and 1 with rheumatoid arthritis, polymyalgia rheumatica, granulomatosis with polyangiitis, juvenile idiopathic arthritis, spondyloarthritis and undifferentiated connective tissue disease. Eight (12.1%) patients had autoimmune thyroiditis, without known rheumatic diseases associated. The presence

of anti-cN1A was also found in the context of infection in 7 (10.6%) patients and malignancy in 2 (3.0%) patients. Half of the patients (50.8%) patients were healthy individuals. No diagnosis of IBM or other myositis was made. Twenty-nine (44.6%) patients showed other antibodies specificities: anti-SSA/Ro52 (20%), anti-Ku (4.6%), anti-Mi-beta2 (4.6%) and anti-DSF70 (4.6%). In the SLE and SS groups, the most frequent presenting clinical features were sicca syndrome (66.7%), lymphopenia (9.2%), arthritis (6.1%) and photosensitivity (3.1%). No patient had signs or symptoms of muscular involvement.

Conclusion: Anti-cN1A was detected in diverse rheumatic conditions, but also in autoimmune thyroiditis and mostly in healthy individuals. SLE and SS were the most frequent systemic autoimmune rheumatic diseases associated with these antibodies. Contrary to expectations, no diagnosis of IBM or myositis was made. Further studies regarding the clinical significance of anti-cN1A are needed to attribute the real diagnostic value of this marker.

AB1540 PREVALENCE AND DISTRIBUTION OF SONOGRAPHIC ELEMENTARY LESIONS IN PSA – RESULTS OF 2 COHORTS

Keywords: Imaging, Ultrasound, Psoriatic arthritis

A. Polachek[1,2], V. Furer[1,2], S. Thib[3], L. Mendel[2], O. Elkayam[1,2], L. Eder[3]. *[1]Tel Aviv Sourasky Medical Center - Ichilov, Rheumatology, Tel Aviv-Yafo, Israel; [2]Sackler faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, Medicine, Tel Aviv-Yafo, Israel; [3]Women's College Research Institute, Women's College Hospital, University of Toronto, Toronto, ON, Canada, Rheumatology, Toronto, Canada*

Background: Psoriatic arthritis (PsA) can manifest with different musculoskeletal (MSK) features. Ultrasound (US) optimizes the assessment of the different MSK features in PsA. However, there is no consensus on which MSK sonographic lesions and what locations should be evaluated by US.

Objectives: To examine the prevalence and distribution of key sonographic MSK lesions in patients with PsA.

Methods: This study included two prospectively recruited PsA cohorts. Cohort 1 included 158 consecutive PsA patients and cohort 2 included 94 patients with active PsA prior to initiation of therapy. All underwent a comprehensive US assessment, including both gray scale (GS) and power Doppler (PD) of 50 joints, 40 tendons and 14 entheses. The following sonographic lesions were assessed by two sonographers blinded to clinical data: I. Inflammatory lesions - Synovitis, tenosynovitis, peritenonitis and enthesitis and II. Structural lesions - erosions and bone proliferations. Presence/Absence of these lesions was determined based on previously suggested definitions by OMERACT (when available) or other publication and their prevalence by joint/tendon site was reported.

Results: In cohort 1, mean ± SD age was 52.7 ± 13 and 55.7% were females. In cohort 2, mean ± SD age was 47.5 ± 13.2 and 48.8% were females. The most prevalent locations of the inflammatory lesions in both cohorts were (Figure 1): Synovitis (small joints) – MCP2 (cohort 1: 11%, cohort 2: 27%), MCP 3 (cohort 1: 7%, cohort 2: 26%), IP1 (cohort 1: 5%, cohort 2: 25%) PIP 3 (cohort 1:3%, cohort 2: 16%), MTP 1 (cohort 1: 31%, cohort 2: 35%), MTP2 (cohort 1: 23%, cohort 2: 30%), MTP3 (cohort 1: 14%, cohort 2: 22%); Synovitis (medium-large joints) – wrist (cohort 1: 27%, cohort 2: 30%) and knee (cohort 1: 13%, cohort 2: 29%); tenosynovitis – 2nd finger flexors (cohort 1: 2%, cohort 2: 12%) 3rd finger flexor (cohort 1: 2%, cohort 2: 10%); extensor peritenonitis – MCP2 (cohort 1: 2%, cohort 2: 7%), MCP3 (cohort 1: 4%, cohort 2: 12%), PIP 3 (cohort 1: 3%, cohort 2: 13%), PIP4 (cohort 1: 2%, cohort 2: 12%); enthesitis – lateral epicondyle (cohort 1: 11%, cohort 2: 14%) and triceps (cohort 1: 7%, cohort 2: 20%); erosions – MCP1 (cohort 1: 4%, cohort 2: 5%), MCP2 (cohort 1: 6%, cohort 2: 7%), IP1 (cohort 1: 2%, cohort 2: 2%) PIP2 (cohort 1: 2%, cohort 2: 1%), MTP5 (cohort 2: 4%); bone proliferations – MCP1 (cohort 1: 12%, cohort 2: 7%), MCP2 (cohort 1: 10%, cohort 2: 17%), MCP3 (cohort 1: 5%, cohort 2: 17%), IP1 (cohort 1: 25%, cohort 2: 41%), PIP2 (cohort 1: 10%, cohort 2: 16%), PIP3 (cohort 1: 14%, cohort 2: 26%), DIP2 (cohort 1: 23%, cohort 2: 42%), DIP3 (cohort 1: 18%, cohort 2: 42%) and DIP5 (cohort 1: 29%, cohort 2: 49%).

Conclusion: This descriptive study provides comprehensive information on the most commonly affected sites for key inflammatory and structural domains in PsA. This information can inform efforts to develop reduced sonographic score to diagnose or monitor disease activity in PsA.

AB1541 THE INTENSITY OR DURATION OF INFLAMMATORY BACK PAIN HAS NO IMPACT ON THE DETECTION OF SACROILIITIS BY MAGNETIC RESONANCE IMAGING IN AXIAL SPONDYLOARTHRITIS

Keywords: Imaging, Spondyloarthritis

G. Sevik[1], E. Bıyıklı[2], O. Buğdaycı[2], K. Abacar[1], S. Kutluğ Ağaçkıran[1], Ş. Çolakoğlu Özkaya[3], G. Ekinci[4], P. Atagündüz[1]. *[1]Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; [2]Marmara University School of Medicine, Department of Radiology, Istanbul, Turkey; [3]Marmara University Institute of Health Sciences, Department of Medical Biology and Genetics, Istanbul, Turkey; [4]Yeditepe University School of Medicine, Department of Radiology, Istanbul, Turkey*

Background: Sacroiliac joint (SIJ) magnetic resonance imaging (MRI) is an established tool in the evaluation of patients with axial spondyloarthritis (axSpA). In the validation study of the ASAS classification criteria for axSpA, only 63.1% of patients had sacroiliitis on the SIJ-MRI.[1] Studies that enrolled patients with axSpA based on expert opinion reported the sensitivity of MRI between 35 to 42% in detecting sacroiliitis.[2,3]

Objectives: This study aimed to evaluate the temporal relationship between ASAS defined positive MRI and the characteristics of low back pain (LBP) in axSpA.

Methods: Following axSpA groups were enrolled in the study whenever an attending physician ordered an SIJ-MRI. Patients fulfilling both the Rudwaleit criteria for inflammatory back pain (IBP) and Amor criteria, patients with a previous classification with either modified New York or ASAS classification criteria.[1] A blinded rheumatologist (GS) recorded the intensity and duration of IBP using a questionnaire before SIJ-MRI. MRI appointments were based on availability. Therefore some patients did not have IBP at acquisition. Two radiologists assessed SIJ-MRIs using the ASAS/OMERACT MRI group definition of active sacroiliitis.[4] In case of discrepant reporting, a third experienced radiologist (GE) adjudicated the SIJ-MRIs. The probability of axSpA is estimated using sum scores for SpA features excluding the SIJ-MRI.[5] The correlation between an ASAS-defined positive MRI and LBP characteristics was analyzed.

Results: Fifty-nine patients (32 F/27 M) were included. Patient characteristics are given in Table 1. Overall, 28 of 59 patients (47.5%) had a positive SIJ-MRI defined by ASAS.

The median duration of LBP was 15 (43) days and the highest intensity of LBP was felt 6.5 ± 1.2 days before the MRI appointment. At acqusition, 13 (22.0%) patients reported no LBP. There was no significant difference between the presence of LBP within 10 days prior to MRI and sacroiliitis on MRI. (p=0.6) (Sacroiliitis in 45.7% with, and 53.8% without LBP) In LBP reporting patients, pain duration and pain VAS score were 3.3 ±2.3 and 7.1 ±1.9 in patients with sacroiliitis, and 8.7 ±3.6 and 6.8 ±1.7 in patients without sacroiliitis on MRI, respectively. (p=0.48, p=0.10) Age, sex, BASDAI, CRP and calculated probability of axSpA had no correlation with the presence of sacroiliitis on MRI. Adding sacroiliitis on SIJ-MRI to axSpA probability score increased the rate of patients with a probability of >90% for axSpA from 71.2 to 83.1% but the rate of sacroiliitis on MRI was similar in all probability groups.

Conclusion: These results suggest that the presence of LBP and the duration of intense pain do not affect the detected rate of sacroiliitis on SIJ-MRI in axSPA. The low prevalence of sacroiliitis in this study population implies its value as a classification tool. Further studies with larger sample sizes are needed to clarify the factors affecting the SIJ-MRI findings in axSpA patients.

AB1542 APPLICATION OF THE OMERACT ULTRASOUND SCORING SYSTEM FOR SALIVARY GLANDS IN PATIENTS WITH SUSPECTED SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Imaging, Ultrasound

R. Bourguiba[1], S. Bellakhal[1], M. Charfi[2], M. Boudokhane[1], H. Bouhaouala[2], M. H. Douggui[1], K. Bouzaidi[3]. *[1]Hopital des Forces de Sécurité de l'Intérieur, Internal Medecine, La Marsa, Tunisia*; *[2]Hopital des Forces de Sécurité de l'Intérieur, Radiology, La Marsa, Tunisia*; *[3]Hopital Taher Mamouri, Radiology, Nabeul, Tunisia*

Background: Primary Sjogren's Syndrome (pSS) is a connective tissue disease characterized by the presence of sicca syndrome. Confirmation of pSS requires immunological test and biopsy of the accessory salivary glands[1]. Salivary gland ultrasonography (SGUS) allows the detection of structural changes of salivary glands and is proposed as a reliable tool to assess involvement of major salivary glands in patients with pSS. Recently, a new semi- quantitative score have been validated by experts: The OMERACT US score to assess salivary gland involvement in pSS [2].

Objectives: The aim of our study was to describe salivary gland involvement in patient with suspected of pSS according to the OMERACT ultrasound scoring system for pSS.

Methods: All patients referred for a suspicion of pSS during the last period june 2022-2023 were enrolled. All underwent measurement of salivary flow, minor salivary gland biopsy, SSA antibody. SGUS was performed for all included patients. Both parotid glands and submandibular glands were exanimated using the scoring system 0-3 (OMERACT). Exact Fischer test was used to compare qualitative variables. Sensitivity, specificity and cutoffs were determined by ROC curve analysis.

Results: We enrolled 73 patients with a suspected pSS. Women represented 80 % of the cohort. Median age was 59 years [Q1 52-Q3 65]. Thirty-four patients were diagnosed with primary SS (pSS) and all fulfilled the 2016 American College of Rheumatology (ACR)/EULAR classification criteria. Thirty-one (91%) patients with pSS had a focus score > 1 in the biopsy of minor salivary gland. Twenty-one (62%) of patients with pSS had a positive SSA antibody. Of the 73 patients, 26 (35%) patients had at least one gland with an ultrasound score of 2 among them, 21 patients were diagnosed with pSS. More patients with pSS compared with non-pSS had score ≥2 in at least one gland (21 pSS vs 5 non pSS) in at least one gland. Among the 26 patients with an ultrasonographic score ≥ 2, 14 patients had positive SSA antibody (p= 0.001). When using ROC analysis, we found that an ultrasound score cutoff ≥2 in at least one gland was associated with a sensitivity at 67 % and specificity at 88%, air under the curve (AUC) was 0.83 [IC95% 0.732-0.93].

Conclusion: More patients with pSS compared with non-pSS had score ≥2 in at least one gland (21 pSS vs 5 non pSS) in at least one gland. An ultrasound cutoff > 1 is associated with a sensitivity at 67 % and Specificity at 88%. Our data supports what have been previously reported in several studies. Fana et al [3] reported in a cohort of 143 patients with suspected pSS that the best ultrasound cutoff value was ≥ 1 gland with a score ≥2 was associated to sensitivity at 72 % and specificity of 91%. Our data supports the importance of use of ultrasound as tool for diagnosing pSS. SGUS should be integrated as a criterion in ACR/EULAR score.

AB1543 POSITIVE MRI OF THE SPINE AS IMAGING CRITERION FOR DIAGNOSIS OF AXIAL PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Spondyloarthritis, Imaging

M. L. Molina[1], D. Rios[2], A. Goecke[1], D. Suarez[2], M. Parada[1,3]. *[1]Hospital Clinico Universidad De Chile, Medicina Interna, Seccion Reumatologia, Santiago de Chile, Chile*; *[2]hospital Clinico Universidad De Chile, Departamento de Radiologia, Santiago, Chile*; *[3]Hospital del Trabajador, Medicina Interna, Providencia, Chile*

Background: MRI is essential for axial spondyloarthritis (axSpA) diagnosis. A positive MRI in the ASAS classification criteria of axSpA is based on inflammatory lesions in the sacroiliac joints. These lesions are defined as one bone marrow edema (BME) highly suggestive of axSpA present on ≥ 2 consecutive slices or ≥ 2 BME A on a single slice. The addition of MRI of the spine as an imaging criterion to the ASAS axSpA criteria had a low yield of newly classified patients and is therefore not recommended. Axial psoriatic arthritis (axPsA) remains poorly defined despite its high prevalence among patients with PsA. Studies comparing axPsA with other axSpA, such as Anquilosing Spondylitis (AS), have found differences in the former, including more frequent asymmetric spine and SIJ involvement, cervical involvement, and isolated spondylitis.

Objectives: Describe the presence of inflammatory and structural lesions on MRI-spine and SIJ in patients with psoriasis. Evaluate the added value of spinal inflammatory lesions on MRI-spine and structural lesions on MRI-SIJ as imaging criterion for axPsA diagnosis.

Methods: We performed a retrospective study of patients with psoriasis with at least a whole spine and sacroiliac joints (SIJ) MRI performed at Universidad de Chile Clinical Hospital between January 2015 and December 2021. MRI were performed in a 1.5 T machine, following a non-contrast protocol. Sagittal T1-weighted (T1w) and T2-weighted fat-suppressed fast spin echo sequences were available for the spine, while semi-coronal T1w and short inversion recovery sequences for the SIJ. Structural and inflammatory lesions were defined according to the ASAS/OMERACT definitions. Results are presented as mean and SD or numbers and percentages.

Results: 34 patients with psoriasis were analyzed, 17 (50%) were male, and the mean age at the time the MRI was performed was 43.7 ± 10.6 years. The

most common type of psoriasis was vulgaris (85%) and time from diagnosis was greater than ten years at least in 65% of patients. The majority of patients experienced chronic back pain (82%), and 15 (44%) patients had IBP according to ASAS criteria. MRI-SIJ showed structural and/or inflammatory changes in 16 patients. In 15 of them, BME was present. Of these 16 patients, 8 (50%) had no lesions in MRI-spine. In MRI-spine, 11 patients showed structural and/or inflammatory changes, and 5 of these 11 patients (55%) had BME suggestive of axSpA according to ASAS/OMERACT criteria. When we analyzed patients with an MRI negative for sacroiliitis (19 patients), 3 had BME on MRI-spine, with only two patients with three or more BME lesions according to ASAS/OMERACT criteria. Finally, when a chronic lesion on MRI-SIJ was considered as a possible criterion for classification, among patients without sacroiliitis, one patient could be deemed to have axSpA. The findings in this image of SIJ were erosions and fatty deposition (Romanus sign).

Conclusion: A positive MRI-spine in patients with suspected axPsA was more frequent than previously described for axSpA. Furthermore, spinal inflammation in the absence of sacroiliitis was present in 2 of the 19 patients in this cohort. Therefore, MRI-spine could be considered in the classification criterion for patients suspected of axPsA.

PARAVERTEBRAL MUSCLES TRIGGER POINTS ATTACHED TO FACET JOINTS ARTHROSIS ARE PREFERRED TARGETS FOR ULTRASOUND-GUIDED INTERVENTION TO TREAT LOW BACK PAIN

Keywords: Physical therapy/physiotherapy, Ultrasound, Rehabilitation

R. Bubnov[1,2], L. Kalika[3], Z. Pilecki[1,4], G. Pilecki[4]. [1]*Jan Dlugosz University in Czestochowa, Health Sciences, Częstochowa, Poland*; [2]*Clinical hospital `Pheophania`, Ultrasund, Kyiv, Ukraine*; [3]*New York Dynamic Neuromuscular Rehabilitation &Physical Therapy, Rehab, New York, United States of America*; [4]*Center of Sport Medicine, Orthopedic, Zabrze, Poland*

Background: Facet joints (FJ) arthrosis can be a cause of pain and spinal instability and considered to be a potential target for injection treatment. However, FJ arthropathy is difficult for diagnosis and confirmation associations with pain syndrome, effectiveness of FJ injections is debated. Trigger points (TrPs) are major cause of pain syndromes, dry needling under ultrasound (US) guidance (DN-US) is a crucial therapeutic for treatment of myofascial pain [1], is a proven and effective method for treatment various pain conditions; can restore muscle function and motion [2], reduce fascia overload [3], and can improve movement in spine and also in FJ.

Objectives: Aim was to evaluate the relevance of US for diagnosis of FJ arthrosis as a cause of pain and evaluate the efficacy of DN-US to treat FJ-associated low back pain and improve movement in spine and facet joints.

Methods: We included 26 consecutive patients (15 females, 23-57 years old) with symptoms of LBP, suspected due to uni- and bilateral FJ arthrosis assessed at MRI and CT with three-dimensional reconstructions. Conditions of rheumatic, paresis, advanced injury background were excluded. All patients received DN-US protocol by R. Bubnov [1]: MTrP were identified according to clinical examination, referred pain pattern, US identification; single fine (28G) steel needle DN under US guidance was applied to elicit local twitch response (LTR) and/or `needle grasp`. Specific recommendations were given to preserve effect after DN-US.

Results: We diagnosed bi- and unilateral FJ arthrosis on US at the levels of Th11-S1 in all patients, assessed fluid in joints, deformation, movement restriction and revealed closely localized TrPs in paravertebral (multifidus) muscles followed by targeted DN-US. We distinguished different pain patterns (referred pain - groin pain, pelvic pain, irradiation to leg, thigh, etc.) which correlated with facet arthrosis localizations. Pain decreased in all patients VAS from 6-8 at baseline to 1-4 immediately and VAS 3-4 at one week after procedure. We noted decreasing in neuropathic pain, detected higher rates of lumbar spine motility, movements in particular segments and FJ were registered on functional US; improvement postural balance in all patients after DN-US. Additional needling sessions to FJ capsule did not induce significant LTR and effective alleviating pain compared to DN-US. All patients had postural imbalance, had multiple bilateral MTrPs: in multifidus muscles at thoracic, lumbar levels; sacroiliac joint dysfunction, shoulders impingement, other associated postural abnormalities; all MTrPs were inactivated, posture imbalance restored.

Conclusion: US is helpful to detect FJ arthrosis; DN-US has a good treatment outcome for low back pain due to FJ arthrosis. Local interventions targeting FJ in most cases not relevant approach; DN-US is not less complicated technically, however, more effective vs targeting FJ. Complex posture assessment and correction is needed.

A COMPARATIVE ANALYSIS BETWEEN THERMAL AND ULTRASOUND IMAGING AT THE ELBOW IN PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Imaging, Rheumatoid arthritis, Ultrasound

Y. K. Tan[1], R. Sultana[2], J. Thumboo[1]. [1]*Singapore General Hospital, Department of Rheumatology and Immunology, Singapore, Singapore*; [2]*Duke-NUS Medical School, Centre for Quantitative Medicine, Singapore, Singapore*

Background: Thermal imaging (TI) is a relatively low cost, non-invasive imaging technique that offers a quick and objective measurement of joint surface temperature. However, TI data at the elbow in patients with rheumatoid arthritis (RA) is presently lacking.

Objectives: The aim of this study is to compare TI outcomes with ultrasound (US) joint inflammation findings at the elbow among patients with RA.

Methods: TI and US imaging were performed at the same study visit. TI was carried out in a draft free room following a standardized protocol. The maximum (Tmax), average (Tavg) and minimum (Tmin) temperatures at the elbow (anterior, posterior, lateral and medial aspects) were summed up to obtain the respective MAX, AVG and MIN temperatures for the right and left elbows. Ultrasound power Doppler (PD) and greyscale (GS) joint inflammation were graded semi-quantitatively (0-3) at the anterior (humeroradial) and posterior fossa recesses of the elbow joint using previously validated scoring methods; and these were summed to obtain the respective PD and GS scores at the right and left elbows per patient. Pearson's correlation coefficient was used to correlate the findings from TI and US imaging, while simple linear regression was used to describe the relationship between parameters.

Results: In this cross-sectional study, 60 elbows were evaluated by TI and US imaging among 30 adult RA patients with the following patient baseline characteristics: 76.7% female; 76.7% Chinese; mean (SD) disease duration 7.3 (6.8) months; mean (SD) DAS28 3.83 (1.19). Table 1 shows the results of the comparative analysis between the TI parameters (MAX, AVG and MIN) and the US PD and GS scores. For Pearson's correlation, the TI parameters (MAX, AVG and MIN) were all significantly correlated ($P<0.05$) with the US PD scores (Table 1) at both the right and left elbows. For US GS scores (Table 1), significant correlation ($P<0.05$) were observed with all the TI parameters (MAX, AVG and MIN) only at the right elbow but not at the left elbow (with P-values all >0.05). The simple linear regression estimates between TI and US imaging parameters at the right and left elbows are summarized in Table 1.

Conclusion: To the best of our knowledge, our study is the first to report on the correlation analysis between TI parameters and US joint inflammation outcomes at the elbow from an RA cohort. Between US PD and GS joint inflammation, TI is more consistently associated with the former at the elbow in RA. TI of the elbow in RA appears promising and will require further validation in independent RA cohorts.

Table 1. Comparative analysis between the thermal and ultrasound imaging parameters

Thermal imaging parameter	Pearson's correlation				Simple linear regression			
	vs. GS score		vs. PD score		vs. GS score		vs. PD score

GRADING SYNOVITIS IN WRIST AND HAND USING THE MRI DERIVED APPARENT DIFFUSION COEFFICIENT FAILS TO SHOW RELIABILITY AND REPRODUCIBILITY

Keywords: Imaging, Validation

J. Møllenbach Møller[1], A. E. F. Hadsbjerg[2,3], M. B. Axelsen[2], R. P. Poggenborg[2], D. Glinatsi[4], I. Eshed[5], M. Østergaard[2,3]. [1]*Copenhagen University Hospital Herlev - Gentofte, Department of Radiology, Herlev, Denmark*; [2]*Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Rigshospitalet, Glostrup, Glostrup, Denmark*; [3]*Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*; [4]*Skaraborg Hospital, Department of Rheumatology, Skövde, Sweden*; [5]*Sheba Medical Center, affiliated to the Sacker School of Medicine, Tel Aviv University, Department of Diagnostic Imaging, Tel Aviv, Israel*

Background: Diffusion-weighted (DWI) magnetic resonance imaging (MRI) of the hand and wrist has been suggested as an outcome measure of synovitis as an alternative to gadolinium enhanced MRI in patients with rheumatoid arthritis (RA) [1-2]. The apparent diffusion coefficient (ADC), which is a derived parameter from the DWI, may be used to grade synovitis, similar to the OMERACT Rheumatoid Arthritis MRI scoring system (RAMRIS) for synovitis [1]. In a small study criterion validity has been measured but no correlation to contrast-enhanced MRI was revealed [2].

Objectives: To test the discriminative validity of ADC in the synovium ("synovitis ADC") in a prospective cohort of patients with RA and psoriatic arthritis (PsA) and healthy controls (HC).

Methods: The right hand and wrist of all participants were imaged in a 3T MRI system with a dedicated 8 channels coil, applying a 2 mm thick coronal turbo spin echo DWI sequence with an in-plane resolution of 1.5x1.7mm. An ADC map was calculated on basis of two b-values (0;800). Assessment of ADC maps was performed in 7 regions of interest according to the same 7 areas which are assessed by the OMERACT RAMRIS (radioulnar-, radiocarpal-, and intercarpal-carpometacarpophalangeal joints and 2nd-5th metacarpophalangeal joints). Repeatability and intra-observer reproducibility were assessed using intraclass correlation coefficients (ICCs) and Bland-Altman plots.

Results: Thirty-eight participants were imaged twice within a week (median 7 days, range 3-14 days). Participant characteristics are provided in Table 1. The repeatability was moderate for RA (ICC=0.68; 95%CI: 0.45-0.83), poor for PsA (ICC=0.10; 95%CI: -0.09-0.29) and poor for HC (ICC=0.28; 95%CI: 0.07-0.47). Intra-reader reproducibility was poor for all three groups: RA (ICC=0.37; 95%CI: 0.12-0.58), PsA (ICC=0.22 95%CI: 0.02-0.40) and HC (ICC=0.34; 95%CI: 0.13-0.52). Bland-Altman plots revealed large absolute differences between 1st and 2nd MRI in all three groups of participants (Figure 1).

Table 1. Participant characteristics. RA, rheumatoid arthritis; PsA, psoriatic arthritis; HC, healthy control; VAS visual analogue scale. Values are median (range), if not otherwise indicated.

Variable	RA	PsA	HC
Age (years)	51 (31-56)	48 (46-52)	35 (30-40)
Female, n, (%)	7 (77.8%)	9 (69 %)	8 (53.33%)
Symptom duration (years)	6 (3.5-17.5)	10 (4-20.5)	-
Peripheral pain (0-100 mm VAS)	34 (30.5-57)	32 (10-65)	0 (0-1.5)
Peripheral patient global (0-100 mm VAS)	50 (23-60)	48 (15-76)	0 (0-0.75)
Number of swollen joints (0-76)	6 (4-7.5	4 (3-8)	0 (0-0)
Number of tender joints (0-78)	8 (3.5-16)	10 (5-18)	0 (0-0)
Number of tender entheses (0-31)	4 (0-8.5)	9 (1-13.5)	0 (0-2)
Serum C-reactive protein (mg/dl)	5 (1.5-7)	5 (1.5-7)	6 (4.25-8)

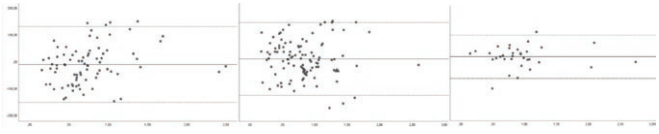

Figure 1. Figure: Bland-Altman plots of the repeatability for the three groups. Left, healthy controls; middle, psoriatic arthritis and right, rheumatoid arthritis. Full line: mean difference. Dotted lines: 95% levels of agreement. The Y-axis indicates the relative difference of apparent diffusion coefficient (ADC) between first and second scanning. The X-axis indicates the mean ADC [$x10^{-3}mm/s^2$] of the first and second MRI.

Conclusion: ADC, determined from DWI-MRI, is not a reliable outcome measure for grading synovitis in the hand and wrist of patients with inflammatory joint diseases.

SHEAR-WAVE ELASTOGRAPHIC ULTRASOUND OF SECOND METACARPOPHALANGEAL IN SYNOVIUM OF RHEUMATOID ARTHRITIS

Keywords: Diagnostic tests

O. Sedano[1], J. Sedano[2]. [1]*Ecosermedic, Reumatologia, Lima, Peru*; [2]*Hospital EsSalud Marino Molina Scippa, Medicina, Comas, Peru*

Background: Shear wave elastography (SWE) is a recent development in elastography ultrasound (SW-EUS). SWE allows quantitative evaluation of the elastic properties and stiffness of tissue and serves as an adjunct to conventional US techniques. There is a hypothesis that rheumatoid arthritis (RA) patients would have softer synovium than controls and this could be quantified with a slower SWV. We also assessed whether SWV varied with disease activity. The challenge in the application of SW-EUS to the synovium is that there are multiple bone tissue interfaces and fluid synovial interfaces in the joint which gave rise to increased chances of fallacious values.

Objectives: To perform a quantitative analysis of SW-EUS in second metacarpophalangeal (2MCP) synovium of RA patients and controls. Determine if there is a correlation between SW-EUS and disease activity.

Methods: A prospective case-control study. Fifteen patients with RA were consecutively recruited and matched with ten controls. Participants underwent clinical assessment, blood sampling, grey scale ultrasound (GSUS), power Doppler ultrasound and SW-EUS of MCP joints 2, on the dominant hand. Ultrasound examination was undertaken by two musculoskeletal trained sonographers. Both were blinded to patient diagnosis, clinical examination results, pathology and previous ultrasound findings. SW-EUS was performed first, followed by GSUS and PDUS. Scanning was carried out using ultrasound using linear array transducer at 6-18 mHz frequency and Virtual TouchTM software. MCP 2 of the dominant hand were scanned with joints resting at 20 degrees of flexion. The dorsal aspect of the joint was imaged in three planes; longitudinal midline (DLM), longitudinal radial (30° radial offset from midline, DLR) and longitudinal ulnar (30% ulnar offset from midline, DLU).

Results: Average age was 50. Mean RA disease activity (DAS28-ESR) was moderate at 3.85. Patients with RA (Figure 1) had lower mean SWV (5.27 m/s vs 12.00 m/s p< 0.001) than controls (figure 2); had lower maximum synovial SWV than controls (6.88 m/s vs. 12.80 m/s P <0.001). EM (RA 168.17 kPa, controls 437.81 kPa). RA low activity SWV (7.48 m/s); EM (168.17 kPa). high activity SWV (2.61 m/s); EM (25.45 kPa) Negative Pearson's correlation coefficients (PCC) were observed between mean SWV and disease activity markers including GSUS graded synovial thickness (PCC = -0.67, p = 0.03) and ESR (PCC = -0.45, p = 0.085).

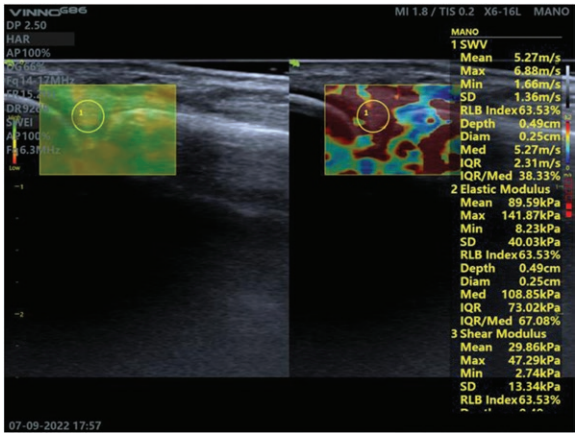

Figure 1. RA patient elastogram

Color elastogram of second metacarpophalangeal (2MCP) synovium, shows shear-wave velocity (SWV) (mean, 5.27 m/s) in RA patient. SWE data were collected using an Vinno G86 US scanner with an L16–6 MHz linear transducer

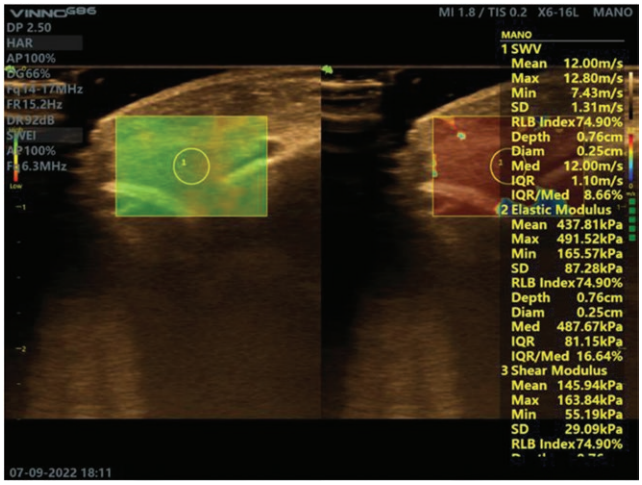

Figure 2. healthy control elastogram

Conclusion: This is the first pilot study in Latin America of SW-EUS in synovium. Mean SWV and elastic modulus was significantly lower in RA than controls. There was a negative correlation between mean and maximum SWV and GSUS synovial thickening and assessing disease activity in RA. Further study is warranted to confirm the role of SW-EUS in diagnosing and assessing disease activity in RA.

ULTRASOUND ASSESSMENT OF SUB-CLINICAL NAIL INVOLVEMENT IN PSORIATIC ARTHRITIS PATIENTS

Keywords: Ultrasound, Psoriatic arthritis, Enthesitis

L. Rouached[1], B. A. Hiba[1], S. Rahmouni[2], O. Saidane[1], S. Bouden[1], A. Ben Tekaya[1], R. Tekaya[1], I. Mahmoud[1], L. Abdelmoula[1]. [1]*Hospital Charles Nicolle, Rheumatology, Tunis, Tunisia*; [2]*RABTA Hospital, Rheumatology, Tunis, Tunisia*

Background: Several studies suggest that psoriatic nail involvement is secondary to local enthesopathy with diffusion of the inflammation to the nail.

Objectives: We aimed to compare parameters of clinically normal nail unit in patients affected by psoriatic arthritis (PsA) with healthy matched controls (HC) using ultrasonography.

Methods: This was a cross-sectional study including patients with PsA and HC. Tender joint count (TJC) (0–68) and swollen joint count (SJC) (0–66) were collected and psoriasis Area and Severity Index (PASI), Disease Activity in Psoriatic Arthritis (DAPSA), were calculated in PsA patients. All patients underwent ultrasound (US) assessment of the fingernails including the study of morphological changes and measurement of the thickness of nail bed (NBT), nail plate (NPT), and adjacent skin (ST). Significant difference was noted if p<0.05.

Results: A total of 22 PsA patients (219 nails) and 21 matched HC (210 nails) were evaluated. PsA group and HC were comparable with respect to age (53.7±12.1 vs 53±11.8, p=0.72) and male gender (13 vs 13, p=0.85). Mean disease duration of PsA was 12.7±10.9 years. The disease activity showed that mean DAPSA was 21.56±14.36 and mean PASI was 2.19 ±3.8. PsA patients had more US morphological changes than HC group (16.89% vs 3.33%,p=0.03). The comparison of NPT between each identical fingernail of PsA and HC did not reveal significant difference. However, NBT was significantly higher in the HC group than the PsA group (1.77mm vs 2.07mm, p=0.027). Additionally, ST was higher in the HC group (2.26mm vs 2.59mm, p=0.003).

Conclusion: The US morphological changes of NBT and ST were contributive to distinguish psoriatic nails from healthy nails.

AB1549 VALUE OF ULTRASOUND FOR THE EARLY DETECTION OF INFLAMMATORY ABDOMINAL AORTIC ANEURYSMS

Keywords: Imaging, Rare/orphan diseases, Vasculitis

B. Slijkhuis[1], S. Konter[1], D. Liesker[2], A. Possel-Nicolai[1,2], E. Brouwer[3], R. Slart[4], A. Van Roon[1], B. Saleem[2], D. J. Mulder[1]. [1]*UMCG, Internal Medicine – Vascular Medicine, Groningen, Netherlands*; [2]*UMCG, Surgery – Vascular Surgery, Groningen, Netherlands*; [3]*UMCG, Rheumatology and Clinical Immunology, Groningen, Netherlands*; [4]*UMCG, Nuclear Medicine, Groningen, Netherlands*

Background: Inflammatory abdominal aortic aneurysm (iAAA), a form of chronic periaortitis, is a frequently overlooked disease, occurring in patients with abdominal aneurysms (AAA). iAAA is strongly associated with underlying systemic inflammatory diseases such as IgG4-related disease (IgG4-RD),[1] potentially leading to retroperitoneal fibrosis (RPF). Ultrasound (US) is a widely available and low-cost imaging tool that may allow the detection of iAAA at an early-stage prior development of severe complications in patients with AAA.
Objectives: This study aims to assess the feasibility of using US to detect iAAA in a small case series (exploratory cohort). And to structurally assess the diagnostic potential and overall incidence of iAAA using US in a larger retrospective cohort of patients in follow-up for AAA (validation cohort).
Methods: In the exploratory cohort, thirteen patients (median age 64 (61;72) years; 100 % male) with an established diagnosis of iAAA of whom US and CT findings were available were retrospectively included. The diagnosis of iAAA was based on a typical cuff surrounding the aneurysm on CT. Other potential causes such as infections and malignancies were ruled out by microbiological studies and when indicated by histology and/or FDG-PET scanning. Secondly, the validation cohort consisted of 191 patients (median age 74 (67;80) years; 73.3 % male) diagnosed with AAA who were in US follow-up for AAA without prior surgical intervention. In patients in whom a CT was (n=157) the diagnostic potential of US was explored using CT imaging as the golden standard. Perianeurysmal inflammation was assessed on US, as illustrated in Figure 1A, using a Siemens Acuson with 6 Mhz convex transducer in B-mode. In the validation cohort, US images were assessed by two independent observers blinded for the diagnosis.
Results: In the exploratory cohort, 62% were smokers, 77% had hypertension, 31% and were diagnosed with IgG4-RD. CRP and BSE levels were 54.5 (±66.2) mg/L and 59.8 (±51,1) mm/h. All patients showed a typical hypoechogenic cuff surrounding the aortic wall eccentric to the calcified medial layer of the aneurysm, see figure 1B). The median anteroposterior diameter of the aneurysm itself was 5.7 cm (4.8; 6.1) and 0.64 cm (0.49; 0.84) of the cuff. In the validation cohort, 180 of 191 (94.2%) patients with AAA showed no evident signs of a hypoechogenic cuff on ultrasound. Of the remaining 11 patients, 8 (4.2%) showed the cuff surrounding the aortic wall and were identified as having iAAA. In 3 (1.6%) an iAAA could not be ruled out based on US. In 149 patients with both a negative US and available CT, all CT scans were negative as well. In the 8 patients with an evident cuff on US, the median age was 66 (65;79) years; and 100% were male, definite IgG4-RD was present in 25% (n=2) of the cases. This amounts to a sensitivity of 100% and a specificity of 98%.
Conclusion: This retrospective study indicates that iAAA can be identified with US as a hypoechogenic cuff surrounding the aortic wall of the aneurysm. US could be used to rule out iAAA safely. However, in inconclusive cases, additional CT imaging is warranted. Besides a possible cost and radiation dose reduction, using US may facilitate earlier recognition and treatment of iAAA and underlying systemic inflammatory diseases such as IgG4-RD. Although this is the first study to structurally investigate US in iAAA, our results need validation in a prospective study.

AB1550 UTILITY OF WHOLE-BODY 18F-FDG PET-CT IN THE DIAGNOSIS OF NEUROSARCOIDOSIS

Keywords: Lungs, Diagnostic tests, Imaging

A. Herrero-Morant[1], L. Sanchez-Bilbao[1], I. Gonzalez-Mazon[1], D. Martínez-López[2], C. Álvarez-Reguera[1], J. L. Martín-Varillas[3], R. Fernández-Ramón[1], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology and Ophthalmology, Santander, Spain*; [2]*Sierrallana Hospital, Rheumatology, Torrelavega, Spain*; [3]*Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain*

Background: Neurosarcoidosis (NS) is one of the most severe manifestations of sarcoidosis [**1**]. NS diagnosis is difficult since clinical features and cranial imaging findings are often unspecific and central nervous system biopsy is unfrequently performed. Flourine-18 fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET-CT) is emerging as a powerful tool for the evaluation of sarcoidosis. Data on the role of 18F-FDG PET-CT in NS is scarce.
Objectives: To assess the utility of 18F-FDG PET-CT in patients with suspected NS.
Methods: Patients diagnosed with sarcoidosis at a University hospital in Northern Spain, between January 1999 and December 2019 were assessed. Sarcoidosis was diagnosed according to ATS/ERS/WASOG criteria as follows: compatible clinical and radiological presentation, histopathologic confirmation, and exclusion of other granulomatous diseases. NS was diagnosed according to the NS Consortium Consensus Group [**2**]. Receiver Operating Characteristic (ROC) curve for Chest Computed Tomography (CT) and 18F-FDG PET-CT were compared.
Results: NS was suspected in 30 (19 women/11 men) patients out of 384 (7.8%) (mean age; 55.0±15.8 years). The underlying neurological manifestations were chronic headache (n=13; 43.4%), peripheral neuropathy (n=6, 20%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10%) and aseptic meningitis (n=3, 10%). Complementary study's findings are described in **Table 1**. 18F-FDG PET-CT was performed in 10 (33.4%) patients. 18F-FDG PET-CT were abnormal in 9 (90%) patients. Abnormalities suggestive of NS were found in 7 (70%) patients. These were located in lymph nodes (n=7, 100%), parotid gland (n=1, 14.3%) and bone (n=1, 14.3%). Other abnormalities were found in 2 (20%) patients in vocal cord (n=1, 50%) and rectum (n=1, 50%). Only 1 (10%) patient had no abnormalities in 18F-FDG PET-CT. All patients (n=2, 100%) in which chest radiography and chest CT were negative, had pathological findings suggestive of NS in 18F-FDG PET-CT. After whole-body 18F-FDG PET-CT, all patients with accessible abnormalities suggestive of sarcoidosis underwent biopsy in lymph node (n=5, 71.4%), parotid gland (n=1, 14.3%) and skin (n=1, 14.3%). In all of them non-necrotizing granulomas were found. 18F-FDG PET-CT and chest CT diagnostic ability was compared (**Figure 1**). 18F-FDG PET-CT had a higher Area Under the Curve (AUC) (0.94 [95% CI: 0.78-1]) than chest CT (0.75 [95% CI: 0.28-1]).
Conclusion: 18F-FDG PET-CT seems to be a useful tool in the evaluation of patients with suspected NS specially when the chest CT is negative or inconclusive.

AB1551 IMAGING OF THE PERIPHERAL NERVOUS SYSTEM IN NOCIPLASTIC PAIN: AN ULTRASOUND STUDY IN PATIENTS WITH FIBROMYALGIA

Keywords: Ultrasound, Imaging, Pain

M. DI Carlo[1], B. Bianchi[1], E. Cipolletta[1], S. Farah[1], E. Filippucci[1], F. Salaffi[1].
[1]*Università Politecnica delle Marche, Rheumatology Clinic, Jesi (Ancona), Italy*

Background: Fibromyalgia (FM) is a condition mainly characterized by the presence of chronic widespread musculoskeletal pain, fatigue, and sleep alterations. The pathophysiological basis of FM has not yet been clarified. It is widely recognized that FM is a condition characterized by the presence of central sensitization. The mechanisms of centralized pain have been studied mainly through functional imaging techniques. However, over the past decade, evidence of peripheral nervous system involvement has emerged alongside pathophysiological mechanisms involving the brain and spinal cord and a detailed analysis of the morphostructural abnormalities of other nerves in FM patients is still lacking.
Objectives: To investigate the sonographic changes [i.e., increased cross-sectional area (CSA)], of peripheral nerves in patients with FM compared to healthy controls and to identify potential clinical correlations associated with increased CSA in patients with fibromyalgia.
Methods: Consecutive female patients with FM included in this cross-sectional observational study underwent sonographic assessment using a standardised scanning protocol. The CSA of 7 nerves was measured bilaterally at 11 anatomic sites by an experienced sonographer. Differences in CSA of nerves were compared with those of healthy subjects by one-way analysis of variance. Patients underwent clinimetric evaluation aimed at investigating disease severity, neuropathic pain features, depression, anxiety, fatigue, and autonomic symptoms to explore the possible correlation between CSA and clinical features.
Results: 47 patients and 20 healthy controls were enrolled. Differences in terms of increased CSA between patients and healthy controls were identified at multiple levels, mainly at the level of the sural nerve, vagus nerve and 6th cervical nerve root (for all, $p < 0.001$). Sonographic findings, however, did not correlate with the clinical features explored.

Table 1. Mean cross-sectional area values (mm^2) of individual nerve scans in healthy controls and fibromyalgia patients.

	Healthy controls (n 20)		Patients (n 47)	
	Mean	SD	Mean	SD
6th cervical root right	3.95	0.75	5.91	1.52
6th cervical root left	3.90	0.64	5.78	1.36
Median distal right	8.00	0.97	8.55	1.62
Median distal left	8.10	0.96	8.36	1.84
Median proximal right	6.95	1.46	8.51	2.30
Median proximal left	7.20	1.39	8.48	2.26
Fibular right	9.10	2.44	9.95	2.27
Fibular left	9.35	2.58	10.29	2.21
Sural right	2.70	0.57	4.68	1.56
Sural left	2.85	0.58	4.42	1.09
Tibial distal right	11.35	2.47	13.89	3.49
Tibial distal left	11.40	2.70	13.76	3.44
Tibial proximal right	13.55	2.58	15.36	3.26
Tibial proximal left	13.95	2.66	15.12	4.03
Ulnar proximal right	6.15	1.34	6.55	1.80
Ulnar proximal left	6.00	1.07	6.48	1.79
Vagus right	2.75	0.78	4.08	0.85
Vagus left	2.85	0.74	3.91	0.90

Conclusion: Patients with FM show higher CSA of nerves than healthy subjects. The increased CSA is most evident at the sural nerve, vagus nerve and 6th cervical nerve root. Ultrasound, a relatively easy-to-use technique, could identify morphological changes, in peripheral nervous structures in patients with FM.

AB1552 PERFORMANCE OF A SOLID-PHASE PHOTOMETRIC SINGLE USE IMMUNOASSAY MICROARRAY PROTOTYPE IN THE DETECTION OF IGG ANTIBODIES AGAINST CENTROMERE PROTEIN B (CENP-B) IN HUMAN SERUM

Keywords: Systemic sclerosis, Diagnostic tests, Autoantibodies

D. Bijlsma[1], E. Lukasik[1], M. Hausmann[1], G. Gomez[2], C. Ginocchio[2], E. Moreau[1]. [1]*Quotient Suisse SA, R&D, Eysins, Switzerland*; [2]*Quotient Suisse SA, Scientific and Medical Affairs, Eysins, Switzerland*

Background: Systemic Sclerosis (SSc) is a chronic multisystem autoimmune (AI) disease, characterized by progressive fibrosis of the skin and internal organs and vascular injury.[1] Biomarker testing plays an important part in disease classification, identification of sub-sets of SSc (e.g., CREST/ Limited SSc), prognosis and progression. Presence of antibodies against centromere proteins (CENP) weighs 3 points in the ACR/EULAR Classification Criteria.[2] Development of highly automated diagnostic tools remains a clinical need.
Objectives: To evaluate the performance of a solid-phase photometric single use immunoassay microarray prototype for the *in vitro* qualitative detection of

IgG antibodies against Extractable Nuclear Antigens (ENA) of CENP-B in human serum when tested using the MosaiQ™ System.

Methods: MosaiQ CENP-B microarray prototypes (Quotient Suisse, Eysins, CH) were prepared by printing CENP-B antigens in duplicate onto Epoxy-silane glass chips, followed by a blocking and preservative step. Microarrays consisting of 2 separate sides were assembled into Magazines (containing 250 microarrays) for processing on the MosaiQ 125 instrument. Human serum samples/buffers/reagents are loaded on the instrument and automatically the microarrays undergo sample/buffer/reagent addition to generate antigen spot signals which are read and interpreted by the instrument using a proprietary algorithm. A cohort of 26 serum samples reactive for anti-CENP-B antibodies (as defined by testing with 2 commercial assays) and 25 non-reactive serum samples from Swiss Red Cross blood donations were tested in duplicate.

Results: 25 out of 26 CENP-B antibody reactive samples were determined reactive by the MosaiQ CENP-B microarray prototype. The only discordant sample was reactive in one of the reference methods and non-reactive in the other, suggesting the potential for a false reactive by one of the reference methods. All 26 non-reactive samples were determined non-reactive by the prototype assay. Derived sensitivity (including presumptive false non-reactive) is 0.96 (95%CI 0.87 – 0.99) and specificity is 1.0 (95%CI 0.93 – 1.0).

Conclusion: These preliminary results support the performance of the investigational microarray prototype for the detection of CENP-B antibodies in human serum using the MosaiQ System. Clinical studies to confirm these observations are ongoing. Additionally, the microarray has the potential to print up to 66 spots per side, allowing for the capability to generate large multiplex panels for the detection and characterization of AI diseases.

INVESTIGATION OF FACTORS ASSOCIATED WITH PET/CT EXPERIENCE AND DIAGNOSTIC VALUE IN RHEUMATOLOGY PRACTICE

Keywords: Imaging

P. Akyüz Dağlı[1], S. C. Güven[1], N. Coşkun[2], Ö. Karakaş[1], B. Armagan[1], K. Gok[1], I. Dogan[3], Y. Maraş[4], Ş. Türkölmez[5], S. Erten[6]. *[1]Ankara City Hospital, Clinic of Rheumatology, Ankara, Turkey*; *[2]Ankara City Hospital, Clinic of Nuclear Medicine, Ankara, Turkey*; *[3]Ankara Yıldırım Beyazıt University Faculty of Medicine, Department of Internal Medicine Division of Rheumatology, Ankara, Turkey*; *[4]University of Health Sciences, Ankara City Hospital, Division of Rheumatology, Ankara, Turkey*; *[5]Ankara Yıldırım Beyazıt University Faculty of Medicine, Department of Nuclear Medicine, Ankara City Hospital, Division of Nuclear Medicine, Ankara, Turkey*; *[6]Ankara Yıldırım Beyazıt University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*

Background: The use of PET/CT is becoming more common in the elucidation of inflammatory processes in which the underlying cause cannot be determined by conventional examinations. Although PET/CT is an effective method for detecting inflammatory foci, the precise diagnosis may not be obtained in all cases.

Objectives: In this study, it was aimed to examine the factors that can predict the differential diagnosis value of PET/CT by retrospectively scanning patients who underwent PET/CT for inflammation of unknown origin(IUO) in rheumatology practice.

Methods: Demographic, clinical and laboratory information of the patients followed up in our clinic and who underwent PET/CT for differential diagnosis were enrolled. Whether they were diagnosed after PET/CT and during the follow-up period, and their diagnoses were examined.

Results: A total of 132 patients were included in the study. A previous diagnosis of rheumatic disease was present in %28.8 of the patients, and a history of malignancy was present in %2.3. The patients were divided into three groups: Group 1 patients with increased FDG uptake in PET/CT and the diagnosis confirmed by PET/CT, group 2 patients with increased FDG uptake in PET/CT but the diagnosis of was not confirmed, and group 3 patients without increased FDG uptake in PET/CT. Increased FDG uptake in PET/CT was detected in %73 of the patients. While PET/CT helped the diagnosis in 47(%35.6) patients(Group 1), it did not help the diagnosis in 85(%64.4) (Group 2,3). Thirty-one (%65.9) of the diagnosed patients were diagnosed with a rheumatologic disease. When the 3 groups were compared, male gender, advanced age, CRP levels, presence of constitutional symptoms, SUVmax values and number of different organs with increased FDG uptake were higher in Group 1. %66 and %74 of the patients in groups 2 and 3 were not diagnosed during the follow-up period. No patient in group 3 was diagnosed with malignancy during follow-up.

Conclusion: PET/CT has high diagnostic value when combined with clinical and laboratory in the diagnosis of IUO. Our study revealed that various factors can affect the diagnostic value of PET/CT. Although detection of involvement in PET/CT is not always diagnostic, it was an important finding that no malignancy was detected in the follow-up in any patient without involvement.

A STUDY TO SHOW THE TOLERABILITY OF ULTRASOUND GUIDED SIJ STEROID INJECTION TO ALLOW APPROVAL OF US GUIDED SIJ SYNOVIAL TISSUE SAMPLING FOR RESEARCH

Keywords: Inflammatory arthritides, Patient reported outcomes, Safety

J. Bunting[1], A. Tan[2], N. Purkayastha[1]. [1]*Southend University Hospital, Mid and South Essex NHS Foundation Trust, Rheumatology, Southend-on-Sea, United Kingdom*; [2]*Southend University Hospital, Mid and South Essex NHS Foundation Trust, Radiology, Southend-on-Sea, United Kingdom*

Background: Sacroiliac joint (SIJ) synovial tissue analysis has the potential to improve specificity and sensitivity of spondyloarthritis (SpA) classification beyond the current Assessment for SpondyloArthritis International Society criteria allowing early diagnosis and reducing disease progression. It can aid the use of molecular biomarkers and identification of drug targets already explored in rheumatoid arthritis (RA) [1]. Furthermore, joint synovial tissue has shown histological differences in RA from psoriatic arthritis [2] and may help characterise SpA subtypes. SIJ steroid injections are used for pain management. A similar procedure, yet to be utilised, can be used to obtain synovial tissue using a co-axial needle. There is evidence of histological disease in patients experiencing sacroiliac pain without MRI features [3, 4]. Synovial biopsy offers possible earlier detection of SpA than MRI, which is limited by cost, patient weight and claustrophobia. Equally fluoroscopic or CT guided injections are limited by cost, time and radiation exposure. Early diagnosis and treatment of SpA is already linked to improved outcomes [5].

Objectives: To determine the tolerability and safety of ultrasound guided (USG) SIJ steroid injections to encourage SIJ tissue biopsies in research.

Methods: We identified 10 patients at Southend Hospital between 2010-2019. The average age was 41 years. Once verbal consent was obtained, a retrospective telephone questionnaire was completed. The USG SIJ steroid injections (Figure 1A) involved injecting Lidocaine 1% around the soft tissue using a 25G and 23G needle. Then a 22G spinal needle was guided into the SIJ and a mixture of Depomedrone 40mg and 0.5ml 0.25% bupivacaine administered. The patients were asked to indicate pain, swelling and stiffness of the injected joint pre and post procedure using a qualitative scale: none, mild, moderate or severe. They were asked to comment on side effects and how likely they were to repeat the procedure.

Results: All patients had severe pain before injection and one continued to have severe pain post procedure. None reported complications of steroid flare or back pain (Figure 1B and 1C). 70% experienced temporary numbness (Figure 1B), an expected side effect of local anaesthesia, which resolved within 24 hours. No permanent numbness was reported. 20% had peripheral arthralgia, which resolved with analgesia in 24 hours. 50% were unlikely to repeat the procedure as the steroid offered little benefit. Most importantly, all patients tolerated the procedure with only mild to moderate discomfort.

Conclusion: SIJ steroid injections are not widely offered, making it difficult to obtain large patient numbers. However, this study shows that SIJ steroid injections are tolerable for patients, an important step in convincing patients to participate in a SIJ synovial tissue biopsy research study. Tissue biopsy using a co-axial needle may be considered more invasive as it is thicker with a longer throw than a 22G spinal needle but the procedure steps and complication risks are ultimately similar. The complication risk rate has not yet be compared between the two procedures but SIJ tissue biopsy is less invasive and traumatic than the alternative SIJ trans-articular bone biopsy [6].

Whilst sample size may not be representative for a larger patient cohort and the retrospective questionnaire may have introduced time bias, the data obtained will hopefully initiate a potential study. This study could provide significant information on complication risk rate in synovial tissue biopsy of the SIJ and associated histological disease information in SpA.

AB1555

CORRELATION BETWEEN HIGH RESOLUTION CHEST TOMOGRAPHY AND CAPILLAROSCOPIC FINDINGS IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Lungs, Prognostic factors

J. Santana Peralta[1], R. A. Alvarez Santana[1], D. Garcia[1], L. Perez[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. [1]*Hospital Padre Billini, Rheumatology, Santo Domingo, Dominican Republic*

Background: Systemic sclerosis (SSc) is a chronic autoimmune multisystemic disease characterized by fibrosis and vasculopathy.[1] Mortality in patients with systemic sclerosis who present with interstitial lung disease can be up to 3x healthy population.[2] It is estimated that 70-90% have interstitial lung disease.[3] High resolution computed tomography (HRCT) of chest is recognized as a sensitive imaging method for evaluating pulmonary involvement.[4,5] Presentation patterns are also described: NSIP (non specific interstitial pneumonia), UIP (usual interstitial pneumonia), COP (cryptogenic organizing pneumonia), LIP (Lymphocytic interstitial pneumonitis). Capillaroscopy allows the study of the microcirculation. Changes are classified into “early,” “active,” and “late” scleroderma patterns.[6]

Objectives: To relate between high resolution chest tomography and capillaroscopic findings in Systemic sclerosis.

Methods: Descriptive, observational, cross-sectional study. Capillaroscopy with Optilia CapiScope 2.0/5.0MP and lung ultrasound with Siemmens Acuson X150 were performed in patients with SSc in the outpatient clinic of the rheumatology service from August-November 2021. Inclusion criteria: > 18 years old, meet criteria for classification of SSc according to ACR/EULAR 2013. Exclusion criteria: history of pre-existing lung disease.

Results: 22 patients met inclusion criteria. 80% were female. Diffuse SSc 81.8% (18), limited SSc 18.2% (4). Mean age 54±17 years, disease duration 58.1% (13) >5 years and 40.9% (9) < 5 years, mean diagnosis 15.3±9.2 years, mean mRSS 19.4 + 13.2 mRSS Mild: 22.7% (5), moderate 18.2% (4), severe 27.3% (6), terminal 31.8% (7). ANA+ 45.5% (10), Topo IA 18.2% (4). Treatment: RTX 77.3% (17), Ca+ antagonists 68.2% (15), Bosentan 36.4% (8), MMF 36.4% (8), Colchicine 31.8% (7), Sildenafil 27.3% (6). Capillaroscopy: normal pattern 59% (13), early scleroderma pattern 9.1% (2), active scleroderma pattern 4.5% (1), late scleroderma pattern 22.7% (5), nonspecific abnormalities 4.5% (1). TACAR: 54.5% (12) normal, pathological findings 45.4% (10): NSIP pattern 80% (8), UIP 20% (2). TACAR/Capillaroscopy correlation: UIP pattern and early scleroderma pattern 4.5% (1) rp=.112, NSIP pattern and active scleroderma pattern 4.5% (1) rp=.769, NSIP pattern and normal capillaroscopy 4.5% (1) rp=. 518, NSIP pattern and late scleroderma pattern 27.2% (6) rp=1, normal TACAR and capillaroscopy

with nonspecific abnormalities 4.5% (1) rp=1, UIP pattern and early pattern 4.5% (1) rp=.622, normal TACAR and normal capillaroscopy 27.2% (6).

Conclusion: We found in this study that capillaroscopic findings of active and late patterns correlated with greater pulmonary involvement. It is recommended to follow patients with early patterns and the existence or not of interstitial pattern and to evaluate response to medication.

AB1556 MACHINE LEARNING APPROACH FOR CLASSIFICATION OF ARTHRITIS ACTIVITY STATE, USING DATA FROM A SINGLE ACCELEROMETER

Keywords: Artificial intelligence, Rheumatoid arthritis, Validation

P. Mielnik[1], A. Myhre Hjelle[2], A. Traseth[2], K. Tokarz[3], B. Pollen[4], M. Fojcik[4]. *[1]Helse Forde, Section for Rheumatology; Department for Neurology, Rheumatology and Physical Medicine, Forde, Norway*; *[2]Helse Forde, Section for Rheumatology; Department for Neurology, Rheumatology and Physical Medicine, Forde, Norway*; *[3]Institute of Informatics Silesian University of Technology, Department of Graphics, Computer Vision and Digital Systems, Gliwice, Poland*; *[4]Western Norway University of Applied Sciences, Faculty of Engineering and Science, Forde, Norway*

Background: Machine learning (ML) potential is not fully exploited in diagnostics and follow up of autoimmune inflammatory rheumatic disease (AIIRD). It is despite the broader use of ML in, e.g. imaging diagnostics. The specific tools for AIIRD are lacking.

Objectives: This is an interim analysis of data from the first checkpoint of the proof-of-concept study on using accelerometer (ACC) data in follow up of patients with AIIRD. The main goal of the study was to investigate the value of single ACC data in the classification of arthritis activity status.

Methods: Subjects with AIIRD are enrolled in the study when they start of new treatment due to the disease activity. Several comorbidities, such as severe neurological and cardiological disorders, as wells as impaired mobility, are part of the protocol exclusion criteria. Volunteers without AIIRD who fulfil other inclusion/exclusion criteria are included as controls. The study was approved by local competent authorities and informed consent was given by all participants. We used data collected up till the first study checkpoint. This analysis covers nine patients with AIIRD (5 rheumatoid and four psoriasis arthritis) and 13 controls. Five patients had 3 study visits, 1 had 2 visits and 3 only one. Controls have only one visit per protocol. We analysed ACC data from 3 minutes of clapping using a home-brewed device based on Arduino nano 33 BLE with 6-axis MTU by Nordic Semiconductor. Data was divided into 6-second chunks that were found optimal in our prior study. We conducted binary classification between any/ no arthritis in any of the upper extremities. We used accuracy and area under curve (AUC) as an efficacy function derived from the receiver operating characteristic curve (ROC). We extracted 54 features from 3 ACC axis signal. The features encompassed, among others, Fourier's components, autoregression coefficients, median absolute deviation (MAD), variance, Fourier's entropy, etc. We built linear discriminant analysis (LDA) models on the train data that were controlled on the test data. We originally built models with all features. Then, we analysed the importance of each feature on the models. Eventually, we constructed the most effective available model formula based on 7 features: the first autoregression coefficient for the X axis, kurtosis for the Z axis, correlation between Y and Z axis, zero point cross count for the Y axis, Z axis MAD, X and Y axis skewness. As we had few subjects included, we built 210 models with all possible data combinations. To avoid model overfitting, we never used data for model training from a subject who was actually in test data. All calculation was performed with R (R Core Team, 2022 www.R-project.org), using package caret (M. Kuhn 2022, CRAN.R-project.org/package=caret).

Results: Median accuracy for all LDA models was 0.78, mean 0.72 (95%CI 0.69-0.76). Median AUC was 1.0, mean 0.82 (95%CI 0.77-0.86). Distribution of the result was skewed to upper values. However, some models showed very low efficacy in classification (Figure 1 A and B).

Conclusion: Our study shows that it is possible to predict if a patient has any arthritis activity. However, we observed some instability in the classification between models. It can be due to small amount of data but also due to other distractors, such as comorbidities or drugs. Further research on the area is required and continuation of our study is justified based on the current results.

AB1557 ULTRASOUND LEARNING CURVE IN INTERSTITIAL LUNG DISEASE OF AUTOIMMUNE RHEUMATIC DISORDERS: A DISEASE ORIENTED TRAINING PROGRAM

Keywords: Lungs, Ultrasound, Mixed connective tissue disease

M. Gutierrez[1], D. Mejia-Arredondo[2], J. C. Arana Ruiz[1], C. Bertolazzi[3]. *[1]Center of Excellence in Musculoskeletal and Rheumatic Diseases, Rheumatology, Mexico City, Mexico*; *[2]Center of Excellence in Musculoskeletal and Rheumatic Diseases, Physiotherapy and Rehabilitation, Villa de Cortes, Mexico*; *[3]Instituto Nacional de Rehabilitación, Rheumatology, Ciudad de México, Mexico*

Background: Ultrasound (US) has elicited considerable interest among rheumatologists because of its usefulness in clinical practice. Recently, it has been demonstrated its ability to assess interstitial lung disease (ILD) in rheumatic patients. While a solid and still growing body of evidence supports its use in daily rheumatologic practice, operator dependency and the long learning curve represent the main limitations.

Objectives: To describe the learning curve of rheumatologists with limited experience using US attending an intensive disease-oriented training program focusing on the skills required to obtain and interpret US signs of ILD in patients with autoimmune rheumatic diseases.

Methods: A total of 5 investigators participated in a seven-day training program involving 15 patients with autoimmune rheumatic diseases. The expert sonographer was a Rheumatologist with >15 years of US experience, whose assessments were used as the gold standard to evaluate the US findings obtained by the remaining 4 investigators. Two beginner sonographers were fellows in rheumatology with 5 months of global US experience, whereas the other 2 beginner sonographers were fellows in rehabilitation and rheumatology with a very basic knowledge of musculoskeletal US (<3 months) and no direct US experience in ILD. The training program lasted for 7 days (at least 5 hours per day) following specific aims and activities for each day during the training program. The agreement between the expert and beginners was calculated in 4 sessions involving 15 patients (13 females and 2 males; 4 rheumatoid arthritis, 6 systemic sclerosis, 3 Sjogren syndrome, 2 dermatomyositis). The US assessment was performed according the previously proposed 14-intercostal spaces (IS) scanning protocol using the following semiquantitative scale [0 = normal (≤5 B-lines); 1 = slight (≥6 and ≤15 B-lines); 2 = moderate, (≤16 and ≥30 B-lines); 3 = severe (≥30 B-lines)] [1]. Additionally the pleural irregularity in each IS was dichotomously recorded.

Results: A total of 210 lung IS were studied. Kappa values and overall agreement percentages of qualitative and dichotomist assessments of US ILD findings

(B-lines and pleural irregularity) at the end of the exercise showed moderate to excellent agreement (between 0.769 and 0.895), while in the first session they showed poor/fair agreement (between 0.325 and 0.435). The comparison between the expert (gold standard) and beginners' examinations at the fourth and final session, including the kappa values, sensitivity, specificity, and negative and positive predictive value were also improved.

Conclusion: After 1 week of the disease-oriented training program, physicians with limited experience in US were satisfactorily able to detect and interpret the main US signs indicative of ILD in patients with autoimmune rheumatic diseases.

AB1558 CLINICAL-ECOGRAPHIC OPTIMIZATION IN RHEUMATOID ARTHRITIS IN SUSTAINED REMISSION

Keywords: Tapering, Ultrasound, Rheumatoid arthritis

G. Añez[1], V. Torrente Segarra[2], M. Bonet[2], M. Castillo Vilella[3], L. Orpinell[3], A. Ponce Fernandez[4], N. Busquets-Pérez[4], M. Pascual-Pastor[4], H. Corominas[5], C. Diaz-Torne[5], P. Moya[5], J. J. De Agustin[1]. *[1]Hospital Universitari Vall d'Hebron, Rheumatology, Barcelona, Spain*; *[2]Hospital Comarcal de l'Alt Penedès, Rheumatology, Vilafranca del Penedès, Spain*; *[3]Hospital Universitari Sagrat Cor, Rheumatology, Barcelona, Spain*; *[4]Hospital General de Granollers, Rheumatology, Granollers, Spain*; *[5]Hospital de la Santa Creu i Sant Pau, Rheumatology, Barcelona, Spain*

Background: In recent years, the high economic impact of biologic therapies (BT) on health care systems has promoted great interest in optimizing BT in Rheumatoid Arthritis (RA) patients in sustained clinical remission (CR). A relevant percentage of those optimized patients present clinical relapses. RA patients in CR have been shown to have active synovitis detectable by ultrasound (U). U can identify synovitis in patients about to present clinical relapse. U can be a useful tool in the optimization decision.

Objectives: The main objective was to demonstrate that the optimization strategy using U is more useful than the strategy using clinical index. U used as an outcome measure, can further refine the choice of patients who are candidates for a reduction in treatment and therefore achieve lower relapse rates. To do this, we calculated the relapse rates in each of the groups and the time from the beginning in which it appears, and we compared them to assess whether they differ significantly and support our hypothesis. Secondary objective was evaluating the ultrasound remission in this group of patients.

Methods: We conducted a multicenter, randomize, prospective study in 5 tertiary centers in RA patients in sustained CR (>9 months). All signed the informed consent. Approval by the ethical committee was obtained (VDH-INF-2017-01). Two blinded and randomize arms, clinical (A) and U (B) were created to decide tapering (1/2, 1/3 or no reduction treatment) and compare flare rates (>1.2 DAS28 or >16 SDAI/CDAI increase) in 52 weeks (basal, 1, 6, 9 & 12 months). Demographic at baseline, US & clinic variables, and ESR & CRP at each visit, were registered. By using U with grayscale (GS) and power Doppler (PD) in a semiquantitative articular (A) and tendon (T) scale we studied: wrist, 1-5 MCP, 1-5 PIP, ankle, subtalar joint, 2nd, and 5th MTP, extensor tendons (Text) and flexors (Tflex) of the carpus, flexor tendons of the fingers, posterior tibial and peroneal tendons. DAS28 <2.6 was used as the clinical remission criteria, and the absence of synovitis was defined as U remission (EG and PD = 0). U activity was defined as GS≥1 and PD ≥1.

Results: 78 patients were included, 48 completed 12 moths follow up and 28 were retired (5 screening failure, 16 flare, 5 lost follow up & 4 patient decision). 33 men and 45 women, 11.92 years of disease. Group A presented a significative more flare rates than group B (10 vs 6). Using SDAI or CDAI only 7 presented a clinical flare, and for SDAI (7 vs 0) & CDAI (7 vs 0) differences were significative (p<0.005), but not for DAS28 (10 vs 6) (Table 1). In U at baseline, the main involved joint was the wrist (28.6%), and of the tendons the Text (11.2%). In 53% a pathological U (A and T) was observed, 46.9% had pathological A and in 30% pathological T was observed. Considering as remission an ultrasound score of EG + PD = 0, only 46.9% were in remission.

Conclusion: Ultrasound can improve tapering strategy when we used SDAI or CDAI score in patients in sustained clinical remission. Clinical and ultrasound remission are not equivalent. More than half of the patients do not fulfill UR and in one fifth of them a strict control should be carried out to avoid a relapse of the disease if it is decided to optimize.

AB1559 AUTOIMMUNE DISEASES ASSOCIATED WITH AUTOIMMUNE HEPATITIS

Keywords: Comorbidities

N. Trad[1], A. Mensi[1], E. Belhadj Mabrouk[1], S. Ayadi[1], Y. Zaimi[1], L. Mouelhi[1], Y. Said[1], R. Dabbeche[1]. *[1]Charles Nicolle Hospital, Gastroenterology, Tunis, Tunisia*

Background: Autoimmune hepatitis (AIH) is a rare pathology characterized by necrotic-inflammatory hepatocyte lesions, the presence of autoantibodies, and high sensitivity to corticosteroid treatment. it is often associated with other autoimmune diseases.

Objectives: Our objective was to study the clinical aspects, associated auto-immune diseases, and response to the treatment of AIH.

Methods: We conducted a retrospective study including consecutive patients with AIH between January 2000 and December 2018.

Results: We included twenty-two patients; 21 women and one man with an average age of 46 [18-95]. Jaundice was the most frequent presenting sign (80%). Biology found cytolysis greater than ten times in 45.5% of cases. A predominant hypergammaglobulinemia on IgG was noted in 77.2% of cases. At the time of diagnosis, 59% of patients were in the stage of cirrhosis. Antinuclear antibodies, Anti-smooth muscle antibodies, and Anti-LKM1 antibodies were positive in 47.6%, 41%, and 13.3% of cases, respectively. The liver biopsy was performed in 8 patients (36.3%) with a compatible histological appearance in 7 patients. In 54.5% of cases, an associated autoimmune pathology was noted; the most common were autoimmune thyroiditis (33.3%) and autoimmune hemolytic anemia (33.3%). There were also two cases of Sjögren's syndrome, one case of systemic lupus erythematosus, and one case of rheumatoid arthritis. An overlap syndrome (AIH-PBC) was found in 22.7% of patients. The combined corticosteroid-azathioprine treatment was prescribed in 15 patients (68.1%). In overlap syndromes, ursodeoxycholic acid has been associated. The mean duration of follow-up was 94.5 months. Under treatment, biochemical remission was achieved in 23% of patients.

Conclusion: In our study, the prevalence of autoimmune diseases associated with AIH was significant, which would underline the importance of systematic screening for clinical and biological immune manifestations in those patients.

AB1560 QUADRICEPS FEMORIS MUSCLE PROPERTIES IN SARCOIDOSIS: FUNCTIONAL AND CLINICAL IMPLICATIONS

Keywords: Sarcopenia, Ultrasound, Lungs

R. Terlemez[1], S. S. Kurtoglu[1], B. Caliskaner Ozturk[2], D. Palamar[1], E. Atahan[2], K. Akgun[1]. [1]*Istanbul University Cerrahpasa, Cerrahpasa Medical Faculty, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey*; [2]*Istanbul University Cerrahpasa, Cerrahpasa Medical Faculty, Department of Pulmonary Medicine, Istanbul, Turkey*

Background: Sarcoidosis is a chronic disease which may involve muscular system subclinically at the onset of the disease. Sarcopenia is a musculoskeletal condition that may be associated with nonspecific symptoms in patients with sarcoidosis such as general weakness, arthralgia, reduced exercise capacity, and fatigue.
Objectives: This study aimed to determine the association between the functionality and the quadriceps femoris muscle (QFM) thickness measured using sonography in patients with sarcoidosis.
Methods: Thirty-one women with sarcoidosis and 27 controls were evaluated for the following outcomes: (i) handgrip strength, (ii) QFM thickness measured using ultrasound (US), and (iii) sonographic thigh adjustment ratio (STAR). The sarcoidosis group was also evaluated using the 30-second chair stand test (30s-CST) and fatigue severity scale (FSS).
Results: The QFM thickness and STAR values of the sarcoidosis group were significantly lower than those of the control group (p=0.0001). However, no statistically significant difference was observed between the handgrip strengths of the groups (p=0.581). There was no statistically significant correlation between the STAR values and handgrip strength in the sarcoidosis group (p>0.05); however, there was a statistically significant positive correlation between the STAR values and 30s-CST (r=0.467, p=0.008).
Conclusion: Probable sarcopenia is one of the musculoskeletal conditions in patients with sarcoidosis that may be associated with nonspecific symptoms, such as general weakness, exercise intolerance, and fatigue. Although the handgrip test is a frequently used test, it may not show prominent findings in the early stages of the disease. Ultrasound appears to be an innovative tool for preventing sarcopenia as it helps detect changes in muscle mass and muscle quality at an early stage.

AB1561 COMPARISON OF DIAGNOSTIC PERFORMANCE OF TRUENAT™ MTB PLUS AND XPERT® ULTRA (GX) IN PATIENTS OF OSTEOARTICULAR TUBERCULOSIS (OATB): EXPERIENCE FROM NORTH INDIA

Keywords: Diagnostic tests

K. Sharma[1], A. Sharma[2], A. Sharma[3]. [1]*Post Graduate Institute of Medical Education & Research, Chandigarh, Medical Microbiology, Chandigarh, India*; [2]*Government Medical College & Hospital, Chandigarh, MBBS Student, Chandigarh, India*; [3]*Post Graduate Institute of Medical Education & Research, Chandigarh, Internal Medicine, Chandigarh, India*

Background: Diagnostic delay and drug resistance not only worsen the outcomes of tuberculosis, but are also important impediments to TB elimination efforts. Prompt and accurate diagnosis of osteoarticular tuberculosis (OATB) along with simultaneous detection of drug resistance is crucial to decrease the morbidity and associated sequelae.
Objectives: Given the need for a near point-of-care test suitable for primary healthcare centers and simultaneous detection of resistance, Truenat MTB Plus (TruPlus), a chip-based real-time polymerase chain reactionassay, was evaluated for the first time for diagnosis of OATB and detection of rifampicin resistance from pus and synovial fluid samples.
Methods: Total of 100 synovial fluid/pus samples (20 microbiologically confirmed OATB[culture-positive], 50 clinically confirmed OATB [culture-negative], and 30 control patients) were subjected to TruPlus assay and Xpert Ultra (GX Ultra) assay; and their performance was compared. Results were evaluated against both culture and composite reference standard.
Results: The overall sensitivity and specificity of TruPlus in diagnosing OATB was 77.14%(54/70) and 100%, respectively. The sensitivity was 90% (18/20) for microbiologically confirmed cases and 72% (36/50) for clinically confirmed cases. Performance of TruPlus was superior to Xpert ultra (sensitivity = 70%). Overall, sensitivity and specificity of GX ultra was 70% and 100%. However, sensitivity of GX Ultra was 85% in culture confirmed cases and 64% (32/50) in clinically suspected cases of OATB. Both TruPlus and Gx Ultra correctly reported Rifampicin resistance in four cases, when compared with phenotypic DST and rpoB gene sequencing.
Conclusion: TruPlus, with its greater portability and higher sensitivity than Xpert, could serve as an important tool for diagnosing OATB and rifampicin resistance at outreach endemic areas.

AB1562 NAIL FOLD CAPILLAROSCOPY IN EVALUATING INTERSTITIAL LUNG DISEASE OF RHEUMATOID ARTHRITIS, SYSTEMIC SCLEROSIS AND IDIOPATHIC TYPE

Keywords: Rheumatoid arthritis, Systemic sclerosis

S. Rashad[1,1,2,3], K. Darwish[4], H. Abdel-Maksoud[4], A. Abas[4], M. Abdelaty[4]. [1]*Suiz University, Faculty of Medicine, Suiz, Rheumatology, Cairo, Egypt*; [1]*Suiz University, Faculty of Medicine, Suiz, Rheumatology, Cairo, Egypt*; [3]*Alazhar University, Chest, Asiut, Egypt*; [4]*Alazhar University, Chest, Assiut, Egypt*

Background: Nail fold capillaroscopy (NFC) is a non invasive diagnostic tool to detect early changes of microcirculation of different collagen diseases as rheumatoid arthritis associated interstitial lung disease (RA-ILD), systemic sclerosis interstitial lung disease (SS-ILD) and idiopathic ILD (Ting et al., 2020).
Objectives: The study aimed to evaluate role of NFC in RA-ILD, SS-ILD and idiopathic ILD, and to determine if there is a correlation of it to disease activity.
Methods: A case control study conducted on 100 patients with ILD, where 30 patients with RA-ILD, 30 patients with SS-ILD and 40 patients with idiopathic-ILD, fulfilling ACR/EULAR criteria, 2013. They were examined clinically and radiologicaly. Pulmonary function tests (PFT) and NFC were done.
Results: Pleural irregularities were found in 42% of RA-ILD, 30% of SS-ILD where subpleural irregularities were found in 31% of RA-ILD and 46.7% of SS-ILD. Ground glass opacity was in 13% of RA-ILD, 76.7% in SS-ILD and70% in idiopathic –ILD. Honeycomb appearance was in 11.5% of RA-ILD, 30% in SSILD and 65% of idiopathic ILD.SS-ILD showed the highest capillary changes especially patients with pneumonia. A significant correlation was found between NFC and PFT in idiopathic-ILD.
Conclusion: NFC is a sensitive and specific adjuvant tool in monitoring micro vascular changes in rheumatologic diseases and can be used as assessment tool in severity of the disease.

AB1563 CORRELATIONS BETWEEN LUNG INJURY AND PERIPHERAL VASCULAR MANIFESTATIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS: A PRELIMINARY STUDY

Keywords: Lungs, Imaging, Cardiovascular disease

B. Ruaro[1], E. Baratella[2], M. Confalonieri[1], P. Confalonieri[1], F. Salton[1]. [1]*Pulmonology Unit, Department of Medical Surgical and Health Sciences, Trieste, Italy*; [2]*Radiology Unit, Department of Medical Surgical and Health Sciences, Trieste, Italy*

Background: systemic sclerosis (SSc) is a rare autoimmune disease characterized by the presence of vascular disease and tissue fibrosis. The alteration of vascular system in SSc is due to dysfunctions of fibroblasts and endothelial cells [1-3]. This dysfunction results in excessive collagen production and vascular damage, which are associated to multiorgan damage. Lung disease in SSc is mainly characterized by interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH). Transthoracic echocardiography is the most commonly used screening tool for PAH in patients with SSc, but definitive diagnosis requires confirmation by right heart catheterization (RHC) [4]. Numerous studies have demonstrated that nail fold videocapillaroscopy (NVC) provides an accurate assessment of microvascular damage in SSc and is able to predict internal organ involvement, such as lung damage.
Objectives: This work aims to evaluate possible correlation between lung injury and peripheral microvascular involvement in SSc patients.

Methods: We enrolled, after obtaining informed consent, 16 patients affected by SSc (classification criteria EULLAR/ACR 2013) (3), who underwent cardiac catheterization for suspicion of PAH (3), in particular we paid attention to the measurement of pulmonary vascular resistance. NVC was performed in all patients, we collected information on the main capillaroscopic alterations such as number of capillaries, megacapillaries, avascular areas and microhemorrhages.
Results: After RHC evaluation, we identified 8 patients with PAH (F/M 6/2; median age 67± 7 SD years) and 8 without PAH (F/M 6/2; median age 66± 8 SD yrs). No significant differences regarding clinical and laboratoristic parameters were observed. At NVC, capillary density was significantly lower in PAH-SSc patients than in SSc patients without PAH (p = 0.04) and avascular areas were more frequent in the first group (p = 0.03). Furthermore, we evaluated a statistically significant correlation between the value of pulmonary vascular resistances at RHC and the number of capillaries at NVC (p = 0.04). We did not observe correlations with the other parameters.
Conclusion: This study confirms the correlation between peripheral microvascular alterations, evaluated by capillaroscopy and the involvement of internal organs, such as pulmonary circulation. Our findings provide additional evidence to the literature data but further studies are underway to confirm these preliminary data.

AB1564 PERIPHERAL BLOOD PERFUSION IN MCTD AND UCTD PATIENTS: A CROSS-SECTIONAL MONOCENTRIC STUDY

Keywords: Imaging, Mixed connective tissue disease, Undifferentiated connective tissue disease

A. Cere[1], E. Hysa[1], A. Lercara[1], A. Pinelli[1], E. Gotelli[1], C. Pizzorni[1], S. Paolino[1], A. Sulli[1], V. Smith[2], M. Cutolo[1]. [1]*Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine (DiMI), University of Genova, IRCCS San Martino Polyclinic, Genova, Italy*; [2]*Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Department of Internal Medicine, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium*

Background: Connective tissue diseases (CTDs) are a heterogeneous group of autoimmune disorders and, among them, mixed connective tissue disease (MCTD) and undifferentiated connective tissue disease (UCTD) show overlap symptoms with other CTDs, but share secondary Raynaud's Phenomenon (sRP) as a typical vascular symptom[1,2]. Laser speckle contrast analysis (LASCA) is a reliable tool to measure the peripheral blood perfusion (PBP) and has already demonstrated to be useful in detecting the peripheral microcirculation status of SSc patients and severe sRP[3].
Objectives: To measure hand PBP in patients with sRP in CTDs (MCTD, UCTD) and to compare it with healthy controls (HCs).
Methods: Twenty-four CTDs patients with sRP (7 with MCTD, 17 with UCTD) and 28 age- and sex-matched HCs were evaluated during standard follow-up assessments. CTDs diagnoses were set up according to the international classification criteria[4,5]. Patients had a stable therapy (mainly glucocorticoids and conventional disease modifying anti-rheumatic drugs) and had not had intravenous vasodilator treatments for the previous three months at least. All subjects underwent a LASCA registration (Laser Speckle Contrast Analysis - Pericam PSI, Perimed, Jarfalla) after acclimatization of 15 minutes at 20-22°C. After recording, PBP was quantified (perfusion units, P.U.) in the following region of interests (ROIs): fingertips (with and without thumbs) and periungual areas (with and without thumbs). Statistical analysis was performed using DATATab®, with parametric tests in case of normally distributed data and non-parametric tests in case of non-symmetrically distributed data.
Results: Although not statistically significant, a trend to a lower PBP was found when comparing MCTD LASCA values versus UCTD LASCA values, particularly for ROIs of periungual areas (see Table 1). In addition, PBP was found significantly lower in MCTD and UCTD when individually compared with HCs. This result was confirmed for all four ROIs (p<0,02; see Table 1).
Conclusion: To our knowledge, no evaluations of PBP by LASCA are available in literature in other CTDs other than SSc[6]. This preliminary study showed, using the LASCA methodology, that the PBP in MCTD and UCTD patients affected by sRP is significantly lower than in age- and sex-matched HCs. A trend with a lower PBP in MCTD patients than UCTD patients was observed but did not reach a statistical significance due to the small sample size. These results may demonstrate a potential role of LASCA in assessing the vascular involvement of CTDs other than SSc. Further investigations on a larger and more homogeneous sample size and a focus on the possible correlations between PBP and the morphological microvascular damage assessed by nailfold videocapillaroscopy have been planned.

AB1565 IBD AND LIGAMENTOUS LAXITY ASSOCIATION

Keywords: Diagnostic tests, Descriptive studies, Clinical trials

C. Bentivenga[1], A. Varani[1], N. E. Politi[1], E. R. Cosentino[1], F. Rizzello[2], C. Calabrese[2], P. Gionchetti[2], C. Borghi[1]. [1]*S.Orsola-Malpighi Polyclinic IRCCS, Medicina Interna Cardiovascolare-Borghi, Bologna, Italy*; [2]*S.Orsola-Malpighi Polyclinic IRCCS, IBD Unit, Bologna, Italy*

Background: Inflammatory Bowel Disease (IBD) is a group of chronic relapsing-remitting diseases characterized by intestinal and extra-intestinal manifestations that unfavourably impact patients' physical and mental quality of life. Recent evidence points to a possible higher incidence of Joint Hypermobility (JH) or "ligamentous hyperlaxity" in IBD patients compared to the general population and particularly in younger and female subjects with IBD. Ligamentous hyperlaxity represents a little-known benign clinical condition characterized in its asymptomatic form by joint and ligament hypermobility.
Objectives: the aim of this study is to determine the prevalence of ligamentous hyperlaxity in a cohort of patients with IBD.
Methods: we evaluated 130 patients afferent to the joint clinic of the "Centro Regionale per le Malattie Infiammatorie Croniche Intestinali "Massimo Campieri" e MI Borghi", located at "Sant'Orsola-Malpighi" University Hospital in Bologna, in the period between June 2021 and November 2022, allocating them into 3 groups: 1) Ulcerative Colitis (UC), 2) Crohn's Disease (CD), 3) Indeterminate Colitis (IC). None of the patients was affected by hereditary collagenopathies. Out of 130 patients, 47 were affected by Ulcerative Colitis (UC), 78 by Crohn's Disease (CD) and 5 by Indeterminate Colitis (IC). The mean age at the time of the visit was 45,32 (±12,86 range 24-78) for patients with UC; 47,35 (±12,65 range 22-70) for patients with CD; 45,00 (±12,16 range 26-62) for patients with IC; in terms of sex: 47 men (20 with UC, 27 with CD, 0 with IC) and 83 women (27 with UC, 51 with CD and 5 with IC).
Results: 34 out of 130 patients presented ligamentous hyperlaxity according to Beighton's criteria (pt ≥ 4) (26,2% of total, 16 UC, 17 CD, 1 IC). Of the 47 patients with UC, 16 had ligamentous hyperlaxity (34%). Of the 78 patients with CD, 17 had ligamentous hyperlaxity (21,8%). Of the 5 patients with IC, 1 had ligamentous hyperlaxity (20%). It emerges from this analysis that the highest prevalence of ligamentous hyperlaxity occurs in patients with UC, compared with CD and IC. Chi-square test for independence was performed by comparing the variable ligamentous laxity with the variables IBD, UC, CD and IC.

The groups CD and IC did not show any statistically significant result with regards to ligamentous laxity whereas we did observe a statistically significant higher frequency of ligamentous laxity (p-value < 0,05) in the UC group.
Conclusion: a close association between Ulcerative Colitis and the presence of JH, especially compared to Crohn's disease and Indeterminate Colitis, clearly emerges from our observation, which could postulate a possible alteration of collagen development in the pathophysiology and clinical spectrum of UC only and not of IBD in general. These data, however, need to be confirmed and further investigated in the future with focused and rigorous prospective clinical studies, excluding confusing factors such as young age or inflammatory joint diseases such as spondyloarthritis.

AB1566 CRYOGLOBULIN TESTING IN A TERTIARY UNIVERSITY TEACHING HOSPITAL

Keywords: Vasculitis, Diagnostic tests

P. Harkins[1], S. Cowley[2], A. Naughton[3], J. Dunne[3], N. Conlon[3], R. Conway[1]. *[1]St. James Hospital, Rheumatology, Dublin, Ireland*; *[2]Tallaght University Hospital, Rheumatology, Dublin, Ireland*; *[3]St James Hospital, Immunology, Dublin, Ireland*

Background: Cryoglobulinaemic vasculitis is a small vessel vasculitis that is typically associated with hepatitis C viral infection (80%), however, it can also be associated with lymphoproliferative disorders and autoimmune diseases. [1] It typically presents with rheumatological, cutaneous or renal manifestations, in addition to peripheral neuropathy. [1] It is associated with significant morbidity and mortality if left undiagnosed. The detection of cryoglobulins in serum is a prerequisite for diagnosis. However, testing methods are frequently influenced by artifact, resulting from ex-vivo cryoprecipitation. Therefore, samples are often unsuitable for analysis, resulting in diagnostic delay, with associated high health care cost, utility, and burden.
Objectives: To assess cryoglobulin testing at a large tertiary hospital in Dublin, Ireland.
Methods: A retrospective analysis was performed on all cryoglobulin tests ordered at a tertiary university affiliated hospital over a five-year period from January 2017 until December 2022. We collected baseline patient demographics, location from which sample was taken (outpatient versus inpatient), suitability of sample for analysis and results of processed samples. Appropriate statistical analysis was then performed.
Results: A total of 524 consecutive samples were sent for cryoglobulin testing over the five-year period. The mean age of patients undergoing testing was 53.29 (SD 17.40). There was a total number of 360 individual patients, of which 166 (46.1%) were females. 223 (43%) samples were unsuitable for analysis and were not processed accordingly. Of those samples not processed 114 (51%) were taken on an inpatient ward, whilst 109 (49%) were taken in the outpatient setting. Of the samples unsuitable for analysis, 209 (93.7%) were received at the incorrect temperature, 11(4.9%) were duplicate samples, 2 had an incorrect serum sample sent, and in one case no sample was received. Notably, of the samples deemed unsuitable for analysis, only 117 (52%) underwent repeat testing. Unexpectedly, there was no statistically significant association between sample suitability and gender, age, date or location of testing.
Conclusion: This study demonstrates the inability to process almost half of cryoglobulin test samples received at our institution. This undoubtedly results in significant diagnostic delay, in addition to unnecessary health care costs and utility. There is a crucial unmet need to increase education and awareness on optimal sample testing, in addition to the implementation of pathways to optimize sample collection and transportation. Finally, the failure to repeat unprocessed samples in a significant proportion of cases raises the question of initial indication for testing, and the need to review criterion for diagnostic testing.

AB1567 DIAGNOSIS OF SACROILIITIS USING LOW DOSE CT COMPARED TO MRI

Keywords: Diagnostic tests, Spondyloarthritis

P. W. V. Chan[1], S. L. Lau[1], J. F. Griffith[2], J. So[1], H. So[1], L. S. Tam[1]. *[1]The Chinese University of Hong Kong (CUHK), Department of Medicine and Therapeutics, Hong Kong, Hong Kong (SAR)*; *[2]The Chinese University of Hong Kong (CUHK), Department of Imaging and Interventional Radiology, Hong Kong, Hong Kong (SAR)*

Background: Establishing a correct diagnosis of sacroiliitis is key to the early diagnosis of axial SPA. Low-dose computed tomography (LDCT) is helpful at revealing the structural changes (erosion, sclerosis and ankylosis) of sacroiliitis. How does LDCT compare with MRI for identifying sacroiliitis?
Objectives: This study compares LDCT and MRI in the diagnosis of sacroiliitis in patients with suspected axial spondyloarthritis (axSpA).
Methods: 25 patients [36 ± 7 years; female 16 (64%)] with back pain over three months and age under 45, clinically suspected of axSpA underwent radiography, LDCT and MRI of the SIJ. All imaging studies were assessed by an experienced radiologist. Radiographs and LDCT revealed erosions, bone sclerosis and ankylosis. MRI, in addition to these structural changes, also revealed osteitis and enthesitis.
Results: Out of the 25 patients, 8 (32%) had radiographic-sacroiliitis. Twelve (48%) patients had sacroiliitis on both LDCT and MRI, including 6 patients with radiographic-sacroiliitis and 6 patients with non-radiographic-sacroiliitis. There is no evidence of sacroiliitis on both LDCT and MRI for one patient, who was reported to have sacroiliitis on x-ray. No diagnosis could be made to 10 (40%) patients due to lack of evidence from imaging and 3 (12%) patients were diagnosed as osteitis condensans ilii. Agreement between MRI and LDCT was 100%, Cohen's kappa coefficient was k=1, positive predictive value was 1, and negative predictive value was 1. Using MRI as the gold standard, sensitivity and specificity of LDCT were 1 and 1 respectively. While the sensitivity and specificity of x-ray were 0.5 and 0.85 respectively.
Conclusion: Low dose CT and MRI showed comparable sensitivity in detecting sacroiliitis. If access to MRI is limited, LDCT is a good alternative to detect sacroiliitis in patients with suspected axSpA.

ENTHESITIC INVOLVEMENT IN PATIENTS WITH SAPHO SYNDROME. ULTRASOUND EVALUATION USING THE MASEI INDEX

Keywords: Diagnostic tests, Enthesitis, Descriptive studies

Á. Andreu-Suárez[1], B. A. Blanco Cáceres[1]. [1]*University Hospital Ramón y Cajal, Rheumatology, Madrid, Spain*

Background: SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, and osteitis) is a rare disease with a prevalence of less than 1 in 10,000 [1]. Among its musculoskeletal manifestations, enthesis involvement has been observed, which, along with the axial manifestations, has led many authors to consider it as part of the spondyloarthropathies group of diseases. Ultrasound assessment of enthesis is known to be more sensitive and specific than physical examination. The Madrid Sonographic Enthesitis Index (MASEI) is one of the most widely used tools for enthesis evaluation in spondyloarthropathies [2]. It examines six entheses (quadriceps, proximal and distal patellar, Achilles, plantar fascia, and triceps) and assesses six possible elementary lesions defined by OMERACT [3], plus Doppler. This allows the assessment of both inflammatory activity and structural damage (structure, thickness, erosions, calcifications, and bursitis) [4]. While there have been some ultrasound studies on enthesic involvement in SAPHO, demonstrating damage even in asymptomatic patients [5], there is currently no validated ultrasound index for enthesis evaluation in this disease.
Objectives: The aim of this study is to describe the ultrasound findings of SAPHO Syndrome patients' entheses using the MASEI index.
Methods: This is a descriptive, cross-sectional, single-center study, carried out in the Rheumatology Service of the Ramón y Cajal Hospital (Madrid, Spain). A convenience sampling was carried out, including all patients with SAPHO under active follow-up in our clinics.
Results: 12 patients were included (83.3% women), with a mean age of 52.41 (±9.4) years at the time of the study. 66.7% were smokers, and 25% ex-smokers. The mean BMI was 26.62 (±5.69). The average number of painful entheses was 0.92 (±1.24) and no swollen entheses were found. 25% of the patients had been diagnosed with previous clinical enthesitis. 38.5% of the patients had a positive MASEI score (>18). The mean score of the MASEI index was 20.42 (±11.02). Of this score, only a mean of 2 (±1.5) was found in the Doppler study; while a mean of 18.25 (±14.50) corresponded to structural damage. The involvement within the different explored entheses is described in Table 1. The greatest involvement was found in the distal patellar enthesis (6.58 ± 3.75) (Figure 1).

Table 1. MASEI score within the different explored entheses.

Enthesis	Triceps		Quadriceps		Proximal patellar		Distal patellar		Achilles		Plantar fascia	
Mean (±SD)	1,58 ±2,392		2,75 ±3,467		3,75 ±3,166		6,58 ±3,753		3,25 ±2,667		2,5 ±2,780	
	R	L	R	L	R	L	R	L	R	L	R	L
	0,5 ±0,52	1,08 ±2,06	1,33 ±1,83	1,42 ±1,73	2 ±1,76	1,75 ±1,91	2,17 ±1,03	4,42 ±3,09	1,50 ±1,09	1,75 ±1,76	1,25 ±1,60	1,25 ±1,60

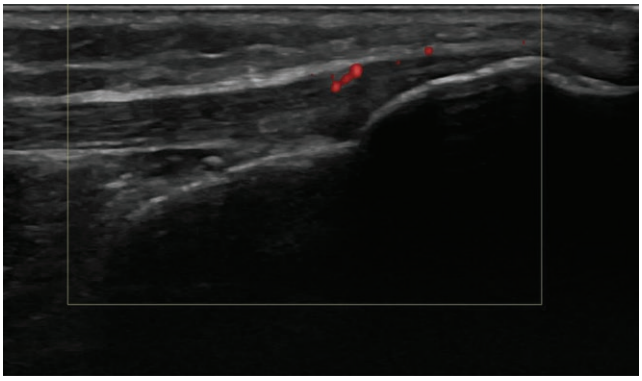

Figure 1. Ultrasound examination of the enthesis of the distal patellar tendon.

Conclusion: The patients with SAPHO Syndrome in follow-up at Ramón y Cajal hospital were found to have ultrasound entheseal abnormalities using the MASEI index. The results revealed a clear predominance of structural damage over the presence of active lesions. Further studies with larger sample size are necessary to fully comprehend the involvement of entheses in SAPHO syndrome.

THE USE OF MACHINE LEARNING IN DIAGNOSING AND DETECTING DAMAGE IN THE HANDS AND FEET OF PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS: A SCOPING REVIEW

Keywords: Imaging, Artificial intelligence, Psoriatic arthritis

A. Antony[1,2], A. Biju[3], A. Rambojun[4], W. Tillett[5,6]. [1]*Monash University, School of Clinical Sciences, Melbourne, Australia*; [2]*Monash Health, Rheumatology, Melbourne, Australia*; [3]*University of Bristol, Bristol Medical School, Bristol, United Kingdom*; [4]*University of Bath, Institute for Mathematical Innovation, Bath, United Kingdom*; [5]*University of Bath, Department of Pharmacy & Pharmacology, Bath, United Kingdom*; [6]*Royal United Hospital, Department of Rheumatology, Bath, United Kingdom*

Background: Machine learning methods have the potential to optimise the diagnosis of inflammatory arthropathies and the quantification of damage over time.
Objectives: To summarise the literature investigating the use of machine learning methods to diagnose and detect damage in the hands and feet of patients with Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA).
Methods: A literature search was undertaken in PubMed, EMBASE, Web of Science and the Cochrane Central Register for Controlled Trials using a pre-specified search strategy. Full-text articles and conference abstracts published in English between the 1st of January 1995 and the 22nd of June 2022 that utilised machine learning (ML) in an imaging modality (X-Ray [XR], Computed Tomography [CT], Ultrasound [USS] or Magnetic Resonance Imaging [MRI]) to diagnose or assess structural damage in the hands and feet of patients with RA or PsA were included. All abstracts were reviewed by two authors (AA and AB) and all eligible full-text articles were assessed by the same authors, who subsequently independently extracted data according to the review protocol. Reference management and data extraction were conducted using Covidence. Data extracted included patient population and numbers, diagnoses, ML models and validation/testing methods, and algorithm performance.
Results: The literature review identified 851 unique references, of which 123 were eligible for full-text review; 26 references met the inclusion criteria for the review (Figure 1: PRISMA Diagram). There were 21 full-text articles and 5 conference abstracts published between 2000-2022, all of which assessed joints in the hands and/or wrists. Most studies utilised XR (n=23) rather than USS (n=1), MRI (n=1) and CT [1]. The number of patients/radiographs included used ranged from 15-5191 and most studies assessed RA only (n=23), with 2 studies assessing RA and PsA and 1 assessing PsA only. 24 studies were cross-sectional while 2 were longitudinal. ML methods were used to diagnose RA (n=9), diagnose PsA (n=2), estimate joint space score (n=5) or measure joint space width (n=3) or estimate change in joint space width (n=1), detect erosions (n=3) or estimate erosion score (n=7), estimate overall damage score (1), detect subluxation/ankylosis (n=1) and detect periarticular textural change (n=1). Additional tasks performed by ML algorithms were cropping of radiographs, localising joints and segmenting bones. Most studies utilised transfer learning on pre-trained neural networks: VGG15, VGG16, DenseNet, AlexNet, Single Shot Multibox Detector, YOLOv3, YOLOv4, LENet, Network in Network, SqueezeNet, ResNet, ResNet50, DeepTEN, U-net and EfficientNet. Some studies incorporated shape models (e.g. active shape, gaussian and local linear mapping models), multiscale gradient vector flow snakes, Graph Convolutional Networks, support vector machines, support vector regression and ridge regression. Complete model assessment with training, validation and testing cohorts were reported in 12 studies (46.2%), and of these 4 utilised n-fold cross-validation rather than hold-out validation. There was significant heterogeneity in the reporting and the performance of the models used.

Conclusion: The use of machine learning in diagnosing and detecting damage has mostly focused on plain radiography in patients with RA; there are limited data in PsA. Heterogeneity in the reporting of results limits succinct comparison of performance between ML methods.

AB1570 MODERN TREATMENT OF ENTRAPMENT NEUROPATHIES, THE HYDROCHEMICAL NEUROLYSIS

Keywords: Ultrasound, Descriptive studies, Best practices

A. Ould Hennia[1]. [1]*Louis Pasteur Hospital, Interventional Rheumatology Unit, Chartres, France*

Background: Entrapment neuropathies (E.N) are frequent and often underdiagnosed leading to significant chronic pain and functional impairment impede the quality of life. Commonly occur at the fibro-osseous tunnels through which the nerves course with various static and dynamic factors. Imaging particularly ultrasound can identify an anatomical cause, detect signs of nerve injury, assess its severity and also aid in the percutaneous treatment like our technique: "The hydrochemical neurolysis" (HCN).

Objectives: We present the US-guided hydrochemical neurolysis of E.N to relieve, in most cases, the pain caused by peripheral nerve compression and its consequences by the mechanical release and decompression of the entrapped nerves. This technique involves using US (fast, accessible, reliable, cheap and radiation-free) to find the nerve and guide a needle around the nerve to cut scat tissue and introduce fluid to mechanically push scar tissue ways from the nerve and create separation between the nerve and tissues. With **18 G needle**, a real mechanical dissection is performed and with the liquid (normal saline) we complete with a hydrodissection.

Methods: Before performing a US-guided HCN, survey imaging should be performed with low or high resolution probes, depending on the depth of the intervention. patient informed and clearly consents.

Technique: what I do.

Patient positioning: patient positioned in a supine, sitting, or prone posture according to the location of the nerve to be treated. Different positions, pillows and/or pads can be used to restrict movement during the procedure and provide comfort for patient and physician. Identification, marking the skin, disinfection and local anesthesia. The needle entry point is calculated based on the distance and inclination angle of the needle from the skin surface to the target for better and optimal visibility of the needle tip. These settings are variable depending on the superficial or deep situation of the nerve to be treated. The entry site is then marked (with skin marker) as well as the projection of the target at the level of the skin, then the skin area is cleaned and prepared for the using standard sterile technique. The US-probe is covered with a sterile semi-transparent bag and a sterile gel is used for further analysis and intervention. A 25 G needle is used to anesthetize the skin with 1% lidocaine, and is then advanced under US-guidance with an intermittent local injection for anesthesia (and hydrolocation) until the needle comes into contact with the epineurium. The in-plan approach is my favorite. Perineural Hydrolocalization, Adhesiolysis, Hydrodissection and injections. With **18 G** needle (variable length according to the site to be treated) we inject under low pressure 5-10 ml of liquid (mix of normal saline and 1% lidocaine) between the compressed nerve and the connective-fatty tissue to make the end of my needle clearly seen (**hydrolocation**), can be repeated for the duration of the procedure. Then with the same needle, we inject 20-60 ml of normal saline all around the nerve and over the entire area where it is compressed to release it completely from all surrounding structures (**hydrodissection**).

Adhesiolysis is carried out when there is scar tissue around the nerve and the hydro-dissection was not effective, in this case a real mechanical needle dissection is carried out or the needle is used like a scalpel to make needling in varying directions all the scar tissue surrounding the nerve. After hydrodissection, we **inject** corticosteroid (5-10 ml of prednisolone acetate 125 mg) for his anti-inflammatory and anti-fibrotic effect.

Results: In my practice, we have at least 70% good results at 12 months, 20 to 25% require a 2nd session of hydrochemical neurolysis and maybe 10% will resort to surgery. The results of neurolysis seem very interesting, much better than a simple US-guided infiltration and avoids surgery in many cases.

Conclusion: Success with this hydrochemical neurolysis procedure requires knowledge of anatomy, US-imaging. The HCN is a simple, safe, precise, rapid, and effective percutaneous treatment of E.N, a great alternative to surgery.

AB1571 IGG4-RELATED AUTOIMMUNE PANCREATITIS MIMICKING PANCREATIC CARCINOMA

Keywords: Malignancy, Undifferentiated connective tissue disease, Mixed connective tissue disease

L. Farrukh[1], M. Akhtar[1], H. H. Waqar[1], F. Sami[2], M. Ebad Ur Rehman[3], R. Peredo-Wende[4]. [1]*Albany Medical Center, Internal Medicine, Albany, United States of America*; [2]*John H. Stroger, Jr. Hospital of Cook County, Internal Medicine, Chicago, United States of America*; [3]*Rawalpindi Medical University, Medicine, Rawalpindi, Pakistan*; [4]*Albany Stratton VA Medical Center, Rheumatology, Albany, United States of America*

Background: IgG4-related disease (IgG4-RD) is a systemic fibroinflammatory disorder characterized by dense infiltration of IgG4-positive plasma cells in the affected tissue. The inflammatory infiltration along with storiform fibrosis can lead to the development of tumefactive lesions that may affect any organ. Type 1 Autoimmune pancreatitis (AIP) is a rare presentation of IgG4-RD that can present as a pancreatic mass and may mimic pancreatic carcinoma.

Objectives: The elevation of CA 19-9 is seen in autoimmune pancreatitis as well as pancreatic carcinoma. Therefore, it becomes difficult to differentiate between the two, especially in the presence of an elevated IgG4 level in the serum. We describe a rare instance of IgG4-related AIP with significantly high CA 19-9 levels.

Methods: Case report.

Results: Our patient is a 65-year-old male with past medical history of IgG-4 related retroperitoneal fibrosis, who presented with the complaint of worsening right upper quadrant abdominal pain, jaundice, and weight loss. Labs showed WBC count 13.7 (4.0-9.0 x 10*3/uL) and eosinophil count 700 (50-300/cmm). ESR 94 (0-15 mm/hr) and CRP 57.9 (0-10 mg/dL). LFTs showed elevated total bilirubin 12.5 (0.1-0.2 mg/dL), alkaline phosphatase 620 (30-115 IU/L), AST 72 (5-45 IU/L), and normal ALT 52 (5-60 IU/L). Absolute CD4 count was 1152 (332-1642 cells/cmm), CD4 percentage was 80% (28-62%), CD4 to CD8 ratio was high 8.86 (0.7-4.8). CA 19-9 was elevated to 2830 (0-35 U/ml). IgG4 was elevated 162 (2-96 mg/dL).

MRCP showed multiple biliary strictures and dilation of the main pancreatic duct. ERCP with stent placement was done to relieve biliary obstruction. EUS showed mass-like enlargement of the pancreatic head with atrophy, around the common bile duct (CBD). Biopsy of the CBD showed inflamed glandular mucosa, negative for malignancy. Pancreatic head biopsy showed normal stroma and benign mucosa, negative for malignancy. Patient had gradual improvement in bilirubin and CA 19-9 levels after ERCP and stent placement. He was started on prednisone which was followed by rituximab infusions. He followed up with rheumatology and had significant improvement in his symptoms and labs including a decrease in bilirubin to 2.8 mg/dL, alkaline phosphatase to 300 IU/L, and CA 19-9 levels to 100 U/ml within 1 month of discharge.

Conclusion: Autoimmune pancreatitis (AIP) can be difficult to distinguish from pancreatic carcinoma. High levels of CA 19-9 are usually indicative of malignancies, whereas high levels of IgG4 are characteristic of AIP. As per Van et al., the measurement of either CA 19-9 or IgG4 level alone is not accurate enough for diagnosis. However, the combination of CA 19-9 < 74 U/ml and IgG4 > 1.0 g/L distinguishes patients with AIP from patients with pancreatic carcinoma with 94 % sensitivity and 100 % specificity [1]. CA 19-9 levels can also be elevated in other GI diseases including primary sclerosing cholangitis, bacterial cholangitis, or choledocholithiasis. Differentiation between these conditions is extremely important due to the vastly different treatments and the morbidity/mortality associated with them [2,3]. IgG4-RD causing biliary obstruction with CA 19–9 elevation is a diagnostic dilemma. It can be misdiagnosed as pancreatic or cholangiocarcinoma. Our patient illustrates that IgG4-RD pseudotumors can significantly elevate CA 19-9. In these cases, further testing and biopsy should be performed to rule out malignancy.

Background: Some maternal systemic connective tissue diseases (CTD) and their associated antibodies are linked with adverse fetal outcomes, including increased risk of congenital heart diseases (CHD)[1,2]. Whether this increased risk also applies to less severe structural or functional cardiac abnormalities in the fetus is currently unknown.

Objectives: Based on a large cohort of newborns born to mothers with CTD, we aim to assess the association between maternal CTD and structural or functional cardiac abnormalities in the offspring. Data used in the study will be a combination of data collected in the Copenhagen Baby Heart Study (CBHS) and data collected via medical chart review to validate the CTD diagnosis and to obtain information about disease severity, treatment, etc.

Methods: In the CBHS we included more than 25,000 newborns between April 2016 and October 2018. All participants underwent systematic transthoracic echocardiography (TTE) within the first 60 days after birth[3,4]. The present study will include newborns from the CBHS born to mothers diagnosed with CTD, as identified through the Danish national health registries. Assuming an overall incidence of CTDs at 2% we expect to include approximately 500 newborns to mothers with CTD. Newborns born to mothers diagnosed with CTD will be matched 1:1 to newborns not exposed to maternal CTD, based on child sex; gestational age at birth; age and weight at time of TTE; and maternal age at delivery. Maternal medical charts will be reviewed to validate the CTD diagnosis and obtain information about disease severity, treatment, etc. The primary endpoint is a composite of functional and structural abnormalities in the heart of the newborns, assessed by echocardiography, including left ventricular structural and functional abnormalities, septum defects, and valve anomalies.

Results: Preliminary results are expected in spring 2023.

Conclusion: It is unclear whether children of mothers with CTD should have routine cardiac evaluation at birth, and whether certain types of maternal CTD have a higher risk of minor/subclinical CHD or less severe cardiac abnormalities in the offspring compared with children born to mothers without CTD. The size of CBHS and the comprehensive assessment of the included children provide a unique opportunity for obtaining new knowledge in this field, including better insights into whether routine TTE after birth should be considered in certain subgroups.

AB1573 AUTOIMMUNE HEMOLYTIC ANEMIA IN CHRONIC LIVER DISEASES

Keywords: Comorbidities, Diagnostic tests

N. Trad[1], G. Mohamed[1], S. Bizid[1], S. Soua[1], B. Ben Slimen[1], K. Boughoula[1], H. Ben Abdallah[1], R. Bouali[1], M. N. Abdelli[1]. *[1]Military Hospital of Tunis, Gastroenterology, Tunis, Tunisia*

Background: Chronic liver diseases can be associated with autoimmune diseases. their association with autoimmune hemolytic anemia (AIHA) is poorly studied.

Objectives: Our objective was to study the prevalence and the characteristics of AIHA in chronic liver diseases.

Methods: We performed a retrospective analysis of data from consecutive patients followed in our department for chronic liver diseases recruited from January 2010 to December 2019. The diagnosis of AHAI was retained in front of regenerative anemia with a positive direct coombs test and stigmata of hemolysis (free hyperbilirubinemia, elevated lactate dehydrogenase, and low haptoglobin) in the absence of other overt causes of constitutional or acquired hemolysis.

Results: A total of 187 patients were included with an average age of 60.2 years [11-89] and a sex ratio of 1.79. Thirteen patients had an AIHA (7%). Anemia was normocytic in 77% of cases and macrocytic in 23% of cases. Five patients had a history of associated autoimmune pathologies (38.4%); autoimmune thyroiditis in two cases, one case of psoriasis, one case of Sjögren's syndrome and one case of autoimmune thrombocytopenia The AIHA was more frequent in cases of viral chronic liver diseases B and C (46.1%). Three patients had non-viral chronic liver diseases (23%): primary biliary cholangitis, autoimmune hepatitis, and alcohol.

Conclusion: In our study, AIHA was present in seven percent of cases, which would underline the importance of evoking it in the face of any anemia in the case of chronic liver diseases.

AB1574 DESCRIPTIVE STUDY OF CAPILLAROSCOPIES PERFORMED IN THE RHEUMATOLOGY SERVICE OF A THIRD LEVEL HOSPITAL

Keywords: Diagnostic tests, Descriptive studies

R. J. Gil Velez[1,2], L. Robles Kirkegard[2], L. Mendez Diaz[1]. [1]*Seville, Rheumatology, Seville, Spain*; [2]*Virgen del Rocio Hospital, Rheumatology, Seville, Spain*

Background: Capillaroscopy is a study technique using direct in vivo images of the skin microcirculation. It constitutes an accessible and non-invasive method to analyze microvascular abnormalities in patients with rheumatic diseases. Its usefulness has been demonstrated in diseases such as Systemic Sclerosis (ES), Sjögren's syndrome, Rheumatoid Arthritis, Dermatomyositis, Systemic lupus erythematosus (SLE) and, above all, Raynaud's phenomenon.
Objectives: To describe the clinical characteristics of a cohort of patients who underwent capillaroscopy in the Rheumatology service during the year 2022.
Methods: -Retrospective descriptive study of 100 patients who underwent capillaroscopy in the rheumatology service. The data obtained were obtained by reviewing the digital medical records and the registry of capillaroscopy images of the same service.
Results: 100 patients were included, of whom 92 were women (92%) and 8 were men (8%) with a mean age of 50 +/-17 years. Of the patients analyzed, 53 presented a normal pattern on capillaroscopy (53%) and 47 presented an abnormal pattern (47%). Of our cohort, 68 patients had Raynaud's (68%), 5 patients were diagnosed with undifferentiated connective tissue disease (5%), limited scleroderma 12 patients (12%), diffuse scleroderma 6 patients (6%), and with psoriatic arthritis, juvenile idiopathic arthritis, Sjögren's, Rheumatoid Arthritis, antiphospholipid syndrome, Bechet and Dermatomyositis, there was a patient with each named disease (7%), and finally there were 2 patients who still do not have a firm diagnosis (2%). Of the patients in our cohort with an abnormal pattern, 12 had an early scleroderma pattern (25.5%), 10 patients had a late scleroderma pattern (21.25%), 8 patients had a lupus pattern (17%), 8 patients had a nonspecific pattern (17%), 6 presented a school of fish pattern (12.75%) and 3 patients presented a pattern of mixed connective tissue disease (6.3%). Within the cohort with a pattern of early scleroderma on capillaroscopy, 4 patients were diagnosed with limited scleroderma, 5 with Raynaud's phenomenon, 1 with diffuse scleroderma, 1 with undifferentiated connective tissue disease, and 1 patient had no diagnosis. With a late-onset scleroderma pattern, there were 2 patients with Raynaud's phenomenon, 4 with diffuse scleroderma, and 4 with limited scleroderma. With a school of fish pattern, there were 3 patients with Raynaud's phenomenon, 1 with diffuse scleroderma, 1 with undifferentiated connective tissue disease, and one with Sjögren's. Of the 100 patients analyzed, 7 had lung involvement (7%), presenting late scleroderma pattern in capillaroscopy (3 patients), diffuse scleroderma pattern 1 patient, 1 patient in school of fish, early scleroderma pattern 1 patient and no alteration in capillaroscopy 1 patient.
Conclusion: The data obtained are consistent with what is reported in the medical literature. The most common abnormal capillaroscopy pattern in our environment is early scleroderma, followed by late scleroderma. Of the patients analyzed, 7 had pulmonary involvement. With the data we have collected, we can conclude that capillaroscopy is a useful, non-invasive technique that can guide us during the diagnostic process in those patients who raise doubts both in clinical judgment and in the evolution of the disease.

AB1575 A RELIABLE METHOD FOR ANNOTATING HAND AND WRIST X-RAYS FOR SUPERVISED MACHINE LEARNING ALGORITHMS

Keywords: Artificial intelligence, Psoriatic arthritis, Imaging

A. Rambojun[1], A. Antony[2,3], Y. Hughes-Roberts[4], W. Tillett[5,6]. [1]*University of Bath, Institute for Mathematical Innovation, Bath, United Kingdom*; [2]*Monash Health, Department of Rheumatology, Melbourne, Australia*; [3]*Monash University, School of Clinical Sciences, Melbourne, Australia*; [4]*Royal United Hospital, Department of Radiology, Bath, United Kingdom*; [5]*University of Bath, Department of Pharmacy and Pharmacology, Bath, United Kingdom*; [6]*Royal United Hospital, Department of Rheumatology, Bath, United Kingdom*

Background: Machine learning (ML) algorithms could facilitate the standardisation of joint damage assessment in Psoriatic Arthritis (PsA) and improve its accessibility in clinical and research settings. ML algorithms trained on manually annotated hand and wrist radiographs have promising performance characteristics[1]. A large volume of annotated radiographs is needed, and annotation is time consuming and subject to reliability issues given X-Rays (XRs) are 2D representations.
Objectives: To develop a reliable method for the annotation of hand and wrist bones on XRs in order to facilitate the development of supervised ML algorithms for joint damage detection.
Methods: 10 bilateral hand and wrist XRs were selected at random from the Bath PsA XR database. 5 XRs were independently annotated by 3 annotators; (AA & WT (rheumatologist) and YHR (radiologist)) using the ASPAX software[2]. Annotations were visually inspected for areas of discordance and consensus annotation guidelines were developed. Annotation was repeated using the annotation guidelines on second set of 5 XRs. With annotator 1 (WT) representing ground truth, the mean error (ME; in pixels) of the annotation (deviation from ground truth) and the mean fractional error (MFE; corrects for the perimeter measurements of the bone), was estimated in pre- and post-training annotations. The ME and MFE within a single annotator (AA) were estimated in 5 radiographs after a 2-month interval.
Results: Visual inspection determined that the areas of discordance in annotation were the 1st interphalangeal joint, the metacarpal bases, the hamate and capitate bones, and the trapezium and trapezoid bones (Figure 1). The MFE between the annotators and ground truth improved for all bones following the development of annotation guidelines, with the largest improvement evident in the annotation of the metacarpal bones (Table 1). The intra-reader and inter-reader MFEs were comparable (Table 1).
Conclusion: Standardised instructions may facilitate reliable hand and wrist bone annotation and enable the acquisition of large volumes of annotated training data for supervised ML algorithms.

PERICORONARY ADIPOSE TISSUE (PCAT) ATTENUATION IS ASSOCIATED WITH INFLAMMATORY RHEUMATIC DISEASES (IMD): A RETROSPECTIVE CROSS-SECTIONAL ANALYSIS

Keywords: Heart, Imaging, Cardiovascular disease

W. Zhu[1], V. Goel[2], A. Antony[1,3], N. Nerlekar[2,3]. [1]*Monash Health, Department of Rheumatology, Melbourne, Australia*; [2]*Monash Health, Department of Cardiology, Melbourne, Australia*; [3]*Monash University, School of Clinical Sciences, Melbourne, Australia*

Background: PCAT attenuation is a non-invasive biomarker of coronary inflammation and is a poor prognostic factor in patients with coronary artery disease.
Objectives: To compare the severity of PCAT attenuation amongst patients with inflammatory rheumatic diseases (IMD) compared to patients with non-inflammatory rheumatic diseases (NIMD) in a retrospective cross-sectional study.
Methods: All patients seen in Monash Health rheumatology clinics over a 12-month period were identified. Patient records were cross-referenced with the hospital computed tomography coronary angiography (CTCA) database to identify patients who had undergone CTCAs. IMD patients who had their CTCA prior to their RMD diagnosis were excluded. Age, sex, co-morbidities, diagnoses, height, weight, and medications were extracted from the patient electronic medical records. CTCA variables were extracted (mA, DLP, contrast volume, kV, CACS, CAD-RADS) or calculated (SIS, SSS, PCAT attenuation).
Results: A total of 117 patients were included (105 with IMD and 12 with NIMD). There were no significant differences in age, sex, co-morbidities or cardiovascular medication use between groups. Patients with IMD had a lower BMI and were less likely to be smokers or have dyslipidaemia, but were more likely to have hypertension and diabetes mellitus, these were not statistically significant. The mean (±sd) PCAT was higher in IMD patients [-84.6 (±12.14) vs. -92.0 (±5.01) p<0.001) compared to non-IMD patients. There were no significant differences in any other CTCA outcomes.
Conclusion: PCAT attenuation is associated with IMD in this retrospective single-center cross-sectional study. Data from larger prospective cohorts with healthy comparator controls are needed to assess the significance of these findings.

Table 1. Baseline Demographics and CTCA Results

	IMD (n=105)	No IMD (n=12)	p-value	Missing (%)
Age (years)	56.6 (12.76)	57.6 (6.97)	0.347	0

EL ÍNDICE DE RESISTENCIA TIENE UNA RELACIÓN ESTRECHA CON LA DESTRUCCIÓN INTRAARTICULAR DE HUESO Y CARTÍLAGO POR DOPPLER ESPECTRAL EN LA ARTRITIS REUMATOIDE

Keywords: Ultrasound

O. Sedano[1,2,3], J. Sedano[4]. [1]*Ecosermedic, Reumatologia, Los Olivos, Peru*; [2]*Ecosermedic, Reumatologia, Los Olivos, Peru*; [3]*Ecosermedic, Lima, Los Olivos, Peru*; [4]*Hospital EsSalud Marino Molina Scippa, Medicina, Comas, Peru*

Background: Recent reports have shown that high-resolution ultrasound is a useful method of detecting pannus vascularization in inflamed finger joints of patients with RA and also is useful in assessing the disease activity or in monitoring therapeutic responses. Power Doppler ultrasonography (PDUS) techniques not only have the ability to detect vascularization but do also depict the flow patterns in the inflamed joints of RA patients by using spectral analysis.
Objectives: To evaluate intra-articular vascularization and flow patterns of the metacarpophalangeal (MCP) joints in rheumatoid arthritis (RA) patients by using power Doppler spectral (PDSUS) technique. The relationship between the flow patterns and bone and cartilage destruction.
Methods: Thirty-two patients (mean age 53.5 ± 13.8) with a disease duration of 7.8 ± 3.9 years were included into the study. Twenty MCP joints of five healthy subjects were also assessed as controls. Clinical activity of MCP joint inflammation was classified according to index for synovitis activity PD based on joint swelling, warmness and pain. Ultrasonography was performed using Vinno G86 unit by means of a 6–18 MHz linear array transducer. Gray-scale US and power Doppler sonography (PDUS) examination was performed. Using spectral Doppler the quality of flow was determined and the indices of pulsatility (PI) and resistance (RI) were measured in longitudinal plane. The erosive scores of the MCP joints were determined on the plain hand radiographs using Sharp/van der Heijde method.
Results: Total 128 MCP joints of 32 patients and 20 MCP joints of five healthy controls were examined in dominant hand. Flow was determined in 30 joints (10 moderately active, 20 active) in eight patients with erosions, whereas twenty-four patients had no erosions in MCP joints. MCP joints of healthy controls had quantifiable flow. Mean PI of these joints were in control (2.34 ± 0.87), in moderately

active (1.01 ± 1.1) and 0.32 ± 0.6 in active MCP joints. RI was in control 0.87 ± 0.12 in moderately active 0.61 ± 0.15 (figure 1) and 0.24 ± 0.12 in active MCP joints. There was significant difference in RI and PI of these active and moderately active MCP joints (p <0.01). There was a significant correlation between erosive scores and PI, RI of total MCP joints (r = 0.40 and r = 0.41, P < 0.05).

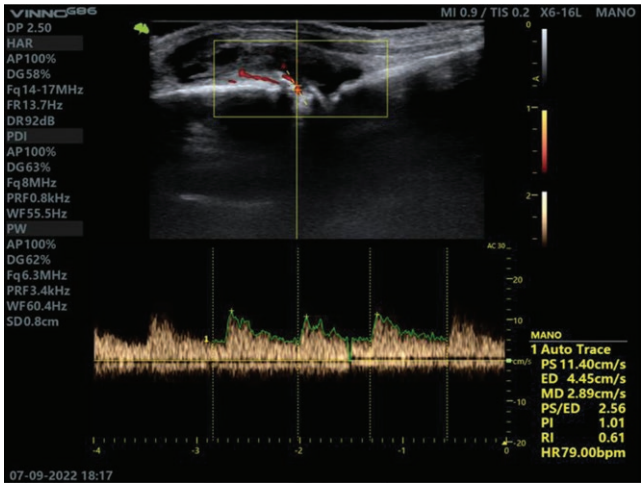

Figure 1. Moderately active

Conclusion: Spectral Power Doppler ultrasonography (PDSUS) is a useful method demonstrating synovial vascularization and flow patterns and offers new alternatives for monitoring disease activity and measurement of therapeutic response. Flow patterns had intimate correlation with intra-articular bone and cartilage destruction.

HEMORRHAGIC RISK ASSOCIATED WITH SPINAL PROCEDURES AND FOCUS ON PATIENTS TREATED BY ANTICOAGULANTS OR PLATELET INHIBITORS: A SYSTEMATIC LITERATURE REVIEW AND META ANALYSIS

Keywords: Safety, Systematic review

C. Langbour[1], A. Agbagni[2], S. Mitrovic[3], F. Rannou[2], B. Fautrel[3], G. Carvajal Alegria[1]. *[1]Hôpital Trousseau, Service de Rhumatologie, Tours, France*; *[2]Hôpital La Pitié Salpétrière, Service de Médecine physique et réadaptative, Paris, France*; *[3]Hôpital La Pitié Salpétrière, Service de Rhumatologie, Paris, France*

Background: Spinal procedures – including lumbar puncture, radiofrequency neurotomy, medial branch injection, facet joint injection, blood patch and epidural injection – are common in daily practice. Side effects can occur during these invasive procedures like hemorrhagic complications. The use of anticoagulants and platelet inhibitors can increase these risks.

Objectives: The aim of this study is to characterize the hemorrhagic risk associated with spinal procedures and to analyze if there is a sur risk of bleeding complications in patients treated with anticoagulants or platelet inhibitors.

Methods: A systematic literature review and metanalysis were made in MEDLINE, EMBASE and COCHRANE, in order to find a prevalence of hemorrhagic complications for each spinal procedure. We classify hemorrhagic risk in two categories. Bleeding and traumatic procedure were not severe complications and epidural hematoma and central nervous system bleeding were severe complications.

Results: Systematic literature analysis found 2407 articles. 75 were included in the metanalysis. The flow chart diagram, according to the PRISMA criteria is shown [Figure 1]. The global prevalence of each hemorrhagic complication according to each spinal procedure is showed in Table 1. There was no difference between patients with anticoagulants or platelet inhibitors and the others according to the epidural hematoma risk with OR of 0.95 IC95 [0.16-5.52] after a lumbar puncture and for the risk of traumatic lumbar puncture with OR of 0.78 IC95 [0.47-1.29].

Conclusion: Hemorrhagic complications during a percutaneous spinal procedure are very low. These findings are in coherence with precedents findings. In this metanalysis there was no difference between patients with anticoagulants or platelet inhibitors and the others during a lumbar puncture according to the epidural hematoma risk and the traumatic puncture risk. Strength of the study is the very important number of procedures. However studies were very heterogeneous. This metanalysis found that severe bleeding risk is very low during a spinal procedure but consequences can be severe. That is why the use of anticoagulants and platelet inhibitors has to be careful.

Durez[1]. *[1]Cliniques universitaires Saint-Luc (UCLouvain), Rheumatology, Bruxelles, Belgium; [2]UZ Brussel, Oncology, Jette, Belgium; [3]Cliniques universitaires Saint-Luc (UCLouvain), Pneumology, Bruxelles, Belgium; [4]Cliniques universitaires Saint-Luc (UCLouvain), Oncology, Bruxelles, Belgium*

Background: CheckPoint Inhibitors (CPI) Induced arthritis (IA) is an immune related adverse event (irAEs) occurring in 0.5 to 2% of CPI-treated patients between 3 weeks up to 24 months after initiation of therapy. IA is usually described as a seronegative oligoarticular inflammatory joint disease but IA has been for long underdiagnosed and inappropriately evaluated.
Objectives: To evaluate the added value of a systematic joint ultrasound assessment in these patients by the rheumatologist.
Methods: Patients referred by their oncologist to the Rheumatology Department for suspected arthritis had a clinical swollen joint count and a joint ultrasound assessment (GE Logiq E9 Ultrasound Machine with ML6-15-D Matrix Linear Probe). Target joints were elbows, wrists, MCP 2-5, knees, ankles and MTP1-5. The swollen joint count performed by the oncologist was compared to the one made by the rheumatologist and the US assessment. A joint was considered as positive by US assessment in case of grey-scale ≥ 1 in a scale of 3.
Results: 9 patients (6 males and 3 females) were assessed. Mean age was 66.1 years (SD 11 years). 4 were treated for metastatic melanoma, 1 for renal cell carcinoma (RCC), 3 for lung cancer, 1 for uterine cancer and 1 for bladder carcinoma. They received a monotherapy with pembrozilumab (4/9), nivolumab (2/9), atezolimumab (1/9), darvalumab (1/9). None had received corticosteroids. 5 out of the 9 patients were referred for an oligoarticular (swollen joint count <5) presentation by the oncologist, 2 out of 9 for a polyarticular (swollen joint count ≥5) presentation and 2 for a PMR-like presentation. Whereas the rheumatological and the US assessments confirmed the polyarticular diagnoses made by the oncologists, the 5 oligoarticular-labelled patients had polyarticular involvement after the rheumatologist and US assessements. In the 2 patients referred for a PMR-like disease, US assessments showed one polyarticular and one oligoarticular presentation. None of the 9 patients had positive rheumatoid factors (RF) or anticitrullinated peptides antibodies (ACPAs).

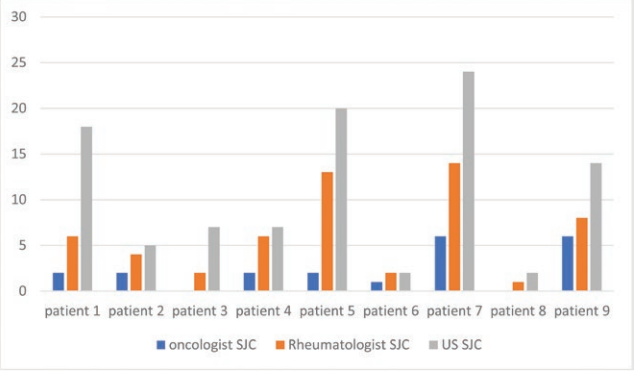

Figure 3. *Number of swollen joints (SJC) for each patient according to the oncologist, the rheumatologist and the ultrasound assessment.*

Conclusion: In this small group of patients with CPI-IA, In this small group of patients with CPI-IA, we found that US joint assessment led to a better classification of polyarticular joint involvement, present in the majority of the cases.
Our results emphasise the importance of a multidisciplinary approach of these patients and support the use of US joint assessments in CPI-IA patients.

ULTRASOUND FINDINGS IN PATIENTS WITH GOUT IN A POPULATION OF THE DOMINICAN REPUBLIC

Keywords: Ultrasound, Gout, Prognostic factors

D. Garcia[1], R. A. Alvarez Santana[1], L. Perez Rodriguez[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Mercedes[1], I. Paulino[1], E. Rodriguez Bautista[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. *[1]Hospital Padre Billini, Rheumatology, Distrito Nacional, Dominican Republic*

Background: Hyperuricemia is an increase in the serum concentration of monosodium urate (MSU). Gout is secondary to the inflammatory response elicited by the deposition of UMS in the tissues. It is the most frequent inflammatory arthropathy in the general population. [1] Its prevalence has been estimated at 2-3% of the adult population. [2] The ultrasound findings observed are considered within the ACR/EULAR 2015 criteria, which derive from the presence of UMS deposits in the subcutaneous tissue and in intra- and periarticular areas (cartilage, tendons, ligaments, and bursae. [3]. There are 2 specific findings of MSU deposits: 1) enhanced echogenicity of the chondrosynovial margin (double contour sign), presence of hyperechogenic aggregates, which, in turn, can have 3 forms of presentation: hyperechogenic dots (<1 mm) within a joint effusion, (cotton-wool areas) (<1 cm) homogeneous without posterior acoustic shadow and larger tophi with calcifications and posterior acoustic shadow [4].
Objectives: To identify the ultrasound findings in patients with gouty arthritis in a population of the Dominican Republic.
Methods: Descriptive, prospective observational study. From the cohort of patients from the Rheumatology service of the Hospital Docente Padre Billini, patients from the outpatient clinic were evaluated from June to December 2022. Inclusion criteria: > 18 years, diagnosis of gouty arthritis according to ACR\EULAR 2015 criteria, presence of at least 1 attack of gouty arthritis, performance of joint ultrasound Exclusion criteria: Osteosynthesis material in areas evaluated by ultrasound and/or infiltration, traumas of less than 3 months in the evaluated joints. Elbows, wrists, 2nd metacarpophalangeal MCP, knees, and 1st metatarsophalangeal MTF were evaluated by ultrasound, recognizing positive findings of double contour sign, hyperechogenic aggregates, erosions, synovitis, and irregularities according to OMERACT definitions. Made with the Siemmens Acuson X 150 ultrasound machine, with a 13 mHz transducer. Descriptive statistics were performed with SPSS 25 V2.
Results: 52 met inclusion criteria. 100% male, mean age 59±16.1 years, mean disease duration 8.6 years, mean serum uric acid 9.5 mg/dL. BMI: overweight 32.7% (17), grade I obesity 21.2% (11), grade II obesity 40.4% (21). Diabetes mellitus 55.8% (29). Arterial hypertension 57.7% (30). Dyslipidemia 80.2% (42). Colchicine 61.5% (32), Allopurinol 48.1% (25). Febuxostat 48.1% (25), NSAIDs 48.1% (25), Prednisone 46.2% (24), Benzbromarone 3.8% (2) Ultrasound findings 55.7% (29): Elbows: irregularities 37.9% (11), Tophi 37.9% (11), erosions 20.7% (6), Carpals: Erosions 10.3% (3), aggregates 10.3% (3), power Doppler 2.69% (2), irregularities 31% (2), Knees: erosions 27.6% (8), irregularities 27.6 % (8), double contour 20.6% (6) power doppler 10.3% (3), tibiotalar: irregularities 27.6% (8), erosions 17.2% (5); 1st MTFs: erosions 48.2% (14), irregularities 27.6% (8), aggregates 3.4% (1).
Conclusion: The study demonstrated that more than half of patients with gout present structural lesions by ultrasound according to OMERACT. The elbows are the most affected joints with the presence of tophi, followed by the first metatarsophalangeal joint with the presence of erosions.

Background: Burnout is frequent among physicians and has significant implications for the healthcare system. However, it seems to be underestimated so far among rheumatologists, with few studies indicating a prevalence of 51-57%.
Objectives: To estimate the prevalence and predictors of burnout among rheumatologists practicing in Arab countries.
Methods: A cross-sectional study was conducted by the Arab League of Associations for Rheumatology (ArLAR) Research Group (ARCH) using an anonymous electronic survey developed and tested by a core steering committee and hosted on the Google Forms platform. All rheumatologists practicing in the Arab countries were invited in spring 2022 to participate in the e-survey by mass e-mail and via societies' WhatsApp groups and ArLAR social media accounts. In addition to demographic data, workload, practice profile, income, and specialty satisfaction (assessed indirectly through choosing another specialty if given a choice), the questionnaire included the Maslach Burnout Inventory (MBI). Rheumatologists were considered as having burnout if at least one of the three MBI domains was positive (Emotional Exhaustion (EE) ≥27, Depersonalization (DP) ≥10, or Personal Accomplishment (PA) ≤ 33). Factors associated with burnout were analyzed using a multivariable binary logistic regression.
Results: Among 3,227 rheumatologists practicing in Arab countries, 408 responded to the survey, and 394 were included in the final analysis (12.2% of all practicing rheumatologists). The mean age was 45.2 years (SD 11.5), 60.7% were females, the median practice duration was 13 years (IQR 6-22), 49% were from North Africa, 33% were from the Levant, and 18% were from the Gulf. In total, 73% worked full-time, 48% worked in the public sector, 21% in the private sector, and 31% in both; 74% worked in an urban setting only, monthly income was <1,000 USD in 31%, 1,000-1,500 USD in 41%, 5,000-10,000 USD in 9% and > 10,000 USD in 8%. The prevalence of burnout among rheumatologists was 61.3%. It was mostly driven by a low PA score (58.1%) (Figure 1). Also, 15.6% had a positive EE score, and 11.6% had a positive DP score. After adjustment for demographics, practice profile, and workload variables, burnout was independently associated with an income < 10.000 USD/ month (OR 2.26 [95% CI 1.01; 5.10), unsatisfaction with rheumatology specialty (OR 2.04 [95%CI 1.20; 3.46) and younger age (OR 1.92 (95%CI 1.20; 3.08) (Table 1).
Conclusion: The prevalence of burnout among rheumatologists in Arab countries is significantly high and driven mainly by a low personal assessment score. Associated factors were a lower income, lower satisfaction with the specialty, and younger age. Therefore, burnout among rheumatologists needs to be adequately addressed to prevent its negative impact on the healthcare system.

Table 1. Predictive factors of burnout in rheumatologists practicing in the Arab countries (multivariable analysis)

Variable	OR	95% CI	p-value
Income < 10.000 USD/month	**2.265**	**1.006 – 5.098**	**0.048**
Specialty unsatisfaction	**2.036**	**1.199 – 3.457**	**0.009**
Age < 44 years	**1.921**	**1.198 – 3.078**	**0.007**
Receiving phone calls from patients on personal phone	1.616	0.714 – 3.659	0.249
Infusion center at the rheumatology practice	0.733	0.435 – 1.236	0.733

AB1582

DEPRESSION IN RHEUMATOLOGIST FROM LATIN AMERICA

Keywords: Quality of life, Epidemiology, Quality of care

M. Intriago[1], G. Maldonado[2], E. Soriano[3], C. Rios[4]. *[1]University of Miami, Internal Medicine, Miami, United States of America*; *[2]Loyola MacNeal Hospital, Internal Medicine, Berwyn, United States of America*; *[3]Hospital Italiano, Rheumatology, Buenos Aires, Argentina*; *[4]Centro de Reumatología y Rehabilitación, Rheumatology, Guayaquil, Ecuador*

Background: Depression, burnout, and suicide are becoming a major problem among physicians. A survey estimated that around 21% are depressed and 1 in 10 had have suicidal thoughts.[1]
Objectives: Determine the prevalence of depression in rheumatologists from Latin America and factors associated with it.
Methods: Cross-sectional study. Data was collected through an online survey distributed by PANLAR, which included demographics and work-related factors. Depression was measured with PHQ-9 questionnaire, burnout with the Maslach Burnout Inventory, happiness with the Subjective Happiness Scale and satisfaction with a 7-point Likert scale. Analysis of data was done with SPSS V 27 and included descriptive statistics and association between variables using Chi square and Student's T test.
Results: 297 rheumatologists were included from 15 countries, mainly Argentina 28.3% and Brazil 26.3%. Most were women 62%, married 65%, practiced adult rheumatology 82% and earned less than $50 K/year 74.8%. Depression

was found in 48.8%: mild 33%, moderate 8.8%, moderate severe 4%, severe 3%. The mean PHQ-9 score was 5.5±5.3. 46.1% reported anhedonia, 40.7% feeling depressed, sleep alterations 57.2%, fatigue 75.1%, appetite changes 46.1%, feelings of failure 37%, decreased concentration 50.2%, psychomotor changes 27.9%, thoughts of hurting oneself 9.8%, 8.2% suicidal thoughts and 8.4% low self-esteem. 56.6% had burnout. 14.5% were taking SSRI/SNRIs and 4% were previously diagnosed. Factors associated with depression were female sex (p=0.008), younger age (p<0.001), administrative duties (p=0.010), annual income less than $25K (p=0.002), low self-esteem (p<0.001), burnout (p<0.001), less satisfaction with career (p<0.001) and lower subjective happiness (p<0.001). Exercise (p=0.035) and practicing academics (p=0.010) were associated with less depression.

Conclusion: Depression affected almost half of the rheumatologists and was more common in females, younger population, with low self-esteem. Lower income, having burnout and less satisfaction with the career were also risk factors. Only a small proportion of the affected population was previously diagnosed and on treatment.

AB1583 EVALUATING THE DIRECT EFFECT OF SLE IN THE PRESENCE OF INTERMEDIATE GC ON HEALTHCARE COST

Keywords: Randomized control trial, Health services research, Systemic lupus erythematosus

K. Zhao[1], H. Xie[1]. [1]*Arthritis Research Canada, Biostatistics, Vancouver, Canada*

Background: Systemic lupus erythematosus (SLE) is a chronic disease with a broad spectrum of autoantibodies and clinical manifestations. SLE imposes a substantial economic burden on patients and the healthcare system with the estimate of annual healthcare costs for SLE patients of $5,062 in Canada. Besides SLE, post-SLE Glucocorticoid (GC) is often associated with severe infection and mortality, hence increased healthcare costs. One recent study showed that GC users had a total of $17,232 in healthcare costs [1]. However, previous studies did not account properly for GC which acts as a mediator between SLE and healthcare costs. In addition, those studies of the costs due to SLE in Canada estimated the costs of SLE via questionnaire survey with a limited sample size. The use of questionnaires subject to selection bias can either over or underestimate the costs associated with SLE because specific groups (those who don't have access to questionnaires) are underrepresented. As a result, their conclusions may lack generalizability to all SLE patients.These limitations call for a new approach to account for post-treatment selection bias and a large dataset in the real-world setting to quantify the healthcare costs due to SLE.

Objectives: The objectives of this study are two-fold: 1) to disentangle and quantify the causal annual healthcare costs directly associated with newly diagnosed SLE accounting for GC use. 2) to identify the charactersitscs of the patients who never took GC (never-users).

Methods: Using linked administrative health data from British Columbia, Canada, we conducted an age- and gender-matched cohort study of all patients with incident SLE between 1997 and 2015. We implemented Principal stratification [2] to identify the annual healthcare costs directly attributed to SLE. Within the strata defined by post-SLE GC use: always-users, never-users, SLE-only users, and non-SLE-only users, we estimated the principal causal effects of SLE on annual healthcare cost. To face identification issues of unobserved principal stratum, estimation was performed with Bayesian Mixture Modelling.

Results: We identified 5,169 SLE patients and matched them with 25,845 non-SLE individuals from the general population. The crude incidence rate ratios for first severe infection and infection-related mortality were 2.59 (95% CI, 2.39-2.80) and 2.20 (95% CI, 1.76-2.73), respectively. The direct annual healthcare cost due to SLE was $1.01k (%95 CI, 0.94-1.10k) which was a weighted average of the cost in always and never-users strata (Figure 1). Always and never users accounted for 20.3% and 73.9% of the total population. Compared to the SLE-only users, those with older age, rural residence, higher income and more medical service visits were more likely to be in the never-user stratum.

Conclusion: This is the first study to examine the direct effect SLE on healthcare cost accounting for the GC-taking behavior using real-world data. Our findings highlighted the direct economic burden due to SLE and can be generalized to the SLE population. Recognizing the economic burden of SLE will inform future interventions for prevention, and medical management in this vulnerable patient population. What's more, when prescribing GC, the treating physicians should pay attention to the patients with with older age, rural residence, higher income and more medical service visits because they are unlikely to adhere to the treatment scheme.

AB1584 CONSENSUS RECOMMENDATIONS ON THE USE OF BIOSIMILARS IN THE TREATMENT OF INFLAMMATORY RHEUMATIC JOINT DISEASES

Keywords: Systematic review, bDMARD, Best practices

K. Alnaqbi[1], N. Al Adhoubi[2], S. Al Dallal[3], S. Al Emadi[4], A. Al-Herz[5], A. El Shamy[6], S. Hannawi[7], M. A. Omair[8], S. Saad[9], T. K. Kvien[10]. [1]*Tawam Hospital, College of Medicine & Health Sciences, Internal Medicine, Rheumatology, Al Ain, United Arab Emirates*; [2]*Royal Hospital, Rheumatology, Muscat, Oman*; [3]*Dubai Health Authority, DHA, Dubai, United Arab Emirates*; [4]*Hamad Medical Corporation, Rheumatology, Doha, Qatar*; [5]*Al-Amiri Hospital, Rheumatology, Kuwait, Kuwait*; [6]*Ministry of Health and Prevention, MOHAP, Dubai, United Arab Emirates*; [7]*Emirates Health Services, Rheumatology, Dubai, United Arab Emirates*; [8]*King Saud University, Rheumatology, Riyadh, Saudi Arabia*; [9]*King Hamad University Hospital, Rheumatology, Busaiteen, Bahrain*; [10]*Diakonhjemmet Hospital, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*

Background: Biosimilars are highly similar to reference products and can help in reducing the financial burden and medication underutilization while still being comparable to reference products in treating rheumatic diseases[1].

Objectives: The objective was to develop evidence-based consensus recommendations and overarching principles aimed at standardizing best practices for the use of biosimilars in treating patients with inflammatory rheumatic joint diseases in the Gulf region.

Methods: A taskforce comprising expert rheumatologists and healthcare economists formulated specific PICO questions on key topics concerning biosimilars: comparability of efficacy, safety and immunogenicity of biosimilars to reference products; extrapolation of indications for biosimilars; switching from reference products to biosimilars or between biosimilars; cost-savings; retention rates; nocebo effect among patients, and general awareness and perceptions of biosimilars in the Gulf region. A systematic literature review was conducted to identify, select, and critically appraise the quality of published evidence that demonstrated the value proposition of biosimilars in rheumatic diseases. Meta-analyses, clinical trials, and systematic reviews of adult patients treated with biosimilars for

rheumatoid arthritis, psoriatic arthritis, spondyloarthritis, and ankylosing spondylitis were included. As the data before 2017 has been previously reviewed in another publication,1 the current review focused on data published between January 2017 and August 2022 (PROSPERO ID CRD42022364002). Consensus on each statement required a level of agreement of 70% or greater. Another group of external stakeholders comprising rheumatologists, nurses, pharmacists, payers, regulators, and patients provided external validation of the statements.

Results: Consensus was reached for all the five overarching principles and eight recommendations by both the taskforce and the external stakeholders. The recommendations are largely congruent with previously published guidelines, with adaptation for regional clinical practice considering the nuances of the healthcare systems within the Gulf region. The overarching principles emphasize the importance of improving the awareness, understanding, and perceptions of biosimilars among rheumatologists, patients, and other stakeholders. They also highlight the need for collaborative efforts to gather regional real-world data and to make affordable biosimilars a viable treatment option for all patients. The consensus recommendations advocate the need for shared treatment decisions between rheumatologists and patients when considering a switch to, or between, approved biosimilars. They further recommend that confirmation of a biosimilar's efficacy and safety in a single indication is sufficient for extrapolation to other diseases for which the reference product has been approved. Finally, they highlight the need for regulated national and regional pharmacovigilance, post-marketing surveillance, and health policies governing the adoption and prescription of biosimilars in clinical practice across the Gulf region.

Conclusion: The outcomes of this initiative represent the second international and the first regional consensus recommendations for the Gulf region based on a systematic literature review, integrating clinical evidence with clinical expertise to optimize decision-making for the use of biosimilars in patients with rheumatic diseases. While the overarching principles and consensus recommendations were developed specifically for the Gulf region, they were formulated based on predominantly international data due to the lack of robust regional data. Therefore, we suggest that these statements can be generalized to serve as recommendations for healthcare providers also in other parts of the world.

ASSOCIATION BETWEEN NECK CIRCUMFERENCE AND ASYMPTOMATIC HYPERURICEMIA IN NEARLY HEALTHY ADULTS

Keywords: Diagnostic tests, Gout, Comorbidities

J. Yeo[1], I. C. Hwang[2], H. S. Suh[2], H. Y. Ahn[3]. *[1]Gil Medical Center, Gachon University College of Medicine, Department of Internal Medicine, Division of Rheumatology, Incheon, Korea, Rep. of (South Korea)*; *[2]Gil Medical Center, Gachon University College of Medicine, Department of Family Medicine, Incheon, Korea, Rep. of (South Korea)*; *[3]Dongguk University, Department of Statistics, Seoul, Korea, Rep. of (South Korea)*

Background: Central obesity, a key component of metabolic syndrome, notably impacts serum uric acid levels. In previous studies, several obesity indicators (e.g., body mass index, waist circumference, and waist-to-height ratio) have been investigated as potential predictors of hyperuricemia. Meanwhile, neck circumference (NC) measurement has been recently developed as a simple and time-saving anthropometric method for predicting cardiovascular risk. Only a few studies have evaluated the relationship between hyperuricemia and NC; however, their populations have consisted only of female individuals or specific populations, or included patients with overt gout.

Objectives: This study aimed to determine the relationship of asymptomatic hyperuricemia with NC, innovative and simple anthropometric method, in the general population.

Methods: This cross-sectional study used data from the 2019–2020 Korea National Health and Nutrition Examination Survey. Among 15,469 individuals, we excluded 6,814 without available data on NC or serum uric acid, and 1,026 with critical confounders: overt cardiovascular disease; gout; chronic kidney disease; and serum creatinine > 1.2 mg/dL. Multivariate logistic regression analysis was used to calculate the odds ratios (ORs) and 95% confidence intervals (CIs) for hyperuricemia according to quartiles of NC.

Results: A total of 7,629 subjects including 6,814 with normouricemia and 815 with hyperuricemia were included. The mean age was fifty nine years in both groups. 56.1% of the hyperuricemia group and 38.7% of normouricemic group were male (p<0.001). The percentage of low income was higher in hyperuricemic than normouricemic group (50.6% vs 46.5%, P=0.027). Co-morbidities including obesity (53.0% vs. 34.8%; P<0.001) and hypertension (37.4% vs. 29.8%; P<0.001), and health-related habits including current smoking (18.8% vs. 14.7%; P=0.002) and frequent drinking (37.0% vs. 22.2%; P<0.001) were higher in hyperuricemic group than normouricemic group. The subjects with hyperuricemia displayed greater NC than normouricemia (36.5 ± 3.3 cm vs. 34.7 ± 3.3 cm; P<0.001). Multivariable regression analysis revealed that NC was significantly associated with hyperuricemia in women (OR 1.17; 95% CI 1.06-1.30), but not in men (OR 1.04; 95% CI 0.96-1.12) (Table 1).

Conclusion: NC was positively correlated with serum uric acid levels and this association was significant in women. Our finding suggests that NC can contribute to detecting asymptomatic hyperuricemia earlier and further to determining risk of metabolic syndrome in healthy adults.

Background: The demand for rheumatology care is consistently exceeding the workforce worldwide, which negatively impacts the care of patients with rheumatic and musculoskeletal diseases (RMDs). The number of rheumatologists per 100,000 inhabitants varies between 0.94 in Latin America to 3.44 in Spain, with a desirable number of 1-2. However, the estimation of the current and projected rheumatology workforce is lacking in Arab countries.
Objectives: To investigate the current number of practicing rheumatologists in the ArLAR countries, provide an estimate of the expected number of rheumatologists in 10 years, and evaluate the current workload, practice profile, and waiting time for a consultation.
Methods: This cross-sectional survey study was conducted by the Arab League of Associations for Rheumatology (ArLAR) Research Group (ARCH) in 16 ArLAR countries in two parts. The first survey was addressed to national societies by e-mail to estimate the current and projected workforce. The second was an anonymous e-survey addressed to all Arab rheumatologists and rheumatology fellows elaborated by the study steering committee on the Google Forms platform and distributed using social media, WhatsApp, and mass e-mails to evaluate their practice profile, workload, and waiting time for a rheumatology consultation.
Results: The mean number of rheumatologists in the ArLAR countries was 0.84 per 100,000 inhabitants (mean age 47.5 years, 55% females), ranging from 0.06 in Sudan to 1.86 in Tunisia (Table 1). The crude number of rheumatologists is expected to increase by 50% in 2032, whereas a 20% parallel increase in the population is also expected, associated with a rise in demand due to an expected increase in RMDs; thus, the percentage per 100,000 inhabitants will increase only by 22%. Data from 446 rheumatologists and rheumatology fellows (mean age 43.9 years, 60.5% females) revealed that 72% worked full-time, 53% were employed in the public sector only, and 75% worked in an urban setting. The median income was 1,000-2,000 USD/ month. There was a certified rheumatology nurse in 25%, access to musculoskeletal ultrasound in 51%, and telemedicine implemented in 29% of practices. The average waiting time for a rheumatology consultation was 19.9 days and was associated with the region, working full-time, working in the public sector, higher income, and the presence of an infusion center at the rheumatology practice.
Conclusion: Considering a desirable arbitrary level of 1-2 rheumatologists/ 100,000 inhabitants, there is a current shortage of rheumatologists in the ArLAR countries, with significant heterogeneity among countries. The projected increase in rheumatologists will probably not match the rising demand for rheumatology care. Considering local demographic disparities and healthcare system differences, national authorities are urged to implement effective intervention plans to optimize the rheumatology workforce.

Table 1. Rheumatology workforce in the Arab Countries in 2022, by country.

Region	Country	Country Population	Rheumatologists/ 100,000 inhabitants	Rheumatologists/ 1,000 physicians
Africa	Tunisia	11,820,000	**1.86**	14.3
	Egypt	102,300,000	**1.17**	2.7
	Algeria	43,850,000	**1.15**	1.2
	Morocco	36,910,000	**1.03**	14.7
	Libya	6,871,000	**0.26**	1.2
	Sudan	43,850,000	**0.06**	2.2
Levant	Lebanon	6,800,000	**0.82**	3.4
	Iraq	40,220,000	**0.61**	6.3
	Syria	17,500,000	**0.38**	1.1
	Jordan	10,200,000	**0.36**	1.3
	Palestine	4,803,000	**0.23**	1.6

Background: Herpes zoster infection is due to the reactivation of the varicella-zoster virus (VZV), having a high prevalence in elderly and immunocompromised patients. Since the beginning of 2022, a new vaccine that prevents herpes zoster virus reactivation has been approved and commercialized. However, there are few studies analyzing its effectiveness in real-world conditions.
Objectives: To analyze the incidence and rate of herpes zoster disease in a population at risk due to suffering from rheumatic diseases and therefore being subsidiary of receiving VZV vaccination.
Methods: A retrospective observational study of patients who started treatment with JAK inhibitors from 2013 to 2022 was performed. Demographic and clinical variables were collected from the electronic clinical history. Vaccination of patients against VZV was analyzed, as well as the incidence of herpes simplex (HSV) and herpes zoster reactivation before and after January 2022, date on which the vaccination program began. In addition, the rate of the VZV disease was calculated based on the follow-up time for both vaccinated and unvaccinated patients and was adjusted by exposure in events/100 patients-year (E/100 PY).
Results: 236 patients with an indication for vaccination against VZV due to being treated with JAK inhibitors were included, of whom the majority diagnosis was Rheumatoid Arthritis (n=179). Their characteristics are shown in the following Table 1. 30 patients were vaccinated against VZV (12.71%). An incidence of 20 herpes cases was observed in unvaccinated patients (8 HSV and 12 VZV). 3 of the VZV reactivations were of multimetameric involvement. No cases of herpes were found in the vaccinated population. The unvaccinated patients were followed up for 3500 months, remaining with a herpes rate in this population of 4.12 E/100 PY. The total follow-up of vaccinated patients was 102 months, with a herpes rate of 0 E/100 PY.

Table 1.

	Total of patients n=236
Age - years (sd)	62.45 (8.2)
Female sex - n (%)	188 (79.66%)
Diagnosis - n (%)	179 (75.84%)
RA	28 (11.86%)
PsA	14 (5.93%)
AS	10 (4.23%)
Others	5 (2.11%)
JIA	
Comorbidities - n (%)	69 (29.23%)
Dyslipidemia	65 (27.54%)
Arterial hypertension	40 (16.95)
Smoking	22 (9.32%)
Mellitus diabetes	
Vaccination	206 (87.29%)
No	30 (12.71%)
Yes	

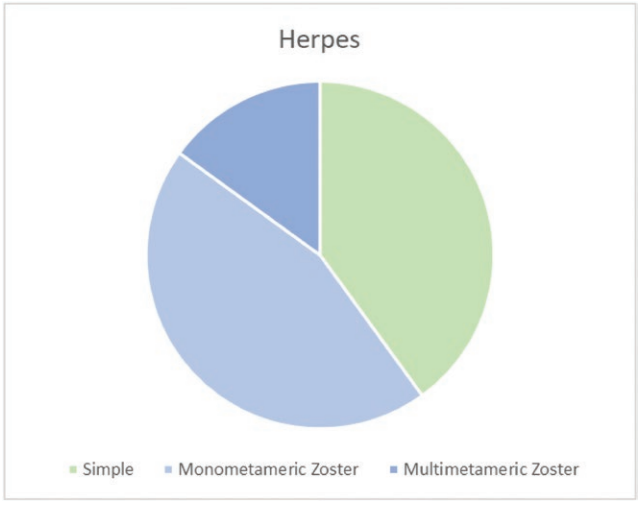

Figure 1.

Conclusion: An incidence of 12 VZV is observed in unvaccinated patients compared to an incidence of 0 in vaccinated patients. The herpes rate in non-vaccinated patients was 4.12 E/100 PY compared to 0 E/100 PY in vaccinated patients. Therefore, we conclude that the herpes zoster vaccine shows its effectiveness in our population but it would be necessary to carry out more studies in the future with a longer follow-up time.

AB1588 REFERRAL PATTERN FROM PRIMARY CARE TO IDENTIFY PATIENTS WITH SUSPECTED RHEUMATOID ARTHRITIS: ROOM FOR IMPROVEMENT

Keywords: Rheumatoid arthritis, Quality of care

M. Sánchez Lucas[1], C. Bourgeois Avella[1], T. Schiaffino[2], J. Molina Collada[1,2], J. Martínez-Barrio[1,2], J. Rivera[1,2], J. M. Alvaro-Gracia[1,2,3], I. Castrejon[1,2,3]. *[1]Gregorio Marañón General University Hospital, Rheumatology, Madrid, Spain*; *[2]Instituto de Investigación Sanitaria Gregorio Marañón, Rheumatology, Madrid, Spain*; *[3]Complutense University of Madrid, Department of Medicine, Madrid, Spain*

Background: Primary care physicians (PCPs) acknowledge the importance of early diagnosis and intensive treatment for rheumatoid arthritis (RA) patients, however the non-specific symptoms early in the disease and the long waiting list to access rheumatology clinics result in a challenge for early and adequate referral.

Objectives: To evaluate patterns for referral in an early arthritis clinic with direct access for PCPs and to explore variables that may influence an adequate referral.

Methods: An early arthritis clinic (EAC) with direct access for PCPs in our area was started in January 2022 providing direct access for patients with suspected RA or undifferentiated arthritis. Referral criteria are strictly clinical, based on previous early arthritis clinics, literature review and approved by a PCP committee. Patients can be referred if > 2 swollen joints, duration of symptoms <2 years and no previous diagnosis by a rheumatologist explaining the symptoms. A total of 180 PCPs from 11 primary care centres have direct access to the EAC. The following data was collected: distance between hospital and primary care center, number of PCP per center, and zip codes as a surrogate for patient income. A descriptive analysis of the referral pattern is presented. A multivariate logistic regression model was performed to identify variables associated with an appropriate referral.

Results: From January to October 2022, 140 patients were referred to the EAC, 66.4% female, with a mean age of 54.2 (15.3) years. A total of 38 (27%) patients fulfilled the predefined referral criteria with initial diagnosis of rheumatoid arthritis (15.8%), psoriatic arthritis (7.9%) and undifferentiated arthritis (76.3%). Patients who did not meet the referral criteria were mainly patients with osteoarthritis (36.7%), non-specific arthralgia (15.7%), gout (8.8%) and fibromyalgia (6.9%). Patients in the adequate referral group were younger (50.4 vs 55.6, p= 0.03), but have similar income and were referred from a PCP centre with similar characteristics in term of size and distance from the EAC. In the multivariate logistic regression model age was the only significant explanatory variable for an adequate referral (Table 1).

Table 1. Logistic regression model to identify variables associated with adequate referral.

	Bivariate analysis OR (95% CI)	Multivariate analysis OR (95% CI)
Age, years	0.96 (0.94 - 0.98)	0.97 (0.94 - 0.99)*
Women	0.82 (0.38 - 1.79)	0.59 (0.26 - 1.38)
Patient income	1.13 (0.73 - 1.76)	1.10 (0.67 - 1.82)
Distance to EAC in km	0.96 (0.79 - 1.16)	1.00 (0.80 - 1.25)
Number of PCPs per centre	0.96 (0.60 - 1.51)	—

*OR odds ratio, 95% CI 95% confidence interval.*Statistically significant results at the 0.05 level*

Conclusion: Only 27% of patients referred to the EAC were adequately referred. PCPs need to enhance clinical skill to detect early RA and discriminate mainly from osteoarthritis and non-specific arthralgias. Younger age was the only variable associated with adequate referral. Strategies with a special focus on PCPs are necessary to promote an early and adequate referral.

AB1589 ESSENTIAL TREATMENT OF RHEUMATOID ARTHRITIS IN ZANZIBAR: A COST EFFECTIVENESS ANALYSIS

Keywords: Quality of life, Disease-modifying drugs (DMARDs), Rheumatoid arthritis

S. Said[1,2,3,4,5], B. T. Svanes Fevang[3,6], T. W. Nystad[6], K. A. Johansson[2,7]. *[1]The State University of Zanzibar - School Of Health And Medical Sciences, Internal Medicine, Zanzibar, Tanzania, United Republic of*; *[2]Bergen Center for Ethics and Priority Setting, Global Public Health and Primary Care, Bergen, Norway*; *[3]University of Bergen, Clinical Science, Bergen, Norway*; *[4]Haukeland University Hospital, Department of International Collaboration, Bergen, Norway*; *[5]Mnazi Mmoja Hospital, Internal Medicine, Zanzibar, Tanzania, United Republic of*; *[6]Haukeland University Hospital, Rheumatology, Bergen, Norway*; *[7]Haukeland University Hospital, Addiction Medicine, Bergen, Norway*

Background: Rheumatoid arthritis (RA) is a major global health problem and a neglected disease in many developing countries. Health care spending is low in these countries and RA services compete with other important life-saving and effective interventions. Effective therapies for RA are now available which improve overall outcomes and prevent disability especially when initiated early and managed aggressively [1]. All these interventions are available in high-income countries but are sparse in developing countries. There are several health economic evaluations of RA treatment from high-income settings, but few are available or relevant for developing countries. More evidence is therefore needed on the benefits and costs of scaling-up RA services in resource constrained settings.

Objectives: To conduct a cost effectiveness analysis of multiple interventions in the management of RA in Zanzibar.

Methods: A cost-effectiveness analysis for a ten-year duration was conducted from a health provider perspective using a Markov model. Interventions were based on a treat to target strategy with add on therapy or switch to biologic therapy when patients did not reach target (remission or low disease activity). The model compares the efficiency of 'methotrexate monotherapy'(option1), 'methotrexate + sulfasalazine + hydroxychloroquine (triple therapy)' (option 2), methotrexate then biologic 1' (option 2b), 'option 2 then biologic 1' (option 3), 'option 3 then biologic 2' (option 4) and 'option 2b then biologic 2' (option 4b). Data on effectiveness of interventions was obtained from literature. Incremental cost-effectiveness ratios (ICERS) were calculated per quality adjusted life year (QALY) gained from treatment. Staff, building, and utility costs were obtained from the hospital administration records. Drug costs were obtained from the government supplier price list, retail pharmacies and pharmaceutical companies. Mean utility values were calculated from a Zanzibar RA- cohort based on the EuroQol-5D questionnaire responses. Willingness to pay threshold (WTP) was set at 568 USD which is two-thirds of GDP/capita for Tanzania for 2021. We conducted a base case analysis with deterministic sensitivity analysis to explore outcomes with changes in key parameters.

Results: Total costs for the treatment options were largely driven by drugs, predominantly the biologics. The lowest cost was for methotrexate therapy (option 1) at USD 1984/patient/10 years and the highest utilities were gained from treatment with methotrexate therapy + two consecutive bDMARDs (option 4b) (Table 1). Changes in drug costs resulted in significant changes in the ICERs. With variations in the WTP threshold, option 1 remained the most CE to just above USD 2500 where option 2b became the more CE option up to USD 3100 and option 3 became the more CE option. All other options were not considered CE up to 3500 USD.

Conclusion: Methotrexate was found to be the only cost-effective treatment option in our population. Other options although available may be too costly to consider feasible for clinical use unless prices drop. This may be possible via wider availability of biosimilars or via government drug price negotiation to acquire drugs at cheaper costs.

AB1590

RECOMMENDATIONS ON HANDLING MEDICINE SHORTAGE: LEARNING FROM HYDROXYCHLOROQUINE 2020 CRISIS FOR SLE PATIENTS

Keywords: Patient reported outcomes, Systemic lupus erythematosus, COVID

A. Cornet[1], M. Olsen[2], H. Stefánsdóttir[2]. [1]*Lupus Europe, HQ, Brussels, Belgium*; [2]*Lupus Europe, PAN, Brussels, Belgium*

Background: Early 2020, short supply of hydroxychloroquine sulfate (HCQ) – then claimed as effective for treatment of COVID-19 in several countries - raised significant concerns for those who use HCQ for chronic diseases including SLE. In April 2020, Lupus Europe launched a survey to quantify the access gap, as well as the anxiety expressed by patients confronted with this outage. 2422 patients responded with an average level of anxiety about access to HcQ of 6.45 on a maximum of 10. After supply issues were resolved, a follow up survey (Aug-Sept 2020 – 1854 answers) showed a significantly reduced anxiety of 4.15. A second follow up survey (Nov 2021 -Feb 2022 - 2255 answers) showed a further reduction to 3.54. Importantly, a core group of 6.2-13.7% of patients remains extremely anxious (scoring 9 or 10) about supply of their medication, substantially more than in Portugal (3.5%) and Finland (0%), where supply remained fair at the heat of the crisis.
Objectives: To provide consensus on how communication should be conducted to minimize the impact of medicine shortages on patient anxiety.
Methods: The Patient Advisory Network (PAN) of Lupus Europe established an extensive list of potential elements of a more effective communication on shortages, that could help reduce patient anxiety. 20 statements were derived from those elements and proposed to PAN members and Lupus Europe member organisations. 101 answers were collected from 17 countries. For each country, the individual ratings of all participants were averaged to assign an individual vote for each country on each statement. Consensus amongst the 17 countries was then considered as obtained if 14 or more of the 17 countries agreed or strongly agreed with statements.
Results: 9 out of the 20 statements reached consensus:
1. Lupus specialists should (a) clarify alternative medication existing and its difference versus current treatments, (b) clarify appropriate emergency procedures and (c) clarify to the patients how to handle a short supply.
2. Specialists and Hospitals should establish alternative supply mechanisms to guarantee minimum availability.
3. pharmaceutical industry should (a) provide all information to all stakeholders and (b) help create emergency supply routes to ensure that no patient is left without his/her medication for a sustained period of time.
4. National authorities should help patients with demonstrated need have priority access to limited supply quantities through a simple process.
5. Hospitals should communicate (by email or postal mail) information on the shortage, how to handle it and how to access emergency supply routes. The same number agreed with Health authorities performing that same communication.
6. pharmaceutical industry should avoid diverting products from one country to another if that would reduce supply below normal consumption level.
7. Patient organisations should stop the rumors that can quickly spread though social media.
8. pharmacists should be better equipped in terms of data (on the reasons and clear timelines for resolution as well as alternatives or recommendations for patients facing shortages)
9. *GP's should clarify alternative medication and appropriate emergency procedures.*
Conclusion: Shortages of medicine create an anxiety that can be long lasting. Even when supply is re-established, the fear remains. For this reason, establishing an effective communication system is necessary to reassure patients when short term shortages are taking place, and is key to avoid fast spreading anxiety relating to this concern. In this process, patient associations, physicians, industries and all the stakeholders should be involved.

POLICY DRIVERS FOR MARKET PENETRATION OF ANTI-TNF BIOSIMILARS: MULTI-COUNTRY COMPARISONS

Keywords: bDMARD, Health services research, Disease-modifying drugs (DMARDs)

W. Zhang[1,2], D. Guh[1], H. Sun[1], A. Tam[1], N. Bansback[1,2], A. Hollis[3], P. Grootendorst[4], A. Anis[1,2]. [1]*Providence Research, Centre for Health Evaluation and Outcome Sciences, Vancouver, Canada*; [2]*University of British Columbia, School of Population and Public Health, Vancouver, Canada*; [3]*University of Calgary, Department of Economics, Calgary, Canada*; [4]*University of Toronto, Leslie Dan Faculty of Pharmacy, Toronto, Canada*

Background: Health systems across countries have used different policy measures (e.g. price discounts, tendering, mandating switches) to encourage the introduction of biosimilars but their differential impact on market penetration is unknown.
Objectives: To evaluate the impact of policy measures on market penetration of anti-TNF biosimilars.
Methods: Quarterly IQVIA MIDAS sales data from 2012-2021 for infliximab, etanercept and adalimumab in 5 countries (Canada, France, Germany, Italy and the United Kingdom (UK)) that used different policy tools were used. Biosimilar market penetration was measured by dividing the number of defined daily dose units (DDDs) of biosimilars sold by the total number of DDDs of the originator and biosimilars sold. Market penetration since the first sale date of the biosimilars was captured by product, setting (hospital vs. retail), and country. Policy impact was examined by comparing market penetration among different policy scenarios (Table 1).
Results: Biosimilars for all three anti-TNFs had higher volume share over time (Figure 1) in the UK than Germany, suggesting that higher prescribing quotas among new and existing patients increases the market penetration of biosimilars given comparable demand-side policies. Since some anti-TNFs are dispensed only in hospitals in some countries, the settings are somewhat different. In France, infliximab biosimilars in hospital setting had faster penetration than other anti-TNF biosimilars in retail setting, indicating that tendering works better than price-links to increase biosimilar uptake. However, infliximab biosimilars in France had slower penetration than in Italy despite the higher discount price-link but absent quotas in France. Similarly, biosimilars had higher volume share over time in UK than Italy, which also suggests that higher prescribing quotas have a greater impact than price-links. Without price-link and tendering measures, Canada had the slowest penetration. By the end of our study period, the limited rollout of mandatory switching policies (3/10 provinces) for existing patients may not be sufficient in fostering market penetration, despite widespread implementation of mandatory prescribing for new patients.
Conclusion: Through comparisons between and within countries, we found that higher prescribing quotas or switching for existing patients and tendering are the key policy drivers for market penetration of anti-TNF biosimilars.

AB1592 WORK-RELATED IMPACT IN YOUNG PATIENTS WITH CHRONIC BACK PAIN AWAITING A MAGNETIC RESONANCE IMAGING

Keywords: Work-related issues, Health services research

D. Benavent[1], M. Tapia-Viñé[2], D. Bernabeu[2], V. Muley[2], C. Plasencia[1], A. Balsa[1], V. Navarro-Compán[1]. [1]*Hospital La Paz, Department of Rheumatology, Madrid, Spain*; [2]*Hospital La Paz, Department of Radiology, Madrid, Spain*

Background: Chronic back pain (CBP) is one of the major causes for medical consultation among young people. Given the limited sources, it is relevant knowing the characteristics associated with a higher burden in order to prioritize the performance of imaging exams.

Objectives: To identify factors associated with sick leave in a cohort of young patients with CBP awaiting an MRI of the spine.

Methods: The project "Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis" (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with CBP that are requested an MRI of the spine by other specialists different than rheumatologists in a tertiary hospital. The study period started in September 2021, and the dataset for this interim analysis was locked in October 2022. Patients completed a questionnaire concerning work status, including sick leave due to CBP (at-visit or prior to this). Besides, socio-demographic and clinical characteristics were collected. Patient-reported outcomes (PROs) for fatigue, Patient Global Assessment (PGA), physical function (Bath Ankylosing Spondylitis Functional Index -BASFI), and overall health (Assessment of Spondyloarthritis international Society Health Index -ASAS HI) were also evaluated. A logistic regression analysis was performed to evaluate the association of patients' characteristics with sick leave.

Results: Of 152 recruited patients, 123 (80.9%) were actively employed, 22 (14.5%) were unemployed and 7 (4.6%) were students. Among the employed patients (52.8% female; mean age 33.8(4.8) years; 57.0 (54.0) months CBP duration), 65 (52.8%) patients had been on sick leave at some point (50 prior to visit and 15 at the study visit). Baseline characteristics are shown in **Table 1**. Night pain was more frequent in patients on sick leave (56.9 % vs 36.2%, p=0.02), and PROs on fatigue, PGA, physical function and overall health and functioning showed worse results in these patients, as compared to patients who had never been in sick leave. Additionally, patients on sick leave had more frequently pharmacological treatment. After multivariable analysis, being male (OR 2.3, 95%CI 1.0-5.6), having night pain (OR=2.4, 95%CI 1.0-5.8) and reporting higher PGA (OR=1.1, 95%CI 1.0-1.4) were associated independently with being on sick leave.

Conclusion: One out of two young patients with CBP awaiting an MRI of the spine are on sick leave at some point. These patients have poorer quality of life and use more pharmacological treatment than active patients with CBP. Male sex and night pain are associated with being on sick leave due to CBP and therefore could be used to prioritize the use of spinal MRI aiming to optimize health resources.

Table 1. Characteristics of employed patients by work status

		Total employed n=123	No sick leave n=58	Ever sick leave n=65	p-value
Demographics	Age	33.8 (4.8)	33.6 (5)	34.1 (4.8)	0.6

AB1593 SEVERE IMPACT OF THE ECONOMIC CRISIS ON TREATMENT PERSISTENCE IN PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: A MULTICENTRIC CROSS-SECTIONAL STUDY IN LEBANON

Keywords: Disease-modifying drugs (DMARDs), Descriptive studies, bDMARD

S. Asmar[1,2], J. Messaykeh[3], N. Hilal[4,5], M. A. Rida[6,7], K. Mroue'[8], K. Aouad[9,10], F. Minkara[11], A. Hajjar[12], N. Ziade[13,14]. [1]*Hotel-Dieu de France Hospital, Medicine, Beirut, Lebanon*; [2]*Saint Joseph University, Medicine, Beirut, Lebanon*; [3]*Monla Hospital, Rheumatology, Tripoli, Lebanon*; [4]*Ain Wazein Medical Village, Rheumatology, Ain Wazein, Lebanon*; [5]*American University of Beirut Medical Center, Medicine, Beirut, Lebanon*; [6]*Clemenceau Medical Center, Rheumatology, Beirut, Lebanon*; [7]*Lebanese American University School of Medicine, Rheumatology, Beirut, Lebanon*; [8]*Al Zahra Hospital University Medical Center, Rheumatology, Beirut, Lebanon*; [9]*Saint George Hospital University Medical Center, Rheumatology, Beirut, Lebanon*; [10]*Saint George University of Beirut, Rheumatology, Beirut, Lebanon*; [11]*Private Practice, Rheumatology, Tripoli, Lebanon*; [12]*Mount Lebanon Hospital, Rheumatology, Beirut, Lebanon*; [13]*Saint-Joseph University, Rheumatology, Beirut, Lebanon*; [14]*Hotel-Dieu de France Hospital, Rheumatology, Beirut, Lebanon*

Background: Due to Lebanon's unprecedented economic crisis, access to healthcare and chronic treatments is compromised, which might affect chronic disease control.
Objectives: The primary objective of this study was to evaluate the impact of the economic crisis on chronic treatment persistence in patients with rheumatic and musculoskeletal diseases (RMDs) in Lebanon and to estimate the predictors of persistence.
Methods: A cross-sectional multicentric national study was conducted between July and October 2022 on patients with RMDs living across Lebanon (patients with chronic inflammatory rheumatic diseases (CIRDs) and controls with non-inflammatory RMDs). A questionnaire hosted on the Google Forms platform was proposed to consecutive patients during the consultation and disseminated on social media and WhatsApp lists. It included sociodemographic, disease, and treatment data, income, PHQ-9, and GAD-7 questionnaires. Treatments were categorized into corticosteroids, NSAIDs, cs-DMARDs, b-DMARDs (IV and SC), ts-DMARDs, and oral immunosuppressants. Persistence was defined quantitatively as the number of tablets or injections taken during the past month compared to prescribed and qualitatively as the percentage of patients who changed or discontinued chronic RMD treatment due to cost or nonavailability. Data were presented descriptively; factors associated with persistence were identified using multivariable linear regression.
Results: In total, 317 patients with RMDs (286 CIRDs and 31 controls) were included (207 by telephone interview and 110 by self-questionnaires); mean age 49.5 years (SD 16), 68% females, median disease duration 10 years (IQR 6-20), 58% had moderate to severe depression, and 40% had moderate to severe anxiety. Persistence was low for b-DMARDs (SC 55%, IV 63%) and ts-DMARDs (36%) and acceptable for oral immunosuppressants 85.3% and cs-DMARDs (88%) (Figure 1). Among patients with CIRDs, 55.8% discontinued or changed their chronic medication due to nonavailability (45.3%) or increased cost (21.2%). Discontinuation or change affected mainly SC b-DMARDs (66.2%), ts-DMARDs (60.0%), and IV b-DMARDs (40.0%). Notably, patients reported a decrease in their financial level in 86% of the cases, and 58% reported they were currently living in a low economic level (compared to only 6% before the crisis). Compared to controls, patients with CIRDs had a reduction in the number of visits to the doctor, more difficulty accessing chronic treatments (91% vs. 33%), and paraclinical exams (84% vs. 77%). They expressed a higher need for financial support for medication, paraclinical tests, and medical consultation. Importantly, patients could find an alternative source for getting their medication in 60% of cases (buying from abroad in 36%, depending on friends or families living abroad in 20%, and charities in 10%). Finding an alternative source for medication was independently associated with a higher persistence of cs-DMARDs, b-DMARDs, and ts-DMARDs. In addition, being unemployed and having a low financial level were associated with a low persistence of cs-DMARDs and oral immunosuppressants.
Conclusion: Chronic treatment persistence was significantly compromised for essential drugs for patients with RMDs and was rather associated with extrinsic causes related to treatment availability and cost than with classically known intrinsic factors.

HOW DO WE PREVENT THE DEVELOPMENT OF MULTIMORBIDITY IN PEOPLE WITH INFLAMMATORY RHEUMATOLOGICAL DISORDERS: A QUALITATIVE INVESTIGATION

Keywords: Health services research, Qualitative research methods, Comorbidities

L. Grey[1,2], L. Bullock[1], C. A. Chew-Graham[1], C. Jinks[1], Z. Paskins[1,2], T. Rule[3], S. Hider[1,2]. [1]*Keele University, School of Medicine, Keele, United Kingdom*; [2]*Midlands Partnership Foundation Trust, Rheumatology Department, Stoke on Trent, United Kingdom*; [3]*Keele University, Public contributor, Stoke on Trent, United Kingdom*

Background: People with inflammatory rheumatological disorders (IRDs) are at high risk of developing multimorbidity, specifically cardiovascular disease (CVD) and mood problems. UK guidelines advocate annual reviews for people with Rheumatoid Arthritis (RA), although not other IRDs. Current healthcare reviews are often condition specific, focus on existing morbidities rather than identifying risk and preventing future illness, and may not include advice and support to change lifestyle behaviours. Before developing a healthcare review to prevent multimorbidity we sought to explore perspectives on existing healthcare reviews.
Objectives: To explore patients and healthcare professional (HCP) perspectives on healthcare reviews for people with IRDs at risk of multimorbidity.
Methods: People with IRDs were invited to take part in individual semi-structured interviews either by telephone or online platform. HCP perspectives (including primary and secondary care clinicians) were explored in online focus groups. These were transcribed verbatim. Inductive thematic analysis was undertaken (LG/LB). Data and codes were discussed, and key themes generated within the team. Ethical approval was obtained (REC Reference 22/PR/0162).
Results: 15 patients (7 male, 8 female, age 49-75) were interviewed. 3 focus groups were held with a total of 13 HCPs. Four themes were identified: content of a future review, preparing for the review, delivering a holistic review and outcomes. People with IRDs struggled to conceptualize a review which included risk of development of future conditions and wanted the review to focus on their IRD (e.g. joint assessment). People felt that current reviews felt like a 'tick-box' exercise. HCPs reported wanting to conduct a holistic review, highlighting challenges aligning patient and HCP agenda. People with IRDs also demonstrated variable attitudes to considering their risk of future conditions, ranging from whether they wanted all, some or no knowledge of their risk for other conditions influenced by whether these could be prevented. Preparation, such as written information or pre-review questionnaires were considered important to help people understand the review aims, align agendas and for the HCP to understand the patient history and context. Participants recognized the challenge of ensuring such materials consider underserved patient groups such as people with limited health literacy who may face difficulties accessing preparation materials. People with IRDs were flexible in considering whether a review should occur in primary or secondary care, whereas HCPs perceived primary care was best placed to provide a holistic approach although both groups agreed practitioner skills and expertise were more important than location. It was considered important to have outcomes from a review (including any actions to be taken by patient or HCP) clearly understood for a review to be perceived as beneficial.
Conclusion: People with IRDs are at high risk of multimorbidity and may benefit from healthcare reviews to address future risks. Such reviews need to be person-centered addressing both patient and HCP agendas to maximise utility and perceived value. Further research is needed to address how such reviews can be effectively implemented into routine care.

REAL-LIFE STUDY OF IMMUNOGENECITY AND SAFETY OF THE RECOMBINANT VACCINE AGAINST VARICELLA ZOSTER VIRUS IN PATIENTS WITH RHEUMATIC DISEASES TREATED WITH JANUS KINASE INHIBITORS

Keywords: Vaccination/immunization, Real-world evidence, Targeted synthetic drugs

A. V. Esteban Vazquez[1], M. Steiner[1], E. Castaneda[1], I. Thuissard Vasallo[2], C. Andreu Vazquez[2], A. Somodevilla[3], C. Garcia Yubero[4], S. Muñoz-Fernández[1]. [1]*Hospital Universitario Infanta Sofia, Rheumatology, Madrid, Spain*; [2]*Universidad Europea, Statistics, Madrid, Spain*; [3]*Laboratorio UR salud, Microbiology, Madrid, Spain*; [4]*Hospital Universitario Infanta Sofía, Pharmacy, Madrid, Spain*

Background: Adjuvanted recombinant varicella zoster virus subunit vaccine (ARZVV) has been recently approved for preventing reactivation of latent varicella zoster virus in selected groups of patients. Patients with chronic inflammatory diseases are at major risk of this reactivation, developing herpes zoster (HZ) infection (shingles). This risk is further increased under immunosuppressive treatment with janus kinase inhibitors (JAKi). ARZVV is available in Spain since March 2021 for patients treated with JAKi, among other indications. At the present, no real-life post commercialization studies have been published in patients with rheumatic diseases and JAKi vaccinated with ARZVV.

Objectives: To assess humoral immunogenicity and safety of ARZVV in patients with rheumatic diseases treated with JAKi.
Methods: Immunogenicity and short-term safety were evaluated in a cohort of patients treated with Janus Kinase inhibitors in a descriptive prospective study. Participants received two intramuscular doses of the vaccine two months apart. Blood was sampled prior to first and 2-6 weeks after the second vaccine dose. Humoral immune response was tested through a chemiluminescence immunoassay (CLIA), using varicella zoster virus glycoprotein E (gE) as the antigen to measure anti-gE levels. The cut-off for the vaccine response assessment was considered an antibody concentration four times higher in the second measure, compared with the first one, according to the results of the clinical trial NCT01165177. The influence of the different treatments on the humoral response to the vaccine was evaluated. JAKi were separated in three groups, according to their mechanism of action: inhibition of JAK 1 (Upadacitinib and Filgotinib), inhibition of JAK 1 and JAK 2 (Baricitinib) and panJAK inhibition (Tofacitinib). Concomitant treatment influence on the humoral response to the vaccine was also determined: classic disease modifying anti-rheumatic drugs (DMARDs) and corticosteroids. The data about adverse events to the vaccination, disease flare or reactivation on HZ infection were collected.
Results: We enrolled 30 patients, 23 were woman (76,7%), with a mean age of 55±12 years. Fifteen (50%) were under treatment with upadacitinib, eleven (36,7%) with baricitnib, two (6,7%) with filgotinib and two (6,7%) with tofacitinib. Six (20%) had concomitant treatment with methotrexate and 5 (16,7%) with leflunomide. Ten (33%) had low dose prednisone. Four (13%) reported clinically HZ previously. We found that 16 patients (53,3%) reached the response assessment marked initially of quadrupling their initial antibody count. Type of JAKi did not significantly influence the humoral response, neither did the concomitant treatment with disease-modifying antirheumatic drug or low dose glucocorticoid. Fiftheen patients (50%) presented mild adverse effects; 7 (23%) of them consisted in injection-side pain, and 8 (26,7%) were systemic (myalgia, fatigue or fever). One patient (3,3%) had an ischemic cerebrovascular complication 2 weeks after the first dose. None of the patients presented a disease flare in the following 4 weeks postvaccination, neither HZ infection after 7 months of follow-up.
Conclusion: Lightly more than half of the patients (53%) with rheumatic diseases treated with JAKi reached the immune response assessment stablished. In clinical trials with non-rheumatic immunosuppressed patients, the response was ranged between 65-96%. This difference could be explained due to that it is a real-life study and in the type of disease and immunosuppression. Safety and prevention of HZ infection was high. To confirm these results higher number of patients is needed.

DETERMINANTS OF TELEMEDICINE ACCEPTANCE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: SECONDARY ANALYSIS OF DATA FROM A GERMAN NATIONWIDE SURVEY

Keywords: Rheumatoid arthritis, Health services research, Telemedicine

F. Muehlensiepen[1,2], P. Petit[2], J. Knitza[2,3], M. Welcker[4], N. Vuillerme[2,5,6]. [1]*Brandenburg Medical School Theodor Fontane, Center for Health Services Research, Neuruppin, Germany*; [2]*Université Grenoble Alpes, AGEIS, Grenoble, France*; [3]*Friedrich-Alexander-University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany*; [4]*MVZ for RHEUMATOLOGY Dr. Martin Welcker GmbH, -, Planegg, Germany*; [5]*Institut Universitaire de France, -, Paris, France*; [6]*Orange Labs & Univ. Grenoble Alpes, LabCom Telecom4Health, CNRS, Inria, Grenoble, France*

Background: Telemedicine (TM) is an effective tool to supplement rheumatology care and address staff shortages [1]. A previous study revealed that patients' willingness to try TM is closely connected to their rheumatic and musculoskeletal disease (RMD) [2]. Yet, it is still unclear which factors are associated with patients' willingness to try TM among specific RMD groups, such as the most prevalent rheumatic arthritis (RA).
Objectives: To identify factors that determine the willingness to try TM (TM-try) among patients diagnosed with RA.
Methods: We conducted a secondary analysis of data from a German nationwide cross-sectional survey [3] among patients with RA. Bayesian univariate logistic regression analysis was applied to the data in order to determine which factors were associated with TM-try. Predictor variables (covariates) studied individually included sociodemographic factors (e.g., age, sex) and health characteristics (e.g., health status). All the variables positively and negatively associated with TM-try in the univariate analyses were then considered for Bayesian model averaging analysis (BMA) after a selection based on the variance inflation factor (≤ 2.5) to identify determinants of TM-try.
Results: A total of 22 variables/factors (22/55, 40%) were found to be positively or negatively associated (ROPE% ≤ 5%) with TM-try among 146 RA patients. A total of 9 determinant factors were identified using BMA (Figure 1). Wishing that TM services were offered by a rheumatologist, having prior TM knowledge, living in a town and considering one's health status as okay were positively associated with TM-try. By contrast, not owning an electronic device, not having internet access at home, considering to have a bad health status and being more than 60 years old were negatively associated with TM-try.
Conclusion: Our results suggest that health status, TM knowledge, age, and access to technical equipment and infrastructure influence RA patients' motivation to use telehealth in Germany. Consequently, training programs and targeted support measures in terms of equipment and infrastructure could help ensure that all patients have equal access to telehealth.

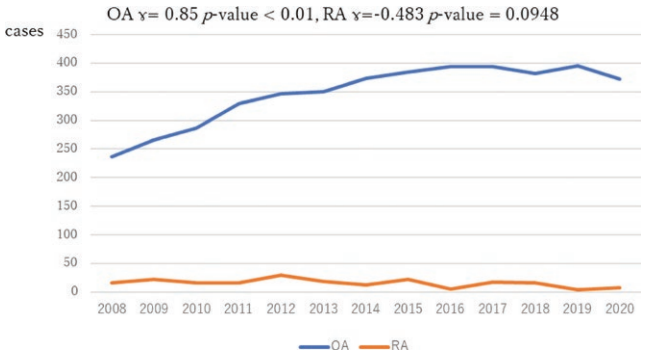
AB1598 TRENDS OF KNEE ARTHROPLASTY FOR PATIENTS WITH OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS IN SUPER-AGING SOCIETY IN THE LAST THIRTEEN YEARS

Keywords: Osteoarthritis, Rheumatoid arthritis



M. Aso[1], Y. Takakubo[1], A. Suzuki[1], S. Yang[1], Y. Wanezaki[1], T. Yamamoto[2], T. Ito[2], S. Fukushima[2], M. Takagi[1]. [1]*Yamagata University, Orthopaedic Surgery, Yamagata, Japan*; [2]*Yamagata Saisei Hospital, Orthopaedic Surgery, Yamagata, Japan*

Background: In Japan, the number of people aged 65 years or older exceeds 35 million, accounting for 28.4% of the total population. It is expected to reach 38.4% by 2065[1]. As a result, the demand for total knee arthroplasty (TKA) and unicompartmental knee arthroplasty (UKA) is increasing year by year[2].
Objectives: The purpose of this study was to investigate the number and trend of patients who underwent knee arthroplasty from 2008 to 2020.
Methods: We analyzed the age, gender, and causative disease of patients who underwent primary knee arthroplasty between January 2008 and December 2020 at two affiliated hospitals. Chi-squared test, Mann-Whitney U test and Spearman's rank correlation coefficient were utilized for statistical analysis. All p-values of 0.05 or less were considered statistically significant. All statistical analyses were conducted using EZR (Saitama Medical Center, Jichi Medical University, Saitama, Japan, Version 1.55)[3].
Results: We recorded 4,199 cases of TKA (87.1%) and 623 cases of UKA (12.9%), the total of knee arthroplasty is 4,822 cases. There were 1,011 males (24.1%) and 3,811 females (75.9%). Male patients made up 18.5-23.2% of all knee arthroplasty cases, with a trend toward an increase (Spearman's rank correlation coefficient: γ= 0.633 p-value = 0.0135). The mean age at surgery was 75.0 (28-94) year-old, with no significant difference between male (75.2 year-old) and female (74.9 year-old) patients (*p*-value 0.354). The Causative diseases included 4515 cases of osteoarthritis (OA, 93.6%), 208 cases of rheumatoid arthritis (RA, 4.3%), 90 cases of osteonecrosis (ON, 1.9%), 8 cases of trauma, and 1 case of infection (Table 1). TKA/UKA for OA exhibited a significant upward trend, with an average of 346.9 cases per year, while TKA for RA showed a downward trend, with an average of 15.5 cases per year (Spearman's rank correlation coefficient: OA γ= 0.85 *p*-value < 0.01, RA γ=-0.483 *p*-value = 0.0948, Figure 1). UKA group had a significantly higher rate of osteonecrosis compared to TKA group (*p*-value < 0.01, Table 1).
Conclusion: The number of TKA/UKA for OA increased due to the growing number of elderly people affected by knee OA in a super-aging society. On the other hand, the number and rate of primary TKA/UKA due to RA decreased over time due to advances in medication therapy[4]. Osteonecrosis was the cause of a relatively high rate in the UKA group.

AB1599 EVALUATING HOW EFFECTIVELY PATIENTS WITH A NEW INFLAMMATORY ARTHRITIS ARE BEING TRIAGED INTO THE APPROPRIATE CLINIC AT A TERTIARY CARE HOSPITAL IN THE UK: A RETROSPECTIVE AUDIT

Keywords: Inflammatory arthritides

A. Vivekanantham[1], A. Soni[1], H. Thrower[2]. [1]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [2]*Oxford University Hospitals, Rheumatology, Oxford, United Kingdom*

Background: Early diagnosis and treatment of inflammatory arthritis (IA) is essential: BSR guidance states patients must be seen within three weeks and started on disease modifying anti-rheumatoid drugs (DMARDs) within six weeks.
Objectives: To evaluate how effectively people referred with a new IA are being triaged, whether national standards are met and analyse variables which may influence triage of patients with new IA.
Methods: A retrospective review was performed of all new patients seen in EIA-clinic and those with new EIA who had been seen in non-EIA clinics from 01/09/21-31/11/21. Data was collected on days' wait from referral to assessment/commencement of DMARD. We calculated the conversion rate (CR) (percentage of referrals triaged to EIA clinic that have EIA) and detection rate (DR) (percentage of new EIA patients that are seen in the EIA clinic). The standard for CR and DR was 50% and 95%, respectively. We then examined why some new EIA patients were not triaged to the EIA-clinic using information provided on the referral.
Results: Of the patients seen in the EIA-clinic 36/73 had a new diagnosis of an EIA, giving CR of 49%. Of the new diagnoses of EIA made during that time-period 36/53 were appropriately triaged to be seen in the EIA clinic, giving a DR 68%. Patients seen in the EIA clinic had an average of 5 weeks wait from referral to assessment/commencement of DMARD. In contrast, patients who had been seen in non-EIA clinics had an average of 10 weeks from referral to assessment/commencement of DMARD. A previous audit performed before COVID-19 (01/11/19- 01/01/20) showed a CR of 25% (115 patients seen in EIA-clinic, 29 new diagnoses) and a DR of 69% (29 new diagnoses, 20 seen in EIA-clinic). Of the 10 patients with new EIA who were inappropriately triaged to non-EIA clinics did not have pattern of joint involvement or ability to make a fist documented, in comparison to the 38 patients with a new EIA who were appropriately triaged to EIA-clinic.
Conclusion: Patients with EIA, seen in the EIA-clinic, do not meet guidance for review within three weeks but do meet the guidance for starting a DMARD within six weeks. Patients seen outside the EIA-clinic do not meet either of these standards. Only 68% of people with a new EIA are being triaged to be seen in the EIA clinics, highlighting the need to improve the triage process. Compared to the previous audit, the CR has improved whilst the DR has stayed steady. We have identified variables which appear to influence the triage process. Next steps include making some details from the referral compulsory, exploring using data collected from patients electronically to improve the CR/ DR rates, and artificial intelligence informed modelling.

TIME TO PUBLICATION AND TIME-LAG PUBLICATION BIAS FOR RANDOMIZED TRIALS ON CONNECTIVE TISSUE DISEASES

Keywords: Epidemiology, Randomized control trial

D. Mongin[1], B. Russo[2,3], J. A. Brigante[4], S. Capderou[1], D. Courvoisier[5], M. Iudici[5]. *[1]University of Geneva, Department of Medicine, division of rheumatology, Geneva, Switzerland*; *[2]University of Geneva, Department of Pathology and Immunology, Geneva, Switzerland*; *[3]Hôpitaux Universitaires de Genève (HUG), Division of Dermatology and Venereology, Genève, Switzerland*; *[4]Sanatorio Güemes, Servicio de Medicina Interna - Reumatología, Buenos Aires, Argentina*; *[5]Hôpitaux Universitaires de Genève (HUG), Department of Internal Medicine Specialties, division of rheumatology, Genève, Switzerland*

Background: Connective tissue diseases (CTDs) are systemic autoimmune diseases, some of which rare, characterized by a dysregulated immune response and a heterogeneous clinical picture. Similarly to nonpublication, a long time from completion to publication of randomized controlled trials (RCTs) results can indirectly harm patients by allowing inefficacious or dangerous intervention being prescribed[1], or by delaying the prescription of useful treatment. We have recently shown that one-third of CTDs-RCTs registered after 2000 never reached publication[2], but we did not estimate the extent of time-lag publication bias, neither analyzed factors associated with delayed publication.

Objectives: To assess the time from completion to publication of randomized controlled trials (RCTs) on connective tissue diseases (CTDs), investigate the factors associated with, and explore the influence of significance of study results on time to publication (time-lag publication bias).

Methods: We included interventional, phase 2/3, 3 or 4 RCTs on CTDs registered in Clinicaltrials.gov from 2000 to 2016, whose results had been published in a peer-review journal less than 5 years after their completion. Two reviewers selected studies according to pre-specified criteria. Main trial features including the significance of primary outcome results were collected. Time to publication was the time from study primary completion to the earliest online publication date. Multivariable linear regression was used to identify association between time to publication and the significance of study results, adjusted for variables previously shown to impact this outcome, e.g. the funder, the size of the trial, the international status, the year of completion and the impact factor of the journal.

Results: We included 62 studies, mostly phase 3 (62%) trials on pharmacologic treatments (94%), recruiting patients with systemic lupus (55%) or systemic sclerosis (23%), and planning to enroll a median of 131 [IQR 61-288] patients. Twenty-two (35%) reported at least a statistically significant primary outcome. Median time to publication was 28 months [IQR 17-36], with more than half studies (n = 34, 55%) published 2 or more year after completion (see Table 1). In multivariable analysis, time to publication progressively improved over time (faster publication in recent years, with the time to publication begin 1.3 [0.3, 2.4] months shorter every year), and was not influenced by the significance of primary outcome results, funder, impact factor of the journal, number of recruiting countries (see Figure 1).

Conclusion: A high proportion of CTDs-RCTs is published beyond 2 years from completion. We did not find evidence of time-lag publication bias, and time to publication improved over time.

PATIENT EXPERT RECOMMENDATIONS ON WAYS TO IMPROVING THE SYSTEMIC SCLEROSIS CARE CONTINUUM ACROSS EUROPE

Keywords: Systemic sclerosis, Patient-led research, Geographical differences

I. Galetti[1], S. Farrington[2], Y. Allanore[3], M. Matucci-Cerinic[4], S. Sandulescu[5], R. Schriemer[6], C. P. Denton[7]. *[1]Federation of European Scleroderma Associations, Vice President, Brussels, Belgium*; *[2]Federation of European Scleroderma Associations, President, Brussels, Belgium*; *[3]Institut Cochin, Professor of Rheumatology, Cochin Hospital Practitioner, Head of the Research Team 'Pathogenesis and Innovative Therapies in Systemic Sclerosis and Other Fibro-Inflammatory Diseases' at Institut Cochin, Paris, Paris, France*; *[4]University of Florence, Professor of Rheumatology at the Department of Experimental and Clinical Medicine, Florence, Italy*; *[5]Patient Advocate, Patient Advocate, Bucareste, Romania*; *[6]Patient Advocate, Patient Advocate, Amsterdam, Netherlands*; *[7]University College London Division of Medicine, Professor of Experimental Rheumatology, Consultant Rheumatologist, London, United Kingdom*

Background: Systemic sclerosis (SSc), also known as scleroderma, is a rare autoimmune disease that stiffens the skin, turning simple daily activities into real challenges for patients. It can affect all organs, and while treatments exist, there is currently no cure. The disease is relatively invisible among general practitioners and policymakers in Europe - meaning hundreds of people affected by this rare condition remain undiagnosed and untreated.

Federation of European Scleroderma Associations (FESCA) took a two-pronged approach to develop new evidence. June 2022 a Position Paper (PP) based on a literature review and a survey for healthcare providers (HCP) was published, followed by a large-scale patient and carer survey, whose results are expected in June 2023.

OBJECTIVES:

- Highlight the unmet needs of SSc patients throughout the care pathway.
- Investigate the health and socio-economic burden of the SSc
- Provide evidence to policy stakeholders on the need for policy actions to address health inequalities.

Methods: For the PP, a total of 15 publications were reviewed. To fill the knowledge gaps identified by the literature review, FESCA developed a survey questionnaire earmarked for Excellence or Reference Centers that work with FESCA member organizations and/or are part of the European Scleroderma Trials and Research group (EUSTAR). Upon validation by the authors, the survey was completed by 78 respondents from 24 countries. The upcoming survey will be distributed across 20 countries, a min. representative sample of 511 patients and 170 carers will provide new insights.

Results: The PP highlighted need for policy action in five action areas to ensure timely treatment initiation for all eligible patients and improved health outcomes and quality of life for people living with SSc, by:

1. Creating patient registries for SSc;
2. Shortening time to accurate diagnosis through expanded HCPs curricula;
3. Ensuring timelier referral of patients to specialized care;

4. Improving treatment recommendations and access to appropriate medicines through fast track pathways;
5. Delivering better quality information to SSc patients.
The survey should provide information on patients' evaluations of physical functioning and overall health as the main factors in the decision-making process and the assessment of a treatment's success, showing the inadequacy of current value attribution and appraisal frameworks. Preliminary results are expected to be published at the EULAR Congress.
Conclusion: The outcomes of the work done by FESCA aims at improving the SSc continuum of care from earlier diagnosis to better treatments as well as creating greater awareness of scleroderma so that those who suffer from it can access proper, equitable care. Most importantly, the results of both studies highlight the need for developing person-centred care pathways integrating more systematically quality-of-life considerations in healthcare and treatment decisions as well as in value attribution frameworks that are more responsive to patient needs.

Background: The development of biologic and targeted synthetic (b/ts)DMARDs contributed to improved treatment outcomes in rheumatoid arthritis (RA). However, high medications costs may limit their use. Previously we showed that in countries with a lower socioeconomic status (SES), b/tsDMARDs were prescribed to fewer patients than in countries with higher SES. In this study we take a more detailed look at b/tsDMARD prescription behavior between countries.
Objectives: To explore cross-country relationships between Gross Domestic Product (GDP) per capita, specific indicators of b/tsDMARDs use and disease outcomes in patients with RA.
Methods: This multinational, observational study included countries that had contributed ≥100 patients using b/tsDMARDs, with available follow up, to one of 2 registries: METEOR, an international registry capturing daily clinical practice data of patients with a clinical diagnosis of RA, and JAK-POT, an investigator-initiated collaboration between national registries aiming to evaluate clinical aspects of b/tsDMARDs in RA. On a per-country basis, mean DAS28 was calculated from the last available follow-up visit per patient. b/tsDMARD usage was determined as mean time to start b/tsDMARD therapy since date of diagnosis, mean number of b/tsDMARDs tried per patient and mean duration of b/tsDMARD therapy. To calculate the time to start a first b/tsDMARD per country included from the JAK-POT registry, only bionaïve patients were included. Possible associations between GDP per capita and country-level indicators of b/tsDMARD use and DAS28 were tested in univariable linear regression models. Regression coefficients (β) are interpreted as the numerical increase in the outcome per 1 point increase in the predictor.
Results: Data from 25,832 patients living in 17 different countries showed varying b/tsDMARD prescription behavior. GDP per capita ranged from 6505 (India) to 93350 Intl$ (Ireland). Time to start b/tsDMARD therapy ranged from 0.5 (Austria) to 11.1 (Finland) years. Mean number of b/tsDMARDs tried per patient ranged from 1.0 (Turkey) to 2.4 (Switzerland). Duration of b/tsDMARD therapy ranged from 0.9 (India) to 5.5 (Portugal) years (Figure 1). Baseline DAS28 ranged between 3.7 and 6.1, but was not related to any of the indicators of b/tsDMARD use: time to start a b/tsDMARD β 0.08 (95% CI -0.7; 0.9), number of prescribed b/tsDMARDs β 0.06 (95% CI -0.03; 0.2), duration of b/tsDMARD treatment β 0.1 (95% CI -0.3; 0.5). No statistically significant associations were observed between GDP per capita and time to start b/tsDMARD therapy (Figure 1A, β 0.09 CI 95% -0.7; 0.9), the number of b/tsDMARDs tried per patient (fig 1B, β 0.07 CI 95% -0.02; 0.2) or the duration of b/tsDMARD treatment (fig 1C, β 0.1 CI 95% -0.3; 0.5). None of the indicators of b/tsDMARD prescription were significantly related to DAS28 at the end of follow up: time to start a b/tsDMARD β 0.02 (95% CI -0.05; 0.1), duration of b/tsDMARD therapy β -0.03 (95% CI -0.2; 0.1) and number of b/tsDMARDs β -0.03 (95% CI -0.6; 0.6).
Conclusion: This study showed varying b/tsDMARD prescription behavior and disease activity across 17 countries worldwide. Overall, differences in b/tsDMARD prescription behaviour did not appear to be related to socioeconomic welfare and, no significant association was observed between b/tsDMARD prescription behavior and disease activity at a country level. This seems to indicate that once patients start a b/tsDMARD, socioeconomic welfare has less impact on b/tsDMARD use.

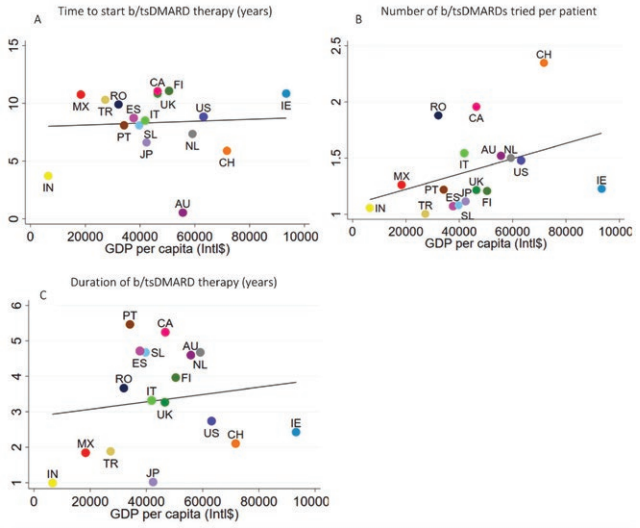

Figure 1. Associations between 'GDP per capita (Intl$)' and the 'Time to start b/tsDMARD therapy (years)' (A), 'Number of b/tsDMARDs tried per patient' (B) and 'Duration of b/tsDMARD therapy (years)' (C)

AB1603 EVIDENTIAL REQUIREMENTS FOR DECISION-MAKING ABOUT WORKPLACE INITIATIVES TO MITIGATE THE IMPACT OF RHEUMATIC AND MUSCULOSKELETAL DISEASES: QUALITATIVE INTERVIEWS WITH REPRESENTATIVES OF UK ORGANISATIONS

Keywords: Work-related issues, Rheumatoid arthritis, Qualitative research methods

M. Eden[1], J. Higgerson[1], K. Payne[1], W. Whittaker[1], S. Verstappen[2]. *[1]The University of Manchester, Manchester Centre for Health Economics, Manchester, United Kingdom*; *[2]The University of Manchester, Centre for Musculoskeletal Research, Manchester, United Kingdom*

Background: Decisions about whether to invest in RMD-related workplace initiatives/adaptations can be made by determining, from the relevant perspective, if benefits outweigh the costs of implementation. Little is known about what information organisations need to facilitate these decisions.
Objectives: This study aimed to explore motivations and evidential requirements for employers to invest in workplace health initiatives.
Methods: Semi-structured online interviews with representatives of large UK-based (not-for-profit and for-profit) organisations were audio-recorded. For each organisation, a line manager, director, and representative with workforce health remit were interviewed. Interview data were transcribed verbatim and subject to thematic analysis by two researchers trained in qualitative methods. Themes were agreed in discussion with the study team.
Results: We recruited 13 representatives (5 directors, 3 line managers, and 4 with a specific remit for workforce health). Three not-for-profit organisations (local authority, university, and National Health Service) were represented by seven participants and three for-profit organisations (restaurant chain, telecoms provider, and technology company) were represented by six individuals.
Motivations: All participants believed that investment in measures to promote employee health and well-being could positively contribute to their organisation's efficiency. *…there's loads of academic research that says… if you look after your colleagues… if you cater to their… individual needs, then that has a very positive impact on organisation performance.* (Director, not-for-profit) Attraction and retention of staff – seen as increasingly difficult - was a motivating factor to invest that was shared by employers, as was the desire to avoid litigation, promote workplace camaraderie, and to maintain organisational reputation. Low RMD prevalence rates in the young workforce in one organisation (a restaurant chain) meant that these conditions did not influence decision-making. For organisations with older workforces doing heavier manual work, higher prevalence rates of RMD were a key reason to act. *... musculoskeletal is, like, the second biggest reason for sickness within the organisation.* (Line manager, not-for-profit)
Evidential requirements: Use of checklists/assessments to reveal individual RMD-related needs was commonplace throughout organisations. Self-identified health needs, typically related to line managers, would instigate a process where occupational therapist (OT) input may be sought. Requests and OT recommendations are reportedly, without exception and irrespective of cost, met and followed. No organisation had set aside a specific budget for workplace initiatives. Decisions involving significant investments in workforce health initiatives were usually made by committees or by small teams comprising senior staff and directors. Line managers and those with a health remit would put forward a case for investment to these bodies: *…we would pull together a bit of a proposal really on what that would look like…what is the impact of it?...we support it with facts…even benchmarks of what's going on in the outside.* (Health remit representative, for-profit) Evidence from OTs/other health professionals, in-house absenteeism data, workforce survey results/informal feedback from colleagues, benchmarking data, and academic/official report findings were used to make a case for investment.
Conclusion: The demand for RMD-specific interventions varies according to needs of particular workforces. Despite diversity of organisation type, workforce factors (i.e. demographic factors, nature of work) and employer roles, common processes for informing investment decisions and typical evidence requirements have been identified. Findings can inform the development and evaluation of workplace interventions to benefit people with RMD.
Acknowledgements: This work is undertaken as part of the Centre for Musculoskeletal Health and Work, funded by Versus Arthritis and the Medical Research Council. We thank study participants.

Background: Vaccination against SARS-CoV2 had a critical role in the fight against COVID19 pandemic. A weaker humoral response to COVID19 vaccine has been found in rheumatic patients treated with Rituximab (RTX) or Mycophenolate Mofetil (MMF)[1]. Despite the evidence that anti-SARS-CoV-2 mRNA vaccines can elicit a T-cell response [2], some data show that even the cellular immunity could be impaired in rheumatic patients [3] but COVID19 serology is the only parameter that is feasible to measure in daily practice. Tixagevimab+cilgavimab are two human-derived monoclonal antibodies administered parenterally and authorized by regulatory agencies in February 2022 for pre-exposure prophylaxis (PrEP) against COVID19 from different virus variants in fragile patients.
Objectives: To demonstrate safety and effectiveness of tixagevimab+cilgavimab.
Methods: Patients with autoimmune rheumatic diseases undergoing immunosuppressive treatment with RTX or MMF during the vaccination campaign were enrolled between April and June 2022. All patients must have anti-spike antibody levels below the protective threshold (defined by anti-spike IgG titre <250 BAU/ml) after receiving at least 2 vaccine doses. Patients were monitored with a questionnaire every month about COVID19 symptoms (including respiratory and gastrointestinal symptoms, anosmia and ageusia, skin rash and potential contact with COVID19+ subjects) and were checked for anti-spike and anti-nucleocapside antibodies titres every 2 months for a total of a 6 month follow-up. MMF dose was reduced at 1 g/die at the time of vaccine administration.
Results: Fifteen patients were enrolled: 9 participants had a connective tissue disease (CTD; 1 dermatomyositis, 3 anti-syntethase syndrome, 4 systemic sclerosis, 1 systemic lupus erythematosus) and 6 had vasculitis (all granulomatosis with polyangiitis). 12 of them received RTX in the preceding 12 months and 3 were taking MMF. About safety, the therapy was very well tolerated and only 4 patients (26%) reported a non-severe adverse event in the 2 weeks following drug administration (2 myalgia, 1 headache, 1 fatigue), none of them requiring hospitalization nor pharmacologic treatment. Regarding effectiveness, 3/15 patients contracted SARS-Cov2 infection (20%) with mild symptoms and no need for hospitalization nor oxygen therapy. Only 1 of them received an antiviral drug (nirmatrelvir+ritonavir). All infected patients had a CTD diagnosis. No significant correlation was observed between the type of rheumatic disease and the risk of infection or response to tixagevimab+cilgavimab.
Conclusion: None of our patients developed severe adverse events after tixagevimab+cilgavimab administration and, among the 3 SARS-CoV2 infected patients, none required hospitalization nor oxygen therapy.
We conclude that in our experience tixagevimab+cilgavimab is a safe and useful complementary immunization strategy to vaccination for COVID19 prophylaxis. These data will be implemented in a larger study, comprehending various immunocompromised patients from several departments.

A PILOT RHEUMATOLOGY-INTERSTITIAL LUNG DISEASE (ILD) SERVICE - OUTCOMES AFTER 12 MONTHS

Keywords: Lungs, Organ damage

C. Riddell[1], J. Lindsay[2], E. Ball[1]. *[1]Musgrave Park Hospital - Belfast Health and Social Care Trust, Rheumatology, Belfast, United Kingdom*; *[2]Belfast Health and Social Care Trust, Respiratory, Belfast, United Kingdom*

Background: Rheumatologists have an important role in the management of interstitial lung disease (ILD). Cross-specialty collaborative working models are increasingly being used, particularly with ILD radiology MDT meetings, attended by respiratory physicians and rheumatologists, to discuss complex clinical cases. However, the infrastructure and format are not standardized) [1]. With the widespread financial and logistical pressures affecting delivery of healthcare in not only NHS setting, but worldwide; there is a need to provide robust evidence to managers and fundholders, of significant benefit to attract allocation of funding and resources towards MDT working in complex disease areas such as ILD.
Objectives: We describe the format and outcomes of a pilot rheumatology-ILD service at a large teaching hospital undertaken from January to December 2022.
Methods: Two rheumatology consultants (EB and CR) worked with the local ILD respiratory lead (JL) to plan for weekly attendance of one or both rheumatologists at a weekly ILD MDT. Prior to this, paper based referrals to general rheumatology were made if advice was felt to be required – generating paperwork, delays in the patient journey and an ad hoc approach across multiple rheumatology clinicians. This MDT is attended by respiratory clinicians, radiologists, ILD nurse specialist and respiratory trainees. Since the COVID-19 pandemic it has been conducted via Microsoft Teams and is scheduled for 1-1.5 hours weekly. Cases to be discussed are added in advance to MSTeam file on a specifically designed proforma. In addition there is a weekly ILD OPC attended by JL with a dedicated ILD nurse specialist. Rheumatology joined this clinic when other clinical commitments allowed which facilitated more focused discussion on management of complex cases.
Results: Over the course of a 12 month period rheumatology attended 24 ILD MDT meetings and 8 ILD out-patient clinics. This equated to approximately 80 hours of rheumatologist time over the pilot period.
On analysis of cases presented, 33% required rheumatology input, most often on the basis of positive antibody screening or a prior history of rheumatological disease.
The breakdown of rheumatology disease presented is detailed in Table 1 below.

Table 1. Diagnosis, Frequency and Outcome of Rheumatology-Related ILD Cases at a Pilot Cross-Specialty Clinic Over 1 Year

	NUMBER OF CASES	PRESENCE OFSIGNIFICANT ANTIBODIES	OUTCOME
ANCA	18	MPO pANCA	Watch and wait =7 cases
	3	cANCA +/- PR3	Immunosuppression (steroid, MMF*, IV cyclo*, ritux*) = 11 cases
			Death (2 cases) – despite intensive immunosuppression
			No classical GPA presented via ILD service
			2 felt to be incidental cANCA
			1 atypical case closely monitored
RA	12		Often no change to treatment, liaise with rheum treating team
Myositis (Mi2b, SAE)	7		All assessed by rheumatology, myositis confirmed in 5 – continue under rheumatology
Lupus	8		4=felt insignificant low-titre antibody 4= referred into rheumatology service
Scleroderma	9		Immunosuppression (steroid, MMF*, toc*)
IgG4	2		Referred into rheumatology
Others: shrinking lung, low titre antibodies, PMR, Sweets	13		Various: clinical advice, rheum OPC, neurology referral, derm referral

*****indicates specialist drug treatment not usually initiated by respiratory teams and requiring rheumatology advice +/- administrating and monitoring*

Conclusion: There are a large number of ILD cases within the respiratory service that require rheumatology input – 33% of all ILD cases in this real-world snapshot. The spectrum of rheumatologically associated disease is vast. ILD can have a catastrophic outcomes and therefore early and continued rheumatology input is vital. Investment is needed for formal MDT infrastructure to include rheumatology. There is a need for data collection, collaborative working and research to improve the quality of care and outcomes for this population.

AB1606

SYMPTOMS OF RAYNAUD'S PHENOMENON ARE NO OBSTACLE FOR BEING PHYSICALLY ACTIVE IN HEALTHY WOMEN

Keywords: Patient reported outcomes, Lifestyles, Quality of life

S. Van de Zande[1], K. Eijkelenkamp[2], A. Eman Abdulle[3], A. Smit4, H. Zwerver[5], I. Van den Akker-Scheek[6], D. J. Mulder4. *[1]University Medical Center Groningen, Vascular medicine, Groningen, Netherlands*; *[2]University Medical Center Groningen, Endocrinology and Metabolic Diseases, Groningen, Netherlands*; *[3]University Medical Center Groningen, Internal Medicine, Groningen, Netherlands*; *[1]University Medical Center Groningen, Vascular Medicine, Groningen, Netherlands*; *[5]University Medical Center Groningen, Center for Human Movement Sciences, Groningen, Netherlands*; *[6]University Medical Center Groningen, Department of Orthopaedics, Groningen, Netherlands*

Background: Women with primary Raynaud's phenomenon (RP) often experience a decreased health related quality of life (HRQoL). A physically active lifestyle could have a positive influence on vascular function and thus might improve HRQoL in women with primary RP.
Objectives: To quantify the amount and type of physical activity (PA) and sedentary behaviour, as well as HRQoL and stress, in women with primary Raynaud's phenomenon (RP), and to compare this to the behaviour of women without RP from a large population-based cohort (Lifelines).
Methods: The connective tissue disease (CTD) screening questionnaire data from the Lifelines database that was available of women ≥ 18 years old was used. This

questionnaire consists of 30 questions to detect possible CTD's. A total of 19820 women, 929 with RP and 18891 without RP, all without other comorbidities were included. By using questionnaires from the Lifelines database other patient characteristics were retrieved including physical activity and sedentary behaviour, HRQoL and stress.
Results: Women with RP reported 300 min/week minutes of moderate to vigorous physical activity (MVPA), which was more than women without RP reported (255 min/week). This difference was mainly due to a difference in vigorous activities (p<.001). 74.3% of women with RP complied to the health enhancing PA guidelines (69.5% in the group of women without RP, p=.003). Time spent sedentary by women with RP was 540 min/week, which was comparable to sedentary time of women without RP (540 min/week, p=.886). Women with RP scored lower on almost all eight domains of the QoL questionnaire (p<.05), except for physical functioning (p=.181). Regarding stress levels, the List of Threatening Experiences (LTE) showed no differences between groups (p=.226), however, the Long-term Difficulties Inventory (LDI) showed a higher stress level in the RP group (p<.001). Furthermore, women with RP were significantly younger (p<.001), had a lower Body Mass Index (BMI) (p<.001), a lower waist-hip ratio (p<.001), had a lower amount of packyears (p<.001) and a healthier diet score (p<.001) compared to the women without RP.
Conclusion: This is the first study to structurally investigate PA in a large population cohort of patients with RP. Most women with RP report they spent a sufficient amount of time on moderate to vigorous PA and thus comply to health enhancing physical activity guidelines. The PA behaviour of women with RP seems comparable to that of women without RP, showing that RP is no obstacle for being physically active. However, HRQoL was lower in women with RP; more research is needed to elucidate the relation between PA and HRQoL in this patient group, preferably using objective measurement instruments to assess PA.

AB1607 TREATMENT OUTCOME OF RHEUMATOID ARTHRITIS IN RURAL AND URBAN POPULATION; A COMPARATIVE STUDY FROM SOUTH INDIA

Keywords: Rheumatoid arthritis

V. Viswanath[1], H. Sreekumar[1], L. Sreekumari Ramachandran[1], A. G. Varier[1]. [1]*Dr Vishad Viswanath's IRIS Centre for Arthritis & Rheumatology, Rheumatology, Thiruvananthapuram, India*

Background: Advances in rheumatology have made the once-disfiguring rheumatoid arthritis (RA) a controllable disease. However, differences in health care delivery exist across the rural and urban populations in South India. Hence disease characteristics may be different across the two groups of patients. [1,2] Herein, we compare the disease characteristics of RA across rural and urban populations based in the state of Kerala in South India.
Objectives: The primary objective was to compare the disease characteristics of RA in rural and urban rheumatology centres in South India.
Methods: A retrospective study of patients attending rural and urban clinics of our Institute was conducted. Consecutive 100 patients who attended the clinics from April to October 2022 and who satisfied the ACR/EULAR 2010 RA criteria were selected for the study in each group. Baseline Demographics were collected, and disease activity was measured using the CDAI score. Extraarticular manifestations and comorbidities associated with RA were also considered. Treatment response was assessed at the end of 6 months.
Results: The mean age of patients was 51 years(± 12SD) and 55 years(±12SD) in urban and rural groups, respectively. Disease activity at baseline and six months was shown in Figure 1. 28% of the rural patients required triple DMARDs for disease control against 14% in the urban group (p-value 0.02). Remission at six months was attained in 47% of the urban population against 30% of the rural population (p-value 0.05). Non-alcoholic Fatty liver disease was more prevalent in the rural population (9%) than the urban population (2%)(p-value 0.05). DMARD-induced elevation of liver enzymes occurred in 15% of patients in the rural group compared to 5% of patients in the urban group(Pvalue-0.03). Even though the prevalence of uncontrolled T2DM and osteoarthritis was more in the rural population, the difference between the two groups was not statistically significant. Similarly, the use of biologicals was more in rural (8%) compared to urban (4%) without any statistical significance.
Conclusion: We observed that baseline disease characteristics and disease activity were identical across both groups. At six months, CDAI and CRP were significantly higher in the rural than urban group suggesting that response to optimal DMARD treatment was better in the urban group than in the rural group. Triple DMARD use was also significantly higher in the rural compared to the urban group. This shows that despite the advances in rheumatology, there are still unmet needs regarding awareness and access to adequate treatment in rural society.

AB1608 THE EFFECT OF REMOTE AND FACE-TO-FACE PREVENTIVE REHABILITATION ON THE THICKNESS OF THE MUSCLES AROUND THE SPINE

Keywords: Telemedicine, Physical therapy/physiotherapy, Ultrasound

Y. Özel Aslıyüce[1], O. Ulger[1]. [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: In these days when it is extremely important to use resources efficiently, ways to reduce the cost caused by low back and neck pain are sought. Investigating the architectural features of the muscles around the spine is also an important part of this search [1]. It is a rational approach to prevent spinal problems before they occur, rather than to treat them. In addition, it is very important for the prevention of spinal health that these approaches can be offered at low cost in pandemic conditions and disadvantageous situations such as settlements in rural areas.
Objectives: This research aims to investigate the effectiveness of remote and face-to-face spinal stabilization exercises on the thickness and activation of the muscles around the spine in asymptomatic desk-based office workers.
Methods: Individuals between the ages of 18-55 who did not have chronic low back and neck pain were included in the study. While the face-to-face group exercised under the supervision of a physiotherapist, the telerehabilitation (TR) group exercised with video conferencing and asynchronous video recordings. Both groups performed progressive spinal stabilization exercises 3 days a week for 8 weeks. The thickness of the Internal Oblique, External Oblique, Sternocleidomastoideus and Upper Trapezius muscles at rest, and the thickness of the Transversus Abdominis (TrA) at rest and during contraction were measured with portable ultrasound (Sonostar, China) (Image 1). TrA activation was measured with a stabilizer. Compliance with exercise was evaluated with an exercise diary.
Results: 24 individuals, 12 in the face-to-face group and 12 in the TR group, with a mean age of 28.41(5.94) participated in the study. Age, gender distribution, and baseline values for muscles were similar between the groups (p>0.05). In both groups, right and left TrA resting and contraction, Internal Oblique thicknesses were increased (p<0.05). It was found that the level of activation of the TrA muscle, the thickness change during contraction, and the thickness of the internal oblique muscle developed more in the face-to-face group. In the TR group, on the other hand, an increase in Upper Trapezius thickness was observed (p<0.05) However, there was no significant increase in TrA activation level in this group.
Conclusion: According to preliminary results face-to-face exercise further improves the thickness, activation, and contraction amount of deep stabilizer muscles. TR, on the other hand, caused positive developments in the deep muscles, but also in the upper Trapezius muscle, which is the superficial muscle. The reason for this situation may be postural compensations that occur during remote exercise [2]. As a result, both methods cause an increase in muscle thickness around the spine. However, if possible, supervision during exercises that require intense attention, such as

stabilization exercises, can increase efficiency. In addition, further studies on compensations that may occur during exercise through TR may be instructive.

AB1609 ECONOMIC IMPACT OF HOSPITAL STAYS FOR UVEITIS PATIENTS IN THE UNITED STATES: AN ANALYSIS OF THE NATIONAL INPATIENT DATABASE

Keywords: Health services research, Uveitis, Epidemiology

K. Chauhan[1]. [1]*Southern Illinois University - School of Medicine, Rheumatology, Springfield, United States of America*

Background: Uveitis is the most common extraarticular manifestation in patients with spondyloarthritis. It may be the first presentation of spondyloarthritis. The combination of effects on vision, systemic disease and side effects of treatment have a significant impact on patient's life. Uveitis affects all age groups and results in visual impairment over a long duration of the patient's lifetime. Hence, treatment cost due to uveitis is similar to the common eye conditions such as cataract, age related macular degeneration and glaucoma.

Objectives: There is a lack of national level data regarding the medical cost of hospital stay of uveitis patients. The objective of our study is to identify health care expenses for patients hospitalized with uveitis in the United States.

Methods: The National Inpatient Sample (NIS) is used for this study. It is a de-identified, random sample data of inpatient hospitalizations in the United States. It is the largest all-payer database containing data on more than seven million hospital stays. Its large sample size is ideal for examining national estimates. We collected data from 2016 to 2020 and ICD-10 codes were used to identify uveitis cases. NIS uses the Clinical Classifications Software Refined (CCSR) categories which aggregates ICD-10 codes into 530 clinical categories. ICD-10 codes for inflammatory eye conditions are assigned to the category uveitis and ocular inflammation. Patients hospitalized with primary diagnosis of uveitis were included. Length of hospital stay; hospital charge and cost were collected. Charge is the amount hospital billed and cost represents the actual cost of hospital stay.

Results: Average charge for hospital stays for uveitis patient is approximately 60,000 US dollars and has increased from 2016-2020. Similarly, cost of hospital stays and length of stay increased during the study period. Majority of uveitis inpatients are discharged to home, smaller percentage are discharged to rehab, nursing home or to home health care. Results are shown in the Table 1.

Conclusion: Economic burden of inpatient uveitis on health care is significant and has continued to increase from 2016 to 2020. Strategy and policy for providing better outpatient care for uveitis patients would help in reducing the number of hospital admissions and costs of stay.

AB1610 NON-PHARMACOLOGICAL AND SELF-MANAGEMENT INTERVENTIONS FOR MAIN OUTCOMES IN RHEUMATOID ARTHRITIS PATIENTS: A SYSTEMATIC REVIEW

Keywords: Rheumatoid arthritis, Systematic review, Self-management

N. Nakhost Lotfi[1], P. Studenic[1,2], N. Weibrecht[3], G. Zauner[3], K. Fechner[4], T. Stamm[4], T. H. Jakobsen[5], T. S. Jørgensen[6], N. Popper[3,7], L. E. Kristensen[6], H. Radner[1]. [1]*Medical University of Vienna, Department of Internal Medicine 3, Division of Rheumatology, Vienna, Austria*; [2]*Karolinska Institute, Division of Rheumatology, Department of Medicine (Solna), Stockholm, Sweden*; [3]*dwh simulation services, dwh, GmbH, Vienna, Austria*; [4]*Medical University of Vienna, Institute for Outcomes Research, Center for Medical Data Science, Vienna, Austria*; [5]*DAMAN, P/S, Copenhagen, Denmark*; [6]*Copenhagen University Hospital, Frederiksberg and Bispebjerg, The Parker Institute, Department of Rheumatology, Copenhagen, Denmark*; [7]*Vienna University of Technology, Institute of Information Systems Engineering, Vienna, Austria*

Background: Rheumatoid arthritis (RA) is accompanied by considerable limitation of the functional abilities and a significant reduction of the patients´ quality of life (QoL).[1] Self-management has been proven to play a role in the improvement of well-being and functioning in daily life. With the help of digital tools, individualized self-management methods can become more accessible to patients.[2]

Objectives: We aimed to identify evidence on efficacy of non-pharmacological self-management interventions on core outcomes in RA. Results will inform development of self-management recommendations into the RheumaBuddy (RB) 4.0 app.

Methods: To identify evidence-based self-management interventions suitable for the inclusion in the app, a systematic literature review (SLR) was conducted. We included clinical trials or randomized controlled trials in adult (≥18years) RA patients, reported in German or English language and excluded nutritional supplements and interventional medical devices. Outcomes of interest were identified via RB4.0 as either predefined or individually used for symptom tracking in the app and agreed upon in an expert panel.

Results: Main outcomes identified and used in the SLR were pain, fatigue, mood, stiffness, and quality of life. In total, 125 studies from 644 identified articles were included for data extraction (Figure 1). Heterogeneity of the studies precluded a meta-analysis. The majority of studies used pain (n=100), mood (n=46) or fatigue (n=35) as outcome. Interventions were grouped into six main categories (Exercise, Diet, Psychosocial, Education, Multicomponent, and other). The number of studies with a significant positive effect on various outcomes per various intervention strategies are displayed in Table 1.

Conclusion: We identified a broad range of non-pharmacological, self-management interventions for RA patients which can be used to further develop self-management recommendations, for implementation into RheumaBuddy 4.0, a new generation of an algorithm-driven digital health tool, designed to support RA patients' disease self-management.

AB1611 INFLAMMATORY ARTHRITIS AND WORK: WHAT PROFESSIONAL ADAPTATIONS?

Keywords: Work-related issues, Inflammatory arthritides, Qualitative research methods

A. C. Rat[1], I. Thaon[2], D. Loyal[2]. [1]*Caen-Normandy University, UNICAEN, Inserm, UMR-S 1075 COMETE, PFRS, Caen, France;, Caen, France*; [2]*Université de Lorraine, APEMAC, Nancy, Nancy, France*

Background: Despite improvements in the management of inflammatory arthritis (IA), the disease still has a significant impact on work and the support for patients with professional difficulties remains insufficient. The questionnaires currently available to us evaluate the societal impact of impact of IA on work (e.g. productivity at work) but not individual intermediate criteria such as work difficulties or possible adaptations.

Objectives: The objective of the study was to better understand the difficulties encountered at work, the coping strategies used and the motivations of patients with IA to continue working. Only the occupational adaptations are presented here.

Methods: 32 individual semi-directed interviews and 2 group interviews were conducted with patients with IA recruited in consultations or by patient associations. The participants were recruited according to a. purposive sampling with maximum variation. Inclusion criteria were: age 18 to 65 years, have IA, be professionally active, have difficulties or concerns at work due to the disease. The interviews. were conducted with an interview guide and were recorded and transcribed in full. The thematic analyses were conducted using an inductive approach.

Results: The analysis of the adaptations implemented revealed 14 main themes: adaptation of positions, tasks and mobilizations; adaptation of equipment; support from colleagues; change of working time, changing schedules and night work; taking breaks at work, splitting activities; Teleworking; reorientation, training; recognition of the status of disabled worker; occupational medicine, administrative difficulties; ergonomists; trade unions; changing position, jobs or employers.

Examples of quotes from the interviews:

Themes	Quotes
Adaptation of positions, tasks and mobilizations	There are meetings that are too long 4-5 hours. There are several of us who get up and spend the meeting standing
Change of working time	Avantages ou désavantages, possibilité et opportunité de modifier le temps de travail, dispositions psychologiques, utilisation des RTT ou des jours de congé, pérennité du travail à temps partiel
Recognition of the status of disabled worker	I've seen too many people considered disabled...put in closets. You put them in an office, doing nothing, in jobs that don't exist. You're not useful
	I went before a commission of thirty people. They ask me to explain how my handicap poses a problem to me on a daily basis.
Administrative difficulties	I don't know how it's going
	These are insane procedures, it's practically a full-time job

Conclusion: Patients discuss multiple possible adaptations, their advantages, disadvantages and difficulties encountered. These data will be useful to occupational health professionals and clinicians in helping patients to keep their jobs in good conditions and develop appropriate services.

EFFICACY OVER TIME OF SUBLINGUAL POLYBACTERIAL VACCINES IN PATIENTS WITH RHEUMATIC DISEASES AND ACTIVE PHARMACOLOGIC IMMUNOSUPRESSION

Keywords: Vaccination/immunization, Innate immunity, Infection-related RMDs

I. Pérez - Sancristóbal[1], M. P. Álvarez Hernandez[1], S. Sanchez - Ramon[2], I. C. Morado[1], E. De la Fuente[2], C. Martinez Prada[1], D. Freites[1], V. Villaverde[3], B. Fernandez[1], G. Candelas[1]. [1]*Hospital Universitario Clinico San Carlos, Rheumatology, Madrid, Spain*; [2]*Hospital Universitario Clinico San Carlos, Clinical Immunology, Madrid, Spain*; [3]*Hospital Universitario de Mostoles, Rheumatology, Mostoles, Spain*

Background: Synthetic and biologic disease-modifying drugs (DMARDs) have improved the prognosis of systemic autoimmune diseases (SAD). However, concerns persist about infectious complications in these patients. Previous studies of our group have shownthat sublingual polybacterial vaccines decrease the rateo of recurrent respiratory tract infections (RRTI) and recurrent urinary tract infections (RUTI).
Objectives: We aimed to evaluate the number of respiratory and urinary tract infections during 2018-2021 in patients who received sublingual polybacterial vaccines until 2018, when their administration was discontinued due to regulatory issues.
Methods: A retrospective observational study was conducted from a cohort of patients with SAD who had received sublingual polybacterial vaccines between 2014 - 2018. From 2018 onward, the incidence of UTI and incidence of RUTI and RRTI was analyzed and compared with anual incidence prior to vaccine administration and after one year post-vaccination.
Results: RRTI and RUTI were analyzed in 41 patients with SAD and active immunosuppression during the years 2018-2021. A significant increase in the number of infections was observed from 2018 to 2021, compared to the post-vaccination year, for both RUTI (1.53±2.17 vs 0.63±1.13;p=0.005) and RRTI (1.63±2.32 vs 0.67±0.92; p=0.003). When categorizing by number of infections, we observed that despite the increase in the average number of RUTI and RRTI, approximately half of the patients had no infections in the 2018-2021 period (51.2% RUTI and 43.5% RRTI). Making a comparison with the pre-vaccine year, despite the increase in the number of infections during the 2018-2021 period with respect to the immediate post-vaccination, the number of RRTI episodes was still lower (1.61±2.26 vs 2.76± 2.57; p= 0.002), as was the number of RUTI (1.56±2.12 vs 2.69±3.07; p= 0.010).
Conclusion: The effect of sublingual polybacterial vaccines was maintained up to 3 years, with a significant decrease in infections with respect to the year prior to vaccination, suggesting that these vaccines may have long-term benefit. The number of respiratory and urinary tract infections increased during the years when the vaccine administration was not available. However, an absence of infections was also observed in half of the patients.

AB1613

MEFV GENE TEST – WHO'S ORDERING THEM AND WHY?

Keywords: Genetics/epigenetics, Diagnostic tests

S. Shan[1], M. Mian[1]. [1]*Northern Health, Rheumatology, Melbourne, Australia*

Background: Familial Mediterranean Fever (FMF) is a rare autosomal recessive illness of periodic fever syndrome that primarily affects the Mediterranean population [1]. No single specific diagnostic test exists to accurately diagnose FMF. Testing of the MEFV gene is the primary investigation of choice to support a diagnosis of FMF [2]. Little is known regarding MEFV testing within Australian cohorts.
Objectives: We aim to describe the pattern of ordering for FMF genetic testing via the ordering of MEFV gene, and the clinical circumstances surrounding its request in a large Australian referral centre.
Methods: We retrospectively identified all MEFV genetic testing ordered within a large public referral centre over a five-year period. We collected information regarding the clinical scenario indicating genetic testing, presenting symptoms and adherence to Tel HaShomer diagnostic criteria as well as whether the genetic testing impacted the final diagnosis.
Results: 64 MEFV genetic testing were ordered through the five-year period, seven were within the paediatric population. The median age of the cohort was 37, 56.3% were male sex. There is a median of five flares of FMF prior to MEFV testing with median time from last flare being two months. 53.1% of the tests were ordered in an inpatient setting, rest were through outpatient. Rheumatology ordered the most MEFV genetic testing in 67.2% of the cohort, followed by Infectious Diseases in 10.9% and General Medicine in 7.8% of the cohort. 79.7% of the participants satisfied the Tel HaShomer criteria for clinical diagnosis of FMF prior to genetic testing. MEFV genetic testing provided a positive diagnostic result in 21.9% (14 participants), there were seven homozygotes, seven compound heterozygotes and eight heterozygotes. Only one of the 14 participants with a positive MEFV test did not satisfy the clinical diagnostic criteria. A total of 36 mutated alleles were identified and M694V was the most frequent mutation appearing in 47.2% of the mutations identified. Peritonitis was the most common presentation in 67.2% of the cohort. One participant had amyloidosis as their presentation. 43.8% of the cohort was commenced on colchicine prior to genetic testing.
Conclusion: MEFV testing is most commonly ordered by Rheumatology than other specialities. While the genetic testing can be useful in a diagnostic dilemma, it also adds further diagnostic certainty if positive in those who satisfy the clinical diagnostic criteria.

AB1614

THE INCREASE IN SAFETY OUTCOME TRIALS AND THE ISSUE OF INFORMED CONSENT

Keywords: Randomized control trial, Safety

A. Ozdede[1], S. N. Esatoglu[1], H. Yazici[2]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, İstanbul, Turkey*; [2]*Academic, Hospital, İstanbul, Turkey*

Background: The randomized controlled trial (RCT) remains a most important research as well as a tool for drug licensing. Informed consent also remains an integral component of this tool. The exact wording of this consent is not in the public domain and we had previously raised that concern and had pointed out it should [1, 2]. As we previously indicated such transparency was important from the point of an organized skepticism an essential element of scientific inquiry [3]. Moreover, we had also indicated that this transparency was even more important in safety outcome trials (SOT)s. We have the impression that such SOTs are becoming more frequent especially with the increasing popularity of pragmatic trials [4] where the safety outcome measures are not infrequently as severe as death.
Objectives: To tabulate the frequency of RCTs with the primary outcome measure of safety in mainline general medicine journals at two time points, thirty years apart.
Methods: RCTs published in 1990-1991 vs 2019-2020 in NEJM, JAMA, LANCET and BMJ were searched by 2 independent reviewers (AO and SNE). Phase 1-2 RCTs, post-hoc analyses of RCTs and RCTs reporting long term follow-up data were excluded. RCTs with an undisputable primary endpoint of efficacy were defined as an 'A trial'. Those trials with declared or obvious primary endpoints of 'safety', 'efficacy and safety' or simply as 'efficacy' in which we unanimously considered the presence of serious harm to the patients in the control arms were defined as a 'B trial'. Finally, the trials that we could not unanimously decide whether designate A or B, were designated as C. Discrepancies were resolved after discussion with the senior author (HY) and if, even then, there was no consensus the trial remained as a C. We then compared the frequencies of the types of RCTs which were published in 1990-1991 vs 2019-2020. Other salient features, like the type and the practice setting, of these patients were also tabulated.
Results: There were 309 RCTs published in 1990-1991 and 600 RCTs published in 2019-2020. Nineteen RCTs on COVID-19 infection were excluded for

fair comparisons. As seen in the Table 1 there was a significant increase in the number SOTs in the later years. Moreover, the number of intensive care unit (ICU) trials, a setting in which obtaining informed consents can often be problematic, significantly increased.

Conclusion: Recently, there is a significant increase in the number of SOTs. Moreover, they are more frequently conducted in the ICUs. We strongly re-emphasize that the informed consents of all RCTs, particularly, those related to SOTs should be public. We strongly consider that such action is necessary a. to continue receiving our patients' vital consent to enable us to continue conducting RCTs and b. for justly addressing the organized skepticism of our peers.

AB1615 EVALUATION OF THE NOCEBO EFFECT WHEN SWITCHING FROM THE ORIGINATOR MOLECULE TO A BIOSIMILAR IN A NORMANDY RETROSPECTIVE COHORT OF PATIENTS WITH INFLAMMATORY RHEUMATISM TREATED WITH ETANERCEPT OR ADALIMUMAB (BIONORIC STUDY)

Keywords: Spondyloarthritis, Rheumatoid arthritis, bDMARD

O. Hagege[1], T. Lequerre[1], C. Marcelli[2], R. Varin[3], D. Alcaix[4], A. J. Weber[5], S. D. Mihailescu[6], E. Duhamel[3], O. Vittecoq[1]. *[1]Rouen, Rheumatology, Rouen, France*; *[2]Caen, Rheumatology, Caen, France*; *[3]CHU Charles Nicolle, Clinical Pharmacology, Rouen, France*; *[4]Groupe Hospitalier du Havre, Rheumatology, Montivilliers, France*; *[5]Évreux, Rheumatology, Évreux, France*; *[6]Évreux, Public Health, Évreux, France*

Background: The cost of treating the major inflammatory rheumatic diseases (rheumatoid arthritis and spondyloarthritis) has increased dramatically since the advent of biotherapies (bDMARD). However, the appearance of the first biosimilars has led to significant healthcare savings. However, the sometimes-negative perception of these treatments by patients and practitioners can lead to the appearance of a nocebo effect.

Objectives: To measure the prevalence of the nocebo effect after switching from an adalimumab (ADA) or etanercept (ETA) originator to one of their biosimilars.

Methods: 183 patients from 4 hospital centers in Normandy (Rouen and Caen University Hospitals, Le Havre and Evreux Hospitals) were included between January 2018 and July 2022 in this retrospective study, within the framework of the Article 51 biosimilars experiment. The subjects had an inflammatory rheumatism (RA or AS) in remission, treated with ADA or ETA originator biological treatment before being switched to a biosimilar. The occurrence of a nocebo effect was considered in patients who did not maintain treatment at 12 months and had a subjective side effect. A comparative analysis of the quantitative data collected was performed before and after the switch. The side effects that led to the discontinuation of the biosimilar were identified. During the switch, a questionnaire was distributed to 30 patients to describe the topics discussed during the consultation and their feelings about the biosimilar. Finally, a univariate and then multivariate analysis was performed to identify potential risk factors associated with the occurrence of a nocebo effect.

Results: The nocebo effect was measured in 13.1% of patients. It was also noted that 9.2% of the group study had presented a side effect objectified by the rheumatologist, and 1.6% mixed side effects. Were considered subjective side effects the sensation of rheumatic recrudescence without objective element found, as well as a certain number of complaints. There were 15.3% of patients who experienced a reactivation of their rheumatism, 8.2% an intolerance, 1.6% an infectious event, 0.5% an allergic reaction. Concerning the evolution under treatment, the comparative analysis did not show any significant difference before and after the switch for the measured parameters, except for the duration of morning stiffness duration in the AS group ($p = 0.01$). Univariate and multivariate analysis did not identify any risk factors associated with the occurrence of a nocebo effect. The responses to the questionnaire made it possible to observe the themes discussed during the consultation (mainly efficacy and cost). The majority of patients interviewed reported that the biosimilar was identical to the originator in terms of safety, efficacy, mode of use and pain at the injection site.

Conclusion: The occurrence of a nocebo effect following a switch to a biosimilar remains acceptable regarding the savings made. It appears less frequent when the switch is supervised by the practitioner, in contrast to the rare data in the literature, where the results differ when the substitution is systematic (up to 33% in some countries). The occurrence of such an effect can be explained by a bad perception of the patient. Therapeutic education as well as a shared medical decision between patient, rheumatologist and pharmacist seems to be essential in a certain population of patients which remains to be defined.

AB1616 ADHERENCE TO THE LIFE'S ESSENTIAL 8 METRICS AND HYPERURICEMIA : A CROSS-SECTIONAL STUDY

Keywords: Lifestyles, Non-pharmacological interventions, Epidemiology

W. Yang[1], L. Cui[2]. *[1]North China University of Science and Technology affiliatedl Hospital, Department of Rheumatology and Immunology,Tangshan, China*; *[2]Kailuan General Hospital, Department of Rheumatology and Immunology, Tangshan, China*

Background: Hyperuricemia (HUA) which with a pooled prevalence of 16.4% in mainland China (1) , is a known cause of gout and is linked to chronic disorders such as myocardial infarction, stroke, type 2 diabetes, chronic renal disease, and cardiovascular morbidity (2,3) . The preventive factors against hyperuricemia are thought to be health-related behaviors and factors. As a result, suggestions for healthy habits have been incorporated into the most recent gout and HUA therapy recommendations (4) . Recently, the American Heart Association released their latest cardiovascular health metric "Life's Essential 8" (LE8M) [5]. The LE8M defined cardiovascular health with eight criteria. It contained five health behaviors (nicotine exposure, physical activity, diet, body mass index, and sleep health) and three health factors (blood lipids, blood pressure, and blood glucose). To confirm whether the LE8M could apply to HUA, these beneficial effects in cardiovascular could apply to the HUA, we looked at the connection between adherence to the LE8MScore and the likelihood of having hyperuricemia using the cross-sectional data of more than 90,000 Chinese participants from the Kailuan Study.

Objectives: Although several individual cardiovascular healths are associated with uric acid status, the association of overall cardiovascular health with hyperuricemia remains unclear. We thus examined the association between the Life's Essential 8 metrics and odds of having hyperuricemia in a Chinese adult population.

Methods: Included were 92,912 Chinese participants of the Kailuan Study (mean age: 51.32±12.45y). The Life's Essential 8 metrics were calculated based on five health behaviors (nicotine exposure, physical activity, diet, body mass index, and sleep health) and three health factors (blood lipids, blood pressure, and blood glucose). hyperuricemia was defined as serum uric acid concentrations of ≥7mg/dl for men and women. Association between the Life's Essential 8 metrics and hyperuricemia was assessed using multiple logistic regression models, adjusting for age, sex, marital status, education, income level, alcohol drinking, triglyceride and renal function.

Results: High the Life's Essential 8 metrics score was associated with low odds of having hyperuricemia (adjusted OR for quartile 4 vs. quartile 1=0.64; 95% CI, 0.59 to 0.70; P-trend, <0.001), after adjusting for potential confounders. The association between the Life's Essential 8 metrics and hyperuricemia was more

pronounced among women and younger participants (<45y), compared with their counterparts.
Conclusion: The Life's Essential 8 metrics was associated with a low likelihood of having hyperuricemia in Chinese adults.

AB1617 DIFFERENCES IN ACCESS TO RHEUMATOLOGICAL CARE OF PATIENTS WITH CHRONIC POLYARTHRITIS AND CONNECTIVE TISSUE DISEASES: A PILOT STUDY USING INTERACTIVE PROCESS MINING ANALYSIS

Keywords: Health services research

A. Madrid García[1], J. L. Bayo-Monton[2], J. C. Estevez-Muñoz[3], G. Ibañez-Sanchez[2], Y. Lopiz-Morales[4], C. Fernández-Llatas[2], L. Rodriguez Rodriguez[1]. *[1]Hospital Clinico Universitario San Carlos, Rheumatology, Madrid, Spain*; *[2]Valencia Polytechnic University, Instituto Universitario de Tecnologías de la Información y Comunicaciones, València, Spain*; *[3]Gerencia Asistencial Atención Primaria, Research Unit, Madrid, Spain*; *[4]Hospital Clinico Universitario San Carlos, Orthopedic Surgery, Madrid, Spain*

Background: Process mining is a research discipline used to derive process-related knowledge from data on event occurrences at different times. In the healthcare domain, these techniques can be applied to outpatient processes to extract information regarding how they take place and identify inefficiencies or points form improvement.
Objectives: Our aim was to analyze how patients that receive a diagnosis of chronic polyarthritis (CP; including conditions such as rheumatoid arthritis and undifferentiated arthritis) or connective tissue diseases (CTD; such a Systemic Lupus Erythematosus, scleroderma or vasculitis) access a tertiary care level rheumatology outpatient clinic, using novel process mining techniques.
Methods: Retrospective study, including patients first seen at the Hospital Clínico San Carlos Rheumatology Outpatient clinic between 2016 and 2019, belonging to the Hospital Clínico San Carlos Musculoskeletal Cohort. We included those patients receiving ICD10 diagnostic codes, by their attending rheumatologists, compatible with Adult-onset Still's disease, undifferentiated polyarthritis, polymyalgia rheumatica and rheumatoid arthritis (which were later grouped under the category of "chronic polyarthritis"), and myositis, antiphospholipid syndrome, sarcoidosis, Behçet disease, polymyositis, scleroderma, mixed connective tissue disease, Sjögren syndrome, systemic lupus erythematosus, vasculitis and Raynaud's syndrome (which were later grouped under the category of "connective tissue diseases"). Information regarding outpatient activity at the Rheumatology clinic (dates of appointments, if they were a first visit in the clinic or a revision, and which department requested the appointment) was obtained from the Hospital Information System (HIS). Process Mining techniques were used to visualize the pathways followed by the patients included in both categories, and to highlight differences.
Results: 174 patients with CTDs and 341 patients diagnosed with CPs were analyzed. Regarding CPs, most patients were initially referred from Primary Care. Furthermore, most of those patients were not referred from other departments. However, we also can see that some patients undergo several referrals from different departments. Regarding CTDs, although Primary Care seems to be the most common level of referral, other origins are more likely. When the pathways of both disease classifications are compared (Figure 1), we can observe that, compared with CPs, CTDs, have a lower chance of being referred from the Orthopedic Department ("TRA-REU" node in blue) and a higher chance of being referred from "other departments" in secondary care ("REU" node in red). Furthermore, it is less likely that a patient with CTD undergo referrals from different departments and care levels during follow-up (seeing by the lines in blue color connecting the nodes "TRA-REU", "URG-REU", "PRI-REU", and "REU Rev").
Conclusion: In this pilot analysis, we have observed that the pathways followed and the referral departments of the patients diagnosed with CPs and CTDs are different. Process mining can be a very useful tool to characterize and identify the pathways that patients undergo within the healthcare system, across levels and specialties.

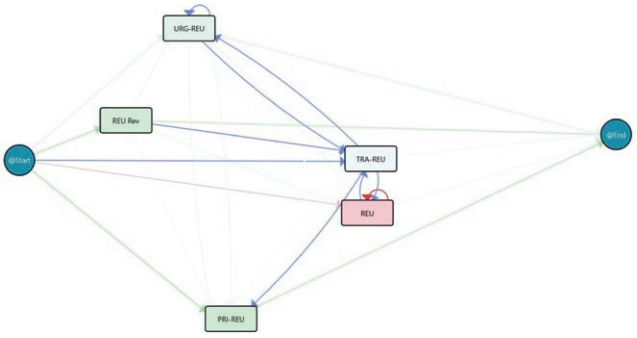

Figure 1. Differences in pathways followed by subjects with connective tissue diseases and chronic polyarthritis (Reu Rev: appointments generated by the emergency rheumatology department; URG-REU: appointments generated by the emergency department; PRI-REU: appointments generated by Primary Care; TRA-REU: appointments generated by the orthopedic department; REU: appointments generated by other departments in secondary care)

AB1618 OUTCOMES OF HEPATITIS B AND TUBERCULOSIS SCREENING IN A COHORT OF PATIENTS ON BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (BDMARDS) FOR RHEUMATIC DISEASE AT A MELBOURNE PUBLIC HOSPITAL

Keywords: Vaccination/Immunization, bDMARD, Quality of care

H. Pourhadi[1], A. Johnson[1], A. Foote[1]. *[1]Northern Health, Rheumatology, Epping, Australia*

Background: Screening for hepatitis B and tuberculosis is recommended prior to the commencement of biologic disease modifying anti-rheumatic drugs [1]. However, in routine clinical practice this can easily be overlooked, sometimes with severe consequences.
Objectives: We aimed to identify the percentage of patients screened for hepatitis B and tuberculosis prior to the commencement of bDMARDs in our rheumatology patients. We also determined if immunisation to hepatitis B was discussed in those with no serological evidence of immunity to the disease, and whether individuals with positive quantiferon gold (QTB) serology were referred for treatment prior to commencing bDMARDs.
Methods: All current rheumatology patients on bDMARDs at the Northern Hospital in Epping, Melbourne Australia were included in this study. By retrospectively reviewing the medical records, data was collected regarding patient demographics, clinical information and pre-treatment screening results including hepatitis B and QTB serology. Ethics committee approval was sought from our institution (Reference number: ALR 63.2020).
Results: There were 138 patients on bDMARD included in this analysis. 97 (70%) were female with a mean age of 51 (SD +/-15) at the time treatment was commenced. Rheumatoid arthritis was the most common indication for biologic

therapy (67%) followed by ankylosing spondylitis (15%) and psoriatic arthritis (14%). Tumour necrosis factor inhibitors (TNFi) and Janus kinase inhibitors (JAKi) were most often utilised, prescribed to 72% and 13% of patients respectively. Prior to commencing bDMARDs, 128 (92%) patients were screened for hepatitis B infection. All of these individuals had hepatitis B surface-antigen (HBsAg) tested; 106 (76%) had Hepatitis B surface-antibody (HBsAb) tested and 92 (67%) had hepatitis B core antibody (HBcAb) tested. Among patients screened, 33 (25%) demonstrated immunity to hepatitis B either by previous infection (6%) or vaccination (19%), 1 (1%) were positive for HBsAg and 100 (75%) were susceptible to infection. Of these susceptible individuals, one (1%) was advised to have the hepatitis B vaccinations prior to commencing bDMARDs. Screening for tuberculosis with QTB serology was performed in 125 (90%) patients. Seven (5%) had a positive result and three (2%) were indeterminate. All patients with positive QTB results were referred to infectious diseases for treatment.

Conclusion: Patient demographics such as age, sex and indication for biologic therapy were similar to other bDMARD registries. Pre-treatment screening for hepatitis B was undertaken in most patients and demonstrated a significant number of non-immune individuals. Counselling on the importance of vaccination prior to commencing bDMARDs was rarely documented. There is a need for further counselling on the importance of immunisations in patients on bDMARDs and better access to vaccinations in public hospital rheumatology clinics.

AB1619 THE INCIDENCE, PREVALENCE AND CHARACTERISTICS OF RHEUMATOID ARTHRITIS ON ARUBA INDICATE AN UNMET NEED FOR AN EARLY ARTHRITIS CLINIC

Keywords: Rheumatoid arthritis, Qualitative research methods, Epidemiology

R. Rellum[1], M. Zethof[2], J. Van Nies3, R. Thurlings[4], A. Den Broeder[4], M. T. Nurmohamed[5]. *[1]dr. Horacio E. Oduber Hospital, Rheumatology, Oranjestad, Aruba*; *[2]Radboud University Medical Centers, Medical Student, Nijmegen, Netherlands*; *[1]dr. Horacio E. Oduber Hospital, Rheumatology, Oranjestad, Aruba*; *[4]Radboud University Medical Centers, Rheumatology, Nijmegen, Netherlands*; *[5]Amsterdam University Medical Centers, Rheumatology, Amsterdam, Netherlands*

Background: A long unmet need was fulfilled in January 2019 with the start of a rheumatology outpatient clinic on Aruba.

Objectives: to assess the incidence, prevalence and patient- and disease characteristics of Rheumatoid Arthritis (RA) on Aruba.

Methods: In this cross- sectional study all health records from RA patients, with an outpatient hospital visit between January 1st of 2019 and 30th of June 2022, were accessed from the hospital database Cerner. Prevalence and incidence rates were determined.

Results: The point prevalence of RA on Aruba (06/30/2022) in the insured population (n = 110.000, i.e. 96% of the total population) was 0.37% (95% C.I.: 0.34% - 0.41%) he estimate half year incidence of RA on Aruba was 0.012%. The female: male ratio within RA patients on Aruba was 4.97:1 with prevalence of 0.57% in women and 0.13% in men. Approximately 25% of RA patients on Aruba had erosions and/or bony deformations, 7% already at time of hospital diagnosis. There was a general delay of 2.5 years since start of symptoms onset until the time of diagnosis.

Conclusion: This study suggests that the prevalence of RA on Aruba is significantly lower than the global, European and North American, pooled prevalence's of 0.46%, 0.54% and 0.70%, respectively [1]. We observed a very long patient – hospital delay, with significantly more joint damage in the newly diagnosed RA patient in comparison to other clinics. Obviously, there is a clear need for an earlier referral of RA patients by primary care physicians to the hospital. Development of an Early Arthritis Clinic could facilitate this process and would ultimately decrease the joint damage of our RA patients.

AB1620 EMERGENCIES IN RHEUMATOLOGIC DISEASES: A REAL-LIFE EXPERIENCE FROM AN ITALIAN RHEUMATOLOGIC CENTRE

Keywords: Epidemiology, Real-world evidence, Best practices

I. Cristiano[1], P. Triggianese[1], C. Minerba[1], A. D'antonio[1], C. Bonini[1], L. Fiannacca[1], A. Bergamini[1], M. S. Chimenti[1]. *[1]Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata, Rome, Italy*

Background: Patients with rheumatic diseases (RDs) may present with severe and/or life-threatening conditions which might require hospitalization. RDs recognize a significant diagnostic delay because of variability of clinical features, often mimicking other systemic disorders. Accordingly, patients requiring hospitalization for new-onset emergencies should raise the suspicion of RDs also in absence of a known rheumatologic diagnosis.

Objectives: In this observational single-centre real-life study we analyse prevalence, distribution and management of RDs among patients hospitalized in a 3rd level Rheumatologic ward.

Methods: We collect demographic and clinical data from medical records of patients hospitalized in the Rheumatologic ward of "Tor Vergata" University Hospital in Rome (Italy), between 1st June 2021 to 31st December 2022. Patients are divided into two groups: known RDs at admission (Group 1) and new rheumatologic diagnoses (NRDs) at discharge (Group 2). Mean and standard deviation (SD) express normally distributed variables. Continuous variables are compared with T test, categorical variables by using Chi-square or Fisher's exact test. $P<0.05$ values are considered statistically significant.

Results: The study cohort includes 179 patients (56% women) with a mean age at hospitalization of 62 ±16 y.o. Most of patients (68%) comes from Emergency Room (E.R.), and half of them (47%) has a defined diagnosis of RD at admission (Group 1). Patients admitted for suspected RD are 47 (26% of study population): among them, most cases (n=35, 74%) has NRD at discharge (Group 2). Comparing Group 1 (n=85, 63±14 y.o.) with Group 2 (n=35, 57±19 y.o.) we observe no difference in women prevalence (63% vs 51%) and referral from E.R. (58% vs 74%). Interestingly, diagnosis of rare rheumatological diseases (RRDs) occurs in a similar prevalence in Group 1 (n=37, 43%) and Group 2 (n=14, 40%). The most common reason for hospitalization in Group 1 is disease-flare (53%), followed by acute RD-related complications (27%) and treatment failure (20%). Patients from Group 2 are mainly hospitalized for new-onset severe joint pain (71%) while myalgia (11%), neuropathy (11%) and fever of unknow origin (6%) represent rare cases. In Group 2 a significantly higher proportion of severe inflammatory arthritis ($P=0.008$) and myositis ($P<0.05$) is observed than Group 1. In the two groups we register a similar prevalence of systemic vasculitis, connective tissue diseases, systemic sclerosis, autoinflammatory diseases and primary antiphospholipid syndrome. A slightly higher proportion of patients is treated with steroids in Group 2 than in Group 1 (66% vs 55%). A quarter of patients receives csDMARDS in a similar prevalence; bDMARDs are used only in patients from Group 1 (7%). Rare cases from both groups are treated with intravenous immunoglobulin and prostanoids. In patients with non-rheumatological diseases at discharge (n=59) respiratory (51%) and renal disorders (34%) represent the main reasons for admission. Comparing them with patients with RD diagnosis (Group 1 + Group 2, n=120), a significantly higher prevalence of referral from E.R. results in the first group ($P=0.002$, Table I).

Conclusion: A relevant rate of RRDs occurs among patients requiring hospitalization in a similar prevalence between RDs and NRDs. Moreover, a new rheumatologic diagnosis is confirmed in most patients referring to E.R. in whom emergencies are suspected to be related to RDs. Accordingly, our preliminary data suggest that clinical suspicion for RDs and, thus, early referral to the Rheumatologic Unit should be adequately addressed also among patients from E.R. to improve the diagnostic delay in RD patients.

Table 1. Rheumatologic and non-rheumatologic patients from the study cohort

	Rheumatologic Diagnosis n=120	Non-Rheumatologic Diagnosis n=59
Women, n (%)	71 (59%)	29 (49%)
Age, years (mean±SD)	61±16	65±16
Caucasian, n (%)	117 (97%)	57 (97%)
Referral from E.R., n (%)	74 (62%)	49 (83%)
Duration of hospital stay, days (mean±SD)	10±11	9±7

AB1621

REFERRAL BEHAVIOUR OF PRIMARY CARE DOCTORS TO RHEUMATOLOGY CLINIC IN MALAYSIA

Keywords: Quality of care, Health services research

C. R. Ng[1]. [1]*Hospital Pakar Sultanah Fatimah, Rheumatology Unit, Department of Medicine, Johor, Malaysia*

Background: The workload at rheumatology clinics have been growing relentlessly and an audit on new. referrals helps to identify referral behaviour of primary care doctors and improvement can be done by providing further training.
Objectives: To audit on new referral cases to rheumatology clinic from 2020-2022 and to identify new cases with misdiagnosis for future training purpose.
Methods: This was a retrospective study. The medical records of all new referral to rheumatology clinic Hospital Sultan Ismail and Hospital Pakar Sultanah Fatimah from 1st January 2020 to 31th November 2022 were reviewed. The referral diagnosis and final diagnosis were identified and analysed.
Results: There were total of 927 new cases referral throughout the 35 months during Covid-19 pandemic. Majority of them were diagnosed to have rheumatoid arthritis (217/927) followed by systemic lupus erythematosus (190/927), psoriatic arthritis (147/927), gout (62/927), osteoarthritis (58/927), systemic sclerosis (25/927), ankylosing spondylitis (25/927), soft tissue rheumatism (24/927), Sjogren syndrome (24/927), mixed connective tissue disease (14/927), vasculitis (11/927), fibromyalgia (10/927), polymyositis (7/927) and miscellaneous (39/927). 45 out of the new cases were diagnosed as unlikely rheumatic diseases. There were 29 pending cases awaiting final diagnosis. 212 of the referrals were identified as misdiagnosis with the highest as nodal osteoarthritis. (55/212) followed by unlikely rheumatic disease (43/212), soft tissue rheumatism (24/212), psoriatic arthritis (20/212), Sjogren syndrome (14/212), gout (8/212), rheumatoid arthritis (7/212), fibromyalgia (6/212), systemic lupus erythematosus (5/212), ankylosing spondylitis (4/212), mixed connective tissue disease (3/212), systemic sclerosis (2/212), polymyositis (2/212) and others (19/212): diffuse idiopathic skeletal hyperostosis, hypermobility syndrome, RS3PE syndrome, idiopathic uveitis, graft versus host disease, juvenile idiopathic arthritis, antiphospholipid syndrome, hypothyroidism, post streptococcal arthritis, prolapsed intervertebral disc, cerebrovascular disease, traumatic sternoclavicular joint subluxation, ledderhose disease, paraspinal muscle spasm and viral myalgia).
Conclusion: Nodal osteoarthritis and soft tissue rheumatism can be great mimicker for inflammatory. arthritis and if wrongly diagnosed will lead to unnecessary anxiety or wrong treatment. More training is needed to improve clinical skills amongst primary care doctors.

ARTRO 360: NEW MANAGEMENT MODEL TO PROGRESS IN THE TREATMENT OF OSTEOARTHRITIS BY OPTIMIZING THE AVAILABLE RESOURCES

Keywords: Quality of care, Health services research, Osteoarthritis

N. Martínez Fernández[1], J. Verges[2]. [1]*Osteoarthritis Foundation International, R&D, Barcelona, Spain*; [2]*Osteoarthritis Foundation International, President & CEO, Barcelona, Spain*

Background: Osteoarthritis (OA) is the most common chronic joint disease and poses a growing public health problem. In Spain, 7 million people suffer from OA [1], and only hip and knee OA represent an average annual cost of 4,738 million euros for the Spanish Health System. In 2016, more than one hundred thousand hip and knee prostheses were placed in Spain [2]. OA generates direct costs and considerable indirect costs for the National Health System, like the associated reduced productivity and labor costs. Therefore, a new OA management model is needed to reduce these expenses by optimizing the available resources.
Objectives: Design and validate a new management model that improves healthcare quality, security, and communication of OA patients.
Methods: The Osteoarthritis Foundation International (OAFI), with the collaboration of the Spanish Association of Osteoporosis and Osteoarthritis (AECOSAR), made an initial proposal with a multidisciplinary expert committee. The different proposals have been reviewed and ratified by scientific and professional organizations of physicians, pharmacists, nurses, and patients.
Results: The model is based on the needs expressed by OA patients and states how the different specialists should intervene and prescribe the most appropriate therapeutic option. The model has three levels of action: preclinical, clinical, and disabling clinical. Several Spanish scientific societies like SEAUS, SECA, SECOT, SETRADE, SER, SEMERGEN, SEMG, semFYC, SEFAC, SEIOM, and SEMDOR have supported the model. The model was presented in the Spanish Senate on September 28th, 2021, and it is being disseminated to the health departments at a regional level. Below are some of the proposals for the model:

- •Promote the participation of patients and professionals in public health policies, research, and management models.
- •Involve the patient in the decisions that affect them, making them responsible for their health and self-care.
- •Accelerate the diagnosis.
- •Facilitate access to optimal pharmacological and non-pharmacological treatment, taking into account the comorbidities and needs of the patient.
- •Raise awareness of the relevant role of patient organizations as an active resource that complements the portfolio of services, strengthens professionals, and produces significant economic savings.

Conclusion: OA is the most common chronic joint disease and poses a growing public health problem. OAFI, with the support of several scientific societies, has developed a new management model to progress in treating OA by optimizing the available resources. With this program, it will be possible to reduce the cost of OA by approximately 100 million euros while improving the quality of health care for our patients. To implement it, it is essential to take coordinated action by health authorities, scientific health authorities, scientific and professional societies, patient organizations, and other relevant organizations.

INFLAMMATORY RHEUMATISM AND WORK: WHAT DIFFICULTIES IN RELATION WITH THE CHARACTERISTICS OF THE JOB?

Keywords: Inflammatory arthritides, Qualitative research methods, Work-related issues

A. C. Rat[1,2], I. Thaon[3], D. Loyal[3]. [1]*Caen-Normandy University, UNICAEN, Inserm, UMR-S 1075 COMETE, PFRS, Caen, France;, Caen, France*; [2]*University Hospital Center of Caen, Rheumatology, Caen, France*; [3]*University De Lorraine, APEMAC, Nancy, Nancy, France*

Background: Despite improvements in the management of inflammatory arthritis (IA), the disease still has a significant impact on work and the support for patients with professional difficulties remains insufficient. Occupational physicians and occupational health specialists are not all aware of the specific impact of IA on difficulties at work and sometimes think that all patients complaining of physical limitations are identical and require the same support.
Objectives: The objective of the study is to better understand the difficulties at work, in particular difficulties related to the employment characteristics of patients with IA.
Methods: 32 individual semi-directed interviews and 2 group interviews were conducted with patients with IA recruited in consultations or by patient associations. The participants were recruited according to a. purposive sampling with maximum variation. Inclusion criteria were: age 18 to 65 years, have IA, be professionally active, have difficulties or concerns at work due to the disease. The interviews. were conducted with an interview guide and were recorded and transcribed in full. The thematic analyses were conducted using an inductive approach.
Results: The analysis of difficulties related to the characteristics of the employment of patients with IA are numerous: physical load of the workstation; speed required by the job; simultaneous tasks; multiple tasks and flexibility; workload; working hours and schedules; routine, scheduling, commuting, job awareness, responsibilities and moral demands; cognitive characteristics; conflict of values; skills and experience; interpersonal characteristics; lack of material resources, inappropriate premises; autonomy, environment and culture of the company; productivity demands and evaluations, job insecurity or security; perceived maladjustment; isolation; lack of recognition. The difficulties are not always specific to patients with IA but are clearly aggravated by the disease for a good number of them. The patients describe the specificities of their difficulties.
Conclusion: Patients discuss multiple characteristics of employment that can be a hardship or an advantage. They explain how the disease makes these characteristics difficult for them. These data will be useful to occupational health occupational health professionals and clinicians to help patients keep their jobs in good condition and develop appropriate services.

These data will help to improve the training of occupational health occupational and to develop a questionnaire for the assessment of the work situation of patients with IA.

AB1624 MUSCULOSKELETAL PROBLEMS IN YOUNG DOCTORS

Keywords: Epidemiology, Pain, Work-related issues

I. Sellami[1], A. Feki[2], M. A. Ghrab[1], M. Hajjaji[1], K. Jmal Hammami[1], S. Baklouti[2], M. L. Masmoudi[1]. [1]*Hedi Chaker Hospital, University of SFax, Occupational Medicine, Sfax,Tunisia*; [2]*Hedi Chaker Hospital, University of SFax, Rheumatology, Sfax,Tunisia*

Background: Musculoskeletal problems (MSP) represent a major problem in the general population and also in occupational settings. Young interns and residents in medicine are exposed to different types of physical constraints (e.g., working long hours, lifting and carrying heavy objects, repetitive movements, etc.), which may lead to musculoskeletal disorders.

Objectives: Evaluate MSP in interns and residents working in the University Hospitals of Sfax, Tunisia.

Methods: We conducted a study during the month of January 2023 using the Nordic questionnaire to screen MSPs. The questionnaire was self-administrated and evaluated along with MSPs on the sociodemographic characteristics and perceived work strain measured with the borg scale.

Results: Our population consisted of 147 interns and residents. The sex ratio was 0.48 and the mean age was 25.41±2.12. Most participants were interns and 1st-year residents (53.7% and 19.7% respectively). Smokers represented 5.4% of the total population. The mean Body Mass index was 22.77± 3.7 and 20.8 % of the population presented as overweight or obese. Among the participants, 6.1% had priors of MSPs. Sixty young doctors (40.8%) reported practising a regular leisure activity with a mean of 3.76+-2.99 hours per week. The physical strain was 6.75± 2.32. Fifty-eight individuals (39.5%) reported having MSPs in the past year and twenty-four (16.3%) during the past week. Neck pain was the most frequent complaint (37.9%) in the past year followed by back pain (24.13% for the upper back and 22.4% for the lower back). The higher perceived physical strain was associated with more frequent musculoskeletal problems during the previous week ($p<0.01$) and priors of MSP were associated with more frequent complaints in the previous year($p<0.01$). BMI was not associated with the presence of MSPs. Smoking tobacco seemed to be a protective factor against neck pain ($p=0.016$).

Conclusion: Exposure to musculoskeletal constraints is frequent in interns and residents and is often underdiagnosed. More attention is needed for this young population to prevent them from developing chronic MSDs in the future.

AB1625 QUALITY OF LIFE OF PATIENTS WITH RHEUMATIC DISEASES

Keywords: Outcome measures, Quality of life, Comorbidities

M. Serrano Warleta[1], L. Villalobos Sanchez[1], A. Corral Bote[1], B. A. Blanco Cáceres[1], J. Bachiller-Corral[1], M. Vázquez[1], P. Lazaro Y de Mercado[2]. [1]*Ramon y Cajal University Hospital, Rheumatology, Madrid, Spain*; [2]*Independent Health Services Researcher, None, Madrid, Spain*

Background: Patients with rheumatic diseases (RD) have more comorbidities and worse health-related quality of life (HRQoL) than the general population. It is recommended that HRQoL be collected in medical records, but it is rarely done in routine clinical practice [1]. RD are among the most common chronic diseases in the general population, which means a large consumption of resources in Primary and Specialized Care. Therapeutic decisions in Rheumatology are usually based on levels of activity measured with disease-specific tools. However, several studies have shown differences between what is perceived by the doctor and what is declared by the patient [2].

Objectives: HRQoL is considered an important indicator to assess the state of population health and measure the impact of medical actions [3,4]. The main objective of this study is to know the HRQoL of patients with RD and compare it with the general population.

Methods: Observational, cross-sectional, single-centre study, with consecutive inclusion of outpatients over 18 years of age seen in the rheumatology hospital outpatient clinic. Sociodemographic and clinical variables were collected, as well as HRQL measured with the 5-dimensional, 5-level EuroQoL (EQ-5D-5L), which includes the EQ-Index (0-1 scale) and a visual analogue scale (VAS, 0-100 scale). A descriptive analysis and a comparison with the Spanish population according to the National Health Survey were carried out.

Results: 1,144 patients were included, 820 (71.68%) of whom were women, with a mean age of 56.1 years (range 18-95). 241 (25.44%) were new patients. In patients with RD, the HRQoL measured with the EQ-Index and with the VAS, was 0.186 and 12 points lower, respectively, than in the general population. HRQoL affected the 5 health dimensions, especially "pain/discomfort", followed by "daily activities" and "mobility". This reduction in HRQoL was maintained in both men and women, and in all age segments, although it was greater between 18 and 65 years of age. The reduction in HRQoL affected all RD subtypes, especially the "Peripheral and axial mechanical pathology" and the "Soft tissue pathology" group.

Conclusion: Patients with RD report worse HRQL compared to the general population in all HRQoL dimensions.

ASSOCIATION BETWEEN PRIOR SEVERE CUTANEOUS ADVERSE REACTIONS(SCARS) AND SUBSEQUENT AUTOIMMUNE DISEASE RISK: A NATIONWIDE POPULATION-BASED COHORT STUDY

Keywords: Epidemiology, Real-world evidence, Safety

C. C. Chang[1,2], T. M. Lin[3], C. K. Chang[3], H. Lee[3]. [1]*Taipei Medical University Hospital, Allergy, Immunology and Rheumatology, Taipei, Taiwan, Republic of China*; [2]*School of Medicine, College of Medicine, Taipei Medical University, Allergy, Immunology and Rheumatology, Taipei, Taiwan, Republic of China*; [3]*Taipei Medical University Hospital, Allergy, Immunology and Rheumatology, Taipei, Taiwan, Republic of China*

Background: Life-threatening severe cutaneous adverse reactions (SCARs) include Stevens-Johnson syndrome/toxic epidermal necrolysis, acute generalized exanthematous pustulosis, and drug-induced hypersensitivity syndrome/drug reaction with eosinophilia and systemic symptoms. Previous report revealed that a gradual loss of regulatory T (Treg) cell function after resolution of SCARs may increase the risk of subsequently developing autoimmune diseases (ADs). The association between patients with SCARs and ADs remain unclear and are scarce.

Objectives: This study explored the association of SCARs with AD risk.

Methods: Individuals with SCARs between 2006 and 2015 were identified and 1:10 matched on age and sex with individuals without SCARs. We performed multivariate and stratified analysis using the Kaplan–Meier method and Cox proportional hazards models in order to estimate the association between SCAR cohort and the risk of developing ADs.

Results: A total of 26844 patients with SCAR and 268440 non-SCAR comparison subjects were selected from NHIRD. For individual organ-specific ADs, SCAR cohort as compared with non-SCAR cohort, adjusted hazard ratio (aHR) were higher for incident autoimmune hemolytic anemia (aHR 3.36, 95% CI: 1.84-6.13), Hashimoto's thyroiditis (aHR 2.26, 95% CI: 1.64-3.12), Henoch-Schonlein purpura (aHR 8.99, 95% CI:6.53-12.4) and inflammatory bowel disease were (aHR 9.78, 95% CI:5.27-18.5) (see Table 1). Furthermore, for individual systemic ADs, SCAR cohort as compared with non-SCAR cohort, aHR were higher for incident ankylosing spondylitis(aHR 1.56), psoriasis(aHR 10.39), polymyositis/dermatomyositis (aHR 10.39), rheumatoid arthritis(aHR 2.48), primary Sjogren syndorme(aHR 5.92), systemic lupus erythematosus(aHR 9.58), systemic sclerosis(aHR 7.56) and systemic vasculitis (aHR 13.54).(see Table 1)

Conclusion: Patients with SCARs have higher risk of ADs than patients with no SCARs. Further mechanistic research should be conducted.

DYNAMICS OF IMMUNOLOGICAL PARAMETERS IN PATIENTS WITH SLE DURING THE YEAR AFTER VACCINATION WITH 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE

Keywords: Systemic lupus erythematosus

G. Koilubaeva[1], G. Tarasova[2], B. Belov3, A. Bolotbekova[1], A. Turatbekova[1], G. Syunbai K[1]. [1]*3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan*; [2]*Kashirskoye Shosse, 34, Rheumatology, Moskva, Russian Federation*; [2]*Kashirskoye Shosse, 34, Rheumatology, Moskva, Russian Federation*

Background: Pneumococcal vaccination in systemic lupus erythematosus (SLE) is designed to reduce the risk of severe respiratory infections in this group of patients. The issues of vaccination safety remain relevant.

Objectives: to study the dynamics of immunological parameters in patients with SLE during the year after vaccination with 23-valent polysaccharide pneumococcal vaccine (PPV-23), their correlation with the clinical picture of the disease.

Methods: 78 patients with SLE were included in the study. 4 patients received monotherapy (GC-1, methotrexate-1, GC-1, anti-B-cell therapy-1), the rest received combination therapy, including 29 - anti-B-cell therapy. 3 groups of patients were identified for analysis: 1. patients (36) who received stable doses of immunosuppressive drugs. 2. patients (31) who had their medication doses reduced during the year. 3. patients (11) who received increased doses of medications during the year. The follow-up period was 12 months after vaccination.

Results: During the observation period, no new autoimmune phenomena, both clinical and laboratory, were recorded. Stable therapy group: in the first 1-3 months after vaccination, 4 out of 36 patients had a transient increase in a-DNA without an increase in ANF and without signs of exacerbation of the disease. Another 4 had an increase in ANF (1 had a transient increase), without an increase in a-DNA and without signs of deterioration. By 12 months, there was an increase in a-DNA in 4 and ANF in 5 patients. Moderate exacerbation of the disease was recorded in 3 patients (after 3.5 months, 5 months, 12 months): in the first case, persistently high immunological activity and clearly insufficient therapy were observed; in the second case, the exacerbation was not accompanied by an increase in immunological activity at all; in the third case, the exacerbation occurred after 12 months with a moderate increase in immunological activity

indicators. In all cases, the association with vaccination has not been verified. The group on the reduction of doses of therapy: 5 cases of a significant increase in a-DNA after 1-3 months were recorded: in 4-transient, in 1-with a transient increase in ANF, in all without signs of exacerbation. Moderate exacerbation was observed in 4 patients (after 4 months, 11.5 months, 12 months, 12 months), in 2 – without an increase in immunological activity, in 2 – with an increase in a-DNA and ANF by 11-12 months. The timing of the exacerbation, the cancellation of cytostatics in one case and a reduction in the dose of glucocorticoids in 3 cases did not allow the exacerbation to be associated with vaccination. Group of patients with increased therapy: no cases of significant increase in a-DNA, ANF, exacerbation of the disease was detected.

Conclusion: 1. The multidirectional dynamics of the main immunological markers observed during the year most likely reflects the immunological instability characteristic of SLE. 2. In the first 3 months after vaccination, in isolated cases, a transient increase in SLE markers is possible without symptoms of exacerbation of the disease. 3. During the year, there were no exacerbations significantly associated with vaccination. 4.There is no need for mandatory immunological monitoring 1-3 months after vaccination, clinical monitoring is necessary.

AB1628 THE INCIDENCE AND PREVALENCE OF RHEUMATOID ARTHRITIS IN ITALY IN THE LAST DECADE

Keywords: Registries, Epidemiology, Rheumatoid arthritis

M. Zen[1], L. Salmaso[2], C. Barbiellini Amidei[3], A. Giollo[1], U. Fedeli[3], S. Bellio[2], F. Arru[1], I. Gennaio[1], M. Saia[4], A. Doria[1]. [1]*University of Padova, Department of Medicine DIMED, Padova, Italy*; [2]*Azienda Zero, Veneto Region, Clinical governance Unit, Padua, Italy*; [3]*Azienda Zero, Veneto Region, Epidemiological Department, Padua, Italy*; [4]*Azienda Zero, Veneto Region, Clinical governance Unit, padua, Italy*

Background: Rheumatoid arthritis (RA) prevalence is believed to be around 1% worldwide, although it varies considerably among different populations.[1] Several environmental factors such as smoking, certain infections, and diet contribute to the risk of RA and differ between populations.[2] The pooled prevalence of RA was estimated to be 0.54% (95% CI 0.50–0.59) in Europe,[1] but no studies have recently evaluated the epidemiology of RA in Italy.

Objectives: We aimed at estimating the incidence and prevalence of RA in northeastern Italy over the period 2012–2020.

Methods: A retrospective population-based study was conducted in the Veneto Region (4.9 million people) using the Population Registry, an administrative health database where all residents are recorded. The population registry was linked with healthcare co-payments exemptions, hospital discharge records, and mortality records. Between 2012 and 2020, RA prevalence was defined by a healthcare copayment exemption for RA (national registry code 006) or any hospital diagnosis of RA (ICD-9-CM 714.x), whichever came first. Incident RA was defined from 2013 to 2020 to exclude prevalent cases. Standardized incidence and prevalence rates were reported by age and gender.

Results: During the study period, we identified 37,996 prevalent RA patients, with 12,875 incident cases. Across the study period, RA standardized prevalence increased from 0.50% (95% CI 0.50; 0.51) to 0.57% (95% CI 0.57; 0.58). RA point prevalence in 2020 according to gender and age is reported in Figure 1. RA incidence corresponded to 33.1 (32.5; 33.7) per 100,000 person-years, with the lowest incidence observed in the last two years of the study: 27.4 (25.9; 28.9) in 2020 and 32.2 (30.6; 33.8) in 2019 (Table 1). The peak for both prevalence and incidence was around the eighth decade of life. Incidence was 2-times higher in females: female-to-male incidence rate ratio (IRR) 2.3 (2.2; 2.4) (p<0.0001), with a peak among people aged 20-29 years, where female-to-male IRR was 3.1 (2.4; 3.9) and the lowest value among patients aged ≥70 years, where F:M IRR was 1.6 (1.4; 1.8).

Conclusion: The prevalence of RA in Italy is 0.57%, in line with data from other European countries. Incidence was confirmed to be higher among females, especially in younger patients.

AB1629 PREVALENCE OF MUSCULOSKELETAL AND WIDESPREAD PAIN IN A REPRESENTATIVE COHORT OF THE FRENCH GENERAL POPULATION

Keywords: Epidemiology, Pain

F. Bailly[1,2], A. Petit[3], S. Kab[4], V. Foltz[5], M. Badard[5], B. Fautrel[1,5]. [1]*INSERM UMRS 1136, Pierre Louis Institute of Epidemiology and Public Health, Paris,*

France; [2]*Assistance Publique - Hôpitaux de Paris, Pain Department, Paris, France*; [3]*CHU Angers, Centre de Consultations de Pathologie Professionnelle, Angers, France*; [4]*INSERM IMS011, Constances Department, Villejuif, France*; [5]*Assistance Publique - Hôpitaux de Paris, Rheumatology Department, Paris, France*

Background: Few studies include a sufficient number of people to be representative of a general population and to estimate the musculoskeletal pain prevalence.
Objectives: To estimate the prevalence of musculoskeletal and widespread pain in the French popualtion using a large and representative cohort.
Methods: The Constances cohort is composed of volunteers, aged 18 to 69 years at inclusion. Eligible subjects were selected at random by stratified sampling with unequal probabilities, over-representing individuals with a higher probability of not volunteering (according to their age, sex, socioprofessional category) with adjustment coefficients weight participation bias. Individuals diagnosed with a cancer were excluded. Musculoskeletal pain was assessed by the Nordic Questionnaire. Significant pain lasted at least 30 days during the last 12 months. Widespread pain concerned at least 4 of the 6 areas. Chronic moderate to severe pain reached a pain score ≥ 4/10 in the last 7 days. Data from the entire cohort were described and then the French population prevalence was estimated, based on people included in 2017 with adjustment coefficients.
Results: 193,436 people were included in the cohort. The French population prevalence of each pain location and widespread pain were estimated among the 25,472 people included in 2017.

	Pain prevalence in the cohort (%)	Moderate to severe pain prevalence in the cohort (%)	Pain prevalence estimation in the french population (% [SD])	Moderate to severe pain prevalence estimation in the french population (% [SD])
Back	24.6	16.0	25.9 [25.4-26.5]	17.9 [17.4-18.4]
Neck	16.6	10.4	17.1 [16.7-17.6]	11.2 [10.8-11.6]
Shoulder	16.3	9.4	17.0 [16.5-17.5]	10.5 [10.1-10.8]
Knee	18.9	11.1	19.8 [19.3-20.2]	12.4 [12-12.8]
Hand	14.0	7.7	14.7 [14.2-15.1]	8.5 [8.2-8.8]
Elbow	8.5	4.3	9.2 [8.2-9.6]	4.9 [4.7-5.2]
Widespread pain	7.0	3.	8.1 [7.8-8.5]	4.2 [4-4.5]

Conclusion: The prevalence of musculoskeletal pain in the French population is high, particularly for chronic pain of moderate to severe intensity, which underlines the need to improve their detection, prevention and management.

RISK FACTORS FOR CARDIAC INVOLVEMENT IN IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Cardiovascular disease, Heart, Myositis

K. Suzuki[1], Y. Kondo[1], S. Ishigaki[1], S. Takanashi[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Idiopathic inflammatory myopathies (IIMs) are heterogenous systemic autoimmune disorders that mainly affect the skin, muscles, and lungs. Whereas cardiac involvement is considered to be rare, it causes cardiac inflammation and fibrosis leading to severe morbidity and mortality. However, little is known about clinical characteristics and risk factors for cardiac involvement in patients with IIMs.
Objectives: The aim of this study was to clarify the frequency and clinical characteristics of cardiac involvement and its risk factors in patients with IIMs.
Methods: We retrospectively reviewed consecutive patients with IIMs who visited Keio University Hospital from 2002 to 2022. We divided patients into two groups according to the presence or absence of symptomatic cardiac involvement and compared their clinical characteristics and autoantibodies between the two groups. We defined symptomatic cardiac involvement as the presence of chest pain, palpitation, cardiogenic leg edema, or respiratory distress accompanied by abnormal findings of cardiac examinations such as electrocardiography, echocardiography, and/or cardiac magnetic resonance imaging (MRI).
Results: We included 145 patients with IIMs in the analysis. The mean age at IIMs diagnosis was 55 years old, and 71.7% were female. Forty patients (27.6%) were polymyositis, 53 (36.6%) were dermatomyositis, 44 (30.3%) were amyopathic dermatomyositis, and 8 (5.5%) were immune-mediated necrotizing myopathy. Among them, 52 patients (35.9%) had abnormal findings on electrocardiography, echocardiography, and/or cardiac MRI, and 17 (11.7%) were diagnosed with symptomatic cardiac involvement at the mean age of 65 years during the mean observation period of 20.0 years. Comparison of clinical characteristics identified no difference in the mean age, sex distribution, and duration from IIM diagnosis to symptomatic cardiac involvement between the two groups. Also, no significant difference was found in the positivity of anti-amynoacyl tRNA synthetase antibody, anti-MDA5 antibody, and anti-SS-A antibody, IIMs subtypes, presence of skin rash, malignancy, interstitial lung disease, history of cyclophosphamide use, and maximum levels of CK, aldolase, CK-MB, troponin T, and CRP. However, the presence of Raynaud's phenomenon and neutrophil/lymphocyte ratio at diagnosis were significantly higher in the cardiac involved group compared to the non-cardiac involved group (53.85% vs 15.24%, p=0.0009; 56.25% vs 18.25%, p=0.0006). Multivariable analysis identified Raynaud's phenomenon (odds ratio [OR] 8.42, 95% confidence interval [CI] 2.10-33.8, p=0.0026) and elevated neutrophil/lymphocyte ratio (OR 6.92, 95% CI 1.73-27.6, p=0.0061) as independent risk factors for symptomatic cardiac involvement. One patient in the cardiac involved group died of cardiac failure during the observation period.
Conclusion: Abnormal findings in cardiac examinations and symptomatic cardiac involvement are frequent in patients with IIMs. Evaluating cardiac involvement is important, especially in patients with Raynaud's phenomenon and elevated neutrophil/lymphocyte ratio at diagnosis.

ASSOCIATION BETWEEN HYPERURICEMIA AND HEARING IMPAIRMENT: RESULTS FROM THE KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY

Keywords: Gout

H. Jeong[1], Y. S. Chang[2], E. J. Park[3], C. H. Jeon[1]. [1]*Soonchunhyang University Bucheon Hospital, Internal Medicine, Bucheon, Korea, Rep. of (South Korea)*; [2]*Sanggye Paik Hospital, College of Medicine, Inje University, Otorhinolaryngology-Head and Neck Surgery, Seoul, Korea, Rep. of (South Korea)*; [3]*National Medical Center, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Hyperuricemia is associated with variety of comorbidities. Researchers suggest that the inflammation and increased oxidative stress produced by uric acid can impact the auditory system.
Objectives: This study investigated the association between hyperuricemia and hearing impairment in Korean adults.
Methods: Audiometric and laboratory test data from the 2019 to 2020 Korean National Health and Nutrition Examination Survey (KNHANES) were used for analysis. Hearing impairment was defined as a pure tone average (0.5,1,2,4 kHz) threshold level of ≥ 41 desibels (dB)s. Definition of hyperuricemia was different in males and females (>7 mg/dL in males and >6 mg/dL in females.
Results: A total of 4,857 (weight n = 17,990,725) subjects were analyzed. Mean age was 56.8 years old and female was 51.7%. Weighted prevalence of hyperuricemia was 12.1%. and hearing impairment was 13.4%. In univariable analysis, hyperuricemia was significantly associated with hearing impairment, but diagnosis of gout was not associated with hearing impairment. In multivariable analysis, hyperuricemia (Odds ratios [OR] 1.41, 95% confidence interval [CI] 1.03-1.92, p = 0.030) was associated with hearing impairment along with age (OR 1.12, 95% CI 1.10-1.14, p < 0.001), female (OR 0.43, 95% CI 0.34-0.64, p < 0.001), education (OR 0.43, 95% CI 0.30-0.63, p = 0.001), and occupational noise exposure (OR 1.67, 95% CI 1.25-2.22, p = 0.001). In subgroup analysis, hyperuricemia was associated with hearing impairment in female group and elderly group aged 60

years or older (OR 1.59, 95% CI 1.02-2.48, p = 0.041 and OR 1.45, 95% CI 1.05-1.99, p = 0.023, respectively).

Conclusion: Hyperuricemia was independently associated with hearing impairment especially in female and older ages.

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease mostly affecting the young women during their third-fourth decade of life. SLE is characterized by variable manifestations and, potentially, every organ can be involved. The course and the complexity of the disease, naturally appeal to manage patients with SLE at high qualified national referral centers. [1]

Despite the relevant burden associated with the disease, both from patient and physician point of view, epidemiological data on SLE in Italy are limited to isolated estimates, captured by different data sources [2-5]; however, no larger data on the prevalence of SLE at the referral centers in Italy are available to date.

Objectives: This study aimed at estimating the prevalence of SLE at tertiary referral Italian centers, representative of the Italian scenario.

Methods: We conducted an observational, cross-sectional study on SLE patients followed by referral centers in district, representative of the North, Centre, South and Isles of Italy (Brescia, Padua, Udine, Ferrara, Florence, Pisa, Rome, Bari, Naples, Cagliari). Data from patients of both sexes and any age, and fulfilling the 2019 ACR/EULAR classification criteria, were obtained from hospital medicals records. To estimate the prevalence, we reported the number of patients with SLE referring to the considered centers (numerator), over the total population resident in the included Italian districts (denominator), according to the Italian National Statistical Institute (ISTAT), responsible for the Italian general population censuses. For the analysis, we considered only complete data sent by January 13th, 2023. [7]

Results: We identified 3251 patients with SLE followed at n° 9 referral centers included in this study. 1163/3251 patients (89.3%) were female, and 1302/3251 (40%) were residing in the districts of the referral centers. The estimated overall prevalence of SLE was 21.37 cases per 100,000 individuals. As we stratified the results by geographical area (North, Centre, South and Islands) of Italy, the estimated prevalence ranged from 14.7 to 27.1 cases per 100,000 individuals. (**Table 1**)

Conclusion: Our study estimated the prevalence of SLE in multiple representative Italian referral centers. These preliminary results show for the first time the proportion of patients with SLE attending tertiary referral centers in Italy, suggesting a different distribution in diverse geographical areas of the country.

AB1633 PREVALENCE TREND OF EGPA AND ANNUAL CHANGES IN ORAL CORTICOSTEROID USE BY PATIENTS WITH EGPA FOLLOWING MEPOLIZUMAB AVAILABILITY IN JAPAN

Keywords: Real-world evidence, Epidemiology, Vasculitis

K. E. Sada[1], T. Suzuki[2], S. Joksaite[3], S. Ju[3], G. Mu[4], J. Logie[3], J. Hwee[5], H. Kunishige[2], T. Ishii[2], A. Adlak[6], H. Vadlamudi[6], R. Alfonso-Cristancho[4]. *[1]Kochi Medical School, Department of Clinical Epidemiology, Nankoku, Japan*; *[2]GSK K.K., VEO, Japan Medical and Development, Tokyo, Japan*; *[3]GSK, VEO, Brentford, United Kingdom*; *[4]GSK, VEO, Collegeville, PA, United States of America*; *[5]GSK, Epidemiology, Mississauga, Canada*; *[6]GSK, VEO, Bangalore, India*

Background: Treatment of eosinophilic granulomatosis with polyangiitis (EGPA) relies predominantly on corticosteroids which are associated with significant adverse effects when used long-term. Therefore, alternative corticosteroid-sparing therapies are needed. Mepolizumab specifically targets IL-5, a key driver of eosinophilic inflammation, and was approved in Japan for the treatment of EGPA in 2018.

Objectives: To describe the prevalence of EGPA over time and changes in OCS daily dose used by patients with EGPA in Japan.

Methods: This retrospective study used the Japanese health insurer claims database (JMDC) to describe EGPA prevalence 2005–2020. The Japanese hospital database (Medical Data Vision [MDV]) was used to describe annual mean daily doses of OCS used by patients with EGPA, comorbidities associated with OCS use, and relapse rates of EGPA 2010–2020. Patients with a record of EGPA in the year of interest and a record of allergic rhinitis, eosinophilic chronic sinusitis or asthma were included, excluding those with granulomatosis with polyangiitis and microscopic polyangiitis, before or during the year of interest. Relapse was assessed in patients who revisited the hospital and was defined as initiation of new OCS (non-OCS users), doubling of existing OCS daily dose, or use of injectable corticosteroid pulse therapy among patients who received continuous treatment from the previous year or earlier. A sub-analysis of the JMDC database assessed OCS daily dose used by patients with EGPA who initiated treatment with mepolizumab 300 mg 2018–2020.

Results: From the JMDC database, ~7.3 million subscribers were included for EGPA prevalence estimations. The reported annual crude prevalence of EGPA increased from 4.2 per million in 2005 to 58.6 per million in 2020 with a greater

prevalence in older age groups (prevalence per million in 2020: <18 years: 7.5; 18–39 years: 42.5; 40–64 years: 93.1; and 65–74 years: 181.3).
From the MDV database, 1870 patients with EGPA were included in 2020, 59.9% of whom were female, and 5.2% were aged 18–39 years, 36.4% 40–64 years, 30.6% 65–74 years, and 27.4% ≥75 years. Mepolizumab was prescribed for EGPA in <1.0% of patients before 2017 and use increased over time from 2.4% in 2017 to 20.6% in 2020. OCS remained the most prescribed treatment through 2020 (83.4%), with azathioprine used by 17.8% and injectable corticosteroids by 15.3%. Proportion of patients that used zero/low prednisolone-equivalent daily OCS doses increased from 2017 (0 mg: 13.6%; >0–≤5 mg: 41.8%) to 2020 (0 mg: 16.6%; >0–≤5 mg: 42.1%); while those who used >10 mg decreased from 2017 (11.9%) to 2020 (10.3%; Figure 1). Median OCS daily dose was 4.9–7.7 mg between 2010 and 2016, and 4.5–4.8 mg between 2017 and 2020, with the lowest dose in 2020 (4.5 mg (IQR 1.6–6.8)). Proportion of EGPA patients with comorbidities related to corticosteroids remained relatively consistent over time, except for infectious disease which showed a decrease from 94.4% in 2010 to 70.9% in 2020. Proportion of patients with other comorbidities in 2020 were dyslipidemia (37.6%), hypertension (33.6%), diabetes (23.4%), fracture (12.3%), mood disorders (10.1%), and cataract (7.2%). Of 1717 revisiting patients in 2020, 41.6% relapsed, which was 5.0–37.4% lower than in the years 2010–2019. In the subgroup of 24 patients new to mepolizumab from the JMDC database, the prednisolone-equivalent mean (SD) daily dose decreased from 11.2 mg (7.1) in the 90 days before to 4.3 mg (2.7) in the 4th quarter after mepolizumab initiation.
Conclusion: Prevalence of EGPA in Japan showed a continued increase through 2020, suggesting improved recognition of this disease. A decrease in OCS daily dosing was observed after mepolizumab was introduced in 2018, yet further improvement in EGPA management is warranted.

RISK FACTORS ASSOCIATED WITH PARCIAL OR NULL REMISSION OF RENAL ACTIVITY IN PATIENTS WITH LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Remission, Kidneys

A. Martínez Badajoz[1], J. R. Hernández Vásquez[2], M. Ocampo Torres[2], A. Ramirez Pérez[2], A. Camargo[2], F. M. Bravo Rojas[1], J. Hernandez Rivera[3].
[1]ESM - Escuela Superior de Medicina - IPN, Social Service, Ciudad de México, Mexico; *[2]XXI Century National Medical Center, Rheumatology service, Ciudad de México, Mexico*; *[3]XXI Century National Medical Center, Nephrological Diseases Medical Research Unit, Ciudad de México, Mexico*

Background: Systemic Lupus Erythematosus (SLE) is a multisystemic autoimmune chronic disease, the severity of organic involvement depends on factors such as sex, race and age of disease presentation. Lupus nephritis is present in up to 40% of patients with SLE. Failure to achieve complete remission at 6 months is associated with a poor long-term prognosis and implies greater use of immunosuppressants.
Objectives: To determine the factors associated with the parcial or null remission in patients with lupus nephritis.
Methods: A nested case-control study was conducted in a retrospective cohort of patients with lupus. Fifty-five patients with renal involvement were included and divided into two groups, those with partial or no remission in response to remission induction (n=30) and those with complete remission (n=25), multiple factors were analyzed and in the case of quantitative variables they were categorized into 2 groups with specific cut-off points in each case. The type of remission of each patient was taken as a factor to be analyzed and the analysis was completed in a bivariate logistic regression with a significance <0.05.
Results: The variables that showed risk of presenting a partial or null response were: not having completed the minimum time of 6 months of the remission induction scheme (Odds Ratio [OR]: 9.590; 95% Confidence Interval [95% CI]: 2.351-39.119; p=0.002), sex male (OR: 8.727; 95% CI: 1.009-75.51; p=0.049); start Renal Replacement Therapy (RRT) (OR: 8.727; 95% CI 1.009-75.513; p=0.049); family history of SLE (OR: 7.304; 95% CI: 0.832-64.098; p=0.073); have a Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) ≤60 ml/min/1.73m^2 (OR: 6.147; 95% CI: 1.577-26.110; p=0.009); Creatinine ≥1.2 mg/ dL (OR: 6.000; 95% CI: 1.767-20.369; p=0.004); C-Reactive Protein (CRP) ≥5g/dL (OR: 5.470; 95% CI: 1.680-17.811; p=0.005); age ≤30 years (OR: 4.250; 95% CI: 1.370-13.188; p=0.012); proteinuria ≥1.5 g/24 hours (OR: 3.560; IC 95%: 1.123-11.285; p=0.31).
Conclusion: The factors observed that are associated with a partial or null remission were: not completing the remission induction scheme, male sex, start with RRT, CKD-EPI ≤60ml/min/1.73m^2, creatinine ≥1.2mg/dL, CRP ≥5g/dL, age ≤30 years and proteinuria ≥1.5g/24 hours. On the other hand, factors such as a family history of SLE, BMI ≥30kg/m^2 and hemoglobin ≤10g/dl although they demonstrated an association, the values weren't statistically significant. These factors make it possible to identify areas of interest when starting remission induction therapy, demonstrating the importance of therapeutic adherence and individualized follow-up for each patient, offering timely intervention in modifiable factors and close monitoring of patients with non modifiable factors.

RATES OF HIGH LEVELS OF POST-PARTUM DEPRESSIVE SYMPTOMATOLOGY IN WOMEN WITH RHEUMATIC DISEASES FOLLOWED DURING PREGNANCY, AND ASSOCIATIONS WITH TYPE OF DISEASE: A STUDY BY A MULTIDISCIPLINARY TEAM

Keywords: Pregnancy and reproduction

F. Crisafulli[1], E. Pedretti[1], I. Andreolassi[1], S. Zatti[2], F. Ramazzotto[2], E. Beretta[3], C. Bani[3], S. Matthey[4], A. M. Della Vedova[4], D. Lini[1], C. Nalli[1], M. C. Gerardi[5], M. G. Lazzaroni[1], P. Semeraro[1], M. Fredi[1], M. Filippini[1], M. Taglietti[1],

F. Franceschini[1], L. Andreoli[1], A. Tincani[1]. *[1]ASST Spedali Civili and University of Brescia, Rheumatology and Clinical Immunology Unit, Brescia, Italy*; *[2]ASST Spedali Civili and University of Brescia, Obstetrics and Gynaecology Unit, Brescia, Italy*; *[3]ASST Spedali Civili of Brescia, Obstetric Psychology Service, Brescia, Italy*; *[4]University of Brescia, Clinical and Experimental Science Department, Brescia, Italy*; *[5]ASST Grande Ospedale Metropolitano Niguarda, Rheumatology Unit, Milano, Italy*

Background: Postpartum depression (PPD) affects 10-15% of Italian women and can lead to adverse outcomes for both mothers and children. Data on the prevalence of PPD in rheumatic diseases (RD) are limited.
Objectives: To assess the frequency of depressive symptoms in post-partum in women with RD using the Edinburgh Post-Natal Depression Scale (EPDS), and to identify potential relationships in patients with arthritis (RA, PsA, SpA, JIA) and connective tissue diseases (CTD: UCTD, SLE, SS, SSc, APS).
Methods: Patients with RD prospectively followed during pregnancy by a multidisciplinary team in an Italian rheumatology unit were included. Disease activity, patient global health (PGH), physician global assessment (PhGA), EuroQoL were collected during pregnancy. EPDS questionnaire was administered at 30-60 days, 6 and 12 months after delivery. Patients with a screen positive EPDS score (9 or more, or a positive response to question 10 -suicidal thought-) were referred to a clinical psychology specialist. Continuous variables are expressed as median (IQR).
Results: From May 2018 to June 2022, 129 patients completed at least one EPDS. Overall, 28 (22%) patients had at least one screen positive EPDS. No differences in health and demographic variables were found between patients screening positive or not, except for a higher PhGA in the 1st trimester in the first group (median VAS: 5 [0-20] vs 0 [0-0], p=0.03). Twelve out of 50 patients with arthritis had at least one screen positive EPDS (24%). These patients had a shorter disease duration (p=0.04), a lower PGH in the 1st trimester (p=0.03), and a higher frequency of anxious/depressive symptoms (evaluated with EuroQoL) during pregnancy (basal visit: p<0.001; 1st trimester: p<0.001; 2nd trimester: p=0.01), compared to patients screening negative (Table 1). Sixteen out of 69 patients with CTDs had at least one screen positive EPDS (23%). This group presented higher frequency of anxious/depressive symptoms (EuroQoL) in the 3rd trimester (p=0.004) to patients screening negative (Table 1).

Table 1. Comparison between patients positive on the EPDS on at least one occasion or never positive, among arthritis and CTDs groups.

*Fisher exact test or chi-square test, p<0.05

Conclusion: More than 1 out of 5 women with RD had substantial level of depressive symptomatology on at least one occasion in the 12 months after delivery on the EPDS. Self-reported symptoms of anxiety and depression should be evaluated during pregnancy and patients could be offered a psychological interview. Our study underlines the need for a closer monitoring of mental health of pregnant women with RD and the opportunity for further studies to identify risk factors and screening procedures.

AB1636 **CLINICAL PHENOTYPES IN SARCOIDOSIS USING CLUSTER ANALYSIS IN A COHORT OF 342 PATIENTS**

Keywords: Epidemiology, Rare/orphan diseases

F. Benavides-Villanueva[1], R. Fernández-Ramón[2], J. J. Gaitán-Valdizán[2], I. Gonzalez-Mazon[1], L. Sanchez-Bilbao[1], J. L. Martín-Varillas[3], D. Martínez-López[4], R. Demetrio-Pablo[2], R. Blanco[1]. *[1]Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; *[2]Marqués de Valdecilla University Hospital, Ophthalmology, Santander, Spain*; *[3]Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain*; *[4]Sierrallana Hospital, Rheumatology, Torrelavega, Spain*

Background: Sarcoidosis is a multi-system disease with unknown etiology characterized by the formation of granulomas in various organs. It affects people of all ethnic backgrounds and occurs at any time of life. This disease can affect any organ with a frequency varying according to ethnicity, sex and age most of the time affecting the pulmonary system with symmetrical bilateral hilar adenopathy. Extrapulmonary manifestations in skin, eyes, liver or lymphatic system can take a great morbimortality in patients.
Objectives: To **a)** indicate the phenotypes with similar characteristics with a cluster analysis and **b)** describe the principal features of those phenotypes.
Methods: A model-based clustering was performed in a cohort of 342 sarcoidosis patients, diagnosed and follow-up from 1999 to 2019 at northern Spain hospital. Four homogeneous phenotypes were proposed in our study (C1: parenchymal lung involvement with dyspnea; C2: erythema nodosum and articular involvement with asthenia; C3: isolated hilar adenopathy; C4: miscellaneous extrapulmonary sarcoidosis). Chi-square test and ANOVA were used to compare, respectively, categorical, and continuous variables among groups. Two-sample t-tests and the partition of Pearson's chi-square statistic for were used in pairwise comparisons.
Results: Cluster analysis identified four groups: C1 (n=128; 37.4%), C2 (n=75; 21.9%), C3 (n=82; 24.0%), and C4 (n=57; 16.7%) **(Table 1).** Lung involvement was predominant in all clusters, ranged from 93.3% (C2) to 100% (C3). Extrapulmonary involvement was significantly higher in C2 (97.3%) and C4 (98.2%). Systemic steroids were significantly more used in cluster 1 (75.8%) compared to the rest (C2: 57.3%; C3: 48.8%; C4: 47.4%) **(Figure 1).**
Conclusion: Sarcoidosis has a heterogenous disease, and a cluster analysis can be a useful tool to identify the clinical patterns and can be useful for the management.

AB1637 DO AFRO-DESCENDANT PATIENTS WITH PRIMARY SJOGREN SYNDROME SHARE CLINICAL AND BIOLOGICAL CHARACTERISTICS? EXEMPLE FROM MARTINIQUE

Keywords: Sjögren syndrome, Epidemiology, Geographical differences

L. S. Fabienne[1], B. Suzon[2], F. Moinet[2], K. Polomat[2], M. De Bandt[1], G. Jean-Baptiste[1], M. Dramé[3], S. Arfi[2], C. Deligny[2]. [1]*Centre Hospitalier Universitaire de Martinique, Rheumatology, Fort de France, Martinique*; [2]*Centre Hospitalier Universitaire de Martinique, Internal Medicine, Fort de France, Martinique*; [3]*Centre Hospitalier Universitaire de Martinique, Public Health, Fort de France, Martinique*

Background: Influence of geolocation and ethnicity on pSS prevalence and phenotype has been reported [1] and black pSS appear to have higher risk of unfavorable outcome[2]. In Europe, pSS prevalence ranges from 10.2 to 92.8/100 000 Inhabitants[3]. Data on primary Sjogren's disease (pSS) in populations of sub-Saharan origin are very limited and concerns mostly Europeans and Asians. Both in Africa and the African diaspora (AAD)[4,5], patients face significant healthcare limitations because of socio-economic disadvantage. In Martinique, a French island of the Caribbean where more than 90% of the population is of Sub-Saharan African descent, access to healthcare is easy and free for every citizen. pSS are treated in the Reference Center for rare systemic autoimmune diseases of the island. No other primary care facility treats pSS.
Objectives: We aim to describe pSS in an Afro-descendant population in healthcare access comparable to Europeans.
Methods: We performed a retrospective study of all patients followed for primary Sjögren's (pSS) in internal medicine and rheumatology at the University hospital of Martinique, only hospital on the island, between 2014 and 2016 included according to international criteria (AECG 2002, ACR/EULAR 2016).
Results: Among 112 patients diagnosed with pSS, 75 and 84 patients were included according to AECG 2002 and ACR/EULAR 2016 criteria respectively. Clinical and biological characteristics are presented in Table 1. In our cohort, major cumulative characteristics are a very high female proportion, young age at diagnostic and high frequency of hypergammaglobulinemia correlated with increased ESR. Considering this AECG 2002 hospital-based cohort and the retrospective aspect of the study, a minimum prevalence of pSS was calculated at 16,87/100 000 inhabitants in 2016.
Conclusion: Our data, shared by other AAD cohorts[4,5], suggest that AD pSS have specific manifestations around the world as AAD Systemic Lupus erythematosus do. A higher prevalence is reported compared to that of 7.1/100 000 inhabitants of France European pSS cohort[3].

AB1638 RISK FACTORS FOR DEVELOPING RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS AFTER IMMUNOTHERAPY WITH IMMUNE CHECKPOINT INHIBITORS

Keywords: Malignancy

M. Liapi[1], K. Chatzidionysiou[1]. [1]*Karolinska Institute, Rheumatology Division, Department of Medicine Solna, Stockholm, Sweden*

Background: Immunotherapy with monoclonal antibodies that block specific immunological check-points has revolutionized the treatment of some forms of cancer, such as melanoma. A new group of adverse events has emerged with these new agents, called the immune-related adverse events (irAEs). Among these irAEs, rheumatic complications are relatively common, although the true frequency is still unclear.
Objectives: We aimed to assess the frequency of ir-AEs and rheumatic ir-AEs in particular, as well as identifying potential risk factors for irAEs in a cohort of patients with malignant melanoma receiving immunotherapy with immune checkpoint inhibitors (ICI).
Methods: Retrospective analysis of a cohort of patients diagnosed with malignant melanoma and starting treatment with a first-ever ICI at Karolinska University Hospital between 2012 and 2020. The type of irAEs, glucocorticoid therapy at immunotherapy start, demographics and type of ICI were collected from patient's journals.
Results: A total of 118 patients were included in the cohort, 75 male (63,6%) and 43 females (36,4%). The type of ICI was nivolumab in 54.2% of patients, ipilimumab in 13.6%, pembrolizumab in 22.9% and combination therapy with ipilimumab and nivolumab in 7.6%, ipilimumab and pembrolizumab in 0.8% and

nivolumab and pembrolizumab in 0.9%. Any irAE developed 72/118 patients (61%), while rheumatic irAEs were seen in 24 patients (20.3%) with the following clinical phenotypes; arthralgia/myalgia in 9 patients (37.5%), PMR like syndrome in 3 patients (12.5%), arthritis in 6 patients (25%), sicca syndrome in 4 patients (16%), sarcoidosis in 1 patient (4.2%) and myositis in 1 patient (4.1%). There was no significant association between the type of ICIs or combination therapy in total with the development av irAEs (OR = 1.79, 95% CI = 0.45 – 7.1, p=0.39). Neither the gender (OR 1.12, 95% CI = 0.52-2.40, p=0.76) nor the glucocorticoid use at the ICI start were associated with the development av irAEs [OR=2.0, 95% CI = 0.38 – 10.36, p=0.38]. No significant associations were observed between demographic factors (age, gender), type of ICI, glucocorticoid use at the start of ICI and rheumatic irAEs.

Conclusion: IrAEs are common and occur in more than half of patients treated with ICI. Rheumatic irAEs are also common and in this study were seen in one fifth of patients. Gender, age, type of ICI and treatment with glucocorticoids at baseline are not associated with increased (or decreased) risk for irAEs in general, or rheumatic irAEs in particular, in this cohort of patients with melanoma, with the risk of type II error due to limited power.

ASSOCIATION BETWEEN HYPERURICEMIA AND BONE MINERAL DENSITY WITH 8-YEAR FOLLOW-UP AMONG CHINESE ADULTS

Keywords: Osteoporosis, Epidemiology, Gout

J. Zeng[1], H. Liu[1], L. MA[1]. *[1]Guangdong Second Provincial General Hospital, Department of Ultrasound, Guangzhou, Guangdong, China*

Background: Hyperuricemia (HUA) have been associated with bone mineral density (BMD) in recent studies, especially for elderly men and peri- or postmenopausal women[1-3]. However, this association is still unknown for the long-term follow-up observation.

Objectives: This study investigated the relationship between hyperuricemia and bone mineral density at 8-year follow-up among Chinese adults.

Methods: The cohort study was collected at Guangdong Second Provincial General Hospital in Guangzhou City, China between January 2010 and December 2018. Physical examinations and laboratory measurement variables were obtained from the medical check-up system. The physical examination population was followed up annually for 8 years. Multivariate Cox proportion models was used to explore the relationship between the hyperuricemia and bone mineral density.

Results: In total, 9017 individuals were included (2620 HUA participants (39.6% female) at baseline with an average age of 44.85 years (SD: 12.35) and average BMD of -0.83 (SD:1.24). The BMD decreased annually at the 8-year follow-up (from -0.82 to -0.93). Compared with normal participants, the Cox regression analysis showed that hyperuricemia was significant associated with lower BMD(T<-2.5) (hazards ratio (HR)=1.169, 95%CI: 1.059–1.290, P <0.05), the male (HR=2.545,95%CI: 2.389–2.710, P <0.05) and the elderly (age≥65) (HR=1.121,95%CI: 1.012–1.241, P <0.05) at follow-up.

Conclusion: Our study observed participants with hyperuricemia had significantly lower BMD, especially for males and the elderly participants. More high-quality research is needed to further support these findings.

PREVALENCE AND ASSOCIATED FACTORS OF ATLANTOAXIAL SUBLUXATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTER RETROSPECTIVE STUDY

Keywords: Rheumatoid arthritis, Imaging

Y. J. Song[1,2], S. Y. Kim[3], C. Lim[2], H. W. Kim[2], E. Nam[2], S. K. Cho[1,2], Y. K. Sung[1,2]. *[1]Hanyang University Hospital for Rheumatic Diseases, Department of Rheumatology, Seoul, Korea, Rep. of (South Korea)*; *[2]Hanyang University Institute for Rheumatology Research, Center for Clinical Research, Seoul, Korea, Rep. of (South Korea)*; *[3]Hanyang University, College of Medicine, Seoul, Korea, Rep. of (South Korea)*

Background: Atlantoaxial subluxation (AAS) is a serious complication of rheumatoid arthritis (RA) that can cause severe neck pain and neurological injury.

Objectives: This study aimed to identify prevalence and associated factors of AAS in Korean RA patients.

Methods: Data of RA patients who visited an academic referral hospital in Korea between September 2007 and August 2020 were extracted. Patients who were <19 years old, had another autoimmune disease, or did not check cervical spine (C-spine) radiography were excluded. The date of the first C-spine radiography was set as the index date, and AAS was defined with anterior atlantoaxial interval (AADI) greater than 3mm. We performed multivariable logistic regression analysis to identify associated factors for AAS. The proportion of patients with AAS progression or those who received surgical treatment for AAS during observation period was investigated.

Results: There were 1,855 patients with diagnostic code of RA, and 1,115 patients with RA who checked C-spine radiography at least once were included. Among them, 156 patients had AAS at the index date with a prevalence of 14.0%, and the mean AADI in patients with AAS was 4.9±1.7 mm. In multivariable logistic regression analysis, longer duration of RA, lower body mass index (BMI), C-spine spondylosis, erosive changes on hand X-ray and higher C-reactive protein were significant associated factor for AAS. Among 156 patients with AAS, 106 patients performed C-spine radiography follow-up (mean interval 5.5±3.7 years). There were 16 patients (15.1%) with progression of AAS or surgical treatment: 12 patients who received surgery for AAS and four patients with AAS progression without surgical treatment.

Conclusion: In this study, 14.0% of patients with RA had AAS. Duration of RA, BMI, C-spine spondylosis, bone erosion at hands and RA activity were factors

associated with AAS. 15.1% of RA-AAS patients showed progression of AAS or received surgical treatment during 5.5 years of observation.

AB1641 TOBACCO SMOKING HAS A PREVENTIVE EFFECT ON THE INCIDENCE OF KNEE OSTEOARTHRITIS: 10-YEAR RETROSPECTIVE COHORT STUDY BASED ON KOREA NATIONAL HEALTH INSURANCE SERVICE-HEALTH SCREENING DATABASE

Keywords: Osteoarthritis, Epidemiology

J. Park[1], M. Son[2], S. Y. Lee[1], W. T. Chung[1], S. W. Lee[1]. *[1]Dong-A University Hospital, Division of Rheumatology, Department of Internal Medicine, Busan, Korea, Rep. of (South Korea)*; *[2]Dong-A University, Department of physiology, Busan, Korea, Rep. of (South Korea)*

Background: Previous cross-sectional studies reported that smoking lowers the incidence of knee osteoarthritis, however, some studies show no correlation between smoking and knee osteoarthritis. Thus the relationship between the two has not been clarified [1,2]. To address this issue, we designed a retrospective cohort study to investigate the association between smoking and knee osteoarthritis, using a large-scale claim database from Korea. To the best of our knowledge, this is the first retrospective cohort study on smoking and knee osteoarthritis in Korea.

Objectives: We intended to investigate whether there was a difference in the incidence of knee osteoarthritis between patients with a history of current smoking, past smoking and those without a history of smoking.

Methods: The Korea National Health Insurance Service-Health Screening database is registered with 98% of Koreans and includes all insurance claims. From this database, a retrospective cohort observational study was conducted on 316,387 adults who had undergone the national health examination. Patients diagnosed with knee osteoarthritis prior to the examination and patients who were diagnosed with knee osteoarthritis in 2002 were excluded. The primary endpoint of this study was a diagnosis of knee osteoarthritis. The operational definition of diagnosis of knee osteoarthritis was knee osteoarthritis code (M17) or any site of osteoarthritis code (M15 to M19) along with a knee x-ray (G720, G721) [3]. The study population was followed from the day of health screening at index year to the date of incidence of knee osteoarthritis, the date of death, or December 31, 2019, whichever comes first.

Results: The patient group was classified into non-smoker, ex-smoker, and smoker groups according to the responses to the health examination questionnaire. The baseline characteristics of each group are included in Table 1. The incidence of knee osteoarthritis was 38.9%, 26%, and 23% in each group of non-smoker, ex-smoker, and smoker group with statistical significance (P-value < 0.001). When the disease-free probability for knee osteoarthritis was presented using the Kaplan-Meier curve, it was confirmed that the risk of osteoarthritis incidence was significantly different between the non-smoker group and the smoker group as time passes (Figure 1, P-value for Log-rank test < 0.001). The hazard ratio and 95% confidence intervals of ex-smoker to non-smoker were 0.95 (0.83-0.97), and those of smoker to non-smoker were 0.89 (0.87-0.91).

Conclusion: This large-scale retrospective cohort study showed a low incidence of knee osteoarthritis in smokers and ex-smokers during a follow-up period when compared to non-smokers in Korea. Additional studies on the relationship between smoking and knee osteoarthritis are required in the future.

Table 1. Baseline characteristics of study population.

All subjects (n = 316,387)	Non-smoker group (n = 187,116)	Ex-smoker group (n = 65,290)	Smoker group (n = 63,981)	P-value

AB1642 A NATIONWIDE POPULATION-BASED STUDY OF EPIDEMIOLOGY, RISK FACTORS FOR CYTOMEGALOVIRUS DISEASE IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES

Keywords: Inflammatory arthritides, Comorbidities, Epidemiology

T. H. LI[1,2,3], Y. S. Chang[4], C. F. Su[5], C. C. Lai[6], C. C. Chuang[1], C. Y. Tsai[3]. *[1]Shin Kong Wu Ho-Su Memorial Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China*; *[2]National Yang Ming Chiao Tung University, Institute of Clinical Medicine, Taipei, Taiwan, Republic of China*; *[3]Fu Jen Catholic University, School of Medicine, New Taipei City, Taiwan, Republic of China*; *[4]Shin Kong Wu Ho-Su Memorial Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China*; *[5]Shuang Ho Hospital, Taipei Medical University, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, New Taipei City, Taiwan, Republic of China*; *[6]Taipei Veterans General Hospital, Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Taipei, Taiwan, Republic of China*

Background: Human cytomegalovirus (CMV) ubiquitously distributes in general population but may cause overwhelming complications in patients with autoimmune inflammatory rheumatic diseases (AIIRDs); hence, the prevalence and associated factors of CMV disease in AIIRDs is worth investigating but the data has been limited.

Objectives: To investigate the epidemiologic data and risk factors of CMV infection in patients with AIIRDs.

Methods: The nationwide population-based cohort study was conducted by using Taiwanese National Health Insurance Database, to compare incidence rates (IR) with incidence rate ratios (IRR) of CMV disease in patients with AIIRDs and non-AIIRDs age- and sex-matched cohort; CMV disease was defined as pertinent ICD codes with concurrent anti-CMV medication administration. The individual data in various AIIRDs were analyzed and risk factors were identified by Cox proportional regression.

Results: 94,429 patients with AIIRDs and 1:1 number of matched subjects were identified; higher incidence rate of CMV disease in AIIRDs group was noted than the matched cohort. Various comorbidities and therapeutic agents including azathioprine, cyclosporin, cyclophosphamide, mycophenolate, intravenous steroid and oral daily dose > 7.5mg prednisolone or equivalence, were associated with CMV disease incidence. Comparing with RA, SLE and DM/PM posed increased risks on CMV disease.

Conclusion: Patients with AIIRDs carry higher risk of CMV disease regardless of etiologies, and attentiveness to one's health is indispensable to facilitate early detection of CMV disease in patients with AIIRDs.

ONE-MONTH HOSPITALIZATION WITH HIGH-DOSE GLUCOCORTICOID THERAPY IS ASSOCIATED WITH SARCOPENIA PROGRESSION IN PATIENTS WITH RHEUMATIC MUSCULOSKELETAL DISEASES

Keywords: Diet and nutrition, Comorbidities, Best practices

H. Hanaoka[1], J. Kikuchi[1], M. Akiyama[1], K. Hiramoto[1], S. Saito[1], Y. Kondo[1], Y. Kaneko[1]. [1]*Keio Universtity School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Sarcopenia refers to a decrease in skeletal muscle mass and function. It is associated with daily life disability and a high risk of all-cause mortality. While sarcopenia is generally an age-related disease, it has been recently recognized to be prevalent in young patients with rheumatic musculoskeletal diseases (RMD). Especially, most patients with RMD with systemic organ manifestations are hospitalized to be treated with high-dose glucocorticoid (GC) leading to extremely low physical activity and prolonged bed rest for a long term. However, little is known about sarcopenia in patients with RMD who are administered high-dose GC in hospital.

Objectives: To clarify the incidence of sarcopenia and its risk factors in patients with RMD treated with high-dose GC therapy in more than one-month hospitalization.

Methods: We reviewed patients with RMD who had been hospitalized in Keio University Hospital from 2020 to 2021 and included those with skeletal mass indices (SMI) before and one-month after high-dose GC treatment available in the analysis. We divided them into two groups according to progression of sarcopenia. Sarcopenia was defined as less than 5.4 kg/m^2 of SMI for woman and less than 7.0 kg/m^2 of SMI for man according to definition of Asian Working Group for Sarcopenia. Progression of sarcopenia was defined as more than 10% decrease in SMI from baselines. We compared clinical characteristics between the two groups and conducted multivariable analysis identify independent risk factors associated with progression of sarcopenia.

Results: Forty-nine patients were enrolled. The mean age was 53.3 years old, and 36 patients (73.5%) were female. The most frequent disease was systemic lupus erythematosus (42.9%) followed by systemic vasculitis (18.4%) and idiopathic inflammatory myositis (14.3%). At hospital admission, 41 patients (83.7%) already met the definition of sarcopenia before high-dose GC treatment. After one-month hospitalization with high-dose GC treatment, two patients newly developed sarcopenia, and 28 (57.1%) patients were diagnosed with progression of sarcopenia. Patients in the sarcopenia progression group were male dominant (60.7 vs 90.4%, p=0.025), had a higher body weight (56.9 ± 12.9 vs 50.5 ± 7.5 kg, p=0.048), and showed higher SMI (5.5 ± 0.8 vs 5.1 ± 0.8 kg/m^2, p=0.008) than those in the non-sarcopenia progression group. Age (52.8 vs 55.8 years, p=0.755), underlying diseases, and starting dose of GC (0.98 ± 0.16 vs 0.96 ± 0.19 mg/kg/day, p=0.35) were not different between the two groups. During the mean observation period of 41.2 ± 10.4 days of hospitailization, the incidence of infection was higher in the sarcopenia progression group than the non-sarcopenia progression group (28.5 vs 5.7%, p=0.042). Multivariable regression analysis revealed body weight reduction from 0 to week 1 was associated with progression of sarcopenia (odds ratio 0.22, 95% confidence interval 0.04-0.61, p=0.007) (Figure 1). Receiver operating characteristic curve identified the reduction in body weight of -1.8 kg in one week predicted sarcopenia progression after one month in-hospital high dose GC treatment.

Conclusion: Sarcopenia is frequent in patients with RMD, and one-month hospitalization with high-dose GC therapy worsened sarcopenia in more than half of patients. Early decrease in body weight can predict significant muscle volume loss after one month in-hospital therapy.

INCIDENCE, PREVALENCE, AND BURDEN OF SYSTEMIC LUPUS ERYTHEMATOSUS IN URBAN CHINA, 2013-2017: A NATIONWIDE POPULATION-BASED STUDY

Keywords: Epidemiology, Systemic lupus erythematosus

M. LI[1], C. LI[2], M. Cao[1], K. Lu[2], X. Tang[2], P. Gao[2,3], M. LI[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital, Department of Rheumatology, Beijing, China*; [2]*Peking University Health Science Center, Department of Epidemiology and Biostatistics, School of Public Health, Beijing, China*; [3]*Peking University Clinical Research Institute, Center for Real-world Evidence Evaluation, Beijing, China*

Background: Systemic lupus erythematosus (SLE) is becoming a public health concern because of increasing disease and economic burdens. However, epidemiological data on SLE, especially its incidence rate, were limited in China, the world's largest population.

Objectives: To investigate SLE incidence, prevalence, and SLE-associated cost burdens in urban Chinese, stratified by gender, age group, and region, using national administrative data from 2013 to 2017.

Methods: We conducted a population-based study using records from the national databases of Urban Employee Basic Medical Insurance and Urban Resident Basic Medical Insurance in China between 2013 and 2017. Data from over 380 million patients during the study period were analyzed, and a total of 132,258 SLE patients (mean age 43.03 years, standard deviation 15.29; 81.34% female) were identified. Incident cases were individuals with a diagnosis of SLE with a 3-year disease-free period[1]. Prevalent cases were defined as patients with at least 1 insurance claim record with the diagnosis of SLE[2]. Primary outcomes, including the overall, age-, gender-, and region-specific incidence and prevalence rates of SLE, were estimated by a two-stage approach assuming a Poisson distribution[3]. Associated annual costs and hospital visit times were also calculated in both inpatients and outpatients.

Results: The crude incidence and prevalence of SLE in China in 2017 were 14.96 (95%CI, 12.69-17.43) and 50.37 (95%CI, 44.19-56.95) per 100,000 person-years, suggesting an incident population of 0.21 million and a prevalent population of 0.71 million (Figure 1). The average annual rate of increase in prevalence was 16.86% during 2013 and 2017. Crude incidence and prevalence of SLE among females were 28.03 (95%CI, 23.20-33.30) and 99.66 (95%CI, 85.47-114.95) per 100,000 person-years, higher than those among males of 6.42 (95%CI, 4.59-8.55) and 19.31 (95%CI, 14.94-24.24) per 100,000 person-years, with a prevalent rate ratio of 5.16:1. The age-specific incidence and prevalence showed unimodal distributions, both peaked at 30-49 years old in females and at 40-49 years old in males. Estimated annual cost per-capita was US$1,599.34 in SLE patients. Female outpatients had higher costs (US$971.20 vs. US$480.76 in males) with more hospital visits (9.20 times vs. 4.85 times in males), whereas male inpatients had higher costs (US$5,095.53 vs. US$3,774.40 in females). Costs of adolescent and young adult patients were the highest among age groups. All results in sensitivity analyses showed similar trends as demonstrated by the main results aforementioned.

Conclusion: Rapidly expanding SLE population and increasing costs associated with SLE have placed considerable burdens on health systems in China. Continued and enhanced efforts are needed to make long-term care and support more accessible and cost-effective for SLE patients, especially young population.

AB1645 CONTRACEPTION IN WOMEN WITH IMMUNE-MEDIATED INFLAMMATORY DISEASE

Keywords: Education, Patient information and education

S. Rodriguez-Muguruza[1], S. Castro Oreiro[1], M. J. Poveda[1], N. Del Castillo[1], M. Menacho[2], G. Valldosera[2], M. Just[3], N. Mohino[3], R. Fontova[1]. [1]*Hospital Universitari de Tarragona Joan XXIII, Rheumatology, Tarragona, Spain*; [2]*Hospital Universitari de Tarragona Joan XXIII, Gastroenterology, Tarragona, Spain*; [3]*Hospital Universitari de Tarragona Joan XXIII, Dermatology, Tarragona, Spain*

Background: Given that teratogenic medications prescribed to women with immune-mediated inflammatory disease (IMID) may cause significant fetal harm, the use of effective contraception is crucial in reproductive-age women receiving potentially teratogenic medications.
Objectives: To determine: Relationship between potentially teratogenic drugs and the efficacy of contraception methods. The prevalence of contraceptive methods in women of reproductive age with IMID.
Methods: Cross- sectional study (May 2021 - May 2022). All women of reproductive age with an IMID (rheumatology, dermatology and gastroenterology external consultation) were invited to participate. Patients with rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, psoriasis, Crohn's disease and ulcerative colitis were included. Patients with hysterectomy, primary or secondary amenorrhea were excluded. A self-administered questionnaire including questions on the use of contraceptive methods was administered. Medications prescribed for IMID were identified and assigned a pregnancy risk category (according FDA): Class A - B (safe to use during pregnancy), C (have not been adequately studied to assign a pregnancy classification) and D-X (potentially teratogenic, their use is relatively/ absolutely contraindicated during pregnancy). For women who were prescribed multiple drugs, we assigned their FDA risk category based on their drug with the highest potential teratogenicity. Contraceptive methods were also classified according to their relative effectiveness (based on World Health Organization (WHO)) (Table 1). When women had more than one contraceptive method we classified according to their most effective method. Our analysis categorizes drugs as either A/B/C or D/X, ("low risk" vs "high risk"). To determine the relationship between the potential teratogenic drug and the effectiveness of contraceptive method we used Chi-square tests.
Results: A total of 59 women participated (Table 2), mean age 41.2 (SD ± 6.8) years. Contraceptive use was referred by 41 (69.5%) of the patients (Table 1): 56.1% (23 patients) used a method classified as moderately effective, 31.7% (13) as highly effective and 9.8% (4) as ineffective. Of women with teratogenic drugs: 37.5% (15 patients) did not use a contraception method or it was considered as ineffective. The relationship between potentially teratogenic drugs and effectiveness of contraceptive methods has a P value of 0.668 (Table 3).
Conclusion: The prevalence of contraception methods in reproductive-age women with IMID is about 70%. In women who used a contraceptive method, contraception considered to be ineffective was the least frequent. We found no relationship between the risk of teratogenicity in drugs prescribed for IMID and the effectiveness of contraceptive method.

AB1646 GENDER DIFFERENCES OF FRACTURE RISK IN PATIENTS WITH POLYMYALGIA RHEUMATICA

Keywords: Descriptive studies, Epidemiology

G. Horton[1], Z. Sultan[2], M. Bukhari[1,2]. [1]*Lancaster University, Health and Sciences, Lancaster, United Kingdom*; [2]*Royal Lancaster Infirmary, Rheumatology, Lancaster, United Kingdom*

Background: Polymyalgia Rheumatica (PMR) is usually treated with steroids, but long-term usage is detrimental to bone health. It is not uncommon for corticosteroid treatment to last for longer than a year [1]. No study has looked at the differential effect of steroids on either gender in this group of patients.
Objectives: To examine the effect of steroids on bone health in patients with PMR by gender.

Methods: Patients with PMR referred for BMD (Bone Mineral Density) estimation in a district hospital in the northwest of England between 2004 and 2011 were examined. Patients' demographics were recorded and Bone mineral density (BMD) were measured in both hips as well as the lumbar spine. Frax(TM) Risk factors (RF's) for osteoporosis were also ascertained at the time of DEXA. Initially RF's were compared between men and women using a students' T test for continuous variables and chi squared test for categorical variables. A logistic model was then fitted to compare RF's for fracture between men and women. Lastly a stepwise multivariate model was fitted using STATA (tm) version 12.
Results: 1051 patients with PMR were referred in the study period, mean age was 81.74 years (SD 9.58). 764 (84.7%) were females. Fractures were sustained in 26.3 % overall and there was a significant difference in males and females. Females were 2.58 times higher odds to sustain a fracture (CI 1.79 - 3.70). Using univariate logistic regression, the RF's for fracture in men were a reduced lumbar spine BMD (OR.794, CI.657 to.959) and a reduced left femur total BMD (OR.748, CI.568 -.984). In women the RF's were increasing age (OR 1.04, CI 1.020 to 1.055), reduced lumbar spine BMD (OR.841, CI.764 -.926), reduced right femur total BMD (OR.738, CI.644 -.845), reduced left femur total BMD (OR.706, CI.615 -.810) and current steroid therapy (OR.573, CI.369 -.889). In the multivariate model the RF's in men were a diagnosis of coeliac disease (OR 17.38, CI 1.746 - 173.03), and a reduced left femur total BMD (.783, CI.588 - 1.042). In women the RF's were increased age at scan (OR 1.025, CI 1.004 - 1.047), history of fracture (OR 1.891, CI 1.104 - 3.238), reduced left femur total BMD (.720, CI.611 -.849) and reduced BMI (OR 1.035, CI 1.002 - 1.068). Characteristics are shown in Table 1 below.
Conclusion: Men and women with PMR differ in their bone health, firstly in their demographics and secondly in their fracture risk with men who malabsorb having the highest fracture risk. This is the first intimation that fracture risk could be different. Limitations included not knowing the steroids' duration before scanning and only using first scan data. Strengths include the large number of subjects. Longitudinal data the collection of which is ongoing will provide further clarity.

NEUROBEHÇET DISEASE INCIDENCE IN NORTHERN SPAIN 1999-2019. A POPULATION-BASED STUDY

Keywords: Vasculitis, Epidemiology, Behcet's disease

A. Herrero-Morant[1], J. L. Martín-Varillas[2], C. Álvarez-Reguera[1], L. Sanchez-Bilbao[1], D. Martínez-López[3], G. Suárez-Amorín[1], R. Fernández-Ramón[1], I. Ferraz-Amaro[4], J. L. Hernández[1], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Ophthalmology and Internal Medicine, Santander, Spain*; [2]*Hospital Comarcal de Laredo, Rheumatology, Laredo, Spain*; [3]*Sierrallana Hospital, Rheumatology, Torrelavega, Spain*; [4]*Hospital Universitario de Canarias, Rheumatology, La Laguna, Spain*

Background: Behçet's Disease (BD) incidence varies widely worldwide. Neurobehcet's disease (NBD) is one of the most severe manifestations of BD [**1].** Data on NBD incidence is scarce and contradictory.
Objectives: To estimate NBD incidence in Northern Spain.
Methods: Population-based cohort study of 120 patients diagnosed with BD in Northern Spain, between January 1, 1999, to December 31, 2019. Finally, 92 were included according to the 2013 International Criteria for BD [**2].** NBD was diagnosed according to the International Consensus Recommendation criteria [**3].** The incidence of NBD between 1999-2019 was estimated by gender, age, and year of diagnosis. Annual incidence is expressed as cases per 100,000 people.
Results: NBD was diagnosed in 23 of 92 (25%) patients (15 women/8 men) (mean±SD age: 44±13.9 years). Ten (43.5%) patients had parenchymatous NBD, 10 (43.5%) had non-parenchymatous NBD and 3 (13%) cases had mixed NBD. Annual incidence of NBD in Northern Spain in the 1999-2019 period was 0.13 per 100,000 people [95% CI: 0.11-0.26] (0.14 [0.04-0.23] in men, 0.24 [0.12-0.37] in women). There were variations in annual incidences, with a minimum value of 0.08 in 2009-2010 and a maximum of 0.26 in 2017-2018 (**Figure 1**). The highest incidence rate was observed in men in the 20-29 years group (0.03 per 100,000 people) and in women in the 30-39 years group (0.07 per 100,000 people). On the other hand, the lowest incidence rate was observed in the 10-19 years group and 80-89 years group (0.008 per 100,000 people). When analyzed the incidence rate stratified by age, there were no statistical differences according to gender. The annual incidence studied by year showed an annual peak incidence over the last 20 years. A comparison between different geographical areas was made (**Table 1**). NBD frequency ranges from 5.6 to 38%. It is usually more frequent in male young adults.
Conclusion: NBD frequency varies widely. The epidemiological characteristics of NBD in our series are similar to other except for gender predominance. Like in other immune mediated diseases this cyclic pattern in annual incidence could possibly be related to infectious environmental factors.

AB1648 THE USE OF DIGITAL TECHNOLOGIES BY PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A CROSS SECTIONAL MULTICENTER OBSERVATIONAL STUDY

Keywords: Patient information and education, Lifestyles, Spondyloarthritis

D. Jerome[1], T. Barnetche[2], A. Charlotte[3], J. Bernard[4], M. Vandersmissen[5], C. Lukas[3], A. Tournadre[4], P. Vergne-Salle[5], J. Landrin[2], A. Ruyssen-Witrand[1]. [1]*Hospital Center University De Toulouse, Rheumatology, Toulouse, France*; [2]*Hospital Center University De Bordeaux, Rheumatology, Bordeaux, France*; [3]*Hospital Center University De Montpellier, Rheumatology, Montpellier, France*; [4]*CHU Gabriel-Montpied, Rheumatology, Clermont-Ferrand, France*; [5]*Hospital Center University De Limoges, Dupuytren 1 - Rheumatology, Limoges, France*

Background: Digital technologies are commonly used by most patients, and the concept of e-health emerged some years ago. These tools, which include specific medical application can deliver prevention messages, allow patients to access information about their condition or treatments, and can be used in everyday life. As axial spondyloarthritis (AxSpA) is a chronic disease, such digital tools could be useful. The aim of the study was to assess digital technologies use in an AxSpA population.
Objectives: The primary objective was to describe the use of digital technologies in patients with AxSpA treated bDMARDs. A secondary objective was to identify the factors associated with digital technology use.
Methods: We conducted a prospective, cross sectional, observational study in 5 departments of rheumatology at French university hospitals. Patients were recruited from June 2021 to June 2022. Data were collected using questionnaires filled by the patient during follow-up. Medical information was collected by rheumatologists.
Results: 500 patients were included (age 49,5 ± 13,8 years, 47% women, 51% with radiograph sacro-iliitis, 71% with HLA-B27. Mean disease activity evaluated with BASDAI was 3,5 (SD ± 2,10). 429 (86%) received TNF inhibitor. 202 patients used digital technologies for their health (40%), 59 (30%) used a medical application for other chronic disease, and 54 (10,8%) had a specific application for spondyloarthritis (or rheumatic inflammatory disease). 39% used cellphone or sport-application for physical activity. Among users of digital technologies for AxSpA, most patients searched for information concerning their disease (65%) or treatment (54%). In multivariate analysis, level of study, radiograph sacro-iliitis (OR: 1,53 [1,50-2,03] p<0,01), and being membership of patient association (OR: 7,06 [1,90-26,19] p<0,01), were still associated with the use of digital technologies. Patient education program (OR: 3,00 [1,61-5,60] p<0,01) remained associated with the use of specific applications, and men used them less (OR: 0,34 [0,18-0,67 p<0,01). Only 54 patients had at least one teleconsultation with their rheumatologist during follow-up. Among them, 17 (32%) thought that teleconsultation was sufficient, as compared with a face-to-face visit.
Conclusion: To date, a significant proportion of patients use digital technologies for their AxSpA, but few a specific application for their rheumatism. The use of medical application is strongly associated with patient education program. Reliable and validated tools should be promoted by rheumatologists.

AB1649 2009 AND 2019-REVISED IWOS CRITERIA FOR OCULAR SARCOIDOSIS. STUDY IN A SERIES OF 384 PATIENTS FROM A SINGLE UNIVERSITY HOSPITAL.

Keywords: Uveitis

C. Lasa[1], J. Gaitán Valdizán[2], L. Sanchez-Bilbao[1], J. L. Martín-Varillas[1], D. Martínez-López[1], I. Gonzalez-Mazon[1], R. Fernández Ramón[2], R. Demetrio-Pablo[2], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; [2]*Marqués de Valdecilla University Hospital, Ophthalmology, Santander, Spain*

Background: Sarcoidosis is a systemic inflammatory disorder which involves many organs, including eyes. International Workshop on Ocular Sarcoidosis (IWOS) criteria for diagnosis of ocular sarcoidosis (OS) were first published in 2009 and revised in 2019 (question-based survey and panel discussion) **[1-2]**. IWOS criteria is a remarkable tool to relate uveitis to sarcoidosis, especially when ocular is the first manifestation in the systemic disease. Due to the consequences of OS, identify and initiate appropriate therapy is essential.
Objectives: To compare the results of IWOS criteria applied in the same population.
Methods: We studied a large cohort (n=384) of all consecutive patients diagnosed with sarcoidosis from January 1, 1999, to December 31, 2019. Finally, 344 patients were included according to the ATS/ERS/WASOG criteria **[3]**. First (2009) and revised (2019) IWOS criteria were applied to patients diagnosed with Sarcoidosis and ocular symptoms and the results were compared in both groups for our population. Concordance between 2009 and 2019 IWOS criteria was evaluated by calculating Cohen´s kappa coefficient.
Results: 65 (51% men) of 344 patients had ocular involvement (18.9%), mean age 56.7±16.3 years. As for nationality, 92.3% were Spaniard and 7.7% were South American. A positive biopsy for sarcoidosis was obtained in 75.4% (n=49) and a negative biopsy in 6.2% (n=4). There was no statistically significative difference between diagnostic groups for IWOS 2009/IWOS 2019 in age (p=0.738/p=0.495), sex (p=0.534/p=0.459) nor nationality (p=0.529/p=0.393). When applied 2009 IWOS criteria, 60% (39 patients) met any of the diagnostic categories (43.1% *Definitive*, 13.8% *Presumed*, 1.5% *Probable*, 1.5% *Possible*). When 2019 IWOS criteria was applied, 53.8% (35 patients) met any of the new diagnostic categories (43.1% *Definitive*, 7.7% *Presumed*, 3.1% *Probable*). Sensitivity for IWOS 2009 was 0.6 and for IWOS 2019 was 0.53. There was statistically significative concordance between 2009 and 2019 IWOS criteria (p<0.0001) with a strong consistency level (kappa = 0.824). When analyzing IWOS categories separately, we found total concordance in the *Definitive* category. *Probable* and *Possible* categories in 2009 criteria have been merged in only probable in 2019 criteria and there is a total concordance when comparing both. *Presumed* category represent the bigger change in the revised criteria. We found statistically significative concordance (p=0.000008) with a moderate consistency level (kappa = 0,524).
Conclusion: The revised 2019 IWOS criteria is less sensitive in our population; however, the main difference is in the category *Presumed*: the requirement of at least 2 intraocular signs of uveitis led to a change of 9 patients (13,8%) in 2009 IWOS down to 5 (7.7%) in 2019. In our population IWOS criteria is still has a low sensitivity.

LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH RHEUMATIC IMMUNE-MEDIATED DISEASES: PREVALENCE AND SCREENING STRATEGY

Keywords: bDMARD, Geographical differences

C. Lasa[1], J. S. Osorio Chavez[2], D. Martínez-López[1], C. Álvarez-Reguera[1], V. Portilla[1], J. M. Cifrián-Martínez[2], I. Ferraz-Amaro[3], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; [2]*Marqués de Valdecilla University Hospital, Pneumology, Santander, Spain*; [3]*San Cristóbal de La Laguna, Rheumatology, San Cristóbal de La Laguna, Spain*

Background: Patients with rheumatic immune-mediated diseases (R-IMID) with latent tuberculosis infection (LTBI) requiring biologic therapy (BT) are at an increased risk of active tuberculosis (TB). The prevalence of LTBI in patients with R-IMID varies depending on geographical location. An accurate diagnosis and prophylactic treatment of LTBI is crucial to reduce the risk of developing TB. No definitive gold standard exists for diagnosing LTBI. Tuberculin skin test (TST) and interferon-γ release assays (IGRAs) are the most used tests.

Objectives: To assess: a) Prevalence of LTBI in patients with (R-IMID), b) determine the importance of using a booster test in negative TST, c) to compare TST with the IGRA test in the detection of LTBI in patients with R-IMID and d) to perform a literature review of prevalence of LTBI in different geographical areas and its relationship with R-IMID.

Methods: Cross-sectional single University hospital study including all patients diagnosed with R-IMID who underwent a TST (±booster) and/or IGRA in a period from 2016 to 2020. If TST was negative, a new TST (Booster) was performed between 1 and 2 weeks after the first TST. Patients were diagnosed with R-IMID by an expert rheumatologist according to well-established ACR/EULAR classification criteria for each R-IMID. LTBI was defined by a positive TST and/or IGRA with no evidence of active TB. Diagnosis with IGRA vs TST was compared using Cohen's kappa coefficient. We performed a literature review in search of previous prevalence studies of LTBI in patients with R-IMID. This search was performed in the month of August 2022. The aim of this review was to compare the prevalence of LTBI in patients with R-IMID in different geographical areas.

Results: We included 1117 patients (741 women/376 men), mean age 53±15 years with LTBI. Overall LTBI prevalence was 31.7 % ranging from 25% in SLE up to 33.3% in BD. Results of prevalence compared to other countries are shown in **Table 1**. Booster was positive in 66 patients (7.7%) out of 857 patients with a negative simple TST. TST (+booster) was positive in 187 patients (22.9%) out of 817 with a negative or indeterminate IGRA test. IGRA test was positive in 30 (3.8%) out of 793 patients with a negative TST(+booster), as it is represented in **Figure 1**. Cohen's Kappa coefficient between TST(+booster) and IGRA (QFT-plus), was 0.381.

Conclusion: LTBI is frequent between patients with R-IMID. LTBI screening is important in patients who need to receive BT. This assessment has to be done performing both TST and IGRA as. complementary methods to ensure the detection of all patients with LTBI, since both tests. can have false negative results, especially in patients with R-IMID receiving. immunosuppressive therapy.

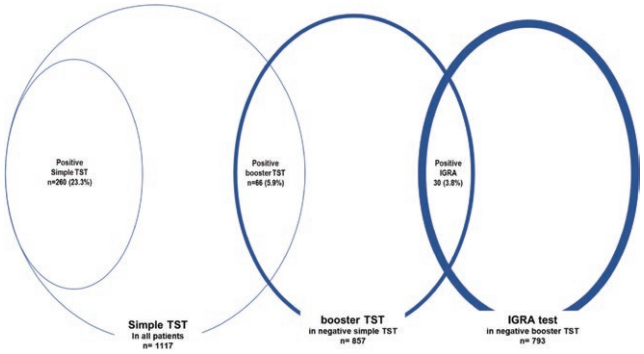

Figure 1. Proportion of positives in different test to diagnosis LTBI in R-IMID patients.

Background: Diffuse alveolar hemorrhage (DAH) is characterized by rapid onset of pulmonary infiltrates and hypoxemia. It is a potentially life threatening complication associated with systemic autoimmune conditions.
Objectives: To describe the presentation, clinical features, etiology, treatment and outcome of DAH in rheumatological conditions.
Methods: This a retrospective, multicentre study involveing 3 rheumatology centers, wherein data about DAH cases seen over the past 5 years was collected.
Results: There were 19 patients (Female = 15). The mean age was 38 years (18 - 67). DAH was the presenting feature in 15 patients (78%). The mean duration of symptoms was 20 days (1 - 60). The symptoms of DAH were: dyspnea 16 (84%), cough 15 (78%), hemoptysis 13 (68%). Other features of DAH like hypoxemia (18 patients), fall in hemoglobin (19 patients) were common. Fever was observed in 9 (47%). Nephritis was noted in 14 (73%). Renal biopsy was done in 6 (Lupus nephritis class 3 & 5 = 1; lupus nephritis class 4 = 1; Pauci immune crescentic glomerulonephritis = 3;Anti GBM associated crescentic glomerulonephritis =1). The most common feature on chest radiograph was diffuse opacities (Image 1). The etiology of DAH was as follows (Table 1) - granulomatosis with polyangiitis (GPA = 8); Systemic lupus erythematosus (SLE =7); anti GBM disease (2); Microscopic polyangiitis (MPA=1) and undifferentiated vasculitis [1]. The treatment of DAH included - Intravenous methylprednisolone (IV MP)=18; Intravenous immunoglobulin (IVIG) = 2; Extracorporeal membrane oxygenation (ECMO) = 1; Therapeutic plasma exchange = 3; Intravenous cyclophosphamide = 11; Rituximab (RTX) = 4; Mycophenolate mofetil (MMF) = 1. Most of the patients were managed in the intensive care unit (ICU) (13/ 19) and needed ventilatory support (11/ 19). Most patients required more than 10 days of hospitalization (12/ 19 = 63%). There were a total of 5 deaths (GPA =2; SLE =2; anti-GBM disease =1).
Conclusion: DAH was the presenting feature in most of the cases. GPA and SLE were the common causes. Dyspnea, cough and Hemoptysis were the common DAH symptoms. Fever and nephritis were the common Non - DAH clinical feature. Most of the patients were treated with IV MP and required ICU care; Approximately half of the patients required ventilatory support. DAH is a potentially life threatening condition with an overall mortality rate of approximately 25%.Early recognition and appropriate treatment is needed for better outcome.

AB1652 **THE PRESENCE OF DISEASE-SPECIFIC ANTIBODIES IN THE ABSENCE OF AN INFLAMMATORY RHEUMATIC DISEASE**

Keywords: Organ damage, Autoantibodies

T. Hoffmann[1], L. Wolff[1], P. Oelzner[1], G. Wolf[1], A. Pfeil[1]. [1]*Jena University Hospital – Friedrich Schiller University Jena, Department of Internal Medicine III, Jena, Germany*

Background: Inflammatory rheumatic disease (IRD) are characterized by the appearance of a specific clinic, the presence of findings in immunological laboratory and imaging. Some patients presented specific IRD autoantibodies without a clinical manifestation of IRD.
Objectives: The objective of this study was to evaluate the frequency of disease-specific autoantibodies in patients with absence of clinical IRD manifestation.
Methods: The study included an analysis of 3793 Caucasian patients from a department of rheumatology localized at a university hospital in Europe specified for screening in IRD between 2015 and 2020. All patients revealed a standardized clinical examination and diagnostic procedure including immunological laboratory and imaging. Biopsies were performed when clinically indicated. Especially autoantibodies for rheumatoid arthritis (rheumatic factor [RF], anti-citrullinated peptide antibodies [ACPA]), connective tissue disease (antinuclear antibodies immunofluorescence test [ANA IFT] and extractable nuclear antibodies [ENA]), vasculitis (anti neutrophil cytoplasmatic antibodies [ANCA]) and myositis (myositis blot) were included.
Results: IRD was diagnosed in 1534 patients (40.4%) with the following distribution: 21.2% (n=325) rheumatoid arthritis, 22.8% (n=350) connective tissue disease, 6.5% (n=100) vasculitis and 2.3% (n=35) myositis. IRD was excluded in 762 patients (20.1%). 39.5% (n=1497) of the patients without a clinical manifestation of IRD presented a disease-specific autoantibody. 94.3% (n=1412). In detail, ANA IFT (≥1:80) with the different stages: 1:80 48.9% (n=691), 1:160 27.2% (n=384), 1:320 12.3% (n=174), 1:640 5.2% (n=73), 1:1280 4.4% (n=62), >1:1280 2.0% (n=28), extractable nuclear antibodies 14.0% (n=208), RF and/ or ACPA 16.8% (n=252), c-/p-ANCA 1.9% (n=29) and myositis autoantibodies 1.8% (n=27). The mean age of the Non-IRD patients was 52.2 ± 15.1 years, with 398 (26,6%) male and 1099 (73,4%) female patients. Both gender and age were significant different to the IRD group (p<0.001).
Conclusion: The study highlighted that in screening of IRD 40 % of the patients presented IRD associated autoantibodies without a clinical manifestation of IRD. As already known, the isolated presence of disease-specific autoantibodies cannot confirm IRD. In this case, systematic and standardized organ screening is indispensable, to evaluate the clinical significance of the autoantibody. A clinical follow-up examination should be performed, especially if there is a change in symptoms or clinical suspicion of a possible organ manifestation of IRD.

EPIDEMIOLOGY AND CLINICAL PRESENTATION OF GIANT CELL ARTERITIS IN A REFERRAL HOSPITAL OF NORTHERN SPAIN

Keywords: Epidemiology, Adaptive immunity, Vasculitis

J. Sanchez-Martin[1], J. Medina-Del Valle[2], J. Loricera[1], M. F. Garcia-Reija[2], R. Blanco[1]. [1]*Hospital Universitario Marqués de Valdecilla-IDIVAL, Rheumatology, Santander, Spain*; [2]*Hospital Universitario Marqués de Valdecilla-IDIVAL, Oral and Maxillofacial Surgery Service, Santander, Spain*

Background: Traditionally, giant cell arteritis (GCA) was described as a disease of the temporal arteries. It is now accepted that the clinical spectrum has become broader and different diagnostic tools such as PET and US have made possible to diagnose patients who have not been included in the last decades, especially in extracranial forms. Moreover, recently, new diagnosed criteria (2022 ACR/EULAR) have been proposed. This implies an evident change of the clinical epidemiology of GCA.
Objectives: To assess the clinical epidemiology of GCA accordingly to new diagnostic tools and 2022 ACR/EULAR criteria.
Methods: Observational study of patients diagnosed with GCA who underwent temporal artery biopsy (TAB) between January 2016 and December,2022. The patients were divided into 3 groups: **a)** only cranial (cGCA), **b)** only extracranial (ecGCA), and **c)** mixed affection (mixGCA). The diagnosis of GCA was made according to **a)** temporal artery biopsy, and/or **b)** EULAR/ACR2022 criteria, and/or **c)** imaging techniques. Demographic, clinical, analytical and imaging techniques characteristics were studied.
Results: We included 191 patients (120 females/71 males), with a mean±SD age of 74.9±9.6 years. The main characteristics of the patients and the differences among phenotypes are shown in **Table 1**. Only a 27.2% of the patients had a positive TAB with a mean±SD length of 16.4±6.3mm. The GCA phenotype most frequent was the cranial GCA (cGCA). Headache (79.6%) was the most common ischemic manifestations, followed by the abnormal examination of temporal artery (46.6%) and visual symptoms (including 8.4% patients with blindness), jaw or lingual claudication (26.3%), and scalp tenderness (25.1%). Polymyalgia rheumatica (PmR) was the most frequent systemic manifestations, observing in 59.2% of the patients. The values of serum CRP and ESR are shown in **Table 1**.
Conclusion: GCA is a vasculitis which has increased its clinical spectrum with extracranial involvement, affecting people with a mean age of more than 70 years and with a female predilection. PmR appears to be present in more than half of the patients, mainly in extracranial phenotype.

IMPACT OF WORK ORGANIZATION ON ROTATOR CUFF TENDINOPATHY

Keywords: Patient information and education

N. Gannoun[1], N. Belhaj[1], M. Lahsisni[1], O. Dhahri[1], A. Khedher[1], A. Omrane[1], A. Mahfoudh[1], T. Khalfallah[1]. [1]*hospital Taher Sfar, Service of occupational medicine and pathologies, Mahdia, Tunisia*

Background: Rotator cuff tendinopathy is one of the common causes of shoulder pain. The etiology of rotator cuff tendinopathy has been reported to be multifactorial. Organizational and psychosocial work factors have also been mentioned as important contributors to work-related musculoskeletal disorders.
Objectives: The objective of this study was to assess the impact of work organization on rotator cuff tendinopathy.
Methods: A descriptive cross-sectional study was conducted at the Tahar Sfar Hospital in Mahdia, it concerned patients who consulted the occupational medicine department for shoulder tendinopathies. The information was collected using a self-questionnaire distributed during the medical visit, in order to collect the socio-professional characteristics and organizational constraints.
Results: A total of 100 patients participated in this study. The population was predominantly female (89%). Sixty-five percent of the patients worked in the manufacturing sector and working as a machine operator was the most common occupation (48%). the average job tenure was 22±9 years. The weekly working hours were 45±7 hours on average. All cases had pain in one or both shoulders. On clinical examination, subacromial impingement maneuvers were positive in 94% of the cases and ultrasound revealed rotator cuff tendinopathy in 69% of the cases. In terms of organization, the most common constraints were the need to respect production standards and deadlines (76.9%), to work at a fast pace in 78% of cases, and to carry out their work under continuous supervision (73.4%). On univariate analysis, ultrasound-diagnosed shoulder tendinopathy was significantly associated with female gender (p=0.003), working according to an imposed rhythm (p=0.008), the need to follow directions in order to perform their tasks (p=0.035), and finally, continuous supervision by the work manager (p=0.001).
Conclusion: This study examined factors that were associated with increased risk of rotator cuff tendinopathy. In conclusion, it is essential to identify these factors in order to develop prevention interventions and further high-quality prospective studies are required to identify the exact risk factors for rotator cuff tendinopathy.

Background: Rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) are diseases where inflammation plays a key role in their development and have an increased risk of developing comorbid conditions. It is important to evaluate the comorbidities associated with these diseases.
Objectives: Our objective was to evaluate the prevalence of comorbidities in RA, PsA and axSpA patients from the PANLAR´s register of rheumatic diseases (PANRED).

Table 1. Prevalence of comorbidities.

	Total (N=708)	RA (N= 632) (89.3%)	PsA (N= 32) (4.5%)	axSpA (N = 38) (5.4%)	Other (N = 6) (0.8%)
Hypertension	39.5%	40.6%	34.4%	27%	33.3%
Stroke	1%	1.1%	0	0	0

Current smoking: CS; pulmonary throboembolism: PT; deep venous thrombosis: DVT; monometameric cutaneous: MC; chronic obstructive pulmonary disease: COPD; active pulmonary: AP; A-ExP: Active Extrapulmonary.

Methods: PANRED includes real world data from Latin American consecutive patients diagnosed with RA, PsA and axSpA (ACR-EULAR 2010/CASPAR 2006-ASAS 2009) from Dec 2021 to Dec 2022. We collected: demographics, disease characteristics (activity, severity, treatment), basal comorbidities (cardiovascular, infections, cancer, gastrointestinal, pulmonary, and others) data. Data were extracted from patients initiating treatment with cDMARDS, TNF alpha inhibitors (TNFi) and Jakinasas inhibitors (JAKi). Categorical variables were expressed as percentage and tables of contingency were analyzed with $\chi 2$ or Fisher test. A p value less than 0.05 was considered significant.
Results: 708 patients were included. RA was the most frequent disease. The most prevalent comorbidities expressed as overall frequency were: hypertension: 39.5%, nonalcoholic steatohepatitis: 35.6%, dyslipidemia: 35.3%, tuberculosis 13.3%. Details of comorbidities are shown in the Table 1. Uveitis was more frequent in axSpA vs RA, RR: 2.5 (95%CI 1.35-4.8), p<0.001. Herpes zoster was present in 3.3%, 3.6% and 0.8% and tuberculosis in 15.85%, 15.1% and 3.8% in Jaki, TNFi and cDMARD groups respectively. Steatohepatitis was significantly higher in the cDMARD group compared Jaki and TNFi (p=0.01) and tuberculosis in the JAKi group (p=0.002) compared bDMARD and cDMARD, as basal characteristics, probably reflecting therapeutic decisions.
Conclusion: Cardiovascular comorbidities and tuberculosis are frequent in Latin American patients and should be considered in treatment selection.

THE USE OF MACHINE LEARNING METHODS IN OPIOID-ASSOCIATED OUTCOMES RESEARCH: A SYSTEMATIC REVIEW

Keywords: Artificial intelligence, Systematic review, Prognostic factors

C. Ramirez Medina[1], J. Benitez-Aurioles[2], D. Jenkins[2], M. Jani[1,3]. *[1]The University of Manchester, Musculoskeletal and Dermatological Science Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; *[2]The University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom*; *[3]NIHR Manchester Biomedical Research Unit, Manchester University NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: Prescription opioids have been a considerable contributor towards the opioid epidemic, a major public health concern with profound economic repercussions and mortality. In order to address the opioid crisis, a need exists to improve understanding on how to personalise prescribing incorporating individual factors to estimate the risk of opioid-related harms. Machine learning (ML) techniques, both supervised and unsupervised, have potential identify patients at risk through the development of risk prediction models and a data-driven redefinition of patient classes. This might be particularly relevant when addressing the changing dynamics of the opioid epidemic, due to its ability to ascertain non-linear relationships between various risk factors and the risk of opioid-related harms.
Objectives: To perform a systematic review of the use of ML methods in prescription opioid-related harms research.
Methods: A systematic literature search was conducted using the databases Ovid MEDLINE, PubMed and SCOPUS databases to identify relevant articles that were published from inception to October 2022. Articles were eligible for review if they described studies that applied ML techniques with a primary outcome that was related to prescription opioid harms and using electronic health records as a main data source for the research. We excuded studies that focused patients with cancer or younger than 18 years old.
Results: A total of 760 abstracts were reviewed, yielding 75 articles for full text review. Four main categories were identified in this area: development of ML algorithms for prediction (n=81, 81%), identification of risk factors n=7, 9%),

patient subtype clustering (n=5, 7%) and the application of natural language processing to understand user-generated text for pharmacovigilance (n=2, 3%). Within the studies that developed ML models for prediction, most of them (n=16, 21%) had prolonged postoperative opioid use as their main outcome (the majority looking at arthroplasty, arthroscopy and spine surgery patient populations). All these studies had skewed outcome proportions but only three studies (4%) addressed it (with either oversampling techniques or reporting the area under the precision-recall curve). Only one study had been externally validated. Other primary outcomes of prediction models developed included opioid use disorder (n=12, 16%), opioid overdose prediction (n=9, 12%), opioid administration and prescribing (n=6, 8%) and chronic opioid use (n=3, 4%). For risk factor identification, ML techniques were limited to understanding the drivers of opioid-overdose (n=2, 3%), opioid dependency (n=2, 3%) and opioid administration and prescribing (n=3, 4%). A very limited number of studies used unsupervised and semi-supervised ML algorithms to address opioid-associated outcomes (n=8, 11%).

Conclusion: To date, application of ML techniques besides logistic regression to classify patients who experience opioid-related harms has been limited, with most publications using electronic health records from the United States in the last 5 years. The majority focused on prediction algorithms for postoperative opioid use and have limited implementation in clinical practice. The current literature lacks external validation studies for developed prediction models using ML. This is especially important if implemented outside of the United States, since the use of opioids is affected by a diverse set of individual and contextual factors that can substantially vary across countries.

AB1657 TIME-DEPENDENT CSDMARDS USE AND INFLAMMATORY BURDEN CAN PREDICT CARDIOVASCULAR RISK IN PATIENTS WITH ANKYLOSING SPONDYLITIS:A POPULATION-BASED STUDY

Keywords: Cardiovascular disease, Prognostic factors, Disease-modifying drugs (DMARDs)

J. L. H. Shi[1], S. H. M. Lam[1], H. Meng[1], H. So[1], L. S. Tam[1]. [1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China*

Background: It is well established that AS patients had a higher risk of cardiovascular disease (CVD) than the general population [1,2]. To date, there is no primary studies directly addressing the relationship between risk factors and MACE in population-level study.

Objectives: To examine whether inflammatory burden and drug use over time increase major adverse cardiovascular events (MACE) independent of traditional cardiovascular (CV) risk factors in ankylosing spondylitis (AS) patients.

Methods: Patients who had been diagnosed with AS (ICD-9: 720.0) from 2006 to 2015 were recruited in a retrospective cohort study. They were followed until the end of 2018. The primary outcome was a first incidence of MACE. Time-varying Cox proportional hazard models were used to assess whether inflammatory burden (c-reactive protein [CRP] and erythrocyte sedimentation rate [ESR]), and drug use (non-steroidal anti-inflammatory drugs [NSAIDs] and disease modifying anti-rheumatic drugs [DMARDs]) can predict the development of first MACE.

Results: Totally 3827 patients (age: 45.2 ± 15.0 years, male: 2911 [76.1%]) were recruited. 135 patients (13.2%) developed a first MACE. ESR level (including ESR≥20 mm/h and ESR≥30mm/h, HR: 2.07-2.41), CRP level (including CRP>3 mg/dl, HR: 1.20-8.77) and use of steroid (HR: 3.48) were associated with a significantly higher risk of MACE during follow-up. Whereas the use of sulfasalazine (SLZ), bDMARDs and non-COXII inhibitor were associated with reduced risk of MACE. After adjusting for time-fixed CV risk scores in the multivariable models, only ESR level (including ESR≥30 mm/h, HR: 1.02-1.94) and CRP level (including CRP>3 mg/dl, HR: 1.14-5.43) remained significant predictor for increased risk of MACE, while SLZ (HR: 0.41-0.52) was protective against MACE.

Conclusion: Increased inflammatory burden was associated with increased risk of MACE, while the use of SLZ may reduce risk of future MACE in patients with AS.

AB1658 COMPARISON OF STERNOCLEIDOMASTOIDEUS FLEXIBILITY, VAGUS NERVE FUNCTION, AND GASTROINTESTINAL SYMPTOMS IN CHRONIC NECK PAIN AND HEALTHY INDIVIDUALS

Keywords: Gastrointestinal tract, Prognostic factors, Non-pharmacological interventions

Y. Özel Aslıyüce[1], Ö. Uysal[1], A. Fanuscu[1], U. Berberoğlu[1], O. Ulger[1]. [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Ankara, Turkey*

Background: The vagus nerve emerges from the jugular foramen and continues through the carotid sheath in the cervical region. The carotid sheath is in contact with the SCM muscle. It has been hypothesized that Sternokleidomastoideus (SCM) muscle tension may affect the carotid sheath and the function of the vagus nerve passing through it. It is known that there is an increase in activation of the SCM muscle in individuals with chronic neck pain (CNP), which may change the passive mechanical properties of the muscle [1]. It has been shown that vagus nerve dysfunction can cause pathologies in the organs it innervates. Although the relationship between vagal dysfunction and gastrointestinal system symptoms is clear, the mechanisms that may affect vagus nerve function have not yet been clarified.

Objectives: This study aims to compare the passive mechanical properties of the SCM muscle, vagus nerve function, and gastrointestinal symptoms in healthy individuals with neck pain.

Methods: Tone, stiffness and elasticity, which are the passive mechanical properties of the SCM muscle, were measured with the Myoton-3 myotonometric medical device (Muomeetria AS, Estonia, EU). Vagus nerve function was evaluated with the Vagus Neurodynamic Test (VAGUS-NDT)[2]. The test was performed bilaterally. Gastrointestinal symptoms were evaluated with the Gastrointestinal Symptom Rating Scale (GSRS).

Results: 29 individuals, 15 healthy, 14 with CNP, who were not diagnosed with gastrointestinal or any systemic disease were included in the study. In individuals with CNP, the positivity of VAGUS-NDI test and GSRS all sub-scores (reflux, indigestion, diarrhea, constipation and abdominal pain) and total score were higher than healthy individuals ($p<0.05$). In addition, right and left elasticity scores for the SCM muscle were lower in these individuals than in healthy individuals ($p<0.05$) while tone and stiffness were similar($p>0.05$).

Conclusion: According to our preliminary results, SCM elasticity was lower and the incidence of vagal dysfunction and gastrointestinal symptoms were higher in individuals with CNP than in healthy. This may be due to compression of the vagus nerve passing through the carotid sheath as a result of decreased SCM muscle elasticity. The increase in the tension of the soft tissues around a nerve in the body restricts the movement of the nerve, affecting its function and making it susceptible to entrapment. Even this slight nerve compression can cause entrapment and lead to neuroinflammation[3]. This research is a preliminary conclusion that neck pain and decreased SCM elasticity may be an important factor that may affect vagal function. This relationship needs to be investigated with a larger sample group and advanced statistical methods.

Background: Limited data have been published on tolerance and efficacy of biotherapy in moroccan patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA).
Objectives: To assess in real life the safety and efficacy of biological treatments in moroccan patients with RA and SpA.
Methods: The RBSMR is a registry of biological therapies in rheumatic diseases from the Moroccan Society of Rheumatology. The patients recruited were over the age of 18 years, diagnosed with RA or SpA, fulfilled ACR/EULAR 2010 criteria and ASAS 2009 criteria respectively and treated with biologics (initiation or ongoing biotherapy) in 10 Moroccan university medical centers. The inclusion period was from May 2017 to January 2019. Follow-up data were collected every 6 months for 3 years. The details of the data collected have been published previously. [1] Statistical analysis was performed using Jamovi software, 1.6.
Results: A total of 225 RA and 194 SpA including 170 ankylosing spondylitis were treated with biologics (bDMARDs). Overall median age at inclusion was 53 and 39 years. The median disease duration was 146 and 131 months for RA and SpA respectively.163 (72.4%) RA and 137(70.6%) SpA received a first line bDMARDs.10.7 % RA and 55.2 % SpA were prescribed bDMARDs in combination with csDMARDs. After 3 years of follow-up, median DAS28 CRP was 2.6 [0.9-4] (p<0.001) and median ASDAS CRP was 1.8 [1-2.4] (p=0.66). The most commonly used drug was rituximab (60%) in RA and etanercept (33%) in SpA. At 3 years-follow up, 18.3% and 17.4% adverse events were reported in RA and SpA patients respectively. The most common adverse events reported in RA and SpA were infections, mainly nonspecific infections, in both diseases (5.8%, 5.2%). One lymph node tuberculosis in an RA patient taking infliximab and 6 cases of tuberculosis in SpA patients taking anti-TNFs were reported in our registry. Malignancy was observed in 3 patients with RA (1 non-Hodgkin lymphoma, 1 bladder cancer and 1 breast cancer) and 2 SpA patients (1 vocal cord carcinoma and 1 multiple myeloma). During follow-up, 38bDMARDs switchers were reported in RA patients (10 at 1 year, 9 at 2 years and 9 at 3 years), while 41 switchers were reported in SpA patients (23 at 1 year, 14 at 2 years and 4 at 3 years).
Conclusion: In this real-world analysis of data from the RBSMR registry, a considerable proportion of patients with RA and Spa had an adequate response to bDMARDs at 36 months. Infections, mainly nonspecific infections, were the main adverse events in both RA and SpA of our registry.

Table 1. Adverse events of bDMARDs in RA and SpA patients during 3 years of follow up

	RA N=225			SpA N=194

ASSOCIATION OF COMMON COMORBIDITIES WITH ASEPTIC OSTEONECROSIS: EXPERIENCE OF RHEUMATOLOGY DEPARTMENT

Keywords: Bone diseases, Comorbidities

H. Bejaoui[1], A. Feki[1], S. Ben Jemaa[1], Z. Gassara[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], R. Akrout[1], S. Baklouti[1]. [1]*Hedi chaker Hospital, Rheumatology Depatment, Sfax, Tunisia*

Background: Osteonecrosis (ON) (avascular necrosis, aseptic necrosis or subchondral avascular necrosis) is not a specific disease entity but the final common pathway of a number of conditions leading to bone death [1].
Objectives: To examine the frequency of ON and to investigate different common comorbidities association with ON in a rheumatology department.
Methods: All patients with a first-time hospital diagnosis of ON in rheumatology department during 1995–2022 were included. We obtained a complete hospital history of comorbidities preceding the diagnosis of ON.
Results: 43 ON cases were included with an average of 1.6 cases/year. The mean age of our patients was 53 years (27-82). The sex-ratio male to female was 1,75 (12 females and 21 males). The different sites of osteonecrosis were distributed as follows: femoral head, femoral condyle, semilunar and humeral head. The diagnosis of ON was confirmed by simple radiography in15 cases, bone scan in 14 cases and with magnetic resonance imagery in 14 cases. Dyslipidemia was the most common comorbidity (13.9 % of patients), followed by high blood pressure, hypothyroidism, allergic asthma, obesity, alcohol abuse, renal failure, rheumatoid arthritis, diabetes, gout, hemopathy, trauma, and coronary artery disease. Among these chronic conditions, the most common recognized risk factor of ON in our series was medications (corticosteroids) followed by dyslipidemia, alcohol abuse, hemopathy (sickle cell anemia, Hodgkin's lymphoma and beta thalassemia) and trauma (fractures and dislocation of the hip). All patients received medical treatment based on painkillers and functional rehabilitation. 12 patients had surgical treatment: 8 total hip prosthesis, 3 Core decompression and bone marrow aspirate concentrate injection for Avascular Necrosis of the femoral head and 1 Proximal row carpectomy for semilunar osteonecrosis.
Conclusion: This monocentric study provides evidence for an increasing ON incidence associated to systemic steroid administration. Hence the need for early and adequate management of this factor to prevent possible complications such as aseptic osteonecrosis.

INCREASED RISK OF TOTAL HIP ARTHROPLASTY IN RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS OVERLAP SYNDROME

Keywords: Rheumatoid arthritis, Comorbidities, Systemic lupus erythematosus

C. C. Lai[1], Y. S. Chang[2], C. F. Su[2], L. Sheng-Hong[2]. [1]*Taipei Veterans General Hospital, Allergy, Immunology, and Rheumatology, Taipei City, Taiwan, Republic of China*; [2]*Shuangho Hospital, Ministry of Health and Welfare, Allergy, Immunology, and Rheumatology, New Taipei City, Taiwan, Republic of China*

Background: Patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) have increased risk of total hip arthroplasty (THA).[1,2] Patients with RA and SLE overlap syndrome (RA+SLE) may have a more common articular involvement than each disease does. However, the risk of THA in RA+SLE patients is not fully investigated.
Objectives: To identify the risk and outcome of THA in RA+SLE patients in a longitudinal cohort.
Methods: We analyzed datasets derived from Taiwan National Health Insurance Research Database from 2000 to 2018. Patients with RA, SLE, and RA+SLE were selected and matched according to the age and gender. Risk and outcome of THA was compared, and multivariable Cox proportional hazards models were used to analyze the risk factors.
Results: 2270 RA+SLE patients were matched with 9080 RA and 9080 SLE patients. RA+SLE patients had the highest rate of THA than RA or SLE patients did (2.16% vs 1.22% or 1.76%, respectively; p=0.0008). Avascular necrosis (1.45%) followed by osteoarthritis (1.28%) were the most common reasons for THA in RA+SLE patients. The rate of THA revision was the highest in RA patients than in RA+SLE or SLE patients (9.91% vs. 4.08% or 6.25%, respectively; p<0.0001). Chronic kidney disease (HR: 4.94, 95% CI: 2.51–9.71, p<0.0001), use of prednisolone or equivalence >10 mg/day (HR: 2.1, 95% CI: 1.53–2.88, p<0.0001), azathioprine (HR: 2.15, 95% CI: 1.68–2.74, p<0.0001), and biologic agents (HR: 2.03, 95% CI: 1.46–2.81, p<0.0001) increases the risk of THA independently.
Conclusion: RA+SLE patients had the highest rate of THA than patients with individual disease alone, however, the rate of THA revision was the highest in RA patients than in the other groups. Comorbidities, treatment with a higher daily dose of steroid, and immunosuppressants may contribute to the risk of THA.

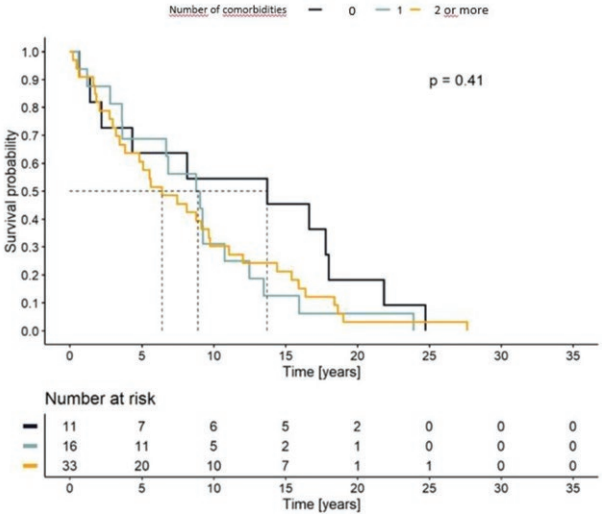
AB1662 IMPACT OF COMORBIDITIES AND FREQUENCY OF ADMISSIONS ON MORTALITY IN PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Comorbidities, Prognostic factors, Behcet's disease



H. Amar Muñoz[1], I. Catrejón[1], A. Ramos[1], F. Montero[1], K. Carpio[1], J. Molina Collada[1], B. Serrano-Benavente[1], J. M. Alvaro-Gracia[1], J. Martínez-Barrio[1].
[1]*Hospital General Universitario Gregorio Marañón, Madrid, Spain., Department of Rheumatology, Madrid, Spain*

Background: Data on mortality in patients with systemic autoimmune rheumatic diseases (SARDs) is limited. Most evidence is restricted to patients with systemic lupus erythematosus and ANCA vasculitis [1-2]. In recent years, mortality has been more closely associated with cardiovascular pathologies and infections and less with disease activity.
Objectives: To assess the impact of comorbidities and hospital admissions on mortality in patients with SARDs in a tertiary referral hospital.
Methods: We conducted a retrospective observational study including adult patients with SARDs (Table 1) followed up in our Multidisciplinary Unit of Systemic Autoimmune Diseases between January 2017 and December 2019. In this cohort, patients were under similar follow-up and treatment protocols. Gathered data includes epidemiological, hospitalization (number of admissions, hospital stay and reasons for admission) and exitus information. In hospitalized patients, associated comorbidities were also reviewed. A comparison was made between patients who required at least one admission during the study period and those who did not, in addition to a description of mortality. Kaplan Meier curves are presented by number of comorbidities and number of admissions.
Results: Of the 1749 patients with SARDs included in our cohort, 432 (24.7%) required hospitalization during the study period. Of those hospitalized, mean age was 64 years and 315 (73%) were women. A total of 61 (14%) deaths occurred among patients admitted to the hospital vs 77 (5.9%) among non-hospitalized, within the study period. Behcet's disease and IgG4-related disease presented highest mortality rate (29%) in our cohort of hospitalized patients, closely followed by antiphospholipid syndrome (23%) and Sjögren's syndrome (20%) (Table 1). No statistically significant differences were observed in mortality according to the number of admissions (p=0.56) or comorbidities (p=0.41), although in the latter, an increasing trend was observed as the number of comorbidities increased (survival according to the number of comorbidities: no comorbidities =14 years, one comorbidity =8.9 years, two or more comorbidities =6.4 years) (Graph 1).
Conclusion: We have found no impact of comorbidities or hospital admissions in mortality in patients with SARDs. Among hospitalized patients, higher mortalities were observed in Behcet's disease, IgG4-related disease, antiphospholipid syndrome and Sjögren's syndrome. In addition, a trend towards greater mortality was observed in relation to the number of comorbidities.

AB1663 MUSCULOSKELETAL (MSK) PAIN IN VILLAGE BHIGWAN (INDIA) IN 2022- CHANGE OVER 25 YEARS: WHO COMMUNITY ORIENTED PROGRAM FOR CONTROL OF RHEUMATIC DISEASES (COPCORD) 1996-2022

Keywords: Epidemiology, Gender/diversity issues, Descriptive studies

H. Rathod[1], K. Adam[1], R. Ghorpade[1], A. Venugopalan[1], M. Saluja[1], A. Chopra[1].
[1]*Center for Rheumatic Diseases, Rheumatology, Pune, India*

Background: COPCORD population surveys (Stage I) have reported the prevalence of MSK pain and rheumatic disorders in several countries. A crude point prevalence rate of 18.2% for MSK pain (adult) was reported by the maiden COPCORD India survey (1996) in rural Bhigwan (Pune) and was continued to date with a free-of-cost local rheumatology clinic and a health education program. Several other factors (development, environment, Chikungunya epidemic 2006, Covid pandemic 2019) are likely to impact the epidemiology of MSK disorders and thus we carried out a resurvey in Bhigwan from April to July 2022. We present early results of MSK pain and related factors.
Objectives: To describe and measure the current MSK pain and rheumatic disorders in Bhigwan rural population and further assess the transformation over time (1996 to 2022).

Methods: The resurvey (Stage I) was carried out using the methods of the previous survey (Bhigwan COPCORD model 1996). Trained voluntary health workers (HW) completed a house-to-house cross-sectional survey (Phase 1) of the adult population(≥ 18 years) and identified current and/or past MSK pain respondents. Pain due to recent trauma (< 3 months) was excluded. Concurrently, the respondents were also evaluated (Phase 2) for pain descriptors and other relevant issues. Rheumatologists examined (Phase 3) the respondents to make a clinical diagnosis, order relevant investigations, and begin treatment. A follow-up was scheduled. The target population was estimated at 8117 (Government records). The database was created using an indigenous software program. Standard population analysis was carried out. Crude point prevalence rates (95% confidence intervals) are presented. Further analysis is being done.
Results: 6970 population (85.9% response, 50% males) was surveyed. The age-gender distribution pattern was comparable with the India rural census 2011; 63% in 18-44 years age groups (Bhigwan). Paradoxically, only 7.6% current population in sharp contrast to about 55% in 1996 admitted working (physically) in fields; now dependent upon temporary migrant labor (not in the survey). 32% population possessed mobile phones. Five hundred eighty-six pain respondents (women 69%) were identified; 46% belonged to the 45-64 years age group. The MSK pain prevalence was 8.2% (7.5%, 8.8 %); male 2.5 (2.2 %,2.9%). female 5.6% (5.1, 6.2). 14.2% population used tobacco in some form, mostly oral; 36.3% of MSK pain respondents (58% women). Hypertension in 7.9%, diabetes in 4.7%, thyroid disorders in 1.6%, and rectal hemorrhoids in 1% was self-reported in the population; correspondingly 25%, 12%, 2.5%, and 3% were reported by the MSK pain cohort. Past history of Chikungunya in 5.7% and COVID-19 in 7.4% of the total population was reported. On univariate analysis, MSK pain was significantly associated ($p < 0.0001$, Chi-square) with Chikungunya, COVID-19, tobacco use, fieldwork, and low education status. Prevalence rates for disease groups were 1.38% (1.12. 1.68) for inflammatory arthritis, 3.66% (3.23, 4.13) for degenerative arthritis and 2.87 % (2.49, 3.29) for non-specific rheumatism/arthritis. Self-reported data, subject recall, and limited investigations were important concerns.
Conclusion: The current COPCORD survey shows that despite a substantial reduction from 1996, MSK pain continues to be a predominant and important self-reported illness in the Bhigwan rural community. Undoubtedly, the lives and livelihoods of the Bhigwan people and their MSK landscape have been transformed substantially. Interestingly, the burden of other non-communicable diseases seems increased. Further research studies will be required to unravel the role of Chikungunya and COVID-19, and other risk factors in MSK disorders.

AB1664 INFLUENZA, PNEUMOCOCCAL, AND TETANUS VACCINE COVERAGE AMONG PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES ON BIOLOGICAL OR TARGETED SYNTHETIC DMARDS AND THE ROLE OF THE RHEUMATOLOGIST

Keywords: Vaccination/immunization

T. Georgiev[1], R. Moraliyska[2], S. Bogdanova-Petrova[1], S. Dimitrov[1], S. Hristova[3], D. Simeonova[1], G. Gerganov[1], T. Shivacheva[1]. *[1]Medical University Varna, First Department of Internal Medicine, Varna, Bulgaria*; *[2]Medical University Varna, Clinical Medical Sciences, Varna, Bulgaria*; *[3]Medical University Varna, Department of General Medicine, Varna, Bulgaria*

Background: Vaccines are one of the most efficient tools to prevent infectious diseases at a population level. Their importance is even greater in immunocompromised patients providing efficient and safe protection against common viral and bacterial infections. According to the current EULAR recommendations based on solid evidence over the recent years, non-live vaccines such as influenza, pneumococcal, tetanus toxoid, and others are safe and can be administered to patients with inflammatory rheumatic diseases during the glucocorticoid and/or disease-modifying antirheumatic drug (DMARD) therapy. Furthermore, influenza and pneumococcal vaccines "should be strongly considered" and the tetanus toxoid vaccination should be received in accordance with the recommendations of the general population[1].
Objectives: We aimed to investigate the coverage for influenza, pneumococcal, and tetanus toxoid vaccination in a cohort of patients with inflammatory rheumatic diseases on biological or targeted synthetic DMARDs.
Methods: Two hundred and one patients, aged 18 or older, were included in this single-center cross-sectional study after signing an informed consent form. They suffered from rheumatoid arthritis (RA), psoriatic arthritis (PsA), or ankylosing spondylitis (AS) and were on biological or targeted synthetic DMARDs. Individuals with psychiatric or neurological diseases preventing understanding or responding to the questions were excluded from the study. Patients' anthropometric, clinical, and demographic characteristics were collected via detailed anamnesis and clinical examination. Disease activity was evaluated using DAS28-CRP for patients with RA and peripheral PsA and ASDAS for those with axial disease (AS and axial PsA). All patients were asked to fill in a survey determining their immunization status for influenza, pneumococcal, and tetanus toxoid vaccines and whether they had a preceeding discussion with their rheumatologist about recommended vaccines during their routine medical visits.
Results: Of the 201 included patients, 40.3% (n=81) were females. Patient distribution according to their disease was as follows: 30.3% (n=61) RA patients, 51.7% (n=104) AS patients, and 17.9% PsA patients (n=36). Mean age, disease duration, and body mass index values were 54.62 (14.4) years, 11.04 (8.6) years and 28.2 (5.3), respectively. 27.4% of patients were on concomitant glucocorticoid treatment. Only 13.9% (n=28) and 1.5% (n=3) were vaccinated against seasonal influenza and pneumococcal infections, respectively. Patients who had a preceeding discussion about seasonal influenza and pneumococcal immunization with their rheumatologist had approximately 13 and 32 times higher probability to get vaccinated than people who did not (OR=12.9, $p < 0.001$ and OR 32.5, $p = 0.01$, respectively). Regular reimmunizations against diphtheria and tetanus according to the Immunization Calendar of the Republic of Bulgaria were carried out by only 44.8% (n=90) of the studied population.
Conclusion: Coverage of recommended vaccines in our group of Bulgarian patients on biological or targeted synthetic DMARDs is very low. Discussion about the potential benefits and safety profile of the recommended vaccines may increase patients' willingness to vaccinate and prevent common infectious diseases in immunocompromised rheumatic patients.

AB1665 NON-IMPAIRED KIDNEY FUNCTION INCREASES HYPERURICAEMIA-ASSOCIATED MORTALITY RISK EFFECT

Keywords: Epidemiology, Kidneys, Gout

J. Timsans[1], J. Kauppi[2], A. Kerola[3,4], T. Lehto[5], H. Kautiainen[6], M. Kauppi[1,4]. *[1]Päijät-Häme Central Hospital, Department of Rheumatology, Lahti, Finland*; *[2]Päijät-Häme Central Hospital, Unit of Physiatry and rehabilitation medicine, Lahti, Finland*; *[3]Helsinki University Central Hospital, Inflammation Center, Helsinki, Finland*; *[4]University of Helsinki, Faculty of Medicine, Helsinki, Finland*; *[5]Fimlab Laboratoriot Oy, Department of Clinical Chemistry, Lahti, Finland*; *[6]University of Helsinki, Folkhälsan Research Center, Helsinki, Finland*

Background: Both hyperuricaemia and reduced kidney function are known mortality risk factors.[1-3] Also, hyperfiltration is associated with elevated mortality risk.[3] It has not yet been studied if renal function has a modifying effect on hyperuricaemia-associated mortality risk.
Objectives: To detect if renal function has a modifying effect on hyperuricaemia-associated mortality risk.
Methods: Data from GOAL (Good Ageing in Lahti region) study was used. It is a large, prospective, population-based study of elderly people (52–76 years) in the Lahti region. Data of serum uric acid (SUA) levels, creatinine, cystatin C as well as several other laboratory variables, comorbidities, lifestyle habits and socioeconomic factors was collected. To estimate glomerular filtration rate, we used CKD-EPI creatinine-cystatin C equation (ml/min/1.73 m^2). Persons with SUA values of >410 µmol/L (75^{th} percentile) are represented as clearly hyperuricaemic. Persons with eGFR of ≤67 ml/min (25^{th} percentile) are represented as having reduced kidney function. The results were adjusted for age, gender, education, smoking status, alcohol consumption, body mass index, hypertension and dyslipidaemia.
Results: Mortality was higher in individuals with reduced kidney function compared to those with eGFR of >67 ml/min both in the group of clearly hyperuricaemic persons and in the group of persons with SUA ≤410 µmol/L. The hazard ratio (HR) for all-cause mortality was 1.53 (95% CI: 1.26 to 1.84) in clearly hyperuricaemic persons with reduced kidney function, 1.26 (95% CI: 1.02 to 1.55) in clearly hyperuricaemic persons with eGFR of >67 ml/min, 1.26 (95% CI: 1.03 to 1.55) in persons with SUA ≤410 µmol/L and reduced kidney function, while the group of

SUA ≤410 µmol/L and eGFR >67 ml/min was used as a reference (Table 1). HR for hyperuricaemia-related premature death however was lowest in individuals with reduced eGFR, and it rises strikingly as the eGFR increases above 80ml/min (Figure 1).

Conclusion: Reduced kidney function is an important risk factor for mortality both in individuals with lower and higher SUA. The mortality risk associated with hyperuricaemia is remarkably higher in individuals with normal or only slightly reduced kidney function. This finding makes it reasonable to speculate that hyperuricaemia caused by overproduction of uric acid (metabolic hyperuricaemia) might be a separate and more deleterious entity than hyperuricaemia that has resulted from renal underexcretion of uric acid (renal hyperuricaemia).

Background: The clinical manifestations of patients with rheumatic diseases are highly heterogeneous. The appearance of adverse events (AEs) related to the treatments received for these diseases considerably increases the morbidity and mortality of these patients. This is why obtaining real-world data on these AEs and analyzing their causes is paramount. The BIOBADASAR registry has data from 5,676 patients over ten years of follow-up. Classifying patients in treatment with biological drugs into subgroups with different phenotypes through unsupervised grouping could provide valuable information on the characteristics associated with specific AE.

Objectives: Through cluster analysis, this study aimed to identify different clinical phenotypes related to Adverse events in patients treated with biological drugs.

Methods: Retrospective, multicenter study of patients with rheumatic diseases treated with original biological drugs, biosimilars, or original and generic targeted therapies in Argentina; follow-up from August 2010 to July 2021. Demographic and clinical data, time of initiation and completion of treatments, data on disease activity, and the AEs presented were collected. Patients were unbiasedly matched based on their clinical and phenotypic profiles using a k-means pooling method. The initiation of biological disease-modifying antirheumatic drugs (b-DMARD) was evaluated in the segregated groups to investigate each group's clinical course and differential characteristics.

Results: A total of 5676 patients were analyzed. Three different clusters were obtained:

Cluster 1: 1041 patients. Was observed an evolution time of the disease of 30.5 years (Q1 25.8; Q3 35.6) longer than other clusters and a longer delay in starting treatment at 18.3 years (Q114.4; Q3 24) p < 0.0001.
Cluster 2: 2136 patients. We observed a higher frequency of patients with Systemic Lupus Erythematosus: 156 (7.3%) p<0.0001 and a lower frequency of AEs 190 (8.9%) p <0.0001
Cluster 3: 2499 patients. We observed a higher mean age than in the other two clusters, 57.3 (SD 8.3) p < 0.001.
The use of systemic corticosteroids was evenly distributed among the 3 clusters.
Conclusion: The unsupervised grouping of patients from the BIOBADASAR registry demonstrated the existence of clusters based on clinical and demographic characteristics. Identifying high-risk patients through a combination of these parameters may be helpful for the early identification of risk factors and their association with adverse events. Based on our hierarchical cluster analysis, we identified different patient phenotypes. Our results show that within the heterogeneity of patient characteristics, common elements provide a basis for future analyses of these variables and their relationship with certain AEs.

UNDERSTANDING THE ROLE AND ADOPTION OF ARTIFICIAL INTELLIGENCE TECHNIQUES IN RHEUMATOLOGY RESEARCH: AN IN-DEPTH REVIEW OF THE LITERATURE

Keywords: Systematic review, Artificial intelligence

A. Madrid García[1], B. Merino Barbancho[2], A. Rodríguez González[3], B. Fernandez[1], L. León[1], L. Abasolo[1], D. Freites[1], E. Menasalvas Ruiz[3], L. Rodriguez Rodriguez[1]. [1]*Grupo de Patología Musculoesquelética. Hospital Clínico San Carlos, Reumatología, Madrid, Spain*; [2]*Universidad Politécnica de Madrid, Madrid, Spain*; [3]*Centro de Tecnología Biomédica, Universidad Politécnica de Madrid, Lenguajes y Sistemas Informáticos e Ingeniería de Software, Madrid, Spain*

Background: Artificial intelligence (AI) is rapidly gaining adoption in the medical field [1]. We review, the original research articles that combine AI and Rheumatic and Musculoskeletal diseases (RMDs) in a five-year period (2017-2021) and classify them into one of the following categories: disease classification, disease prediction, predictors identification, patient stratification and disease subtype identification, disease progression and activity, and treatment response.
Objectives: The present review arises with the aim of characterizing how rheumatology researchers are employing AI techniques and to study to what extent these techniques have been adopted by rheumatologists.
Methods: A literature search was conducted to identify publications related to RMDs in which AI techniques played a relevant role in four different sources: PubMed, Web of Science, Scopus and in the search engines of rheumatology journals classified as Q1 and Q2 according to Journal Citation Reports 2019. The keywords employed were artificial intelligence, supervised learning, unsupervised learning, deep learning, big data, data mining, machine learning, rheumatology, musculoskeletal diseases, rheumatic. Only original research articles related to RMDs with a PubMed identification number (PMID), not duplicated, written in English, in which there was not animal involvement and in which at least one AI technique was employed, fulfilled the inclusion criteria. Later, an abstract and title filtering followed by a full text review of selected articles was performed.
Results: After applying the inclusion and exclusion criteria (see Figure 1) and performing the full text review, 91 articles remained. From those, the article title, the identifiers (DOI, PMID), the journal, the publication year, the disease, the algorithms/techniques, the programming language, the number of patients, the validation type, the objective, and the authorship information were collected. In addition, an illustrative table with more than twenty different RMDs, including arthritis, vasculitis, fibromyalgia, gout, spondylitis, sarcopenia, Sjögren, systemic sclerosis, and back and neck pain was obtained. The publication trend has increased each year, from 20% to 48%, in relation to the previous year. The techniques employed are variable, including supervised and unsupervised learning, and traditional machine learning and deep learning approaches. Some of the topics addressed are classification, regression, clustering, dimensionality reduction, topic modelling, computer vision, reinforcement learning, few-shot learning, and trajectory analyses. Osteoarthritis, rheumatoid arthritis, systemic lupus erythematosus and osteoporosis are the RMDs that accounts for most of the research studies in which AI techniques are used more assiduously. However, AI is also playing a key role in rare diseases research, such as vasculitis, with approaches such as topic modelling. The amount of data in the studies reviewed is variable, from just hundreds of observations to hundreds of thousands, showing that "big data" cohorts are not mandatory to take advantage of such techniques.
Conclusion: The outstanding and upward trend in the number of published research related to rheumatic and musculoskeletal diseases, in which AI plays a key role, has exhibited the interest of rheumatology researchers in using these techniques to answer their research questions. We can conclude that the rheumatology research community is increasingly adopting novel AI techniques.

RESPIRATORY INFECTIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS, PRIMARY AND SECONDARY AFS BEFORE AND AFTER VACCINATION WITH 23-VALENT POLYSACCHARIDE PNEUMOCOCCAL VACCINE

Keywords: Vaccination/immunization

G. Koilubaeva[1], G. Tarasova[2], B. Belov[2], A. Bolotbekova[1], G. Syunbai K[1], A. Turatbekova[1]. [1]*3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan*; [2]*Kashirskoye Shosse, 34, Rheumatology, Moskva, Russian Federation*

Background: Infections are one of the main causes of morbidity and mortality in patients with autoimmune inflammatory rheumatic diseases (AIIRD). Pneumococcal vaccination can significantly reduce the number of serious respiratory infections in this group of patients.
Objectives: To analyze the frequency of respiratory infections in systemic lupus erythematosus (SLE), secondary and primary antiphospholipid syndrome (AFS) before and after vaccination with 23-valent polysaccharide pneumococcal vaccine (PPV-23).
Methods: 91 patients were included in the study, 78 of them with SLE, including 18 with secondary AFS; 13 patients with primary AFS. The follow-up period was 12 months. All patients with SLE and secondary AFS received immunosuppressive therapy, including 29 anti-B-cell therapy. With primary AFS, 6 patients received immunosuppressive therapy, including 1- rituximab.
Results: All LRTI were more common in SLE (48.3%, 27.8%, 11.8%, respectively), mainly due to the more frequent development of pneumonia (Pn) (20%, 11%, 7.7%, respectively). After vaccination, the number of pneumonias decreased from 15 (16.5%) to 4 (4.4%) and were registered only in patients with SLE, p=0.01. These were not severe pneumonia, did not require hospitalization; in all cases there were predisposing factors (anti-B-cell therapy with the absence of an adequate vaccine response - 3, interstitial lung disease (ISL) - 1). Before vaccination, among ENT infections, sinusitis was more common with SLE than with SLE + secondary APS (16.7%, 8.3%, respectively), with primary APS it was not detected.After vaccination, infections of ENT organs in patients with primary and secondary AFS were absent, with SLE there was a significant decrease (from 30% to 10%). With primary AFS, respiratory diseases have not been registered after vaccination.

Table 1. The frequency of respiratory infections in patients with SLE, secondary and primary AFS, n=91.

	SLE		SLE + secondary AFS		primary AFS	
	Before vaccination **n=60**	After vaccination **n=60**	Before vaccination **n=18**	After vaccination **n=17**	Before vaccination **n=13**	After vaccination **n=13**
LRTI:	**29 (48,3%)**	9 (15%)	5 (27,8%)	2 (11,8%)	3 (23%)	**-**
Pneumonia	**12 (20%)**	**4 (6,7%)**	2 (11%)	-	1 (7,7%)	**-**
Acute bronchitis	**10 (16,7%)**	3 (5%)	**3 (16,7%)**	2 (11,8%)	1 (7,7%)	**-**
Exacerbation of chronic bronchitis	**7 (11,7%)**	2 (3,3%)	-	-	1 (7,7%)	-
ENT infections:	**18 (30%)**	**6 (10%)**	3 (16,7%)	-	3 (23%)	**-**
Sinusitis	**10 (16,7%)**	**5 (8,3%)**	1 (5,5%)	-	-	-
Pharyngitis	4 (6,6%)	-	1 (5,5%)	-	1 (7,7%)	-
Exacerbation of chronic tonsillitis	3 (5%)	-	1 (5,5%)	-	1 (7,7%)	-
Otitis media	1 (1,7%)	1 (1,7%)	-	-	1 (7,7%)	-

Notes: LRTI - Lower Respiratory Tract Infections; ENT infections - otorhinolaryngological infections.

Conclusion: The clear clinical efficacy of PPV-23 in patients with SLE and AFS has been demonstrated. In primary AFS, fewer respiratory infections and their absence after vaccination are naturally explained by less aggressive immunosuppressive therapy. A possible reason for the lower number of INDO in secondary AFS, in comparison with SLE without AFS, may be the absence of ISL in these patients.

CLINICAL, HISTOLOGICAL FEATURES AND PREDICTORS OF RELAPSE IN PATIENTS WITH IDIOPATHIC GRANULOMATOUS MASTITIS

Keywords: Disease-modifying drugs (DMARDs), Rare/orphan diseases, Epidemiology

B. Abbi[1], N. Sanghavi[2], S. Lanjewar[3], S. Fineberg[3], X. Xie[4], A. Gupta[5], A. Kumthekar[6], B. Ayesha[6]. [1]*Lahey Hospital and Medical Center, Rheumatology, Beverly, United States of America*; [2]*Westchester Medical Center, Internal Medicine, Valhalla, United States of America*; [3]*Montefiore Medical Center, Pathology, Bronx, United States of America*; [4]*Albert Einstein College of Medicine, Epidemiology and Population health, Bronx, United States of America*; [5]*Montefiore Medical Center, Surgery, Bronx, United States of America*; [6]*Montefiore Medical Center, Rheumatology, Bronx, United States of America*

Background: Idiopathic Granulomatous mastitis (IGM) is a chronic benign inflammatory breast disease characterized by non-caseating granuloma with multinucleate giant cells and micro-abscesses[1]. It presents as painful breast lump, with axillary lymphadenopathy, nipple retraction, and peau d'orange appearance of the skin mimicking inflammatory breast cancer [1]. Till date, there are no consensus guidelines of managing IGM and it is increasingly being treated with steroids and steroid-sparing agents as it now considered to be driven by inflammatory process [2]. Since the relapse rate varies from 5-50% [3], identification of risk factors that predict relapse can help clinicians triage patients who might need close monitoring and prolonged treatment with immunosuppressive therapy.
Objectives: The objective of our study is to describe clinical, laboratory and histopathological features of IGM from a single center and identify distinguishing features of relapsing disease compared to remission.
Methods: We queried databases at our institution December 1990- January 2021 to include females ≥ 18 years with biopsy-proven diagnosis of IGM, excluding patients with breast cancer, lymphoproliferative disorders, solid organ malignancy, foreign body reaction in breast, plasma cell mastitis, and ductal ectasia. Remission was defined as three-month period without recurrence of symptoms or imaging findings. Relapse was defined as recurrence after three months of remission. Clinical and histopathological features were compared using two-sample t-tests (continuous variables) and chi-squared tests (categorical variables).
Results: 27 patients met our inclusion criteria and were included in the final analyses. The mean age at diagnosis was 35.8 years (± SD 9.4 years) with a mean body mass index of 31.7 kg/m2 (± SD 6.7 kg/m2). 11 (41%) were Hispanic, 25 (93%) had at least one previous full-term pregnancy prior to diagnosis and 8 (30%) were on oral contraceptives. 18 patients (66%) had remission and 9 (33%) had relapse. Six of these patients received steroid after antibiotics, while 5 patients were received methotrexate. Three (33%) patients with relapse and 14 (77%) with remission, had abscess formation confirmed on histopathology (p=0.04).
Conclusion: We did not identify any differences in clinical or laboratory features of patients with relapse and remission. Patients with remission had a higher number of abscesses on histopathology and history of oral contraceptive use was associated with more relapse. By identifying key histopathological findings in this population may guide prognosis and treatment of these patients.

PREVALENCE OF PNEUMOCYSTIS JIROVECI PNEUMONIA(PJP)IN PATIENTS WITH RHEUMATOLOGICAL CONDITIONS ON IMMUNOSUPPRESSIVE MEDICATIONS AND THE NEED FOR PROPHYLAXIS

Keywords: Infection-related RMDs, Disease-modifying drugs (DMARDs)

D. Ramachandran[1], W. Mushtaq[1], D. Makkuni[1], H. Reddy[1]. [1]*James Paget University Hospitals, Rheumatology, Great Yarmouth, United Kingdom*

Background: Pneumocystis jirovicii pneumonia (PJP) is a life-threatening opportunistic fungal infection with a high mortality rate (30-50%) among non-HIV immunosuppressed patients. According to previous studies cotrimoxazole prophylaxis is given for patients when their risk of PJP is greater than 3.5%[1] however these guidelines were established for patients with malignancies, stem cell and solid organ transplantations[2].The data from British registries showed a slightly higher risk in patients treated with Rituximab than Anti TNF therapies. The ACR recommends PJP prophylaxis in their recently published guidelines on ANCA associated vasculitis (AAV) and studies have shown higher PJP infection in patients with GPA than other vasculitis. The benefit for prophylaxis treatment is not clearly established in inflammatory conditions like RA and other autoimmune Rheumatological conditions(ARDs)
Objectives: To investigate the incidence of PJP infection in patients with ARDs and explore the potential common risk factors.
Methods: Using our, electronic health record (EHR) cohort, we investigated the prevalence of PJP infections in Rheumatic patients on immunosuppressants over a period of one year.
Results: We identified 6 non HIV patients with a confirmed diagnoses of PJP infection over a period of one year. All patients were diagnosed following bronchial lavage looking for PJP DNA in the aspirate. Only 2 out of six patients were identified to have ARDs on immunosuppressant drugs. Case1: 68 yr old gentleman, was on longstanding methotrexate for RA, presented with breathlessness and dry cough. The blood showed CRP of 200 and CT thorax revealed features consistent with RA-ILD with superimposed ground-glass changes keeping with an acute infection. He did not respond to IV antibiotics and went on to have a bronchial lavage which tested positive for PJP and was started on high dose of steroids and intravenous cotrimoxazole followed subsequently by Vancomycin and Clindamycin after not improving on cotrimoxazole. Despite ongoing medical treatment, patient deteriorated and passed away. Case 2: 77 yr old lady on rituximab for AAV(with positive MPO >129) with an established ILD secondary to the vasculitis for 7years. She presented with breathlessness and cough. Rituximab was started 7 years ago for the AAV and due to its relapsing nature, rituximab was continued with a maintenance dose of prednisolone 5- 10mg. Blood tests showed low IgM levels with normal IgG and A levels. There was no evidence of active vasculitis and she was commenced on antibiotics which made no difference to her symptoms. A HRCT thorax was done which revealed Interval progression of ILD (UIP) bilateral ground-glass changes. Bronchoscopy and lavage showed evidence of PJP DNA on PCR and the patient was commenced on IV cotrimoxazole. Patient made a slow recovery.
Conclusion: Our survey did not identify a high incidence of PJP in the ARD cohort however, the common denominator for PJP in the two patients we have identified seem to be an underlying ILD. The commonest CT findings noted was ground glass shadowing in addition to ILD in both cases. A strong index of suspicion, early HRCT and bronchial lavage is crucial for the diagnosis.Failure to respond to conventional treatment should alert the clinician to cotrimoxazole resistant PJP.There are case reports of emerging resistance to cotrimoxazole trin in the non-HIV immunosuppressed group, increasing the mortality. We could not make any firm recommendation based on this observational study as the numbers were very small but the clinician should consider PJP prophylaxis in RA ILD patients and patient with AAVs on long term Rituximab therapy. There is a need to incorporate prophylaxis treatment in to the guidelines.

COMORBIDITIES AND CARDIOVASCULAR RISK FACTORS IN A MEXICAN MESTIZO COHORT OF RHEUMATOID ARTHRITIS PATIENTS

Keywords: Comorbidities, Epidemiology, Rheumatoid arthritis

D. Á. Galarza-Delgado[1], I. J. Colunga-Pedraza[1], J. R. Azpiri-López[2], V. Gonzalez-Gonzalez[1], V. M. Beltran-Aguilar[1], A. G. Arias Peralta[2], N. De Avila Gonzalez[1], J. A. Cardenas-de la Garza[1], G. García-Arellano[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*; [2]*Hospital Universitario Dr. José Eleuterio González, Cardiology, Monterrey, Mexico*

Background: Rheumatoid arthritis (RA) has been associated with a 3 to 10 years life expectancy reduction as compared to general population, with atherosclerotic disease being the leading cause of death [1].
Objectives: To determine the prevalence of comorbidities and associated cardiovascular risk factors in Mexican patients with rheumatoid arthritis.
Methods: Observational, prospective, cross-sectional, and analytic study. Patients aged 40 to 75 years who met the ACR/EULAR 2010 Classification Criteria for the diagnosis of Rheumatoid Arthritis in a period from August 2014 to December 2022 were included. Patients with a history of cardiovascular disease (myocardial infarction, cerebrovascular event, or peripheral arterial disease) were excluded. The distribution was evaluated with the Kolmogorov-Smirnov test. Normally distributed variables were described with mean and standard deviation (SD) and the 25th and 75th percentiles (p25-p75) were used to report variables without normal distribution.
Results: A total of 487 patients were included. The mean age was 55.3 ±8.9 years, women 92.2%. The median for disease duration was 7.0 (2.8-14.5) years. In this cohort, 163 (33.3%) of patients were in remission, 67 (13.8%) had low, 198 (40.7%) moderate and 60 (12.3%) high disease activity according to DAS28-CRP. Of these patients, 401 (82.3%) were on methotrexate, 296 (60.8%) were on prednisone (median dose of 5.0 mg per day), and 260 (53.4%) were in both. The cardiovascular risk factors with the highest prevalence were overweight in 208 (42.9%) and obesity in 153 (31.4%). The most prevalent comorbidity was dyslipidemia in 150 (30.9%), the rest are shown in Table 1.
Conclusion: Although patients with rheumatoid arthritis have a lower prevalence of traditional cardiovascular risk factors and comorbidities compared to the general Mexican population, they continue to have a higher cardiovascular risk and increased mortality at 3 – 10 years, which raises the question: should RA be included as a cardiovascular risk factor?

SCREENING OF SYMPTOMS IN THE AT-RISK OF RHEUMATOID ARTHRITIS CZECH COHORT USING SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS (SPARRA) QUESTIONNAIRE

Keywords: Autoantibodies, Rheumatoid arthritis

N. Růžičková[1], K. Prajzlerová[2], P. Hánová[3], J. Vencovský[1], L. Šenolt[1], M. Filková[1]. *[1]Institute of Rheumatology, Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic*; *[2]Institute of Rheumatology, Experimental Rheumatology, Prague, Czech Republic*; *[3]Institute of Rheumatology, Department of Rheumatology, Prague, Czech Republic*

Background: With growing knowledge about the course of rheumatoid arthritis (RA), the focus shifts to the pre-clinical phase. The presence of RA-associated autoantibodies e.g., anti-citrullinated protein antibodies (ACPA) and rheumatoid factors (RF) increases up to 10 times the risk of developing RA in comparison to the common population. The positivity of these autoantibodies and multiple symptoms without clinical arthritis enable the characterization of individuals who are considered at risk for progression to RA. The "Symptoms in Persons at Risk of RA" (SPARRA) questionnaire was created to screen symptoms occurring in at-risk individuals. This questionnaire comprises 13 symptoms (joint pain, swelling and stiffness, burning and tingling sensations, numbness, changes in skin color over joints, muscle cramps, weakness, fatigue, emotional distress, concentration and sleep difficulties) and explores their duration, location, intensity and impact on daily activities.

Objectives: To explore the symptoms in our prospective observational cohort of individuals with arthralgia at-risk of RA (ARRA cohort) using the SPARRA questionnaire.

Methods: Individuals at-risk of RA, defined as having arthralgia without arthritis on the examination of 66/68 joints at baseline and being either ACPA+ and/or meeting the European Alliance of Associations for Rheumatology (EULAR) definition of clinically suspect arthralgia (CSA, having at least 3 out of 7 parameters), cross-sectionally filled out the SPARRA questionnaire. All individuals signed informed consent before study enrolment. Differences between ACPA+ and ACPA- individuals were analysed using Fisher's exact test.

Results: The study included **77** at-risk individuals (75% were females) with a mean age of 48,08±12,62 years, symptom duration of 34,66±35,56 months with CRP 3,17±4,24 mg/l and 5,43±7,32 tender joints on examination, out of which 61% were ACPA+, 59% met the CSA definition, and 20% were both ACPA+ and met the CSA definition. The most frequent symptoms at the time of SPARRA completion were joint pain (97%), joint stiffness (83%), fatigue (82%), emotional distress (70%), sleep problems (66%), and joint swelling reported by the patient (65%). Joint stiffness (100% vs. 71%, p=0,0005), sleep problems (84% vs. 53%, p=0,0067), and concentration difficulties (69% vs. 29%, p=0,0010) were more prevalent in ACPA- individuals than in ACPA+ group. Similarly, the intensity (none/mild vs. moderate/severe) of fatigue (p=0,0197), emotional distress (p=0,0270), and sleep problems (p=0,0054) was higher in ACPA- group; along with emotional distress (p=0,0136) and sleep problems (p=0,0407) being of higher impact on daily activities in ACPA- individuals. Joint pain was most frequently described as aching, and localized in fingers with up to mild severity and with none to a small impact on daily activities in both groups. The pain was intermittent, typically with periods without any symptoms in the ACPA+ group and always with some residual symptoms in the ACPA- group (p=0,0015). When assessing the most prevalent symptoms in ACPA+ individuals, joint stiffness appeared more frequently in ACPA+ individuals meeting the CSA definition compared to ACPA+ individuals not fulfilling the CSA criteria.

Conclusion: Symptoms of the at-risk individuals appeared more frequently and with higher intensity and impact on daily activities in ACPA- individuals, who as per the inclusion criteria, met the CSA definition, with joint pain being the most prevalent. The value of the SPARRA questionnaire in the assessment of the risk of arthritis development in at-risk individuals needs to be determined in further prospective studies.

THE USE OF DIGITAL FOOT SCANNING (PELMATOGRAPHY) FOR IDENTIFICATION OF STANCE ABNORMALITIES IN A YOUNG HEALTHY POPULATION

Keywords: Work-related issues, Epidemiology, Health services research

I. Katsigianni[1], E. Skouvaklidou[1], G. Vounotrypidis[1], D. Deligeorgakis[1], D. Zisopoulos[1], G. Sakellariou[1], P. Vounotrypidis[1]. *[1]424 Military Hospital Thessaloniki, Rheumatology,Thessaloniki, Greece*

Background: Clinical evaluation of pes anatomy and abnormalities are rarely reported in rheumatology literature. Often deviations from normal are not evaluated, unless subsequent pathology and symptoms are overt. Foot symptoms may occasionally lead to overdiagnosis of seronegative arthropathies.

Objectives: This study aims to identify any foot abnormalities in a healthy young population of army recruits, using clinical and digital foot scanning – pelmatographic (PLM) examination.

Methods: One hundred and ten (M/F:65/54) of a total of 129 new army recruits of a Military Academy in Greece participated voluntarily in the study. Subjects' informed consent and proper ethical approvals were obtained. The study conducted according to Declaration of Helsinki. A small percentage (1.12 %) reported short-term lower leg symptoms during vigorous athletic activities, the past five years. We used clinical evaluation of pes morphology on stance and compared to data obtained during the stance phase of examination using a 3400-sensors plantar pressure foot scan machine. Descriptive statistics were used for the statistical analyses.

Results: Agreement between clinical and pelmatographic observation was noted in 59.1% of subjects. In particular, clinical and pelmatographic normal pes was observed in 48.2% and 68.8% of subjects, respectively. High arched foot was observed in 23.6% and 17.2%, while flat foot in 23.6% and 9.7% respectively. There was no statistical difference between clinical and pelmatographic evaluation of high arched foot (chi-square test, p=0,815). Discrepancy between clinical and pelmatographic evaluation of flat feet was noted (p=0.04, OR:0.47, 95%CI:0.165-0.730). Finally, 37.3% of the participants presented foot pronation while in 60.8% subjects [M:41 (60.2%), F:27 (39.3%)] brachymetatarsia of the 1st toe (Morton's toe) was observed.

Conclusion: Prevalence of pes abnormalities are high and unattended in an otherwise healthy young population. These variations may predispose to future foot symptoms under specific circumstances. Digital foot pressure scanning may facilitate diagnosis and contribute to solution with foot orthotics.

TOWARDS A GUIDE FOR EVIDENCE-BASED TELEMONITORING: SENSITIVITY OF PATIENT REPORTED OUTCOMES TO CHANGE IN DISEASE ACTIVITY STATUS IN EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS

Keywords: Patient reported outcomes, Rheumatoid arthritis, Telemedicine

A. Looijen[1], E. Van Mulligen[1,2], A. Van der Helm – van Mil[1,2], P. De Jong[1].
[1]*Erasmus MC, Rheumatology, Rotterdam, Netherlands*; [2]*Leiden University Medical Centre, Rheumatology, Leiden, Netherlands*

Background: In the treatment and follow up of rheumatoid arthritis (RA) patients, it has become more desirable to detect changes in disease activity through telemonitoring, for which patient reported outcomes (PROs) might be useful. So far associations between PROs and changes in disease activity have been mostly investigated on a continuous scale. However, in daily practice and in line with the EULAR recommendations, treatment decisions are mainly based on the patient's disease activity status. Earlier literature has shown that functionality, joint pain, morning stiffness, general health (GH), health-related quality of life and fatigue change with the development and resolution of a disease flare.
Objectives: Therefore, our aim is to determine if PROs that cover functionality, joint pain, morning stiffness, health-related quality of life and fatigue are sensitive to disease activity status alterations (from active to low disease activity to remission, and vice versa) in patients with early and established RA.
Methods: Early RA patients from the tREACH-trial and established RA patients from the TARA-trial were included. Both studies were multicentre, single blinded trials with a treat-to-target design. Treatment alterations were based on the disease activity score (DAS44) and PROs were collected at 3-montly fixed intervals. The following PROs were studied: (1) the Health Assessment Questionnaire Disability Index (HAQ-DI), (2) joint pain (numeric rating scale, NRS 0-10), (3) morning stiffness severity (NRS 0-10), (4) GH (visual analogue scale, VAS 0-100mm), (5) health-related quality of life (EQ-5D) and (6) fatigue (VAS 0-100mm).

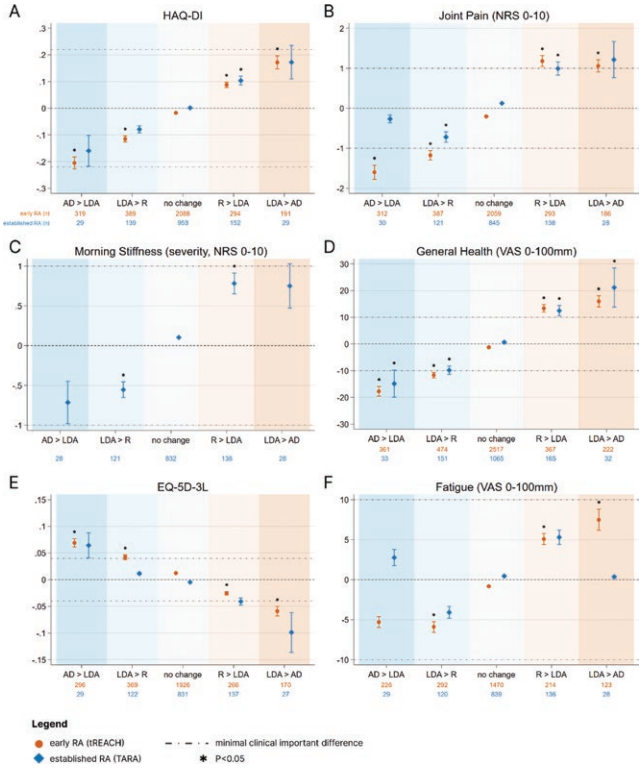

Figure 1. Mean changes in patient reported outcome per disease activity status alteration

Figure 1A-F show the mean change (95%CI) in PRO per disease activity status alteration for early and established RA patients. * indicates that the change in PRO is significantly (p<0.05) different compared to stable disease activity status.

Abbreviations: AD, active disease; HAQ-DI, Health Assessment Questionnaire Disability Index; LDA, low disease activity; NRS, numeric rating scale; R, remission; VAS, visual analogue scale.

Disease activity statuses were defined as: (1) active disease (DAS≥2.4), (2) low disease activity (LDA, DAS<2.4 and ≥1.6) and (3) remission (DAS<1.6). Differences in disease activity status between two consecutive visits were compared to changes in PROs. Mean changes in PROs per disease activity status alteration were compared to stable disease activity status, using generalized estimated equation-models.
Results: Respectively 587 and 189 early and established RA patients were included. The median symptom duration (IQR) was 0.4 (0.2-1.8) and 6.2 (4.1-8.9) years, respectively. The mean DAS (95%CI) at baseline was 3.0 (3.0-3.1) in the early and 1.0 (0.9-1.1) in the established RA group. **Figure 1** shows the mean change (with 95%CI and significance) in PROs per change in disease activity status. HAQ-DI, joint pain, morning stiffness, GH, EQ-5D and fatigue (in early RA) were in concordance with improvement or worsening of disease activity status. Change from active disease to LDA or vice versa had a larger effect on HAQ-DI, GH, and EQ-5D compared to change from and to remission to LDA. Respectively, change in HAQ-DI was 1.9 and 1.8 times greater going from active disease to LDA compared to a shift from LDA to remission and vice versa. For GH this was 1.6 and 1.2 and for EQ-5D 2.1 and 2.0 respectively.
Conclusion: Changes in HAQ-DI, morning stiffness, joint pain, GH and EQ-5D correspond to changes in disease activity status. These results suggest that changes in aforementioned PROs may be helpful in telemonitoring of RA.

DEEP PHENOTYPING OF IMMUNE MICROENVIRONMENT IN ULCERATIVE COLITIS BY INTEGRATIVE SYSTEMS ANALYSIS

Keywords: Adaptive immunity

Q. Wang[1,2], M. R. Chen[1,2], J. W. Hao[1,2], M. J. Chang[2,3], S. X. Zhang[1,2], Q. Yu[4], P. F. He[3]. [1]*Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [2]*Shanxi Medical University, Ministry of Education, Key Laboratory of Cellular Physiology, Taiyuan, China*; [3]*Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision, Taiyuan, China*; [4]*Shanxi Medical University, School of Management, Taiyuan, China*

Background: Ulcerative colitis (UC) is an inflammatory bowel disease characterized by idiopathic and recurrent mucosal inflammation [1]. The pathogenesis is multifactorial, involving genetic susceptibility, epithelial barrier defects, dysregulation of the immune response, and environmental factors. UC is a highly heterogeneous disease [2]. Despite efforts to characterize disease subgroups and predict differential outcomes in UC patients, disease heterogeneity is not adequately translated into current clinical subclassifications.
Objectives: This study seeks to unravel this complexity by using an integrated systems approach that classifies UC patients into different phenotypes based on the immune microenvironment, capable of providing new insights into the development of stratified therapies.
Methods: RNA sequencing datasets of 602 colon tissue samples from 455 patients with UC and 147 healthy controls (HC) was imported from GEO database. The microarray datasets were transformed into immune cell components by CIBERSORT, and patients were stratified by a consensus clustering algorithm. Then, the cellular characteristics of the subtypes and the overall role of specific pathways were determined by immune cell infiltration and pathway enrichment. The clinical characteristics of the different subtypes were also analyzed to clarify the characteristics of these classifications.
Results: Patients can be classified into two distinct immune phenotypes (Subtype A, B) based on their specific RIME, which have different cellular and pathway characteristics. (Figure A, B) The results show that Subtype A is mainly enriched in immune cells such as B cells, CD8+ T cells, CD4+ memory T cells, DC cells, macrophages, mast cells and plasma cells. Acidic granulocytes and neutrophils were more active in Subtype B. It was also significantly enriched in the peroxisome proliferator-activated receptor (PPAR) signaling pathway in Subtype B. In contrast, Subtype A showed a strong enrichment for most inflammatory pathways B cell and T cell receptor signaling, IL-17 signaling pathway, TNF, and interleukin 4 and interleukin 13 signaling pathway. (Figure 1 D, E) In addition, there was a significant difference between molecular subclassification and disease status, with Subtype A being more active in patients (69.3% of Subtype A vs.30.6% of Subtype B subtypes in 137 cases), while inactive patients, Subtype B were more prevalent (44.8% of Subtype A vs. 55.2% of Subtype B in 105 cases). (Figure 1C)
Conclusion: Analysis of the immune microenvironment of colonic mucosal tissue provides good insight into the pathophysiological characteristics of UC. These results can be used as a model for future studies. the response and clinical outcomes of patients with different classification need to be further investigated.

REASSESSMENT OF THE SIGNIFICANCE OF PATIENT GLOBAL ASSESSMENT IN REMISSION CRITERIA FOR RHEUMATOID ARTHRITIS IN TERMS OF 68/66 JOINT COUNTS

Keywords: Rheumatoid arthritis, Registries, Patient reported outcomes

T. Nishino[1], S. Tohma[2], T. Matsui[1]. [1]*National Hospital Organization Sagamihara National Hospital, Department of Rheumatology Research, Clinical Research Center for Allergy and Rheumatology, Sagamihara, Kanagawa, Japan*; [2]*National Hospital Organization Tokyo National Hospital, Department of Rheumatology, Kiyose, Tokyo, Japan*

Background: One rationale for including patient global assessment (PtGA) in Boolean remission is that PtGA ≤1 reduces the probability of joint findings outside the 28 joints and complements the limitations of 28-joint count assessment [1]. Meanwhile, the criterion of PtGA ≤1 has been questioned, leading to establishment of Boolean2.0 or proposal of 3V-remission [2-3]. However, the significance of PtGA as a complement to the limitations of the 28-joint assessment has been forgotten.

Objectives: This study aimed to evaluate the discriminative power of PtGA for the presence of joint findings outside the 28 joints within the framework of Boolean2.0 and 3V-remission in the real-world setting.

Methods: We analyzed 8,684 patients with rheumatoid arthritis who achieved 3V-remission (28-tender joint count (TJC), 28-swollen joint count (SJC) and C-reactive protein (mg/dL) all ≤1) registered in the National Database of Rheumatic Diseases in Japan (NinJa) in 2020, a large observational database. Based on TJC68 and SJC66, patients were divided into two groups of patients with and without joint findings outside the 28 joints (JFO28). The values and distributions of PtGA were compared between the two groups, and the positive likelihood ratio for no findings outside the 28 joints was calculated, varying cut-off values of PtGA. Receiver Operating Characteristic (ROC) analysis was performed to assess the discriminative power of PtGA for the presence of JFO28 and optimal cut-off value.

Results: Among 8,684 patients, 6,901 were patients without JFO28 and 1,783 were patients with JFO28. The values of PtGA were significantly higher in patients with JFO28 (the difference of 25% trimmed mean, 1.12 [95% CI, 1.01 to 1.24]). However, the distribution of PtGA was largely overlapping (Figure 1). About 12%, 15%, and 21% of patients had JFO28 when the cutoff values for PtGA were 1.0, 2.0 (Boolean2.0), and none (3V-remission), respectively. The positive likelihood ratios were 1.90 and 1.44 when the cutoff values of PtGA were 1.0 and 2.0, respectively. The area under the ROC curve was 0.68 [95% CI, 0.66 to 0.69], indicating low discriminative power. The optimal cut-off value was 1.0 based on Youden index.

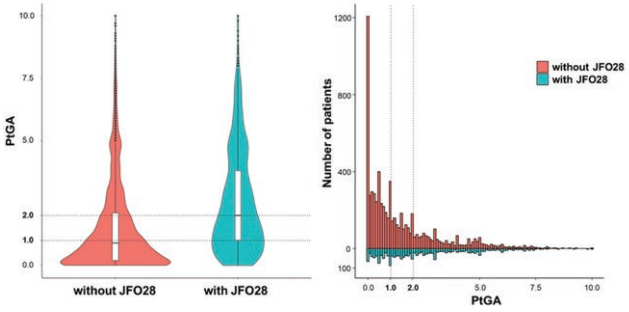

Figure 1. The distribution of PtGA in patients with and without JFO28

Conclusion: A cutoff value of 1.0 for PtGA seems reasonable in terms of 68/66 joint findings. It may be pragmatic to evaluate PtGA and joint findings separately in accordance with the concept of dual target therapy because PtGA has low discriminative power for the presence of JFO28 in patients achieving 3V-remission. However, our results suggested that there is a need to extend the criteria for joint assessment in 3V-remission to 68/66 joints, considering not a few patients had JFO28 even if they had reached 3V-remission.

Background: There is currently no agreement on which scale should be used to evaluate systemic lupus erythematosus (SLE) disease activity. PGA describes an instrument for a global assessment of the degree of disease activity by the clinician and it is generally regarded as the gold standard. Despite its wide use and some degree of validation, the psychometric properties of this scale have not been formally evaluated and it is unclear whether more commonly used analogue scales for global assessment of rheumatic disease activity by the clinician, such as a VAS from 0 to 10, would be more appropriate.
Objectives: The aim of this study was to assess the construct and criterion validity of the physician global assessment (PGA), from 0 to 10, in a wide sample of SLE patients from Spain, analyzing the correlation with SLEDAI, health-related quality of life (QoL) and its ability to predict damage in order to promote its more widespread use.
Methods: An observational, longitudinal and prospective design was carried out. A total of 1821 patients from the RELESSER-PROS registry and data from 5 annual consecutive visits were tested. Activity was estimated using PGA from 0 to 10 transformed to AM-PGA (mean-adjusted PGA)(AMP), and AM-SLEDAI (mean-adjusted SLEDAI)(AMS); damage through SLICC/ACR Damage Index (SDI) and QoL by means of EuroQoL 5D y Lupus Impact Tracker (LIT) tools. The correlation between indices and their ability to predict damage progression (defined as any increase of 1 unit in SDI from baseline) and QoL was calculated. Pearson's or Spearman's correlation coefficients were calculated for each variable in comparison.
Results: The correlation between PGA and SLEDAI was higher for lower PGA values and there was a correlation between AMP and AMS, ranging 0.4 and 0.5. AMS explains a percentage of AMP variation that rises to 27% when introducing the number of domains affected by SLEDAI, in non-parametric model. AMS and AMP values are discrepant, especially for patients with low AMS and high AMP values and differs significantly in 3 domains: serological, neuropsychiatric, and renal. Excluding patients from the model, who were marked as discrepant, a significant linear relationship between AMS and AMP, around 0.5 shown up. Regarding damage, the correlation between AMP, AMS and SLICC/ACR (SDI) explained only 13% of SDI variance. SLEDAI accounts for a higher percentage of SDI variance than PGA (10.18% vs. 5.65% in smoothed model), but both do it independently. Analysis the discrepant and non-discrepant patients showed a fairly discrete linear relationship, less than 3%, between the AMS and AMP with the LIT and the EQ5D6 only for the non-discrepant patients.
Conclusion: The correlation between PGA and SLEDAI is low and both should be used together. PGA could improve the assessment of disease activity and its use adds the possibility to improve damage prediction.

CONSTRUCTION OF A COMPOSITE SCORE FOR PATIENT SELF-REPORT OF FLARE IN OSTEOARTHRITIS: A COMPARISON OF METHODS WITH THE FLARE-OA-16 QUESTIONNAIRE

Keywords: Pain, Patient reported outcomes, Outcome measures

F. Queiroga[1], J. Epstein[1], M. L. Erpelding[1], L. King[2], M. Soudant[1], E. Spitz[1], J. F. Maillefert[3], B. Fautrel[4], L. Callahan[5], L. March[6], D. Hunter[7], F. Guillemin[1]. *[1]Université de Lorraine, Apemac, Nancy, France*; *[2]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada*; *[3]Hôpital Universitaire, Department of Rheumatology, Dijon, France*; *[4]Sorbonne Université, Assistance Publique Hôpitaux de Paris, Rheumatology Dept, Paris, France*; *[5]University of North Carolina, Thurston Arthritis Research Center, Chapel Hill, United States of America*; *[6]University of Sidney, Faculty of Medicine and Health, Sidney, Australia*; *[7]University of Sidney, Sydney Musculoskeletal Health, Sidney, Australia*

Background: Having a score to assess the occurrence and severity of flares of knee or hip osteoarthritis (OA) to guide interventions is essential.
Objectives: To compare different methods of constructing a composite score for the Flare-OA-16 self-reported questionnaire for measuring knee and hip OA flare, defined as a cluster of symptoms of sufficient duration and intensity to require initiation, change or increase in therapy [1].
Methods: Participants with a physician diagnosis of knee and hip OA completed a validated 16-item questionnaire [2,3] assessing five dimensions of flare in OA: pain, swelling, stiffness, psychological aspects, and consequences of symptoms, endorsed by OMERACT. Three estimation methods were compared: the score obtained i) by second-order confirmatory factor analysis (CFA) weighting the factor loadings in a linear combination of the five dimensions; ii) by logistic regression, modeling the probability of having a flare according to the participant's self-report (yes/no); and iii) by Rasch method, using the average of the weighted scores from a Rasch model in each dimension. For the scores obtained by the three methods, the disordered items were modified, and then the scores were standardized on a scale from 0 to 10. The distribution (floor effect without flare (FF) and ceiling effect with flare (CF)) of the scores in each model was compared. The similarity between the scores was analyzed by intraclass correlation coefficient (ICC) and their performance were compared by areas under the ROC curves (AUC) and 95% confidence interval. The intra-score test-retest reliability at 15 days was assessed by ICC.
Results: In a sample of 381 participants with complete questionnaires, 247 reported having a flare. With CFA, good fit indices (CFI=0.94; RMSEA=.08) justified the estimation of an overall score mean=3.90 (SD=2.79), with FF effect 27.6% and CF 2.0%. For the logistic regression estimation, the overall score was mean=6.48 (SD=3.13), with FF 0% and CF 34.0% effect. With the Rasch model, the composite score was mean=4.15 (SD=2.45), with FF 18.7% and CF 0% effect. Similarity analysis indicated a greater concordance between the CFA and Rasch scores (ICC=.99) than between the logistic regression score and the two others (ICC=.87 for each). The ROC curve indicated similar performance of the overall scores estimated by logistic model (AUC=.88 [.85-.92]), by CFA

(AUC=.86 [.82-.90]) and by Rasch model (AUC=.86 [.82-.90]). The performance in terms of reproducibility was ICC=.84[.95-.90] for Rasch and CFA scores and ICC=.78[.66-86] for logistic model.

Conclusion: This comparison of methods for constructing a global score for knee and hip OA flare explored three satisfactory alternatives. The second-order CFA confirmed the uniqueness of the flare construct measure, the logistic model had a slight superiority explained by the anchor variable used (patient-reported flare), and the Rasch model ensured that an interval scale was obtained for each dimension. The distribution of scores with the lowest combination of floor and ceiling effects was in favor of the Rasch model. The next step will be to document their respective performance in terms of sensitivity to change. A score obtained from the patient's point of view can help increase the adherence to the prescribed treatment and help physicians to optimize the scheduling and delivery of medical consultation.

AB1679 VASCULITIS DISEASE ACTIVITY SCORES BEFORE AND DURING THE COVID-19 PANDEMIC: A COMPARISON OF FACE-TO-FACE CLINICIAN SCORING AND PROMS COLLECTED USING REMOTE MONITORING IN A SINGLE-CENTRE COHORT

Keywords: Telemedicine, Vasculitis, Patient reported outcomes

D. Kurzeja[1], K. Song[2], M. Mirza[3], M. Ashraf[4], R. Luqmani[1]. [1]*Nuffield Orthopaedic Centre, Rheumatology, Oxford, United Kingdom*; [2]*University of Oxford, Medical Sciences Division, Oxford, United Kingdom*; [3]*Great Western Hospital, Rheumatology, Swindon, United Kingdom*; [4]*Stoke Mandeville Hospital, Rheumatology, Aylesbury, United Kingdom*

Background: During the COVID-19 pandemic, asynchronous consultations were introduced for patients with vasculitis. To assess disease activity without of face-to-face clinical reviews and blood testing, patients submitted patient reported outcome measures (PROMs) via electronic survey forms, which were subsequently triaged by clinicians.

Objectives: 1. To investigate how patients' vasculitis disease activity was affected by the COVID-19 pandemic through retrospective comparison of clinician-assessed scores recorded pre-pandemic with intra-pandemic self-reported patient reported outcome measures (PROMs) and disease scores submitted by patients remotely.

2. To assess patients' clinical outcomes, including allocation of follow-up and further management/treatment escalation during this period.

3. To validate self-reported BVAS scores against an existing PROM.

Methods: This is a retrospectively study of patients with a known diagnosis of vasculitis under the care of the Nuffield Orthopaedic Centre, Oxford. For the purposes of this study, we included patients with all vasculitis diagnoses. Clinician-reported scores (Bristol Vasculitis Activity score v.3, BVAS) were recorded during in-person clinics pre-pandemic (defined as 01/01/2019-31/12/2019) [1]. Patients' self-reported BVAS (SR-BVAS) and AAV-PRO (ANCA-associated vasculitis patient-reported outcomes) scores were submitted by patients via electronic forms containing the requisite questionnaires sent out during-pandemic (defined as 01/12/2020-31/03/22) [2]. SR-BVAS has not been validated but was collected to allow clinical comparison to disease activity scores completed by clinicians. Response were stored and analysed in a secure database. Score comparison was performed using Wilcoxon Sign Rank testing. Clinical outcome data was collected from the local Electronic Patient Record. Data analysis was performed in Microsoft Excel and R (version 4.2.1).

Results: We noted a significantly higher overall level of patient-reported disease activity during the pandemic than was recorded in clinics prior. In the total cohort of all vasculitis patients for whom we had data, the median BVAS increased from 2 pre-pandemic (N = 335, range 0-21) to 6 intra-pandemic (N = 143, range 0-42) (p <0.001). The overall proportion of patients with severe/active disease (defined as BVAS ≥4) increased from 27% to 36% during the pandemic period. In a smaller cohort of 64 patients for whom we had paired pre- and during-pandemic scores, increased disease activity was reported (p<0.01). Notably, the number with a BVAS consistent with severe disease increased from 7 (11%) to 19 (30%). There was a significant positive correlation between SR-BVAS and AAV-PRO (r=0.61, p< 0.001) submitted by patients during-pandemic; however, at low BVAS (≤3), the AAV-PRO ranged widely (28-87) Follow-up data was available for all 64 patients in this cohort: 8/19 (42%) with a during-pandemic SR-BVAS ≥4 were seen in clinic within 3 months (telemedicine or face-to-face).

Conclusion: Patients reported worsening of vasculitis disease activity during the COVID-19 pandemic. This may be attributable to impacts on well-being or access to healthcare services. We note that disease activity scores in vasculitis may be limited in their ability to capture the whole picture disease activity in the absence of clinical assessment [3]. 42% of patients with self-reported high disease activity were seen within 3 months. There was a significant positive correlation between AAV-PRO and SR-BVAS, suggesting it has some use as a PROM.

AB1680 BIOMARKERS IN PATIENTS WITH VIBRATION INDUCED RAYNAUD'S PHENOMENON AND IN REFERENTS

Keywords: Biomarkers, Comorbidities, Work-related issues

E. Tekavec[1], T. Nilsson[2], L. Dahlin[3], C. Nordander[1], A. Axmon[1], J. Riddar[1], M. Kåredal[1]. [1]*Division of Occupational and Environmental Medicine, Department of Laboratory Medicine, Lund, Sweden*; [2]*Division of Sustainable Health and Medicine, Department of Public Health and Clinical Medicine, Umeå, Sweden*; [3]*Lund University, Department of Translational Medicine – Hand Surgery, Malmö, Sweden*

Background: Secondary Raynaud's phenomenon (RP) due to occupational exposure to hand-held vibrating tools is a well-recognized part of the Hand arm vibration syndrome (HAVS) [1]. Different pathophysiological mechanisms for HAVS-induced RP have been proposed, e.g., localized structural vascular and neuronal injuries as well as systemic inflammatory processes by increased oxidative stress [2-5]. Elevated plasma levels of thrombomodulin (TM), a marker for endothelial damage, have been shown in vibration-exposed workers [6, 7] with equal levels as in collagen diseases [7]. Von Willebrand factor (vWF) has been suggested as biomarkers for vibration induced RP [8]. Elevated levels of vWF have been found in RP patients who subsequently develop scleroderma or other connective tissue diseases, even in the absence of capillaroscopic abnormalities [9]. It is however still not clear whether the mechanisms for vibration related RP are similar to those for other forms of RP. Biomarkers for vascular injuries may shed light on this.

Objectives: To investigate serum levels of TM and vWF in patients with HAVS, with or without RP.

Methods: Blood samples were collected in the morning from 92 patients with HAVS. Forty-five (49%) of these had RP, 47 (51%) did not. Serum was removed and stored at -80 °C until analysis. TM and vWF were measured by using commercially available ELISA assays. Distributions were compared with Mann-Whitney U tests.

Results: Higher values of TM were found in HAVS patients with RP (median 6.1 ng/ml; range 2.7 – 30), compared to those without RP (5.2 ng/ml; 2.3 – 39; p = 0.02). Further higher levels of vWF were found in HAVS patients with RP (18 µg/ml; 6.2 – 33) compared to without RP (14 µg/ml; 6.9 – 34; p = 0.008).

Conclusion: As in patients with RP due to connective tissue disorders higher levels of biomarkers for endothelial damage were shown in HAVS patients with RP. Increased serum levels of TM have been shown in previous studies on vibration injured patients [8, 9] but in one of the studies, no significant difference was shown between patients with RP and those without RP [9]. Our data indicates that RP symptoms is required to detect a significant change in the biomarker TM in vibration injured patients. Our data strengthen earlier findings that biomarkers of endothelial damage could be a useful tool in the assessment of vibrational induced injuries.

AB1681 ARE PR3 ANTIBODY TITERS REALLY IMPORTANT FOR ROUTINE CLINICAL PRACTICE?. STUDY FROM A SINGLE UNIVERSITY HOSPITAL

Keywords: Vasculitis, Autoantibodies

V. Calvo-Río[1], S. Al Fazazi[2], M. Renuncio-García[3], M. Rodriguez Vidriales[4], C. Escagedo Cagigas[4], J. Irure-Ventura[3], L. Martín-Penagos[4], A. Herrero-Morant[1], M. Lopez-Hoyos[3], R. Blanco[1]. [1]*Marqués de Valdecilla University Hospital, Rheumatology, Santander, Spain*; [2]*Hospital Puerta Del Mar, Rheumatology, Cádiz, Spain*; [3]*Marqués de Valdecilla University Hospital, Immunology, Santander, Spain*; [4]*Marqués de Valdecilla University Hospital, Nephrology, Santander, Spain*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA). Anti-proteinase 3 are one of the main ANCA subtypes. There are contradictory studies on the relation between ANCA levels and the severity of the disease and its prognosis [1].

Objectives: In patients with positive anti-PR3 antibodies from a university hospital we assess: **a)** associated diseases, **b)** specificity in diagnosing AAV and, **c)** determine if there is a cut-off point that allows to correlate the levels of anti-PR3 antibodies with the severity and prognosis of AAV.

Methods: Observational study of patients with positive anti-PR3 from a University Hospital, from 2003 to 2022. ANCA was determined by chemiluminescence. The specificity of anti-PR3 for AAV diagnosis, predictive value of severity and prognosis were determined with Receiver Operating Characteristic (ROC) curves. At diagnosis, AAV with renal disease (hematuria and/or proteinuria) and lung involvement (hemoptysis, asthma and/or respiratory failure) were considered severe. During follow-up, the prognosis was considered worse if the patient needed dialysis, a transplant, or died.

Results: We study 54 patients with positive PR3. Most of them (81.5%) had an underlying AAV being the most frequent GPA (61.1%). The non vasculitic disease more frequent was Ulcerative colitis (11.1%). **Table** 1 summarizes the prevalence of these antibodies in different diseases. The frequencies are equivalent to those previously described and it is noteworthy the presence of anti-PR3 in drug-induced vasculitis, mainly by cocaine. Anti-PR3 antibodies for a diagnosis of vasculitis (n=44), an area under the curve (AUC) was calculated (AUC=0.7318), and a cut-off point of 20.5 IU/ml was determined **(Figure 1).** Significant differences in anti-PR3 levels were observed between those patients with renal or pulmonary dysfunction (n=30) and those without them (n=24) (p=0.0048), and a cut-off threshold of 41.5 IU/ml was established. Finally, after examining the illness's prognosis an AUC= 0.5643 was obtained, being no significant differences between those patients who had a worse disease progression (n=14) and those who did not (n=40) (p=0.4847).

Conclusion: The presence of anti-PR3 is mainly associated with AAV, although in up to a fifth of cases it can be associated with other diseases. Anti-PR3 antibodies levels, at the moment of AAV diagnosis, correlates with disease diagnosis (specificity) and with severity but not with disease outcome.

AB1682 ARE CHANGES IN SELF-REPORTED NSAID DOSE ASSOCIATED WITH MEANINGFUL CHANGES IN PAIN OR OTHER HEALTH OUTCOMES IN RHEUMATIC DISEASES?

Keywords: Patient reported outcomes, Osteoarthritis, Pain

K. Michaud[1,2], S. Pedro[2], N. Goel[3,4]. [1]*University of Nebraska Medical Center, Medicine, Omaha, United States of America*; [2]*Arthritis Research Center: National Data Bank for Rheumatic Diseases, Research, Wichita, United States of America*; [3]*TrialSpark, Research and Development, New York, United States of America*; [4]*Duke University - Main Campus, Medicine, Durham, United States of America*

Background: Rheumatic disease primary treatment effectiveness research inconsistently addresses confounding effects of nonsteroidal anti-inflammatory drugs (NSAIDs) on pain and inflammation. Further, NSAID comedication use is often captured either as a simplified binary measure (eg, yes/no) or with a more burdensome high level of detail (eg, daily pill dose).

Objectives: Evaluate if moderate complexity items measuring changes in monthly NSAID dose are associated with changes in pain.

Methods: Patient-reported data from 1998-2021 were analyzed from the Forward Databank, a US-based longitudinal rheumatic disease registry, with questionnaires completed every 6 months. Eligible participants with RA or OA reported NSAID use on ≥1 questionnaire and had ≥1 follow-up (FU) questionnaire. NSAID use recorded type of drug, initiation, discontinuation, dose, and

frequency by 0-10, 11-20, or >20 days a month. Primary exposure was change in NSAID dose from baseline (increase, no change, decrease). Increase was defined as initiation, increase in frequency, increase in dose, or any combination of the 3; decreases were similarly defined directionally. Primary outcome was change in the pain visual analog scale (VAS, 0-10). Gaussian generalized estimating equations (GEE) models with robust standard errors [SE] were used to assess the association between pain and NSAID change or type of change (increase, decrease). Models were adjusted for demographics, rheumatic disease comorbidity index (RDCI), total joint replacement, other treatments (eg, opioids, disease-modifying antirheumatic drugs), and NSAID type.

Results: A total of 22,445 RA and 5,278 OA patients initiated ≥1 NSAID. Median (IQR) FU time of NSAID exposure was 4.5 (2–9) years for RA and 2.5 (1–5) for OA. Patients with RA vs OA were younger (59 vs 64 years [y]), but similar on other characteristics (male 20% vs 15%, White 96% vs 94%, disease duration 14 vs 16y, and RDCI [1.5 ±1.5 vs 1.7±1.5]). Overall, 24% of RA 6-month observations (~160700 observations) included an NSAID increase and 18% a decrease; in OA (~39800 observations), 30% increased and 18% decreased. 70% of RA patients (OA 77%) had an NSAID increase during FU and 69% (OA 67%) decrease. Starting or stopping an NSAID was the most common change (Figure 1). In RA, any NSAID increase was significantly associated with increased pain of 0.15 units (and for any NSAID decrease, decreased pain of 0.06) (Table 1), supported by the statistically significant directional changes in pain for any individual category of NSAID increase or decrease. In OA, any NSAID increase was significantly associated with increased pain of 0.06 units but were not significant for any decrease; only the individual categories of NSAID initiation and increased dose were significantly associated with increased pain and decreased NSAID dose associated with decreased pain.

Conclusion: We quantified the change in pain associated with change in NSAID dose generally, directionally, and by change type. All types were important for an increase in pain, but a decrease in NSAID frequency was more significant than other types for RA. Further work is needed to extend the definition of change by including other confounding treatments, eg. analgesics and opioids, and to understand optimal collection of concomitant medications that may influence trial results, especially in OA.

Table 1. Pain VAS Change (95% CI) GEE Models in RA and OA Cohorts

	RA	OA
	N=22,429 β	N=5,274 β
Change in NSAID (ref. no change)		
Increase	**0.15* (0.12; 0.17)**	**0.07* (0.03; 0.12)**
Decrease	**-0.06* (-0.09; -0.03)**	-0.03 (-0.08; 0.03)
Increase type (ref. no change/decrease)		
Start an NSAID	**0.15* (0.12; 0.17)**	**0.08* (0.03; 0.13)**
Time frequency	**0.18* (0.10; 0.26)**	0.04 (-0.10; 0.18)
Dose	**0.16* (0.12; 0.20)**	**0.08* (0.00; 0.16)**
Decrease type (ref. no change/increase)		
Stop an NSAID	**-0.06* (-0.10; -0.03)**	-0.02 (-0.09; 0.05)
Time frequency	**-0.25* (-0.32; -0.18)**	-0.13 (-0.27; 0.02)

VALIDITY AND PSYCHOMETRIC CHARACTERISTICS OF THE DURUÖZ HAND INDEX IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Outcome measures

M. T. Duruöz[1], S. Acer Kasman[2], N. Öz[3], H. H. Gezer[4], E. Uzun[5], K. Nas[6].
[1]*Marmara University School of Medicine, PMR Department, Rheumatology Division, Istanbul, Turkey*; [2]*Kartal City Hospital, Rheumatology, Istanbul, Turkey*; [3]*Pendik Training and Research Hospital, Rheumatology, İstanbul, Turkey*; [4]*Ümraniye Training and Research Hospital, Rheumatology, Istanbul, Turkey*; [5]*Sakarya University School of Medicine, PMR Department, Sakarya, Turkey*; [6]*Sakarya University School of Medicine, PMR Department, Rheumatology Division, Sakarya, Turkey*

Background: The Duruöz Hand Index (DHI) is a valuable scale developed for evaluating hand functions of patients with rheumatoid arthritis and has subsequently proven to be valid and reliable in various diseases.

Objectives: This study aims to investigate the validity and reliability of DHI in patients with psoriatic arthritis (PsA).

Methods: Patients diagnosed with PsA according to CASPAR criteria were enrolled. The demographic, clinical, and functional characteristics of patients were evaluated. Functional assessment was performed with DHI, Hand Functional Index (HFI), Health Assessment Questionnaire (HAQ), and VAS-disability scale. C-reactive protein level, patients' and physicians' global VAS, swelling and tenderness of the hand joints, gross grip strength and thumb strength, and disease activity assessments were recorded as non-functional parameters related to active disease status. The reliability of DHI was assessed by internal consistency (Cronbach's alpha coefficient). Face, content, and construct validity (convergent and divergent) were evaluated. Face and content validities were assessed via cognitive debriefing interviews with the patients. The correlations of the DHI with HAQ, HFI, and VAS disability were assessed for convergent validity. The correlations of the DHI with DAPSA, BASDAI, MDA, PSAQoL, Jenkins index, PASI, and grip strength were evaluated for divergent validity.

Results: One hundred and forty-four patients (74.3% female) with a mean age of 45.33 (SD: 11.58) years were included in this study. Cognitive debriefing showed the DHI to be clear, understandable, and relevant. It was easy to complete and calculate, with the 4 minutes and 30 seconds, respectively. The Cronbach's alpha coefficient was 0.963, and for the test–retest reliability of the DHI, the intraclass correlation coefficient was 0.904 (p<0.001). DHI showed good correlations with the functional disability scales (HAQ, HFI, VAS-disability), indicating its convergent validity and moderate to non-significant correlations with the non-functional parameters supporting its divergent validity (Table 1).

Conclusion: The DHI is a valid and reliable scale to evaluate the functional disability of hands in patients with PsA.

DIFFERENCES BETWEEN DISEASE ACTIVITY MEASURED BY ULTRASOUND VERSUS THE STANDARDIZED CLINICAL ACTIVITY INDEX (DAS28 AND DAPSA) FOR RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS BEFORE STARTING BIOLOGICAL THERAPY: A RETROSPECTIVE STUDY

Keywords: Psoriatic arthritis, Rheumatoid arthritis, Ultrasound

I. M. Fernández-Maeztu Palacín[1], D. Ruiz-Montesinos[1], P. Muñoz Reinoso[1], A. Fernández Reboul Fernández[1], J. Rodas[1], J. J. Pérez Venegas[1]. [1]*Hospital Universitario Virgen Macarena, Rheumatology, Sevilla, Spain*

Background: Numerous studies have been written about the role of ultrasound as an objective tool for measuring damage and to predict subsequent progression of inflammatory joint diseases, as well as to detect low-grade synovitis, even in patients with low disease activity.[1] It has been suggested that some patients with subclinical inflammation may experience radiological progression and joint damage despite being in clinical remission.[2]
Objectives: The main objective of this study is to analyze the differences between the disease activity measured by ultrasound versus the standardized clinical activity index (DAS28 and DAPSA) for Rheumatoid Arthritis (RA) and Psoriatic Arthritis (APS) before the start date treatment with biological therapies.
Methods: A retrospective, non-interventional study was performed by reviewing the databases of RA and APS patients from the Hospital Universitario Virgen Macarena's Rheumatology department as well as an inferential study comparing the disease activity measure by ultrasound to the standardized clinical activity index.
Results: 85 ultrasounds of patients with RA (N=54) and APS (N=31) have been included and correlated with the baseline ultrasound activity before the start date treatment with biological therapies. The contrast of the baseline DAS28 and DAPSA means for the different ultrasound findings did not show significant differences (Table 1).
Conclusion: In our daily clinical practice, an adequate correlation is found between the finding data. However, approximately 24% of patients with moderate/high clinical activity by DAS28/DAPSA had no ultrasound activity. While the results are not statistically significant, this fact can be explained by the small sample size limitation. More studies are needed to make recommendations about the role of ultrasound (in conjunction with the standardized activity index) to ensure the proper therapeutic strategies in inflammatory joint diseases.

ANTI-DFS70: ARE THEY HELPFUL WHEN ASSESSING FOR SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES?

Keywords: Descriptive studies, Autoantibodies, Diagnostic tests

D. Galarza[1], I. Carrion[1], C. Veloza[1], H. Sirera Perello[1], T. Salman-Monte[1], A. Pros[1], E. Villegas[2], J. Eguía[2], C. Pérez[1], J. Monfort[1]. [1]*Parc de Salut Mar - Hospital del MAR, Rheumatology, Barcelona, Spain*; [2]*Laboratori de Referència de Catalunya, Immunology, El Prat de Llobregat, Spain*

Background: Autoantibodies against DFS70 (dense fine speckles 70) antigen (anti-DFS70) are purported to rule out systemic autoimmune rheumatic diseases (SARD) when detected in the absence of other SARD-related antibodies. They are recognized using indirect immunofluorescence (IIF) and are a common finding among antinuclear antibodies (ANA)-positive healthy individuals. Data published so far highlights the negative association between anti-DSF70 and SARD.
Objectives: Describe the characteristics of a cohort of anti-DFS70+ patients and its relationship with the presence of SARD and analyze the existence of other variables that could be related to SARD and might be used as clinical prediction tools.
Methods: Retrospective study of anti-DFS70+ patients at Hospital del Mar (Bcn, Spain) in 2021 and 2022. Demographic, clinical and biological data were collected. Presence of anti-DFS70 was determined by immunoblot using EUROLine-EUROIMMUN kit, which allows qualitative in vitro determination of human autoantibodies of IgG isotype. Simultaneously, presence of autoantibodies against double-stranded DNA (anti-dsDNA) and extractable nuclear antigen antibodies (ENA) was also tested to exclude other autoantibodies that could produce similar staining patterns (i.e., AC-1 or AC-1 with AC-4,5). A descriptive and correlations statistical analysis was performed using SPSS 23 IBM®.
Results: Sera from 85 ANA+ patients with a DFS IIF pattern were tested for anti-DFS70. 52 patients tested positive and were included: 10 males and 42 females. Mean age to first anti-DFS70+ determination was 40.67 ±16.99 years. Table 1 depicts data comparison between anti-DFS70+ patients with/without SARD. No SARD was found in 44 patients (84.6%). From 8 patients with SARD, 2 tested positive for other autoantibodies. A correlation was found between higher ANA titers and presence of SARD. No other significant correlation was found.
Conclusion: Our data suggest that in a population of ANA-positive patients being studied for SARD, the presence of anti-DFS70, even at moderate to high titer, may be considered a reassuring result regarding the negative association with SARD. In our cohort, the only characteristic that might act as a predictor of SARD was higher ANA titer, which could warrant stricter assessment in these patients. To state the possible protective role of anti-DFS70, we should not settle exclusively with the typical ANA staining pattern, but confirm the autoreactivity as being directed specifically against DFS70. Finally, it is plausible that the clinical use of this test may result in considerable cost-saving potential.

AB1686 SPECIFYING CLINICAL PHENOTYPES RELATED TO MYOSITIS ANTIBODIES

Keywords: Myositis, Lungs, Autoantibodies

F. Schumacher[1,2], M. Kanbach[2], M. Berger[2,3], M. Wollsching-Strobel[2,3], S. Wigbert[4], D. Kroppen[2,3], S. Schwarz[2,3], W. Windisch[2,3], J. Strunk[1]. [1]*Krankenhaus Porz am Rhein gGmbH, Rheumatology, Köln, Germany*; [2]*Witten/Herdecke University, Faculty of Health/School of Medicine, Witten, Germany*; [3]*Kliniken der Stadt Köln, Pneumology, Köln, Germany*; [4]*Wisplinghoff, Medical Laboratories, Köln, Germany*

Background: The increased availability of myositis-specific-auto-antibodies (MSA) and myositis-associated auto-antibodies (MAA) represent new possibilities and challenges in everyday clinical practice for the classification of possible inflammatory rheumatic diseases (IRD). In order to achieve improved evidence regarding rare MSA and MAA and their possible significance regarding IRD other than idiopathic inflammatory myopathies (IIM), further studies are required for the classification of these new and heterogeneous disease groups.
Objectives: The aim of this study is a retrospective data analysis with positive MSA/MAA to analyse the significance in rheumatological clinical routine. Regarding the rather rarely autoantibodies, the occurrence and clinical association between MSA/MAA and clinical phenotypes with different disease manifestation, in this cohort should be examined.
Methods: A retrospective monocentric analysis of all orders to determine MSA or MAA in the period from July 2019 to May 2022 in the inpatient and outpatient sector of the Department of Rheumatology, Krankenhaus Porz am Rhein, Cologne, Germany, was carried out. A focus was placed on the following MSA and MAA: EJ, PL-7, OJ, PL-12, Mi-2, TIF1-γ, MDA5, SAE, NXP2, SRP, Ku, PM-Scl100, PM-Scl75. For each patient in whom at least one of these autoantibodies had occurred, the documented medical history was analysed retrospectively using the available files. In addition to demographic data, the existing diagnoses, documented anamnestic parameters, the various clinical examination findings and other existing diagnostic laboratory findings as well as radiological or functional examination findings has been documented at different times.
Results: In the defined time interval, a total of 33045 laboratory values, for the antibodies mentioned above, was ordered. A total of 238 different positive MSA/MAA were determined in 209 various patients (duplicate determinations of different autoantibodies in one patient were not excluded). The distribution of the present MSA and MAA in the various rheumatological diagnosis groups are shown in Table 1. IIM was diagnosed in 37 patients (18%) and IRD other than IIM was diagnosed in 90 patients (43%). In 82 patients (39%) no diagnosis of an IRD was made. Computed tomography of the thorax (CTtx) was performed in 92 patients. 40 examinations showed different inflammatory interstitial patterns. Of these patients, IIM was diagnosed in 14, IRD other than IMM in 19, and no IRD in 7. The number of patients with a pathological CTtx in the individual diagnosis groups is shown in Figure 1.
Conclusion: MSA and MAA are also positively determined in rheumatological diagnostics in patients in whom no IMM or even no IRD has been diagnosed. Nevertheless, clinical peculiarities, like changes in the CTtx can also be detected in the group of other IRDs than IMM or without IRD but with a positive status of MSA/MAA. Further investigations into specific phenotypes associated with MAA/MSA, also in the group of patients without IRD, are needed.

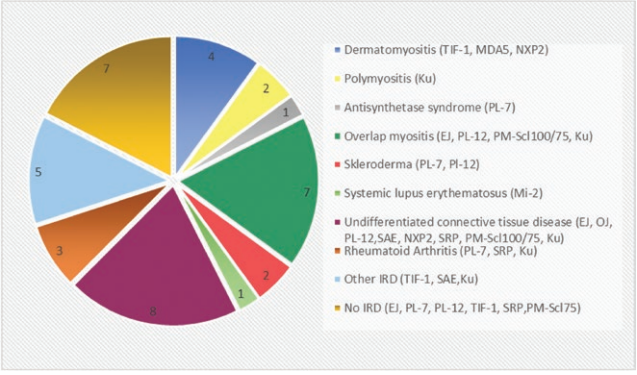

Figure 1. Number of patients with a pathological CTtx in the individual diagnosis group (n=40).
Other IRD: microscopic polyangiitis, mixed connective tissue disease

Background: Health-related quality of life (HRQoL) is the ultimate objective of treatment in axial spondylarthritis (axSpA) [1]. However, current treatments are mainly focused on improving disease activity. Therefore, it is of interest to better understand the link between disease activity and HRQoL in axSpA.
Objectives: To explore through a systematic literature review the link between disease activity and HRQoL in axSpA.
Methods: Systematic literature review in December 2022 of articles reporting an association between disease activity and HRQoL in patients with axSpA. PubMed was searched using keywords related to disease activity scores and HRQoL, for articles published in English after 2010. Disease activity was assessed by ASDAS or BASDAI. For HRQoL, we analysed the ASAS Health Index (ASAS-HI) as key outcome. All statistical measures of a potential link between ASDAS and HRQoL were collected; correlations were prioritsed for homogeneity. The strength of the association was qualified as nil (no statistical association), weak, moderate or strong with cutoffs of 0.50 and 0.70 for correlations. No meta-analysis was performed.
Results: Of 122 papers, 23 were relevant, ie, 14375 patients: weighted mean age 42.5 years, weighted mean disease duration 14.3 years, 67.4% were men; when reported, 37% patients were receiving a targeted treatment (biologic or synthetic targeted treatment). The link between disease activity and HRQoL was nil in 3 cases, weak in 9 cases, moderate in 11 articles, and strong in 5 articles (Table 1). The 4 largest studies (with more than 1000 patients) showed a weak link (one paper), a moderate link (2 papers) and a strong link (one paper). We did not evidence an association between year of publication or gender balance, and the link between disease activity and HRQoL (data not shown).
Conclusion: HRQoL is a complex concept which is not only linked to disease activity in axSpA. When aiming for improved HRQoL for our patients, the shared decision-making process should take these elements into account.

FINDING THE NEEDLE IN THE HAYSTACK: SEROLOGICAL AND URINARY BIOMARKERS IN BEHÇET'S DISEASE; A SYSTEMATIC REVIEW

Keywords: Behcet's disease, Biomarkers, Diagnostic Tests

M. Arbrile[1], M. Radin[1], D. Medica[1], P. Miraglia[1], M. L. A. Rilat[1], I. Cecchi[1], S. G. Foddai[1], A. Barinotti[1], E. Menegatti[1], D. Roccatello[1], S. Sciascia[1]. [1]*University of Turin, Clinical and Biological Sciences,Turin, Italy*

Background: Urinary and serological markers play an essential role in the diagnostic process of autoimmune diseases. However, to date, specific and reliable biomarkers for diagnosing Behçet's disease (BD) are still lacking, negatively affecting the management of these patients [1]
Objectives: We aimed to systematically review the currently available literature on the identification and characterization of serological and urinary BD biomarkers investigated in the last 25 years.
Methods: We performed a systematic literature review using the PICO (Population, Intervention, Comparison, and Outcomes) strategy on serological and urinary BD biomarkers investigated in the last 25 years.
Results: One hundred-eleven studies met the eligibility criteria (6301 BD patients, 5163 controls). Most of them were retrospective, while 5 (5%) were prospective. One hundred-ten studies (99%) investigated serological biomarkers, and only 2 (2%) focused on urinary biomarkers. One hundred-three studies (93%) explored the diagnostic potential of the biomolecules, whereas 62 (56%) tested their effect on disease activity monitoring. Most articles reported an increase in inflammatory markers and in pro-oxidant molecules, with a decrease in antioxidants. Several miRNAs (including miR-93, miR-106b, miR-25, miR-146a, miR-326, and miR-181b) were assessed by three studies (3%) included in this systematic review, with contrasting conclusions. Promising results have been shown by the –omics sciences, offering a more holistic approach. Interestingly, the distribution of the country of origin of each study showed the characteristic spread of BD along the ancient Silk Road.
Conclusion: Despite the vast number of investigated markers, existing evidence indicates a persistent gap in BD diagnostic/prognostic indices. While new steps have been taken in the direction of pathogenesis and disease monitoring, international efforts for a diagnostic marker are still further needed.

AB1689 CROSS-CULTURAL ADAPTATION AND VALIDATION OF THE TURKISH VERSION OF THE FLARE OA QUESTIONNAIRE FOR HIP AND KNEE OSTEOARTHRITIS

Keywords: Outcome measures, Osteoarthritis

M. T. Duruöz[1], H. H. Gezer[2], E. Jonathan[3], M. Soudant[4], F. Guillemin[5]. *[1]Marmara University School of Medicine, PMR Department, Rheumatology Division, İstanbul, Turkey*; *[2]Ümraniye Training and Research Hospital, Rheumatology, İstanbul, Turkey*; *[3]Université de Lorraine, Epidémiologie clinique, Nancy, Turkey*; *[4]Université de Lorraine, Epidémiologie clinique, Nancy, France*; *[5]Université de Lorraine, EA 4360 Apemac, Nancy, Turkey*

Background: The Flare-OA self-reported questionnaire with five domains (painful, swelling, stiffness, consequences of symptoms, and psychological aspects) (0-100) was recently developed to measure the occurrence and severity of flares in the knee and hip osteoarthritis (OA).
Objectives: This study aimed to translate and cross-culturally adapt the Turkish version of the FLARE-OA questionnaire according to the results of the French/English version using classical psychometric analysis methods.
Methods: The French/English version of the FLARE-OA questionnaire was cross-culturally adapted and translated into Turkish following an established forward–backward translation procedure. After an expert committee reviewed the Turkish version, the final version was checked for the translation's understandability, interpretation, and cultural relevance with ten patients. Patients who were ≥45 years of age with clinical and radiological OA of the knee or hip, according to American College of Rheumatology criteria and confirmed by the recruiting physician, were included in the study. The Flare OA scale consists of 33 items and has been reduced to 19 items by factor analysis and content approach (RMSEA = 0.06; CFI = 0.96; TLI = 0.94) [1]. The reliability of Flare-OA was assessed by internal consistency (Cronbach's alpha coefficient). Face, content, and construct validity (convergent) were evaluated. The correlations of the Flare-OA with the Hip Disability and Osteoarthritis Outcome score (HOOS), Knee Injury and Osteoarthritis Outcome Score (KOOS), and the Mini Osteoarthritis Knee and Hip Quality of Life Questionnaire (Mini-OAKHQOL) were assessed for convergent validity.
Results: A total of 185 (71.9% females) patients with knee or hip OA with a mean age of 63.2 (SD:9.1) years participated in the study. One hundred-sixty (86.5%) of the patients had knee OA, 25(13.5%) had hip OA, and 70 (37.8%) had experienced worsening of the knee or hip OA during the last four weeks. The confirmatory factorial analysis retained a model with 19 items (RMSEA=0.08; SRMR =0.05; and CFI =0.95). Internal consistency Cronbach's alpha coefficient was 0.987 (95% CI: 0.984 - 0.990) for 33-item and 0.978 (95% CI: 0.973 - 0.982) for 19-item. The intraclass correlation coefficient was 0.913 and 0.915 for the test–retest reliability of the 33 and 19 items, respectively. Sensitivity to change was good in patients improving (SRM 1.2 and 1; 33 and 19 items, respectively) over the period. The discriminant validity was evidenced by a significant score difference (36.2 and 36.6; 33 and 19 items, respectively) between patients with and without flare. Pearson's correlation coefficients of the Flare-OA questionnaire with the other parameters for construct validity are represented in Table 1.
Conclusion: This study demonstrated that both the 33 and 19-items Turkish versions of the Flare OA questionnaire are reliable and valid tools for assessing flaring in patients with knee and hip OA.

AB1690 SERUM PEPTIDES AS CANDIDATE BIOMARKERS FOR RELAPSING POLYCHONDRITIS

Keywords: Biomarkers

M. Kurokawa[1], T. Sato[2], M. Sato[2], K. Nagai[3], M. Fukasawa[4], Y. Nagashima[1], T. Uchida[1], A. Tsutiya[2], K. Omoteyama[2], M. Arito[2], Y. Takakuwa[5], S. Ooka[5], N. Suematsu[2], K. Kawahata[5], Y. Yamano[6,7], T. Kato[2]. *[1]St. Marianna University Graduate School of Medicine, Disease Biomarker Analysis and Molecular Regulation, Kawasaki, Japan*; *[2]St. Marianna University Graduate School of Medicine, Clinical Proteomics and Molecular Medicine, Kawasaki, Japan*; *[3]Kindai University, Department of Genetic Engineering, Faculty of Biology-Oriented Science and Technology, Kinokawa, Japan*; *[4]St. Marianna University School of Medicine, Department of Otolaryngology, Kawasaki, Japan*; *[5]St. Marianna University School of Medicine, Division of Rheumatology and Allergology, Department of Internal Medicine, Kawasaki, Japan*; *[6]St. Marianna University School of Medicine, Division of Neurology, Department of Internal Medicine, Kawasaki, Japan*; *[7]Institute of Medical Science, St. Marianna University School of Medicine, Department of Rare Diseases Research, Kawasaki, Japan*

Background: For relapsing polychondritis (RP), no useful biomarkers have yet been identified.
Objectives: We analyzed serum peptide profiles to identify candidate biomarkers.
Methods: Patients with RP or rheumatoid arthritis (RA) and healthy control (HC) subjects were divided into training (RP, n=19; RA, n=21; HC, n=17) and testing (RP, n=18; RA, n=21; HC, n=18) sets. Seven patients demonstrating granulomatosis with polyangiitis (GPA) were used for validation. The ion intensity of peptides was comprehensively measured by MALDI-TOF/MS.
Results: 160 serum peptides were detected. In the RP group of the training set, 24, 8, and 7 peptides showed a ≥1.2-fold difference in ion intensity in comparison to the HC, RA, and HC+RA (non-RP) groups, respectively ($p<0.05$). Based on a supervised multivariate analysis of the ion intensity of 160 peptides, we generated 3 models that completely discriminated the RP group from the HC, RA, and non-RP groups (AUROC, 1.000). By selecting 11, 9, and 14 peptides, the RP group was also completely discriminated from the 3 groups (RP/HC-11P model, RP/RA-9P model, and RP/nonRP-14P model; AUROC, 1.000). We attempted to identify the peptides with a ≥1.2-fold difference in ion intensity between the RP group and one of the 3 groups and the peptides comprising the RP/HC-11P, RP/RA-9P or RP/nonRP-14P models. Nineteen peptides were identified. Most were fragments of proteins associated with coagulation. As biomarker models for RP which consists of a few peptides, we found that 4 models consisting of 4 peptides

(RP/nonRP-4P-2, -10, -11, and -38 models) provided ≥65.0% sensitivity and specificity (AUROC, 0.779-0.836) in the training and testing sets and the testing set with GPA group. Notably, the RP/nonRP-4P-2 model provided 83.3% sensitivity and 71.7% specificity in the testing set with GPA group (AUROC, 0.802).
Conclusion: Serum peptide profiles provided useful candidate biomarkers for RP and may be implicated in the pathophysiology of RP.

AB1691 BURDEN OF AFFECTED FACE IN PATIENTS WITH SYSTEMIC SCLEROSIS: A TRANSLATION AND VALIDATION STUDY IN TURKISH

Keywords: Quality of life, Validation, Patient reported outcomes

F. Sarİ[1], Z. Bazancİr Apaydİn[2], H. Apaydın[3], M. Kayaalp[4], A. Erden[5], S. C. Güven[3], B. Armagan[3], A. Omma[6], O. Küçükşahin[4]. *[1]Bingol University, Physiotherapy and Rehabilitation, Bingöl, Turkey*; *[2]Ankara Medipol University, Physical Therapy and Rehabilitation, Ankara, Turkey*; *[3]Ankara City Hospital, Rheumatology, Ankara, Turkey*; *[4]Ankara Yıldırım Beyazıt University, Department of Internal Medicine, Ankara, Turkey*; *[5]Gazi University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey*; *[6]University of Health Sciences, Clinical of Rheumatology, Ankara, Turkey*

Background: Facial involvement is crucial for patients' quality of life in patients with systemic sclerosis (SSc). The effect of the facial signs on health-related quality of life is assessed the several questionnaires, however, these are not specific to assess disability involving the face in SSc patients. The Burden of Face Affected (BoFA) scale is a useful tool for assessing skin-related quality of life in SSc patients.
Objectives: The aim of this study was to evaluate the reliability and validity of an adapted Turkish version of the BoFA.
Methods: The translation and cross-cultural adaptation of the French version of the BoFA was conducted, all steps of the cross-cultural adaptation process were performed by Beaton guidelines. The Turkish version of the BoFA, the Mouth Handicap in Systemic Sclerosis (MHISS), the Rosenberg Self-Esteem Scale (RSS), and Perceived Stress Scale (PSS) were performed to the 49 patients with SSc patients. Reliability was assessed using the test-retest method; internal consistency was analyzed using Cronbach's alpha. Construct validity was assessed by correlating the BoFA with the MHISS, RSS, and PSS questionnaires.
Results: The BoFA showed excellent test/retest reliability with an intraclass correlation coefficient of 0.96 for total score. Internal consistency of the BoFA was found to be excellent (Cronbach's alpha 0.96). The BoFA demonstrated good construct validity with the MHISS ($r = 0.55$, $p < 0.001$), the RSS ($r=0.53$, $p < 0.001$), and the PSS ($r=0.50$, $p < 0.001$). Also, the factor analysis showed the BoFA has four-factor subgroup by scree plot graph. There were no BFAs found to be related to the floor and ceiling effects.
Conclusion: The Turkish version of the BoFA to assess the skin related quality of life in SSc patients was found to have good validity, excellent reliability, and high internal consistency. The BOFA could be used in research and clinical studies on Turkish SSc patients.

AB1692 A NEW, RELIABLE AND PRECISE HIGH-THROUGHPUT SERUM CALPROTECTIN ASSAY TO ASSESS THE INFLAMMATORY STATUS OF PATIENTS

Keywords: Rheumatoid arthritis, Biomarkers, Diagnostic Tests

A. Melone[1], D. Vogt[1], A. Ohmann[1], J. Afonso[1], C. Moniz[2], D. Guschin[1], C. B. Gerhold[1], T. Schuster[1]. *[1]Bühlmann Laboratories AG, Development, Schönenbuch, Switzerland*; *[2]Bühlmann Laboratories AG, Global Marketing, Schönenbuch, Switzerland*

Background: Serum calprotectin (sCAL) is a promising biomarker to detect the inflammatory status of patients in rheumatoid arthritis, juvenile idiopathic arthritis and systemic onset juvenile idiopathic arthritis diseases. Serum calprotectin can be a useful tool to monitor disease activity and predict treatment response in these patients.
Objectives: The aim of this work was to evaluate the analytical performance of a new sCAL turbidimetric assay, a high throughput test on clinical chemistry analyzers, to determine calprotectin levels in serum.
Methods: CLSI guidelines (CLSI C28-A3, EP05-A3, EP07-A3, and EP09-A3) were used to establish sCAL turbidimetric assay characteristics.111 samples were measured with 3 lots over 3 days and compared to another commercially available assay.
Results: The assay presented an analytical measuring range from 0.23 to 15 µg/mL, extended to 225 µg/mL with an additional dilution in an automated rerun on a clinical chemistry analyzer. Reference limits of 1.77 and 1.10 µg/mL were obtained with 160 self-declared healthy adults (m/w) aged 18 to 83 years when sampled either in native tube or tube with gel separator and processed within 3.4 hours after collection respectively. The method is precise, reliable and suitable for routine use, with a within-laboratory precision up to 5.1% and a reproducibility up to 11.1%. No interference was shown with tested concentrations of oral and injectable pharmaceuticals. Hemolyzed samples are not recommended. A method comparison with another commercial assay presented a good agreement with a bias of 2.45% (Bland-Altman) and a slope of 1.16 (Passing Bablok).
Conclusion: The new sCAL turbidimetric assay is a high throughput quantitative method performed on clinical chemistry analyzers to reliably and precisely assess the inflammatory status of patients.

AB1693 RECOMBINANT CALPROTECTIN IN A CONTROLLABLE OLIGOMERIC STATE COULD HELP TO HARMONIZE MRP-8/MRP-14 IMMUNOASSAYS

Keywords: Biomarkers, Diagnostic Tests

A. Ohmann[1], D. Guschin[1], J. Afonso[1], P. Spies[2], D. Tobler[3], T. Villiger[3], D. Meinel[2], C. B. Gerhold[1]. *[1]Bühlmann Laboratories AG, Development, Schönenbuch, Switzerland*; *[2]School of Life Sciences FHNW, Institute for Chemistry and Bioanalytics, Muttenz, Switzerland*; *[3]School of Life Sciences FHNW, Institute for Pharma Technology, Muttenz, Switzerland*

Background: Calprotectin is a major granulocyte and monocyte alarmin protein. It can natively occur as dimeric and tetrameric complex of Mrp-8 and Mrp-14. Although, serum calprotectin is emerging as an important biomarker for rheumatoid arthritis and juvenile idiopathic arthritis, fecal calprotectin is already established as the gold standard for diagnostics and monitoring of inflammatory bowel diseases. However, standardization of fecal calprotectin assays differs significantly among providers leading to varying clinical cut-offs. A suspected reason is that calprotectin's oligomeric states can generate different quantitative results. Yet trapping calprotectin in a distinct oligomeric state is challenging.
Objectives: The aim of this work was to produce pure calprotectin as calibrator material with a controllable oligomeric state.
Methods: The oligomeric state of a recombinant fusion protein between Mrp8 and Mrp14 that expressed solubly in E. coli was assessed by size-exclusion chromatography. Direct comparison to native calprotectin regarding antibody affinities were measured and its use as calibrator material in various immunoassay formats was tested.

Results: The fusion protein was purified as a calprotectin dimer mimic. Calcium addition could successfully transform calprotectin dimer into a calprotectin tetramer. Affinities to monoclonal and polyclonal calprotectin antibodies were comparable to native calprotectin. Spiking of different concentrations of recombinant calprotectin showed linear correlations in ELISA and turbidimetric assays. A perfect correlation (slope=1.009; R^2=0.999) was shown when measuring 23 human serum samples based on native and recombinant calprotectin calibrators with a turbidimetric assay.
Conclusion: The recombinant protein can be purified in large quantities in defined oligomeric states and it shows immunological properties comparable to native calprotectin. Recombinant calprotectin presents as a promising tool to overcome the prevalent fecal calprotectin standardization problem and prevent future standardization discrepancies for serum calprotectin.

AB1694

IN VIVO MEASUREMENT OF POTENT AND DURABLE HUMAN ADIPOSE 11B-HYDROXYSTEROID DEHYDROGENASE TYPE 1 INHIBITION BY SPI-62

Keywords: Clinical Trials, Vasculitis, Targeted synthetic drugs

D. Katz[1], G. An[2], C. Schmicker[3], B. Engel[4], T. Magers[4], R. Basu[5], J. Gutierrez[6,7]. *[1]Sparrow Pharmaceuticals, n/a, Portland OR, United States of America*; *[2]University of Iowa, College of Pharmacy, Iowa City, United States of America*; *[3]Q2 Biosolutions MD, Project Management, Indianapolis IN, United States of America*; *[4]Q2 Biosolutions MD, Method Development and Validation, Indianapolis IN, United States of America*; *[5]University of Virginia, Medicine, Charlottesville VA, United States of America*; *[6]ProSciento, n/a, Chula Vista CA, United States of America*; *[7]Scripps Clinic, Medicine, La Jolla CA, United States of America*

Background: 11β-hydroxysteroid dehydrogenase type 1 (HSD-1), an intracellular enzyme that converts glucocorticoids (GC) from inactive (e.g., prednisone, cortisone) to active (e.g., prednisolone, cortisol) form is a main source of intracellular GC that can bind to intracellular GC, mineralocorticoid, and non-genomic receptors. Prior clinical and non-clinical results support the hypothesis that HSD-1 inhibitors have potential to mitigate GC toxicity without eliminating GC efficacy. Results from tissue-specific HSD-1 knockout mouse studies indicate that adipose is a key target tissue for GC cardiometabolic toxicity prevention or reversal. However, several HSD-1 inhibitors have shown tachyphylaxis on adipose inhibition in human within 14 days of dosing.
Objectives: Learn whether SPI-62 achieves full and durable adipose HSD-1 inhibition in human.
Methods: Participants with type 2 diabetes and BMI 30-45 kg/m^2 received SPI-62 daily for up to 14 days in an open label Phase 1 clinical trial. Microdialysis catheters (Type 63, μ dialysis, Stockholm Sweden) inserted in subcutaneous abdominal adipose were infused continuously with [2,2,4,6,6,9,12,12-$^2H_8$]cortisone (D8E) 1 μg/mL at 1 μL/min. Following selected SPI-62 doses, dialysate samples were collected at 0-2, 2-4, 4-6, 6-8, 8-10, 20-22, and 22-24 hours. D8E and [2,2,4,6,6,9,12,12-$^2H_8$]cortisol (D8F) concentrations in dialysate were measured using a validated LC-MS/MS assay. D8E results below the limit of quantitation (LOQ = 0.100 ng/mL) were imputed as the LOQ. The molar ratio D8F/D8E was used as a biomarker of adipose HSD-1 activity.
Results: Data from the 2 participants who received SPI-62 6 mg QD for 14 days, and from whom data were collected on Days 1, 2, and 14, are presented. D8F/D8E declined from baseline 90.8% and 93.5% during Day 1. D8F/D8E was on average decreased from baseline 94.2% and 95.6% during Day 2, and 92.0% and 93.9% during Day 14.

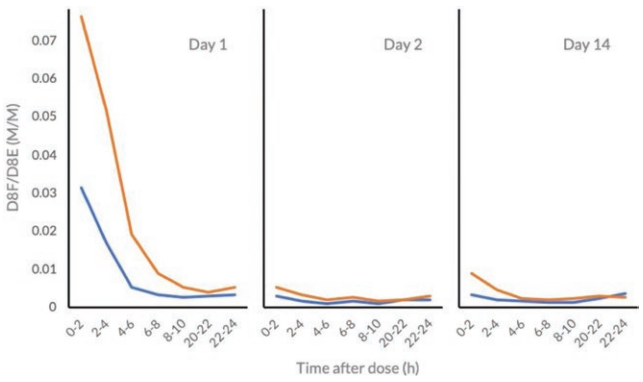

Figure 1.

Conclusion: Human adipose HSD-1 activity and inhibition can be quantitated via D8E infusion of subcutaneous tissue via measurement of the molar ratio of the corresponding HSD-1 product D8F/D8E in dialysate. SPI-62 does not show tachyphylaxis on adipose HSD-1 inhibition within 14 days. A combination product of prednisolone with the HSD-1 inhibitor SPI-62 is now in a Phase 2 clinical trial as a steroid symptom sparing agent, initially for patients with polymyalgia rheumatica. The selected regimen for that trial, SPI-62 6 mg QD, is appropriate to assess clinical effects that might be associated with adipose HSD-1 inhibition. Data from all 12 participants will be used to model dose-exposure-response relationships to refine dose selection for future clinical trials.

AB1695

THE EFFECTS OF TELE-REHABILITATION-BASED STABILIZATION EXERCISES ON BALANCE, GAIT, FUNCTIONALITY, PAIN AND DEPRESSION IN INDIVIDUALS WITH CHRONIC IDIOPATHIC NECK PAIN

Keywords: Rehabilitation, Physical therapy/Physiotherapy, Non-pharmacological interventions

H. Ayan[1,2], B. Kara[3], R. Erbayraktar[4]. *[1]Izmir Katip Çelebi University Vocational School of Health Services, Department of Medical Services and Techniques, Izmir, Turkey*; *[2]Dokuz Eylul University, Institute of Health Sciences, Izmir, Turkey*; *[3]Dokuz Eylul University, Faculty of Physical Therapy and Rehabilitation, Izmir, Turkey*; *[4]Dokuz Eylul University, Department of Neurosurgery, Faculty of Medicine, Izmir, Turkey*

Background: Chronic neck pain is associated with balance and gait disturbances [1,2]. The effects of tele rehabilitation- based stabilization training on balance and gait in chronic idiopathic neck pain (CINP) are still unknown.
Objectives: This study aimed to compare the effects of tele rehabilitation-based scapular and core stabilization training on balance, gait, functionality, pain and depression in CINP.
Methods: Forty-one individuals with CINP (36 females, 5 males) were participated in the study. Participants were randomized into two groups as scapular stabilization (SS) group (n=20, 17 females, 3 males, age 20.00 [19.0-21.0] years, visual analogue scale (VAS) score 6.00 [5.0-6.0]) and the core stabilization (CS) group (n=21, 19 females, 2 males, age 20.00 [19.0-21.0] years, VAS score 5.00 [5.0-6.0]). Tele rehabilitation-based exercise sessions were conducted with mutual videoconferencing synchronously in groups of 2-3 participants, 45-60 minutes' duration, once a-week for 8 weeks. Postural stability (PS) and limits of stability (LOS) were measured by a computerized balance platform. Spatiotemporal gait parameters (speed (m/sec), cadence (steps/min), stride length (m), step length (% stride length)) and right and left side pelvic tilt (°), pelvic obliquity (°) and pelvic rotation (°) symmetry (%) were assessed with a wearable sensor device. The gait was assessed during two different walking conditions.

Firstly, the participants walked at usual (normal) walking speed on the 10-meter walking path. Secondly, they walked this distance at the maximum speed they could walk safely. Neck Disability Index (NDI) for functionality, VAS for pain intensity and Beck Depression Inventory (BDI) for depression were used at baseline and after 8 weeks. Normally distributed variables were presented as mean and SD, non-normally distributed variables were presented as median (interquartile range[IQR]).

Results: After 8 week tele rehabilitation-based training, pain intensity, functionality, depression, PS (overall, anteroposterior), LOS, cadence, speed, and stride length (left) during normal walking, stride length (right) during fast walking, pelvic tilt and pelvic rotation symmetry for both walking condition significantly improved in the both groups ($p < 0.05$). Cadence (120.90 ±9.70 vs. 127.11 ±10.10, $p < 0.001$) and stride length-left (1.49 ±0.21 vs. 1.51 ± 0.20, p= 0.005) during fast walking, stride length-right (1.32 ± 0.19 vs. 1.38 ± 0.21, p= 0.001) during normal walking and pelvic oblique symmetry during both normal (98.10 [97.65-98.85] vs. 98.60 [97.95-98.85], p=0.002) and fast (97.40 [96.15-98.10] vs. 98.50 [97.90-98.95], $p < 0.001$) walking improved in the CS group, while no improvement occurred in the SS group ($p > 0.05$).

Conclusion: This study showed that tele rehabilitation-based stabilization training improved balance, gait, functionality, pain and depression in CINP significantly. Core stability training appears to be more effective than scapular stability training in improving LOS, gait parameters, and pelvic symmetry in this population.

AB1696 COMPARISON OF THE EFFECTIVENESS OF THE PERSONALIZED SCHROTH EXERCISE AND CONVENTIONAL THERAPY FOR SCOLIOSIS IN CHILDREN WITH RHEUMATIC DISEASE

Keywords: Randomized control trial, Physical therapy/Physiotherapy, Rehabilitation

E. P. Kisa[1], E. Tarakci[2], G. Leblebici[3], M. Cacan[4], O. Kasapcopur[5]. *[1]Biruni University, Physiotherapy and Rehabilitation, Istanbul, Turkey*; *[2]Istanbul University Cerrahpasa, Physiotherapy and Rehabilitation, Istanbul, Turkey*; *[3]Istanbul Medeniyet University, Physiotherapy and Rehabilitation, Istanbul, Turkey*; *[4]Medipol University, Hospital of Bagcılar Medipol Mega, Orthopedics and Traumatology, Istanbul, Turkey*; *[5]Istanbul University Cerrahpasa, Cerrahpasa Faculty Of Medicine, Department Of Internal Medicine, Department Of Child Health And Diseases, Istanbul, Turkey*

Background: Childhood rheumatic disease is one of the most common chronic diseases in childhood and adolescence [1]. In particular, it causes weakness, pain, problems in the musculoskeletal system, displacement of the center of gravity, deteriorating biomechanics and muscle imbalance results in scoliosis [2]. Scoliosis is one of the most common musculoskeletal problems encountered in children and adolescents today. In the literature, there are many current studies describing various exercise methods (especially Personalized Schroth Exercise-PSE) that are effective on scoliosis [3, 4]. However, there are no studies investigating the effectiveness of these exercise methods in children with rheumatism.

Objectives: Our study, it was aimed to compare the conventional theraphy program with PSE in children with scoliosis and rheumatic disease.

Methods: PSE for the first group (n=25) and conventional therapy (CT) exercises for the second group (n=25) were applied for 6 months. Demographic features were measured using the "Sociodemographic data Form". Pain states (involved joint pain and back pain) were measured with a numerical rating scale (NRS), flexibility was measured with sit and reach and trunk lateral flexion test, angle of trunk rotation (ATR) was measured with forward bending test, scoliosis angle was measured with Cobb angle. Perception of cosmetic deformity was questioned via The Walter Reed visual assessment scale (WRVAS) and PostureZone program. SPSS 24.0 was used for statistical analysis. $p<0.05$ was considered statistically significant.

Results: There was no statistically significant difference between the groups in terms of age, height, weight, BMI and disease duration and bone development, gender, diagnosis of rheumatism, pain status, flexibility, ATR, Cobb angles, WRVAS and posture parameters at the beginning of the study. The comparison of pain, flexibility, ATR, Cobb angles, and SRS-23 scores of the cases within and between groups is shown in Table 4.6. After the treatment, significant changes were obtained between the trunk rotation angles and Cobb angles of the patients in both groups, while the pain score in the involved joint changed only in Group 1. There were no statistically significant results in spine pain. In the changes obtained after treatment, joint pain, pain, sit and reach, ATR and Cobb angles showed statistically significant improvement in Group I compared to Group II. The comparison of the results of the WRVAS and PostureZone scores of the cases within and between groups, while the sub-parameters of WRVAS and PostureZone of the patients increased significantly in both groups within the post-treatment group, a significant improvement was observed in the sub-parameters of WRVAS and PostureZone in Group I.

Conclusion: At the end of this study, PSE and CT applied to children with rheumatism had a corrective effect on flexibility, ATR, Cobb, WRVAS, posture. PSE were more successful than CT in improving these parameters. The results of our study, which we planned to investigate the effectiveness of PSE, showed that this method has superior aspects in many parameters compared to CT in children with rheumatism, and it may be beneficial to be included in the treatment plan.

AB1697 COMPARISON OF DISEASE ACTIVITY, INFLAMMATORY BIOMARKER, FUNCTIONALITY, PARTICIPATION AND BIOPSYCHOSOCIAL STATUS OF INDIVIDUALS WITH JIA ACCORDING TO THE PRESENCE OF UPPER EXTREMITY INVOLVEMENT

Keywords: Physical therapy/Physiotherapy, Pain, Inflammatory arthritides

S. Buran[1], N. B. Karaca[2], M. O. Tüfekçi[2], E. N. Atabey Gerlegiz[3], E. Aliyev[4], Y. Bayindir[4], V. Yıldız Kabak[3], S. Atasavun Uysal[3], Y. Bilginer[4], E. Ünal[1], S. Özen[4]. *[1]Hacettepe University Faculty of Physical Therapy and Rehabilitation, Department of Heart and Respiratory Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Hacettepe University Institute of Health Sciences, Department of Basic Physiotherapy and Rehabilitation, Ankara, Turkey*; *[3]Hacettepe University Faculty of Physical Therapy and Rehabilitation, Department of Basic Physiotherapy and Rehabilitation, Ankara, Turkey*; *[4]Hacettepe University Faculty of Medicine, Department of Child Health and Diseases, Ankara, Turkey*

Background: Musculoskeletal involvements due to synovitis and tenosynovitis in the upper extremity joints of individuals with JIA negatively affect their daily living activities with the progression of the process [1-2].

Objectives: The aim of this study is to compare the disease activity, inflammatory biomarker, functionality, participation and biopsychosocial status of individuals with JIA according to the presence of upper extremity involvement.

Methods: Forty individuals (21 girls, 19 boys) who were followed up with the diagnosis of JIA between March and December 2022 were included in our study. Individuals whose demographic information was obtained were divided into two groups as those with isolated upper extremity involvement (JIAUE+, n=11) and those without active and/or sequela joint involvement in the upper or lower extremities (JIAULE-, n=29). Disease activity (JADAS-71 and BASDAI), inflammatory biomarker (ESR and CRP), functionality (Childhood Health Assessment Questionaire (CHAQ)) [3], participation (The Child and Adolescent Scale of Participation (CASP)) [4] and biopsychosocial status (Juvenile Arthritis Biopsychosocial and Clinical Questionnaire (JAB-Q)) [5] was evaluated.

Results: While there was no difference between the two groups in terms of age, gender and BMI($p>0.05$), in the JIAUE+ group, JADAS-71 (p=0.012), CRP (p=0.041), CHAQ-Pain (p=0.048), CHAQ-Overall Impact (p=0.003), JAB-Q Child Form functionality (p=0.033) and total score (p=0.009) were found to be significantly higher than the JIAULE- group. All sub-parameters (home (p=0.009), community ($p<0.001$), school (p=0.005), home and community living activities (p=0.044)) and total score of CASP (p=0.003) were found to be significantly lower in the JIAUE+ group.

Conclusion: Disease activity and inflammatory biomarker levels of JIAUE+ individuals were higher than JIAULE- individuals. In addition, pain, functionality, participation and biopsychosocial status of JIAUE+ individuals were worse than JIAULE- individuals. Our results were consistent with the literature, which

revealed that functionality, school performance, and general quality of life were negatively affected in JIAUE+ individuals [6]. The data obtained from the study revealed that the upper extremity joint involvement of individuals with JIA showed more negative effects than those without involvement. With these results, the need for a rheumatologist-physiotherapist-occupational therapist interdisciplinary team understanding was emphasized in order to include individuals with JIA with upper extremity involvement in the exercise-physical activity and participation processes in daily life at the earliest stage, taking into account the disease activity.

AB1698

HIGH-VELOCITY LOW-AMPLITUDE SPINAL MANIPULATIONS FOR THE MANAGEMENT OF LUMBAR RADICULAR SYNDROME: A SYSTEMATIC REVIEW WITH META-ANALYSIS

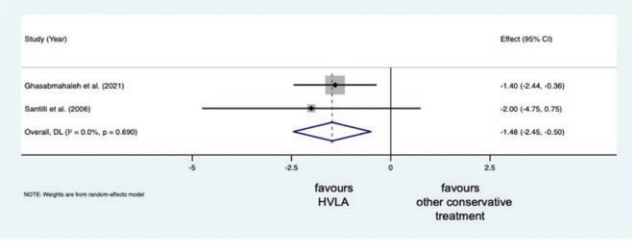
Keywords: Systematic review, Rehabilitation, Physical therapy/Physiotherapy

G. Bertoni[1], R. Serio[1], F. Andreoletti[1], F. Maselli[1], M. Testa[1], S. Battista[1].
[1]*University of Genova, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Savona, Italy*

Background: Lumbosacral Radicular Syndrome (LSRS) is a condition characterised by pain radiating in one or more dermatomes (Radicular Pain) and/or the presence of neurological impairments (Radiculopathy) [1]. Physiotherapy plays a crucial role in LSRS management [2]. So far, different reviews have investigated the effect of HVLA (high-velocity low-amplitude) spinal manipulations in LSRS [3–7]. However, these studies included 'mixed' population samples (LBP patients with or without LSRS) and treatments other than HVLA spinal manipulations (e.g., mobilisation, soft tissue treatment, etc.). Hence, the efficacy of HVLAT in LSRS is yet to be fully understood.

Objectives: This review investigated the effect and safety of HVLATs on pain, levels of disability, and health-related quality of life in LSRS, as well as any possible adverse events.

Methods: A systematic review with meta-analysis. We searched Randomised Controlled Trials (RCT) published in English in the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE (PubMed), EMBASE, PEDro and Web of Science up to June 2022. We considered eligible RCTs on an adult population (18-65 years) with LSRS that compared HVLATs with other non-surgical treatments, sham spinal manipulation, or no intervention. Two authors selected the studies, extracted the data, and assessed the methodological quality through the 'Risk of Bias (RoB) Tool 2.0' and the certainty of the evidence through the 'GRADE tool'. A meta-analysis was performed to quantify the effect of HVLA on pain levels.



Results: A total of 308 records were retrieved from the search strings. Only two studies met the inclusion criteria. Both studies were at high RoB. Two meta-analyses were performed for low back and leg pain levels. HVLA seemed to reduce the levels of low back (MD = -1.48; 95% CI = -2.45, -0.50) and lower limb (MD = -2.36; 95% CI = -3.28, -1.44) pain compared to other conservative treatments, at three months after treatment. However, high heterogeneity was found ($I^2 = 0.0\%$, $p = 0.735$). Besides, their certainty of the evidence was 'very low'. No adverse events were reported.

Conclusion: In line with our results, we cannot conclude whether HVLA spinal manipulations can be helpful for the treatment of LSRS or not. Future high-quality RCTs are needed to establish the actual effect of HVLA manipulation in this disease with adequate sample size and LSRS definition.

COVID-19 IMPACT ON SECOND YEAR MEDICAL STUDENTS EXPERIENCE WITH INTERACTIVE PATIENT ENCOUNTERS AS A SUPPLEMENT TO TEACHING THE SKIN AND RHEUMATOLOGY COURSE

Keywords: Education, COVID

E. Littman[1], S. Beg[1]. [1]*UCF College of Medicine, Internal Medicine, Orlando, United States of America*

Background: The use of interactive patient scenarios has long been a valuable component of medical school curricula, as this type of learning facilitates empathy, comprehensive understanding, and cultural sensitivity.[1] The COVID-19 pandemic, however, has precipitated a shift to more virtual strategies to keep students, faculty, and patients safe.[2]
Objectives: To evaluate second year medical students' (MS2s) perceptions on the use of live patient encounters during the teaching of the skin and rheumatology course (BMS 6635) using different teaching formats due to changes from the COVID-19 pandemic.
Methods: Four to five patients with dermatologic, autoimmune, and musculoskeletal diseases volunteered to participate in an interactive teaching session with MS2s at the University of Central Florida College of Medicine. MS2s enrolled in BMS 6635 were asked to voluntarily complete a survey about their learning experiences using these patient cases. Students who did not respond to the survey were excluded. Data analysis using Chi Square testing was performed on survey responses obtained pre-pandemic as compared to those collected in academic years 2020-2021 and 2021-2022 during the COVID-19 pandemic.
Results: 700 surveys were obtained after patient cases given in different formats. When the interactive patient cases were given in person before COVID-19, 93% of students enjoyed the cases and 95% of students believed that the cases were an appropriate learning experience in their education. When these cases were delivered virtually beginning in the academic year 2020-2021, however, students' enjoyment of these cases decreased to 86%, with 92% of students believing that the cases were an appropriate learning experience. This is a 7% and 9% decrease, respectively, from pre-pandemic years. During the academic year 2021-2022, use of a hybrid model, with students and faculty in-person and patients participating virtually, resulted in 81% of students enjoying the interactive patient cases and 83% of students believing that the cases were an appropriate learning experience. This was a 12% decrease from before the COVID-19 pandemic (p <.001) and a 5% and 9% decrease, respectively, from the previous year (p <.001) (Figure 1). 37% of students who had their cases in a completely virtual format preferred the interactive patient sessions to stay completely virtual, while 51% of students who participated in hybrid sessions during COVID-19 preferred the sessions to be completely virtual (p<.029) (Table 1).

Table 1. Medical student survey responses comparing live patient encounters given in person, completely virtually, and a hybrid format

	In person pre-Covid (2016-2020)		Completely virtual-Covid (2020-2021)		Hybrid Format-Covid (2021-2022)		Total	p-value
I enjoyed the Live Patient cases	439	93%	91	86%	98	81%	628	<.001*
The Live Patient cases were an appropriate learning experience at this stage in my education	448	95%	97	92%	101	83%	646	<.001*
The Live Patient cases helped me remember the diseases well for the exam	95	83%	80	75%	86	71%	261	.111
Would you prefer the Live Patient sessions to be on Zoom?			39	37%	62	51%	49	.029*

* = Statistical significance defined as p<0.05

Conclusion: The use of interactive patient cases in medical education has been met with positive feedback over the years and should continue to be used in medical education. This study showed that MS2s enjoyed the patient encounters more when delivered in-person vs a virtual or hybrid format. Careful consideration should be given to delivery format to optimize student learning and enjoyment.

RHEUMATOLOGIST'S ASSESSMENT OF ACUTE SARCOIDOSIS

Keywords: Systematic review

G. Koilubaeva[1], O. Egorova[2], A. Bolotbekova[1], A. Turatbekova[1], G. Syunbai K[3]. [1]*3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan*; [2]*Kashirskoye Shosse, 34, Rheumatology, Moskva, Russian Federation*; [3]*3 Togolok Moldo St3, Rheumatology, Bishkek, Kyrgyzstan*

Background: Löfgren syndrome (LS) is the acute form of sarcoidosis, characterized by erythema nodosum (EN), joints involvement, fever and intrathoracic lymphadenopathy. LS clinical polymorphism leads to diagnostic errors.
Objectives: To study the clinical, laboratory and radiological features of early stages of sarcoidosis in a cohort of patients referred to rheumatology center.
Methods: The study included 135 patients (107 females and 28 males, mean age 37 ± 9,4 y) with clinical and radiological features of LS. All patients were referred to rheumatology center with EN diagnosis. The median duration of disease was 1 [0,5–2,0] months. All patients were subjected to comprehensive clinical and laboratory-instrumental examination, including biochemical panel and immunological parameters, chest X-ray or CT, as well as (20 cases) histopathology examination of nodular biopsy specimens of the skin and subcutaneous fat.
Results: In 97 % pts EN involved the lower legs, mostly the anterior surface, in 35 % - the hips, in 25 % - the upper limbs and in 3 % - the trunk. Symmetric lesions were documented in 50% of patients. Confluence of nodules forming conglomerates was registered in 48% pts. The involvement of more than 50 % of lower leg surface (68 %) was directly associated with the number of nodules (p < 0.002; r = 0.54) and C-reactive protein level (p = 0.005; r = 0,34). There was a direct correlation between the number of nodules and EN duration (p = 0.03; r = 0.20), and also the tendency to nodules confluence (p < 0.001; r = 0,37). Joint involvement was documented in 115 (85 %) patients, with predominantly ankle (67,4%) and knee (40%) joints affected. Asymmetry of joint involvement was documented in 9% pts. Articular manifestations preceded the emergence of EN in 51 (38 %) patients by mean 9 ± 4 days. There was a significant direct correlation between the duration of articular syndrome and appearance of nodules and their number (p = 0.01; r = 0.42). Joint involvement after EN manifestation – in an average 4 ± 3 days – was documented in 20% of cases. Male gender (odds ratio (OR) 6.5; confidence interval (CI) 1.2–35; p = 0,024) and presence of nodular conglomerates (OR 4,8; CI 1.4 - 16.1; p = 0.01) were the key predictors of ground glass opacity CT phenomenon. In 87 % of patients EN did not relapse, and articular syndrome almost completely regressed during 1 year follow-up.
Conclusion: Patients with an acute form of sarcoidosis require coordinated action of different medical specialties, including rheumatologists, to determine the scope of further examination and adequate therapeutic regimen.

HOW TO MAKE A VIRTUAL PRESENTATION USING ARTIFICIAL INTELLIGENCE?

Keywords: Artificial Intelligence, Best practices, COVID

A. C. Genç[1,2], F. Turkoglu Genc[1], Z. N. Kaya[3], E. Gönüllü[4]. [1]*Hendek State Hospital, Internal Medicine, Sakarya, Turkey*; [2]*Bahcesehir University Graduate School of Education, Artificial Intelligence, Istanbul, Turkey*; [3]*Saratoga High School, High School, Saratoga, California, United States of America*; [4]*Sakarya University Faculty of Medicine, Rheumatology, Sakarya, Turkey*

Background: Virtual presentations have become increasingly common due to the COVID-19 pandemic and advancements in technology. However, it is not yet clear how to effectively use artificial intelligence (AI) in virtual presentations to enhance their effectiveness.
Objectives: The aim of this study is to investigate the current state of AI in virtual presentations and to develop practical guidelines for using AI to enhance the effectiveness of virtual presentations.
Methods: ChatGPT is an artificial intelligence chatbot [1]. The final version contains information up to years of 2021. We wrote to ChatGPT: "I want to submit a study for the European League Against Rheumatism (EULAR) 2023. Title: "How to make a virtual presentation using artificial intelligence?". Prepare a summary consisting of background and objectives sections for me." The texts generated by ChatGPT were transferred to another virtual platform to be converted to audio and video. The text in the background and objectives sections in this abstract was voiced by the speaking avatar [2].
Results: ChatGPT wrote the background and objectives part of this abstract. As the authors, we have not made any changes in order to be objective. Thanks to another artificial intelligence, the content in this text was voiced by an avatar and turned into a video (Figure 1).
Conclusion: In the near future, artificial intelligence will be used more effectively in the preparation and presentation of scientific articles. In this way, artificial intelligence will help scientists to use their time more efficiently. Developing technology also offers equal opportunities for scientists with social phobia and visual or speech disabilities.

SECOND YEAR MEDICAL STUDENT FEEDBACK ON LIVE PATIENT ENCOUNTERS AS A SUPPLEMENT TO TEACHING THE SKIN AND RHEUMATOLOGY COURSE

Keywords: Education

E. Littman[1], S. Beg2. [1]*UCF College of Medicine, Internal Medicine, Orlando, United States of America*; [1]*UCF College of Medicine, Internal Medicine, Orlando, United States of America*

Background: Live, interactive patient cases have shown to be a valuable resource in medical education. Although a few studies have shown that using patients as teachers helps students develop clinical reasoning, motivates students to learn, and has important educational benefits, there is little research understanding medical student feedback during these interactive patient cases.[1,2]
Objectives: To evaluate second year medical students' perceptions on interactive patient encounters during the teaching of the skin and rheumatology course (BMS 6635) based on surveys collected from 2016-2022.
Methods: Second year medical students completed a survey on their experience from four to five interactive patient cases at University of Central Florida College of Medicine. The interactive cases, involving patients with diagnoses of systemic lupus erythematosus, psoriatic arthritis, dermatomyositis, scleroderma, and pyoderma gangrenosum. Second year medical students enrolled in BMS 6635 from 2016-2022 were included. Students who did not respond to the survey questions were excluded. Chi Square test was performed on survey responses. Regression analysis was performed on significantly different survey responses.
Results: A total of 700 surveys were completed after the interactive patient encounters. 90% of participants answered that they enjoyed the interactive patient cases with 92% of students agreeing that the interactive patient cases were an appropriate learning experience for their education. 76% of students agreed that the patient encounters helped them retain knowledge of the disease processes. However, only 36% agreed that the number of patients in the interactive patient cases should be increased (Table 1). From 2016 to 2022 there has been a slight decrease in enjoyment in the interactive patient cases over time (97%, 88%, 93%, 94%, 86%, 81%, $p<.001$, respectively per year). From 2016 to 2022, there was a slight decrease in students agreeing that the interactive patient cases were an appropriate learning experience in their education (98%, 92%, 94%, 95%, 93%, 84%, $p=.001$, respectively per year) (Figure 1).

Table 1. Medical student survey responses of agreement to live patient cases comparing those who agree to those who disagree

	Student Responses				
Values	**Agree**		**Disagree**		**Total**
I enjoyed the live patient cases	628	90%	72	10%	700
The live patient cases were an appropriate learning experience at this stage in my education	646	92%	54	8%	700
We should increase the number of patients in the live patient cases	123	36%	219	64%	342
The live patient cases helped me remember the diseases well for the exam	261	76%	81	24%	342

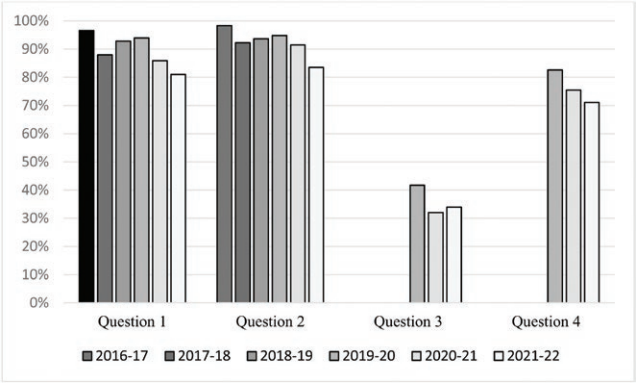

Figure 1. Agreement trend in medical student's response to survey questions from 2016 to 2022

Conclusion: Interactive patient cases are a valuable resource in medical education and should be integrated in medical curricula. Overall, students enjoyed the interactive patient cases, believed they were an appropriate learning addition to their medical education even with a minimal number of cases, and aided in retention of material. However, from 2016 to 2022 a slight decrease in positive feedback regarding this approach was noted, which could be attributed to technological advancements and the increasing use of third-party resources among students. The decrease, while minimal, is an important consideration for academic institutions.

AB1703

EVALUATION OF A TRAINING COURSE ON BREAKING BAD NEWS IN RHEUMATOLOGY

Keywords: Patient information and education, Education

G. Khaldi[1], S. Miladi[1], W. Abdelghaffar[2], A. Fazaa[1], H. Boussaa[1], M. Yasmine[1], K. Ben Abdelghani[1], R. Rafrafi[2], M. A. Laatar[1]. [1]*Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia*; [2]*Hôpital Mongi Slim, Psychiatry, Marsa, Tunisia*

Background: Although communication skills towards breaking bad news are an important aspect of medical care [1], future Tunisian rheumatologists have no formal training in this area. The gaps in communication skills are significant to date in the field of rheumatology.
Objectives: The aim of this study was to evaluate the impact of a training workshop on the disclosure of bad news in rheumatology.
Methods: We conducted a prospective, multicenter, interventional study over a six-month period during the academic year 2021-2022. 31 residents were

recruited on a voluntary basis. Two groups were individualized: The training group A (N=16) and the control group B (N=15). The training session included interactive lectures, video-case studies, role-playing and peer-to-peer discussions. A self-administered survey was used to assess residents' abilities to deliver bad news before and three months after the training.

Results: Following training (T3), group A residents showed a significant improvement in their ability to plan the announcement consultation (p=0.004), prepare the patient for the announcement of bad news (p=0.009), deliver the bad news itself (p=0.003), as well as in their self-assigned skill level (p=0.003). Their post-training ratings were significantly better than those of control group B. However, the training group's progress in handling patients' emotions was not statistically significant (p=0.488), and there was no distinction between the two groups after the training. Although both groups of residents were quite adept at managing their stress, their reactions to the announcement were primarily negative (sorrow and sadness). The inclusion of this training in the rheumatology curriculum received "extremely important" or "important" ratings from all residents (100%). when looking at the determinants of a successful announcement, the year of residency was the only factor that showed a statistically significant association with enhanced theoretical knowledge (p = 0.049).

Conclusion: This study highlighted the improvement of the residents' competencies as well as their self-assigned skill level related to the use of role-play in the acquisition of competencies related to a particular situation such as the announcement of bad news. The training seminar on breaking bad news was beneficial and had a positive impact on the residents' performance. It enabled them to pick up several new abilities.

AB1704 CORRELATION BETWEEN LUNG ULTRASOUND AND HIGH-RESOLUTION CHEST CT IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Ultrasound, Validation

J. Santana Peralta[1], D. Garcia[1], R. A. Alvarez Santana[1], L. Perez Rodriguez[1], T. Polanco Mora[1], L. Concepción Sanchez[1], I. Paulino[1], I. Mercedes[1], E. Rodriguez Bautista[1], T. Valdez[1], A. Feriz[1], R. Muñoz Louis[1]. [1]*Padre Billini, Rheumatology, Santo Domingo Este, Dominican Republic*

Background: Systemic sclerosis (SSc) is a chronic, autoimmune, multisystemic disease characterized by fibrosis and vasculopathy. Mortality in patients with systemic sclerosis who present with interstitial lung disease can be multiplied up to 3 times in comparison with subjects who do not present it. It is estimated that 70-90% of patients with SSc have interstitial lung involvement, mainly of the diffuse type. It has been proposed that high-resolution chest tomography (HRCT) may have a role in the evaluation of interstitial lung disease in patients with autoimmune inflammatory rheumatologic diseases, with involvement of more than 20% of the lung parenchyma being a sign of poor prognosis and increased mortality. Its evaluation is determined by the detection and quantification of B lines.

Objectives: To correlate findings between lung ultrasound and high-resolution chest CT in patients with systemic sclerosis.

Methods: Descriptive, observational, cross-sectional study. Lung ultrasound was performed with a Siemmens Acuson X150 equipment, with 13mHz transducer and CT high-resolution (HRCT) in the rheumatology service of the Hospital Docente Padre Billini between August to November 2021. Inclusion criteria: ≥ 18 years, diagnosis of SSc according to ACR/EULAR 2013 criteria. Exclusion criteria: history of pre-existing lung disease.

Results: Descriptive, observational, cross-sectional study. Lung ultrasound was performed with a Siemmens Acuson X150 equipment, with 13mHz transducer and CT high-resolution (HRCT) in the rheumatology service of the Hospital Docente Padre Billini between August to November 2021. Inclusion criteria: ≥ 18 years, diagnosis of SSc according to ACR/EULAR 2013 criteria. Exclusion criteria: history of pre-existing lung disease.

Conclusion: Our study showed a positive correlation between lung ultrasound findings and HRCT. The most frequent pattern in HRCT was NSIP, while the most frequent ultrasound finding was the.

AB1705 KNOWLEDGE ABOUT CORTICOSTEROID THERAPY AMONG PATIENTS FOLLOWED FOR RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Patient information and education

H. Bara[1], F. Idrissi Zaki[1], F. E. Bennani[1], A. Mougui[1], I. El Bouchti[1]. [1]*University Hospital Mohammed VI Marrakech, Rheumatology, Marrakech, Morocco*

Background: Rheumatoid arthritis is a frequent chronic inflammatory rheumatic disease requiring a global management of the patient and his disease, for this, the evaluation of the level and sources of information among RA patients concerning their treatments is necessary.

Objectives: The objective of our study is to evaluate the level and sources of information regarding corticosteroid therapy among patients with RA.

Methods: This is a prospective cross-sectional study of RA patients undergoing corticosteroid therapy. Data collection was done by means of a questionnaire to which patients responded after informed consent. The patients' level of knowledge about corticosteroid therapy was assessed by 4 criteria: the purpose of the treatment, the methods of taking corticosteroids, the need for good compliance with the treatment and the action to be taken in case of forgetfulness. Good knowledge of the treatment was defined by citing of at least three criteria of the four criteria assessed.

Results: A total of 94 patients were included in this study, 83.2% were women with a mean age of 50.7 years. RA was immunopositive in 73.7% of patients, deforming in 59.6% and active (DAS28>3.2) in 82.1% of the subjects. 76.8 % of the patients were on methotrexate and 14.1% on salazopyrine. All patients were on prednisone-based corticosteroids with an average dose of 10 mg/day and an average duration of 3 years. Concerning the educational level of the patients, 57.6% were illiterate, 35.78% had received primary or secondary education. 61.6% of the patients were of low socioeconomic level. Among our patients, 73.7% were informed about the modalities of taking and weaning the treatment, 5.2% had no information and 69.4% of the patients were informed about the side effects of corticosteroids, 23.2% knew that they can induce osteoporosis, 21.2% were aware of the hyperglycemic effect, 11.1% were informed about the hypertensive effect and 44.4% of the patients linked corticosteroids to weight gain. 76.8% of patients admitted having received therapeutic education about corticosteroid therapy from a doctor, 6.1% from pharmacists, 7.1% from internet research and 3% from relatives. The level of knowledge about corticosteroid therapy was good in 47.5% and was correlated with young age, education level and a medical source of information (p at 0.0001,0.0005 and 0.0002 respectively).

Conclusion: The level of information of the patients included in this study on corticosteroid therapy seems insufficient, hence the need to reinforce therapeutic education in these patients.

AB1706 THE USE OF SELF-MEDICATION BY PATIENTS ADMITTED TO RHEUMATOLOGY

Keywords: Education, Safety

H. Tebaa[1], F. E. Bennani[1], H. Arabi[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed VI Marrakech, Rhumatology, Marrakech, Morocco*

Background: Self-medication is a frequent practice, especially in patients with painful and chronic pathologies. This is favored by the easy access to medication.

Objectives: The objective of this study was to evaluate the different aspects of self-medication among patients admitted in rheumatology departmen.t.

Methods: We realized a monocentric transversal study including 88 patients. The data were collected by a questionnaire including sociodemographic conditions, background pathology, drugs used, and resulting risk attitudes. Data processing was done with SPSS version 2021.

Results: A total of 88 patients were included, 54 women and 34 men. The mean age was 43.1 ± 10.1 years. Rheumatoid arthritis (RA) was found in 39%. Spondyloarthritis (SpA) in 19%, gonarthrosis in 20%, chronic mechanical low back pain in 9%, cervicobrachial neuralgia in 7%, gout in 3%, degenerative shoulder pathology in 5% and mechanical talalgia in 2%. The average duration of the disease was 6 ± 3 years. Self-medication was reported in 63% of patients. Concerning the type of self-medication, 88% of the patients used a treatment not prescribed in the initial prescription, 9% increased the doses of treatments already prescribed and 3% prolonged the duration. The most frequently used self-medication drugs were level 1 analgesics (66.7%), level 2 analgesics (6.1%), general non-steroidal anti-inflammatory drugs (NSAIDs) (39.4%), topical NSAIDs (30.3%), proton pump inhibitors (PPI) (12.1%) and corticosteroids (36%). Risk attitudes were detected in 32% of patients, of whom 6% exceeded 4 g per day of paracetamol, 15% combined 2 systemic NSAIDs, 2% took long-term NSAIDs, and 9% used PPIs for a long time without indication. The use of self-medication was not associated with sex (p = 0.5), level of education (p = 0.6) or professional activity (p = 0.58). Only one significant association was found with the duration of the disease (p 0.025).
Conclusion: Self-medication is practiced by the majority of our patients, motivated by various reasons and concerns the various analgesic drugs. The objective would be to rationalize the easy access to medication, to include therapeutic education in our medical practice in order to avoid the potential risks incurred.

AB1707 FACTORS ASSOCIATED WITH SEDENTARY BEHAVIOR IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASE

Keywords: Non-pharmacological interventions, Education

S. Bahloul[1,2], H. Rkain[1,2], S. Ez-Zaoui[1], F. El Joumani[1], F. Kronbi[1], R. Honsali[1], S. Farih[1], I. Bensaghir[1], C. Nouri[1], T. Latifa[1], H. H. Najia[3], F. Allali[1]. *[1]Hospital Al Ayachi, Rheumatology B, Salé, Morocco*; *[2]Faculty of Medicine and Pharmacy of Rabat, Laboratory of Physiology, Rabat, Morocco*; *[3]International University of Rabat, Health Sciences College, Rabat, Morocco*

Background:
Objectives: To determine factors related to sedentary behavior in patients with a chronic inflammatory rheumatic disease(CIRD).
Methods: We conducted a cross-sectional study of 140 patients (mean age of 47.1 years, 68% females) affected by CIRD (Rheumatoid arthritis 56.4%, ankylosing spondylarthritis 32.1%, psoriatic arthritis 8.6% and juvenile idiopathic arthritis 2.9%). information on patients and disease characteristics were collected. Physical activity was measured objectively using the short version of the IPAQ questionnaire (International Physical Activity Questionnaire) for 7 consecutive days. Activity levels were subdivided into low physical activity and moderate to vigorous physical activity. We analyzed factors associated with sedentary behaviors.
Results: IPAQ Average was 413 (0.760) MET-min/week. The sedentary behavior was noted in 75.2% of patients. Table 1 summarizes factors associated with sedentary behavior in patients with chronic inflammatory rheumatic disease.

Table 1. Analysis of factors associated with sedentary behavior in patients with chronic inflammatory rheumatic disease.

Factors related to sedentary behavior	P
female gender	0,001
Lack of regular physical activity before the disease	0,03
professional inactivity	0.04
Functional disability caused by CIRD	0,01

Conclusion: Sedentary behavior is very prevalent among CIRD patients. Awareness-raising actions on the importance of physical activity in CIRDs should be a priority for women and people with reduced mobility.

AB1708 SOCIAL MEDIA AS A SOURCE OF INFORMATION AMONG MOROCCAN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

Keywords: Education, Inflammatory arthritides

N. El Mansouri[1], F. Z. Taik[1], R. Bensaid[1], H. Fouzia[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. *[1]Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco*; *[2]Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan Al Hoceima, University Hospital Center TangierTetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Little research has been conducted on the use of different type of social media as a source information by Moroccan patients with chronic inflammatory rheumatic diseases and on the evaluation of the quality of this information that give an impact on the quality of life which that still poorly known in our context.
Objectives: The objective of our study is to evaluate the use of different type of social media by our patients and to identify the factors that may be associated with them.
Methods: This is a cross-sectional study that included any patient followed in our rheumatology department for chronic inflammatory rheumatic diseases. Sociodemographic data, comorbidities, chronic inflammatory rheumatic diseases related findings (type, pain assessment, disease activity and treatment) were collected. Patient's beliefs and attitudes regarding the various social media were assessed by a questionnaire. A list of 7 type of social media was provided, for which patients were asked to indicate the type of social media used and their confidence in them, followed by their experience with the usefulness of the sources used. Catastrophizing, trust in physician, and concerns about medicines were assessed by the validated Moroccan versions of the pain catastrophizing scale (PCS), trust in physician scale (TPS), and beliefs about medicines questionnaire (BMQ specific concerns).
Results: we included 189 patients. The average age was 47.49 ±13.7, 75.7% of patients were women, 52.4% had comorbidities, and 49.2% were illiterate. The median duration of the disease was 8 [3-16.75]. Mean pain VAS was 4.77 ±2.76. 37.6% of patients were in remission. 56.1% of the patients declared to look for information related to their chronic inflammatory rheumatic diseases on social media as a source of information. The 3 main sources were: Youtube (30.7%), Google (25.9%) and Facebook (16.9%). 19% have already applied some of this information. Only 20.1% discussed the information they found with their treating physicians and 67.2% would like to have health professionals in their virtual spaces to answer their questions. In univariate and multivariate analysis (Table1), age, education level, comorbidity, and concerns about medication were statistically significantly associated with the use of social media.

Table 1. Univariate and multivariate analysis of social media use in patients with chronic inflammatory rheumatic diseases

	Univariate analysis		Multivariate analysis	
	OR(IC 95%)	p	OR(IC 95%)	p
Gender	0,86 (0,44-0,17)	0,682		
Age	0,93(0,91-0,95)	**0,000**	0,96(0,93-0,99)	**0,028**
Level of education	4,04(2,75-5,91)	**0,000**	3,59(2,39-5,38)	**0,000**
Habitat	0,21(0,05-0,75)	**0,016**	0,25(0,04-1,5)	0,131
Comorbidity	0,58(0,39-0,86)	0,007	0,52(0,29-0,95)	**0,035**
Disease duration in years	1(0,97-1,03)	0,72		
Pain VAS	0,9 (0,81-1,01)	0,076		
Disease activity	0,76(0,6-0,97)	**0,032**	0,99(0,7-1,4)	0,993
PCS	0,98(0,54-1,76)	0,948		
TPS	0,98(0,94-1,02)	0,40		
BMQ-Concerns	1,058(1-1,11)	**0,029**	1,08(1-1,16)	**0,034**

Conclusion: Our study showed that Moroccan patients with chronic inflammatory rheumatic diseases especially are actively seeking information about their disease in social media. Moroccan rheumatologists need to be more involved, especially in virtual spaces, to meet these demands.

AB1709 AWARENESS OF EDUCATIONAL AND RESEARCH OFFERINGS OF EULAR AND EMEUNET AMONG YOUNG RHEUMATOLOGISTS WORKING IN TURKEY

Keywords: Education

M. Oztas[1], G. Ayan[2], E. Bilgin[2], E. C. Bolek[3], U. İlgen[4]. *[1]Istanbul Research and Training Hospital, Rheumatology, Istanbul, Turkey*; *[2]Hacettepe University, Department of Rheumatology, Ankara, Turkey*; *[3]Kars State Hospital, Rheumatology, Kars, Turkey*; *[4]Tatvan State Hospital, Rheumatology, Bitlis, Turkey*

Background: EULAR (European Alliance of Associations for Rheumatology) has various educational and research offerings for physicians working in rheumatology. Emerging EULAR Network (EMEUNET) aims to address educational

needs and promote the research interests of aspiring young academics. A considerable number of young physician work or train in rheumatology in Turkey.
Objectives: To assess the awareness of the educational and research offerings of EULAR and EMEUNET among young rheumatologists working in Turkey.
Methods: We sent an e-mail to rheumatology trainees and consultant rheumatologists below the age of 40 years. We surveyed the general information about the offerings of the EULAR School of Rheumatology and EMEUNET. Data were analyzed descriptively.
Results: The response rate of 61% (116/190) was obtained. A slightly over half of the respondents were female (n=62,53.5%). Most of the respondents (n=75, 65%) were rheumatology fellows in training, and the remaining respondents were consultant rheumatologists. EULAR School of Rheumatology courses and EULAR research webinar series were well known (74% and 59%, respectively) among the participants (Table 1). However, less than half of the respondents who were aware of these events attended to a course or a research webinar previously (37.5% and 43%, respectively). The major obstacles to participation in these events were lack of enough time due to the clinical duties (50%) and language barrier (35%). Only 14% and 25% of the respondents were aware of the EULAR research consultation service and the EULAR scientific grant. 76 (65%) participants were aware of EMEUNET while only 13 (17%) of them were attended an EMEUNET event previously.
Conclusion: Educational offerings of EULAR and EMEUNET were well known by the young rheumatologists in Turkey. However, participation rate was not satisfactory. Majority of the respondents were unaware of the EULAR research offerings. Conducting a survey across Europe could show the main obstacles in a larger scale, thereby it helps to disseminate further offerings among young rheumatologists.

AB1710 LEARNING TO CARE FOR OLDER ADULTS WITH RHEUMATIC DISEASES: A NATIONAL SURVEY TO ASSESS CANADIAN RHEUMATOLOGY RESIDENTS' KNOWLEDGE AND INTEREST IN GERIATRIC-RHEUMATOLOGY

Keywords: Comorbidities, Education, Qualitative research methods

S. M. Cho[1], H. Mcdonald-Blumer[2,3], L. Romanovsky[4,5], A. Bookman[2,6], A. Omar[2,3]. [1]*University of Toronto, Medicine, Toronto, Canada*; [2]*University of Toronto, Rheumatology, Toronto, Canada*; [3]*Mount Sinai Hospital, Rheumatology, Toronto, Canada*; [4]*University of Toronto, Geriatric Medicine, Toronto, Canada*; [5]*Mount Sinai Hospital, Geriatric Medicine, Toronto, Canada*; [6]*University Health Network, Rheumatology, Toronto, Canada*

Background: As the global population ages, the number of older adults with musculoskeletal and rheumatologic disorders is expected to rise.[1] This presents a challenge for rheumatologists, as the evaluation and management of older adults often requires understanding the unique considerations of multi-morbidity, polypharmacy, and geriatric syndromes.[2] Despite this growing need, it is currently unknown if rheumatology trainees receive sufficient education in geriatric-rheumatology during their training.
Objectives: To understand the perspectives and needs of rheumatology residents regarding geriatric-rheumatology education during their training in Canada.
Methods: The study conducted a cross-sectional needs assessment of rheumatology trainees in Canada who were enrolled in a residency or advanced fellowship training program within rheumatology. The survey underwent a pilot phase to ensure user-friendliness prior to its distribution. The survey was distributed to program directors of rheumatology training programs across Canada from December 2022 to January 2023, which was then forwarded to the residents within the respective rheumatology programs. The survey included multiple choice and open-ended questions exploring the residents' demographic data, exposure to geriatric-rheumatology education, knowledge gaps in managing older adults with rheumatic diseases and attitudes towards learning about geriatric-rheumatology. Data was analyzed using descriptive statistics.
Results: Fourteen rheumatology residents participated in the study, with an estimated response rate of 31.1%. Most residents (79%) had not received formal geriatric-rheumatology training during their rheumatology training. Residents (85%) were also unaware of any clinical tools or educational resources to help assess and manage older adults with rheumatic diseases. Most residents (71%) reported that geriatric-rheumatology training would be useful for their future practice and for taking care of older adults. Additionally, 65% of residents felt that formal rheumatology training curriculum should include geriatric-rheumatology contents. Areas where residents reported least confidence were applying the geriatric 5M framework, managing frailty, and providing end-of-life care to older adults with rheumatic diseases. They were most interested in learning how presentations and management of vasculitis, systemic lupus erythematosus and inflammatory arthritis differ in older adults and recognizing the indications of and risks associated with the use of DMARDs and biologics in this age group.
Conclusion: Our research revealed that rheumatology residents do not receive sufficient training in geriatric-rheumatology, indicating the need for a specialized curriculum in this field. Additionally, we discovered specific areas of interest among residents that can inform the development of future training initiatives. Overall, our study emphasizes the significance of incorporating geriatric-rheumatology education into rheumatology training programs.

AB1711 EVALUATION OF KNOWLEDGE AND OBSERVANCE OF PRESCRIBED TREATMENTS FOR HOSPITALIZED PATIENTS IN A RHEUMATOLOGY DEPARTMENT

Keywords: Education, Safety

H. Tebaa[1], H. Arabi[1], A. Mougui[1], I. El Bouchti[1]. [1]*Centre Hospitalo-Universitaire Mohammed VI Marrakech, rhumatology, Marrakech, Morocco*

Background: Patients' knowledge of their treatment is part of therapeutic education programs.
Objectives: We studied this knowledge in patients hospitalized in a rheumatology department and the impact on therapeutic compliance.
Methods: We conducted a monocentric prospective observational study. 104 Patients of the rheumatology department who were major and autonomous with their treatments had to answer a questionnaire in 2 parts: the first part concerned the global knowledge of their medication formalized in 4 criteria (name, indication, dosage, specificity), a global knowledge score on 4 points was elaborated with the 4 previous criteria. The second part evaluated therapeutic compliance with the Morisky test.
Results: 104 patients were included. Women represented 71% and men 29%. The middle socioeconomic statut was found in 33% of cases. Chronic pathologies represented 72%. The most prescribed drug classes were: synthetic conventional drugs or csDMARDs (methotrexate, sulfasalazine) in 51% of cases, corticosteroid therapy in 69%, proton pump inhibitors in 20%, anti-hypertensives in 19%, and anti-arthritis drugs in 13%, non-steroidal anti-inflammatory drugs in 23%, topical treatments in 45%, oral antidiabetics in (17%), insulin in 6%, analgesics level 1 in (60%) and level 2 in (5%), bisphosphonates in (5%), pregabalin in (13%). Patients who had completed a maximum global knowledge score (score = 4) represented 16%. The mean compliance score (measured by Morisky test) was 6.48 ± 1.41. A significant association was found between global

knowledge score and male gender (p=0.001). The compliance score was negatively correlated with age (0.01; rs -0.65) and number of prescription drugs (0.01 rs -0.65) (p 0.014; rs -0.57), and positively correlated with the duration of disease progression (p 0.001; rs 0.87). No relationship was found between knowledge and compliance (p = 0.15).

Conclusion: The utilization of a score could be a method to evaluate knowledge and to adapt the content of educational actions to increase adherence to treatments.

AB1712 THE BELIEFS OF MOROCCAN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES REGARDING MEDICATION AND THEIR IMPACT ON THERAPEUTIC ADHERENCE

Keywords: Self-management, Education, Inflammatory arthritides

N. El Mansouri[1], F. Z. Taik[1], R. Bensaid[1], F. Z. Aharrane[1], N. Soba[2], M. Fourtassi[2], F. E. Abourazzak[1]. [1]*Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco*; [2]*Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan-Al Hoceima, University Hospital Center TangierTetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Adherence is one of the key elements of management in patients with chronic inflammatory rheumatic diseases, and it is likely to be influenced by beliefs about medications, which will influence the management and quality of life of patients.

Objectives: Objective is to assess chronic inflammatory rheumatic diseases patient's beliefs about medications, the factors associated with them, and their impact on therapeutic adherence.

Methods: This was a cross-sectional study that included any patient followed for chronic inflammatory rheumatic diseases. Sociodemographic data, comorbidities, information on inflammatory rheumatism ds (type, pain and activity assessment and and treatments) were collected. Beliefs about medication were assessed by the validated Moroccan version of the Belief on Medicine Questionnaire (BMQ). Catastrophizing, trust in physician and adherence to therapy were assessed by the validated Arabic versions of the pain catastrophizing scale (PCS), trust in physician scale (TPS) and Compliance Questionnaire Rheumatolgy (CQR)

Results: 189 patients were included. The average age was 47.49 ±13.7, 75.7% of the patients were women, 52.4% had comorbidities, 49.2% were illiterate, 56.6% were followed for rheumatoid arthritis, 35.4% for spondyloarthritis and 7.9% for undifferentiated chronic inflammatory rheumatic. The median duration of evolution of chronic inflammatory rheumatic diseases was 8 [3-16.75]. 41.3% of patients were on synthetic DMARDs and 4.2% on biotherapy. The mean VAS pan was 4.77 ± 2.76. 37.6% of patients were in remission. The average CQR was 55.16±8.14 The mean BMQ specific necessity was 20.75±4.77. 67.4% of the patients strongly believed that medication is essential to maintain their health. The mean of the specific BMQ concerns was 14.47±5.8. The main concerns of the patients were the fear of being dependent on the medication they were taking (36.2%) and the potentially harmful consequences of their treatment in the long term (35.5%). The median necessity-concern differential was 6[1-12] suggesting a positive benefit-risk ratio perceived by the patients. In multivariate analysis (Table1), there was a statistically significant association between education level, catastrophizing, trust in the physician. and the necessity-concern differential. There was also a signification correlation between the therapeutic compliance score and the BMQ necessity score and the BMQ differential necessity-concerns.

Table 1. Uni- and multivariate analysis for patient's beliefs about medications

	Univariate analysis		Multivariate analysis	
	OR(IC 95%)	p	OR(IC 95%)	p
Gender	0,74 (-1,55 -3,41)	0,46		
Age	3 (0,04 -0,19)	**0,003**	0,89(-0,05- 0,13)	0,373
Level of education	-2,83 (-2,2 - -0,39)	**0,005**	-2,49(-2,51- -0,28)	**0,04**
Comorbidity	0,05(-1,3 -1,4)	0,96		
Disease duration in years	0,35(-0,09-0,15)	0,725		
VAS pain	0,62(-0,26-0,51)	0,535		
Disease activity	2,22 (0,11 – 1,86)	**0,027**	0,8 (-0,61-1,44)	0,423
Corticotherapy	0,14 (-0,06-4,11)	**0,05**		
Methotrexate	0,22(1,18-5,38)	**0,002**		
bDmards	0,11(-0,88-7,95)	0,117		
PCS	-2,39 (-4,83 - -0,46)	**0,018**	-1,8 (-4,82- 0,14)	**0,03**
TPS	3,768 (0,13 – 0,439)	**0,000**	1,9 (-0,005- 0,33)	**0,05**

Conclusion: Moroccan patients followed for chronic inflammatory rheumatic diseases have a rather positive perception of their medication. This perception seems to influence their adherence to treatment.

AB1713 EVALUATION OF A TRAINING COURSE ON EMOTIONAL MANAGEMENT WHEN BREAKING BAD NEWS IN RHEUMATOLOGY

Keywords: Education, Patient information and education

G. Khaldi[1], S. Miladi[1], W. Abdelghaffar[2], A. Fazaa[1], H. Boussaa[1], M. Yasmine[1], K. Ben Abdelghani[2], R. Rafrafi[2], M. A. Laatar[1]. [1]*Hôpital Mongi Slim, Rheumatology, Marsa, Tunisia*; [2]*Hôpital Mongi Slim, Psychiatry, Marsa, Tunisia*

Background: In recent years, attitudes towards breaking bad news have changed dramatically to emphasize patient autonomy and avoid psychological harm [1]. As a result, learning how to deliver bad news efficiently became a fundamental clinical skill in professional practice. [2]. In the field of rheumatology, with learning focused on technical skills, gaps in communication skills are to date significant.

Objectives: The aim of this study was to evaluate the impact of a training workshop on the disclosure of bad news in rheumatology.

Methods: We conducted a prospective, multicenter, interventional study over a six-month period during the academic year 2021-2022. 31 residents were recruited on a voluntary basis. Two groups were individualized: The training group A (N=16) and the control group B (N=15). The training session included interactive lectures, video-case studies, role-playing and peer-to-peer discussions. A self-administered survey was used to assess residents' abilities to deliver bad news before and three months after the training.

Results: The comparison of the patient emotion management scores between the two groups in the post-training period showed no significant difference (p=0.115). And although there was a slight improvement in the scores in post-training, no significance was found either in the training group (p=0.488) or in the control group (p=0.523).

In terms of managing residents' emotions, most residents in both groups experienced neutral feelings during the periods of silence during the announcement consultation, and there was no discernible difference between the two groups at either time. The percentage of residents in group A who felt negatively during the times of silence significantly decreased by 38% after the training (T3) (p=0.013), while the percentage of residents who felt positively increased by 25% (p=0.033). In Group B, no significant difference was found between the two time periods in terms of feelings during quiet time. Although the basic skills of the residents in dealing with stressful moments were quite good as more than 50% of the residents in both groups were able to maintain their neutrality during these difficult moments, it was shown that the training had a positive impact on the residents' feelings during stressful moments such as the silent moments. At the end of the announcement, most residents in both groups unanimously had negative feelings (desolation and sadness) with no significant difference between the two groups at either time.

Conclusion: Emotional skills training requires a lot of practice and review, which was not possible during our one-day training intervention. However, our training workshop, although short in duration, had partially improved residents' ability to respond to emotional cues.

AB1714 GOUT TREATMENT: ARE TUNISIAN INTERNS FOLLOWING INTERNATIONAL RECOMMENDATIONS?

Keywords: Gout

F. Alia[1], O. Hamdi[1], S. Miladi[1], H. Boussaa[1], M. Yasmine[1], L. Souebni[1], K. Ouenniche[1], S. Chekili[1], S. Kassab[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Gout is a common metabolic disease affecting at least 1% of the population. Its therapeutic management was recently redefined by the recommendations of the French society of rheumatology (SFR) 2020 [1,2].
Objectives: We aimed to determine the level of adherence of Tunisian rheumatology interns to these recommendations.
Methods: We conducted a 26-item online questionnaire via Google Drive Forms destined to rheumatology interns. The questionnaire intended to assess the degree of application of the French recommendations for the treatment of gout.
Results: The online questionnaire was sent to 50 rheumatology interns, 19 of whom (38%) responded. Thirty-one percent of participants were in first year, 15.7% in second year, 16% in third year and 31.5% in fourth year. The mean age was 28.3 ±8.7 years [26-33]. All participants were female. The average number of rheumatology internships performed was 3.9 ±0,2 [1-6]. All of the participants declared informing their patients of their pathology. The information given concerned the disease (94.7%), the aim of treatment (78.9%), the need for long-term adherence to treatment (94.7%), the risk of onset of gout symptoms at initiation of treatment (84.7%) and necessary adaptations to lifestyle (94.7%). Eighteen interns (94.7%) advised their patients to avoid certain foods: soda (84.2%), beer (89.4%), wine (36.8%), red meat (84.2%), fish (63.1%), chicken (26.3%) and seafood (73.6%). Almost all physicians screened for comorbidities (94.7%): hypertension (73.6%), dyslipidemia (78.9%), obesity (63.1%) and renal failure (78.9%). The therapeutic means that can be used in gout flares according to the doctors questioned were the following: non-steroidal anti-inflammatory drugs (NSAIDs) (94.7%), colchicine (100%), corticosteroid therapy (94.7%) and anti-interleukin1 (36.8%). Faced with a gout flare, 17 interns (89.4%) prescribed colchicine within 12 hours after the symptoms' onset. Eleven interns (57.8%) followed the therapeutic regimen recommended by the SFR for flare treatment with colchicine. In the event of the onset of diarrhoea under colchicine, 8 interns (42.1%) stopped the treatment. Regarding corticosteroid therapy, the recommended dose of 30 to 35 mg/day was prescribed in 42.1% of cases. In case of kidney failure, doctors avoided prescribing NSAIDs in 89.4% of cases and colchicine in 63.1% of cases. Eighteen physicians (94.7%) prescribed allopurinol from the first gout flare. Colchicine was prescribed simultaneously with allopurinol in 47.3% of cases. Sixteen interns prescribed colchicine for six months in combination with urate-lowering treatment. Interns were aiming for a therapeutic uricemia target of 50mg/L in 15.7% of cases and 60mg/L in 73.6% of cases. The urate-lowering treatment was maintained for life by 57.8% of the interns, while it was stopped as soon as the therapeutic target was reached in 26.3% with retreatment if recurrence in 21% of the cases. Faced with a decrease in renal clearance, no intern stopped allopurinol and 78.9% of doctors prescribed it subject to monitoring. Once the therapeutic target had been reached, 84.2% of participants recommended monitoring uricemia every 6 to 12 months.
Conclusion: Tunisian rheumatology interns do not fully follow the new French recommendations for the treatment of gout. Thus, medical training on the subject seems necessary in order to optimize the treatment of this pathology in Tunisian hospitals.

AB1715 ASSESSING KNOWLEDGE AND PRACTICES OF MOROCCAN RHEUMATOLOGISTS ON PNEUMOCOCCAL VACCINATION IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES(CIRD)

Keywords: Vaccination/Immunization, Education, Inflammatory arthritides

S. Ez-Zaoui[1], H. Rkain[1,2], F. Kronbi[1], T. Latifa[1], S. Bahloul[1], I. Bensaghir[1], R. Honsali[1], S. Farih[1], F. El Joumani[1], N. Hajjaj-Hassouni[3], F. Allali[1]. [1]*Hospital Al Ayachi, Rheumatology B, Salé, Morocco*; [2]*Faculty of Medicine And Pharmacy of Rabat, Exercise Physiology and Autonomous Nervous System Team, Physiology Laboratory, Rabat, Morocco*; [3]*International University of Rabat, Rheumatology, Rabat, Morocco*

Background:
Objectives: To assess rheumatologists' knowledge and practice about pneumococcal vaccination in patients with CIRD.
Methods: This is a cross-sectional study conducted by the vaccination working group of the Moroccan Society of Rheumatology. The survey collected data on the knowledge and practice of pneumococcal vaccination by rheumatologists.
Results: Out of 350 questionnaires sent, 125 valid responses were received (35%).The mean age of rheumatologists was 42.4+/-12.1 years and the average duration of practicing in rheumatology was 13.1+/-11.1 years. The sector of practice was respectively 31.2 %,34.4 %,34.4 % for the public, private and Univesity Hospital sectors. Knowledge accurency about the nature of vaccine and vaccination protocol was noted in respectively 62.4% and 46.4% of rheumatologists. Figure 1 illustrates situations of pneumococcal vaccine prescription by Moroccan rheumatologists.

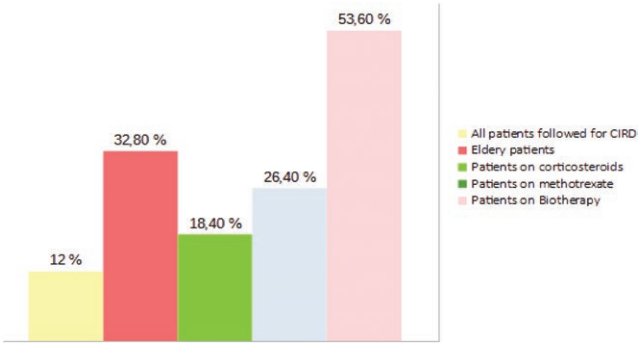

Figure 1. Situations of pneumococcal vaccine prescription by Moroccan rheumatologists.

Regarding Medication management of patients during vaccination, rheumatologists recommended reducing corticosteroid dose, holding methotrexate for 2 weeks after vaccination, postponing corticosteroid bolus and stopping the biotherapy in respectively 5.6, 20.8,16.8 and 20 % of cases. The lack of knowledge about pneumococcal vaccination was associated with rheumatology practice duration (p=0.03) and practice in the public sector (45% p=0.008).

Conclusion: This survey illustrates a lack of pneumococcal vaccinal prescription by Rheumatologists and suggests the necessity to improve rheumatologists' knowledge concerning pneumococcal vaccination.

AB1716 TREATMENT MODALITIES IN ANTI-MDA5 DERMATOMYOSITIS: A CASE SERIES FROM SOUTH INDIA

Keywords: Myositis

D. R. Puligari[1], S. C. Veeravalli[1]. [1]*Krishna Institute of Medical Sciences, Rheumatology, Hyderabad, India*

Background: Anti-MDA 5 antibody – associated DM presents with rapidly progressive interstitial lung disease (RP-ILD), and is known to have poor prognosis. Early detection of ILD,given the risk of rapid deterioration and best treatment guidelines are of extreme importance due to high disease burden and mortality. As we encountered different cases of DM in our OPD at a renowned tertiary care centre in Hyderabad, India, we too had tailor-made diverse treatment regime based on patients' condition and their circumstances, and henceforth we present 10 of such cases wherein the customized treatment plan brought about significant relief in their condition.
Objectives: To study and report 10 cases of Anti -MDA5 ILD and treatment outcomes.
Methods: Among 10 patients newly diagnosed with Anti- MDA5 ILD at our hospital, 5 patients had RP-ILD, out of which 3 suffered with refractory ILD. Among the varied treatments given 2 patients required IVIG and Plasma Exchange was used as an adjunct to standard treatment in 1 refractory ILD patient as salvage therapy. All patients were followed at least for six months post management and 7 patients reported significant improvement with maximum reversal of HRCT findings.

RESULTS:

Pt.	Age/Sex	Symptoms and Signs Common symptoms : Constitutional + Dyspnoea	Laboratory Parameters (Raised levels)	Antibodies Positive	HRCT Chest Findings
1	60/M	Skin darkening and thickening , Mechanic's hands, Healed papular lesions over fingers.	ESR, CEA, Ferritin	Anti-Ro 52, Anti-MDA 5	Ill-defined GGO's Dense sub-pleural consolidation Multifocal traction bronchiectasis Subcutaneous soft tissue emphysema Pneumomediastinum
2	40/M	Non scarring alopecia, Heliotrope rash, Gottron's papules , Erythematous tender palmar papules, Mechanic's hands	CPK, Ferritin	Anti-Sm, Anti -RNP/Sm , Anti-MDA 5	Subpleural GGO's bilaterally with early fibrotic changes.
3	38/M	Constitutional symptoms, Erythematous scaly rash (face, scalp, shoulders), Shawl sign, Gottron's papules.	ESR, SGOT, SGPT, CPK, CRP, Ferritin, D-dimer	ANA IF :1+ (Speckled) Anti-MDA 5	Sub-pleural GGO's and reticulations bilaterally Pneumomediastinum Loss of volume
4	42/M	Polyarthritis , facial skin thickening, Erythematous tender palmar papules, Inverse Gottron's sign.	Ferritin	Anti-Ro 52, Anti-MDA 5	Early ILD changes
5	33/F	Malar rash sparing nasolabial folds, Shawl sign, Polyarthritis, Painful oral ulcers	ESR, CRP		Sub-pleural patchy ground-glass opacities
6	44/M	Skin darkening, Polyarthritis with progressive fixity of both shoulders and knee joints, Alopecia., Ulcers in both axillae with necrotic base.	ESR, CRP, Ferritin	Anti-Mi 2, Anti-MDA 5	Subclinical ILD
7	22/M	Polyarthritis of both wrist joints and ankle joints, Heliotrope rash, facial hyperpigmentation, alopecia, symmetric b/l muscle weakness of upper as well lower limbs.	ESR, CRP, CPK	ANA IF : 4+(Homogenous) Anti-MDA 5	Early ILD changes
8	16/F	Pruritic rashes over the arms, shoulders , upper chest , back , Polyarthritis of both elbows and PIP joints of hands, Painful ulcers over b/l extensor surface of elbows.	ESR, CRP	Anti-MDA 5	Early ILD changes
9	55/F	Erythematous rashes over face , neck , Gottron's papules , ulcers over elbows and fingers, auricular papulo-pustular lesions with necrotic base.	CRP, Ferritin, D-dimer, CEA	Anti-MDA 5	B/L GGO's with mild traction bronchiectasis
10	56/F	Heliotrope rash , Progressive muscle weakness .	ESR, CPK,	ANA IF : 3+ (Cytoplasmic) Anti-SSA, Anti-Ro 52, Anti-SSB, Anti-MDA 5	B/L lower lobe ground glass opacities Traction bronchiectasis Sub-pleural consolidations

7	Oral (later tapered)	Methotrexate	-	-	Anti-tubercular treatment
8	Oral	-	Oral Tofacitinib	-	-
9	Injectable pulse steroids (IV Methyl Prednisolone 500mg x 3days) Followed by Oral 0.5 mg/ kg/bwt.	Inj Cyclophosphamide Tacrolimus Mycophenolate mofetil	-	Nintedanib	IVIG Plasma exchange therapy
10	Oral	Hydroxychloroquine Methotrexate Inj Cyclophosphamide Mycophenolate mofetil Rituximab	-	-	NSAIDs IV Antibiotics IVIG

Figure 2.

Conclusion: Taking into account the clinical features with which patients presented to our OPD as well as our personal experience in managing such troublesome cases, we also had to custom-make the therapeutic regimes and include different therapeutic modalities, so as to not only relieve them of their symptoms but to also ameliorate their quality of life as well as afford them with an early and sustained period of remission.

AB1717-PARE

DERMATOMYOSITIS BURDEN OF DISEASE MANIFESTATIONS AND QOL IMPACT: PATIENT-REPORTED SURVEY RESULTS

Keywords: Patient reported outcomes, Myositis

L. Christopher Stine[1], J. Feldman[2], T. Smith[2], P. Mudd[2], J. Paik[1]. [1]*Johns Hopkins Medicine, Johns Hopkins Myositis Center, Baltimore, United States of America*; [2]*Priovant Therapeutics, Clinical Development, Durham, United States of America*

Background: Dermatomyositis (DM) is a rare, multi-system idiopathic inflammatory myopathy characterized by skin rash and muscle weakness that is often accompanied by pain and fatigue. Other manifestations include interstitial lung disease and calcinosis. Malignancy is also highly associated with DM. The profound negative clinical impacts of DM on patients' quality of life (QoL) are not yet well-characterized in the literature.[1]

Objectives: To capture patient perspectives on the impact of DM on QoL (physical function, mental health, personal relationships, and work productivity), most bothersome symptoms (MBS), and severity of symptom burden in adults.

Methods: A 60-question survey was developed via sponsor-conducted focus groups and adaptions from existing patient-reported outcome (PRO) tools (e.g., WPAI-GH, SLE-FAMILY, and PROMIS). After IRB approval, members of The Myositis Association (~4000 individuals with DM) were invited to complete the online survey (eligibility criteria: 18 – 75 years of age, self-reported DM diagnosis, and current DM symptoms persistent for ≥ 1 year). Responses were collected per the following Likert scales: DM severity rated from "mild" to "very severe" (4-point scale), overall health rated from "poor" to "excellent" (5-point scale), life impact questions rated from "never" to "always" or "not at all" to "a great deal" (5-point scales), and severity of symptoms rated from "never experienced" to "very severe" (6-point scale).

Results: Of 195 respondents (97% from US), the median age was 57 years, 88% female, and 82% White. 53% and 35% had experienced DM symptoms for 3 to 10 years or > 10 years, respectively. 92% were currently receiving medication(s) to manage DM symptoms. The 5 MBS reported were muscle weakness (44%, n = 86), fatigue (43%, n = 84), muscle pain (30%, n = 59), itchy skin (24%, n = 46), and skin rash (19%, n = 37). A majority of respondents indicated DM had at least a "moderate" negative impact on the following domains: ability "to do the things they enjoy" (83%, n = 162), ability to engage in social activities (75%, n = 146), sexual desire and ability to engage in physically intimate relationships (64%, n = 125), relationships outside of family (57%, n = 112), and relationships with family (51%, n = 100). A majority reported negative impacts on mental health (83%, n = 162), defined as having felt "anxious or nervous" or "down, depressed or hopeless" at least "sometimes" due to DM. Almost half reported being "usually" or "always" worried about symptom flares (49%, n = 96) and about their ability to carry out daily activities (42%, n = 82). DM symptom severity was associated with negative impact on overall health. "Fair" or "poor" health was reported by 50% (n = 98) of those experiencing "moderate" DM symptoms, by 85% (n = 27) of those with "severe" symptoms, and by 100% (n = 7) of those with "very severe" symptoms. All with "very severe" DM responded "usually" or "always" to questions about DM limiting their ability to "do the things they enjoy", concern about symptoms "getting worse", and ability to "carry out daily activities." DM symptoms hindered physical functioning, with 63% and 65% of respondents, overall, reporting that DM limited their ability to climb stairs and perform usual daily activities. DM also affected respondents' ability to work; nearly half were unemployed (47%, n = 92) and had to change their employment status due to DM (49%, n = 95), while 24% (n = 47) were receiving disability assistance. Of respondents who were working, 69% (n = 77) reported that DM negatively impacted their career/career choices.

Conclusion: The survey results highlight the marked physical and psychosocial burden of DM in adults and the impact of disease severity on the ability to perform daily activities, mental health, interpersonal relationships, and work productivity. These results underscore the unmet need for new treatment options to ameliorate the progressive and debilitating consequences of DM and further inform PRO-focused research in DM.

Background: Psoriatic arthritis (PsA) is a disease with heterogenous manifestations, which affects personal and professional aspects of patients' lives. Perception of disease state in PsA affects patients significantly. However, studies examining PsA patients' outlook about their disease are scarce and there are no studies from India examining PsA patients' viewpoints about their disease.
Objectives: The main objective of this multi-centric multiple domain survey was to study the PsA patients' perspectives.
Methods: A survey questionnaire with items on PsA patients' demographics, knowledge, awareness and perception of disease, its treatment, physical therapy, quality of life and the care they received was designed. After internal and external validation, a pilot survey was conducted, and survey modified. The final survey was (with translations in local languages) administered by the participating 16 centres across India.
Results: There were 262 respondents with mean age of 45.14±12.89 years (56% male). Forty percent of the patients had first consultation more than a year after the onset of joint pain and in a majority their current diagnosis was made by a rheumatologist. Most of the patients had psoriasis (92%) and arthralgia (78%) for more than one year, however, only 60% respondents took a doctor's opinion for joint symptoms within one year. For two third of the patients', a rheumatologist made the diagnosis of PsA followed by a dermatologist (15%) and general physicians (8%). Over 83% of patients were consulting their rheumatologist once every three months or earlier and were fully compliant with the treatment. Busy schedules and cost of therapy were the most common reasons for non-adherence to therapy (Table 1). Eighty-eight patients (34%) were not fully satisfied with their current treatment. Twenty-one. % of the survey respondents were still unaware of the term PsA and 10% were unaware of their current diagnosis. Over two-third of patients had never seen a physiotherapist and listed lack of time, pain, and lethargy as the main barriers to exercising. PsA had affected social and employment status of about half of the survey patients. Fatigue, busy work schedule, not able to lift weights, not able to travel without pain were elucidated by patients as main reason for this effect. Most of the patients were satisfied with disease information provided by rheumatologist and dermatologists. Eighty five % patients in this survey reported not taking any form of complementary alternative medicine therapy. The unmet needs of patients identified in this survey were better provision of remote or online consultation, reduction in pill load, better patient education on disease and drugs and financial help for biological therapies.
Conclusion: This survey informs that although survey participants are satisfied with care given by rheumatologist and dermatologists, the disease is influencing their quality of life significantly by affecting socialization and occupation.

Table 1. Common themes identified in open ended responses

Themes of open ended questions	Patient Responses
Common side effects with medications	Dyspepsia and nausea after medications (most common), fatigue, hair loss
If you are not taking the medications regularly, what are the reasons for the same?	Busy work schedule and high cost of medications (most common cause), intolerance to medications, fear of injections, high pill load, high cost of medications, lack of proper guidance
What, if any, would you say are the barriers to exercising for you?	Lack of time, pain during exercises, feeling of lethargy/tiredness so not able to do exercises
Has PsA affected your employment status? If yes, in what way?	Not able to lift weights, not able to sit for long time, lack of energy
Has PsA affected your ability to do your regular daily activities (housework, shopping, childcare, socializing) other than work at a job? If yes, in what way?	Can`t travel to socialize, can't socialize due to constant pain, getting tired quickly, need assistance, lethargy, fatigue

AB1719-PARE

MAPPING THE JOURNEY OF PEOPLE WITH RHEUMATIC DISEASES TO DIAGNOSIS IN GREECE

Keywords: Gout, Patient-led research, Real-world evidence

K. Spanidou[1], K. Koutsogianni[1], F. Asimakopoulou[1], E. Repa[1], I. Papadakis[1], M. Chatzigeorgiou[1], P. Pratsidou-Gertsi[1], A. Verikiou[1], M. Chatziioannou[1]. *[1]PanHellenic Federation ReuMAZein, PanHellenic Federation ReuMAzein, Thessaloniki, Greece*

Background: Rheumatic diseases (RD) are chronic mostly autoimmune diseases, multi- dimensionally affecting the musculoskeletal system and possibly other organs. Additionally, they impact the patient and family quality of life in respect to health, work, socialization and future perspectives. Previous data indicate that early diagnosis of inflammatory and other RDs is important in order to improve long-term outcome.
Objectives: To capture the journey of RD Greek patients from disease onset to diagnosis aiming to define gaps regarding the early management and uneventful outcome of these potentially debilitating chronic diseases.
Methods: An online questionnaire survey of patients with several types of RDs was uploaded by the Greek Federation REUMAZEIN, an acronym meaning co-living with an RD. 463 patients - all members of the Federation- responded to the call and were enrolled in the study.
Results: The majority were females (81%), mostly under 60yrs old (73%) and were residents of urban/suburban areas (65%). In respect to education, they were mainly graduate or postgraduate degree holders (56%). The prevailing RDs were RA (178) 38%, SLE (105) 23%, AS (61) 13% and PsA (58) 13%, respectively. The total lag time (mo) was 10.3. In respect to RD kind, it ranged from 5.9 for JIA to 19.7 for AS, respectively. The delay from disease onset to diagnosis was mainly attributed to patient underassessment of symptoms (53%) or ignorance of the proper MD specialist for these conditions (45%). Only a minority of participants (36%), reported that the diagnosis was made by the first specialty they had initially visited. The initial physician's (MD) specialist for all but SLE patients, was an orthopedic surgeon (33-60%), whereas for SLE ones, an internist (32%). The initial MD failed to establish the diagnosis in 64% pts, principally in AS ones (82%). Alternatively, rheumatologists as the primer reached MD, established the diagnosis in 60% of patients. Lag time to first visit in non-Rheumatology specialists and the corresponding diagnosis was 26mo; for AS pts it reached 50.9mo, respectively. The average lag time from symptom appearance to the first MD visit was 21.3mo and from the 1st visit to final diagnosis 72.2 mo. All patients reported as the most important problem until the final diagnosis, the lag time to diagnosis (36%), followed by a misdiagnosis (33%). Interestingly, those who looked for a second assessment pre-diagnosis, reported higher percentage either of delay or misdiagnosis (49%, 44%, respectively). The degree of satisfaction regarding information received by the MD who established the final diagnosis was totally high (3.5/5) and was irrespective of the RD type. At final diagnosis, patients were highly satisfied regarding information received by the MD for their most important problem, too. In respect of satisfaction to final diagnosis by rheumatologists vs. non-rheumatologists, the rates did not significantly differ.
Conclusion: Findings of this study indicate that the initial patient visit with an RD to the proper MD specialty, is highly important. A visit to a trained Specialist for RD as a Rheumatologist, significantly reduces lag time to diagnosis and leads to an early management and optimal prognosis. Most of the patients expressed a high rate of satisfaction at the establishment of final diagnosis in respect to the MD and his/her skill in problem solving. Therefore, informing and educating the public regarding the early recognition of initial symptoms and early guiding to

an experienced MD specialty, would effectively improves the management and co-living with RDs.

AB1720-PARE NEGATIVE ILLNESS BELIEF ASSOCIATED WITH MORE ACTIVE DISEASE ACTIVITY AND POORER FUNCTION IN THAI PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS

Keywords: Spondyloarthritis, Patient reported outcomes, Mental health

P. Chiowchanwisawakit[1]. [1]*Faculty of Medicine, Siriraj Hospital, Mahidol University, Department of Medicine, Bangkok, Thailand*

Background: Regarding the common sense self-regulatory model[1], illness beliefs plays an essential role in both physical and psychological adjustment to illness. There were few studies about the value of illness representations in the outcome of spondyloarthritis[2] and no study in Thailand.

Objectives: To explore the illness perception and their associated factors in AS and PsA patients.

Methods: This was a cross-sectional study. Spondyloarthritis patients visiting at Siriraj Hospital for treatment were recruited between 27 April 2021 and 31 October 2022. They were invited to fill out the Thai version of brief Illness Perception Questionnaire(BIPQ) [total range 0 (no or best)-80(worst)], the medication taking behavior measure for Thai patients(MTB) [range 4(low adherence)-24 (high adherence)], demographic data, Ankylosing Spondylitis Disease Activity Score(ASDAS), and Bath Ankylosing Spondylitis Disease Activity Index(BASFI) were collected. The variables were associated with total BIPQ were computed by linear regression.

Results: A total of 132 patients with 73(55%) male, mean(SD) age of 49(12) years, median(IQR) disease duration of 11(14) years, median ASDAS of 1.7(1.2), median BASFI of 0.9(2.2), median BIPQ of 26(12), and mean MTB of 23.2(1.0) were recruited. The BIPQ was significantly positive associated with ASDAS and BASFI in multivariate analysis. Consequences, timeline, identity, illness concern, and emotional representation were positively associated with ASDAS while identity and emotional representation were positively associated with BASFI (Table 1). Positive emotional representative in BIPQ was associated with higher MTB ($p<0.05$).

Conclusion: The patients with positive illness perception were associated with better function, lower disease activity, and higher medication adherence. The goal of treatment should be inactive or low disease activity and normalized function as soon as possible may lead to positive illness belief and psychological strength, or vice versa. The positive illness belief may maintain the good health outcome. A longitudinal study is needed to support this association.

Table 1. The association of the brief illness perception and disease activity, and function

		Unstandardized B coefficient	
Item	Total	ASDAS[1]	BASFI[2]
1.Consequences	2(3)	0.233#	0.126*
2.Timeline	8(5)	0.071#	0.037*
3. Personal control	5(4)	-0.056	0.008*

AB1721-PARE PATIENT REVIEWERS OF APPLICATIONS FOR RESEARCH FUNDING - A PILOT STUDY

Keywords: Patient-led research

H. Thorseng[1], C. Ziegler[1]. [1]*The Rhematism Association, Politics and Knowledge, Gentofte, Denmark*

Background: Each year the Danish Rheumatism Association supports research in the field of rheumatology with approx. 1.5-2 Million EUR to strengthen the basis for developing better prevention strategies and treatment and thus increase the quality of life for many people.

Since 2014 it has been mandatory for researchers applying for funding from the research committee of The Danish Rheumatism Association to indicated whether and how they involve patient representatives in their research. Our annual measurements show that involvement of patient representatives by researchers receiving a grant from The Danish Rheumatism Association has increased from 14 % in 2015 up to 65 % in 2021. To strengthen the patient involvement in research further The Danish Rheumatism Association would like patients to have a say in the research funding decisions by reviewing applications for research funding to the research committee of the Danish Rheumatism Association.

Objectives: To carry out a pilot study with patients as reviewers of applications for research funding to The Danish Rheumatism Association.

Methods: Three patients, one man and two women, with different RMDs participated in the pilot study and were requested to try to represent all patients with RMDs. The study was carried out from August to December 2022. The Danish Rheumatism Association provided the patients with an online introduction to the work as patient reviewer, they were provided with information material and The Danish Rheumatism Association supported them throughout their time with us. The patients reviewed a summary of 6-26 research funding applications in plain language at home individually. The applications were scored from zero to five, where zero was the lowest score and five the highest. The research committee of The Danish Rheumatism Association was presented the patients mean score of the applications and comments from one or more patients before their meetings and oral on the meetings in September 2022 and December 2022 respectively.

Results: When the research committee met to decide which research should receive funding, they took the patients mean score and comments for each application reviewed into their decision as with other parameters like methodology, research outcome, involvement of patient representatives in the research etc.

Conclusion: The patients in the pilot study represented patients with RMDs. They reviewed the applications for the research committee of The Danish Rheumatism Association based on their experience of being a patient and had a say in research funding decisions. In spring 2023 the pilot study will be evaluated and it is expected that patients with RMDs will be involved in the future research funding decisions in The Danish Rheumatism Associations and maybe in a larger scale than in the pilot study.

AB1722-PARE LINKING PATIENT PERCEIVED TREATMENT GOALS OF PEOPLE WITH RHEUMATOID ARTHRITIS (RA) AND SEVERE LIMITATIONS IN FUNCTION TO THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH (ICF)

Keywords: Patient reported outcomes, Treat to target, Rheumatoid arthritis

M. Teuwen[1], S. Van Weely[1], T. P. M. Vliet Vlieland[1], T. Douw[2], M. Van Wissen[1], A. Den Broeder[3,4], D. Van Schaardenburg[5], W. Peter[1], C. Van den Ende[4,6], M. G. J. Gademan[1,7]. [1]*Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands*; [2]*University of Applied Sciences Leiden, Department of Physiotherapy, Leiden, Netherlands*; [3]*Sint Maartenskliniek, Department of Rheumatology, Ubbergen, Netherlands*; [4]*Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands*; [5]*Center for Rehabilitation and Rheumatology, Reade, Amsterdam, Netherlands*; [6]*Sint Maartenskliniek, Department of Research, Ubbergen, Netherlands*; [7]*Leiden University Medical Center (LUMC), Department of Clinical Epidemiology, Leiden, Netherlands*

Background: There is a lack of knowledge about the nature and frequency of the main limitations in activities and participation experienced by a subgroup of people with rheumatoid arthritis (RA) and severe limitations in physical functioning. More insight is essential to optimize treatment for this subgroup and can be obtained by linking the treatment goals perceived by the patient to the International Classification of Functioning, Disability and Health (ICF) as a frame of reference. Goal setting is widely recognized for tailoring and optimizing treatment, and for this purpose the Patient Specific Complaint (PSC) instrument is recommended in physiotherapy practices in the Netherlands [1]
Objectives: To describe the nature and frequency of limitations in activities and participation of people with RA and severe limitations. Limitations will be derived from the PSC [1] and linked to the ICF and the comprehensive and brief ICF Core Sets for RA.
Methods: Baseline data from a randomized controlled trial on the effect of long-term exercise therapy in people with RA and severe limitations in functioning were used. For each participant, the three most limited activities were identified and prioritized using the PSC. Two researchers independently identified meaningful concepts within each PSC activity and linked them to the most specific ICF category within the "Activities and Participation" component, following standardized ICF linking rules [2]. In case of disagreement, this was discussed with a third researcher until consensus was reached. The frequencies of ICF categories were calculated overall and for PCS activities ranked 1, 2 and 3. Finally, the uniquely identified ICF categories were compared to the content of the comprehensive and brief RA ICF core sets for the component "Activities and Participation".
Results: From 206 RA patients (90.8% female, 58.7 (12.9) years of age, 1.5 (0.5) HAQ-DI score), 618 PSC activities were recorded, including 911 meaningful concepts. These concepts were subsequently linked to 909 ICF categories, with 72 unique ICF codes. Overall, the most prevalent ICF categories were: 1) d4501 walking long distances (n=121; 59%); 2) d4502 walking on different surfaces (n=79; 38%); 3), d451 stairclimbing (n=62; 30%) 4) d4103 changing body position from sitting (n=60; 29%) and 5) d4401 grasping (n=51, 25%). The categories for the ranked PSC activities differed slightly, and manipulating, d4502, often proved limited too (see Table 1). The uniquely identified ICF codes covered 21 of 32 items (66%) of the comprehensive and 4 of 6 items (67%) of the brief ICF core set for RA patients. Performing daily routine, d230 and rewarding work, d850, were limitations included in both core sets that were not identified in this subpopulation. However, stair climbing limitations were prevalent in this population, but are not part of the RA core sets.
Conclusion: The most prevalent limited activities involved walking (long distances, on different surfaces and climbing stairs), changing body position from sitting and hand use (grasping and manipulating). To optimize treatment for this specific subgroup, clinicians should be aware that not all RA core set items are prevalent in practice and that some frequent problems are not included in the core sets.

AB1723-PARE **A CANADIAN PATIENT-DRIVEN SURVEY TO HIGHLIGHT WHICH PREDNISONE-RELATED SIDE EFFECTS MATTER THE MOST**

Keywords: Patient-led research, Vasculitis

G. K. Yardımcı[1], C. Pagnoux[2], J. Stewart[3]. [1]*Mount Sinai Hospital, Department of Rheumatology, University of Toronto, Vasculitis Clinic, Toronto, Canada*; [2]*Mount Sinai Hospital, Vasculitis Clinic, Toronto, Canada*; [3]*CanVasc and Canada Vasculitis Foundation, Rheumatology, Toronto, Canada*

Background: Management of vasculitis has evolved for the last two decades; however, glucocorticoids (GC) remain the cornerstone of the treatment. Although the side effects (SE) of prednisone are well recognized by the clinicians, their importance for vasculitis patients has not been investigated extensively.
Objectives: We conducted a patient centered survey to identify the relative importance of GC-associated SE among patients with vasculitis.
Methods: An online questionnaire surveyed patients registered with the Vasculitis Foundation Canada about their experience and SE of GC. The questionnaire consisted of demographics and diagnosis, 5 questions about GC dose and duration, 21 about specific SE (with a rating of some pre-specified SE), 4 about knowledge and perception about possible alternatives to prednisone.
Results: 97 patients (53 GPA/MPA,44 other vasculitides) completed the survey. The mean age was 56.9 years, and disease duration was 10.6 years. Mean duration of GC use was 62.7±83.7months, and 49.5% of patients were still on GC (daily dose, 8.4±6.2mg). All the patients reported ≥1GC-related SE, with 67.1% of them reporting having had ≥11/19 SE of interest. The SE reported most frequently included mood change in 93 (95.8%) patients, insomnia and weight gain in 91 (93.8%), and body disfiguration in 89 (91.7%) patients (Table 1). Among ranked SEs, acne was ranked with the lowest score, whereas moon face/torso hump had the highest ranking, just above weight gain, insomnia and impaired quality of life (Figure 1). Half of the GPA/MPA patients and one-third of the others have heard about avacopan, and 68% of patients (similarly in both groups) stated they would prefer being the first to take a very new medication, such as avacopan, instead of prednisone.
Conclusion: This patient-driven survey emphasizes the patient experience and perspectives on GC-related SE, with weights given to some SE that may differ from those given by physicians. GC toxicity indexes should reflect this, and alternative treatment options should be developed.

Table 1. Demographics, prednisone dose and duration, and prednisone-related side effects of the patients

	GPA/MPA patients n: 53	Other Vasculitis patients n: 44	P value

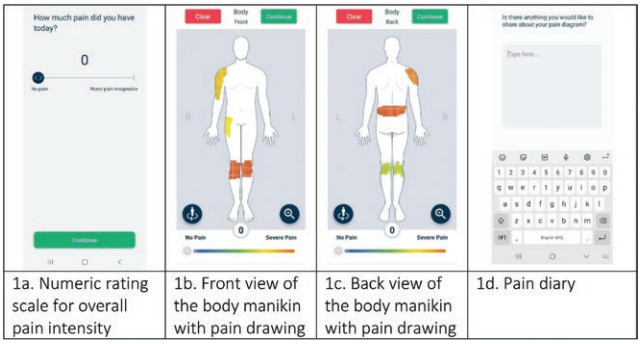
AB1724-PARE



WHAT DO PEOPLE LIVING WITH MUSCULOSKELETAL PAIN CONDITIONS DESCRIBE ABOUT THEIR PAIN? AN EXPLORATORY ANALYSIS OF ELECTRONIC FREE TEXT PAIN DIARIES

Keywords: Qualitative research methods, Self-management, Pain

S. M. Ali[1], R. Santisteban[1], W. Dixon[1], S. Van der Veer[2]. [1]*The University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; [2]*The University of Manchester, Centre for Health Informatics, Manchester, United Kingdom*

Background: People living with musculoskeletal pain conditions prefer pain self-reporting for better pain management [1]. In a recent feasibility study, 104 people living with musculoskeletal pain conditions completed daily pain manikin reports, along with an optional free text pain diary using their own smartphone [2]. People shared their motivation to daily self-report their pain if that could improve their self-management [3]. There is a potential of electronic pain diaries to improve pain management [4], while it is unknown what people would describe in an optional pain diary to improve thier pain managment.
Objectives: The objective was to explore what people have described in their free text electronic pain diaries, which could be useful for improving their pain management.
Methods: In a recent study, we assessed the feasibility of daily pain self-reports for 30 days. A daily pain self-report included a single overall pain intensity question, a two-sided two-dimensional pain diagram, and a free text pain diary (see figure 1). For the latter, people could provide additional information in response to the question: Is there anything you would like to share about your pain diagram? We conducted a secondary thematic content analysis of the free text pain diary entries and identified key domains and ideas described by people. We presented themes descriptively.
Results: Out of 104 people, 94 completed 957 unique pain diary entries. We have presented key domains, ideas and illustrative quotes in the table 1. People described how medication and self-management practices (e.g., heat therpy, physical activity) helped them in managing their pain. They also described different aspects of their pain, including pain descriptors (e.g., pain location, quality, radiation), perceived causes (e.g., physical activity, cold weather) and consequences of pain (e.g., limited mobility, lack of sleep). People perceived some factors, such as medication, and level of physical activity, as both cause and consequence of their pain.
Conclusion: Electronic free text pain diaries provide useful information about people's pain management practices. However, how best to track pain and self-management practices for effective pain management requires research.

AB1725-PARE

SEQUENCE PATIENT SURVEY: PERCEPTION OF THE USE OF ADVANCED THERAPIES FOR PSORIATIC ARTHRITIS IN THE UNITED KINGDOM

Keywords: Psoriatic arthritis, Patient-led research, bDMARD

C. Gollins[1,2], A. Vivekanantham[3], M. Brooke[4], L. Coates[3], W. Tillett[1,2]. [1]*Royal National Hospital For Rheumatic Diseases, Rheumatology, Bath, United Kingdom*; [2]*University of Bath, Department of Life Sciences, Centre for Therapeutic Innovation, Bath, United Kingdom*; [3]*University of Oxford, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*; [4]*Bath Institute For Rheumatic Diseases, British Psoriatic Arthritis Consortium, Bath, United Kingdom*

Background: Due to the chronic nature of psoriatic arthritis (PsA) and the increase in therapeutic options, many people are receiving multiple sequential lines of biologic and targeted synthetic disease modifying anti-rheumatic drugs (b/tsDMARDs). There is limited data on treatment response to advanced lines of therapy and therefore in the rationed UK National Health Service, some regions are limited in the number of sequential b/tsDMARD per patient. Patients have higher levels of treatment satisfaction with biologics compared to conventional DMARDs[1] but little is known about patient satisfaction with access to b/tsDMARDS in the UK.
Objectives: To assess the perceptions of people treated with b/tsDMARDS in the UK for PsA, focusing on the experience of access to advanced treatments.

Methods: The cross-sectional SEQUENCE patient survey was developed as an anonymous online questionnaire on the SurveyMonkey platform, available to be completed by people with self-reported PsA and current or previous b/tsDMARD treatment. The freely available online survey was promoted through PsA support groups via websites and social media. Descriptive analysis of the results was performed, with categorical variables summarised with frequencies and percentages.
Results: 67 people from England, Wales and Scotland responded (male 8, female 59), mean age 54.5 years, mean psoriasis duration 22 years (range 0-55) and PsA 14 years (range 1-50). The number of lines of previous b/tsDMARD treatment per respondent is outlined in Fig 1. The most common first line treatments were adalimumab (33/60) or etanercept (12/60) with secukinumab the most common second line drug (15/42). Switching treatments was most commonly due to primary or secondary failure. 46.7% (28/60) of people felt that a decision to switch treatment had been a joint decision between patient and physician. Only 9% (6/67) had been advised that there was a maximum number of biologics permitted in their region. 24% (16/66) had been advised that a particular b/tsDMARD had to be prescribed first line for PsA in their region, 76% (13/17) of whom reported this was a TNF inhibitor. One respondent had to move hospital or region to obtain access to further biologics. 32% (21/65) had been told that an individual funding request had been applied for to fund their next b/tsDMARD (likely due to limited funded treatment options), and this was successful for 90% (20/23). Qualitative responses highlighted the significant improvement that b/tsDMARDs make to people with PsA e.g. 'They have given me my life back'. However, there was frustration towards perceived delays in access: 'We should not need to suffer cDMARDS and fail, losing months of our lives, to get to a biologic.'
Conclusion: Within this UK PsA population, a minority reported limitations on the class or line of b/tsDMARD available in their region. There was an overall positive response to treatment with biologics, and perception of access generally. However, when patients have difficulty accessing later lines of treatment, it has an adverse effect on their lives. The small proportion of respondents who have had difficulty with access suggests that the overall cost of creating equitable access to b/tsDMARDs in the UK may be relatively low but would have a meaningful impact.

AB1726-PARE

IN WHAT EXTENT DO RHEUMATOLOGISTS DISCUSS PHYSICAL ACTIVITY WITH THEIR PATIENTS AFFECTED BY CHRONIC INFLAMMATORY RHEUMATIC DISEASE AND WHAT ARE THE PATIENTS' EXPECTATIONS?

Keywords: Non-pharmacological interventions, Patient information and education

S. Bahloul[1,2], H. Rkain[1,2], S. Ez-Zaoui[1], F. El Joumani[1], F. Kronbi[1], R. Honsali[1], S. Farih[1], I. Bensaghir[1], C. Nouri[1], T. Latifa[1], H. H. Najia[3], F. Allali[1]. *[1]Hospital Al Ayachi, Rheumatology B, Salé, Morocco*; *[2]Faculty of Medicine And Pharmacy of Rabat, laboratory of physiology, Rabat, Morocco*; *[3]International University of Rabat, Health Sciences College, Rabat, Morocco*

Background:
Objectives: To assess the level of communication about physical activity (PA) between rheumatologists and their patients and to identify patients' needs in this topic.
Methods: This is a cross-sectional study conducted on 140 patients (mean age of 47.1 ± 14.6 years, 68% females) followed for CIRD (Rheumatoid arthritis 56.4%, ankylosing spondylarthritis 32.1%, psoriatic arthritis 8.6% and juvenile idiopathic arthritis 2.9%). Physical activity was measured using the IPAQ-SF (the international physical activity questionnaire - short form). We asked patients if their rheumatologist has ever discussed or encouraged them or even explained how to do adapted physical activity. Patients ' preferences for physical activity practice were collected by specifying if patients preferred to practice it at home or outside, single or in groups. Finally, we also asked them about their needs for both audiovisual support on adapted physical activity and participation in an educational workshop.
Results: The physical activity level was low with a mean IPAQ-SF score of 413 (0,760) MET-min/week. The topic of PA was discussed by rheumatologists with 37.1% of patients. Rheumatologists advised patients to practice adapted PA and show them how to practice it, in respectively 38 and 21.4% of cases. Figure 1 illustrated patients' expectations of PA.

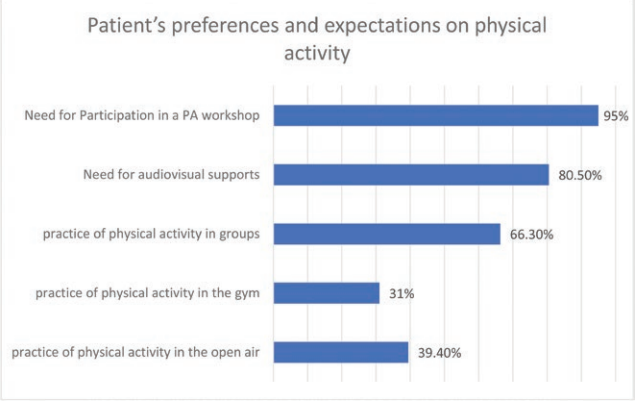

Figure 1. Patient's preferences and expectations on physical activity.

Conclusion: This study shows the lack of rheumatologist-patient communication on PA and the significant need for PA education. Hence there should be greater involvement of rheumatologists in patient education about physical activity to fight against sedentary behavior in CIRD patients.

Psychosocial support

AB1727-PARE OPTIMISM AND PESSIMISM ARE ASSOCIATED WITH SELF-REPORTED DISEASE ACTIVITY AND PSYCHOSOCIAL FACTORS IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Prognostic factors, Patient reported outcomes, Quality of life

H. Mammen[1], S. Salzmann[2], J. Riecke[2], M. Schneider[1], J. Mucke[1]. [1]*University Hospital of Duesseldorf, Rheumatology, Duesseldorf, Germany*; [2]*Philipps-University Marburg, Clinical Psychology, Marburg, Germany*

Background: The primary goal in patients (pts) with rheumatic diseases is to control disease activity, prevent irreversible damage and reduce disease burden. Despite a broad armamentarium of effective treatments in most rheumatic diseases, a substantial number of pts does not achieve disease control.
Objectives: As psychosocial factors and mindset might influence the treatment response of pts with rheumatoid arthritis (RA)[1], the EXPERD (Expectations in Rheumatic Diseases) study aimed to assess these factors and their association with disease activity in pts with various rheumatic diseases.
Methods: For this cross-sectional analysis, pts with diagnoses of RA, systemic lupus erythematosus (SLE), spondyloarthropathy (SpA) and inflammatory vasculitis treated in the outpatient clinic of the university hospital Duesseldorf were included. In all pts the following psychosocial factors were assessed by patient reported questionnaires: health related quality of life (HRQoL) (Short Form-12), depressive symptoms (Patients-Health-Questionnaire-9), anxiety symptoms (Generalized-Anxiety-Disorder-Scale-7), disease duration (in years) and trustworthy relationship with the treating physician (Numeric-Rating-Scale 0-10). Pts´ optimism and pessimism was assessed by the Life-Orientation-Test. Pts´ reported disease activity was captured on a numeric rating scale from 0 (no disease activity) to 10 (high disease activity). Statistical analysis was performed using linear regression models with a significance level of 5%.
Results: A total of 158 pts completed the questionnaires: 51 pts with RA, 32 pts with SLE, 43 pts with SpA and 32 pts with inflammatory vasculitis. Univariate analyses adjusted for sex, age and number of comorbidities found higher pessimism associated with higher disease activity (est. 0.14, CI 0.008-0.27, p 0.04). Further, lower HRQoL was correlated with higher pessimism (physical component (PCS): est. -0.05, CI -0.08 - -0.02, p 0.003; mental component (MCS): est. -0.05, CI -0.09 - -0.01, p 0.02) and lower optimism (PCS: est. 0.04, CI 0.01 – 0.07, p 0.01; MCS: est. 0.05, CI 0.01 – 0.08, p 0.007). Referring to this, pts´ depressive symptoms and pronounced anxiety symptoms manifested the strongest association with lower optimism (depression: est. -0.28, CI -0.34 - -0.22, p <0.001; anxiety: est. -0.36, CI -0.42 - -0.29, p <0.001) and higher pessimism values (depression: est. 0.22, CI 0.14 – 0.3, p <0.001; anxiety: est. 0.26, CI 0.17 – 0.35, p <0.001). In contrast, a longer disease duration and a trustworthy doctor-patient relationship showed primarily lower pessimism values (est. -0.07, CI -0.11 - -0.02, p 0.002; est. -0.26, CI -0.47 - -0.06, p 0.01).
Conclusion: Mindset in terms of optimism and pessimism was associated with several psychosocial factors and self-reported disease activity in pts with rheumatic diseases. While pessimistic pts tended to have higher self-reported disease activity and considered their physicians less trustworthy, optimism was associated with higher HRQoL. Our results emphasize the relevance of encouraging psychological support to improve a pessimistic mindset. A longitudinal analysis of this investigation is currently ongoing.

AB1728-PARE CASE OF PERIODIC FEVER SYNDROME IN PEDIATRIC PATIENT FROM PARENTS' AND DOCTORS' PERSPECTIVES

Keywords: Best practices, Prognostic factors

I. Romankevych[1], N. Torres[2], I. Sanders3, L. King3, P. Garcia Rodriguez[4]. [1]*Jackson Memorial Hospital, Pediatrics, Miami, United States of America*; [2]*Jackson Memorial Hospital, University of Miami Miller School of Medicine, Pediatrics, Miami, United States of America*; [1]*Jackson Memorial Hospital, Pediatrics, Miami, United States of America*; [4]*Jackson Memorial Hospital, Family Medicine, Miami, United States of America*

Background: every patient experiment own disease differently as well as their families. Even modern medicine sometimes can't address all explanation to each clinical question, cover all needs and cure all diseases. Rheumatology is one of medical filed with more question than answer sometimes. And this uncertainty usually is difficult for patient. What if doctor can't answer your question? What if treatment patient is asking for is not the best option or even harmful?
Objectives: show through our case different prospective and expectation between parents and doctors view on pediatric patient medical care based on past family experience, standards of medical care and possible future health outcomes.
Methods: analysis of own experience managing patient with periodic fever syndrome.
Results: L., 3 yo boy, originally from country in South America, with past medical history of periodic fever, myelodysplastic syndrome associated with pathologic polymorphism of gene SRP72 (C1384C>T), multiple café au lait spots and autism spectrum disorder was admitted to our hospital due to fever. Fever episodes occurred since 6-month-old (up to 40C), every 3 months and lasted 5-15 days. The episodes associated with rash, conjunctivitis, arthralgias, reactive lymphadenopathy, oral and duodenal ulcers, Raynaud syndrome and elevation of C-reactive protein level. The initially managed the fever with Prednisone due to concerns for an autoimmune condition or PFAPA. The fever responded to steroid in the early course of disorder but haven't had effect with following episodes. Extensive work up has been done. Autoimmune, immunology, oncology was negative, but genetic testing was positive for pathologic polymorphism of gene SRP72. At 18-months of age, he was diagnosed with neutropenia first time. Family history was significant for periodic fever and lupus-like symptoms in his mother and rheumatoid arthritis in maternal uncle. Tests results were inconclusive for possible reason of his symptoms. So, his parents moved to the USA with hope to find some answers. Next comprehensive evaluation has been performed at National Institute of Health in June 2022 and unfortunately studies were still inconclusive and without a certain diagnosis. Only pending test that might shed light on the cause was full genome sequencing. During admission to our hospital with taking into account results of previous evaluations and clinical symptoms that did not completely coincide with any of the common or rare periodic fever disorders, diagnosis of syndrome of undifferentiated recurrent fever was made. A few possible treatments were discussed. Recommendations were against using prednisolone for treatment. Continue treatment at home country or US after establishing care with local medical house were discussed. Excessive discussions with family took place multiple times. However, parents have continued expressed extreme frustration with requests for definitive diagnosis and appropriate treatment.
Discussion: There is no doubt that parent and medical team have the same goals and try to find answers to the same questions. And there is no doubt that understanding and parents' perspectives are different from medical team ones often. Different previous medical experience, no clear answers make waiting without any treatment extremally hard for family. However, modern medicine is matter of tries and hope sometimes. This bring us as doctors to ethical dilemma: *what can and what should we do?*
Conclusion: it is difficult for parent to make right decision due to numerous biases and expectations. The effort of medical team should be directed to work together with patient family and shared decision making with parents in order to provide the best care to a child.

AB1729-PARE BEING "THE HEALTHY ONE": THE HARD LIVING WITH A SICK BROTHER/SISTER

Keywords: Real-world evidence, Patient information and education, Lifestyles

U. Viora[1], G. Mascarino[1], D. Rava[1], D. Romagnolo[1], M. T. Mascarino[1]. [1]*AMaR Piemonte, Executive committee, Turin, Italy*

Background: In 2019 our project "A paw? Yes, thank you", in which even healthy brothers and sisters of patients with JIA (Juvenile Idiopathic Arthritis) could benefit from playing with dogs and cats and live the same experience, highlighted their (more or less disguised) discomfort. All attention, even by the patients' associations, is focused on the needs of the sick people and nobody take care of brothers, sisters and relatives who feel neglected.
Objectives: AMaR Piemonte (Rheumatic Patients Association of Piedmont) would like to know exactly the unmet needs of these young people to help them to overcome their condition and have the best possible quality of life.
Methods: A Psychologist developed two different questionnaires - one for children (easier and more intuitive) and one for the teenagers - to assess the discomfort and the unmet needs of healthy brothers and sisters living with a sick one. The questionnaires will be administered online on the websites and social media of the association (www.amarpiemonte.org – Facebook: @amarpiemonte – Instagram: amarpiemonte) since February 2023 for 6 months to reach as many contacts as possible. Teenagers will be asked also to share posts, videos, papers, podcast on an dedicated platform, created to preserve their anonymity.
Results: Preliminary results will be available in September 2023 and the final report will be ready in October.
Conclusion: Healthy brothers and sisters are nearly always neglected by their parents, whose attention is mostly focused on the specific needs of their sick sons/daughters. The quality of life of these children and teenagers is poor and they are ashamed to show their discomfort, often ending up feeling negative feelings towards their sick brother/sister and their family. With this survey we expect to have a broad and clear picture of the discomfort and poor quality of life of these people, to design specific projects in order to help their families to overcome this unintentional discrimination and to help them to restrict it and to speak about it with their parents without fear of creating further problems for them.

Arthritis research

AB1730-PARE **CAVIPA, THE SURVEY EXPLORING PATIENTS' QUALITY OF LIFE WITH OSTEOARTHRITIS DESIGNED BY PATIENTS FOR PATIENTS**

Keywords: Quality of life, Quality of care, Osteoarthritis

N. Martínez Fernández[1], J. Verges[2]. [1]*Osteoarthritis Foundation International, R&D, Barcelona, Spain*; [2]*Osteoarthritis Foundation International, President & CEO, Barcelona, Spain*

Background: Osteoarthritis (OA) is the most common chronic joint disease and poses a growing public health problem. In Spain, 7 million people suffer from OA [1], and only hip and knee OA represent an average annual cost of 4,738 million euros for the Spanish Health System. In 2016, more than one hundred thousand hip and knee prostheses were placed in Spain [2]. In the Spanish population, errors in the quality of care and a deterioration in OA patient care have been described from the perspective of health professionals [3]. However, a comprehensive analysis of the OA patients' profile, experience, and needs is still missing.
Objectives: The objective is to determine the perception of the quality of life (QoL) of patients with knee and/or hip OA in Spain, focusing on critical factors associated, such as knowledge of the disease, satisfaction with their treatment plan, diagnosis, symptoms, functional disability, and limitations on daily activities.
Methods: Cross-sectional observational study including data collection through a telephone survey of 200 patients living through the Spanish territory. The survey was prepared by a group of patients, clinical experts, and methodologists and validated by a pilot with 10 patients. The final version, approved by the CEIC of the Hospital la Paz in Madrid, was divided into 8 parts that investigate socio-demographic, diagnostic, therapeutic, assistance, and joint functionality, focusing on patient satisfaction and perception of health and QoL.
Results: Patients reported that pain is the first word that comes into their minds when they think about OA. Although pain contributes to the loss of QoL and health, our results show that pain is a multidimensional affection since comorbidities such as depression and anxiety profoundly influence their QoL. Another factor that negatively affects the perception of QoL is the diagnostic delay, where the mean delay obtained in our results was 3.12 years. Regarding their pharmacological treatment, only half of the patients are satisfied, and only a fifth of the respondents believe it can alleviate their pain. Despite this lack of satisfaction, patients take a very long time to make it known to their doctors since they think their doctor will not listen to them or believe another therapeutic option does not exist. Moreover, only half of the patients received non-pharmacological recommendations from their doctors, of which only 20% received professional support for their implementation. Moreover, they reported the need for more treatments to improve their condition and advocated for more information, empathy, and comprehension since they feel their situation is poorly understood by their family, friends, and healthcare providers.
Conclusion: The Osteoarthritis Foundation International (OAFI) designed and conducted the first Spanish survey on QoL of OA patients: the CAVIPA study, to analyze the perception of QoL by patients. Our results show that OA severely impacts patients' QoL due to associated functional limitations, comorbidities, diagnostic delay, and treatment satisfaction. These results provide a portrait of patients' perceptions of OA to give a baseline to take better quality performance in the future. Also, it was a proof-of-concept study designed to prove the strength and capacity of patients and their organizations to contribute to the scientific community. Empowering patients to have a more active role in their health and engaging them in research are key aspects to ensure the effective implementation of interventions aimed at improving the QoL of patients and, consequentially, the current OA management strategies.

Patient information and education

AB1731-PARE **INFLUENCE OF A MULTICOMPONENT EDUCATIONAL PROGRAM ON PATIENT REPORTED OUTCOMES MEASUREMENTS IN A GROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS**

Keywords: Patient information and education, Rheumatoid arthritis

N. Pinto-Florez[1], Z. Castaño[1], F. Rodriguez[2], G. S. Rodríguez-Vargas[3], J. A. Rubio-Rubio[4], A. Rojas-Villarraga[4], P. Santos-Moreno[3]. [1]*UniversitAR, Expert Patient, Bogotá, Colombia*; [2]*BIOMAB, Patients Education, Bogotá, Colombia*; [3]*BIOMAB, Scientific Direction, Bogotá, Colombia*; [4]*Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: Educational strategies in patients with rheumatoid arthritis (RA) are a fundamental tool for the objective measurement of clinimetry by patients (Patient Reported Outcomes Measurements- PROMs).
Objectives: The objective of this study is to evaluate whether there are differences in the measurement of clinimetry when performed by a medical group (MG) with PROMs in an educational context.
Methods: Cross-sectional study. A group of adult patients with RA who participated in a multicomponent RA education program (EMRA) and another who did not participate in this program (NEMRA) were included. The multicomponent educational program is responsible for educating the patient for self-management and management of their health condition, providing different knowledge regarding the disease, including clinimetry, with a duration of 14 months (divided into three levels, mixed face-to-face and virtual). The group of EMRA and NEMRA patients performed the PROMs, through a form designed in "Google forms". Clinimetry measurements were performed by a medical group, MG (blind to the type of patient group) with a difference of 1 week. Clinical, sociodemographic, and clinimetry variables were included in the RedCap platform. The MDHAQ, RAPID3, PAS, EQ5 and Fatigue scales were evaluated by the MG and the two groups of patients. Univariate and bivariate analysis was performed. A comparison of the medians of the variables evaluated by PROMs and by the MG (Wilcoxon for paired data) was made. The ethics committee approved the study design.

Results: 91 women were included. The median duration of the disease was 10.9 years (12.1). 30.8% had polyautoimmunity. The EMRA group had a higher proportion of education above secondary school (p=0.013). In the EMRA group, there were no significant differences between the clinimetry evaluated by the MG and the PROMs. In the NEMRA group, significant differences were found in 4 of the 6 variables evaluated (Table 1).

*Median (Interquartile range) ** Wilcoxon test for paired samples.PROMs: Patient reported outcomes measurements. C: Clinimetry.EMAR: Multi-component educational program in RA. MG: Medical Group.NEMAR: Non-participation in a multi-component education program in RA

Conclusion: PROMs measurements have a value comparable to the clinimetry performed by the MG in those patients who are under an educational program with emphasis on self-management of their disease. This can be valuable to have an objective measurement by the patient with RA that can be useful at the time of the consultation, save time in its development and facilitate the adoption of therapeutic behaviors. It is suggested that for a good development of PROMs, patients have prior educational training so that these measurements are similar to those performed by the MG.

AB1732-PARE "FLARE, DID YOU SAY FLARE?" FLARES IN SJÖGREN'S DISEASE: THE PATIENT PERSPECTIVE

Keywords: Sjögren syndrome, Outcome measures, Patient information and education

C. Bouillot[1], K. M. Hammitt[2], A. Hjertviksten Lindland[3], M. Oosterbaan[4], M. Pincemin[1], L. Stone[5]. *[1]AFGS, Patient Association, Paris, France*; *[2]Sjögren's Foundation, Patient Association, Reston, United States of America*; *[3]Diagnosegruppe Sjögrens Syndrom, Patient Association, Oslo, Norway*; *[4]Nationale Vereniging Sjögrenpatiënten, Patient Association, Maarssen, Netherlands*; *[5]BSSA, Patient Association, Birmingham, United Kingdom*

Background: "Flare" is a word often used by Sjögren's patients and medical professionals, without any official definition or consensus on what it means. In addition, the heterogeneous nature of Sjögren's symptoms means that the definition of a "flare" will vary greatly from patient to patient. As part of the European Necessity project, www.necessity-h2020.eu, 7 Sjögren's patients from the Patient Advisory Group (PAG) addressed this issue and hereby present our definition of a Sjögren's flare from the patient perspective.

Objectives: To provide a common definition of a flare in Sjögren's despite the heterogeneity and subjectivity of symptoms and provide patients and medical professionals with a mutual, basic understanding of flares.

Methods: The Necessity PAG Members discussed which symptoms should be included in the definition of a flare. Flares are as heterogeneous and variable as the disease, but some symptoms appear more prominent than others. The symptoms selected by the PAG were compared with findings from the 2021 U.S. Sjögren's Foundation survey. The 9 symptoms determined as the most commonly reported by patients were: dryness, fatigue, morning stiffness, global pain (joints, muscles, nerves, headache), forgetfulness and brain fog, depression and anxiety and sleep disorders. It was agreed that these are among the symptoms most likely to worsen the patient's condition from the patient's perspective. Not all of these symptoms are included in the usual assessment indices, such as the ESSDAI* or ESSPRI*. However, the different impairments experienced by patients should be taken into account when defining and assessing a flare. In addition, it is also important to clarify and mention that a flare is not necessarily systemic. It may relate to only one of the symptoms, e.g. the dryness, without necessarily leading to a worsening of the other symptoms.

Results: The PAG agreed on the following definition: "A flare is the temporary and sudden onset of symptoms that become significantly worse before resolving and, on average, last at least 3 days."

Conclusion: The PAG considers agreement on how the term "flare" is used to be important for clinical trials as well as for patients and clinical management. For trials, use of a tool to measure flares as a patient reported outcome (PRO) would add value in gauging the patient experience in a global way and provide another potential index for evaluating treatments. Further discussion and validation is needed, however, as the high variability and subjectivity of symptoms makes establishing such a tool especially difficult. Nevertheless, patients need to be aware of flares so they can identify potential organ damage and obtain the best care possible. A flare assessment tool can allow the patient to be better informed, to better monitor their condition and to facilitate communication with their doctor.

AB1733-PARE SHARED DECISION MAKING ABOUT RMD TREATMENT: WHICH VALUES MATTER TO PEOPLE WITH A MIGRATION BACKGROUND?

Keywords: Outcome measures, Patient reported outcomes, Treat to target

P. Pennings, Msc[1], P. Borsje, Msc[2], B. Maat[3], A. Pasma[4], N. Kammah[5], R. Buijs[6], H. Geerders[5], L. J. Kranenburg - van Koppen[7], M. Beekman Msc[8], G. Willemsen- de Mey Msc[9]. *[1]National Association ReumaZorg Nederland, Coordinator at the Department of Patient Participation and Communication, Nijmegen, Netherlands*; *[2]National Association ReumaZorg Nederland, Patient Expert and Coordinator at the Department of Patient Participation and Communication, Nijmegen, Netherlands*; *[3]National Association ReumaZorg Nederland, Patient Research Partner at the Department of Patient Participation and Communication, Nijmegen, Netherlands*; *[4]Erasmus Medical Centre, Advisor Value Based Healthcare Department of Quality and Patientcare, Rotterdam, Netherlands*; *[5]Erasmus Medical Centre, Rheumatology Nurse at the Department of Rheumatology, Rotterdam, Netherlands*; *[6]Erasmus Medical Centre, Data-Manager at the Department of Rheumatology, Rotterdam, Netherlands*; *[7]Erasmus Medical Centre, Rheumatologist at the Department of Rheumatology, Rotterdam, Netherlands*; *[8]Erasmus Medical Centre, Educational Consultant at the Department of Rheumatology, Rotterdam, Netherlands*; *[9]National Association ReumaZorg Nederland, Chairman Board and CEO, Nijmegen, Netherlands*

Background: In the Netherlands, Shared Decision Making (SDM) between healthcare professionals and patients with a migration background stays behind, when compared to SDM with patients with a Dutch background. This can be due to the fact that patients with a migration background might hold different values when deciding on treatment. Values they find difficult to express. Values that health care professionals find difficult to talk about or understand.[1] Research into the values of inflammatory arthritis patients (IA) with a migration background will help health care professionals to better take these values into account, when deciding together on a best fitting treatment.

Objectives: In the Netherlands:

• Which values are important to people with IA and a 1st or 2nd generation migration background when deciding on the best fitting IA treatment?

• Do these values differ from those of the general Dutch population with IA?

Methods: To get an idea of the values that play a role in the choice of treatment, the National Association ReumaZorg Nederland (RZN) conducted research in 2020 amongst people with IA. It resulted in a list of most important values that was published[2]. People with a migration background were underrepresented in the group of respondents. That is why RZN organized a focus group session in 2021 together with the Erasmus Medical Center (MC) in Rotterdam amongst 6 people with IA and a 1st or 2nd generation migration background. The focus group gave an insight into the values that play an important role, when choosing IA treatment. In order to verify these values within the broader migrant community of people with IA, RZN set out a questionnaire based on outcomes from the focus

group and previous research[2] in June 2022. The questionnaire consisted of 56 values that could be scored on a 6-point Likert scale. Patient research partners of RZN provided feedback on the questionnaire. The approved questionnaire was then translated into Polish, Arabic, Turkish, English and Spanish. After translation, the questionnaire was made available through a unique online link. Adult patients, treated at the Erasmus MC with IA and a migration background, were invited to complete the questionnaire during their visit with their rheumatology nurse. Twenty-four patients completed the questionnaire.

Results: • Values that were scored as (very) important by most respondents focused on the effectiveness of IA treatment (on pain, fatigue, inflammation and on physical functioning). Respondents also placed great importance on clear information about IA treatment. Values with regards to the healthcare professional (someone: who helps to make a decision about treatment, who is involved, who has time and who listens) were also perceived as important. Finally, respondents placed great value on their wish not to depend on other people for their daily activities.

• Values amongst people with IA and a migration background were ranked very similarly to the values amongst people with IA in the general study in 2020[2]. Due to differences in the way values were scored in both studies, no statistical conclusion can be drawn from this.

Conclusion: Values with regard to the effectiveness of treatment and the supporting role of the healthcare professional are experienced as very important by patients with IA and a 1st and 2nd generation migration background. Healthcare providers should be aware of this and adapt their communication, if necessary.

A safe environment is key for the willingness of people with IA and a migration background to participate in research. The question is if this safe environment is possible in a hospital setting.

AB1734-PARE THE JOURNEY TOWARD DISEASE MANAGEMENT: A NATIONAL SURVEY OF GOUT PATIENTS SEEN BY A RHEUMATOLOGIST

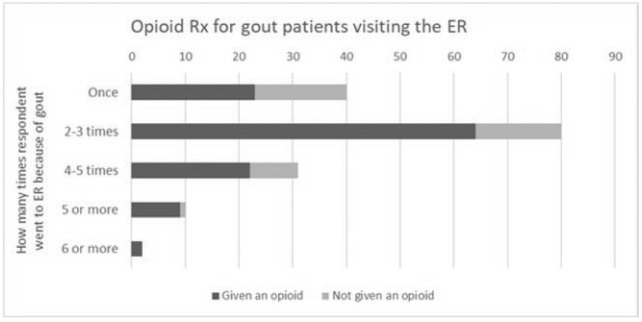
Keywords: Patient information and education, Quality of care, Gout

J. Cooper[1], M. Winokur2, K. Serota2. *[1]Alliance for Patient Access, Alliance for Gout Awareness, Washington, United States of America*; *[1]Alliance for Patient Access, Alliance for Gout Awareness, Washington, United States of America*

Background: The purpose of this survey is to assess the multifaceted impact of gout patients' physical and emotional wellbeing prior to their seeking treatment from a rheumatologist.

Objectives: The objective of the survey is to better understand patients' experience related to obtaining a gout diagnosis and care seeking for their symptoms. This information is helpful in that it can improve rheumatologists' understanding of their patients' experience and provide better patient-centered care.

Methods: An online survey of self-reported, physician-diagnosed individuals with gout was conducted between May and July 2022. The 30-question survey collected responses pertaining to frequency of gout flares, point of care location(s), point of care provider(s), comorbidities, and a 4-point Likert-scale (strongly agree, agree, disagree, strongly disagree) on experiences living with gout. Sociodemographic data was also collected.



Results: At total of 355 self-reported, physician diagnosed individuals participated in the survey; results presented are unweighted. Among respondents, 88% reported a gout flare has negatively impacted their ability to do their job, care for loved ones, participate in activities, remain socially active, and/or enjoy their life (Table 1). Just four in 10 participants saw a rheumatologist within a year of first suffering with symptoms of gout. It took 37% of patients 2-5 years, 13% 6-10 years, and 6% more than 10 years to see a rheumatologist for their gout. Moreover, 56% of respondents reported to have visited multiple health care providers without getting a clear answer about their gout, and 46% saw multiple health care providers without getting an effective treatment plan. Close to half of respondents reported having gone to the emergency department because of a gout flare, and of those, about three-quarters were prescribed an opioid for pain relief (Graph 1). Additionally, 58% reported anxiety, depression or hopelessness because of gout pain. However, after seeing a rheumatologist, 82% reported their gout is getting better, and they are learning how to manage it – even with other co-morbid conditions. A full 84% of respondents reported living with at least one co-morbid condition, the most common being high blood pressure (48%), cardiovascular conditions (30%), diabetes (28%), obesity (27%), kidney disease 20% and kidney stones (19%). The male to female distribution of gout patient respondents is 64% male, 36% female. Most respondents (58%) identified as white, 16% as Black and 15% as Hispanic with the remaining 11% representing other racial/ethnic groups. The mean age was 43, and 42% are employed full-time. Roughly six in 10 are married and 43% have children under the age of 18.

Conclusion: Survey results demonstrate a substantial burden of disease has been placed on those suffering with undiagnosed, misdiagnosed or undertreated gout. The survey results confirm that many of those suffering with gout spend years searching for a diagnosis. Results also elucidate patients' struggle to connect with a health care provider who is knowledgeable about gout and to receive an effective treatment plan for managing their gout. Without appropriate care, patients continue to live with the pain and receive opioids to urgently mask symptoms. As opioids do not actually treat gout, these patients are not receiving appropriate care. This is unfortunate as gout can be successfully managed by working with knowledgeable health care providers and adhering to a plan of care.

Table 1.

Gout flares have impacted my ability to…	Percentage affected
Do my job	41%
Care for my children, spouse, or other family members	30%
Participate in hobbies or community activities	50%
Maintain friendships and stay socially active	28%
Enjoy my life	56%
Other	6%
None of the above	12%

Note: Respondents could select multiple categories.

AB1735-PARE DIETARY PRACTICE AND CHRONIC INFLAMMATORY RHEUMATIC DISEASES. WHAT DO OUR PATIENTS?

Keywords: Diet and Nutrition, Inflammatory arthritides

M. Labrousse[1], C. Alleyrat[2], E. Gervais[1]. *[1]Poitiers University Hospital, Rheumatology, Poitiers, France*; *[2]Poitiers University Hospital, Plateforme Méthodologie Biostatistique Data-Management, Poitiers, France*

Background:

Objectives: Patients show interest in non-drug approaches in particular by the mode of feeding. The objectives of this study are to evaluate the prevalence of dietary changes among patients with.

chronic inflammatory rheumatism, describe their practices and food designs, to compare them between the different subgroups of patients as well as describe the potential impact on care and well-being of the patients.

Methods: Questionnaire survey of patients followed in the Rheumatology department of Poitiers University Hospital, France, for rheumatoid arthritis or spondyloarthritis, including psoriatic arthritis.
Results: Two hundred and three patients were included (112 rheumatoid arthritis, 91 spondyloarthritis, including 25 psoriatic arthritis). They are 45.3% to have been informed of beneficial dietary practices, and 34.5% to have discussed the subject with a professional (13.3% with a rheumatologist). The prevalence of dietary changes is 42.9% (IC95%: [36% - 50%]), and 14.77% of patients were on a diet or taking a dietary supplement at the time of the survey. Diets mainly tested are the reduction in the consumption of dairy products, Seignalet-type diets, fasting, the gluten-free diet and the reduction in meat consumption. For the majority of patients, there was no improvement in pain, fatigue, general condition or reduction in drug intake, except with fasting (n=9) for which a decrease in drug intake was reported at 66.7% (n=7). The discussion on the subject with a health professional is a factor associated with the modification of dietary practices (p=0.001).
Conclusion: Changes in dietary practices concern nearly half of patients, but are only slightly in line with recent recommendations. The information by the physician is often absent and deserves to be improved.

AB1736-PARE CHALLENGES FOR PATIENTS WITH RMD'S IN BULGARIA DURING THE COVID-19 PANDEMIC

Keywords: COVID, Rheumatoid arthritis, Spondyloarthritis

A. Marinkov[1], Z. Batalov[1], R. Karalilova[1], A. Batalov[1], B. Boteva[2]. [1]*Medical University of Plovdiv, Department of Internal Medicine, Plovdiv, Bulgaria*; [2]*Bulgarian Organization for People with Rheumatic Diseases, Bulgarian Organization for People with Rheumatic Diseases, Sofia, Bulgaria*

Background: The Covid-19 pandemic has put patients with rheumatic diseases in front of a number of obstacles that had to be solved together with Bulgarian rheumatologists. The lockdowns and restrictive measures have made it difficult for people with rheumatic diseases to have access to timely hospital and pre-hospital care. A number of digital solutions have been implemented to address these issues.
Objectives: To highlight the problems that patients with rheumatic diseases had during the Covid-19 pandemic; access to rheumatologists and the effectiveness of hospital and pre-hospital care during the pandemic, access to treatment, changes of treatment; communication between physicians and patients, the impact of the pandemic on work, social contacts, hobbies.
Methods: An anonymous survey was conducted online and by telephone. The survey was developed by Medical university, Plovdiv, University hospital "Kaspela":, Plovdiv, Bulgarian Association for Musculoskeletal Ultrasound, Bulgarian organization for people with rheumatic diseases; Association for patients with autoimmune diseases. Number of participants: 1205 patients with RMD's. Age range: 18-82
Results: Face to face meetings with doctors have been limited during the pandemic. Visits to the rheumatologist's office are significantly reduced and phone, email, text messaging, online consultations were preferred as communication channels. Before the pandemic, 76% of respondents most often communicated with their physicians by visiting their practice, during the pandemic their relative share decreased to 46%, with a significant difference of 30% Phone consultations: patients using this type of communication increasing from 38% before the pandemic to 56% during the pandemic, a significant difference of 18% The percentage of patients who communicated via text or email rises from 10% to 17 %. It has become apparent that Digital transformation is needed and patients and physicians should work together to achieve it and to be established in Bulgaria. 245 patients reported a change in their treatment. Of these: (30%) reduced the dose of their medications, 119 (49%) increased the dose and the remaining 55 (21%) stopped their therapy. From the responses of the respondents, it is clear that 71% have not experienced a change in their work during the COVID-19 pandemic, 17% have worked from home. From the responses of the respondents, it is clear that 71% have not experienced a change in their work during the COVID-19 pandemic, 17% have worked from home, 4% have been fired, 3% have left their jobs due to the risk of their health and 5% left their jobs for other reasons.
Conclusion: The Covid-19 pandemic has shown that the digital transformation in rheumatology care can be an efficient alternative to some of the services offered to patients with rheumatic diseases in Bulgaria (especially secondary examinations and therapy monitoring examinations). The results of the conducted survey could be used to support digitization in healthcare in Bulgaria. Very important was the collaboration between the patient organizations and the Bulgarian Association for Musculoskeletal Ultrasound, Medical University, Plovdiv and the rheumatologists from University hospital "Kaspela" Plovdiv.

AB1737-PARE IN WHAT EXTENT DO RHEUMATOLOGISTS DISCUSS PHYSICAL ACTIVITY (PA) WITH THEIR PATIENTS AFFECTED BY KNEE OSTEOARTHRITIS AND WHAT ARE THE PATIENTS' EXPECTATIONS?

Keywords: Patient information and education

S. Ez-Zaoui[1], H. Rkain[1,2], S. Bahloul[1], T. Latifa[1], F. El Joumani[1], I. Bensaghir[1], R. Honsali[1], S. Farih[1], F. Kronbi[1], N. Hajjaj-Hassouni[3], F. Allali[1]. [1]*Hospital Al Ayachi, Rheumatology B, Salé, Morocco*; [2]*Faculty of Medicine And Pharmacy of Rabat, Exercise Physiology and Autonomous Nervous System Team, Physiology Laboratory, Rabat, Morocco*; [3]*International University of Rabat, Rheumatology, Rabat, Morocco*

Background:
Objectives: To Assess the level of communication between patient and rheumatologist and to identify patients' expectations and needs in terms of PA.
Methods: This is a cross-sectional study conducted on 130 Knee osteoarthritis patients. Physical activity was measured using the IPAQ-SF (the international physical activity questionnaire - short form). We asked patients if their rheumatologist has ever discussed or encouraged them or even explained how to do adapted PA. Patients' preferences for PA practice were collected by specifying if patients preferred to practice it at home or outside, single or in groups. Finally, we also asked them about their needs for both audiovisual supports on adapted physical activity and participation in educational workshop.
Results: The mean age of the patients included was 59.9+/-10 years with 110 (84.6%) females. The PA level was low with a mean IPAQ-SF score of 130 (0.500) MET.Min/week. The topic of PA was discussed by rheumatologists with 49.2% of patients. Rheumatologists advised patients to practice adapted PA and show them how to practise it, in respectively 40 and 39.8% of cases. Figure 1 illustrated patients' expectations on PA.

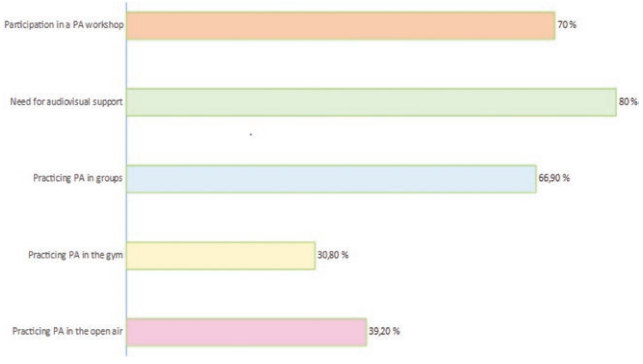

Figure 1. Patients' preferences and expectations on physical activity.

Conclusion: This study shows a lack of rheumatologist-patient communication on PA and a significant need for PA education. Hence there shoud be greater involvement of rheumatologists in patient education about physical activity to fight against sedentary behavior in Knee Osteoarthritis patients.

AB1738-PARE RELATIONSHIP BETWEEN DEPRESSION, ANXIETY, AND STIGMATIZATION IN RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Mental health, Cognitive Function

L. Rouached[1], E. Hannech[1], S. Bouden[1], A. Ben Tekaya[1], I. Mahmoud[1], R. Tekaya[1], O. Saidane[1], L. Abdelmoula[1]. *[1]Charles Nicolle Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Depression and anxiety are common comorbidities associated with rheumatoid arthritis (RA). Despite their impact on patients' quality of life, their detection is often neglected.

Objectives: We aimed to assess the anxiety state in patients with RA and to search for associated factors.

Methods: We conducted a cross-sectional study that included patients followed for RA. Patient and disease data were recorded. Patients completed the Hospital Anxiety and Depression Scale (HAD) [1] and the Stigma Scale for Chronic Illnesses-Short Form (SSCI-8) [2] during their day hospital visit or consultation. Disease activity by DAS28-CRP and functional impairment by the HAQ score were calculated.

Results: There were 100 patients. They were mostly women (81%) with a mean age of 55.33±10.08 years [25-76]. Concerning professional status, 61.8% were unemployed, 26.5% were employed, and 11.6% were retired. The mean disease duration was 14.21±10.10 years [1-46]. The mean DAS28-CRP was 3.81±1.56 [0.12-6.90]. The mean HAQ score was 0.91±0.64 [0-2.4]. The mean anxiety score was 7.6±3.2 [1-15]. A definite anxiety state was noted in 21% of patients. The mean depression score was 10.1±3.1 [3-16]. A definite depressive state was noted in 56% of patients. The mean SSCI-8 score was 17.85±6.02 [8-32]. None of the parameters related to the patient, disease activity and functional impairment were correlated with anxiety and depression. The presence of anxiety was influenced by the number of swollen joints (p=0.037). The stigma score was statistically significantly greater in the presence of depression (19.3±6.2 vs 16±5.2, p=0.006). It was also correlated with disease activity (p=0.034, r=0.244). There was no association between stigma scale/HAQ (p=0.754) and stigma scale/anxiety (p=0.137).

Conclusion: According to the results of our study, depression was frequently present in patients followed for RA (56%). Moreover, the stigma is finely related to this comorbidity. This encourages the systematic psychological management of chronic pathologies such as RA.

AB1739-PARE COVID-19 PANDEMIC: THE IMPACT ON PSORIATIC DISEASE PATIENTS' LIFE

Keywords: Real-world evidence, COVID, Psoriatic arthritis

U. Viora[1], G. Mascarino[1], D. Rava[1], D. Romagnolo[1], M. T. Mascarino[1]. *[1]AMaR Piemonte, Executive Committee, Turin, Italy*

Background: In last years, "psoriatic disease" identifies a complex pathology, characterized by the involvement not only of the joints but also of other organs and systems such as skin, eyes, bowl, cardiovascular system. About 30% of patients with psoriasis may manifest involvement of the musculoskeletal system, involving joints in its various anatomical components and enthesis. Psoriatic arthritis and psoriasis have certainly been – during the pandemic - among the most neglected pathologies from the care perspective.

Objectives: AMaR Piemonte (Rheumatic Patients Association of Piedmont) and ANAP (National Association "Friends for the skin") due to the number of phone calls received during the first stages of pandemic and interacting with rheumatologists, dermatologists and psychologists made a specific survey to assess the impact of the pandemic both on people suffering from psoriatic disease and by their caregivers. In this abstract we focus our attention to the "caregivers world".

Methods: A specific questionnaire for caregivers, developed by a dermatologist and a psychologist and aimed to assess the experience during the pandemic (feelings, changes in care, interpersonal relationships, possible recourse to the intake of "comfort goods" such as smoking, alcohol, food, substances, etc.) was administered in parallel with that for patients online on the websites and social media of the two associations from mid-October to mid-December 2020 and from mid-January to mid-March 2021.

Results: 251 were the complete answers, mainly (84%) provided women who cared for family members (75%) suffering from Psoriatic Arthritis (37%). The average age was 46 years and people reported dealing with people with moderate (46%) or severe (41%) disease, whose symptoms worsened in 69% Impotence, anxiety, stress, sadness and frustration are the emotions most often reported by the caregiver who, moreover, believes they are also experienced by the assisted person. The assistance is worsened in 59% of cases, especially due to the inability to contact the doctor (16%) and undergo examinations/ checks (35%).

Conclusion: The COVID-19 pandemic has deeply changed the life of caregivers, mainly women of working age and patient's relatives or partners. Caregivers and patients, however, developed a full agreement, manifesting the same emotions and resorting to refuge substances in overlapping percentages. The need not to suffer interruptions or changes in care by the attending physician is felt with greater intensity by caregivers, perhaps due to they have no specific preparation to assist their loved ones.

AB1741-PARE THE IMPACT OF THE DISEASE'S ANNOUNCEMENT ON RHEUMATOID ARTHRITIS PATIENTS

Keywords: Rheumatoid arthritis, Patient information and education

E. Rabhi[1,2], K. Maatallah[1,2], H. Ferjani[1,2], D. Ben Nessib[1,2], D. Kaffel[1,2], W. Hamdi[1,2]. *[1]Kassab Orthopedics Institute, Rheumatology Department, Ksar Said, Tunisia*; *[2]Faculty of Medicine of Tunis, Manar, Tunisia*

Background: Rheumatoid arthritis is a chronic disease that can cause irreversible joint damage and significant disability [1]. The announcement of this diagnosis remains one of the most unpleasant moments in the medical practice for both patients and caregivers. For the physician, whose primary mission is to provide relief, knowing that it may cause psychological distress is a challenging task.

Objectives: We aimed to study the impact of the disease's announcement on rheumatoid arthritis patients.

Methods: We conducted a cross-sectional study including patients fulfilling the American Congress Of Rheumatology/ European League Against Rheumatism (ACR EULAR) 2010 criteria. We collected epidemiological, clinical, biological (C-reactive protein: CRP, erythrocyte sedimentation rate (ESR), immunological status (rheumatoid factor RF and anti-citrullinated protein/peptide antibody ACPA), disease activity index (The Disease Activity Score 28 DAS 28). Patient's experience during the announcement of diagnosis was assessed using a questionnaire.

Results: Thirty patients were enrolled. There were 25 women and five men. The mean age was 67.10 ± [29-75]. The mean duration of the disease was 10.41 ± [2.5-38] years. The mean DAS 28 VS was 4.5 ± [1.36-6.27]. Among 30 patients, 66.67 % received the news with anxiety, particularly because of the chronic nature of the disease and possible multi-organ involvement. Nine patients were reassured and felt less anxious for having understood the cause of their pain. Seventy patients (56.67 %) found that the doctor was empathetic and tried to explain the therapeutic alternatives reducing their stress. However, 30% of patients (n=9) found the announcement shocking and would have preferred a gradual approach.

Conclusion: Our study showed stress and anxiety are common feelings for most patients, highlighting the importance of a patient-centered approach to improve initial acceptability of. their disease.

AB1742-PARE **HEALTH INFORMATION UTILIZATION IN RHEUMATOID AND PSORIATIC ARTHRITIS**

Keywords: Patient information and education, Psoriatic arthritis, Rheumatoid arthritis

E. Duffey[1], N. Bhanusali[1], K. Camargo Macias[1], S. Beg[1], S. Chalise[1].
[1]*University of Central Florida, College of Medicine, Orlando, United States of America*

Background: Technology has facilitated widespread general access to health information publicly. However not all health information available for consumption is accurate, reliable, updated, and of equal value to people seeking to be informed advocates of their own health. This cross-sectional study sought to establish the preferred resources patients with rheumatologic conditions seek out for health information. This study provides recent evidence to inform patient education, open dialogue, with the hope to improve clinical practice and patient outcomes.
Objectives: To describe utilization of health information preferences to inform physician-patient shared decision-making and best clinical practice.
Methods: From December 2019 to March 2020, 236 Rheumatoid Arthritis (RA) and 43 Psoriatic Arthritis (PsA) patients receiving care at an academic rheumatology practice in the USA were enrolled in this study. Subjects were provided with a brief, voluntary, and anonymous Qualtrics survey which gathered data on health information utilization, willingness to discuss information gathered with physicians, and desire for resources to be provided.
Results: Modern technology has provided multiple ways for patients to gather additional health information of variable accuracy. This information impacts patient willingness to adhere to clinical recommendations. These data show that patients seek open and honest discussion of health information gathered from other sources. A substantial percentage of patients also desire guidance towards reliable online health resources from their physicians.
Conclusion: Modern technology has provided multiple ways for patients to gather additional health information of variable accuracy. This information impacts patient willingness to adhere to clinical recommendations. These data show that patients seek open and honest discussion of health information gathered from other sources. AB1743-PARE **PUBLIC INTEREST IN LUPUS IN AFRICA**

Keywords: Systemic lupus erythematosus, Patient information and education

A. Guiga[1], M. Ansar[1], A. Amara[2], Y. Boussoukaya[1], B. Y. Wissal[1], A. Atig[1], N. Ghannouchi[1]. [1]*Faculty of Medicine of Sousse - University of Sousse, Internal Medicine, Sousse, Tunisia*; [2]*Faculty of Medicine of Sousse - University of Sousse, Family and Community Medicine-LR12ES03, Sousse, Tunisia*

Background: Accessibility to internet has allowed people to have a better knowledge of Systemic lupus erythematosus (SLE), however, this interest in doing research is influenced by several factors, including socio-economic conditions. Google Trends (GT) is the most popular tool for examining online behavior because it provides information regarding trends and changes in online interest at certain times during a particular period.
Objectives: The aim of this study was to use the Google Trends data to evaluate the public interest in Systemic lupus erythematosus (SLE) in different African countries and to assess people's interest in Africa comparing to worldwide.
Methods: Google Trends provides the relative interest of Google Searches (RSV), on a range of 0–100. We analysed a large amount of data generated by Google Trends concerning the search of the word 'lupus' in a 7-year web-based research (2016-2022) in Africans' countries. Student's t-test was used to compare means. Analyses were performed with SPSS 21.0. P values less than 0.05 were considered statistically significant.
Results: Googling "lupus" was variable depending on the country. The mean annually research volume (RSV) in Africain countries was 18.20±3.92. Annual RSV was more important in Morocco50.89±16.52, Algeria 49.19±23.84. There was a significant difference in the mean annually research volume between African countries and all over the word (versus 50.86± 14.58, p<10-3). (Figure1)

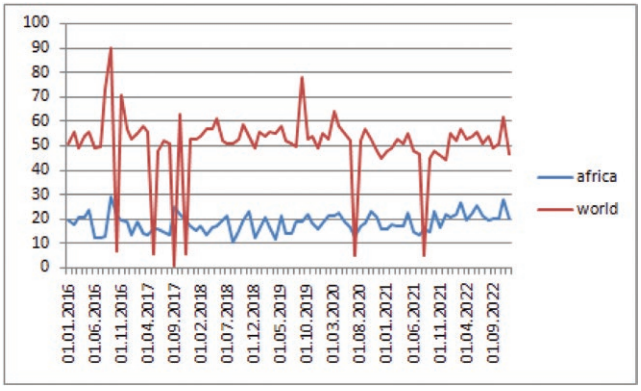

Figure 1. Search volume of lupus variation in African Countries Versus all over the world s from 01.01.2016 to 01.09.2022

Conclusion: Google Trends allows us to find useful information about SLE on the internet. However lack of internet coverage, low socio-economic level and low education level can explain this difference between African countries and the rest of the world.

AB1744-PARE **TREATMENT ADHERENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) DURING THE COVID-19 PANDEMIC**

Keywords: COVID, Rheumatoid arthritis, Patient reported outcomes

L. L. Holguín Arias[1], V. V. Castro Coello[1], C. Soliz[1], G. Gómez[1], L. Sorrentino[1], A. Hamaui[1], D. Dubinsky[1]. [1]*Sanatorio Güemes, Rheumatology, Buenos Aires, Argentina*

Background: During the last 2 years, the SAR COV2 pandemic has impacted the lifestyle, health care, physical and psychological health status of people with rheumatic diseases. In the REUMAVID study, almost half of the respondents stated that their state of health had worsened during the pandemic[1]. It's known that aspects such as fear, job loss, social isolation, uncertainty about their treatments, worsening of symptoms due to the interruption of treatment and hospital visits, increased his fatigue and pain[2]. Treatment adherence estimates in patients with RA are usually low (Between 30 and 80%)[3]. Adherence lack has been associated with worsening symptoms and increased disability[4].

Objectives: The aim of this work is to evaluate SARS COV2 pandemic impact on the adherence perception in a cohort of patients with RA and their clinical associations.

Methods: Descriptive cross-sectional study; included patients ≥18 years old with RA (ACR/EULAR 2010 criteria), between June 1 and July 31, 2022 who gave their written consent to perform the questionnaire. Data sociodemographic, socioeconomic level (Graffar modified), clinical, laboratory, treatments, previous COVID-19 infection and vaccination status were consigned. Activity was evaluated by DAS28-PCR and functional ability with HAQ-II. Questions about the perception of the impact of the pandemic on adherence, follow-up, health status deterioration or fear of continuing treatment were included. They were measured by a visual analogue scale, with 0 being no impact and 10 being the maximum. These answers were compared with adherence measured by the Compliance Questionnaire for Rheumatology (CQR5).

Results: Sixty nine outpatients with RA were included. 45 patients (65%) did not perceive adherence changes during the pandemic while 24 (35%) perceive some degree of adherence disturbances. Sociodemographic characteristics are detailed in Table 1. Having an independent laboral status and the modification or suspension of work activity was statistically associated with the perception of impaired adherence (p=0.04 and 0.01 respectively). Patients with a perception of impaired adherence had significantly higher means in the VAS of affected follow-up, deterioration in their health status, and fear of infection (p= <0.001, <0.001 and 0.04 respectively). DAS28-PCR, HAQ-II, ERS and CRP were also significantly higher in this group (p= 0.002, 0.005, 0.01 and 0.04 respectively). No association was found between the perception of adherence disturbance and adherence measured by CQR5 (p= 0.20).

Conclusion: The SARS COV2 pandemic has a great impact on adherence, rheumatological follow-up and quality of life of patients with RA. Although the perception of adherence disturbance during the pandemic period is a subjective parameter, we found a significant association between this perception and higher rates of suspension or modification of work activity, greater disease activity, functional impairment, and higher acute phase reactants. Studies with a larger number of patients are needed to corroborate these findings.

AB1745-PARE **ROLE OF DIET IN INFLUENCING RHEUMATIC DISEASE ACTIVITY: A TUNISIAN PATIENTS SURVEY**

Keywords: Spondyloarthritis, Diet and Nutrition, Rheumatoid arthritis

S. Rekik[1], S. Nouicer[1], S. Rahmouni[1], K. Zouaoui[1], S. Boussaid[1], H. Sahli[1], M. Elleuch[1]. [1]*Rabta, Rheumatology, Tunis, Tunisia*

Background: The possible influence of diet on rheumatic disease (RD) is a controversial issue. However, rheumatic patients often ask for specific diet because they experience change in joint symptoms after taken some food. Few studies have been conducted regarding patients' perceptions of the influence of diet and fasting on their RD. None of such studies have been conducted so far in countries.
Objectives: The main purpose of this study is to survey patients regarding diet and RD symptoms.
Methods: This is a survey based on a questionnaire that included patients followed for rheumatoid arthritis (RA) (ACR/EULAR 2010 criteria) and spondyloarthritis (SA) (ASAS 2009 criteria), in remission or low disease activity, who presented to the rheumatology department. We didn't include patients with inflammatory bowel or malabsoption diseases or current smokers. Socio-demographic data, co-morbidities, and data of RD (disease duration, disease activity (Disease Activity Score (DAS28) and Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) and medication (Disease-modifying antirheumatic drugs (DMARDs)) were recorded. The questionnaire consisted of 7 major questions with variety of sub-questions. Patients were asked whether they believe diet had a major role on the RD onset, if they have experienced aggravation or improvement of their symptoms with food intake, and if the answer was yes, then they were asked to name the food item. The patients were also asked if they have changed their dietary habits since the diagnosis of RD, if they believe that healthy dietary habit may improve their disease, and if fasting relieve their disease.
Results: We enrolled 39 RA (34 female) and 22 SA (2 female) patients with respective mean age of 52.74±11.31 years and 54.54±11.2 years. Among patients with RA, 53.8% and 22.7% had primary school level, 45.5% of SA patients had secondary educational level. Half of RA and SA patients had comorbidities: 56.4% and 54.5% respectively. The mean disease duration was 8.68±6.6 years and 14.77±9.1 in RA and SA respectively. Half of patients (53%) with RA had obesity and overweight and 40.9 % of SA. The mean DAS28 was 2.06±0.71 and the mean ASDAS-CRP was 1.28±0.41. The majority of RA patients were on conventional synthetic DMARDs (82.1%) and SA patients on biologic (72.7%). Among RA patients, 64% believed that diet have some role in the onset of their RD and 68 % of SA. The main food incriminated were red meat in 64 % and 68%, fried food in 31% and 27% and pasta in 23% and 32% of RA and SA respectively. In addition, 84% of RA and 91 % of SA patients reported improvement of their joint disorder by consuming certain food and 90 % of RA and 91 % of SA reported aggravation of their disease. Most often the positive influence was assigned to green leavy vegetables in 74% and 86%, citrus in 67% and 77%, olive oil in 26% and 32% of RA and SA patients respectively. In our study, red meat was the major constituent of diet which aggravated the symptoms in RD as 87% and 91 % of RA and SA patients respectively, reported aggravation of symptoms with red meat. Modifying in dietary habit occurred in 12.8% of RA and 4.5% of SA to improve their disease activity. The majority of patients thought that healthy dietary habit could be a disease therapy: 94.9% of RA and 95.5 % of SA. Only 5.1% of RA patients reported receiving dietary advice from their rheumatologist and none of the SA patients, while an average of 80% of RA and SA patients showed interest in such discussion. All patients reported relief of joint symptoms after fasting Ramadan.
Conclusion: In this real-life population, there is an ultimate need to investigate the nutritional states in patients with RD, since certains food may improve or aggravate joint symptoms. Red meat release alert signals on RD health patients. Studies of the molecular mechanisms behind these phenomena attract increasing attention.

AB1746-PARE THE CORRELATION OF FUNCTIONAL DISABILITY AND MENTAL DISORDERS IN PATIENTS TREATED FOR SPONDYLODISCITIS

Keywords: Patient reported outcomes, Infection-related RMDs, Quality of life

Y. Mabrouk[1], L. Rouached2, A. Ben Ammou[3], Z. Syrine[4], S. Akremi[3], S. Larbi[5], A. Ben Abid[3], M. Ben Salah[3]. *[1]Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*; *[1]Charles Nicolle Hospital, Rheumatology, Tunis, Tunisia*; *[3]Charles Nicolle Hospital, Orthopedic Surgery, Tunis, Tunisia*; *[4]Hedi Chaker Hospital, Rheumatology, Sfax, Tunisia*; *[5]Razi Hospital, Psychiatry, Manouba, Tunisia*

Background: Although it still remains a rare disease, spondylodiscitis has been on the rise in the past decades. Early diagnosis can be difficult, but Improved diagnostic techniques and modern treatments have reduced patient mortality. However, studies reporting the outcome of spondylodiscitis are scarce.
Objectives: To assess the influence of functional impairment on mental health in patients surgically treated for spondylodiscitis.
Methods: A prospective study was carried out on patients treated for spondylodiscitis over a two-year period at a single spine center. The socio-demographic data, clinical, radiological, biological and therapeutic parameters were collected. A questionnaire was conducted on all eligible patients with the hospital anxiety and depression scale: HAD and the Oswestry disability index: ODI. All data was collected after patient consent and was analyzed using the SPSS statistical package.
Results: Thirty –six patients were selected for the study, with a sex ratio (M/ F) of 1.57. The average age was 56 [18_73]. 22% had comorbidities: 16% diabetes, 6% psychiatric illnesses. 22% were smokers. 72% had a sedentary lifestyle. Mycobacterium tuberculosis was the predominant pathogen(33%) followed by Staphylococcus aureus (22%). Culture was negative in 5 % of patients. Of these, 33% patients received antituberculosis medical treatment. The lumbar spine was the most frequent level of spinal focus (55%). 22% of patients had more than one focus in the spine. 54% of patients had neurological impairment: paraplegia 33%, sensory deficit 11% and confusion 6%. All patients were treated surgically: 32% internal corset, 31% fixation, 20% arthrodesis, 11% corporectomy, 6% laminectomy. The mortality rate was 6%. Average HAD score was 13.3[0-40]: depressive dimension: 6.6[0-20], anxiety dimension 6.8[0-20], with scores indicating very likely depression and anxiety in 22% and 25 % of patients, respectively. Mild, moderate and severe functional disability was noted in 44%, 18% and 6%, respectively, according to the ODI score. In our series, there were positive correlations between gender, VAS (visual analog scale) spinal pain and ODI score: p=0.025 and p=0.007, respectively. In the same way, there were positive correlations between the ODI score and the HAD depression dimension (p=0.001) and the anxiety one (p=0.001).
Conclusion: Two years after surgery, patients treated for spondylodiscitis have significant functional disability. Anxiety and depression, mainly due to interaction with the disability level, are two comorbidities to consider in spondylodiscitis. Screening and psychological support is then necessary.

AB1748-PARE CYLPER'S SUPPORT GROUPS: STRUCTURE AND BENEFITS

Keywords: Pain, Mental health, Self-management

The GPSD (Groups of People with the same disease of CYLPER) are subordinated and report to the Board of CYLPER and operate within the framework of its goals and programs. The role of the Groups is particularly important for the organisation of events and activities of information/ education/ self-management. The contribution of the groups to events of wider information/ public awareness is equally important.

S. Makri[1]. *[1]Cylper - Cyprus League for People with Rheumatism, N/A, Nicosia, Cyprus*

Background: When someone is first diagnosed, he/she is faced with a number of feelings and changes in their life. Such feelings are usually shock, anger, sadness, fear, the feeling of being judged, the feeling of a sense of loss of control. Usually, the supportive environment like family members, friends and colleagues cannot understand exactly how the person feels unless they have received a rheumatic diagnosis themselves. Doctors and health professionals may sometimes offer minor emotional support, but their primary focus is always medical. This may cause feelings of loneliness, misunderstanding or isolation. And here is where the role of support groups finds its place.
OBJECTIVES:
Methods: The general coordination of the Groups is done by the Vice President of CYLPER and the Psychosocial Support Officer, in collaboration with the Social Officer of CYLPER. Members of each Group can become Registered Rheumatism Members of CYLPER. The coordination of the operation of each Group is done by the coordinator who is elected by the members of the committee. The GPSD will be responsible for organising their events through their volunteers, and for this purpose an amount will be approved that will be available to the team to carry out its work.
Results: Finding a support group is a way for people with rheumatism to interact with other people who have similar, first-hand experiences with rheumatism. People can talk about their experiences and share their own. This can help reduce stress. In a support group, members can feel more comfortable sharing feelings and experiences that may be too difficult or too awkward to share with their family and friends. Being part of a group often creates a sense of belonging that helps each person feel more understood and less isolated. They can also discuss practical information in a support group such as: What to expect during treatment; How to manage specific side effects; How to find support services; How to communicate with health care providers and family members. Talking about these topics within the support group could provide a sense of control and reduce feelings of helplessness. Many studies have shown that support groups help people with a chronic disease cope with anxiety and depression.
Conclusion: Running a support group is a good way to reach out and get people interested in the other things your organisation or initiative does. With relatively little effort and cost, a support group can make a significant impact in the lives of people dealing with a problem.

Baklouti[1]. *[1]Hedi Chaker University Hospital, Rheumatology, Sfax, Tunisia*; *[2]Military Hospital of Instruction of Tunis, Physical Medicine and Rehabilitation, Tunis, Tunisia*

Background: The dimensions of self-concept and body image are essential for assessing the quality of life of individuals with chronic diseases. Systemic sclerosis (SSc) is characterized by facial involvement that can lead to aesthetic changes, functional disability as well as psychological impact.
Objectives: To assess the influence of face involvement on self-esteem in SSc patients.
Methods: A cross- sectional study was carried out on patients followed for Systemic sclerosis at a rheumatology department. Included patients completed the Burden of Face Affected (BoFA) questionnaire as well as the Rosenberg self-esteem scale (RSES). All data was collected after patient consent and was analyzed using the SPSS statistical package.
Results: Forty patients who fulfilled the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis were included. There were 8 male and 32 female with a sex ratio female to male of 4. The median age was 45 years old [19-71] and median disease duration 1 year. The majority of our patients (85%, n=34) suffered from diffuse form of SSc. 15%(n=6) had a limited form. Fingertip ulcers were observed in 13 patients (32.5%) and telangiectasia in 16 patients (40%). Raynaud's phenomenon was found in 34 patients (85%). Severe organ involvements were detected as interstitial lung disease in 17 patients (42,5%), pulmonary hypertension in 7 patients (17.5%) and renal involvement in 2 patients (5%). Mean (±SD) Rodnan score was 19.6 ± 6.2 and 70% (28 patients) had a limited mouth opening. Mean(±SD) BoFA score was 68±10.3; 0 implying no impact and 100 for major impact of face affection. Mean Rosenberg self-esteem scale was 26.6±3.3 reflecting low self-esteem. Rosenberg self-esteem correlated negatively with BoFA scores r = -0,36; p=0,02 with low levels of self-esteem associated with more face affection symptoms and no significant correlation between RSES and gender, age or Rodnan score.
Conclusion: Patients' perception of their face affection in SSc is poor and can be considered as an important component of patients' self-esteem. Effective interventions need to be directed during follow-up to improve function and satisfaction with body image.

AB1750-PARE PATIENT-DOCTOR COMMUNICATION FROM PERSPECTIVE OF STENE PRIZE TOPIC 2023

Keywords: Patient information and education, Self-management, Quality of care

J. Grygielska[1]. *[1]Polish Rheuma Federation 'REF', National Board, Warsaw, Poland*

Background: Poland participates in European Edgar Stene Prize Competition from early eighties 20th century. Three times our participants won this Prize – last time in 2018. Every competition on national level starts from appropriate translation of topic into Polish and invitation to participate in this using different channels of information to reach as many as possible potential participants. This year topic: "How better communication with my doctor improved my life with an RMD" gave an opportunity for every person living with rheumatic and musculoskeletal disease to present his/her experiences in building good cooperation with his/her physician. Patient-doctor communication was a topic of many educational events for people with RMDs including 2 perspectives: of patient and doctor. It was used Polish version of PART (prepare, ask, repeat, take action) from "Challenging arthritis" by Kate Lorig and James Fries to be more aware and responsible for his/her own health. This important topic didn't find interest among patients with RMDs and national jury received no entry for this year competition.
Objectives: Lack of entry on topic of patient-doctor communication among rheumatic patients was surprised and identifying the causes of this situation can be important in two areas: future Stene Prize competition and personal cooperation with health professionals including physicians.
Methods: Invitation for participation in competition was shared using the same channels how always. There were: websites of associations, social media (facebook and Twitter), e-mailing to leaders of associations, online meeting on occasion of World Arthritis Day, personal contacts with potential authors. Before deadline of submitting entries reminders were sent and put in social media. Reasons of lack of entries were discussed with active members of our associations.
Results: In opinion of people living with RMDs reality is different than model of good practice in communication patient-doctor. Asking potential authors of essays there were responses like: "what I can write – true?", "what communication?", "it will be some day in future but not today". Patients note the lack of time during medical consultation for open discussion. Physician during 15-20 minutes should examine patient, check results of tests, issue a prescription and referral using electronic system what can be added stress for some doctors and takes time devoted for talk with patient for technical issue. If discuss is started it's from initiative of patient mostly, but patient should be aware and active in process of treatment not only passive participant of consultation. Appropriate sources of information and knowledge help patient to take responsibility for his/her own health and life.
Conclusion: Pandemic COVID-19 accelerated involving e-prescriptions and e-referrals in health care system. Pandemic involved remote consultation on place of consultation in-person. This new form of consultation needed concrete and short exchange of information between doctor and patient. Return to consultations in-person didn't change form of consultation to more friendly for patient. Remote consultation stays like an alternative to consultation in-person.

AB1751-PARE MUSCULOSKELETAL DISORDERS IN THE ERA OF THE COVID-19 PANDEMIC

Keywords: Work-related issues, Descriptive Studies

L. Ben Afia[1], D. Brahim[1], I. Youssef[1], Z. Athimni[1], M. Mersni[1], N. Mechergui[1], H. Ben Said[1], G. Bahri[1], N. Ladhari[1]. *[1]Faculty of Medecine of Tunis, Occupational Department at Charles Nicolle Hospital, Monastir, Tunisia*

Background: In Tunisia, during the last decade, the number of MSDs declared as compensable occupational diseases has been increasing. So, what is the impact of the COVID-19 pandemic on the MSD reporting rate.
Objectives: To describe the socio-professional characteristics of workers with musculoskeletal disorders (MSDs) and to determine the reporting rate of MSDs as occupational diseases.
Methods: A descriptive cross-sectional study among workers with work-related MSDs who consulted the occupational medicine department of the Charles Nicolle Hospital for medical advice between January 2021 and September 2022.
Results: A total of 109 workers with MSDs were included in this study. The workers were 64.2% female. The average age was 46 ± [21-61 years]. The sectors most prone to MSDs were the health sector (27.5%), food processing (16.5%) and textiles (15.6%). The workers reported MSDs of the upper limb in 31.2%, MSDs of the lower limb in 33.9% and of the spine in 69.7%. These MSDs reported included 5/13 cases of rotator cuff tendinopathy, 6/13 cases of carpal tunnel syndrome, one case of achilles tendonitis and one case of Dequervain's tenosynovitis.

Conclusion: During the COVID-19 pandemic, the reporting of MSDs as occupational diseases has declined considerably. This decline can be explained by the difficult access to hospital facilities.

AB1752-PARE THE RATE OF COVID-19 VACCINATION IN PATIENTS WITH RHEUMATOID ARTHRITIS. SINGLE-CENTER CROSS-SECTIONAL PILOT STUDY

Keywords: Rheumatoid arthritis, COVID, Vaccination/Immunization

H. Elhani[1,2], L. Taoubane[1,2], N. EL Ouardi[1,2], H. Taoufik[1,2], A. Majjad[1,2], A. Bezza[1,2]. [1]*Mohamed V Military Training Hospital, Rheumatology, Rabat, Morocco*; [2]*Faculty of Medicine and Pharmacy of Rabat, Rheumatology, Rabat, Morocco*

Background: The rate of COVID-19 vaccination in patients with rheumatoid arthritis. Single-center cross-sectional pilot study.

Objectives: Morocco was the first country in Africa to launch the COVID19 vaccination campaign. Vaccination of immunocompromised subjects was recommended from the beginning by the Moroccan Society of Rheumatology. The primary objective of this study was to assess the vaccination rate of patients with rheumatoid arthritis two years after the start of the pandemic. The secondary objective was to investigate factors associated with vaccination.

Methods: This was a 3-month monocentric cross-sectional study from 31.05.22 to 31.08.22, including patients whose age was greater than 18 years, who have rheumatoid arthritis according to ACR/EULAR 2009 criteria. Socio-demographic data, comorbidities and disease characteristics were collected by the attending physician at the time of the consultation using a questionnaire. Statistical analysis was performed using JAMOVI software.

Results: The study included 73 patients, 82.2% of whom were women. The mean age was 57±11years, with a median disease progression of 8 years. 58 patients (80.6%) were vaccinated against COVID19. Among the vaccinated patients, 30 (51.7%) were illiterate, 8 patients (13.8%) had primary education, 11 (19%) had secondary education and 9 (15.5%) had higher education 53 (91.4%) patients were previously on or on corticosteroids, 8 patients (14, 3%) had a history of tuberculosis, 10 patients (17.5%) had diffuse interstitial lung disease routinely detected on computed Tomography (CT) Scan of the Chest, 26 patients (45.6%) had received a pneumococcal vaccination (p=0.24), and 21 (36.2%) had received an influenza vaccination. 15 patients (25.8%) were on Tumor necrosis factor-alpha inhibitors, 25 patients (43.1%) were on Rituximab, 6 patients (10.3%) were on Tocilizumab, 4 patients (6.9%) were on Methotrexate, 1 patient (1.7%) was on Leflunomide, 1 patient (1.7%) was on Salazopyrine, 2 patients (3.4%) were on csDMARD combinations, and 4 patients (6.9%) were not on any disease-modifying treatment.Only the level of education was statistically significantly different between vaccinated and non-vaccinated patients (p=0.06).

Conclusion: In this study, almost 80% of patients were vaccinated. Further studies are needed to develop population-specific education programs.

AB1753-PARE APPLICATION OF THE THEORY OF PLANNED BEHAVIOR: THE ROLE OF FAMILY AND PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: Self-management, Rheumatoid arthritis, Education

S. Al-Shamali[1], M. Al-Sabah[1], A. Alsaber[1]. [1]*American University of Kuwait, College of Business and Economics, Salmiya, Kuwait*

Background: The TPB suggests that patient attitudes, subjective norms, and perceived behavioral control predict behavioral intentions and behaviors regarding health behavior (Yaoyao et al., 2021). Behavioral theories aid in improving the behavioral changes in the self-management of diabetes (Damayanti et al., 2018) and other lifestyles changes such as healthy eating (Rahmati-najarkolaei et al., 2017). Most recently, Jormand et al. (2022) uses TPB for the self-care behaviors of knee osteoarthritis patients in which TPB aided educational intervention, by examining variables such as their attitudes and perceived behavioral control. Saffari et al. (2018) explains that although they are not as popularly researched and surgical interventions, the benefits of non-medical approaches endorsing healthy lifestyles can improve symptoms and reduce the need for other treatments.

Objectives: This study will use three variables in the TPB model, namely, attitude, PBC (self-efficacy) and family support to examine the intention of self-management behaviors on a sample of patients with rheumatoid within a developing country and collectivist society.

Methods: The model proposed for this research includes independent variables; support from family (novel variable), attitude and perceived behavioral control. Dependent variables include intention and total self-management (cognitive, physical and communication with a health professional). Adult patients who meet the criteria of the American College of Rheumatology (ACR) and live with family will be asked to complete a self-administered questionnaire. This cross-section study proposes a model that will be tested using regression analyses and structural equation model.

Results: Data is still under analysis and will be available at the time of the conference. However, based on previous studies it is hypothesized that TPB variables and relative support will be reported as significant.

Conclusion: Insights through the model proposed could aid healthcare professionals in understanding elements that support or hinder rheumatoid patients from initiating or maintaining self-management behavior.

AB1754-PARE INFLAMMATORY RHEUMATIC DISEASES AND RELIGIOUS RITUALS: WHICH IMPACT?

Keywords: Descriptive Studies, Quality of life, Patient reported outcomes

K. Maatallah[1], R. Ben Aissa[1], H. Ferjani[1], D. Ben Nessib[1], D. Kaffel[1], W. Hamdi[1]. [1]*Mohamed Kassab Institute of Orthopedics, Department of Rheumatology, Mannouba, Tunisia*

Background: Religious events are privileged occasions for sharing and conviviality. In a joyful atmosphere, festive meals are shared with family, neighbors, and friends, and gifts are exchanged. Little is known about the impact of chronic inflammatory rheumatic diseases on patients' celebrations of religious events.

Objectives: To study the satisfaction of patients with their religious rituals during Islamic holidays.

Methods: We conducted a transversal study, including patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA). Patients were invited to answer to a satisfaction scale (SS) composed of four domains: prayer practice, religious food preparation, family visits, and satisfaction with spiritual fulfillment. For each domain, there were 6 degrees of satisfaction (extremely satisfied, satisfied, slightly satisfied, slightly dissatisfied, dissatisfied, extremely dissatisfied) rated from 1 to 6 from best to worst satisfaction. The sub-SS for each domain ranged from 1 to 6, and the global SS ranged from 4 to 24.

Results: Seventy-one patients (45 females) answered the SS with a median age of 48±13 [20-81] years. Thirty-three patients had RA and thirty-eight SpA with a mean disease duration of 8±7.3 [0.04-36] years. The RA and SpA were active according to DAS28 and BASDAI in, respectively, 78% and 47% of cases. The mean global SS was 13.2±3.1 [6-23] and the mean sub-SS for prayer practice was 3.3±1.3 [1-6], for religious food preparation was 4±1.4 [1-6], for family visits was 3±1.3 [2-6] and for satisfaction for spiritual fulfillment was 3.3±1.4 [1-6]. A better satisfaction with prayer practice and religious food preparation was correlated with age (p=0.04, p=0.043, respectively) and married marital status (p=0.021, p=0.008, respectively). SpA patients reported less satisfaction with prayer practice than RA patients (sub-SS means 3.44 versus 3.13), but this did not reach a statistically significant level (p=0.337). Patients with inactive disease reported better satisfaction with family visits than those with active disease (sub-SS means 2.46 versus 3.04) but without statistically significant difference (p=0.178). The satisfaction with spiritual fulfillment correlated with age (p=0.001), whereas there were no associations with gender (p=0.216), type of the rheumatism (p=0.653) and disease activity (0.516). There was no correlation between the global SS and the type of rheumatism, disease activity, and gender (p=0.631, p=0.403, p=0.569, respectively).
Conclusion: Our study showed that RA and SpA affect negatively patients' religious practices, especially prayer practice, religious food preparation, and spiritual fulfillment. Therefore, the impact on religious rituals should be taken into account when assessing the quality of life of patients with rheumatic diseases.

AB1755-PARE EVALUATION OF THE FRAGILITY OF ELDERLY PATIENTS HOSPITALIZED IN THE RHEUMATOLOGY DEPARTMENT

Keywords: Quality of life

A. Saad[1], N. Hafdhouni[1], R. Ben Tekaya[1], G. Mouna[1], J. Mahbouba[1], S. Zrour[1], I. Bejia[1], M. Touzi[1], N. Bergaoui[1]. [1]*University Hospital Fattouma Bourguiba Monastir, Rheumatology, Monastir, Tunisia*

Background: Fragility is defined by a clinical syndrome that reflects a decrease in physiological capacities altering the mechanisms of adaptation to stress[1]. Elderly patients hospitalized in the rheumatology department are at risk of significant fragility.
Objectives: The aim of our study is to evaluate the fragility of elderly patients considering the bio-psycho-social parameters.
Methods: Prospective study started in July 2022 in the rheumatology department including 40 patients who were subject to questionnaires assessing their fragility and quality of life.
Results: 40 patients were collected including 27 women (67.5%) and 13 men (32.5%). 15 (37.5%) patients were hospitalized for chronic inflammatory rheumatism, 19 (47.5%) for a degenerative disease and 6 (15%) for a tumoral disease. The mean age of the patients was 72.6 ± 5.4 years. The social context of each patient was assessed: 30 (90%) patients lived with their family and 10 (25%) lived alone. 19 (47.5%) patients reported having financial difficulties and 17 (42.5%) patients needed daily help with household chores. We studied the level of frailty of our patients using the Tilbourg Fraility Indicator (TFI): 29 (72.5%) patients had a score ≥ 5 indicating significant frailty. 21 (52.5%) patients presented a risk of depression evaluated at 5 according to the geriatric depression scale (GDS15). A nutrition assessment was made using the Mini Nutritional Assessment (MNA) test, concluding with poor nutritional status in 10 (25%) patients. Finally, five (12.5%) patients had a dependency score ≤ 3 according to the Activities of Daily Living (ADL) scale.
Conclusion: Elderly patients with rheumatological disease hospitalized in our department show an alteration in their quality of life and a significant level of fragility which should motivate us to adapt care programs for the elderly concerned.

AB1756-PARE FACTORS ASSOCIATED WITH QUALITY OF LIFE AMONG SCLERODERMA PATIENTS

Keywords: Quality of life, Systemic sclerosis

Z. Syrine[1], A. Feki[1], S. Ben Jemaa[1], Y. Mabrouk[2], A. Cyrine[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], R. Akrout[1], S. Baklouti[1]. [1]*Hedi Chaker University Hospital, Rheumatology, Sfax, Tunisia*; [2]*Military Hospital of Instruction of Tunis, Physical Medicine and Rehabilitation, Tunis, Tunisia*

Background: Systemic sclerosis (SSc) is an autoimmune multi-systemic disease with predominant affection of connective tissue resulting in progressive fibrosis of the skin and internal organs. Monitoring measures of functioning and disability is crucial during follow up to identify quality of life impairment.
Objectives: To assess the influence of functional impairment on quality of life in SSc patients.
Methods: A cross- sectional study was carried out on patients followed for systemic sclerosis at a rheumatology department. Included patients completed the Hospital Anxiety Depression scale in its Arabic validated version. The SF-36 short form questionnaire score with its domains (general health, physical function, role physical function, emotional role function, vitality, mental health, social function, body pain, general health) in its arabic Tunisian version was used to assess quality of life. All data was collected after patient consent and was analyzed using the SPSS statistical package.
Results: Forty patients who fulfilled the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis ACR criteria for SSc were were included. 80% of the patients were female, the median age was 45 years old and median disease duration 1 year. 15%(n=6) had a limited form, and 85% (n=34) had a diffuse form of SSc. Fingertip ulcers were observed in 13 patients (32.5%) and Raynaud's phenomenon was found in 34 patients (85%). Severe organ involvements were detected as interstitial lung disease in 17 (42,5%), pulmonary hypertension in 7 patients (17.5%) and renal involvement in 2 patients (5%). 38 % patients had an HAD scoring rate for "possible clinical anxiety" and for 42% for "possible clinical depression". The SF-36 questionnaire score of each domain was significantly lower in patients with diffuse than in limited form, especially the score in the dimension of Role Physical function and Body Pain, p=0.04 and p=0.02 respectively. Skin involvement and organ damage were also significantly associated with lower SF36-PF (physical function) (p=0.001) and SF36-MH (mental health) p=0.0025 with no significant association with the other score components.
Conclusion: Systemic Sclerosis has a significant effect on patient quality of life. Body image, fatigue, pain, and psychological morbidity should be screened in patients with SSc to promote quality of life.

AB1757-PARE PATIENTS WITH SPONDYLOARTHRITIS SUFFER IN SILENCE: THE IMPACT OF THE DISEASE ON THEIR QUALITY OF LIFE

Keywords: Quality of life, Spondyloarthritis, Patient reported outcomes

E. Hannech[1], S. Boussaid[1], S. Rekik[1], S. Rahmouni[1], K. Zouaoui[1], H. Ajlani[1], H. Sahli[1], M. Elleuch[1]. [1]*La Rabta Hospital, Rheumatology Department, Tunis, Tunisia*

Background: Spondyloarthritis (SpA) is a chronic disease that often causes functional impairment, resulting in a negative impact on patients' quality of life (QoL).
Objectives: We aimed to assess QoL of patients with SpA using a validating tool.
Methods: We conducted a cross-sectional study including patients with SpA. Sociodemographic, clinical, and therapeutic data were collected. Patients' QoL was assessed using the validated Tunisian version of the EQ-D5 questionnaire, which is a standardized measuring instrument that assesses the state of health according to five dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression. The answers were converted into EQ-5D index.
Results: There were 100 SpA patients with a mean age of 43.68±10.3 years [20-76]. Regarding mobility, 2 patients reported extreme problems, 61 patients had some problems, and 37 patients had no problems. Six patients were totally non-autonomous, 55 were partially autonomous, and 39 patients had no problems in the self-care domain. Thirty-five patients had no problems in their usual activities, 60 patients had some problems, and 5 patients had extreme problems. Twenty-six patients had significant pain or discomfort at the time of the study, 61 patients had moderate pain or discomfort, and 13 patients had no pain. A significant level of anxiety/depression was observed in 12 patients, 46 patients had moderate depression or anxiety, and 42 patients had no psychological problems. The global VAS of health status had a mean value of 59± 25% [7-100]. The mean EQ-5D index was 0.485±0.378 [-0.448-1]. In 12 cases the index was negative, defining an extremely large effect of the disease on QoL, while 7 patients had an index equal to 1, showing that the disease had no effect on their QoL.
Conclusion: Despite therapeutic advances, patients with SpA still suffer in their daily living. So, an early and appropriate management is necessary.

HPR Measuring health (development and measurement properties of PROs, tests, devices)

AB1758-HPR IDENTIFYING THE RISK OF STEROID INDUCED ADRENAL INSUFFICIENCY IN RHEUMATOLOGY PATIENTS WEANING FROM PROLONGED STEROID THERAPY

Keywords: Tapering, Diagnostic Tests, Inflammatory arthritides

E. Quinlan[1], M. Khatun[1], M. Kazmi[1]. [1]*Sheffield Teaching Hospitals NHS Foundation Trust, Rheumatology, Sheffield, United Kingdom*

Background: Rheumatologists often prescribe steroids, and long-term use can lead to suppression of the hypothalamic-pituitary-adrenal (HPA) axis, leading to Steroid Induced Adrenal Insufficiency (SIAI). Our departmental guidelines suggest patients on steroid weaning regimes should have morning serum cortisol levels once weaned to 3mg.
Objectives: We aimed to identify what proportion of cortisol levels were abnormal in patients weaning from steroids in various Rheumatological conditions. There are currently no established guidelines to identify patients for possible SIAI, which is usually only assessed if a patient develops steroid withdrawal symptoms at low doses. We wanted to investigate if SIAI was seen commonly and analyse whether patients who had abnormal cortisol levels went on to have a Short Synacthen Test (SST), Endocrinology input and SIAI diagnosis.
Methods: Retrospective review of Rheumatology patients who had morning serum cortisol levels whilst weaning from oral prednisolone at Sheffield Teaching Hospitals. Patients identified via the Clinical Laboratory Database.
Results: Data collected Sept'19 – Oct'22, only samples taken pre-9AM assessed (n=58). 33 Female, 25 Male. Age 21-83 years; mean 65 years. Starting dose prednisolone 5mg-60mg (IQR 15-40mg). Treatment length 6-96 months (IQR 14-48). Samples taken when 84.5% (n=49) taking 3mg, 10.3% (n=6) 2mg and 5.2% (n=3) 2.5mg, (IQR 3mg). Cortisol levels <300 nmol/L in 43.1% (n=25), 300-350 nmol/L in 15.5% (n=9) and >350 nmol/L in 41.4% (n=24). 68% (n=17) of <300 nmol/L (n=25) referred for a SST. SST results were <430 nmol/L in 35.3% (n=6) and >430 nmol/L in 64.7% (n=11). All patients with SST <430 nmol/L (n=6) referred to Endocrinology. 33.3% (n=2) had "borderline" SST results (421nmol/L, 415nmol/L) and advised to wean steroids by 1mg every 4 weeks and discharged. 66.7% (n=4) diagnosed with SIAI, with only one (25%, n=1) having documented symptoms. All (n=4) had further Endocrinology investigation; 100% (n=4) had a repeat SST and pituitary function tests and 75% (n=3) had or awaiting Waking Salivary Cortisol (WSC). 75% (n=3) showed recovery of HPA axis on repeat testing and so advised to slowly wean steroids. 25% (n=1) had persistently abnormal results suggesting ongoing SIAI and advised to remain on 3mg prednisolone. All patients with an abnormal SST (n=6) remained on prednisolone and did not change to hydrocortisone. 90.1% (n=10) of patients with an SST of >430 nmol/L referred to Endocrinology concurrently with SST request and outcome for all patients was to continue slowly weaning steroids. 32% (n=8) patients with a cortisol <300 nmol/L did not have an SST. 37.5% (n=3) had alternative WSC testing; 33.3% (n=1) discharged after normal WSC, 33.3% (n=1) awaiting WSC and 33.3% (n=1) require ongoing Endocrine input as WSC indicated SIAI. This patient awaits steroid clinic and remains on 3mg prednisolone. 62.5% (n=5) had no further investigations. Outcomes: steroids continued by Rheumatology (n=3), steroids weaned by Rheumatology (n=1), too early for further tests (n=1). 15.5% of patients (n=9) had a cortisol between 300-350 nmol/L. None had an SST due to not having symptoms, in line with our guidelines. 33.3% (n=3) had a repeat cortisol, all repeats >350 nmol/L. Outcomes: Rheumatology weaned steroids (n=5), dose increase due to flair (n=2), no further documentation (n=1), moved away (n=1).
Conclusion: 10.3% (n=6) of all patients who had a serum cortisol measurement had an abnormal SST and 8.6% (n=5) of all patients were diagnosed with SIAI. Only one patient had documented symptoms of SIAI. Given the introduction of the more sensitive WSC as an alternative to the SST we aim to modify our department guidelines in collaboration with the Endocrinologists. In line with the 2020 National Patient Safety Association alert and 2022 British Society for Rheumatology guidance the focus is to recognise adrenal insufficiency, which our guidelines are designed to do. Adrenal insufficiency is unpredictable and rare but adrenal crisis can be fatal, so Rheumatologists must be aware of it.

AB1759-HPR THE USE OF PROMIS MEASURES IN CLINICAL STUDIES IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A SYSTEMATIC REVIEW

Keywords: Inflammatory arthritides, Patient reported outcomes, Systematic review

M. Teuwen[1], I. Knaapen[1], T. P. M. Vliet Vlieland[1], J. Schoones[2], C. Van den Ende[3,4], S. Van Weely[1], M. G. J. Gademan[1,5]. [1]*Leiden University Medical Center (LUMC), Orthopaedics, Rehabilitation and Physical Therapy, Leiden, Netherlands*; [2]*Leiden University Medical Center (LUMC), Directorate of Research Policy, Leiden, Netherlands*; [3]*Sint Maartenskliniek, Department of Research, Ubbergen, Netherlands*; [4]*Radboud University Medical Center, Department of Rheumatology, Nijmegen, Netherlands*; [5]*Leiden University Medical Center (LUMC), Department of Clinical Epidemiology, Leiden, Netherlands*

Background: Patient-reported outcome measures (PROMs) are of vital importance to evaluate the outcomes of inflammatory arthritis and its management, but limitations of conventional PROMs include a lack of precision and/or comparability across conditions. Patient Reported Outcomes Measurement Information System (PROMIS) measures [1-2] were developed since 2007 to overcome these disadvantages. They use a standardized metric (T-score), centered around the general population (score 50), enhancing their interpretability. The use of PROMIS measures in patients with inflammatory arthritis was recommended by the International Consortium for Health Outcomes Measurement (ICHOM) [3], but little is known about the extent and nature of their actual use in clinical research.
Objectives: We aimed to describe the use and outcomes of PROMIS measures in clinical studies involving people with rheumatoid arthritis (RA) or axial spondyloarthritis (axSpA).
Methods: We conducted a systematic review according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. A search of nine electronic data bases on July 29th, 2022 was conducted to identify clinical studies in patients with RA or axSpA, reporting the use of PROMIS measures and written in English, Dutch or German. Study characteristics, details of PROMIS measures and, if available, their outcomes, were extracted. Both the selection and the data extraction were performed independently by two researchers and disagreements were resolved by consensus, either or not with a third researcher.
Results: In total, 714 records were retrieved (272 unique references), of which 29 studies met the inclusion criteria (25 RA, 3 axSpA and one both RA and axSpA). In total, 15 different PROMIS measures were used, 13 of which were domain-specific and 2 pertained to general health (PROMIS Global Health, PROMIS-29). The five most frequently used domain specific measures were the PROMIS Pain Interference (n=17), Physical Function (n=14), Fatigue (n=13), Depression (n=12) and Anxiety (n=7) measures. The general PROMIS Global Health and PROMIS-29 were both reported in 3 studies. The PROMIS measures that were used varied considerably, with a total of 74 unique identified measures, as a result of differences in their typology into Item Banks, Computer Adaptive Tests, Short Forms, the described name or the version number. In total, 21 studies reported on 98 PROMIS results in terms of T-scores, of which 91 were worse than the general population mean (score 50), indicating impaired health status. The other 8 studies did not report actual T-scores but psychometric properties of PROMIS measures (e.g. the validity, reliability, correlations with other questionnaires, responsiveness, meaningful change).
Conclusion: Given the availability of PROMIS measures since 2007 and the vast amount of clinical studies in RA and axSpA, PROMIS measures seem to be relatively underused. Among the studies there was considerable variety regarding the PROMIS measures that were used as well as their versions. The reported PROMIS outcomes overall reflected the impaired health status of patients with in RA and axSpA as compared to the general population. Apart from the promotion of the use of PROMIS measures, more standardization regarding the type of measures and their versions is needed to facilitate comparisons across studies.

AB1760-HPR THE RELATIONSHIP BETWEEN DISEASE ACTIVITY LEVEL AND WRIST JOINT POSITION SENSE, GRIP STRENGTH AND DYNAMIC GRIP ENDURANCE IN PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Physical therapy/Physiotherapy

M. Köprülüoğlu[1], İ. Naz[1], D. Solmaz[2], S. Akar[2]. [1]*Izmir Katip Celebi University, Department of Physiotherapy and Rehabilitation, İzmir, Turkey*; [2]*Izmir Katip Celebi University, Department of Internal Medicine, İzmir, Turkey*

Background: Dynamic grip endurance in psoriatic arthritis is one of the affected functional parameters during the disease process. However, there are limited studies about dynamic grip endurance related factors.
Objectives: To investigate the relationship between disease activity level and joint position sense and dynamic grip endurance in psoriatic arthritis.
Methods: A total of 27 PsA patients (age:53.33 ±11.85 years, women/men:16/5) who were classified by the Classification Criteria for Psoriatic Arthritis (CASPAR) criteria and followed in outpatient clinic were included in our study. The socio-demographic characteristic of all patients recorded. Disease activity level was assessed with the DAPSA score. Wrist joint position sense was evaluated by a goniometric re-position error test. Grip strength and endurance were examined by a hand dynamometer (Lafayette Professional Hand Dynamometer, USA). Data analysis was performed with Spearman Correlation Coefficient.
Results: Patients' diagnosis year, tender joint on hand, and swollen joint on hand were 4.50 years, 23, and 18, respectively. DAPSA scores were 28.67 ±14.85 and moderate-high level. There was no relationship between DAPSA scores and joint position error and dynamic grip endurance on both sides (p>0.05). A moderate level correlation was found between the DAPSA score and grip strength on both sides (p<0.05, r=-0.516 and -0.570 dominant and non-dominant side, respectively).
Conclusion: Our study showed that PsA patients had lower grip strength during the exacerbation period. Since joint position sense and grip endurance were low independents of disease activity, they may not are associated with disease activity in this study. We think that in cases where disease activity increases, approaches that protect grip strength can be added to the disease management process.

AB1761-HPR A TELE-MONITORING PROGRAM FOR TIGHT CONTROL OF TREATMENT SAFETY IN PATIENTS WITH RHEUMATIC DISEASES

Keywords: Health Services Research

M. Fedeli[1,2], J. Saini[3], H. Ibsen[4], M. James[5], T. Hügle[2]. [1]*Hôpital du Jura, Department of Rheumatology, Délemont, Switzerland*; [2]*University Hospital Lausanne (CHUV), Rheumatology, Lausanne, Switzerland*; [3]*Vtuls, IDEARK, Martigny, Switzerland*; [4]*Opentelehealth, OTH.IO, Aarhus, Denmark*; [5]*Mediservice AG, Distance Health Care, Zuchwil, Switzerland*

Background: Initiation of an immuno-modulatory treatment is a vulnerable part of the patient journey. Distance monitoring via patient reported outcomes (PROs) and wearables are used to assess treatment efficacy. In combination with remote vital sign measurement and tele-nursing, remote care may also increase safety and save resources. However, it is unclear how such telemedicine services integrate into the clinical workflow.
Objectives: Feasibility and User Experience (UX) study of a combined app-based and nurse-assisted tele-monitoring program in rheumatic patients with different risk profiles starting a new biologic treatment.
Methods: In this quantitative and qualitative study, we explored a distance monitoring service including contactless optical vital sign measurement and tele-nursing in ambulatory rheumatic patients in Switzerland. System Usability Scores (SUS) and semi-structured interviews were performed with patients, tele-nurses, and rheumatologists. Patients collected weekly PROs and vital signs via an app (Vtuls, Switzerland) after instruction by tele-nurses. Vital sign deterioration triggered automated notification (categorized in yellow, green, and red) allowing corrective actions. Rheumatologists received monthly summaries of PRO and vital signs in PDF form.
Results: 15 patients with rheumatoid arthritis or spondylarthritis with a mean age of 43.9 years (32-79) were included and monitored up to three months with the app and phone calls of the tele-nurse. 15/15 patients found the program useful, mainly for staying in contact with their rheumatologist after therapy start or switch. 13/15 patients measured their vital signs regularly, the adherence to PRO questionnaires was significantly lower. 6 patients had technical problems with the contactless blood pressure measurement. The app generated in average 16 vital sign alarms per patient, of those 7.1 green, 1.1 yellow and 2.2 red alarms. The rheumatologists considered the program as useful, especially in one patient with high-level comorbidity who experienced infection and in another patient after dosing error of the new treatment. The number of consultations (e.g. routine control 1-2 months after starting the new treatment) were significantly lower in this cohort compared to patients without remote care. PDF reports via email were considered as suboptimal and digital integration into the workflow needs to be implemented in future versions of the care program. Tele-nurses considered patients with high comorbidity, shorter disease duration and younger age as most suitable for remote control. False alarms initially increased the workload of the nurses, but this later reduced through technical advice and adjustment of the thresholds. SUS scores were slightly higher in patients (median 97.5) compared to tele-nurses (median 77.5). One patient outlier (17.5) had higher expectations in the responsiveness of tele-nursing, based on entered PROs.
Conclusion: Tight remote control of safety and efficacy through a combined app, biosensor and tele-nursing program was appreciated by all stakeholders, especially in patients with high comorbidity. A better integration of data and communication in the clinical workflow is required, ideally through the electronic medical record. A reduced workload in the rheumatology clinic was observed, but a complete reorganization of the processes was necessary.

AB1762-HPR CAN PATIENT-REPORTED OUTCOMES BE USED TO TRIAGE PATIENTS WITH ANKYLOSING SPONDYLITIS TO MOBILITY MEASUREMENTS OR TESTING OF C-REACTIVE PROTEIN?

Keywords: Spondyloarthritis, Patient reported outcomes, Outcome measures

C. Fougman Mccarthy[1,2], K. Hörnberg[3], T. Weitoft[1,4], M. Björklund[2], B. Sundström[3,4]. [1]*Gävle Hospital, Department of Rheumatology, Gävle, Sweden*; [2]*Umeå University, Department of Community Medicine and Rehabilitation, Physiotherapy, Umeå, Sweden*; [3]*Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden*; [4]*Uppsala University/Region Gävleborg, Centre for Research and Development, Gävle, Sweden*

Background: Patients with Ankylosing Spondylitis are assessed by healthcare with regular controls of mobility and disease activity. If these controls can be replaced by valid patient-reported index, it would unburden both patients and healthcare.
Objectives: In this study we analysed associations between healthcare measured mobility and disease activity and patient-reported disease activity, physical function and well-being in patients with AS.
Methods: This register-based cross-sectional study used data from 1541 visits (of which 1093 visits were men and 448 women) in the Swedish Rheumatology Quality Register. Variables for healthcare measured spinal mobility and disease activity were Ankylosing Spondylitis Metrology Index (BASMI) and C-Reactive Protein (CRP). Variables for patient-reported disease activity, physical function and well-being were Bath Ankylosing Spondylitis Disease Activity Index (BAS-DAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Global Score (BAS-G). First, associations were tested with Pearsons correlation. Secondly, discriminative ability to identify subnormal BASMI, or CRP [defined as below the 2.5th percentile of healthy individuals, and >3, respectively [1,2], was determined by means of receiver operating characteristic (ROC) curve analysis for variables with coefficients r >0.4.
Results: Associations with r >0.4 was found only between BASMI and BASFI (r=0.49), resulting with an area under the curve (AUC) of 0.74 (95% CI; 0.72-0.76) in the ROC analyses. Among the subquestions of BASMI/BASFI, the highest association was seen between measured cervical rotation and the self-assessed ability to look over shoulder (r=-0.69), resulting in AUC of 0.85 (95% CI; 0.83-0.88) in the corresponding ROC analyses, using cervical rotation below 2.5th percentile of healthy individuals as discrimination value.
Conclusion: A significant association with r >0.4 was seen between BASMI and BASFI. The resulting AUC of 0.74 between BASMI and BASFI, and 0.85 between measured cervical rotation and self-assessed ability to look over shoulder, can be deemed as acceptable and excellent, respectively [3]. BASFI and its sub-questions may therefore be of interest for further evaluation if they could be used for screening and triaging patients to spinal mobility measurements with BASMI. Neither of the self-reported indices associated with CRP to any higher degree (r <0.4).

AB1763-HPR RELIABILITY AND VALIDITY OF THE TURKISH VERSION OF SCLERODERMA SKIN PATIENT-REPORTED OUTCOME IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Patient reported outcomes, Validation

F. Sarİ[1], Z. Bazancİr Apaydİn[2], H. Apaydın[3], M. Kayaalp[4], A. Erden[5], S. C. Güven[3], B. Armagan[3], A. Omma[6], O. Küçükşahin[3]. *[1]Bingöl University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Bingöl, Turkey*; *[2]Medipol University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Ankara, Turkey*; *[3]Ankara City Hospital, Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Ankara, Turkey*; *[4]Yıldırım Beyazıt University, Department of Internal Medicine, Faculty of Medicine, Ankara, Turkey*; *[5]Gazi University, Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Ankara, Turkey*; *[6]University of Health Sciences, Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Ankara, Turkey*

Background: Systemic sclerosis (SSc), which is characterized by fibrosis of the skin and, internal organs and vasculopathy, is an autoimmune rheumatic disease. Skin fibrosis is the most seen feature of SSc patients and affects nearly all patients with SSc at different levels and severity. Skin involvement is generally evaluated with the modified Rodnan skin score (mRSS). However, several studies have indicated that there is no relation between mRSS and appearance self-esteem. Based on evidence from previous studies that it is significant to comprehensively evaluate the effects of skin fibrosis on QoL in SSc patients. There is a need for an instrument to assess the effects of skin involvement on the quality of life of the Turkish population in SSc patients.

Objectives: Scleroderma Skin Patient-Reported Outcome (SSPRO) is useful scale to evaluate the skin related quality of life in SSc patients. This study purposed to translate the SSPRO questionnaire to Turkish (SSPRO-T) language and to assess its validity and reliability.

Methods: Fifthy-four SSc patients (female:male, 51:3) participated in the reliability and validity analysis. The translation and cross-cultural adaptation of the original version of the SSPRO were applied in accordance with the procedure described by Beaton guidelines. The SSPRO-T, the Scleroderma Health Assessment Questionnaire (SHAQ), the Health Assessment Questionnaire Disability Index (HAQ-DI), Skindex-29 and patient global skin severity were conducted to 54 patients with SSc for construct validity. The SSPRO-T was re-tested to assess its reliability after seven days.

Results: The SSPRO-T had a four-factor structure. The total SSPRO-T score and its subgroups correlated positively with SHAQ, HAQ, Skindex-29 and patient global skin severity. The internal consistency and reliability were excellent the SSPRO-T and physical effects subgroup, emotional effect subgroup, physical limitation subgroup and social effect (Cronbach's α = 0.94, 0.80, 0.95, 0.93 and 0.84, respectively) (Table 1). The SSPRO-T had excellent test-retest reliability (r=0.91, p<0.001). In addition; it was not seen floor effect and ceiling effect related SSPRO-T.

Conclusion: The SSPRO-T questionnaire is an excellent a reliable and valid tool. It could be used in research and clinical studies in the Turkish patients with SSc.

EXPRESSION OF CYTOKINES RELATED TO "INFLAMMAGING" AND ARTERIAL STIFFNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS: A GENE ONTOLOGY AND PATHWAY ENRICHMENT ANALYSIS

Keywords: Rheumatoid arthritis, Cytokines and chemokines

J. Carvajal-Veloza[1], J. A. Rubio-Rubio[2], G. Salguero[3], L. D. Gutiérrez-Castañeda[1,2,3], G. S. Rodríguez-Vargas[4], P. Santos-Moreno[4], D. Echeverri[5], P. K. Bautista-Niño[6], L. Saenz[7], A. Rojas-Villarraga[2]. *[1]Fundación Universitaria de Ciencias de la Salud FUCS, Basic Sciences Group, Bogotá, Colombia*; *[2]Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*; *[3]4. Instituto Distrital de Ciencia Biotecnología e Investigación en Salud, IDCBIS, Research, Bogotá, Colombia*; *[4]BIOMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia*; *[5]Fundación Cardioinfantil-La Cardio, Cardiovascular Prevention Program, Bogotá, Colombia*; *[6]Fundación Cardiovascular de Colombia (FCV), Research Laboratory, Bogotá, Colombia*; *[7]Fundación Cardioinfantil-La Cardio, Cardiology, Bogotá, Colombia*

Background: Cardiovascular disease is the leading cause of premature death among patients with rheumatoid arthritis (RA). Inflammatory cytokines play a pivotal role in this process, leading to impaired artery elasticity by priming endothelial dysfunction and enhanced arterial stiffness.

Objectives: To assess the expression of inflammatory cytokines associated to cardiovascular alterations such as arterial stiffness among patients with RA and osteoarthritis (OA) through Gene Ontology and Pathway Enrichment analysis.

Methods: Inclusion criteria for this analytical cross-sectional study were patients with RA and OA between 40 and 70 years old. Sociodemographic and clinical characteristics as well as inflammatory, metabolic markers, acute phase reactants, autoantibodies were analyzed. Levels of 18 cytokine: including VCAM1 (CD106), ICAM1(CD54), CCL7 (MARC), MCP1, SPP1 (OPN), PDGF, CXCL10 and inflammaging related cytokines: INF-γ (IFNG), IL-10, IL-1RA, IL-1β, IL-6, TNF-α, MMP1, MMP2, MMP9, TIMP-1, TIMP2, were measured using a Luminex Assay (Invitrogen, Carlsbad, CA, United States). Cardiovascular measurements (Including Pulse Wave Velocity -PWV and aortic augmentation index – Aix) were performed within one month after blood sampling using the TensioMed Arteriography. A protein-protein interaction network (PPI) was built using the string App plugin from Cytoscape v3.9.1. Gene Ontology and pathway analysis were carried out using ClueGO (v2.8.9) + Cluepedia (v1.5.9) Cytoscape plugin for the proteins that showed a significant overexpression against GO biological processes, KEGG, and Reactome pathways databases (*Homo sapiens*).

Results: A total of eighty patients were included (71.3% women). The average age was 57 years, interquartile range (IQR) 10. OA patients had higher waist circumference, weight, and body mass index values than RA patients. There were no differences in lipid profile or glucose levels. CRP levels were higher in RA patients. Levels of disease activity in RA patients was low according to the measurement of the DAS-28-PCR. 12.5% of patients with RA had polyautoimmunity. There were no significant differences in the measurement of cardiovascular variables between the two groups except for Brachial diastolic blood pressure, which was higher in the RA group (p=0,049). Plasma levels of VCAM1 (CD106;), MARC (CCL7; p=0.000), OPN (SPP1; 0.040), IL-1RA; p=0.015) and IL-1β (p=0.031) were significantly higher in the group of RA patients. ICAM1 (CD54), MARC, and INF-γ levels were correlated with Aix in the RA group. In the OA group, IL-10 levels positively correlated with Brachial pulse pressure and other central and peripheral pressure measurements (mild or moderate). The merged network between upregulated cytokines (VCAM1, SPP1, PDGF1, IFNG, ICAM1 and CCL7), RA query in DISESASE database and "Arterial stiffness" query (PubMed) resulted in a PPI network with 26 nodes and 88 interactions. (Figure 1.) The nodes with BC above 0.05 (VCAM1, TNF, JAK1, ICAM1, IL-10, CD4, PTK2B, FN1, ITGB1) represents the key genes. Ten *GO* terms and twelve pathways were significantly enriched (Figure 2). The principal GO terms were as follows: "membrane to membrane docking" (34% genes), "response to type II interferon" (7.89% genes), and "regulation of lipid biosynthetic process" (5.26% genes). KEGG and REACTOME included: signaling by PDGF (7.89%), integrin cell surface interaction (2.63%), extracellular matrix organization (2.63%).

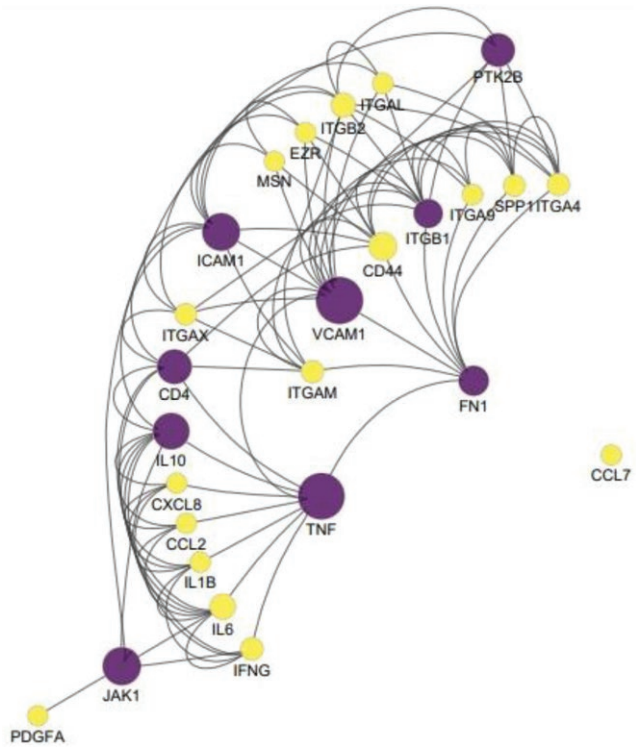

Figure 1. Protein-protein interaction network (PPI)

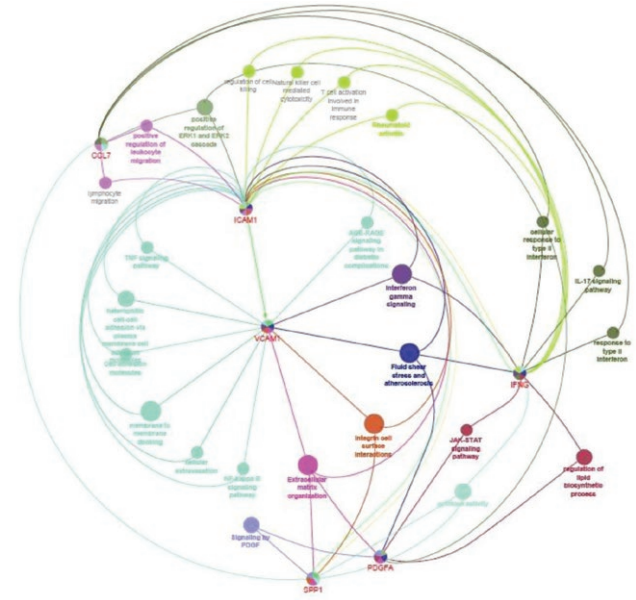

Figure 2. Molecular function and Pathway analysis

Conclusion: Cytokines related to "Inflammaging" shown significant relationship with arterial stiffness parameters measured in RA patients and IL-10 in OA group. These representative nodes/proteins were related with cellular adhesion, MAPK activation pathway and proinflammatory responses showing that those are key processes in arterial stiffness and rheumatoid arthritis.

APPLICATION OF THE EULAR SYSTEMIC SCLEROSIS IMPACT OF DISEASE (SCLEROID) QUESTIONNAIRE IN AN ITALIAN COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS: ANALYSIS OF PATIENT-REPORTED OUTCOMES AND THEIR ASSOCIATION WITH MAIN DISEASE FEATURES

Keywords: Patient reported outcomes, Outcome measures, Systemic sclerosis

I. Bisconti[1], D. M. Reza Beigi[1], G. Pellegrino[1], M. Cadar[1], F. R. DI Ciommo[1], K. Stefanantoni[1], S. Truglia[1], F. Conti[1], V. Riccieri[1]. [1]*Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Roma, Italy*

Background: Systemic sclerosis (SSc) is characterized by a chronic and frequently progressive course and by a high patient-to-patient variability. Due to the lack of disease-specific, patient-reported outcome measures for use in clinical trials and in clinical practice, EULAR recently validated the Systemic Sclerosis Impact of Disease (ScleroID) questionnaire, calculated as a composite score of 10 different health dimensions with Numeric Rating Scales (NRS) from 0 to 10 (from best to worst)(Figure 1). For each dimension, the NRS score is multiplied by the specific weight for its item and the weighted scores are summed up.

Objectives: The aim of this study was to apply ScleroID questionnaire to an Italian cohort of patients affected by SSc and to find any possible association with their main demographical, clinical and serological features.

Methods: 55 consecutive patients with SSc (defined by 2013 ACR/EULAR criteria) were enrolled, ScleroID was administered. Socio-demographic variables and clinical features were recorded. Data were analyzed using GraphPad Prism 8 software. Wilcoxon nonparametric test was used to compare data. Spearman's rank correlation coefficient was used and Linear regression analysis (r correlation coefficient) was employed to identify significant correlations, defined by a p value <0.05.

Results: The main demographic, clinical and serological features of the study population are shown in table 1. ScleroID total score median value of our patients was 42 (IQR 21-57). Significant associations were found among the presence of DU and higher values in the domains of Raynaud's phenomenon (p 0.03), impaired hand function (IHF)(p 0.005), pain (p 0.013), life choices (LC)(p 0.03) and body mobility (BM)(p 0.01). Anti-SCL70 positivity was associated with higher DU domain score (p 0.01). Diffuse SSc form was associated with higher values of IHF (p 0.006), pain (p 0.02), LC (p 0.002), BM (p 0.0005) and DU domains (p 0.003). Moreover, a positive correlation was found between mRSS and IHF (p 0.02), LC (p 0.006), BM (p 0.02) and DU (p 0.04), as well as between lower gastrointestinal symptoms domain and age (p 0.02). A higher ScleroID global score was associated with the diffuse SSc form (p 0.002), the use of immunosuppressive therapy (p 0.01) and the presence of DU (p>0.0001). Finally, this last result was confirmed on multivariate analysis (p0.007).

Conclusion: Our results confirm the reliability of ScleroID questionnaire in the real life of ScS patients, highlighting the impact of an extensive cutaneous involvement and the presence of DU in several health quality dimensions. Thus ScleroID appears to be a valid and easy to perform tool, able to assess the disease activity by a patient reported outcome.

How much have the different aspects of systemic sclerosis affected you during the last week? Please mark your responses on the scale by choosing the appropriate number for each of the following dimensions:

Raynaud's phenomenon:
Circle the number that best describes the severity of your Raynaud's phenomenon during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Hand function:
Circle the number that best describes your hand function limitations due to your systemic sclerosis during the last week:
No limitation 0 1 2 3 4 5 6 7 8 9 10 Extreme limitation

Upper gastrointestinal tract symptoms (e.g. swallowing difficulties, reflux, vomiting):
Circle the number that best describes the severity of your upper gastrointestinal tract symptoms due to your systemic sclerosis during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Pain:
Circle the number that best describes the pain you felt due to your systemic sclerosis during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Fatigue:
Circle the number that best describes the impact of overall fatigue due to your systemic sclerosis during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Lower gastrointestinal tract symptoms (e.g. bloating, diarrhea, constipation, anal incontinence):
Circle the number that best describes the severity of lower gastrointestinal tract symptoms during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Limitations of life choices and activities (e.g. social life, personal care, work):
Circle the number that best describes how severe the limitations of life choices and activities due to your systemic sclerosis were during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Body mobility:
Circle the number that best describes how much your body mobility was affected due to your systemic sclerosis during the last week:
Not affected 0 1 2 3 4 5 6 7 8 9 10 Extremely affected

Breathlessness:
Circle the number that best describes how severe your breathlessness due to systemic sclerosis was during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Digital ulcers:
Circle the number that best describes how much your digital ulcers affected you overall during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

THE IMPACT OF FASTER DIAGNOSIS THROUGH ARTIFICIAL INTELLIGENCE ON THE QUALITY OF LIFE OF PATIENTS WITH RARE DISEASES

Keywords: Quality of life, Descriptive Studies, Artificial Intelligence

L. Willmen[1], L. Völkel2, T. Willmen2, A. Pankow2, R. Rychlik[3], T. Deckersbach[4], S. Geyer[5], A. D. Wagner2. *[1]Department of Nephrology, Department of Nephrology, Hannover, Germany*; *[1]Department of Nephrology, Department of Nephrology, Hannover, Germany*; *[3]Institute for Empirical Health Economics, Institute for Empirical Health Economics, Burscheid, Germany*; *[4]Psychology, Psychology, Bad Sooden-Allendorf, Germany*; *[5]Medical Sociology, Medical Sociology, Hannover, Germany*

Background: Diseases that affect fewer than 2000 people in the general population are defined as rare diseases [1]. The rarity and the associated limited experience with these diseases, but also the large number of about 8000 rare diseases [2], pose a major diagnostic challenge for physicians. On average, affected patients need 5.6 to 7.6 years until they receive a diagnosis and thus the correct therapy [3]. These diagnostic odysseys place a heavy financial, health, and psychological burden both on patients and their families. Diagnostic decision support systems (DDSS) have great potential to assist physicians in diagnostic decision-making and can indicate the presence of a rare disease much earlier. An exploratory study conducted at the Outpatient Clinic for Rare Inflammatory Systemic Diseases with Renal Involvement at Hannover Medical School showed that the diagnostic process can be shortened by a DDSS. The median lead between diagnosis and the hypothetical time of diagnosis by a DDSS was three months [4]. A follow-up study showed that health economic savings were also possible by making the diagnosis so early [5].
Objectives: Measured against the hypothetical diagnosis time points determined in the previous study [4], this study aimed to investigate, in the same patient population, the extent to which earlier diagnosis using a DDSS would have influenced patients' quality of life (QOL).
Methods: To determine the potential for improving QOL through artificial intelligence (AI), 71 patients from the patient cohort of the previous studies were surveyed [4][5]. The questionnaire was composed of established questionnaires such as the WHO HPQ and the SF-36. In five interview sessions from the onset of the disease, the time of professional diagnosis, to the current time, the development of QOL was retrospectively recorded. To analyze the development of QOL during the disease, but also to show the influence of the DDSS on QOL, data were also collected for the time points at which the DDSS would have indicated the correct diagnosis as the first suggestion or among the first five suggestions.
Statistical analysis, graphical presentation and interpretation of the questionnaires were performed using statistical software.
Results: The study showed that the QOL of most patients improved with a correct diagnosis. The graphically depicted progression of the patients' health perception are shown in **Figure 1**: with the onset of the first symptoms, 65% of the patients found their state of health to be less good or bad, in course of disease, this number increased to 70%. At the current time, the time of the interviews, the number declined to 28%. Originally, no patient was in excellent health, but at the current condition after the diagnostic odyssey, 10% were able to describe their state of health as excellent. The interviews show an overall decline in well-being during the diagnostic odyssey, which slowly increases with the correct diagnosis.
Conclusion: The study showed how much a correct diagnosis affects the patients' QOL. The use of a DDSS would have significantly shortened the diagnostic odysseys and thus improved patients' QOL at an earlier stage.

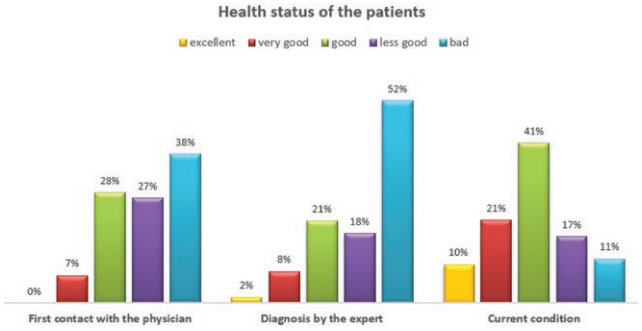

Figure 1. Retrospective development of health perception over the course of the disease among the study participants (n=71). Displayed are the results as an extract of the SF-36.

DOCUMENT SEARCH IN LARGE RHEUMATOLOGY DATABASES: ADVANCED KEYWORD QUERIES TO SELECT HOMOGENEOUS PHENOTYPES

Keywords: Artificial Intelligence, Systemic lupus erythematosus, Systemic sclerosis

C. Gérardin[1], Y. Xong[1,2], A. Mekinian[3], F. Carrt[4], X. Tannier[5]. *[1]IPLESP, UMR1136 INSERM, Paris, France*; *[2]Shanghai Unversity, Shanghai Jiaotong University, Shanghai, China*; *[3]Service de Médecine Interne and Inflammation-Immunopathology-Biotherapy Department (DMU 3iD), Hôpital Saint-Antoine, APHP, Sorbonne Université, Paris, France*; *[4]Institute Pierre Louis Epidemiology And Public Health, UMR1136 INSERM, Paris, France*; *[5]LIMICS, Sorbonne Université, Inserm, Université Sorbonne Paris Nord, Paris, France*

Background: Natural language processing tools are powerful for mining rheumatology databases, extracting patient information directly from clinical notes. However, these algorithms come with a high computational cost and are often not applicable at the scale of very large databases in the temporality of clinical practice.

Objectives: The objective of our study is the automatic detection of clinical documents of interest for a specific clinical question, with low computational cost, to be applied on a database of millions of documents. These sets of documents of interest constitute a pre-screening to allow the development of more complex algorithms.
Methods: The task was considered as an information retrieval task in French clinical texts. Two different methods were compared. For the first method, we used several state-of-the-art document vector representations: TF-IDF, doc2vec, docBERT and tested if the closest documents are relevant. The second method consists in building a powerful query expansion from a key term entered, its French synonyms from the UMLS and the synonyms found by similarity with the embeddings of the CODER algorithm. These methods are developed and evaluated on a set of 8 and on 20 phenotypes respectively (e.g. "pericarditis in lupus", etc.). Our database corresponds to 2 million documents from a cohort of patients suffering from four autoimmune diseases: systemic lupus erythematosus, scleroderma, antiphospholipid syndrome, and Takayasu's disease, coming from the AP-HP's data warehouse.
Results: Our experience does not support the vector representation model of clinical notes for searching similar patients. However, searching with an advanced synonym search method can lead to very good results without additional burden for the clinician: we achieved a precision (or positive predictive value) of 0.93 [0.90; 0.96] evaluated manually by a physician and a recall (or sensitivity) of 0.78 [0.71; 0.85] evaluated on the basis of the ICD10 codes of the retrieved patients.
Conclusion: We propose a new advanced keyword search method with automatic synonym search with very good accuracy and recall performance.

Background: Immune checkpoint inhibitors (ICI) have changed the landscape of treatment for many cancers. However, most cancer clinical trials for ICI excluded patients with pre-existing autoimmune disease (PAD). Efficacy and safety data on the use of ICI in patients with rheumatic PAD (Rh-PAD) is limited to retrospective case series and reports, and many do not differentiate between Rh-PAD and non-rheumatic PAD. In addition, little is known about optimal use of concurrent immunosuppression and its impact on PAD flares and development of de novo irAE. There is some data that patients on immunosuppression at baseline are at risk for poorer tumor outcomes [1].
Objectives: To explore the safety and efficacy of ICI in patients with Rh-PAD and to determine if immunosuppression at baseline impacts risk of PAD flare, de-novo irAE and early tumor outcomes using data from the CanRIO prospective cohort.
Methods: The CanRIO cohort includes adult patients with Rh-PAD treated with immune checkpoint inhibitors (ICI, including CTLA-4, PD-1 or PDL-1 inhibitors), recruited across 9 Canadian academic sites and followed prospectively at regular intervals as per a standardized study protocol. In this study, we evaluated patients with Rh-PAD who received at least one dose of ICI.
Results: Forty patients with Rh-PADs were recruited into the CanRIO prospective cohort between Jan 2020 and Nov 2022, including 14 (35%) with rheumatoid arthritis, 11 (27.5%) psoriatic arthritis, 7 (17.5%) polymyalgia rheumatica, 5 (12.5%) ankylosing spondylitis and 7 (17.5%) other. The most frequently observed cancers were melanoma 14 (35%) and lung cancer 10 (25%), with stage 3 and stage 4 disease each making up 37.5% of all cases. 25 patients (62.5%) were on baseline immunosuppression prior to ICI start. Anti-PD-1 therapy was most common (45%), followed by combination ICI therapy (22.5%), with a median exposure of 2 months (IQR: 0.5-3.0). Over a median (IQR) follow-up of 3.0 (1.0–6.0) months, 55% experienced a de-novo irAE (68.2% with rh-irAE; of which 46.7% were on baseline immunosuppression), 25% had Rh-PAD flare, of which 60% were on baseline immunosuppression. Of these, 40% were severe (of which 50% on baseline immunosuppression); 70% required corticosteroid treatment; and 40% required a change in immunosuppression. ICI was continued in 50%, transiently held or delayed in 40% and stopped in only 10%. Of the 9 patients on baseline immunosuppression who had been re-staged, 8 had a favorable tumor response (i.e., stabilization, partial or complete response) and only 1 had disease progression.
Conclusion: Early data from patients with Rh-PAD in the CanRIO multi-center prospective cohort suggests that (1) ICI can be effective for cancer treatment in patients with Rh-PAD and should be offered as indicated; (2) flares of Rh-PAD are common but can be managed with corticosteroids or escalation of immunosuppression; (3) baseline immunosuppression did not significantly change rate of de-novo irAE or rate/severity of PAD flare (3) most patients with Rh-PADs had good tumour response despite baseline immunosuppression.

AB1769-HPR **HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SEPTAL PANNICULITIS**

Keywords: Quality of life

G. Koilubaeva[1], O. Egorova[2], A. Bolotbekova[1], A. Turatbekova[1], G. Syunbai K[1].
[1]3 Togolok Moldo St, Rheumatology, Bishkek, Kyrgyzstan; *[2]Kashirskoye Shosse, 34, Rheumatology, Moskva, Russian Federation*

Background: Idiopathic lobular panniculitis (ILP) or Weber-Christian disease is a rare understudied disease, which manifests itself in recurrent *subcutaneous fat* necrosis often involving damage of the internals. Treatment of the disease is not standardized, and as a matter of fact it is provided empirically.
Objectives: to assess the efficiency of therapy in case of various forms of ILP.
Methods: We studied 34 patients (30 women, 4 men) with ILP, age 30-74, duration of disease 7.4±2.3 years. Besides general clinical examination we determined the level of *α1-antitrypsin,* amylase, lipase, *ferritin, creatine phosphokinase,* made chest CT scan *and carried out the pathomorphological study* of *skin biopsy specimen taken from the area of a node*. The following forms of the disease were identified: nodular form (NF) (14 patients), plaque form (PF) (9 patients), mesenteric form (MF) (5 patients) and infiltrative form (IF) (6 patients). In all cases the lobular panniculitis was verified by means of histopathological examination. All patients took glucocorticoids (GC), average daily dose of 12.8 ± 1.6 mg, including 8.4± 1.7 mg (for NF), 17.6± 3.2 mg (for PF), 8,6 ± 1,6 mg (for MF), 23.6 ± 5.3 mg (for IF). In case of NF, we additionally prescribed Plaquenil, the dose of 600 mg per day (8 patients), and Mycophenolate Mofetil 1.5-2 g per day (6 patients); in case of PF – Cyclophosphamide (Cph), the dose of 200 mg per week (4 patients) or Mycophenolate Mofetil (1.5-2 g per day, 5 patients); in case of MF – Mycophenolate Mofetil (1.5-2 g per day, 5 patients). Patients with IF took Cph (200 mg per week). In case there was no effect after 3 months, we prescribed Mycophenolate Mofetil (1.5-2 g per day). With an unsatisfactory effect, after 3 months, genetically engineered alpha-TNF antagonist drugs were used. On average, the observation period was 12 months.
Results: The treatment made it possible to achieve a significant positive dynamics in patients with NF, PF and MF: the body temperature got back to normal and there was regression of indurations (26 patients), joint pain intensity was reduced (16 patients), laboratory data on inflammatory intensity revealed decrease (24 patients). Average daily dose of GC was reduced to 4.5±0.7 mg and 11.4±1.1 mg, respectively. In general, a significant improvement was evident in all patients with NF and MF, in 75 % of patients with PF. In case of IF an average daily dose was increased to 25.4±1.7 mg per day. In all patients of this group, an unsatisfactory effect was noted, which required discussion of the appointment of genetically engineered biological therapy. The tolerability of treatment was regarded as good, no adverse events were noted. After 14 weeks, 3 patients had a syndrome of "eluding" the effect and IL-1 inhibitor drugs were prescribed for the first time.
Conclusion: To work out dosages and treatment schedules for patients with ILP further studies are required.

Background: Hydroxychloroquine (HCQ) remains one of the most valuable therapies in SLE, and its use is supported by every recent international guideline regardless of the severity of the disease. It is however associated with long term side effects, mainly ophthalmologic whereby is recommended ophthalmologic screening. Little is known on the risk of systemic lupus erythematosus (SLE) flares associated with hydroxychloroquine (HCQ) reduction or cessation, especially following ophthalmologic screening.
Objectives: We analyzed the risk of SLE flares after HCQ reduction or cessation in the context of detection of early signs of ophthalmological toxicity.
Methods: Among 109 patients included in the prospective PERFOCTAPS study and treated with HCQ for at least 5 years, we included all patients with SLE. Patients were divided in three groups: group maintenance corresponding to patients with no ophthalmological alterations maintaining their treatment at the same dose, group reduction corresponding to patients with mild ophthalmological alterations that led to reduction of HCQ dose, and group discontinuation corresponding to patients with retinal abnormalities that led to stopping HCQ. Occurrence of flares (SELENA-SLEDAI flare index) was assessed in the two years following HCQ reduction or discontinuation or following inclusion in PERFOCTAPS study for the maintenance group.
Results: 85 patients were included (98% female, mean age 40.0 years, mean duration of SLE 14.4±7.7 years and of HCQ treatment 12.9±7.2 years, mean dose per kilogram of HCQ was 5.6±1.8 mg/kg/day). PERFOCTAPS study identified ophthalmological abnormalities in 25 patients (29.4%) that led to dose reduction in 20 patients and discontinuation in 5. At inclusion groups maintenance and reduction were very similar; patients in group discontinuation were significantly older with a longer SLE and HCQ treatment duration. There was no significant difference in HCQ dose (mg/kg/day) between the three groups. After reduction, the proportion of patients with a dose of HCQ <5 mg/kg/day became significantly higher in the reduction group than in the maintenance group (85% vs. 35% P<0.001). Flares occurred in 29 patients (34.1%): 17 (28.3%) in the maintenance group, 10 (50%) in the reduction group, and 2 (40%) in the discontinuation group. Flares were severe in 6 patients (10%) in the maintenance group, 4 (20%) in the reduction group and none (0%) in the discontinuation group. After adjustments on potential confounders, HCQ reduction was independently associated with the risk of flare (adjusted HR 2.57; 95% CI 1.14-5.75). The same trend was observed in the discontinuation group but without reaching statistical significance (adjusted HR 3.03; 95% CI 0.66–13.87).
Conclusion: In this prospective study, HCQ reduction due to an early suspicion of retinal toxicity was associated with a statistically significant increased risk of disease flare. This adds data to the growing pendulum return regarding HCQ dose reduction and we should always balance the potential benefits of tapering or discontinuing HCQ with the risk of SLE flare and subsequent need to increase or start other drugs, especially corticoids or immunosuppressors that have well-known adverse effects.

Background:
Objectives: To explore rheumatologists' reasons for non prescription of pneumococcal vaccination in CIRD patients and to collect solutions proposed by rheumatologists.
Methods: This is a cross-sectional study carried out by the vaccination working group of the Moroccan Society of Rheumatology. The survey collected data on reasons of pneumococcal vaccination abstinence in rheumatology practice, and solutions proposed to improve pneumococcal vaccination in CIRD patients.
Results: This survey included 125 rheumatologists (mean age 42.4 +/-12.1 years). The sector of practice was respectively 31.2 %,34.4 %,34.4 % for the public sector, private sector and University Hospital. 36.9% of rheumatologists have never prescribed pneumococcal vaccination for their CIRD patients. Table 1 illustrate reasons given by rheumatologists for non vaccination of their CIRD patients against pneumococcal infection.

Table 1. Reasons for not prescribing the pneumococcal vaccine

I don't vaccine my CIRD patients because	%
The pneumococcal vaccine is not recommended for CIRD patients	2,4
The pneumococcal vaccine is expensive	30,4
I don't master enough the protocol	40,8
I forget to prescribe it	57,6
Patients refuse the pneumococcal vaccination	10,4

Concerning proposed solutions, rheumatologists recommended reinforcing pneumococcal vaccination awareness among rheumatologists, Integrating the vaccine into the social security reimbursement protocol, and including the pneumococcal vaccination for CIRD patients in respectively 92 %,71.2 %,60 % of cases.

Conclusion: The main obstacles to the pneumococcal vaccination prescription by rheumatologists are related to the lack of knowledge of vaccination protocol and the forgetfulness. Therefore, the Optimization of pneumococcal vaccination would necessarily focus on combating the obstacles to this preventive practice in CIRD patients.

HPR Interdisciplinary research

AB1773-HPR CONNECTIVE TISSUE DISEASE-RELATED INTERSTITIAL LUNG DISEASE: AN EXPERIENCE OF A MULTIDISCIPLINARY TEAM IN COLOMBIAA

Keywords: Lungs, Descriptive Studies, Imaging

C. Borda Samper[1], J. S. Sierra[2], D. G. Fernández-Ávila3, C. Celis Preciado[2], M. Díaz3. *[1]Hospital Universitario San Ignacio, Rheumatology, Bogota, Colombia*; *[2]Hospital Universitario San Ignacio, Pulmonology, Bogota, Colombia*; *[1]Hospital Universitario San Ignacio, Rheumatology, Bogota, Colombia*

Background: Interstitial lung disease (ILD) occurring in a person with a known or classifiable connective tissue disease (CTD) is referred as CTD-ILD. Approximately 15% of ILDs will have a background CTD. The presence of ILD is the primary determinant of prognosis. High-resolution CT (HRCT) is the diagnostic image of choice. Interstitial involvement can have different patterns, with nonspecific interstitial pneumonia (NSIP) being the most frequent. CTD-ILD is a challenging entity and its approach requires multidisciplinary teams (MDT).
Objectives: To describe clinical, serological, and radiological characteristics of patients who present with CTD-ILD at a reference ILD center in Colombia between 2021 and 2022
Methods: A descriptive study of patients with ILD diagnosed by HCTR who have a confirmed autoimmune disease or at least one autoimmune feature, clinical or serological. Every case was evaluated by our MDT composed by pulmonologists, radiologists, rheumatologists, and pathologists. We developed an ILD registry from our inpatient and outpatient ILD-clinic between 2021 and 2022. The continuous variables were described as the mean and standard deviation, and nominal variables were evaluated based on frecuencies and percentages. All analysis were done in statistical package for the social sciences (SPSS) v. 21.0.
Results: Forty patients with ILD were included; 57% were hospitalized, and 65% were women. The majority of patients with ILD were diagnosed as interstitial pneumonia with autoimmune features (IPAF, 30%), followed by multiple autoimmune syndromes (22,5%), rheumatoid arthritis (15%) and primary Sjogren's syndrome (12,5%). The most common radiologic pattern was usual interstitial pneumonia (40%), followed by fibrotic NSIP (22.5%). The most common clinical finding where lung crackles (61,5%), sicca symptoms (57,5%) and arthritis (30%). Mean CVF in L(%) was 173 ± 89,8(72,6±27,2) and mean DLCO(%)52,6 ± 21. Progressive pulmonary fibrosis was frequent (20%), and 12.5% received antifibrotic therapy. Our mortality rate related to ILD was 21.7%.

Table 1. General characteristic of patients with CTD-ILD

Characteristic	N= 40
Age - yr	65 ± 11.6
Female sex – no. (%)	26 (65)
Inpatient – no (%)	23 (57,5)
Mortality – no. (%)	5 (21,7)
Diagnosis confirmed by biopsy	9 (22,5)
Autoimmune disease no. (%)	N= 40
SLE¥	1 (2,5)
SSp ¥	5 (12,5)
RA¥	6 (15)
SSc¥	3 (7,5)
AAV ¥	1 (2,5)
IPAF¥	12 (30)
Poliautoimmunity & multiple autoimmune syndrome	9 (22,5)
Radiologic pattern no. (%)	
NSIP¥	5 (12,5)
Fibrotic NSIP¥	9 (22,5)
NSIP & OP ¥	1 (2,5)
UIP ¥	16 (40)
UIP & OP¥	2 (5)
Indeterminate UIP ¥	3 (7,5)
Probable UIP¥	2 (5)
OP¥	2 (5)

¥SLE systemic lupus erythematosus, SSp: Sjogren syndrome, RA: rheumatoid arthritis, SSc: systemic sclerosis,AAV: anti-neutrophil cytoplasmic antibody-associated vasculitis, IPAF: Interstitial pneumonia with autoimmune feature,NSIP: non-specific interstitial pneumonia, OP: organizing pneumonia, UIP: usual interstitial pneumonia

Conclusion: In our 1-year cohort, we found that IPAF was the most prevalent CTD-ILD, followed by multiple autoimmune syndromes. The most common radiologic pattern overall was UIP, followed by fibrotic NSIP. CTD-ILD had a high mortality rate. Most of these cases were related to ILD. Our results highlight the importance of early disease detection and early therapeutic interventions. Treatment decisions must be individualized, and the risk of disease progression must be considered.

AB1774-HPR SAFETY OF THE RECOMBINANT HERPES ZOSTER VACCINE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH JAKI DRUGS

Keywords: Epidemiology, Vaccination/Immunization, Health Services Research

A. Pons-Bas[1], J. Rosas[1], L. Pons-Canet[1], J. M. Senabre-Gallego[1], G. Santos Soler[1], J. A. Bernal[1], J. C. Cortés-Quiroz[1], C. Raya-Santos[1], R. Gallego-Campuzano[1], M. Lorente Betoret[2], X. Barber[3], J. A. García-Gómez[3]. *[1]Hospital Marina Baixa, Rheumatology, Villajoyosa, Spain*; *[2]Hospital Marina Baixa, Rheumatolgy, Villajoyosa, Spain*; *[3]Universidad Miguel Hernández de Elche, CIO, Elche, Spain*

Background: Patients receiving JAK inhibitor drugs (JAKi) have an increased risk of herpes zoster (HZ). A new recombinant vaccine effective against HZ (Shingrix-RV) is currently recommended for patients treated with JAKi.
Objectives: To evaluate the safety of first and second dose of the recombinant vaccine against HZ (HZ-RV) in patients with RA, in treatment with JAKi.
Methods: Retrospective study of the safety after receiving the first and after 2 months, second dose of the HZ-RV in patients with RA treated with JAKi.
The following variables were collected: general information of the patients, type of JAKi and time in treatment; use and dosage of DMARDcs drugs and/or corticosteroids. Regarding HZ: infection prior to HZ-RV and time elapsed; occurrence and type of side effects after vaccination.
Results: Of 138 patients treated with JAKi, 9 (7%) refused vaccination, 129 (93%) received the first dose on HZ-RV, but 38 (28%) patients received it before starting JAKi and 98 (72%) being a mean of 36 months in treatment with JAKi. The second dose was administered in 113 (82%) patientes, 21 (15%) patients had suffered HZ, before vaccination. One hundred and eight (84%) are female (mean age: 64 [SD: 3] years), on JAKi treatment a mean of: 2.4 (SD: 1.6) years: 89 (69%) baricitinib (2 mg/day: 29 [33%] patients; 4 mg/day: 60 [67%]), upadacitinib: 48 (44%) and 3 (3%) patients with tofacitinib. Eighty seven (67%) patients were receiving DMARDcs: methotrexate: 55 (63%), mean weekly dose: 17.5 mg (SD: 3.5), leflunomide: 22 (25%), hydroxychloroquine: 8 (9%), sulfasalazine: 2 (2%). Fity six (40%) patients received prednisone: mean daily dose: 5.2 mg (SD: 1.8). During one month after first dose of vaccine, 97 (75%) and 62 (55%) after second dose had side effects (p=0.68): local pain: 95 (74%) vs 62 (55%) patients, p=0.014; fatigue: 27 (21%) vs 15 (13%), p=0.17; arthralgia-myalgia: 21 (19%), p=0.17; fever < 38ºC: 10 (8%) vs 15 (13%), p=0.69; headache: 9 (7%) vs 3 (3%), p=0.72; local itching: 3 (2%) vs 2 (2%), gastrointestinal symptoms: 2 (2%) vs 2 (3%), p=0.943; and after first dose, others in 4 (4%) patients: urinary tract infection, oral ulcer, dizziness, injection site erythema. Lymphadenopathy, hospital admission, flare of RA or serious secondary effects were not detected. After 90 days of second vaccine, a 58-year-old woman (0.8%) undergoing 5-month treatment with baricitinib 4 mg/day and methotrexate, without corticosteroids, presented a slight facial HZ reactivation dose.
Conclusion: 1. Vaccination with HZ-RV was safe. 2. Although a great percentage of pacients have experienced any side effect, especially after the first dose of vaccine, these were mild. 3. No flare of RA has been detected in this period. 4. Less than 1% of patients suffered HZ reactivation after vaccination.

AB1775-HPR

ECONOMIC BURDEN OF PRENATAL CARE FOR WOMEN WITH RHEUMATIC DISEASES

Keywords: Health Services Research, Pregnancy and reproduction, Quality of life

C. M. Skinner Taylor[1], L. Pérez Barbosa[1], J. A. Cardenas-de la Garza[1], A. Carrazco Chapa[1], M. E. Corral Trujillo[1], F. R. Arevalo Nieto[1], A. L. Guajardo Aldaco[1], A. Aguilar-Leal[1], D. Á. Galarza-Delgado[1]. [1]Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico

Background: Autoimmune rheumatic diseases (ARDs) affect childbearing women. To prevent adverse maternal and fetal outcomes, multidisciplinary attention is needed, leading to increased costs of pregnancy attention [1].The financial burden that pregnant women with ARDs have,lacksprofound research.
Objectives: This study aims to estimate the total cost of prenatal care in pregnant women with ARDs in northeast Mexico.
Methods: A cross-sectional and descriptive study was carried out at the University Hospital "Dr. Jose E. Gonzalez", offering affordable care to uninsured patients. We estimatedthe direct costs of prenatal care for women with rheumatoid arthritis(RA), systemic lupus erythematosus (SLE), and Sjögren's syndrome(SS) from the ACR/ EULAR perspective[2, 3]. National standardswere used to determine the regular prenatal care requirements [4].To calculate the total expense, prices declared by the University Hospital in 2021 were used. The used currency is USD, considering an equivalence of USD 1 = 20.28 MXN. Calculating indirect costs, such as transportation, medication, or other interventions, was not performed. No sociodemographic data from patients was used.
Results: The itemized costs for medical appointments, ultrasounds, laboratory tests and vaginal delivery or cesarean section for women without ARDs, with SS, RA andSLE are in **Table 1.**Prenatal care total costs for women without ARDs, with SS, RA and SLE are exposed in **Figure 1.** Our findings reported an average cost of pregnancy per trimester was up to 102.76% in women with ARDscompared to women without ARDs (USD 386.52 vs 783.72) Limitations include the variability of service prices and the absence of indirect cost calculations.
Conclusion: In conclusion, ARD-affected women had a high economic burden secondary to prenatal costs. In this vulnerable population, creating programs for prenatal care that consider the patient's financial statusshould be a priority for public health officials and institutions.

HPR Interventions (educational, physical, social and psychological)

AB1776-HPR

REVMAMAS – A PODCAST FOR PEOPLE WITH RHEUMATIC DISEASE WHO ARE PLANNING A PREGNANCY OR ARE PREGNANT

Keywords: Patient information and education, Pregnancy and reproduction

B. Jakobsen[1], L. Helbostad[1], N. Lian[2], I. R. Nilssen[1]. [1]*St.Olavs Hospital, Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Trondheim, Norway*; [2]*St.Olavs Hospital, Department of Communications, Trondheim, Norway*

Background: A survey distributed by patient organisations in rheumatology in 2019 have uncovered an unmet need for high quality and accessible patient information on pregnancy and rheumatic diseases. Previous publications have presented the same results (1, 2). During the pandemic, we have seen a shift from healthcare with physical consultations to digital follow-up of the inflammatory rheumatic disease. The Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases (NKSR) primary task is to spread updated knowledge, including patient information, regarding different aspects of pregnancy and rheumatic diseases. To reach out to the target population in this digital era, NKSR have started using social media, such as Facebook and Instagram, in addition to YouTube to spread patient information. As a natural next step we wanted to establish a podcast on different topics related to pregnancy and rheumatic diseases so patients and partners could have easy access to high quality reliable information at all times and for all of Norway.
Objectives: To develop a podcast with different topics related to pregnancy and rheumatic diseases. The podcast is primary aimed at people with inflammatory rheumatic disease and their partners, but is also relevant for healthcare professionals.
Methods: Based on webinars published on YouTube from NKSR during the pandemic, we edited and published six podcast episodes. We had help from the department of communications to adjust the podcast for publication. We chose a platform for podcasts without fees and easy access to make sure it was available for everyone.
Results: We published six podcast episodes as season one. A multidisciplinary team with rheumatologist, nurse, midwife, patient representatives, partner and occupational therapist participated in the podcast. The episodes have the following topics: Planning a pregnancy, preparing for birth, patient experience, fatigue and everyday activities with small children, partners perspective and men and anti-rheumatic medications. The episodes lasts from 16 to 27 minutes. The podcast is available on the most used platforms for podcast listeners in Norway. We used NKSR platforms in social media to spread the word about the podcast.
Conclusion: Using podcast as a platform to spread high quality and knowledge based patient information can be effective to increase accessibility of patient information. The episodes are available on demand, regardless of where you live. People with rheumatism can stream the short episodes whenever convenient, for example in the car, one the buss to work, when walking the dog or when doing chores. Planning of season two has already begun.

INVESTIGATION OF THE EFFECT OF HAND EXERCISES ON GRIP STRENGTH, FUNCTIONALITY, DISEASE ACTIVITY AND QUALITY OF LIFE IN INDIVIDUALS WITH PSORIATIC ARTHRITIS: A RANDOMIZED CONTROLLED TRIAL

Keywords: Randomized control trial, Psoriatic arthritis, Physical therapy/ Physiotherapy

S. Yardım[1], S. Y. Cetin[1], A. Ayan[2]. [1]*Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey*; [2]*Health Sciences University, Division of Rheumatology, Antalya, Turkey*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory musculoskeletal disease accompanied by psoriasis in the spondyloarthritis group and often progresses with peripheral arthritis, dactylitis, enthesitis and spondylitis [1]. Majority of PsA patients have peripheral arthritis involvement [2]. In addition to peripheral arthritis in PsA patients, structural damage occurs in the joints as the process is chronic and progressive. This structural damage causes worsening of the functional status of the patients [3]. Worsening functionality reduces patients' quality of life. Also EULAR (Recent European League Against Rheumatism) recommends physical therapy in inflammatory arthritis including PsA [4]. It is known that individuals with PsA have lower hand strength, dexterity, coordination and functionality compared to their healthy peers [5]. There is no scientific study that applies a hand-focused home exercise program to improve the grip strength and functionality of the hand in individuals with PsA.
Objectives: The aim of this study was to examine the effect of hand exercises on grip strength, functionality, disease activity, and quality of life in patients with PsA.
Methods: 37 PsA patients (29female, 8 male) with an average age of 50.32± 9.12 were included in this study. Patients were randomized into intervention (group 1) and control (group 2) groups. Group 1 received hand home exercises for 4 days a week for 8 weeks. Group 2 was on the waiting-list and they received the same exercises when the study was finished. The Disease Activity Index for Psoriatic Arthritis (DAPSA) was used to evaluate the disease activity. Hand Dynamometer and pinchmeter was used to evaluate the hand grip and pinch strength. Duruoz Hand Index (DHI), Michigan Hand Outcomes Questionnaire (MHQ), Hand Functional Index (HFI), Nine Peg Hole Test (NPHT) were used to evaluate the hand functionality. Psoriatic Arthritis Quality of Life was used to evaluate the quality life. All evaluations were performed at baseline and at the end of the 8th week.
Results: When the groups were compared before training, there was no significant difference (p> 0.05). In post-training comparisons, there was a significant difference in MHQ, hand grip and pinch strength in hand exrecises group. (p:0.02-0.00). In addition, after post-training, hand exercises group was found to be superior in terms of MHQ and NPHT compared with control group.
Conclusion: According to this study, hand exercises have a positive effect on grip strength and functionality in patients with PsA. Hand exercises should be included in rehabilitation programs as a home exercise to improve grip strength, functionality and daily living activities for patients with PsA.

AB1779-HPR

ASSESSING THE INTERNAL VALIDITY OF THE BSR PAIN MANAGEMENT FOR INFLAMMATORY ARTHRITIS QIP TOOL

Keywords: Patient reported outcomes, Inflammatory arthritides, Pain

A. Bhatti[1], L. West[1], N. Shenker[1]. [1]*University of Cambridge, School of Clinical Medicine, Rheumatology, Cambridge, United Kingdom*

Background: Pain management is an important component of many Inflammatory Arthritis consultations. The BSR Pain Management for Inflammatory Arthritis Quality Improvement Tool uses 11 questions and 38 sub questions that assess three domains; background information (3 questions), pain management in the consultation (5 questions) and pain management in previous consultations (3 questions) [1]. The questions are based on the EULAR Guidelines for Pain Management in Inflammatory and Osteoarthritis [2]. The tool is free to use, produces results in real time in anonymised PDF form. The project is sponsored by Cambridge University Hospitals NHS Foundation Trust Audit Department (Number 2200).
Objectives: To assess the internal validity of the Pain Management for Inflammatory Arthritis Quality Improvement (QIP) tool 2020.
Methods: Two independent researchers (A & B) reviewed appointment/clinic notes from 33 patients who had attended Rheumatology appointments at Addenbrooke's Hospital. 20 of these patients were found to experience pain during the consultation and the QIP tool questionnaire was used to assess their pain management. To assess the internal validity of the QIP tool; results from each reviewer were compared to generate a Cohen's Kappa Score for each question.
Results: The overall Kappa Score for the QIP tool was 0.75, with 570 congruent results and 190 incongruent results. The congruence was found to be high across the majority of questions. 87/190 (46%) of the incongruent scores were from just 6/38 questions. The QIP tool questions can be modified to improve clarity. There was systematic bias in the questions with lower kappa scores (A answering "Yes" and B answering "No").
Conclusion: The Pain Management for Inflammatory Arthritis QIP Tool has a high internal validity as shown by the Kappa scores generated by results from two independent reviewers. To overcome the low Kappa scores on individual questions; additional guidance on how to answer specific questions may need to be provided to those filling out the questionnaire.

FIBROMYALGIA PATIENTS' EXPERIENCES AFTER ONE-WEEK SELF-MANAGEMENT PROGRAMME FOUR TO TEN MONTHS AFTER DISCHARGE: A QUALITATIVE STUDY

Keywords: Fibromyalgia, Qualitative research methods, Self-management

B. Hamnes[1]. [1]*Norwegian University of Science and Technology, Faculty of Medicine and Health Sciences in Gjøvik, Gjøvik, Norway*

Background: The European League Against Rheumatism (EULAR) emphasizes in its guidelines for the treatment of fibromyalgia (FM) that Health professional should aim to improve health-related quality of life, which often requires a combination of non-pharmacological and pharmacological treatment methods. Non-pharmacological approaches have been shown to be effective In this study, a multidisciplinary self-management programme (SMP) was used to treat patients with (FM).
Objectives: To investigate and understand the experiences of individuals with FM who participated in a one-week SMP.
Methods: A qualitative study using semi-structured interviews was used to investigate the participants' experiences. A total of 22 women and 2 men with

FM were interviewed 4 to 10 months after participating in a one-week SMP. The participants' goals and action plans after the SMP were used together with an interview guide. All the interviews were audio-recorded, transcribed verbatim and analysed using thematic analyses. The large body of material is divided into three sub-studies. The first sub-study is presented here.

Results: The mean age of the participants was 54.7 years (range 32–68). The participants' experiences were categorized into four main themes: recognition of the diagnosis, a turning point for a better life, changing one's way of thinking and having control over one's own life. Giving up the past was one description that the participants used as a way of changing their mindset. They could then focus more on the present and the future. To have control over their own lives, it became important to accept the opportunities and limitations they had in everyday life.

Conclusion: Four to ten months after completing the SMP, the participants in this study experienced that they were taken seriously with their FM diagnosis. The participants had attained a heightened awareness of what they could do to take control and manage their disease and daily life.

Acknowledgements: The author would like to thank all the informants who shared their experiences.

The study was supported by the Norwegian Fibromyalgia Association and the Norwegian Rheumatism Association.

AB1781-HPR PERFORMANCE OF A NURSE-LED INTERVIEW FOR MALIGNANCY SCREENING AND ALERTING PHYSICIAN PROGRAM

Keywords: Malignancy, Rheumatoid arthritis, Nursing

S. Tamaki[1], S. Fukui[2], M. Suda[3], H. Tamaki[4], M. Okada[4]. *[1]St.Luke's International Hospital, Department of Nursing, Tokyo, Japan*; *[2]Kyorin University Hospital, General and Emergency Medicine, Tokyo, Japan*; *[3]Suwa Central Hospital, Department of Rheumatology, Nagano, Japan*; *[4]St. Luke's International Hospital, Immuno-Rheumatology Center, Tokyo, Japan*

Background: Malignancy is one of the leading causes of death in patients with rheumatoid arthritis (RA). While there has been a debate about whether or not biological disease-modifying antirheumatic drugs (bDMARDs) increase cancer development in RA patients, these patients should be screened appropriately for their malignancies. However, there has been limited data about the method to increase malignancy screening.

Objectives: We implemented a nurse-led malignancy screening and alerting physician program into our daily clinical practice. The aim of this study is to evaluate the performance of this program.

Methods: Our program included patients with RA treated with intravenous biological DMARDs between September 2015 and October 2020. We first created a list of the required malignancy screening based on the patient's gender and age (Figure 1). Nurses interviewed the patients during the administration of bDMARDs to assess if they were appropriately screened for malignancies as required and thereafter provided education about the importance of malignancy screening. Nurses recorded the patient's malignancy screening status and alerted physicians by sharing the results if the patient needed additional screenings. This program was periodically repeated once a year. We assessed the difference in the proportions of completed per required screening between repeated assessment time points.

Results: A total of 154 patients were included in the analyses. The mean (standard deviation) age was 64.6 (13.2) at the first screening, and 113 (73.4%) were female. Ninety-three, forty-five, and fourteen patients underwent 2nd, 3rd, and 4th interviews, respectively. Repeating this program numerically increased the proportion of conducted malignancy screenings per required screening. (58.6%, 66.5%, 60.6%, and 73.1% at the 1st, 2nd, 3rd, and 4th interview, respectively) (Table 1). In addition, several patients understood, for the first time, the importance of malignancy screening during this interview with nurses.

Conclusion: Implementing a nurse-led interview for malignancy screening and alerting physician program numerically increased the screening of malignancy in RA patients treated with bDMARDs. This multi-disciplinary cooperation can potentially improve the quality of healthcare for patients with RA.

AB1782-HPR USABILITY AND ACCEPTABILITY OF A NEW AUTOINJECTOR DEVICE AND ITS ASSOCIATED APP IN RHEUMATOLOGY PATIENTS

Keywords: Self-management, bDMARD, Inflammatory arthritides

R. Alten[1], G. Citera[2], M. Latymer[3], D. C. Gruben[4], H. Kameda[5]. *[1]Schlosspark-Klinik University Medicine, Internal Medicine, Rheumatology, Berlin, Germany*; *[2]Instituto de Rehabilitación Psicofísica, Department of Rheumatology, Buenos Aires, Argentina*; *[3]Pfizer Ltd, I&I Medical Affairs, Sandwich, United Kingdom*; *[4]Pfizer, Global Biostatistics and Data Management, Groton, United States of America*; *[5]Toho University (Ohashi Medical Center), Division of Rheumatology, Tokyo, Japan*

Background: SMARTCLIC is a new reusable autoinjector with a dose-dispensing cartridge for subcutaneous self-administration of biotherapeutics for patients. The device can connect to the optional SmartClic mobile app to aid in tracking injections and other treatment or symptom data.

Objectives: The aim of this study was to assess patient opinion data on ease of use and usability of the SmartClic injector and app.

Methods: This study presents final data of all patients (N=264) from a global study. Patients from Argentina (n=50), Australia (n=15), Germany (n=46), France (n=28), Japan (n=75), and Spain (n=50), were included. After completing a patient profiling questionnaire, adult patients (≥18 years old) with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or juvenile idiopathic arthritis (JIA), and prescribed an injectable biologic, each received training to use the device and cartridge and performed simulated injections. Participants completed a device evaluation questionnaire with including the following categories: 'ease of use' (14 questions), 'usability effectiveness' (11 questions), 'benefit of device features' (8 questions) and 'form factor' (7 questions). Participants also received a storyboard presentation summarizing key features of the optional app, which they could test on an Android/or iOS device,

before completing up to 16 questions on connectivity and the app. Responses to device/and app questions were recorded as Likert scale ratings from 1 (extremely negative) to 7 (extremely positive). Estimates of patient training time for the device were also provided. Hand function based on the Functional Index of Hand Osteoarthritis Arthropathies (FIHOA) score, hand pain in the injection hand due to arthritis and grip strength were also recorded. Mean values are reported. The percentage of negative (Likert scale rating 1-2), neutral (3-5) and positive (6-7) responses for each category were determined.

Results: A total of 264 patients (mean age [range], 50 [18-85] years; 76% female) participated in the study. Patient diagnosis was, RA (71%), PsA (24%) and JIA (5%). The majority of patients (90%) were right-handed. While most patients (73%) always self-injected their medication, 19% of patients reported that they were mostly assisted with their injections or never self-inject. Most patients performed injection simulations using the dominant hand (77%) and chose the abdomen (54%), thigh (36%) or both (10%) abdomen and thigh as the injection site. Hand function based on the mean FIHOA score was 5.6 (range 0-24), and hand pain in the injection hand due to arthritis was 2.8 (range 1-7). Mean grip strength (range) was 19 (0-60) kg and 18 (2-54) kg in the dominant and non-dominant hand, respectively. Patients reported being “extremely comfortable” (58%) or “slightly comfortable” (35%) with digital equipment. Mean device evaluation scores (% positive responses) were: device ease of use 6.4 (87%), usability effectiveness 6.4 (87%), benefit of device features 6.6 (92%), form factor 6.2 (80%) and connectivity and app 6.2 (79%). The mean time (range) estimate for training a patient to effectively use the device and cartridge was 9.6 minutes (range 0-30 minutes).

Conclusion: Patients with RA, PsA or JIA, and experienced at receiving biologic treatment for their conditions, responded positively to the new autoinjector device and app across all categories. These features will contribute to a better experience of self-injection.

AB1783-HPR VALIDATION OF AN ELECTRONIC VISUAL ANALOG SCALE APP FOR PAIN EVALUATION IN CHILDREN AND ADOLESCENTS WITH SYMPTOMATIC HYPERMOBILITY: CROSS-SECTIONAL STUDY

Keywords: Mixed connective tissue disease, Patient information and education, Pain

M. Maarj[1], V. Pacey[2], L. Tofts[2], X. Garcia[3], M. Clapham[4], A. Coda[1]. *[1]Central Coast - Ourimbah Campus,The University of Newcastle,Australia, School of Health Sciences, College of Health, Medicine and Wellbeing, Ourimbah, Australia*; *[2]Macquarie University, Department of Health Sciences, Macquarie Park,Australia*; *[3]Facultat de Ciències de la Salut de Manresa, Universitat de Vic-Universitat Central de Catalunya, Manresa, Spain*; *[4]Hunter Medical Research Institute, Equity in Health and Wellbeing Research Program, New Lambton Heights,Australia*

Background: Rapid advances in mobile apps for clinical data collection for pain evaluation have resulted in more efficient data handling and analysis than traditional paper-based approaches. As paper-based visual analogue scale (p-VAS) scores are commonly used to assess pain levels, new emerging apps need to be validated prior to clinical application with symptomatic children and adolescents.

Objectives: This study aimed to assess the validity and reliability of an electronic visual analogue scale (e-VAS) method via a mobile health (mHealth) App in children and adolescents diagnosed with hypermobility spectrum disorder/hypermobile Ehlers-Danlos syndrome (HSD/HEDS) in comparison with the traditional p-VAS.

Methods: Children diagnosed with HSD/HEDS aged 5-18 years were recruited from a sports medicine center in Sydney (New South Wales, Australia). Consenting participants assigned in random order to the e-VAS and p-VAS platforms were asked to indicate their current lower limb pain level and completed pain assessment e-VAS or p-VAS at one time point. Instrument agreement between the 2 methods was determined from the intraclass correlation coefficient (ICC) and through Bland-Altman analysis.

Results: In total, 43 children with HSD/HEDS aged 11 (SD 3.8) years were recruited and completed this study. The difference between the 2 VAS platforms of median values was 0.20. Bland-Altman analysis revealed a difference of 0.19 (SD 0.95) with limits of agreement ranging -1.67 to 2.04. An ICC of 0.87 (95% CI 0.78-0.93) indicated good reliability.

Conclusion: These findings suggest that the e-VAS mHealth App is a validated tool and a feasible method of collecting pain recording scores when compared with the traditional paper format in children and adolescents with HSD/HEDS. The e-VAS App can be reliably used for pediatric pain evaluation, and it could potentially be introduced into daily clinical practice to improve real-time symptom monitoring. Further research is warranted to investigate the usage of the app for remote support in real clinical settings.

AB1784-HPR COMPARISON OF POSTURAL CHANGES AND FUNCTIONAL LEVELS AMONG DIFFERENT SUB-TYPES OF AXIAL SPONDYLOARTHRITIS PATIENTS

Keywords: Physical therapy/Physiotherapy, Patient reported outcomes, Outcome measures

Y. Akkubak[1], T. Duger[2], A. Kucuk[3]. *[1]Necmettin Erbakan University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Konya, Turkey*; *[2]Hacettepe University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Ankara,Turkey*; *[3]Necmettin Erbakan University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Konya,Turkey*

Background: Axial Spondyloarthritis (axSpA) is divided into two sub-types as radiographic axSpA which is commonly known as ankylosing spondylitis, and non-radiographic axSpA which defines no structural radiographic damage in sacroiliac joints. The systemic, inflammatory nature of axSpA, chronic pain, inflammatory cytokines, changes in the bone and ligaments of the spine may affect spine posture and functional level.

Objectives: The aim was to compare spine posture and functional levels differences among radiographic axSpA, non-radiographic axSpA patients and healthy controls.

Methods: Twenty patients with radiographic axSpA (mean age; 39.95± 9.75, 15 female), 20 patients with non-radiographic axSpA (mean age; 38.55± 2.74, 15 female), and 20 age and sex-matched healthy controls (15 female) were included in the study. The patients were evaluated with Bath Ankylosing Spondylitis Metrology Index, Bath Ankylosing Spondylitis Disease Activity Index, Bath Ankylosing Spondylitis Functional Index, Ankylosing Spondylitis Quality of Life Questionnaire. Thoracic and lumbar curvature tests were measured with a digital inclinometer (Acumar, Dual Digital Inclinometer, Lafayette Instrument Company, IN, USA).

Results: No differences were detected in disease activity level, disease-related functional status, disease-related quality of life between radiographic and non-radiographic axSpA patients ($p>0.05$). However, time since onset of symptoms, spinal mobility were higher in radiographic axSpA patients ($p<0.05$, Table 1). Radiographic axSpA patients showed higher thoracic curvature degree compared to non-radiographic axSpA patients and healthy controls ($p<0.05$, Table 1). Radiographic and non-radiographic axSpA patients presented lower lumbal lordosis degree compared to healthy controls ($p<0.001$, Table 1).

Conclusion: The results of the present study suggest that disease sub-types of axSpA may affect the spine posture, in particular thoracic curvature degree. Every effort should be taken to impove spine postüre in axSpA patients; however, sub-type specific considerations should be kept in mind for planning exercise/physical activity programs.

AB1785-HPR RELIABILITY, AND VALIDITY OF THE TURKISH VERSION OF THE EXERCISE THERAPY BURDEN QUESTIONNAIRE

Keywords: Outcome measures, Patient reported outcomes, Validation

F. Sarİ[1], S. Sari[2]. [1]*Bingöl University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Bingöl, Turkey*; [2]*Sanliurfa Training and Research Hospital, Department of Internal Medicine, Sanliurfa, Turkey*

Background: Chronic diseases, as demonstrated by the 36 million deaths they caused in 2008, are the most common cause of death worldwide. Exercise is one of the non-pharmacological treatment methods. The main objectives of exercise, one of the treatment methods, is to reduce pain, prevent loss of function in daily activities and work, and increase the quality of life, exercise capacity, and muscle strength. Although exercise benefits are known, more than half of the population does not exercise due to some exercise burden. However; there are no measurement methods assessing exercise burden patients with chronic disease.

Objectives: The objectives of the current study were to evaluate the Turkish validation of the Exercise Therapy Burden Questionnaire into Turkish (ETBQ-T) and to investigate its reliability and validity.

Methods: 100 participants (69 female and 31 male) who were diagnosed with at least 1 chronic disease participated in the translation validity, and reliability analysis of the study. Cross-culturally adaptation of the ETBQ-T was performed according to Beaton's guideline. The ETBQ-T, the European Quality of Life 5 Dimensions (EQ-5D), pain, satisfaction, and self-efficacy were applied for convergent validity. The ETBQ-T was retested to examine its reliability after seven days.

Results: The internal consistency and reliability were excellent (Intraclass correlation coefficient= 0.959; Cronbach's alpha= 0.919) (Table 1). The ETBQ-T had a good correlation with pain (r = 0.564, p <.001), satisfaction (r = 485, p <.001), and self-efficacy (r = 0.582, p <.001). However; The correlation of the ETBQ-T with EQ-5D (r = 0.364, p <.001) was weak. A factor was extracted, accounting for 58.289% of the total variation. There were no floor and ceiling effects.

Conclusion: The ETBQ-T is a reliable and valid tool to evaluate the exercise burden in the Turkish population with chronic disease.

AB1786-HPR ASYNCHRONOUS TELECONSULTATION BY WHATSAPP CHATBOT IN CONTROLLED AXIAL SPONDYLOARTHRITIS (SPA) PATIENTS UNDER BIOLOGICAL THERAPY: CLINICAL RESULTS OF A SINGLE CENTER

Keywords: Spondyloarthritis, bDMARD, Telemedicine

E. Abad Plou[1], N. Rivera[2], E. Galindez[1], E. Cuande[1], A. R. Inchaurbe[1], J. M. Blanco[1], L. Vega[1], C. García[1], M. Enjuanes[1], O. Fernandez[1], M. R. Exposito-Molinero[1], M. E. Ruiz Lucea[1], I. Torre[1], I. Gorostiza Hormaetxe[3], M. L. García Vivar[1]. [1]*Basurto University Hospital, Rheumatology, Bilbo, Spain*; [2]*Biocruces Bizkaia Health Research Institute, Research Area, Bilbao, Spain*; [3]*Basurto University Hospital, Research and Innovation unit, Bilbo, Spain*

Background: The use of telehealth in the control of rheumatic diseases had been scarce, but COVID pandemic forced to try alternatives to classic face-to-face consultation, and an overflow of telehealth consultations appeared, mainly synchronous (phone, video calls), and finally asynchronous. We try to demonstrate that asynchronous WhatsApp teleconsultation is a good alternative, at least for followup of patients that find it difficult to attend face-to-face visits. We chose axial spondyloarthritis (AxSPA) patients under biological therapy with controlled disease and we proposed teleconsultation with a WhatsApp platform chatbot created for this purpose. The chatbot sends PROMS (BASDAI, VAS for patient global disease assessment, ASDAs, and 3 questions for extraarticular disease), and receive feedback and schedule for the following visits.

Objectives: To prove that teleconsultation through WhatsApp platform is not inferior to face-to-face consultation in terms of maintaining axial SPA patients disease controlled.

Methods: Prospective study with retrospective control of patients diagnosed of Axial SPA, fulfilling ASAS criteria and with stable disease under biological therapy for the previous year, recruited from 01 jan to 30 nov 2021. We recruited 62 patients, but two of them gave up (personal reasons, one moved to other region), so we finally include 60 patients. We offer them two teleconsultation visits with their personal mobile device, every four months, and a face-to-face final visit one year after inclusion. In the case of lab test or PROMs deviation or when the patient asks for contact (possible via WhatsApp) he/she is called up by the person in charge (nurse/doctor) that solves the question and arranges an additional presential visit if needed. We consider disease controlled if BASDAI <4, ASDAS < 2,1 or if in rheumatologist´s opinion there is no need to change treatment. We collect patient and disease information (age, gender, employment, characteristics of the disease, previous and actual treatment), activity (BASDAI, PCR, ASDAS), physical function (BASFI), and Quality of life (AsQol).

Results: 60 patients (50 men, 83,3%) were included, mean aged 48,22 years (SD 12,128), 36% were under 45 years at the time of inclusion. They were mostly Ankylosing Spondylitis (AS) (90%; only 6 non radiographic SPA), positive HLA B27 (85%) and with longstanding disease (mean 23 years, SD 12,8), and only 6 patients less than five years. 25% had peripheral impairment (arthritis/dactylitis/enthesitis), and more than 40% presented extraarticular manifestations, mainly psoriasis (26,7%) and uveitis (21%)

71,7% were under their first biological (TNF inhibitor, mostly adalimumab), 23,3% were refractory to the first, and 3 patients to at least two biologicals. 51,7% of patients were treated with tapered dose of TNF inhibitors. At inclusion 93,3 %

presented remission/LDA by ASDAS/BASDAI-RCP. Only 4 patients included presented higher activity scores but were considered clinically controlled.

Table 1.

	BASAL MEAN	FINAL MEAN	MEAN DIFFERENCE
BASDAI	1,725 (SD 1,496)	2,268 (SD 1,3420)	0,5434 (SD 1,1483)
BASFI	2,108 (SD 1,619)	1,943 (SD 1,6228)	0,1492 (SD 1,3420)
ASDAS-RCP	1,288 (SD 1,496)	1,608 (SD 0,6297)	0,3198 (SD 0,6005)
AsQOL	2,53 (SD 3,311)	2,35 (SD 2,906)	0,2456 (SD 1,7856)

We did not find meaningful clinical differences between basal to final visits in BASDAI, BASFI, ASDAS-RCP or AsQOL.
3 patients with reduced dose of biological drug needed to increase to standard dose with no other need to treatment adjustment.
Conclusion: We consider asynchronous teleconsultation is promising, and not inferior to face to face consultation in terms of keeping disease control and quality of life, especially for follow-up in patients with stable rheumatic disease, The clinical results presented here are consistent with this considerations.

AB1787-HPR A REAL-LIFE OF EXPERT PATIENT WITH RHEUMATOID ARTHRITIS. AN EVALUATION OF THE PATIENT ACTIVATION MEASURE PAM-13

Keywords: Rheumatoid arthritis, Patient reported outcomes

F. Rodriguez[1], G. S. Rodríguez-Vargas[2], A. Rojas-Villarraga[3], P. Santos-Moreno[2]. *[1]BIOMAB - Center for Rheumatoid Arthritis, Patients Education, Bogotá, Colombia*; *[2]BIOMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia*; *[3]Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: In 2021, a group of rheumatoid arthritis (RA) patients were certified as an expert patients. These were trained for the care and management of their disease. During their training, they answered the Patient Activation Measure PAM-13 questionnaire, which measures people's knowledge, skills and confidence in self-managing their health and medical care.
Objectives: The aim of this study is to know the activation and empowerment levels of the patients in their daily life and in their exercise as expert patients in RA, determining the self-management they have of their disease and the perspective they have developed towards their health and towards their health care team.
Methods: A group of expert patients with a diagnosis of RA were included. A sociodemographic characterization was carried out and variables such as age in years, marital status, educational level and support networks, among others, were measured. Patients filled out the PAM-13 questionnaire. This tool contains some phrases that people use to talk about their health. Each sentence contains response options that include: "strongly agree", "agree", "disagree" and "strongly disagree". This exercise seeks to find out what patients think about aspects related to the care of their health condition and medical care. Descriptive statistics were done and the responses of the first two options were totalized ("strongly agree" and "agree").
Results: A total of 91 patients were evaluated with the PAM-13 tool. General sociodemographic and clinical characteristics are shown in table 1. With respect to the responses of the 13 variables of the PAM-13 questionnaire, the patients state [n(%)] that they have developed a high level of awareness in the care management of their disease [83 (91)], they have developed a high therapeutic adherence [83 (91)], understand that lifestyles are essential to avoid complications [83 (91)], adopted an effective and clear communication language with their medical team [82 (90)], developed self-care lifestyles [80 (88)], understand the importance of using prescribed medications [80 (88)], developed habits oriented towards a healthy and active life [78 (85)], understand the nature and symptoms of their disease [78 (85)], are aware that they are the main co-managers of their condition [78 (85)], frequently assist their medical team and use emergency services [79 (87)], act in crisis situations [80 (88)), follow instructions of their medical team [73 (80)] and make shared decisions as [65 (71)] (see Figure 1).

Table 1. Demographic characterization of the participating patients.

Participant´s characteristics		n= 91
Gender (n %)	Male	6 (7)
	Female	85 (93)
Age in years, mean		61
Age in years, group (n %)	<65	62 (68)
	≥65	29 (32)
Marital status (n %)	Married	46 (51)
	Divorced	11 (12)
	Single	29 (32)
	Widowed	5 (5)
Education (n %)	Primary School	8 (9)
	High School	34 (37)
	Vocational training	26 (29)
	University or more	22 (24)
	None	1 (1)
Duration of disease in years (n %)	≤20	52 (57)
	>20	39 (43)
Support and family (n %)	Direct support	81 (89)
	No support	10 (11)

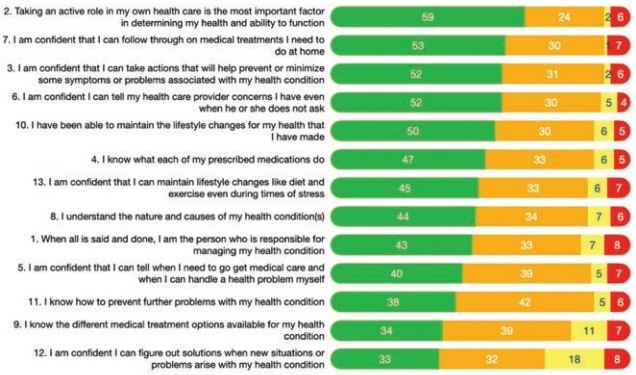

Figure 1: Results of the PAM-13 tool in expert patients with RA

Conclusion: In general, expert RA patients are proactive with their health and have developed strong self-management skills evaluated through PAM-13. The use of these tools is important to assess the role of the patient in their treatment. This allows generating strategies that increase the commitment of patients during their therapy.

AB1788-HPR ASYNCHRONOUS TELECONSULTATION BY WHATSAPP CHATBOT IN CONTROLLED AXIAL SPONDYLOARTHRITIS PATIENTS UNDER BIOLOGICAL THERAPY: PATIENTS' PERSPECTIVE

Keywords: Telemedicine, Spondyloarthritis, Quality of life

M. L. García Vivar[1], E. Abad Plou[1], N. Rivera[2], E. Galindez[1], E. Cuande[1], A. R. Inchaurbe[1], J. M. Blanco[1], L. Vega[1], C. García[1], M. Enjuanes[1], O. Fernandez[1], M. R. Exposito-Molinero[1], M. E. Ruiz Lucea[1], I. Torre[1], I. Gorostiza[3]. *[1]Basurto University Hospital, Rheumatology, Bilbo, Spain*; *[2]Biocruces Bizkaia Health Research Institute, Research Institute, Bilbao, Spain*; *[3]Basurto University Hospital, Research and Innovation Unit, Bilbo, Spain*

Background: Before COVID pandemic, rheumatologists were not confident with telehealth for the need to adquire new technology, need of specific training and poorer reimbursement [1]. Two groups of rheumatoid arthritis (RA) patients have been identified in a study of PROMS-based telehealth use (2): the keen and the reluctant. We proposed teleconsultation followup with a whatsapp platform chatbot to our axial spondyloarthritis (AxSPA) patients with controlled disease and we asked them for preferences at the end of the study.

Objectives: To explore the degree of acceptance of asynchronous telehealth followup with whatsapp platform chatbot among our controlled AxSPA patients under biological therapy, and to search for a patient profile more prone to telehealth consultation.
Methods: A prospective study with retrospective control was performed, chosing AxSPA patients under biological therapy with stable disease, visited in our centre from 01/01 to 30/11/2021. We recruited 62 patients, but finally include 60 (2 quit for home moving or personal reasons). We offered them two teleconsultation visits (using their personal mobile), every four months, and a presential final visit one year after inclusion. The chatbot sends PROMS (BASDAI, VAS for patient global disease assessment, ASDAS, and 3 questions for extraarticular disease), and feedback and schedule for the following visits. In the case of lab test or PROMs deviation or when the patient asks for contact, he/she is phoned by nurse/doctor who solves the question and/or arranges an additional presential visit. We collect patient and disease characteristics (age, gender, educational level, employment, disease activity, duration and treatments), and patient´s satisfation and preferences in the final visit.
Results: We included 60 patients (83,3% men), mean aged 48,22 years (SD 12,128), 36% under 45 years at inclusion. 27% had received primary, 33.9% secondary and 39% tertiary education. 83.3% were active working and only 10 patients were jobless or retired. They were Ankylosing Spondylitis (AS) (90%), HLA B27 positive (85%) with longstanding disease (mean 23 years, SD 12,8), and were receiving the first (71%), or the second (23%) biological therapy (51,7% tapered anti-TNF). 50% were never smokers and 70% presented no remarkable comorbidity; 25% presented peripheral impairment, and over 40% extraarticular manifestations. At inclusion 93,3% were at remission/LDA by ASDAS/BASDAI-RCP and 4 patients were considered clinically controlled in spite of higher scores. At followup 3 patients with reduced dose needed to increase to standard dose of biological drug, with no other need of treatment change. There was no worsening from basal to final visits according BASDAI, BASFI, ASDAS-RCP or AsQOL. Patients final VAS score (1-10) assessment of telehealth consultation was very high: mean 9,14 (DS 1,498); 91.7% ≥ 8 and 76.7% ≥ 9. 83,3% preferred telehealth followup. There was a trend towards telehealth preferences in higher educational levels, and active working (86% vs 70%) but not statistically significant. We found no correlation with gender, age and disease characteristics tested.
Conclusion: Asynchronous teleconsultation seems promising, not inferior to presential consultation and preferred for follow-up by our AxSpa patients with stable disease with biological drugs. We met some "reluctant patients", that were more inactive working and with lower educational levels, but the differences were not significant. Further reserarch is needed with this telehealth model in other age and disease populations (RA), in order to characterize the reluctant and keen patients.

AB1789-HPR

30 SECONDS CHAIR STAND TEST - FEASIBLE AS SELF-ASSESSMENT TEST FOR KNEE OSTEOARTHRITIS?

Keywords: Self-management, Diagnostic Tests, Outcome measures

C. M. Ho-Henriksson[1,2], C. A. Thorstensson[1,3], L. Nordeman[1,4]. [1]*Institute of Neuroscience and Physiology, Sahlgrenska Academy, Gothenburg University, Health and Rehabilitation, Göteborg, Sweden*; [2]*Region Västra Götaland, Primary Care Rehabilitation, Närhälsan Lidköping Rehabilitation Centre, Lidköping, Sweden*; [3]*Region Halland, Research and Development Department, Halmstad, Sweden*; [4]*Region Västra Götaland, Research, Education, Development and Innovation, Primary Health Care, Research, Education, Development and Innovation Centre Södra Älvsborg, Borås, Sweden*

Background: A reliable self-assessment test to evaluate physical performance could be useful for patients with knee osteoarthritis to monitor physical function over time. However, studies comparing a self-assessment test with standardized testing in the clinic supervised by a physiotherapist is lacking. The 30 seconds chair stand test is part of a test battery which is recommended both in research and in clinical settings for patients with osteoarthritis [1]. The chair stand test is a reliable physical performance test for patients with knee osteoarthritis [2, 3].
Objectives: The purpose is to evaluate the 30 seconds chair stands test as self-assessment test for patients with knee osteoarthritis and when it is supervised by a physiotherapist.
Methods: A sample size of 147 patients with knee osteoarthritis will be recruited. Each patient will perform two self-assessment tests with two days in between. Another test supervised by physiotherapist will be conducted within a week after the second self-test. Demographic data, knee-related quality of life using knee injury and osteoarthritis score – short version (KOOS-PS) [3], pain duration, pain intensity using numeric rating scale (NRS) 0-10 [4]; pain sites, experienced intermittent and constant knee pain (ICOAP) [5], will be collected. Data collection is ongoing and preliminary data will be presented descriptively.
Results: So far, 91 patients have been recruited, whereas 60 patients (58% females) with a mean age of 69 years, and mean body mass index of 30 (SD 5) have been included in the preliminary analysis. Patients reported mean pain duration of 46 months (SD 52), rating mean pain intensity 3/10 (SD 2), and 83% had pain in more than one joint. Patients reported mild to moderate pain (total mean ICOAP-score 44/100, SD 21). KOOS-PS score was 60/100 (SD 14) showing moderate difficulties in knee-related daily activities. Mean number of chair stands for self-assessment tests 1 and 2 were 13.7 (SD 5.6) and 14.7 (SD 6.0) respectively and mean number supervised by physiotherapists were 13.3 (SD 4.8).
Conclusion: Preliminary results of this study indicate that 30 seconds chair stand test as self-assessment test might be an option for patients with knee osteoarthritis to monitor their own physical performance. Yet, to ensure the agreement between self-assessment and physiotherapist assessment, a reliability study is needed.

HPR Epidemiology and public health (including prevention)

AB1790-HPR COVID-19: AFTER TWO YEARS OF IATROGENIC AND BIOLOGIC IMMUNIZATION/ VACCINATION DO WE ACTUALLY NEED FURTHER BOOSTER IMMUNIZATION/ VACCINATION?

Keywords: COVID, Vaccination/Immunization, Epidemiology

C. Pohl[1]. [1]Internistisch-Rheumatologische Hausarztpraxis, Dr. Med. Christoph Pohl, Berlin, Germany

Background: The Covid19 pandemic started in late 2019 and went through different phases by spreading from China around the whole globe. During the pandemic different mutation types got predominant from original Wuhan type through Alpha, Delta and Omicron variate BA 1/2 to BA 4/5 with different infectiousity and different potential to harm people´s health status. Immunization/ vaccination program started late 2020, first booster phase started midst of 2021, second booster phase in late 2021/ beginning of 2022 and Omicron specific booster phase midst of 2022.
Objectives: Is there a need of further iatrogenic (booster) immunization/ vaccination after 2 years of immunization/ vaccination program from efficacy driven analysis and safety issues standpoint?
Methods: Analysis of Covid-19 antibody development every three months since August 2021 with comparison of infection rates and assessment of safety parameters by assessing D-Dimers as potential endothelium damage marker in 725 patients (600 female, 125 male, age mean: 62,2 years) of a German rheumatological practice to improve the medical care.
Results: In 99 % of the patients longstanding immune memory could be shown by analyzing the antibody curves in different exemplary shown biologic and iatrogenic immunization pathways after 2 years of immunization/ vaccination program and biologic immunization, mainly by Delta variate since late 2021 and Omicron variate since beginning of 2022. In 38.5 % of the patients the safety concerns of potential endothelium damage by analysing D-Dimers every 3 months showed a side effect potential of at least 8 months after every MRNA/ Vector immunization, but not after protein based vaccination and even not after infections in that amount.
Conclusion: Out of the obligation “nil nocere” no further iatrogenic Covid-19 immunization/ vaccination is of need in nearly all (99 %) already immunized people. At present only adult people with very low antibody levels (at least below 64 BAU/ml) (considering the infection or iatrogenic immunization/ vaccination status and time since last spike protein contact) and not yet immunized adult people should be forseen for iatrogenic immunization/ vaccination with protein based or attenuated viral vaccines or in rare cases one Omicron specific MRNA immunization drug. In that case D-Dimer controls for up to 8 months should be obligatory to detect endothelial damage side effect of MRNA (or Vector) technique. Intense cardiovascular monitoring (small vessels) of MRNA/ Vector immunized people in the next 10 – 20 years is necessary.

AB1791-HPR EVALUATION OF DIAGNOSTIC AND THERAPEUTIC DELAY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

Keywords: Education, Inflammatory arthritides, Health Services Research

M. Iacovantuono[1], S. Ferrigno[1], P. Conigliaro[1], P. Triggianese[1], A. D'antonio[1], F. R. Spinelli[2], A. Bergamini[1], M. S. Chimenti[1]. [1]*University of Rome Tor Vergata, Rheumatology, Allergology and Clinical Immunology, Department of Systems Medicine, Rome, Italy*; [2]*Sapienza University of Rome, Rheumatology Unit, Department of Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome, Italy*

Background: Inflammatory arthritis, such as Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA), are diseases that require timely therapeutic intervention to reduce or stop the progression of joint damage and diseases flares. Early diagnosis and rapid accessibility to care lead to a better patient management.
Objectives: We conducted a monocentric study in a cohort of patients affected by RA and PsA to assess factors related to diagnostic delay and accessibility to treatments, in order to improve patients management.
Methods: Between June and September 2022, clinical and serological characteristics, time (months-years) between symptoms onset and the diagnosis and the initiation on csDMARDs-ts/bDMARDs therapy, of RA patients - according to EULAR/ACR 2010 criteria - and PsA patients - according to CASPAR criteria - were collected. In addition we evaluated place of residence (small/big city (>200.000)), who made referral to the rheumatology center, physician who made the diagnosis (rheumatologist/other specialist/family doctor), possible wrong diagnosis previously made. Statistical analysis was conducted using Student T-test/ Mann-Whitney U Test/one-way ANOVA when appropriate, via GraphPad Prism version 8.0.2. *P* values <.05 were considered significant.
Results: 100 RA patients and 100 PsA patients were included *(table I)*. Statistical significant differences were observed concerning: diagnostic delay (PsA patients 5.2±7.6 yrs vs versus RA patients 2.5±4.6 yrs, *p=0.003*), time passed between symptoms onset and initiation of csDMARDs therapy (PsA 5.3±7.6 vs RA 2.7±5.1, *p=0.006*), and between diagnosis and initiation of ts/bDMARDs therapy (PsA 3.5±5.5 vs RA 7.1±8.6, *p=0.0007*). In the two groups: **-** In the residents of small and medium sized cities compared to the big cities residents, in the diagnostic delay (6.1±10.2 vs 2±1.8, *p=0.02*), in the time between symptoms onset and the start of first line therapy with csDMARDs (6.4±10.7 years vs 2.3±1.9 years, *p=0.02*). **-** In patients who have been diagnosed by another physician rather than rheumatologist, in the diagnostic delay (4.7±11.1 vs 3.9±6.2, *p=0.034*) and in the start of I-line therapy (4.7±11 vs 4.2±6.7, *p=0.019*) In RA: - In the group of patients who had a previous diagnosis - mostly osteoarthritis (35.5%) and UCTD (16.1%) - in diagnostic delay (3.7±6.7 vs 1.9±3.1, *p=0.03*) and in the time between symptoms onset and initiation of a csDMARD (4±6.8 vs 2.1±4, *p=0.05*). In seronegative RA: - Delay in diagnosis (4.2±4.7 vs 1.8±4.6, *p=0.02*) and starting of I-line therapy (4.5±5.3 vs 2±5.1, *p=0.03*) and II-line therapy from symptoms onset (11.6±9.6 years vs 7.9±7.8 years, *p=0.04*) compared with the seropositive ones. In PsA: - In patients with previous diagnosis - mostly osteoarthritis (34.1%) and fibromyalgia (19.1%) - in the diagnostic delay (8.1±10 vs 3±4.1, p=*0.003)*, in the time passed between symptoms onset and initiation of csDMARDs (8.1±10 vs 3.1±4.2, *p=0.001*) and ts/bDMARDs therapy (12±11.1 vs 6±6.5, *p=0.0004*).
Conclusion: Diagnostic delay is greater in PsA than in RA, in both groups of patients living in small-medium cities and in those who have been diagnosed by another specialist. Major diagnostic delay is present in both groups of patients who

have previously been misdiagnosed and in the seronegative RA patients. Consequence is a delayed starting of therapies, with possible permanent joint damage.

Table 1. Clinical, serological and demographic features of the study population.

	PsA	RA	Total
Sex			
Male (n/%)	35 (35)	23 (23)	58 (29)
Female (n/%)	65 (65)	77 (77)	142 (71)
Age (±SD)	55±139	61.3±12	58. 1±13.3
RF (n/%)	-	66 (66)	-
ACPA (n/%)	-	63 (63)	-
PsO (n/%)	68 (68)	-	-
Previous diagnosis (n/%)	44 (44)	32 (32)	76 (38)
Big city (n/%)	46 (46)	47 (47)	93 (46.5)
Small/medium city (n/%)	54 (54)	53 (53)	107 (53.3)
Diagnosed by rheumatologist (n/%)	85 (85)	81 (81)	166 (83)
Referral			
Spontaneous (n/%)	43 (43)	36 (36)	79 (39.5)
Family doctor (n/%)	17 (17)	36 (36)	53 (26.5)

HPR Interventions (educational, physical, social and psychological)

AB1793-HPR SPINAL INVOLVEMENT IN PAGET'S DISEASE OF BONE

Keywords: Bone diseases

A. Hriz[1], S. Ben Jemaa[1], A. Feki[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], R. Akrout[1], S. Baklouti[1]. [1]*Hedi Chaker University Hospital, Rheumatology Department, Sfax, Tunisia*

Background: Paget's disease of bone (PDB) is a benign acquired osteodystrophy characterized by excessive and disorderly bone remodeling that may affect one or more bones. The spine is the second site affected by Paget's disease (53%) after the pelvis (70%). Vertebral involvement is therefore likely to lead to complications which are fortunately relatively rare.
Objectives: to describe the clinical, biological and radiological aspects of the of PDB with spinal involvement, to highlight certain complications and to describe the management of patients with spinal localization.
Methods: This is a retrospective and descriptive study of the files of patients hospitalized for Paget's disease of bone with spinal involvement over a period of 20 years (Year 2000- Year 2020).
Results: Twenty-six patients (12 women and 14 men) were included. The average age of our patients was 66,8 years. The discovery of the PDB was fortuitous on standard radiographs and an elevation of PAL in 7,6% of cases. PDB was symptomatic in 92,4% of cases. Spinal pain was mechanical in 95,2% of cases. Three of our patients had spinal cord compression: Two patients had cervical compression and one patient had lumbar compression with Brown Sequard syndrome. Phosphocalcium balance was normal according to laboratory standards in all cases. An increase in PAL was found in 73% of cases. Standard X-ray of the dorsal spine showed condensation with widening affecting the vertebral bodies of D4, D8 and D11 in 43% of cases. Vertebral compression at levels D4, D8, D10 and D11 was found in 28.5% of cases. The radiograph of the lumbar spine showed condensation with hypertrophy of the vertebrae L1, L2, L3, L4, L5 in 37.5% of cases. A vertebral compression of L1, L2 and L4 was found in 31.25% of cases and an aspect of ivory vertebra in L3 and L4 in 12.5% of cases. A fibrillar aspect of the vertebral bodies of L1, L2 and L3 was objectified in 18.75% of cases. An aspect of vertebra in frame of L2 was observed in 6.25% of cases. Hypertrophy of the posterior L4 joints was reported in 6.25% of cases. Technetium 99m bone scintigraphy showed hyperfixation of a single seat in 9% of cases and multiple in 91% of cases. It had highlighted asymptomatic localizations in 9% of cases. Spinal CT was performed when there was doubt about the metastatic origin of the bone lesions in 5 cases, when there was low back pain or lumbo-radiculalgia in 5 cases. It showed signs in favor of PDB with corticomedullary dedifferentiation type in 6 cases, lytic bone lesions in 1 case and condensing lesions in 1 case, hypertrophy of the cortex and vertebral bodies in 1 case and vertebral collapse in 1 case. Spinal magnetic resonance imaging (MRI) was performed in 7 patients (27% of cases) when in doubt about the secondary metastatic origin of bone lesions in 3 cases (42.8%) or in search of a spinal cord compression in 4 cases (58.2%). It showed hypertrophy of the vertebral bodies, vertebral compression with recoil of the posterior wall in 4 cases and intramedullary hypersignal in 1 case. Sensorineural complications such as sensorineural hearing loss and occipital headache in 1 of our patients. Sarcomatous degeneration was observed in 1 of our patients. Drug treatment based on calcitonin or bisphosnate was administered in 77% of patients. The general evolution was good in 77.3% of cases (17 cases) with disappearance of pain in 95.3% of cases and normalization or maintenance of a normal level of ALP in 71.5% of cases.
Conclusion: Paget's disease of bone with spinal involvement is a serious disease that can compromise the functional and sometimes life-threatening prognosis of our patients. Diagnosis, early management and close monitoring of our patients are necessary to prevent its complications.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

AB1794-HPR SPONDYLOARTHRITIS: IS THERE A GENDER DIFFERENCE?

Keywords: Gender/diversity issues, Spondyloarthritis

S. Miladi[1], O. Hamdi[1], F. Alia[1], H. Boussaa[1], Y. Makhlouf[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim hospital, Rheumatology, Tunisia, Tunisia*

Background: Spondylarthritis (SpA) affects men more frequently than women. Few studies have analysed gender differences in clinical and biological characteristics of SpA, hence the purpose of this study.
Objectives: We aimed to analyse gender differences in SpA manifestations and disease activity.
Methods: We conducted a cross-sectional study including 30 men and 30 women with SpA meeting the 2009 ASAS criteria. The comparison between men and women included the following data: age at onset, disease duration, clinical and biological characteristics, activity scores (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS)), and functional impact (Bath Ankylosing Spondylitis Functional Index (BASFI)).
Results: Compared to women, male patients had a younger age at disease onset (male (M)= 24.7 ±7.7 vs female (F)= 28.9 ±5.8, p= 0.00), a longer disease duration (M= 14.3 ±6.1 vs F= 11.9 ±4.2, p= 0.05), a longer morning stiffness (p=0.01) and a greater number of nocturnal awakenings (p=0.01). Similarly, SpA was more active in male patients compared to female patients: CRP (M= 22 ±3.5 vs F= 14 ±2, p=0.00) and ASDAS (M= 3.7 ±0.7 vs F= 2.9 ±0.2, p= 0.01). Coxitis was more common among male patients: M= 28.3% vs F= 13.3%, p= 0.00. However, no gender differences were observed for VS, BASDAI, BASFI and therapeutic strategy. Comorbidities were predominant in male patients: cardiovascular disease (M= 18.3% vs F= 8.3%, p=0.00), osteoporosis (M= 16% vs F= 13.3, p=0.05), hypertension (M= 15% vs F= 6.6%, p=0.01) and dyslipidemia (M= 11.6% vs F= 6.6%, p=0.00). However, depression was more common among female patients (p= 0.01).
Conclusion: Our study showed that SpA was more active in male patients. Comorbidities were more common among men compared to women. Further studies should be conducted to better illuminate gender differences in SpA.

AB1795-HPR COXITIS IN RHEUMATOID ARTHRITIS: IS THERE ANY CORRELATION BETWEEN CATASTROPHIZING AND FUNCTIONAL DISABILITY?

Keywords: Rheumatoid arthritis

O. Hamdi[1], H. Boussaa[1], S. Miladi[1], B. A. Hiba[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], F. Alia[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunisia, Tunisia*

Background: Coxitis is a marker of severity in rheumatoid arthritis (RA) since it is associated with a functional disability. Therefore, it leads to a loss of autonomy with a significant psychological impact.
Objectives: We aimed to assess the correlation between catastrophizing and functional disability associated with rheumatoid coxitis.
Methods: We conducted a cross-sectional study including patients with RA (2010 ACR/EULAR criteria). Clinical, biological and radiological data were collected. RA activity was assessed using the Disease Activity Score (DAS_{28} ESR). The quality of life was assessed using the Health Assessment Questionnaire (HAQ). Hip function was assessed using the Lequesne algofunctional index (IAF). Catastrophizing was evaluated by the Pain Catastrophizing Scale (PCS), which is composed of 13 items. PCS total score varies from 0 (no catastrophizing) to 52 (significant tendency to catastrophizing). The correlation between Lequesne IAF and PCS was evaluated using the Spearman test.
Results: We included 80 patients (76 women and 4 men) with an average age of 47±12 years [37-77]. The average age at diagnosis was 29±7.5 years. The mean disease duration was 11±6.2 years. RA was erosive in 90% of cases. Rheumatoid factor and anti-citrullinated peptides antibodies were positive in 83% and 85% of cases, respectively. Seventy-five percent of patients were on corticosteroids with an average dose of 10 mg per day of Prednisone equivalent. All patients were on DMARDs: methotrexate (85%), leflunomide (11.2%), and bDMARDs (37.5%). The mean pain Visual Analog Scale was 5.5 cm. The mean overall patient assessment was 4 cm. The mean number of nocturnal awakenings was 1.5. The mean duration of morning stiffness was 45±7.5 minutes. The mean ESR was 29.4±6. The mean CRP was 19.5± 4.4. The mean DAS_{28} ESR was 4.5±2.2. The mean HAQ was 1.2±0.4. The mean PCS was 34±3. Coxitis was noted in 28.7% of patients. It was inaugural in 52.1% of cases and bilateral in 14 cases. The mean coxitis duration was 6.8 years. The mean Lequesne IAF was 10.5±3.2. A statistically significant correlation was noted between Lequesne IAF and PCS (r=0.41; p=0.01).
Conclusion: Our study showed that functional disability associated with rheumatoid coxitis was moderately correlated with catastrophizing. Comprehensive management, taking into account the cognitive behavioural sphere, is thus recommended in RA patients with coxitis.

AB1796-HPR ALTERED ANKLE AND KNEE MUSCLE ARCHITECTURE AND FOOT PRESSURE DISTRIBUTION IN KNEE OSTEOARTHRITIS PATIENTS: A COMPARATIVE CROSS SECTIONAL STUDY

Keywords: Ultrasound, Osteoarthritis, Physical therapy/Physiotherapy

N. Cigercioglu[1], H. Apaydın[2], G. Baltacı[3], H. Guney Deniz[1]. *[1]Hacettepe University, Department of Musculoskeletal Physiotherapy and Rehabilitation, Ankara, Turkey*; *[2]Ankara City Hospital, Department of Rheumatology, Ankara, Turkey*; *[3]Eastern Mediterranean University Faculty of Health Science, Department of Physiotherapy and Rehabilitation, Famagusta, Cyprus*

Background: Osteoarthritis (OA) of the knee is a common degenerative and chronic disease as well as a major cause of knee pain and functional disability. Alterations in lower extremity biomechanics may lead adaptive changes in walking, foot pressure distribution, lower extremity muscle strength as well as the architectural characteristics of the knee and ankle muscles in patients with knee OA.
Objectives: The aim of this study was to compare the knee and ankle muscle architecture and foot pressure distribution differences in knee OA patients with healthy individuals.
Methods: Twenty patients with knee OA (mean age= 53.35±1.21 years, mean BMI=31.69±0.93 kg/m2) and twenty healthy controls (mean age= 51.05±0.63 years, mean BMI=29.28±1.15 kg/m2) were included in the study. Rectus Femoris (RF), Vastus Medialis (VM), Peronalis Longus (PL) and Medial Gastrocnemius (MG) muscles thickness, pennation angle and fat thickness were evaluated using B-Mode ultrasonography (Esaote MyLab X8 eXP Ultrasound System, Florence, Italy). Ultrasound images were analyzed offline using an image analysis software (Image J, National Institutes of Health, Bethesda, MD, USA) program. Plantar pressure distribution was evaluated using the Digital Biometry Scanning System and Milletrix software (DIASU, Italy). Mann-Whitney U test was used to compare knee OA patients with the healthy individuals.
Results: The age (p=0.189) and BMI (p=0.367) were comparable between groups. The muscle architectural characteristics of RF, VM, PL and MG were different between groups (Table1). The distribution of foot pressure parameters were altered in knee OA patients compared to healthy controls (Table1).
Conclusion: The fat thickness of ankle and knee muscles were higher in knee OA patients compared to healthy controls. Clinicians should consider adding aerobic and resistance exercises to their treatment programs that will increase muscle thickness and decrease fat thickness. The medial load of the foot increased while the lateral load decrease in these patients. Medial supported insoles may be recommended to reduce the medial load on the foot.

AB1797-HPR HIGH AWARENESS AMONG NURSES OF THE SYMPTOM BURDEN PATIENTS WITH SSC-PAH IS IMPORTANT TO PROVIDE THE BEST POSSIBLE PATIENT CARE

Keywords: Systemic sclerosis, Qualitative research methods, Nursing

M. L. Ramsli[1], Ø. Midtvedt[1], T. Garen[1], H. J. Bjørkekjær[2,3], D. Karterud[4], A. M. Hoffmann-Vold[1,3,5]. *[1]Oslo universitetssykehus HF, Rikshospitalet, Department of Rheumatology, Oslo University Hospital, Oslo, Norway*; *[2]Hospital of Southern Norway, Department of Rheumathology, Kritiansand, Norway*; *[3]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*; *[4]Oslo Metropolitan University, Department of Nursing and Health Promotion, Oslo, Norway*; *[5]University Hospital Zurich, Department of Rheumathology, Zurich, Switzerland*

Background: Systemic sclerosis (SSc) is a severe disease with significant increased morbidity and mortality. A feared organ manifestation is pulmonary arterial hypertension (PAH). Little is known how the development of PAH affects SSc patients in their symptom burden. It is therefore important to explore the health-related quality of life (HRQoL) in patients with SSc-PAH. A major purpose of care is to reduce symptoms and disability, and be able to improve the HRQoL.
Objectives: 1) To explore SSc patients perceived HRQoL.
2) The nurses role to influence the patients to improve their HRQoL for the best possible care in the clinical practice.
Methods: Six SSc patients diagnosed with PAH from the Oslo University Hospital were assessed by in-depth interviews conducted in the period June to August 2022. The interview guide contained 21 questions. The results were coded into ten subthemes and five main themes. The study had a qualitative phenomenological-hermeneutical design, based on individual semi-structured interviews. This means we focused on the patients` subjective opinions to gain insight of each patient about their individual experiences of HRQoL based on their meeting with nurses within the special health care. We assessed symptom burden using VAS-scale based on patients` pain, general health and fatigue, and wanted to see if there was an association between the symptoms and what was told in the interviews. The patients experience in the meeting with nurses

was one of the questions in the interview, where the patients themselves elaborated on their answers.

Results: Of the included six SSc patients with PAH, 4 (67%) were female and 2 (33%) men with mean disease duration of 5 years since PAH diagnosis (Table 1). NYHA functional class varied from 1 (mild) to 4 (severe) with a median of 3. Patients reported fatigue (VAS) was the most prominent symptom (Figure 1), confirmed by the results from the interviews. This also lead to physical and psychological challenges in everyday life, and reduced HRQoL. The patients` were mostly satisfied with the nurses, but felt some nurses had not the time when the patients needed it the most. The patients also highlighted that they felt that some of the nurses did not have enough knowledge about the diagnosis. This led to patients` repetition and explanation why their oxygen level was reduced, why they had heavy breathing or why it was not possible to measure pulse or oxygen level on the fingers, due to reduces peripheral circulation. The patients` wish was also to be seen and understood by their caregivers and friends.

Conclusion: Our study revealed that fatigue was the main symptom causing reduced HRQoL. Moreover, we show the importance of educated expert nurses in the management of PAH in SSc and the inclusion of information to caregivers, patients and next of kin. Nurse's awareness about the symptom burden and unmet needs of patients with SSc-PAH is important to give the best possible patient care.

AB1798-HPR FOOT ALTERATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A 1-YEAR LONGITUDINAL STUDY

Keywords: Systemic lupus erythematosus, Patient reported outcomes

L. Cano Garcia[1], J. Marco-Lledó[2], A. Garcia Studer[1], L. Ramos Petersen[3], A. Reinoso Cobo[3], J. García-Campos[2]. [1]*Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA)., Rheumatology, Málaga, Spain*; [2]*Universidad Miguel Hernández; Instituto de Investigación Sanitaria y Biomédica de Alicante, Departamento de Podología, Alicante, Spain*; [3]*Universidad de Málaga, Departamento de Podología, Málaga, Spain*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease mediated by autoantibodies, with involvement of various organs[1,2]. El 95% of patients with SLE have musculoskeletal involvement[1], most often in the form of arthralgias or non-erosive arthritis affecting mainly the hands and knees. Although the feet are equally affected and can result in significant disability, they have been little studied.

Objectives: To determine changes in foot involvement in patients with SLE after 12 months of follow-up.

Methods: Longitudinal case series. Thirty-six subjects with a diagnosis of SLE were consecutively recruited in the Rheumatology Unit between March and June 2021 and followed up at 12 months. Inclusion criteria were: patients with a diagnosis of SLE according to EULAR/ACR 2019 criteria, with at least one year of evolution and age equal to or older than 18 years. A Rheumatology nurse collected information on socio-demographic data and the questionnaires at baseline and at 12 months. The questionnaires were: SLEDAI (Systemic Lupus Erythematosus Disease Activity Index) and SLICC (Damage Index for Systemic Lupus Erythematosus), quality of life: EQ-5D, foot function: FFI (Foot Function Index), FAAM (Foot and Ankle Ability Measures Questionnaire), FAAM-Sport, FPI (Foot Posture Index). A descriptive analysis of the main variables, and a paired t-test or Wicoxon t-test, as appropriate, were performed between the baseline and 12-month follow-up visits.

Results: Thirty-six patients with SLE (97.2% women) with a mean (SD) age of 49.31 (11.4) years with a range 23-66 years participated. Regarding treatment a total of 22/36 patients (66.2%) had immunosuppressive treatment, 4/36 (11.1%) biological therapy and 26/36 (72.2%) hydroxychloroquine treatment. After 12 months of follow-up, the disease remained stable and there were no significant differences in the SLICC and SLEDAI indices of SLE. There were also no significant differences in the different foot questionnaires administered: FAAM, FAAM-Sport, FPI, FFI after 12 months of evolution. There was only a worsening in VAS EQ5D (p=0.028) although there was no significant change in EQ5D (p=0.773) (Table 1).

Conclusion: In SLE patients with stable disease over one year of follow-up, assessments of foot function and ability remain unchanged. It is important to integrate foot assessment into the joint evaluation because of the high impact on the patient's quality of life and patient functionality.

Table 1.

	Baseline (Mean± SD)	12 months (Mean± SD)	P value
EQ5D	0,54±0,25	0,55±0,23	0,773
EVAEQ5D	66,43±21,61	57,36±24,77	0,028
FFI	37,52±25,23	36,24±25,29	0,965
FAAM	0,65±0,23	1,05±2,57	0,322
FAAM-Sport	0,51±0,28	0,57±0,28	0,779
FPI rigth	2,33±2,19	2,37±2,21	0,324
FPI left	1,36±1,85	1,37±1,88	0,248
SLICC	0,86±1,45	0,72±1,16	0,257
SLEDAI	1,44±1,94	1,02±1,87	0,117

AB1799-HPR COMPARISON OF EXERCISE CAPACITY, PHYSICAL ACTIVITY LEVEL, AND PERIPHERAL MUSCLE STRENGTH IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH HEALTHY INDIVIDUALS

Keywords: Systemic lupus erythematosus, Physical therapy/Physiotherapy, Quality of life

F. Sarİ[1], S. Bayram[2], D. Oskay[2], A. Tufan[3]. [1]*Bingöl University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Bingöl, Turkey*; [2]*Gazi University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Ankara, Turkey*; [3]*National Human Genome Research Institute, Inflamatuar Disease Section, Rockville Pike, United States of America*

Background: Systemic lupus erythematosus (SLE) is a chronic, autoimmune, inflammatory rheumatic disease that causes tissue damage through autoantibodies and immune complexes. Patients with chronic diseases such as SLE fall into a vicious circle. Fatigue and depression can negatively affect the quality of life and cause patients to stay at home and hence, be physical inactivity. As a result of physical inactivity; the exercise capacity and muscle strength of SLE patients can decrease.

Objectives: The aim of this study is to investigate the physical activity, peripheral muscle strength, exercise capacity, sleep, fatigue, anxiety, and depression levels between patients with SLE and healthy individuals.
Methods: Twenty-six patients with SLE (32.5 (24.75/43.25) years) and 29 healthy individuals (30 (23/32) years) were compared. Exercise capacity (6-minute walk test (6MWT)), peripheral muscle strength (dynamometer), physical activity (the Xiaomi Mi Band 4 smart bracelet device), fatigue (Fatigue Severity Scale (FSS)), anxiety and depression (Hospital Anxiety Depression scale (HAD)), quality of life (SLE-specific QOL scale (SLEQoL)), and sleep (Pittsburgh Sleep Quality Index (PSQI)) were assessed.
Results: Demographic characteristics were similar in both groups except for cigarette consumption (pack*years) ($p>0.05$). 6MWT distance, peripheral muscle strength, physical activity level, SLEQoL, and PSQI scores were significantly lower; FSS and HAD scores were higher in patients with SLE ($p<0.05$). Moreover; the difference between post and pretest values of heart rate, dyspnea, fatigue, and quadriceps femoris muscle fatigue was higher in patients with SLE compared to healthy individuals.
Conclusion: Patients with SLE had lower exercise capacity, muscle strength, quality of life, and sleep quality, and higher fatigue, anxiety, and depression. In addition; These patients were physically inactive. Further studies are needed to investigate the effects and efficiency of these symptoms on patients with SLE.

AB1800-HPR EVALUATION OF KNOWLEDGE AND PRACTICES OF PATIENTS WITH SPONDYLOARTHRITIS

Keywords: Spondyloarthritis, Patient information and education, Best practices

S. Farih[1], T. Latifa[1], R. Honsali[1], H. Rkain[1,2], I. Bensaghir[1], C. Charoui[3], B. Amine[3], R. Bahiri[3], S. Elhilali[4], R. Razine[4], C. Nouri[1], F. Kronbi[1], S. Ez-Zaoui[1], F. El Joumani[1], S. Bahloul[1,2], N. Alami[1], F. Allali[1]. *[1]Al Ayachi Hospital, Rheumatology B, Sale, Morocco*; *[2]Execise Physiology and Autonomous and Nervous System Team, Physiology Laboratory, Rabat, Morocco*; *[3]Al Ayachi Hospital, Rheumatology A, Sale, Morocco*; *[4]Faculty of Medicine and Pharmacy of Rabat, Departement of Public Health, Rabat, Morocco*

Background: Spondyloarthritis is a chronic inflammatory rheumatic disease mostly affecting young adults, causing functional disability and impaired quality of life. Thus, patient education is a major component to improve their knowledge of the disease, therapeutic compliance and quality of life.
Objectives: The aim of this study is to evaluate the knowledge and practices of patients with spondyloarthritis and determine the factors associated with them.
Methods: This is an observational, descriptive, analytical and monocentric study, in patients followed up at Al Ayachi University Hospital in the Rabat-Sale region of Morocco. The study duration was from the beginning of May 2022 to the beginning of July 2022. The consent of the study population was free and informed. The participants were interviewed and voluntarily responded to a questionnaire drawn up by a team of rheumatologists, which includs socio-demographic information, prior knowledge and practices of patients with spondyloarthritis.We calculated a score of correct answers ranging between 0 and 10 for each patient.
Results: We recruited 100 patients with a mean age of 39.3 years ± 12.9, 59% were men and 17% were illiterate. 85% of the population came from an urban environment, and 79% were unemployed. 68% of the patients suffered from ankylosing spondylitis, 17% had psoriatic arthritis, 13% were affected by inflammatory bowel disease associated arthropathy and 2% had juvenile spondylarthritis. 31% of patients considered that the disease can affect young adults, wherein 43% reported a male predominance. 47% reported that the cause of the disease is genetic, 34% declared that it is related to immunity whereas entheses affection was known by 52% of patients. 81% find that therapeutic management helps prevent deformities and 97% see that it improves the quality of life. Furthermore, only 4% of patients knew that NSAIDs are a disease-modifying treatment and 7% were aware that pneumopathy could be a potential complication of Methotrexate. 73% of patients knew what a biologic drugs is, when biosimilar was only known by 10% of them, yet 45% knew that tuberculosis is one of the infections that can occur under biologic drugs. This study revealed that 63% of patients had a total score of correct answers superior to 5 (for a max score of 10) and 37% had a total score between 0-5.
Conclusion: Althought this study showed decent knowledge and good practices among the Moroccan patients with spondyloarthritis. The doctor-patient contact and the multimedia information as well as patients' associations remain as useful means to improve this knowledge.

AB1802-HPR PAIN IN AXIAL SPONDYLARTHRITIS MAY NOT BE ALWAYS INFLAMMATORY

Keywords: Pain, Spondyloarthritis, Inflammatory arthritides

İ. Kurut Aysin[1], G. Alp[1], E. Durak Ediboglu[1], E. Otman Akad[1], H. Cinakli[1], E. Erpek[1], A. Özkan[1], H. Kocaayan[1], D. Solmaz[1], S. Akar[1]. *[1]İzmir Katip Çelebi University Atatürk Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey*

Background: Many patients with axial spondyloarthritis (axSpA) report persistent pain even when treated with anti-inflammatory agents. Therefore, it can be hypothesized that this persistent pain may not be always entirely of inflammatory origin and additional pain mechanisms may play a role (1)
Objectives: To evaluate the frequency of central sensitization (CS) and neuropathic pain (NP) in patients with axial spondylarthritis (axSpA) and its relationship with disease activity and functional status.
Methods: Patients classified as axSpA according to ASAS 2009 criteria were included in this cross-sectional study. Presence of CS was evaluated with the CS inventory (CSI; a 25-item questionnaire that a score of ≥40 point scored out of 100 is positive for CS. Presence of depression and anxiety were evaluated with Hospital Anxiety and Depression questionnaire (HADS), and fibromyalgia syndrome (FMS) by ACR 2016 criteria. Neuropathic pain (NP) was assessed with DN4 (Douleur Neuropathique en 4 questions) questionnaire. In addition, the patients' BASDAI, ASDAS-CRP, BASFI, ASQoL, ASAS-HI/environmental scores were also calculated.
Results: 121 axSpA patients[102 (84.3%) radiographic axSpA, 74 (61.2%) male, mean age: 43.9 ± 10.6 years] were included in the study. Of our patients 84% were receiving biological therapy. Other characteristics of the patients are summarized in **Table 1**. CS was detected in 35 (28.9%), NP in 12 (10.1%) and FMS in 9 (7.7%) patients. Age and advanced treatment usage rates were similar between the groups. Among patients with CS the percentage of female was higher, there was no sex difference for patients with NP and FMS. Duration of the disease was shorter in the CS group. Pateints and physician global assessment of disease activity (PGA and PhGA recpectively), BASDAI, Leeds enthesitis *index* (LEI), ASQoL, ASAS-HI were found to be significantly higher in patients with CS and NP. In addition, BASFI and ASAS-HI environmental scores were worse in those with CS. While anxiety was higher in those patients with CS and NP according to the HADS questionnaire, the rates of depression were similar. Six (17.1%) patients with CS also had NP and 6 (50%) patients with NP had also CS. While all 9 patients with FMS had CS, only 2 had NP. CS severity and disease activity and quality of life scores showed a strong positive correlation **(Figure 1)**.
Conclusion: Approximately one-third of axSpA patients, most of which received advanced therapy, have CS and %10 of them have NP. Both quality of life and activity measures were found to be higher in patients who have CS. Therefore it should be kept in mind that in axSpA patients pain may not be always due to inflammatory origin of the disease, but may be due to non-inflammatory causes of pain.

EVALUATION OF THE FACTORS ASSOCIATED WITH THE BIOPSYCHOSOCIAL STATUS OF PATIENTS WITH AS WHO WERE DECIDED TO BE TREATED WITH ANTI-TNF THERAPY FOR THE FIRST TIME

Keywords: Spondyloarthritis, Patient reported outcomes, Cognitive Function

N. B. Karaca[1], E. Ünal[1], U. Kalyoncu[2], S. Kiraz[2]. *[1]Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Department of Physiotherapy and Rehabilitation, Ankara, Turkey; [2]Hacettepe University, Faculty of Medicine, Department of Rheumatology, Ankara, Turkey*

Background: Ankylosing spondylitis (AS) is a rheumatic disease that affects patients in a biopsychosocial framework due to its chronic inflammatory nature. It is known that anti-TNF therapy is given to patients with persistently high disease activity despite conventional treatments according to the ASAS recommendations [1].
Objectives: The aim of this study was to examine the factors associated with the biopsychosocial status of patients with AS who were decided to be treated with anti-TNF therapy for the first time.
Methods: 76 AS patients who were decided to treated with anti-TNF therapy included in the study. Socio-demographic informations of patients were collected. The Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) values were recorded for disease activity levels. Biopsychosocial status of the patients was evaluated by the BETY-Biopsychosocial Questionnaire (BETY-BQ). The Bath Ankylosing Spondylitis Functional Index (BASFI) and Health Assessment Questionnaire (HAQ) were used to assess functional and and daily living activities. The Hospital Anxiety and Depression Scale (HADS) was used to assess anxiety and depression levels.
Results: The mean age of the patients was 39.99 ± 10.0 years. The mean BASDAI scores indicated active disease and were 5.98 ± 1.78. There was a statistically significant moderate correlation between the BETY and the anxiety and depression subscales of HADS and BASDAI, in the positive direction (r= 0.692, p <0.001 and r= 0.685, p <0.001 and r= 0.552, p <0.001). A statistically significant, strong correlation was found between the BETY, HAQ and BASFI scores in the positive direction (r= 0.834, p <0.001 and r= 0.747, p <0.001) (Table 1). It was observed that patients showed anxiety and depression characteristics according to HADS cut-off values (>10 and >7).
Conclusion: It was concluded that the biopsychosocial status of anti-TNF naive patients with AS was affected by anxiety-depression levels, functionality, and disease activity score. In addition to anti-TNF therapy, it was interpreted that the treatment of biopsychosocial characteristics of patients should also be taken into consideration in disease management.

IMPROVING PATIENT SAFETY THROUGH THE ESTABLISHMENT OF A PHARMACIST-LED BLOOD MONITORING CLINIC FOR JAK INHIBITORS IN RHEUMATOLOGY

Keywords: Safety

M. Murphy[1,2], J. Whiteman[1,2], N. Maiden[2], S. Walker[2], V. Mcgoldrick[2], N. Liggett[2], E. Savage[2], R. Stewart[2], L. A. Neville[2], E. Wylie[2], C. Mcateer[2], L. A. MC Williams[2], S. Mccourt[2], A. Mcmullan[2], D. Dermott[2], J. Mcknight[1]. *[1]Pharmacy Department, Craigavon Area Hospital, Southern Health & Social Care Trust, Craigavon, United Kingdom; [2]Rheumatology Department, Craigavon Area Hospital, Southern Health and Social Care Trust, Craigavon, United Kingdom*

Background: Janus kinase inhibitors drugs (JAKi) are novel small molecule medications known to cause abnormalities such as elevations in hepatic transaminases, decreases in neutrophil and lymphocyte counts and elevations in cholesterol and creatinine kinase. Blood monitoring is recommended and dose adjustments are advised if abnormalities arise. Recent warnings by the EMA and MHRA have highlighted the importance of monitoring these medications. Timely review and management of patients on JAKi drugs is difficult to maintain with increasing workload amongst the rheumatology team. A baseline audit (2020) demonstrated that hospital blood monitoring guidelines for JAKi drugs were not being followed. The rheumatology multidisciplinary team met and utilised Quality Improvement methodology including fish and driver diagrams to address this. This led to the creation of a pharmacist-led JAKi blood monitoring clinic.

Objectives: To establish a pharmacist-led rheumatology blood monitoring clinic for the JAKi drug class in order to: increase patient safety with increased compliance to blood monitoring, save consultant/nurse time, improve communication with primary care on the frequency of blood testing required, increase patient understanding of the importance of blood monitoring with JAKi drugs, reinforce counselling advice such as risk of infections, shingles and thrombosis and promote medication adherence.
Methods: The clinic was established in March 2021. Patients commencing JAKi drugs are referred to the pharmacist-led clinic by the medical team. The pharmacist contacts the patient by phone following delivery of their medication. The patient is counselled on their new medication and dates for blood checks are agreed. A letter is sent to the patient and their GP providing this information. The patient is booked into virtual telephone appointments and bloods are monitored every month for the first 3 months and every 3 months thereafter. Any change or abnormality in blood results are flagged early in the patient's treatment and if necessary, discussed with the consultant. Adjustments are made to the patient's dose if appropriate.
Results: In order to evaluate the benefit of the pharmacist clinic a re-audit of compliance with blood monitoring (March 2021- September 2022) was carried out alongside a patient satisfaction postal survey (August 2022). A total of 58 patients were sampled in the re-audit. The re-audit found an increase in compliance in blood monitoring since the introduction of the pharmacist clinic. 98% of patients had their full blood count performed at 3 months compared to 56% in audit 1 and 95% of patients had their lipid profile completed at 3 months compared to 15% in audit 1 (Table 1). A patient satisfaction survey (N=62, response rate 48%) found that 28 (93%) patients either agreed or strongly agreed that they were more aware of the importance of attending for regular blood monitoring when prescribed JAKi therapy as a result of the clinic. The pharmacy team made several significant interventions (self-graded Eadon grade 4 and 5). For example by improving medication adherence, detecting haematological abnormalities that required JAKi dose reduction, identifying patients suffering from infection requiring intervention including shingles and Covid-19.

Table 1. Comparison of audit results pre (Audit 1) and post (Audit 2) clinic establishment

	Audit 1 (N=48)	*Audit 2 (N=58)*
Number of patients with full blood count completed at weeks 4, 8 & 12	27 (56%)	57 (98%)
Number of patients with lipid profile completed at week 12	7 (15%)	55 (95%)
Number of patients LFTs completed at weeks 4, 8 & 12	26 (54%)	54 (93%)

Conclusion: Introduction of the pharmacist-led clinic has increased patient safety by ensuring compliance with blood monitoring as per hospital guidelines. The clinic has paved the way for improved communication with primary care teams and has provided patients with extra support during their first months on treatment with their JAKi. It has also expanded the role of the rheumatology pharmacy team and saved nursing and medical time.
Acknowledgements: I wish to thank the SHSCT Rheumatology team for all their help, support and guidance with this project.

AB1805-HPR

SERVICE EVALUATION OF COMBINED RHEUMATOLOGY/ OBSTETRIC CLINIC, SOUTH TEES NHS FOUNDATION TRUST, UNITED KINGDOM''

Keywords: Pregnancy and reproduction, Patient information and education, Quality of care

F. A. Khan[1], G. Janakiraman[1], M. Shivanath[1], R. Gul[1], S. Chin[1], E. Steele[2], D. Kong[3]. [1]*The James Cook University Hospital, Rheumatology, Middlesbrough, United Kingdom*; [2]*Newcastle University, Undergraduate Department., Newcastle, United Kingdom*; [3]*The James Cook University Hospital, Obstetrics and Gynaecology, Middlesbrough, United Kingdom*

Background: Multidisciplinary management in a combined clinic improves patient experience and outcomes for pregnant women with inflammatory rheumatic diseases (IRD). Achieving better IRD control pre, during, and post-pregnancy with pregnancy-compatible disease-modifying anti-rheumatic therapies (DMARDs) reduces maternal and foetal mortality/ morbidity minimising complications. EULAR published recommendations for core data sets around maternal, pregnancy, and treatment information for pregnancy registries in Inflammatory rheumatic diseases.
Objectives: Service evaluation of the Combined Rheumatology Obstetrics clinic held in our hospital to evaluate pregnant patients with Inflammatory rheumatoid diseases against the EULAR recommendations.
To improve Patient and disease outcome in terms of maternal health and fetal health.
Methods: Retrospective data was collected on interventions and outcomes of pregnancies in 40 women with Inflammatory rheumatic diseases seen in the-Combined Rheumatology/ Obstetric Clinic from November 2020 to February 2022 reviewing clinic letters and medical notes.
Results: 77% of patients had inflammatory arthritis including rheumatoid, psoriatic, juvenile idiopathic, and axial spondylo-arthritis.15% had connective tissue disease (CTD) including lupus with anti-phospholipid syndrome, Bechet's and undifferentiated CTD. 2%patients did not have a formal IRD diagnosis. 12.5% of patients had only pre-pregnancy counselling, 2.5% had miscarriages. Of the remaining 85% of pregnant patients' 10% had obstetric care/ delivery in other trusts. Treatment received by patients 12 months prior to conception included DMARDs (37%), biologics (24%), combination (8%), and steroids (10%). 25% were on no treatment.During pregnancy 29% received oral DMARDs, 11% biologics and 16% needed steroids. 50% of patients did not require any treatment. Interventions done in the clinic included medication review (100%), VTE assessments (100%), commenced VTE prophylaxis (7.5%), change in DMARD dosage (10%), additional medication added (10%), intramuscular/ intra-articular steroid injections (16%) and physiotherapy referrals (10%). Maternal adverse outcomes include 5% preeclampsia, 0.07% gestational diabetes and 0.02% pregnancy-induced hypertension and foetal growth restriction. 93.3% were full-term deliveries. Only 10% had adverse neonatal outcomes including 6.6% preterm births. None had congenital heart block. 3.3% had congenital malformations unrelated to IRD/ DMARD therapy.Patient satisfaction surveys were sent out to 40 patients with a 30% response rate. The patient satisfaction questionnaire revealed all patients had their consultation with rheumatology and obstetric consultants with 100%satisfaction. 100% felt the staff was supportive and they would recommend our service to friends and family. Of 66.7% of patients receiving pre-pregnancy counselling, 50% were in the combined clinic. Of the 33.3% of patients not receiving counselling 22.2% felt they would have benefitted from it.
Conclusion: Our service evaluation of the combined rheumatology/ obstetric clinic revealed favourable outcomes for the mother and baby with high patient satisfaction rates. The clinic offered appropriate timely interventions to control IRD improving pregnancy outcomes. The future aim is to deliver this high-quality service to all pregnant patients with IRD through robust referral pathways to improve the patient experience.

EXPECTED FEATURES OF THE COURSE LEADER IN THE REHABILITATION HEALTHCARE PROFESSIONALS' HIGHER EDUCATION: A QUALITATIVE STUDY ON STUDENTS' PERSPECTIVES

Keywords: Education, Qualitative research methods, Rehabilitation

B. Giardulli[1], E. Marchesini[1], L. Furri[2], M. Testa[1], A. Dell'isola[3], S. Battista[1,2,3]. [1]*University of Genoa, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, Genova, Italy*; [2]*University of Verona, School of Medicine and Surgery, Verona, Italy*; [3]*Lund University, Department of Clinical Sciences Lund, Lund, Sweden*

Background: Previous evidence showed that Healthcare Professionals (HPs) working with rheumatic and musculoskeletal diseases (RMD) from Mediterranean countries have higher educational needs than Northern-European ones [1]. Hence, it is necessary to find new strategies to improve their training. Course leaders (CLs) are the responsible of the quality and delivery of the training of rehabilitation HPs, since they oversee designing and directing degree courses that are experienced by students first-hand [2]. To better understand their leadership role, it is helpful to focus on the people with whom the leader interacts daily [3–5]. Therefore, students become an essential source on that matter [2].

However, little attention has been given to the expected features that course leaders should hold, starting from students' perspectives.
Objectives: This study explored students' expected features of a course leader.
Methods: A qualitative study was carried out based on semi-structured interviews. A panel of recent graduates and students of the Master of Science in 'Healthcare Professionals Rehabilitation Sciences' (University of Verona, Verona, Italy) was recruited using purposive sampling. Data were analysed using the 'Reflexive Thematic Analysis' by Braun&Clarke [6].
Results: Ten HPs in training agreed to partake in the study (age 30 ± 9; men N=2; women N=8). Five themes were generated from the analysis: 1) 'A Collaborative Manager', as students perceived the CL as a non-authoritarian manager who involved all the stakeholders in the decision-making process; 2) 'A Diplomatic yet Honest Communicator', as students needed someone capable of communicating with them transparently; 3) 'A Flexible Mediator', as the CL should actively listen to all their stakeholders and mitigate conflicts; 4) 'An Empathic and Available Guide', as students need someone available and ready to help or guide them; 5) 'An Experienced Healthcare Professional', since students felt that the CL should have a clinical background related to the course they lead.
Conclusion: The results of this study suggest that students expect CL to have a wide range of qualities and attitudes more related to soft (i.e., adaptation, communication, organisation skills, teamwork) rather than hard skills (i.e., clinical experience). They expect a CL that considers all stakeholders' needs and preferences to guarantee course harmony and satisfaction.

HPR Interdisciplinary research

AB1807-HPR INVESTIGATION OF RELATIONSHIP BETWEEN NUTRITIONAL STATUS AND PHYSICAL ACTIVITY LEVEL IN RHEUMATIC DISEASES

Keywords: Diet and Nutrition, Patient reported outcomes, Physical therapy/ Physiotherapy

M. S. Karacil Ermumcu[1], S. Y. Cetin[2], S. Yardım[2], A. Ayan[3]. *[1]Akdeniz University, Nutrition and Dietetics, Antalya, Turkey*; *[2]Akdeniz University, Physiotherapy and Rehabilitation, Antalya, Turkey*; *[3]Health Sciences University, Rheumatology, Antalya, Turkey*

Background: Rheumatic diseases are chronic diseases that negatively affect the quality of life. Ankylosing spondylitis (AS) and rheumatoid arthritis (RA) are the most common clinical manifestations. Non-pharmacological treatments include exercise, healthy and balanced diet recommendations [1,2].
Objectives: The aim of this study was to investigate nutritional status and the physical activity level and relationship between those in patients with rheumatic diseases.
Methods: 108 patients (64 AS, 22 RA and 22 others (Sjogren, scleroderma, psoriatic arthritis)) with rheumatic diseases (47.92±12.26 years) were included in the study. The International Physical Activity Questionnaire (IPAQ) was used to assess physical activity. Food consumption records of the patients included in the study were recorded using a 24-hour retrospective reminder method. The adherence of the patients to the Mediterranean diet was evaluated using the 'Mediterranean Diet Scale' and their diet quality was evaluated with the Healthy Eating Index.
Results: The majority of patients (67.6%) were adapting to the Mediterranean diet and 56.5% had poor overall diet quality. Patients with AS had the worst adherence to the Mediterranean diet 8.21±1.99), while patients with RA had the worst overall diet quality (51.19±14.47, Graph 1). The physical activity level of the patients was inactive (n:49, 39.8%) and there was no significant relationship between nutritional status and physical activity level (p<0.05).
Conclusion: According to the results of the study, although the majority of patients had adherence to the Mediterranean diet, the overall diet quality was poor and the level of physical activity was low. These results show that patients cannot be fed adequately and in moderation. Since these patients live in the Mediterranean region, although the consumption rate of vegetables and fruits is high, they cannot be fed with high quality. It is recommended that future studies be conducted in different regions with larger numbers of patients with rheumatic diseases. These results show that patients should also be evaluated in terms of balanced and healthy nutrition.

AB1808-HPR VIOLENCE: A REALITY IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES?

Keywords: Pregnancy and reproduction, Quality of life, Mental health

A. Carrazco Chapa[1], D. C. Rubio Torres[1], M. E. Corral Trujillo[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], I. Pelaez Ballestas[2], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*; *[2]Hospital General de México "Dr. Eduardo Liceaga", Rheumatology, Ciudad de México, Mexico*

Background: Intimate partner violence (IPV) is defined as any aggression that includes physical, psychological and sexual harm by a current or former intimate partner. In Mexico, 39.9% of women aged 15 years or over have experienced IPV throughout their romantic relationships [1]. IPV in pregnancy and postpartum can lead to mood disorders, obstetric comorbidities, and low birth weight. Pregnant women with autoimmune rheumatic diseases (ARD) are a high-risk population. Using screening tools to detect women experiencing abuse and explore its severity helps us to intervene appropriately and prevent complications [2].
Objectives: The aim of this study is to describe the frequency of IPV in patients with ARD.
Methods: A descriptive, cross-sectional, exploratory study at the Hospital Universitario "Dr. José Eleuterio González" in Mexico. We included women from the pregnancy and rheumatic diseases clinic (CEER) with a screening of IVP with the HITS scale and categorized them as reproductive-age women and pregnant-postpartum women. We defined reproductive age as the age range of 18-45 years and postpartum up to 1 year after the birth of the last child. The demographic characteristics and ARD data were obtained from the clinical record. Women without ARD were matched (1:1) by age and condition (reproductive age and pregnant-postpartum. A virtual survey was applied including sociodemographic data and the Spanish version of HITS. The Kolmogorov-Smirnov test was used to determine normality. To analyze the differences between groups Mann–Whitney U test, Chi-square or Kruskal–Wallis test were employed. A $p < 0.05$ was considered statistically significant. The statistical analysis was performed with the statistical program SPSS version 25.

Results: 96 women were included: 48 with ARD and 48 without ARD. The median age was 27 (IQR 24 – 32). In both groups, 24 were reproductive-age women and 24 were pregnant-postpartum women (18/ 75% postpartum and 6/ 25% pregnant). In the ARD group, the most frequent diagnoses were rheumatoid arthritis (22/ 46%) and systemic lupus erythematosus (20/ 42%). The sociodemographic characteristics and HITS results are in **table 1**. 18 (19%) women suffered IVP: 11 (23%) women without ARD and 7 (15%) women with ARD **(figure 1)**; in both the most reported item was being insulted (10 without ARD vs 7 ARD) followed by being screamed (6 without ARD vs 6 ARD). Threatened with harm was reported in 3 ARD women while physical hurt was reported in 3 women without ARD. We found significant differences between the HITS scores of ARD women and women without ARD (p= 0.007). No differences in IVP frequency in women without ARD and in the ARD group were found (p= 0.433). Overall, more pregnant-postpartum women were identified as IPV victims than reproductive-age women (p= 0.433).
Conclusion: Pregnant and postpartum women are prone to report IPV than women of reproductive age. The current rise in IPV requires us to actively participate in research to prevent complications in pregnant and postpartum patients with ARD.

DETERMINATION OF PRE-SARCOPENIA IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Quality of life, Sarcopenia, Inflammatory arthritides

Ö. Öztürk[1], Ö. Feyzioğlu[1], D. Şahin[2], N. N. Uzun[2], S. Acer Kasman[2], M. E. Tezcan[2]. *[1]Acıbadem Mehmet Ali Aydınlar University, Physiotherapy and Rehabilitation, Istanbul, Turkey; [2]Kartal City Hospital Dr. Lütfi Kırdar Research and Training Hospital, Rheumatology, Istanbul, Turkey*

Background: Sarcopenia is described as the decline in muscle mass and strength that generally occurs with increased age which may cause increased fall risk, mortality, disability, and adverse health outcomes. Patients with axial spondyloarthritis (axSpA) may be more prone to sarcopenia due to the presence of chronic inflammation.
Objectives: This study aims to determine the presence of sarcopenia or pre-sarcopenia and to clarify the associated factors with pre-sarcopenia.
Methods: This cross-sectional study recruited 39 patients with axSpA. Sarcopenia was assessed according to the European Working Group on Sarcopenia in Older People in 2018 (EGSWOP2) criteria by evaluating muscle mass, gait speed, and grip strength. Muscle mass was measured using a bioimpedance body analyzer. Physical performance was assessed with the five times sit-to-stand (FTSTS) test and Short Physical Performance Battery (SPPB). Quality of life (QoL) and physical activity level were evaluated using Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire and the International Physical Activity Questionnaire – Short Form (IPAQ-SF) respectively. Between-group comparison and correlation analysis were performed.
Results: The mean age of the patients was 47.58±6.78 with (64.1 % women), the mean disease duration was 8.17±7.33 years, and the mean body mass index was 28.05±4.74 kg/m2. Pre-sarcopenia was detected in 43.6% of all patients which was defined by low grip strength and no patients had sarcopenia. Patients with pre-sarcopenia were more physically inactive, had worse quality of life, and had lower physical performance compared with those without pre-sarcopenia ($p < 0.05$). The grip strength as the indicator of pre-sarcopenia was significantly moderately correlated with the SPPB ($r = -0.48$, $p = 0.002$), FSST ($r = -0.43$, $p = 0.006$), ASQoL ($r = -0.45$, $p = 0.003$), and IPAQ-SF ($r = 0.48$, $p = 0.002$).
Conclusion: Pre-sarcopenia is commonly detected in axSpA patients and physical performance is impaired which may result in a further decline in functional status. Maintaining adequate muscle strength and muscle function in patients with axSpA may contribute toward improving QoL. Patients with axSpA should be assessed in terms of sarcopenia-related findings.

RESILIENCE AND PERINATAL LOSS IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Quality of life, Mental health, Pregnancy and reproduction

M. E. Corral Trujillo[1], R. A. Cerda González[1], H. G. Martínez Sandoval[1], A. Carrazco Chapa[1], K. M. López Serna[1], J. C. Riega-Torres[1], L. Pérez

Barbosa[1], C. M. Skinner Taylor[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: Resilience has been defined as the capacity of individuals to successfully maintain or regain their mental health in the face of significant adversity or risk. [1]. The Wagnild and Young Resilience Scale (RS) from 1993 is one of the most widely used instruments in the evaluation of resilience [2]. Having an autoimmune rheumatic diseases (ARDs) and perinatal losses (PL) have been considered traumatic events [3,4]. Identifying women at risk is important for developing psychological support strategies.
Objectives: Evaluate the resilience capacity in patients with and without ARDs with PL.
Methods: Descriptive, cross-sectional, comparative study at the Hospital Universitario "Dr. José Eleuterio González" in México. We included women from the Pregnancy and Rheumatic Diseases Clinic (CEER) that answer a virtual survey with the RS. The demographic, ARD and PL data were obtained from the clinical records. The women without ARD were invited to fill a virtual survey with the RS, sociodemographic and PL data. The RS is a Likert-type scale that consists of 25 items with seven response options. The responses are summed to produce a total score that ranges from 25 to 175; the greater the score the greater the resilience capacity. The Kolmogorov-Smirnov test was used to determine normality. To analyze the differences between groups Mann–Whitney U test, Chi-square, T- test were employed. A $p < 0.05$ was considered statistically significant. The statistical analysis was performed with the statistical program SPSS version 25.
Results: A total of 50 women were included: 25 with ARD and 25 without ARD. The median age for the group with ARD was 42 (38.5-51) and 34 (26-42.5) for the without ARD group. In the ARD group the most frequent diagnosis were systemic lupus erythematosus (7/28%), rheumatoid arthritis (6/24%) and Antiphospholipid Syndrome (4/16%). For the RS scores, women without ARD have a greater median 137.56 (SD =22.14) than the group with ARD 132.72 (SD =31.03). No statistically differences were found in other variables between groups. The sociodemographic and PL data and the RS score for both groups are included in **table 1.**
Conclusion: Even though there were no significant differences between groups, our results suggest that higher education (> 9 years) and suffering only 1 PL can be variables that enhance the resilience capacity of women with PL. Our limitation was the sample size for both groups.

AB1811-HPR **CATASTROPHIC HEALTH EXPENSES IN PREGNANT WOMEN WITH RHEUMATIC DISEASE**

Keywords: Quality of life, Pregnancy and reproduction, Health Services Research

F. R. Arevalo Nieto[1], A. Carrazco Chapa[1], D. P. Pérez Campos[1], D. C. Rubio Torres[1], M. E. Corral Trujillo[1], A. Aguilar-Leal[1], S. J. Pech Mora[1], D. Ramos[1], J. C. Riega-Torres[1], J. A. Cardenas-de la Garza[1], L. Pérez Barbosa[1], C. M. Skinner Taylor[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: Rheumatic diseases (RD) have an impaired quality of life and a high cost of healthcare. Out-of-pocket health expenses are those expenditures that households make to acquire medicines and associated services that come from family income [1]. A disease with catastrophic health expenses is a condition that, due to its high cost and the expenses derived from treatment and medications, exceeds 30% of the family income [1]. Such catastrophic expenses can negatively influence the therapeutic adherence of patients and the prognosis [2]. A policy challenge has been the achievement of universal coverage of health services. A key was the implementation of "Seguro Popular" (SP) in 2003; however, the abolition of the SP in 2020and the foundation of "Instituto de Salud para el Bienestar" (INSABI) by the current government, created uncertainty due to some omissions detected regarding the clarity of its performance [1].
Objectives: To estimate the frequency of pregnant patients with RD who experienced catastrophic health expenses when using medical services.
Methods: An observational cross-sectional, retrospective study was carried out at the Pregnancy and Reproductive Health Clinic for Rheumatic Diseases (CEER) from the University Hospital "Dr. José Eleuterio González", in Mexico. The data of all pregnant patients was collected from the clinical record. From the socioeconomic study, sociodemographic data, family nucleus, family's monthly income, monthly health expenditures, as well as the type of health insurance they had, were obtained. The percentage of out-of-pocket health expenses (medication) of each patient was calculated, and if this exceeded 30%, it was defined as a catastrophic expense. For statistical analysis, the sociodemographic and clinical characteristics of the population are presented as frequencies, percentages, or standard deviations.
Results: A total of 54 patients were included in the period from 2019 to 2022 with a mean age of 28.02 (±6.45) years. The rheumatic diagnoses were rheumatoid arthritis with 24 (44.4%), systemic lupus erythematosus with 13 (24.1%), antiphospholipid syndrome with 5 (9.3%), dermatomyositis with 3 (5.6%),juvenile idiopathic arthritis with 2 (3.7%),Sjögren's syndrome with1 (1.8) and others with 6 (11.1%).The sociodemographic characteristics are described in **Table 1**. Most of the patients had health insurance coverage with 43 (79.6%), where SP stood out as the main one with 24 (55.8%). Of the 43 patients who had health insurance coverage, 5 (11.6%) experienced catastrophic health expenses, which we can see in **Figure 1**. Of the 11 (20.4%) patients who did not have health insurance coverage, 1 (9.1%) experienced catastrophic health expenses.
Conclusion: The 11.6% of the patients who had health insurance coverage reported having catastrophic health expenses, in which they spent more than 30% of the family's monthly income. 9.1% of those who did health insurance coverage presented catastrophic health expenses. It is of vital importance that rheumatic diseases should be recognized as catastrophic illnesses to ensure quality patient-tailored care.

AB1812-HPR VACCINATION UPTAKE IN A COHORT OF PATIENTS ON BIOLOGIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS (BDMARDS) AT A MELBOURNE PUBLIC HOSPITAL

Keywords: COVID, bDMARD, Vaccination/Immunization

H. Pourhadi[1], A. Johnson[1], A. Foote[1]. [1]*Northern Health, Rheumatology, Epping, Australia*

Background: As a result of immunosuppression, rheumatology patients (particularly those on bDMARDs) are at a greater risk of infections. However, little is known about the number of rheumatology patients who have are vaccinated for influenza, COVID-19, Hepatitis B and Pneumococcal vaccinations.
Objectives: To ascertain the number of patients on bDMARDs who received the COVID-19, Influenza, Hepatitis B, Pneumococcal and Shingles Vaccines. With regards to the Influenza vaccine information was obtained over the years 2018 – 2022 to determine if rates of influenza vaccination increased during the COVID-19 pandemic.
Methods: All rheumatology patients on bDMARDs at the Northern Hospital in Epping, Melbourne Australia were included in this study. By retrospectively reviewing the medical records, data was collected regarding patient demographics, clinical information and vaccination to COVID-19, Hepatitis B, Pneumococcal and Influenza. Information for influenzae was obtained over the period from 2018 to 2022. Ethics committee approval was sought from our institution (Reference number: ALR 75.2022).
Results: There were 201 patients on bDMARDs included in this analysis. 139 (69%) were female with a mean age of 54 (SD +/-15.0). Rheumatoid arthritis was the most common indication for biologic therapy (55%) followed by psoriatic arthritis (19%) and ankylosing spondylitis (18%). Tumour necrosis factor inhibitors (TNFi) and Janus kinase inhibitors (JAKi) were most often utilised, prescribed to 62% and 18% of patients respectively. With regards to the influenza vaccine 99 patients (49%) were vaccinated in 2022, compared to 49 patients (24% in 2018). Women were more likely to be vaccinated than men (54% versus 38% using Chi-squared test (p=0.05). No significant difference was seen by disease category or class of bDMARD. Older patients were more likely to be vaccinated (57, SD = 15) versus younger patients (50, SD = 14) p <0.001. In terms of COVID-19 vaccinations 7% were unvaccinated, 24% received 2 vaccinations, 42% received 3 vaccinations and 25% received 4 or more vaccinations (the recommended number of vaccinations as per current health advice). Finally, regarding the other vaccines 15% received the hepatitis B vaccine, 15% the Pneumococcal vaccine, and 8% received the shingles vaccine.
Conclusion: In this cohort of bDMARD patients there was a significant increase in the proportion of patients who received the influenza vaccine during the pandemic. This finding is novel in a rheumatology cohort. Despite this there remains under-utilisation of COVID-19, hepatitis B, Pneumococcal and Shingles vaccinations. Further work looking at the reasons for the low vaccinations rates in immunosuppressed populations is needed to address this public health issue.

AB1813-HPR PREVALENCE AND EVOLUTION OF OCCUPATIONAL SHOULDER TENDINITIS OVER A PERIOD OF 10 YEARS IN THE TUNISIAN CENTER REGION

Keywords: Epidemiology, Work-related issues, Descriptive Studies

G. Asma[1], A. Brahem[1], A. Chouchen[1], R. Mejri[1], I. Kacem[1], M. Maoua[1], O. El Maalel[1], H. Kalboussi[1], S. Chatti[1], N. Mrizek[1]. [1]*Faculty of Medicine of Sousse, Department of Occupational Medicine, sousse, Tunisia*

Background: Shoulder pain is one of the most common regional pain syndromes. Shoulder tendinitis is the second recognized cause of musculoskeletal disorders of the upper limbs after carpal tunnel syndrome. Symptoms can be persistent and disabling in terms of an individual's ability to carry out daily activities both at home and in the workplace with significant and socio-economic costs.
Objectives: To assess the prevalence of occupational tendinitis of the shoulder and its evolution during the study period, and to describe the socioprofessional characteristics of the workers.
Methods: This is a retrospective cross-sectional study of all cases of tendonitis of the rotator cuff, working in the private sector, recognized by the competent medical commission of the National Medical Care Fund of the region of Tunisian center over a period of 10 years.
Results: During the study period, we identified 635 cases of shoulder tendinitis, i.e. 29.5% of all musculoskeletal disorders of the upper limbs. The average age of the population was 44.56 years ± 7.7 years. Our study population was mainly women (82.5%) with a sex ratio of 0.21. The majority of patients worked in the textile sector (76.2% i.e. n= 487) and the electronic sector (4.5% i.e. n= 28). Average seniority of workers in their jobs was ranging from 1 to 36 years. Seamstress (63.4%) and workman (17.7%) were the most affected jobs. The cases of shoulder tendinitis were in continuous rise over the 10 years (p=0.001, r=0.86).
Conclusion: Our study add an evidence to suggest that shoulder disorders may be increased among some workers, particularly those with jobs involving combinations of exposure to: overhead work and repetition. Most of the research on management of shoulder disorders has rarely included occupational outcomes. Adequate and rigorous prevention is essential to reduce the prevalence of this with painful consequences.

AB1814-HPR RHEUMATOLOGY NURSING OUTPATIENT CLINIC IN PORTUGAL

Keywords: Patient information and education, Inflammatory arthritides, Nursing

L. Barbosa[1], J. Santos[1], A. Cordeiro[1], M. J. Santos[1,2], E. Pereira[1]. [1]*Hospital Garcia de Orta, Rheumatology Department, Almada, Portugal*; [2]*Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Lisboa, Portugal*

Background: Systemic inflammatory rheumatic diseases are characterized by being chronic diseases. These diseases affect the person, in their various dimensions and are often associated with pain, loss of mobility and function, fatigue, anxiety and depression (Matcham, Norton, Scott, Steer & Hotopf, 2016; Primdhal & Esbensen, 2020; Ryan, 2020). The complex needs of these patients require and benefit of an advanced nursing practice and a guided and specialized attention that can be provided in a nursing clinic. The awareness of rheumatic patient needs and lack of this type of care led, to our knowledge, to the development of the first rheumatology nurse clinic in Portugal.
Objectives: Characterize a guided nursing clinic with the aim to support patients with systemic inflammatory rheumatic diseases, mainly initiating subcutaneous (sc) classic and biological DMARDs.
Methods: Summarized description of first guided rheumatology nurse clinic in Portugal.

Results: This nurse clinic was created and developed during the pandemic period of SARS-CoV 2 (starting February 2020). For the last three years a total of 556 appointments was performed. The targeted patients had systemic inflammatory rheumatic diseases, mainly rheumatoid arthritis, psoriatic arthritis and spondylarthritis treated with sc classic and biological DMARDs. Appointments are scheduled at week 0 and 4 of starting these therapeutics and also whenever needed, at the request of the patient or the treating physician, in order to ensure a good nurse availability to clarify doubts at the beginning of these treatments. In the specific case of sc methotrexate, a protocol was created by the Rheumatology multidisciplinary team, defining the parameters eligible for evaluation, and the respective procedures of care. During appointments nurses also assess specific disease implications in the person's daily life, both physical, emotional and social domains. Additionally, this is an opportunity to reinforce reliable information on disease management, coping strategies, including information how to manage medication side effects.

Conclusion: The rheumatology nursing outpatient clinic provides key additional care and monitorization to patients with systemic inflammatory rheumatic diseases, treated with sc classic and biological DMARDs. Nurses improve the management of chronic diseases, namely by promoting autonomy of the patient in self-administration of sc therapies at home, counselling and informing about possible adverse effects and respective management strategies, constituting a valid contribution to disease control and patient engagement and education.

AB1816-HPR

RELIABILITY AND VALIDITY OF THE LIE-TO-SIT-TO-STAND-TO-WALK TRANSFER TEST IN TOTAL KNEE ARTHROPLASTY

Keywords: Osteoarthritis, Outcome measures, Comorbidities

B. Unver[1], K. S. Kacmaz[2], V. Karatosun[3]. *[1]Dokuz Eylul University, Physical Therapy and Rehabilitation, Izmir, Turkey*; *[2]Izmir Katip Celebi University, Physical Therapy and Rehabilitation, Izmir, Turkey*; *[3]Dokuz Eylul University, Orthopedics and Traumatology, Izmir, Turkey*

Background: Total knee arthroplasty (TKA) is the gold-standard procedure for end-stage knee osteoarthritis, however, some residual problems may still continue and cause a variety of dysfunctions, such as pain, impaired strength, proprioception, postural instability, dynamic balance, and gait deficiencies [1]. Falls are the most frequent cause of injuries in elderly people, accounting for 90% of hip and wrist fractures and 60% of head injuries [2] requiring expensive and difficult procedures such as fracture surgeries and arthroplasties [3]. The most frequent cause of falling was transfer activities while shifting body weight which accounted for 41% of falls [2] especially getting up from bed and walking to the bathroom [2,4,5]. Additionally, the three major classes of activities—walking, sitting down, and standing—were the most common precipitants of falls. These findings emphasize the need to target each of these activities in fall risk assessment and prevention strategies [2,5]. The Lie-to-Sit-to-Stand-to-Walk Transfer Test (LSSWT) incorporates a multitask approach to measure complicated transfer abilities in older people. However, there is no study investigating the reliability and validity of the LSSWT in TKA patients.

Objectives: The aim of the study is to determine the reliability, validity, and minimal clinically important difference (MCID) of the LSSWT in patients with TKA.

Methods: Twenty-one patients with TKA were included in the study. The LSSWT, the Timed Up and Go Test (TUG), and the Hospital for Special Surgery (HSS) were administered to the patients. Patients rested between the tests for an hour to prevent fatigue.

Results: The mean age was 68.1 ± 2.59 years and the mean HSS Knee Score was 85.43± 3.47. The relative (ICC coefficient) and absolute (SEM and SRD95) reliability values were 0.88, 1.21, and 3.33 respectively. The Spearman correlation coefficient of the LSSWT with the TUG was 0.63.

Conclusion: The LSSWT has excellent reliability and high validity in evaluating fall risk and complex dynamic balance and mobility for the activities of daily living in patients with TKA. The low MCID value (3.33) shows that it is sensitive and identifies little alterations in a patient's condition over time or management strategies. Therefore, it is advisable to use the LSSWT for assessing the fall risk, dynamic balance, and mobility for living in the community, discharging, or admitting to a facility.

CROSS-CULTURAL ADAPTATION AND VALIDATION OF THE TURKISH VERSION OF THE NORWICH PATELLAR INSTABILITY SCORE IN PATIENTS WITH PATELLAR INSTABILITY

Keywords: Patient reported outcomes, Outcome measures, Validation

I. Ayas[1], Z. Hazar[1], I. Kaya[2], M. Ataoglu[2], U. Kanatli[2]. *[1]Gazi University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitaton, Ankara, Turkey*; *[2]Gazi University Faculty of Medicine, Department of Orthopedics and Traumatology, Ankara, Turkey*

Background: The Norwich Patellar Instability Score (NPIs) score is a tool for evaluating the impact of patellofemoral instability on joint function. It has not been translated or culturally adapted for the Turkish population before.

Objectives: The aim of this study was to translate and validate the NPIs in Turkish patients with patellar instability.

Methods: Sixty-four individuals with patellar instability were included in this cross-sectional study. Test-retest reliability of the Turkish version of NPIs was assessed by the intraclass correlation coefficient (ICC) and Cronbach's alpha for internal consistency. For construct validity, correlation coefficients between the Turkish version of NPIs developed by the translation-back translation method, Kujala patellofemoral disorder score, and Lysholm knee score were analyzed.

Results: The Turkish version of the NPI score showed high internal consistency (Cronbach's alpha = 0.97) and excellent test-retest reliability ($ICC_{2,1}$ = 0.90). The Turkish version of the NPI score had a strong correlation with Kujala patellofemoral disorder score (Rp = -0.85, p< 0.001) and the Lysholm knee score (Rp = -0.89, p< 0.001). A floor effect was observed in the present study and there was no ceiling effect.

Conclusion: The Turkish version of the NPIs is a reliable and valid tool in patients with patellar instability. The Turkish version of the NPIs will be a guide for clinicians and researchers to understand the functional status of patients with patellar instability.

AB1818-HPR QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Quality of life

L. Bohmat[1], I. Bessonova[1], N. Shevchenko[1,2], T. Holovko[1,2]. [1]*SI "Institute of Children and Adolescents Health Care of NAMS of Ukraine", Department of Rheumatology and comorbid conditions, Kharkiv, Ukraine*; [2]*V.N.Karazin Kharkiv National University, Department of Pediatrics, Kharkiv, Ukraine*

Background: According to the Treat to Target strategy, in addition to monitoring the activity of the process and monitoring the formation of irreversible organ damage, it is necessary to recognize the Health-Related Quality of Life, which allows a full assessment of the patient's condition. Quality of life is defined as an integral characteristic of the patient's physical, psychological, emotional and social functioning, based on his subjective perception. Often, changes in quality-of-life indicators precede the dynamics of clinical manifestations of the disease, so they can be used as auxiliary criteria for the effectiveness of treatment already in the early stages of the course of the disease.
Objectives: To evaluate the quality of life of children and adolescent patients with systemic lupus erythematosus (SLE) depending on the activity and duration of the disease.
Methods: 18 children and adolescents with SLE aged from 8.5 to 18.6 years (14.3 ± 0.7) were examined. The average duration of SLE was 3.1 ± 0.7 years, the age of onset was 11.4 ± 0.8 years. Most of the examined were girls (94.4%). The diagnosis was established according to the classification criteria EULAR/ASR 2019 for SLE[1] with at least 10 points. High activity of SLE was found in 5.56% of patients, moderate in 33.33%, minimal in 61.11%. The patients' quality of life was assessed using the Lupus QoL questionnaire, which is a questionnaire with 34 questions, combined for 2–8 questions in 8 separate blocks: physical health, pain, planning, intimate relationships, dependence on other people, emotional health I, body image (the patient's assessment of his body), fatigue. The questionnaire was filled out by the patients themselves, the answers to the questions were modeled on a five-point Likert scale (0 – constantly, 1 – almost always, 2 – quite often, 3 – occasionally, 4 – never). Zero points corresponded to the worst quality of life, 100 points to the best state of quality of life for each domain (scale) of the questionnaire.
Results: Hhe quality of life related to health was worsened in all persons. The average total score for all domains was 65.51 ± 2.09 points and ranged from 38.41 to 89.45 points. The spheres "intimate relations" and "body image" were the most disturbed, which had the lowest score according to the test data (35.58 ± 4.87 and 62.08 ± 6.89, respectively). The best the quality-of-life indicator was recorded in the "pain" domain, which scored the highest number of points (82.41 ± 4.99 points). According to other scales of Lupus QoL, the quality of life was equal: in the domain "physical health" 77.60 ± 4.17 points, "planning" - 79.63 ± 5.52 points, "dependence on other people" - 66.21 ± 5.74 points, "emotional health" and "fatigue" - 76.15 ± 4.24 and 75.00 ± 4.46 points, respectively. Correlation analysis revealed inverse correlations between the degree of disease activity and the domains "pain" ($r = -0.530$; $p < 0.05$), "planning" ($r = -0.529$; $p < 0.05$), "intimate relationships" ($r = -0.720$; $p < 0.05$), "emotional health" ($r = -0.728$; $p < 0.01$). Direct correlations were found between the age of patients and indicators of the domain "pain" ($r = 0.647$; $p < 0.01$) and "planning" ($r = 0.642$; $p < 0.01$, respectively), the age of patients at the onset of the disease and the indicator the "body image" scale ($r = 0.611$; $p < 0.01$), the duration of the disease and the "fatigue" scale ($r = 0.638$; $p < 0.05$).
Conclusion: In all patients with SLE, a violation of the health-related quality of life was established. Its deterioration was recorded in all domains and was due to the activity of the disease. Monitoring the quality of life of adolescents with SLE in combination with disease activity monitoring will allow for a better assessment of the health status of patients and timely identification of the need for correction of therapy and the selection of the most effective treatment program.

AB1819-HPR INTRA-RATER RELIABILITY OF SHEAR WAVE ELASTOGRAPHY FOR THE QUANTIFICATION OF THUMB MUSCLE ELASTICITY

Keywords: Ultrasound

F. Karademir[1], A. E. Yıldız[2], T. Fırat[1], O. Ulger[1]. [1]*Hacettepe University, Physical Therapy and Rehabilitation, Ankara, Turkey*; [2]*Hacettepe University, Radiology, Ankara, Turkey*

Background: Shear wave elastography (SWE) is a technique that evaluates tissue elasticity by applying an acoustic radiation force impulse [1]. It is undetermined how reliable this modality is in assessing thumb muscles. Quantitative evaluation of muscle stiffness in conditions such as trapeziometacarpal osteoarthritis where increased fibrosis, muscle tone, spasm, and contractures can be seen can provide important information about the pathophysiology and prognosis of the diseases [2].
Objectives: This study aimed to assess the intra-rater reliability of thumb muscle elasticity and thickness in healthy people.
Methods: Ten healthy participants (20 hands) enrolled in the study. Thickness and shear wave velocity (SWV) of adductor pollicis (AdP) and first dorsal interosseous (FDI) muscles were obtained using an ACUSON S3000 Ultrasonography System and a 9L4 probe (4-9 MHz) (Siemens Medical Solutions, Mountain View, California). Ultrasound data (SWV, thickness) were collected and analyzed by an experienced radiologist. Three repeated SWV and thickness measurements were recorded in the resting position and an average was taken. Two sessions were performed at a 15-minutes interval.
Results: Ten healthy participants (20 hands; 5 female; 5 male; mean age: 25.9±2.68 years; BMI: 22.4±1.39 kg/m2) were included in this study. Nine subjects had right-hand dominancy and 1 had left-hand dominancy. The mean (±SEM) shear wave velocity for the AdP was 1.86 ± 0.6 m/s (=10.86 kPa), and for the FDI was 1.76 ± 0.5 m/s (=9.72 kPa). The intra-rater trial agreement was excellent, with intraclass correlation coefficients of 0.887 and 0.828 respectively. The mean (±SEM) muscle thickness for the AdP was 12.4 ± 3.93 mm, and for the FDI was 12.0 ± 3.68 mm. The intra-rater trial agreement was excellent, with intraclass correlation coefficients of 0.953 and 0.984 respectively.
Conclusion: SWE ultrasound was a reliable imaging technique to assess the stiffness and thickness of thumb muscles.

AB1820-HPR BIOELECTRICAL IMPEDANCE ANALYSIS SHOWED HIGH AGREEMENT AND SPECIFICITY TO ASSESSMENT OF LOW APPENDICULAR SKELETAL MUSCLE MASS IN WOMEN WITH SYSTEMIC SCLEROSIS: PRELIMINARY DATA

Keywords: Validation, Sarcopenia, Systemic sclerosis

L. Denardi Dória[1], R. Cavalheiro Do Espírito Santo[1], V. Hax[1], L. Santos[1], É. Pena[1], A. L. Mallmann[1], S. Pilotti[1], D. Moraes[1], T. J. Santos de Souza[1], B. Da Silva[1], I. Bosak[1], V. Lovison[1], J. A. Tessari[1], P. Jesus[1], L. Steinmetz[1], R. Legati[1], P. Espíndola Correia[2], T. Muniz Fighra[2], F. Gerchman[2], P. M. Spritzer[2], R. Xavier[1], R. Chakr[1]. [1]*Hospital de Clínicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil*; [2]*Hospital de Clínicas de Porto Alegre, Division of Endocrinology, Porto Alegre, Brazil*

Background: Patients with systemic sclerosis (SSc) are particularly prone to skeletal muscle wasting, affecting nearly one-third of patients, increasing the risk of disability[1,2]. To assess muscle mass, there are direct methods, such as magnetic resonance imaging, computed tomography and dual-energy X-ray absorptiometry (DXA), considered the gold standard[3]. DXA is widely used in clinical practice and in population studies, but it has some disadvantages, such as specific technical skills and higher costs[3]. Bioelectrical impedance analysis (BIA) is a validated method in healthy individuals of body composition assessment with greater affordability and minimum requirements[4]. To our knowledge, in patients with SSc only one study compared DXA with BIA. Soanjer et al found agreement between these two techniques only for fat-free mass, without evaluating appendicular skeletal muscle mass (ASM)[5].
Objectives: (1) Our objective was to compare ASM measured by BIA versus DXA and (2) to verify the associations with clinical features in women with SSc.
Methods: Women with SSc according to ACR/EULAR 2013 criteria were consecutively included at a tertiary public hospital in Rio Grande do Sul, Brazil (Hospital de Clínicas de Porto Alegre, HCPA) in 2022. Modified Rodnan's skin score (mRSS), EUSTAR activity index were calculated. The ASM by BIA (In Body 370s) and DXA (GE FamBeam 4500A) were calculated from sum lean mass of arm and legs (kg). Low muscle mass (BIA or DXA) was defined according to the European Working Group on Sarcopenia in Older People 2 (EWGSOP2) less than 15 kg. Pearson's and intraclass correlation coefficients, dependent samples t-test and simple linear regression for Bland–Altman plot were performed. The significance level was set at $p<0.05$.
Results: Until this moment, 62 women with SSc were included. The mean age was 62.0 ± 10.1 years-old and median disease duration was 15.0 (7.0–21.0) years. Forty-one patients (66.1%) had limited cutaneous disease, 14 (22.6%) diffuse-cutaneous and 7 (11.3%) *sine scleroderma*. The median mRSS was 4.0

(2.0–8.0) and the EUSTAR index was 1.5 (0.6 - 2.4). The mean appendicular skeletal muscle mass measured by DXA was 16.0 ± 2.2 kg while by BIA was 15.5 ± 2.3 kg (Δ = 0.5 kg; p = 0.005), underestimating the ASM. On other hand, the mean differences between DXA and BIA showed within the confidence interval (p= 0.358; CI 95%: -2.8 – 1.8; Figure 1). ASM by BIA was strongly correlated (r= 0.866, p < 0.001) and had a high agreement (Intraclass Correlation Coefficient = 0.919, p < 0.001) with ASM by DXA. We found only weak association between ASM by BIA and age (r= -0.282; p= 0.026). Low muscle mass in women with SSc was found in 18 patients (29%) by DXA and in 26 patients (42%) by BIA with a sensitivity of 80% and specificity of 94%.

Conclusion: BIA and DXA show high correlation and agreement in ASM assessment of women with SSc. Our findings suggest BIA as a useful tool due to its high specificity with DXA for the early assessment of low ASM in women with SSc. Furthermore, completion of this study is needed to confirm these results.

AB1821-HPR FUNCTIONAL CAPACITY AND WORK ABILITY IN PATIENTS WITH COMMON SCIATICA

Keywords: Work-related issues, Quality of life, Pain

H. Bejaoui[1], A. Feki[1], I. Sellami[2], S. Ben Jemaa[1], M. Ezzeddine[1], M. H. Kallel[1], H. Fourati[1], R. Akrout[1], S. Baklouti[1]. [1]*Hedi Chaker University Hospital, Rheumatology Department, Sfax,Tunisia*; [2]*Hedi Chaker University Hospital, Occupational Medicine Department, Sfax,Tunisia*

Background: Spinal radicular syndromes are a serious healthcare issue in the society nowadays. A common form of ailments related to the syndromes is sciatica, manifesting with severe pain radiating along the course of the sciatic. In many patients the pain limits the ability to perform daily routine at work and at home [1].

Objectives: The aim of study was to assess the functional capacity in patients with sciatica and its influence on their quality of life, their ability to function in daily life and at work.

Methods: We conducted a cross-sectional study including patients suffering from documented common sciatica evolving for more than 3 months collected in a rheumatology department over a period of 3 years. The Quality-of-life SF-36 questionnaire - Short Form Health Survey was used in the study, along with a supplement specifying the study group, with an indication of the pain location and the patients' occupations. Additionally, the Oswestry Disability Index, the work ability index (WAI) -and the Visual Analogue Scale (VAS) were applied.

Results: The study covered 104 patients, both male and female (71 women and 33 men with sex ratio male/female of 0.46). The mean age of our patients was 55.4 years-old (23-74). The most common etiology of sciatica was herniated disc, followed by lumbar spinal stenosis and spondylolisthesis. The root path was L5 in 74 cases and S1 in 30 cases. the average duration of sciatica was 6.4 months. The mean oswestry score was 25(15-38). The mean of the VAS was 7.4(4-9). The mean of WAI was 25.2(15-38). The Quality-of-Life index, at a statistically significant level ($\alpha < 0,05$), is higher (hence the quality of life is lower) in females suffering from sciatica. The duration of sciatica was a factor strongly correlated with the intensity of pain - the Oswesty score and the WAI were negatively correlated with age ($p<0.05$, r= -0.6 and r=-0.4 respectively).

Conclusion: In our series sciatica affects the quality of life of the female patients studied in this research to a greater extent than the male patients. The intensity of pain associated with sciatica duration. WAI and Oswestry were negatively associated with age.

AB1822-HPR EXPERIENCE AND PRELIMINARY DATA IN IMPLEMENTATION OF PRO (PATIENT REPORTED OUTCOME) IN THE DAILY ROUTINE IN INFLAMMATORY ARTHRITIS PATIENTS BASED IN ICHOM-ARTHRITIS MODEL AND A NEW ELECTRONIC PLATFORM (QÜESTCLINIC)

Keywords: Outcome measures, Quality of life, Patient reported outcomes

R. Morlà[1], N. Sapena[2], A. Azuaga[1], Y. Romero[1], R. Sanmartí[3], J. A. Gómez-Puerta[1]. [1]*Hospital Clinic de Barcelona, Rheumatology Department, Barcelona, Spain*; [2]*Hospital Clinic de Barcelona, Rheumatology Department, Barcelona, Spain*; [3]*Hospital Clinic de Barcelona, Rheumatology Department, Barcelona, Spain*

Background: In clinical practice of patients with chronic rheumatic inflammatory disease: rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA) it is not used to assess quality of life issues in relation to the disease. Patient Reported Outcomes (PROs) can inform about these symptoms suffered by patients using questionnaires or patient reported outcome measures (PROMs). International Consortium Health Outcomes Measures has the main purpose to recognize the crucial role of patients in outcome measures in value-based health, providing a specific ICHOM-arthritis model [1].

Objectives: To describe the pilot study and some very initial data of the implementation of PROs in an Arthritis Unit of a tertiary hospital based on ICHOM-arthritis through an electronic platform.

Methods: Rheumatologists, nurses, and quality management staff have worked for a period of 2 years in two aspects based on the ICHOM-arthritis model: 1. the use of the "standard set" described that includes the main clinical, and demographic data and a list of generic and specific questionnaires or PROMs to collect for RA, PsA, and axSpA patients. 2. the typology and frequency of visits to establish. MyClinic is an electronic bidirectional platform provided for the Hospital to connect patients and doctors. We designed the Qüestclinic, a space where place questionnaires to send to patients and where patients could answer them. Patients with the 3 diagnoses of adult inflammatory arthritis (RA, PsA, and axSpA) are invited to participate in their visit to outpatient clinics, accepting and signing their informed consent.

Results: We selected 4 generic questionnaires sent to patients to answer in the QuestClinic: MDHAQ (VAS_pain, PGA, VAS_fatigue), EuroQoL, HADS anxiety and depression, and FACIT(FS), and also a disease-specific one: RAID for RA, PsAID for PsA, and BASDAI and BASFI for axAspA. The 12-month visits set at baseline (Vb), 6 months (V6), and 12 months (V12) were performed in a double integrated format (Figure 1). In Vb, 3 tasks are performed: 1. Check questionnaire completion. 2. Initial characteristics (only in Vb): Demographic data (level of studies) and pathological history: smoking, hypertension, heart disease, stroke, COPD, diabetes mellitus, neoplasms, depression, bone fracture, gastric ulcer, other gastric problems, obesity. 3. Monitoring: vital signs and calculation of BMI; adherence to oral or parenteral treatment. Then, in the standard visit the rheumatologist reviews the PROM scores met by the patients in the QüestClinic. Preliminary data in V6 were: A total of 74 records belonging to 55 patients, 40 (54%) female, 39 (53%) RA, 20 (27%) axSpA, and 15 (20%) PsA were collected from February to December 2022. 54 (73%) patients have only visited in baseline and 20 (27.03%) had already 2 visits (V6). The first "snapshot" of the median of generic PROMs (VAS-pain, PGA, VAS-fatigue, HADS-anxiety, and depression) for the diseases were around a median of 4 for pain, PGA, fatigue, and depression, but higher for anxiety in an unselected group of inflammatory chronic rheumatic disease patients (Table 1).

Conclusion: We describe the functional model proposed to implement PROMs in clinical routine to cover the most important PRO dimensions of quality of life of disease and we present here the first picture of preliminary data.

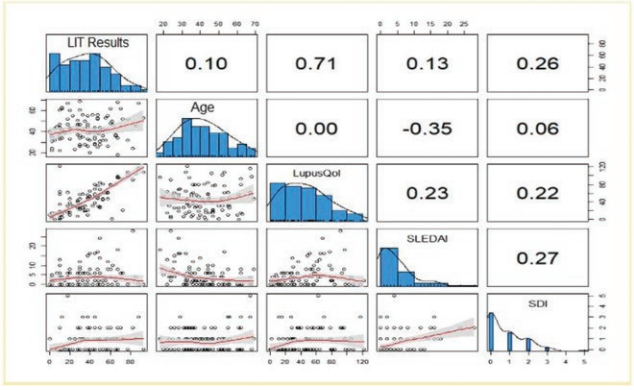
Padilla, CABA, San Miguel de Tucumán, Argentina*; *[5]Rio Grande, Rio Grande, Rio Grande, Argentina*; *[6]Hospital Británico de Buenos Aires, CABA, AEB, Argentina*; *[7]Medical Research Institute Alfredo Lanari, CABA, Buenos Aires, Argentina*

Background: The Lupus Impact Tracker (LIT) is a patient reported outcome (PRO) questionnaire. The results demonstrated their reliability in clinical practice for evaluation and follow-up.

Objectives: To validate the LIT and the degree of correlation with other scores in SLE patients in Argentina.

Methods: Observational, analytical and multicenter study. Patients older than 18 years with SLE (2019 ACR/EULAR criteria) were included. In the first stage, we evaluated the reproducibility in a period of 7 days measured by intraclass correlation (ICC) as well as the time to answer the questionnaire. In a second stage, the scores LIT, LupusQoL, PGA, SLEDAI and SLICC SDI were calculated for each patient and the Spearman correlation coefficient between scores was analyzed.



Results: Initially the LIT was performed in 10 patients. The average time to complete the questionnaire was 2,1 minutes. The mean of LIT (T0) was 57,1 (SD 24,2) and 51,5 (SD 25,5) seven days later. The ICC was 0,808 (95% CI 0,431 – 0,948). In the second stage, 100 SLE patients were included consecutively. Table 1 shows the main characteristics of the patients. The Spearman correlation coefficient between LIT/ LupusQol was 0.71, LIT/ SLEDAI was 0.13, and LIT/ SLICC was 0.26 (Graphic 1).

Conclusion: The median of the LIT questionnaire was 37 points. LIT demonstrated test-retest reliability and linear correlation with LupusQol. There was no correlation with SLE activity. LIT is a practical, quick and easy tool to evaluate he patient's perspective in relation to the disease in daily practice.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

AB1824-HPR MULTIPLE TNFI TREATMENT CYCLES AND THE FAILURE OF TRIAL-AND-ERROR CARE FOR PATIENTS WITH RHEUMATOID ARTHRITIS

Keywords: bDMARD, Patient reported outcomes, Rheumatoid arthritis

S. Helfgott[1], C. Adams[2], A. Frick[3], K. Huston[4], S. Milligan[3], J. Singh[5], N. Soloman[6], C. Edgerton[2]. [1]*Harvard Medical School, Division of Rheumatology and the Division of Medical Communications, Boston, United States of America*; [2]*Articularis Healthcare, Clinic, Summerville, United States of America*; [3]*Trio Health, Analytics, Louisville, United States of America*; [4]*Kansas City Physician Partners, Clinic, Kansas City, United States of America*; [5]*University of Alabama at Birmingham, School of Medicine, Birmingham, United States of America*; [6]*Arizona Arthritis, Clinic, Phoenix, United States of America*

Background: Inhibitors of tumor necrosis factor-alpha (TNFi) are central to management of rheumatoid arthritis (RA) though continued use beyond initial failure is negatively associated with response to subsequent TNFi treatment.
Objectives: To assess the patterns of recurrent TNFi use relative to reasons for switch as observed in community rheumatology care in the US.
Methods: Data: PIONEER-Rheumatology, an EMR and open text-extracted database specific to care given by the American Rheumatology Network (ARN). Study population: Adult (18+ years old) patients with RA, TNFi-treated in 2018 to 2021. Full histories were assessed for each patient and index was set as the initiation date of the last TNFi observed for each patient prior to 2022. Reasons for discontinuation were extracted from chart notes and broadly classified (and subclassified) as attrition (death, moved/left practice, non-clinical reasons), lost to follow up (LTFU, patient disengaged), or clinical (treatment goal achieved, lack/loss of efficacy, or condition resulting from disease, treatment, or patient burden).
Results: 13994 patients and 19925 episodes (defined as distinct patient & TNFi drug) were examined. Of 13944 patients, 9399 (67%) received 1 TNFi, 3527 (25%) 2 TNFi, 1068 (8%) ≥3 TNFi; treatment patterns may have included intervening non-TNFi treatment cycles. [TABLE]

Table 1.

No. (% row, % column) patients by years history (rows) and # of distinct TNFi drugs (columns)

Years History	1 TNFi	2 TNFi	≥3 TNFi	Total

1<2 years	1476 (65%, 16%)	680 (30%, 19%)	118 (5%, 11%)	2274 (100%, 16%)
2<3 years	957 (59%, 10%)	530 (33%, 15%)	139 (9%, 13%)	1626 (100%, 12%)
3<4 years	634 (53%, 7%)	410 (35%, 12%)	144 (12%, 13%)	1188 (100%, 8%)
4<5 years	606 (55%, 6%)	352 (32%, 10%)	135 (12%, 13%)	1093 (100%, 8%)
≥5 years	1464 (48%, 16%)	1078 (35%, 31%)	495 (16%, 46%)	3037 (100%, 22%)
Total	9399 (67%, 100%)	3527 (25%, 100%)	1068 (8%, 100%)	13994 (100%, 100%)

Reasons for discontinuation/switch were available for 4254/4595 (93%) and 998/1068 (93%) patients treated with 2+ or 3+ distinct TNFi, respectively. Lack/loss of efficacy was the reason for 1 or more TNFi discontinuations prior to the last TNFi received for 2689/4254 (63%) and 829/998 (83%) of patients with 2+ or 3+ TNFi, respectively. For a patient subset with ≥1 year history pre-index, prior failure of 1+ TNFi was observed for 2690/3765 (71%) and 814/936 (87%) patients who received 2+ or 3+ TNFi, respectively.
Conclusion: A third of TNFi-treated study patients received >1 TNFi with most discontinuing prior TNFi due to lack/loss of efficacy. Though trial-and-error care is seemingly standard to RA management, this study suggests that some patients do not benefit from this approach.

AB1825-HPR DECISION TO INITIATE A TUMOR NECROSIS FACTOR INHIBITOR IN RHEUMATOID ARTHRITIS UNCOUPLED FROM DISEASE ACTIVITY MEASURES

Keywords: bDMARD, Real-world evidence, Rheumatoid arthritis

J. Singh[1], C. Adams[2], A. Frick[3], S. Helfgott[4], K. Huston[5], S. Milligan[3], N. Soloman[6], C. Edgerton[2]. [1]*University of Alabama at Birmingham, School of Medicine, Birmingham, United States of America*; [2]*Articularis Healthcare, Clinic, Summerville, United States of America*; [3]*Trio Health, Analytics, Louisville, United States of America*; [4]*Harvard Medical School, Division of Rheumatology and the Division of Medical Communications, Boston, United States of America*; [5]*Kansas City Physician Partners, Clinic, Kansas City, United States of America*; [6]*Arizona Arthritis, Clinic, Phoenix, United States of America*

Background: Previous studies have demonstrated discordance between patient-based (e.g. RAPID3) and predominantly physician-based (e.g. CDAI) disease activity measures (DAMs).
Objectives: To examine the relationship between DAMs and decision to initiate TNFi following csDMARDs.
Methods: Data: PIONEER-Rheumatology, an EMR and open text-extracted database specific to care given by the American Rheumatology Network. Study population: Adult RA patients who received TNFi as initial targeted synthetic or biologic DMARD treatment between Jan 2014 to Apr 2022 after csDMARDs. Assessments: CDAI, RAPID3, DAS28 (includes DAS28-CRP, DAS28-ESR), tender/swollen joints (TSJ), pain score, and HAQII closest to but within -180 days of TNFi initiation. Paired (+/- 30 days) CDAI, RAPID3, and DAS28 assessed via Pearson correlation.
Results: 2811/3682 (76%) patients had 1+ DAM prior to TNFi initiation; 2332/3682 (63%) pain score, 2047/3682 (56%) TSJ, 1570/3682 (43%) DAS28, 1442/3682 (39%) RAPID3, 1430/3682 (39%) CDAI, and 143 (4%) HAQII. Of the 2331/3682 patients with RAPID3, DAS28, or CDAI, 982/2331 (42%) had near-remission/low disease by at least 1 DAM prior to index. 582 patients had paired CDAI and RAPID3 scores; moderate/severe disease was indicated for 474/582 (81%) by CDAI and 395/582 (68%) by RAPID3 ($p<0.001$) and 163/582 (28%) of patients were indicated as near-remission/low by one DAM but as moderate/severe by the other. Correlations between paired DAMs: strong for CDAI:DAS28 (n=1063, r=0.788) and moderate for CDAI:RAPID3 (n=582, r=0.399) and for RAPID3:DAS28 (n=637, r=0.225).
Conclusion: DAMs were not present for 24% of study patients at initiation of TNFi. Of patients with RAPID3, DAS28, or CDAI, 42% patients started TNFi despite near-remission/low disease activity. Where conducted, paired DAS28:RAPID3 and CDAI:RAPID3 scores were moderately correlated though severity categories for CDAI:RAPID3 were discordant for 28% of evaluated patients. These results suggest that clinical decision-making to initiate TNFi does not rely solely on standard DAMs.

AB1826-HPR HOW TO ASSESS THE SATISFACTION OF PATIENTS WITH CHRONIC INFLAMMATORY DISEASES AFTER SWITCHING TO A BIOSIMILAR? INSIGHTS FROM AN EXPLORATORY QUALITATIVE STUDY PRELIMINARY TO AN OBSERVATIONAL STUDY

Keywords: Patient reported outcomes, Quality of life, bDMARD

G. Bouguen[1], L. Peyrin-Biroulet[2], A. Buisson[3], D. Lafarge[4], S. Tropé[5], G. Montagu[6], A. Denis[7], C. Habauzit[7], S. Benkhalifa[7], H. Marotte[8]. *[1]CHU de Rennes, Maladies de l'appareil digestif, Rennes, France*; *[2]CHU de Nancy, Hépatologie gastro-entérologie, Vandoeuvre-lès-Nancy, France*; *[3]Afa Crohn Rch France, Afa Crohn Rch France, PARIS, France*; *[4]Association France Spondylarthrites, Association France Spondylarthrites, TULLE, France*; *[5]Association National de Défense contre l'Arthrite Rhumatoïde, ANDAR, Clermont l'Hérault, France*; *[6]Unknowns, Unknowns, PARIS, France*; *[7]Celltrion Healthcare France, Medical, Issy Les Moulineaux, France*; *[8]CHU de Saint-Etienne, Rhumatologie, Saint-Etienne, France*

Background: Patients experience may be negatively impacted when starting biosimilar due to a poorly executed switch which could result in poor adherence and nocebo effect.

Objectives: This study aims to identify suitable patient satisfaction dimensions to design an observational study on real-life switches.

Methods: A qualitative exploratory study was performed. In-depth, semi-structured interviews were conducted by a sociologist with patients with inflammatory diseases treated by anti-TNF biosimilar to determine patient switching experiences and expectations, identify dimensions for the observational study's questionnaire (ePRO). Patients were recruited with the help of patients' associations.

Results: Four patients (3 females) were included: 2 with rheumatoid arthritis and 2 with Crohn's disease. Two patients had adalimumab biosimilar, 1 etanercept biosimilar and 1 adalimumab originator (switch-back). The following dimensions were identified:

● **Information transparency:** patients were unfamiliar with biosimilars and some did not know they were using them. Some reported distrusting biosimilars but accepted them because they trust their physician.

● **Patient Involvement:** physicians decide whether to offer a biosimilar, but patient acceptance is determined by their interpretation of the situation. Patients found it difficult to express their treatment preferences and reported that physicians didn't always prompt these discussions.

● **The time of injection:** patients had to learn the injection procedures but received relatively little support during the switch in handling the new device. Some experienced greater pain, differences in comfort or reported errors in use.

● **Transition:** the sustainability of the switch may have been constrained by delays in supply in the city. In some cases, the pharmacy dispensed the originator drug as a replacement.

These led to the following ePRO composition: BMQ, HLSEU-Q16 (health literacy), ad hoc items on shared decision making, expectations, patient training, satisfaction with provided information and injection. All 4 patients understood the final questionnaire. The study design is an open label multicentric study of 300 patients in 30 sites (rheumatology and gastroenterology, hospital, and private practice) when offered a switch. The primary objective is to assess patients' overall satisfaction with injections 3 months post-initiation compared to the previous adalimumab. The first patient was included in June 2022.

Conclusion: This work proposes an original methodology for the selection and design of criteria for an observational study. An exploratory qualitative study highlighted different factors of patient satisfaction during the switch to adalimumab biosimilar. It guided the choice of e-PROs and the construction of specific items.

AB1827-HPR PAIN MANAGEMENT IN OLDER POPULATION FROM GERMANY AND SWEDEN: SUB-GROUP ANALYSIS FROM A TOPICAL DICLOFENAC PROSPECTIVE REAL-WORLD EVIDENCE STUDY

Keywords: Pain, Quality of life, Patient reported outcomes

V. Rampartaap[1], K. Fabrikant[2], D. Nair[3], V. Sood[4], G. Shanga[5], T. Wilcox[6], J. R. Norrefalk[7], E. Csoke[8]. *[1]Haleon (formerly known as GSK Consumer Health), Medical Affairs, Amersfoort, Netherlands*; *[2]Haleon (formerly known as GSK Consumer Health), Medical Affairs, London, United Kingdom*; *[3]Haleon, Medical Affairs, Stockholm, Sweden*; *[4]Haleon (formerly known as GSK Consumer Health), Medical Affairs, Singapore, Singapore*; *[5]Haleon (formerly known as GSK Consumer Health), Biostatistics, New Jersey, United States of America*; *[6]Former PPD Employee, n.a., Maryland, United States of America*; *[7]Karolinska Institutet, Rehabilitation Medicine Occupational Health, Stockholm, Sweden*; *[8]n.a., n.a., Basel, Switzerland*

Background: Adequate pain management in older individuals is essential to support functional lifestyle and enable robust quality of life (QoL). Topical non-steroidal anti-inflammatory drugs (NSAIDs) such as diclofenac gel, with limited systemic exposure, provide a better pharmacological alternative to oral NSAIDs for musculoskeletal pain management especially in elderly due to favorable benefit-risk profile[1].

Objectives: To evaluate impact of over the counter (OTC) topical diclofenac (1.16% & 2.32%) use in an older German and Swedish population on different aspects related to QoL such as pain, functional status, and treatment satisfaction.

Methods: A subgroup analyses of older participants (≥65 years) from a prospective real-world evidence study conducted among 731 adult (≥18 years) consumers (467 in Germany and 264 in Sweden) of OTC topical diclofenac (1.16% & 2.32%). Treatment satisfaction, functional status and pain relief were assessed using electronic surveys (baseline, Week 4, and Week 12) via personalized link. Numerical Rating Scale (NRS-11) and Likert scale were used for questionnaire-based response collection.

Results: Data from 279 (72.3%) older participants, 203 German and 76 Swedish, were included. Baseline characteristics of participants and reported outcomes are shown in Table 1. Majority purchased 2.32% strength, were repeat users and reported having previously identified cardiovascular conditions. Improvement in pain score ≥ 1 point was observed in >57% of users at Week 12. Participants reported reduction of pain interference in different functional activities at Week 4 and 12. >70% of participants were satisfied with the treatment at Week 4 and >75% at Week 12.

Conclusion: Older participants reported reduction in pain over time, improvements in their ability to participate in daily life activities, treatment satisfaction with the use of OTC topical diclofenac and thus improved QoL.

AB1828-HPR ASSOCIATION BETWEEN COMPLEMENTARY AND ALTERNATIVE MEDICINE USE AND TRUST IN THE PHYSICIAN IN PATIENTS WITH INFLAMMATORY RHEUMATISM?

Keywords: Diet and Nutrition, Rheumatoid arthritis, Spondyloarthritis

F. Z. Aharrane[1], F. Z. Taik[1], N. Takhrifa[1], R. Bensaid[1], M. Fourtassi[2], F. E. Abourazzak[1]. [1]*Abdelmalek Essaidi University, Faculty of Medecine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco*; [2]*Abdelmalek Essaidi University, Faculty of Medecine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Generally, patients with chronic rheumatic diseases use complementary and alternative medicine (CAM) in addition to their conventional treatments to manage their health. Discussing these treatments with their physician is still rare, which might be directly related to patients' trust toward them.

Objectives: The primary objective of this study was to assess the association between patients' trust in their physician and the use of complementary and alternative medicine. As a secondary objective, to estimate the prevalence of complementary and alternative therapy use among patients with chronic inflammatory rheumatism.

Methods: This is a cross-sectional study, which included patients with established chronic inflammatory rheumatism, followed at the University Hospital Center in Tangier. The questionnaire included demographic and clinical information, use of conventional therapy, complementary and alternative therapy, as well as the interpersonal trust in patient-physician relationships using the Trust in Physician Scale (TPS).

Results: The study included 189 patients. 57.14% of patients reported using complementary medicine at least once, most patients were women (77.78%), mean age was 46.67±13.25 years with an average course of the disease 11.11±9.23 years. The most frequent used complementary and alternative treatments were cupping therapy (45.90%), massage (40.40%) and the ingestion of a mixture of plants (27%). Mean±SD Trust in Physician Scale was 47.64 ±7.2, and there were no significant differences between CAM users vs. non-users (48.08±6.9 vs. 47.04±7,4; p=0,35).

Conclusion: More than half of patients with inflammatory rheumatism reported the use of complementary and alternative medicine. However, the association between their use and trust in the physician assessed with TPS was not established.

AB1829-HPR FACTORS ASSOCIATED WITH SEDENTARY BEHAVIOR IN PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Education, Pain

S. Ez-Zaoui[1], H. Rkain[1,2], S. Bahloul[1], T. Latifa[1], F. El Joumani[1], R. Honsali[1], F. Kronbi[1], S. Farih[1], I. Bensaghir[1], N. Hajjaj-Hassouni[3], F. Allali[1]. [1]*Hospital Al Ayachi, Rheumatology B, Salé, Morocco*; [2]*Faculty of Medicine And Pharmacy of Rabat, Exercise Physiology and Autonomous Nervous system Team, Physiology Laboratory, Rabat, Morocco*; [3]*International University of Rabat, Rheumatology, Rabat, Morocco*

Background:

Objectives: To determine factors related to sedentary behavior in patients with Knee Osteoarthritis.

Methods: we conductued a cross-sectional study of 130 patients affected by knee osteoarthritis. Information on patients and disease characteristics were collacted. Physical activity was measured objectively using the short version of IPAQ questionnaire (International Physical Activity Questionnaire) for 7 consecutive days. Activity levels were subdivided into low physical activity and moderate to vigorous physical activity. We analysed factors associated with sedentary behaviour.

Results: The mean age of the patients included was 59.9+/-10 years with 110 (84.6%) females. The median IPAQ was 260 (0.500) MET-min/week. The sedentary behaviour was noted in 69.2% of patients. Table 1 summuriezed factors associated with sedentary behaviour in knee osteoarthritis patients.

Table 1. Analysis of factors associated with sedentary behavior in knnee osteoarthritis patients.

Factors related to sedentary behavior	P
Age	0,005
Lack of regular PA before the disease	0,01
Socio-cultural and/or economic barriers	0,01
Pain caused by knee ostoarthritis	0,02
Functional disability caused by knee ostoarthritis	0,01

Conclusion: Sedentary behaviour is prevalent among knee osteoarthritis patients. It is important to overcome this unhealthy lifestyle and to encourage practice of physical activity in this population by combating the barriers reported by patients.

AB1830-HPR **MUSCULOSKELETAL DISORDERS DURING COVID-19 INFECTION: A SURVEY OF HEALTHCARE WORKERS**

Keywords: COVID, Health Services Research, Epidemiology

H. Ziedi[1], D. Brahim[1], I. Youssef[1], M. Mersni[1], Z. Athimni[1], N. Mechergui[1], G. Bahri[1], H. Ben Said[1], N. Ladhari[1]. [1]*Charles Nicolle Hospital, Department of Occupational Pathology and Fitness for Work, Tunis, Tunisia*

Background: COVID-19 infection has revealed a considerable number of extra-pulmonary manifestations, especially rheumatological. The detection of these manifestations, which herald the infection, is of great value in the early diagnosis of the disease, especially in health care workers (HCWs) who are at considerable risk of infection. Although myalgia is a common clinical feature of COVID-19, other musculoskeletal disorders (MSDs) have been rarely described.
Objectives: To describe MSDs during SARS-COV2 infection in HCWs.
Methods: Prospective descriptive study conducted at the department of occupational pathology and fitness for work of Charles Nicolle Hospital in Tunis, having included the HCWs affected by COVID-19 during the period from 01 September 2020 to 28 February 2021. Data collection was carried out by regular telephone follow-up during the containment period using a pre-established form.
Results: During the study period, 656 HCWs were infected with SARS COV 2, of whom 134 (20.4%) had at least one musculoskeletal event. The mean age was 42±9 years with a sex ratio (M/F) of 0.2. The most represented occupational category was nurses (33.6%) followed by health technicians (23.1%). The median professional length of service was 12 [7; 20] years. The presence of comorbidity was noted in 58.2% of HCWs. A pre-existing osteoarticular disease was found in 8.2% of cases. Obesity was noted in 25.4% of the population. Active smoking was reported by 14.3% of respondents. A known vitamin D deficiency was noted in 16.5% of patients. Spinal pain was the most reported MSD, present in 87.3% of cases. Low back pain was the most frequent spinal pain (56.7%) followed by back pain (37.4%) and neck pain (5.9%). MSDs of the lower limbs were found in 12.7% of patients. They were represented by gonalgia in 11.9% of cases, ankle pain in 5.2% of cases and hip pain in 4.3% of cases. MSDs of the upper limbs were described by 7.5% of the patients, 92.5% of whom presented with shoulder pain. The median duration of MSDs during COVID-19 was 5 [3; 8] days. These manifestations were persistent on return to work in 21.1% of cases.
Conclusion: Knowledge of the frequency and consequences of musculoskeletal manifestations related to COVID-19 infection is of great importance, particularly in HCWs, in order to optimise management and ensure a rapid return to work.

AB1831-HPR **SYSTEMATIC REVIEW OF LABORATORY MONITORING GUIDELINES OF CONVENTIONAL SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS**

Keywords: Systematic review, Best practices, Disease-modifying Drugs (DMARDs)

A. Kermond[1], P. Robinson[1]. [1]*Royal Brisbane and Women's Hospital, Rheumatology, Herston, Australia*

Background: Conventional synthetic disease modifying anti-rheumatic agents (csDMARDS) have a significant role in the management of multiple rheumatological disorders. Several clinical practice guidelines (CPG) exist to guide practitioners in the appropriate frequency and type of laboratory monitoring during csDMARD use, however few appraisals of the quality of these guidelines have been performed.
Objectives: The purpose of this study was to summarise the content and appraise the quality of CPGs for laboratory monitoring during csDMARD use.
Methods: A systematic search of electronic databases, online guideline repositories and the websites of professional societies was conducted to identify CPGs for the frequency and type of laboratory monitoring in csDMARD use. A pair of reviewers screened CPGs using predetermined selection criteria and reported according to the PRISMA-P statement. Recommendations from included CPGs were extracted and compared across guidelines. The list of csDMARDS this study reviewed includes methotrexate, leflunomide, hydroxychloroquine, mycophenolate, sulfasalazine and azathioprine.

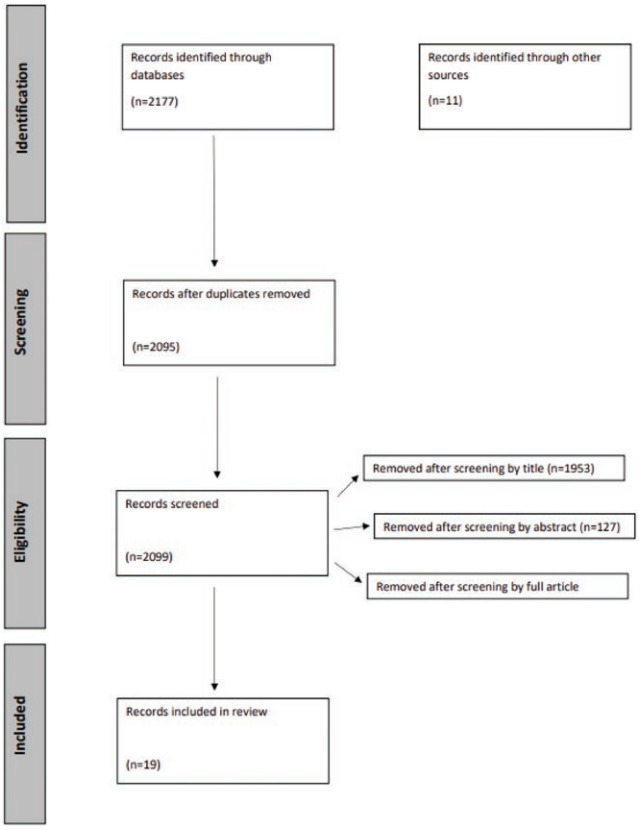

Figure 1.

Results: The review identified 19 sources, resulting in 33 guidelines for laboratory monitoring of conventional synthetic DMARDS (see table 1) Within the 33 guidelines seen there were 10 for methotrexate, 7 for sulfasalazine, 6 for leflunomide, 5 for hydroxychloroquine, 3 for azathioprine and 2 for mycophenolate. There was a notable variation in terms of detail, specifics and monitoring intervals.
Conclusion: In summary, this review identified several possible recommendations going forward. There is an argument to be made for a more uniform international guideline of laboratory monitoring to be synthesised, as there could be an element of uncertainty for those noting and comparing the variation between recommendations. A role for a more extensive review of the incidence of treatment complications and implications as a result of the laboratory monitoring would be of benefit. This poses an additional role for a cost-effective analysis, as was commented on within the discussion and literature reviews.

REMOTE SCREENING OF SELF-REFERRALS FOR JOINT INJECTION CLINIC

Keywords: Telemedicine

B. Choy[1], T. Mccoll[2], M. Reed[2], S. Bawa[2]. [1]*Queen Elizabeth University Hospital, Rheumatology, Glasgow, United Kingdom*; [2]*Gartnavel General Hospital, Rheumatology, Glasgow, United Kingdom*

Background: Intra-articular steroid injections are a valuable option in the management of inflammatory joint flare-ups.[1] The Gartnavel General Hospital (GGH), Glasgow operates a joint injection clinic for rheumatological patients via a self-referral system. This allows patients to book clinics directly and enables prompt access to an appointment. This system was modified in July 2022 to include remote screening, allowing for the evaluation of self-referrals prior to booking appointments. Waiting times have decreased significantly from 3 months to 1 week since the use of remote screening.
Objectives: To determine the efficacy of remote screening on self-referrals and identify self-referring patient groups where joint injections are not indicated.
Methods: Retrospective analysis was conducted on patient self-referrals to the joint injection clinic from 07/07/2022 to 07/12/2022. Patient demographics, diagnoses, reasons for rejection and outcomes were analysed.
Results: 108 patients self-referred for a joint injection during this period. There was a 41.7% (n=45) decrease in clinic bookings with remote screening. 50.9% (n=55) were refused on screening; 81.8% (n=45) of these patients were not indicated for a joint injection. 35.2% (n=38) of patients were not under rheumatology review. 25.9% (n= 28) of patients had solely osteoarthritis; 71.4% (n=20) of these patients were rejected and directed to outpatient physiotherapy services.
Conclusion: Remote screening was effective in reducing the patient waiting list for joint injections. The self-referral system used in isolation has significant limitations and has led to clinic booking beyond its capacity. This issue is also exacerbated by self-referrals from non-rheumatological patients.

STUDY OF THE DEMAND FOR REFERRALS FROM PRIMARY CARE TO THE RHEUMATOLOGY DEPARTMENT OF A TERTIARY HOSPITAL

Keywords: Descriptive Studies

N. De la Torre Rubio[1], M. Pavía Pascual[1], J. Campos[1], J. Sanz[1], M. Machattou[1], P. Navarro Palomo[1], M. Alonso de Francisco[1], C. Navarro Joven[1], C. Merino Argumánez[1], B. Garcia-Magallon[1], M. Fernandez Castro[1], H. Godoy[1], C. Barbadillo Mateos[1], L. F. De Villa[1], J. L. Andreu Sánchez[1]. [1]*Hospital Universitario Puerta de Hierro Majadahonda, Rheumatology, Majadahonda, Spain*

Background: EPISER study has confirmed the great burden of rheumatic diseases, which represent almost 30% of primary care medical consultations in Spain[1,2]. Electronic consultation could be an alternative response[3] as well as rheumatologist-led update programmes and joint case discussion with primary care physicians have shown to reduce the burden of care and waiting times in rheumatology units[4].
Objectives: To analyze the demand from primary care to the rheumatology service of a tertiary hospital.
Methods: Retrospective descriptive study of the data consecutively collected from 15 to 30 May 2022 from new rheumatology consultations at the reference hospital requested from primary care (PC) health centers in the area. The following variables were collected: waiting time (median and range in days), referral route (ordinary, preferential or e-consultation), reason for derivation, type of visit (discharge or follow-up), suspicion of inflammatory disease by the specialist in Family and Community Medicine (Yes/No), confirmation diagnosis of inflammatory disease by the specialist in Rheumatology (Yes/No), time from onset of inflammatory symptoms to rheumatology consultation (median and range in months), referral with analytical tests (Yes/No/With acute phase reactants) and with musculoskeletal image requested by the PC physician (Yes/No); those provided by patients in private centers were excluded. Descriptive statistics were used for the presentation of results and Cohen's Kappa coefficient was calculated to quantify the degree of agreement in the diagnosis of inflammatory disease between primary care physicians and rheumatologists.
Results: A total of 116 new consultations were registered in the system referring to 100 patients, 16 did not attend their appointment. Results are shown in *Table 1*. The degree of agreement according to Cohen's Kappa index was 0.53, representing 80% of agreement (moderate degree). No differences were found between health care centers in the referral rate according to the population assisted by each health care center.
Conclusion: Main reasons for consultation were 'osteoporosis assessment' and 'polyarthralgias'. Ordinary route was the most frequently used with a median waiting time of 80 days and 50 days for preferential route. Thirty percent of patients were referred with analysis and 75% with some musculoskeletal image. The degree of agreement was moderate in the diagnosis of inflammatory disease between primary care physicians and rheumatologists.

AB1834-HPR A SURVEY OF OPHTHALMOLOGISTS REGARDING CLINICAL PRACTICE FOR DRY EYE AND RHEUMATIC DISEASES

Keywords: Education

G. Vukatana[1], A. Carbone[2], P. Versura[3], L. Boling[2], M. Reta[4]. [1]*Rheumatology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*; [2]*Allergy and Clinical Immunology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*; [3]*Ophthalmology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy*; [4]*Rheumatology Unit, AUSL Ospedale Maggiore - IRCCS Azienda Ospedaliero- Universitaria di Bologna, Bologna, Italy*

Background: Diagnostic delay is a major problem in rheumatic diseases that can present with symptoms often underestimated by patients. Often, the rheumatologist is not the first specialist to encounter these patients, and the lack of referral can lead to a significant delay in diagnosis.[1] Dry eye disease is a condition seen frequently by ophthalmologists that can be one of the first signs of a serious rheumatic condition such as Sjögren's Syndrome.[2] Thus, collaboration is needed between specialists for the diagnosis and treatment of these diseases. One study addressed this issue in the United States, showing a significant under-referral to rheumatologists.[2] To date, no such investigations have been done in Italy.
Objectives: The aim of our study was to evaluate the use of functional tests and validated scores among ophthalmologists in the work-up of patients with dry eye to investigate the possible presence of a rheumatic condition.
Methods: A multiple-choice questionnaire was submitted to participants of the Ocular Surface Inflammation course held in Bologna in September-October 2022. The questionnaire was administered to all the participants before the start of the course. The questions were designed to assess the knowledge of specialists in ophthalmology regarding signs and symptoms of rheumatic diseases associated with dry eye, their preferences regarding the use of functional tests to investigate dry eye in their clinical practice, and whether or not they used validated ocular scores. Functional tests investigated included were fluorescein staining of the cornea, tear break-up time, lissamine green staining of the conjunctiva, rose bengal staining of the conjunctiva, and Schirmer's test. Ocular scores considered were the National Eye Institute Visual Function Questionnaire (NEI-VFQ), Ocular Staining Score (OSS), and Dry Eye Disease (DED) severity grading scale.
Results: Twenty ophthalmologists participated in the survey. The estimated prevalence of dry eye among the participants' patients is summarized in Table 1. Ten ophthalmologists reported rheumatology referrals in <5% of cases, four in 5-20% of cases, three in 20-50% of cases, and three in >50% of cases. When presented with patients with dry eye, other signs and symptoms investigated by the ophthalmologists during the patient history and clinical examination were: arthritis or arthralgia (95%, n=19), xerostomia (85%, n=17), dry skin or cutaneous rash (65%, n=13), and periodontitis or cavities (30%, n=6). When asked to rank the most frequent functional tests performed in patients with dry eye, 55% (n=11) reported that the fluorescein test was their top choice, followed by Schirmer's test (35%, n=7) and tear break-up time (10%, n=2). More than half of the participants reported not using clinical scores in the management of patients with dry eye, while 15% (n=3) used the DED severity grading scale, 10% (n=2) used NEI-VFQ, and 10% (n=2) used both NEI-VFQ and OSS.
Conclusion: This preliminary data suggests that dry eye is a very frequent condition encountered by ophthalmologists that is often underestimated, and patients are not always properly screened for associated rheumatological conditions using validated scores and functional tests or referred to a rheumatologist. Large studies to further investigate awareness of potential rheumatological diseases in the field of ophthalmology are needed, and the creation of "dry-eye teams" comprised of ophthalmologists and rheumatologists may be useful to avoid diagnostic delay.

AB1835-HPR WHAT IS THE ROLE OF RHEUMATOLOGY NURSES IN THE MANAGEMENT OF GOUT PATIENTS IN PRACTICE? A MULTICENTRIC MOROCCAN STUDY

Keywords: Nursing, Gout

F. Kronbi[1], H. Rkain[1,2], S. Ez-Zaoui[1], T. Latifa[1], S. Bahloul[1,2], S. Farih[1], F. El Joumani[1], R. Honsali[1], I. Bensaghir[1], N. Alami[1], N. Hajjaj-Hassouni[3], F. Allali[1]. [1]*Hospital Al Ayachi, Rheumatology B, Salé, Morocco*; [2]*Faculty of Medicine and Pharmacy of Rabat, Physiology Laboratory, Rabat, Morocco*; [3]*International University of Rabat, International University of Rabat, Rabat, Morocco*

Background:
Objectives: The aim of this study was to assess nurses' skill level and educational needs on gout disease.
Methods: This is a multicenter cross-sectional study carried out in 10 rheumatology departments in different university hospitals in Morocco. We invited nurses working in those departments to participate in the study. Nurses answered to a questionnaire provided data on their professional activity and socio-demographic status. The questionnaire collected also nurses' management skills on gout disease including systematic measurement of the different clinical parameters of patients, visual pain analogic scale (VAS) pain, collecting comorbidities, identification and verification of adherence to the treatment, therapeutic education of patients and treatment side effects notification.
Results: Our study has included 45 nurses (mean age of 34.2 years, 77.8% females). The mean work duration at a rheumatology department was 7.2 ± 4.6. Table 1 summarized assessment results of the competencies which are required for the management of patients suffering from gout.

Table 1.

Acquired skills	(%)
Systematic measuring of clinical parameters:	**97.8**
Arterial tension	**97.8**
Waistline	**100**
Weight	**71.1**
BMI	
Systematic assessment of pain by VPAS: visual pain analogic scale	**62.2**
Collecting comorbidities	**42.2**
Identifying gout treatments	**71.1**
Differentiating symptomatic treatments from background Gout treatments	**42.2**

Conclusion: Gout is the prototype of chronic diseases where the nurse plays a central role in the multidisciplinary care of patients.
We realize through our study the urgent need to remedy to alarming shortcomings in nurses management of patients suffering from gout.

HPR Interdisciplinary research

AB1836-HPR SERUM LEVEL OF VITAMIN D IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS CORRELATION WITH BONE MINERAL DENSITY AND THE DISEASE ACTIVITY

Keywords: Vitamin D, Systemic lupus erythematosus, Osteoporosis

S. Shevchuk[1], L. Denyshchych2, L. Marynych2. [1]*National Pirogov Memorial Medical University, Vinnytsia, Internal Medicine #2, Vinnytsia, Ukraine*; [1]*National*

Pirogov Memorial Medical University, Vinnytsia, Internal Medicine #2, Vinnytsia, Ukraine

Background: Decrease in vitamin D levels in patients with systemic lupus erythematosus (SLE) arouses particular interest. Vitamin D levels and their correlation with bone mineral density (BMD) loss are still seen as contradictory.
Objectives: To study serum vitamin D levels in SLE women and to estimate their correlation with BMD and disease activity.
Methods: 101 SLE women and 30 individuals in a control group participated in the study. The activity of SLE was evaluated by SLEDAI. The average age of patients was 47.12 ± 0.14 years, in the control group it was 46.17 ± 0.12. Serum levels of C-reactive protein (CRP) and 25-hydroxyvitamin D (25(OH)D) were measured in all participants. Changes in BMD of the lumbar spine and hip were determined by dual-energy X-ray densitometry.
Results: In patients with SLE, the average level of 25(OH)D equalled 14.6 ± 1.19 ng/ml, and in the individuals from the control group, it was 1.9 times higher, constituting 24.7 ± 1.32 ng/ml. In SLE women with normal BMD (T score > -1.0 SD) vitamin D deficiency (< 20 ng/ml) was detected in 18.3%. In the group with osteopenia (T-score from -1.0 to -2.5 SD), the proportion of individuals with vitamin D deficiency has increased to 26.7%. In women with osteoporosis (T-score ≤ -2.5 SD), vitamin D deficiency was found in 63.9%. In the group of patients with the maximum CRP level there were only 10% of persons with the optimal (> 30 ng/ml) 25(OH)D level, 40% had insufficiency (20-30 ng/ml), while deficiency (< 20 ng/ml) was detected in every second patient. Among patients with optimal CRP levels, only every fourth person was diagnosed with vitamin D deficiency, 10% of the individuals had vitamin D insufficiency, while 65% had optimal vitamin D levels. Decrease in vitamin D level was closely associated with SLE activity revealed by SLEDAI ($r = -0.44$; $p < 0.05$).
Conclusion: The average vitamin D level in SLE women is likely to be lower than that in the control group. Decrease in vitamin D levels was associated with BMD loss and high inflammatory process as well as the disease activity according to CRP and SLEDAI.

AB1837-HPR THE NON-INFLAMMATORY RHEUMATIC DISEASES AND CARDIOVASCULAR RISK: THE UNKNOWN COMORBIDITY

Keywords: Cardiovascular disease, Osteoarthritis, Ultrasound

Y. Mabrouk[1], H. Ferjani[1], H. Riahi[2], D. Ben Necib[1], E. Labben[2], D. Kaffel[1], K. Maatallah[1], M. Bouaziz[2], W. Hamdi[1]. *[1]Kassab Institute, Rheumatology, Tunis, Tunisia; [2]Kassab Institute, Radiology, Tunis, Tunisia*

Background: Several factors were associated with non-inflammatory rheumatic diseases such as diabetes and overweight. As far as we know, no previous research has studied cardiovascular risk in this population. For this goal, we used the carotid intima-media thickness (cIMT) screening as a relevant tool for CV risk assessment.
Objectives: This study mainly aimed to determine the importance of CV risk in non-inflammatory rheumatic diseases.
Methods: The present study is a study conducted on Tunisian non-inflammatory rheumatism patients in the rheumatology department. We collected the characteristics of the patients and those of the disease. The CV risk was assessed using the measurement of cIMT. According to the American Society of Echocardiography guidelines, the cIMT thickness was measured using high-resolution B-mode carotid US with a Philips machine with the patient in the supine position. The cIMT was measured using the two inner layers of the common carotid artery and an increased IMT was defined as ≥0.09 cm.
Results: Fifty patients were collected, of which 82% were women. 64% of them were followed for knee osteoarthritis, the rest were chronic low back pain patients. The mean age was 53 ± 11.08 years. 10% of patients were active smokers. Two percent were hypertensive and 4% were diabetics. The average BMI was 28,1±4,5 kg/m2. It was greater than 25 kg/m2 in 76% of them. [cholesterol] was 4,9±0,9 mmol/l. 48,9% had a high rate. [Cholesterol HDL] was1,1±0,2 mmol/l. The mean [cholesterol LDL] was 3,3 ±0,8 mmol/l. [triglyceride] was 1,3±0,6 mmol/l. The mean IMT in the left common carotid (LCC) was 0,06±0,02, in the left internal carotid (LIC) was 0,06±0,01, in the left external carotid (LEC) was 0,05±0,01. The mean IMT was 0,05±0,018 in the right common carotid (RCC), 0,06±0,01 in the right internal carotid (RIC), and 0,05±0,01 in the right external carotid (REC). Thirty six percent had an atheroma plaque. Twenty six percent had a high CV risk according to the IMT. There was no correlation in our series between diabetes, high blood pressure, smoking, BMI, and high CV risk p=1; p=1; p=1, and p=0.5, respectively.
Conclusion: While the absence of systemic inflammation in non-inflammatory osteoarticular diseases, the cardiovascular risk is higher in our study. Therefore, cardiovascular risk screening should not be limited to chronic inflammatory rheumatism.

HPR Epidemiology and public health (including prevention)

AB1838-HPR THE TYPE AND THE EFFECT OF PHYSICAL ACTIVITY ON QUALITY OF LIFE AND FATIQUE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN GREECE: A CROSS-SECTIONAL STUDY

Keywords: Systemic lupus erythematosus, Quality of life, Epidemiology

D. Bonia[1]. *[1]Institute of Occupational Science and Rehabilitation, Health Science, Marousi, Greece*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with sever symptoms, such as fatigue and has a high impact on patient's quality of life.
Objectives: The aim of this study was to determine the rate, the type, and the effect of physical activity (P.A.), and exercise in patients with SLE on quality of life and fatigue in Greece.
Methods: Three questionnaires were used to measure quality of life (SF-36), fatigue (FSS), and P.A. (mIPAQ). 101 patients with SLE from Greece answered about their personal choices. For statistics the IBM SPSS 25 was used for the statistical analysis. Descriptive analysis conducted to describe quantitative variables of interests. Data normality was verified from Kolmogorov-Smirnov test, and Pearson Correlation test was performed to determine the relationship between P.A. and QoL and Fatigue.
Results: The results showed that the sample average for QoL was 48.3(±19,3), for Fatigue 41,73(±7,2). The total score of P.A. was 1603,79(±1695.8) METs. Furthermore, for vigorous P.A. was 557,79(±987,6) METs, for moderate P.A. 824,65(±811,6) METs, and for low P.A. 239,87(±405) METs. The most common type of P.A. was housekeeping and cleaning for 74% of the sample, and even thought it is not considered as P.A. activity there was an option. A high average (50,5%) of the sample was presented by patients who chose to remain seated during the day. Positive correlation between P.A. and QoL was found (R=,385, P<,01). Negative correlation between P.A. and Fatigue was also found (R=-,384, P<,01).
Conclusion: The conclusions were that the patients with SLE in Greece do not perform high level of P.A. and exercise. The moderate level of P.A. was more likely activities of day living, that are classed as P.A., than exercise. Furthermore, the sample choose a sedentary lifestyle, although correlation between P.A. and QoL and Fatigue in patients with S.L.E. was found.

AB1839-HPR PERINATAL GRIEF IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Mental health, Quality of life, Pregnancy and reproduction

M. E. Corral Trujillo[1], R. A. Cerda González[1], H. G. Martínez Sandoval[1], A. Carrazco Chapa[1], K. M. López Serna[1], J. C. Riega-Torres[1], L. Pérez Barbosa[1], C. M. Skinner Taylor[1], D. Á. Galarza-Delgado[1]. *[1]Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: Perinatal loss (PL), defined as a loss from any gestational age or in the neonatal period [1] lead women to the process of grieving. Perinatal Grief (PG) involves suffering and reaction such as sadness, disbelief and anger [2]. PL and PG symptoms affect many women around the world; women with autoimmune rheumatic diseases (ARDs) have greater risk of PL. The Perinatal Grief Scale (PGS) can help health providers prevent complicated grief in their patients [3].
Objectives: Determine which PL and sociodemographic variables are associated factors to a complicated grief in women with ARDs.
Methods: Descriptive, cross-sectional, comparative study at the Hospital Universitario "Dr. José Eleuterio González" in México. We included women from the Pregnancy and Rheumatic Diseases Clinic (CEER) that answer a virtual survey with the PGS. The demographic, ARD and PL data were obtained from the clinical records. For the control group, women without ARD were invited to fill a virtual survey with the PGS, sociodemographic and PL data. The PGS is a Likert-type scale that consists of 27 items with four response options. The questions are distributed in four subscales: active grief (10 items), guilt (8 items), depression (6 items), acceptance (3 items). Scores greater than 50 points suggests a complicated grief comorbidity.

The Kolmogorov-Smirnov test was used to determine normality; to analyze the differences between groups, Mann–Whitney U, Chi-square tests and T-test were employed. A $p < 0.05$ was considered statistically significant. The statistical analysis was performed with the statistical program SPSS version 25.

Results: A total of 50 women were included: 25 with ARD and 25 without ARD. The median age for the group with ARD was 42 (38.5-51) and 34 (26-42.5) for the without ARD group. In the ARD group the most frequent diagnosis were systemic lupus erythematosus (7/14%), rheumatoid arthritis (6/12%) and Antiphospholipid Syndrome (4/8%). For the PGS, twenty (40%) of the 50 women got a score >50; 11 (55%) were women without ARD and 9(45%) have ARD. The PL, suffered by these 20 women were 18 during the pregnancy (17/85% on the first trimester and 1/5% on the second trimester) and 2 (10%) after birth. No statistically differences were found in the total score and subscales of the PGS between groups. The sociodemographic and PL data and the PGS score for both groups are included in **table 1.**

Conclusion: Even though there were no significant differences between groups; we hypothesize that the greater number of PL in women with ARD serves as a protective factor and prevents that the PG evolve to a complicated grief. On the other hand, having the PL during the first trimester of the pregnancy can be a risk factor for complicated grief. Our limitation was the sample size for both groups.

ANTI-MYELOPEROXIDASE ANTIBODY-POSITIVE GRANULOMATOSIS WITH POLYANGIITIS MIMICKING MUCOSAL LEISHMANIASIS: A RARE CASE REPORT

Keywords: Autoantibodies, Descriptive Studies, Vasculitis

I. Nogueira[1], M. Montenegro[1], V. Alcantara[1], T. N. Albuquerque Gomes Nogueira[2]. *[1]Faculty of Medicine - Federal University of Ceará, Departamento de Medicina Clinica, Fortaleza, Brazil*; *[2]Faculty of Medicine - Federal University of Ceará, Departamento de Patologia e Medicina Legal, Fortaleza, Brazil*

Background: Granulomatosis with polyangiitis (GPA) features necrotizing granulomatous inflammation of the upper and lower respiratory tracts, with vasculitis of small- and medium-sized vessels [1]. Anti-proteinase 3 antibodies (PR3-ANCA) are found in the majority of cases, yet anti-myeloperoxidase (MPO-ANCA) may be identified in approximately 10% of patients with GPA [2, 3]. One of the differential diagnoses is mucosal leishmaniasis, especially in patients from endemic regions. Atypical presentations of GPA may delay diagnosis.

Objectives: To report a case of a female patient previously diagnosed with and treated for mucosal leishmaniasis due to upper respiratory tract lesions. As the symptoms returned alongside arthritis, further investigation concluded to a diagnosis of anti-myeloperoxidase-positive GPA.

Methods: Case report and discussion.

Results: A 51-year-old woman from Brazil presented in 2021 with epistaxis and joint pain. The patient reported a prior history of recurring bilateral epistaxis and maxillary pain since 2008. At that time, she had a wide nasal septal perforation. CT scan of the sinuses showed maxillary and ethmoidal sinusopathy. A nasal biopsy showed epithelioid granulomas without amastigotes, but the patient had a 25mm Montenegro skin test (strongly positive). Syphilis, hepatitis B, hepatitis C and HIV screenings and acid-fast bacilli smear were negatives. As Brazil is an endemic region for leishmaniasis, a presumptive diagnosis of mucosal leishmaniasis was made and the patient was appropriately treated. In 2016, she was lost to follow-up. In 2021, she returned with fever, epistaxis, important unspecified weight loss and arthralgia with edema in ankles, distal interphalangeal joints, metacarpophalangeal joints and wrists. Blood screening revealed an RCP of 9.5 and an ESR of 28. Urine tests were normal. A thoracic CT scan showed multiple lung nodular formations, including a subpleural nodule in the anterior lower right lobe, with a size of 3.8 x 3.1 x 2.9 cm. Lung histopathology revealed foci of poorly formed, non-necrotic granulomas in centrilobular parenchyma and angiitis in small-caliber arteries (image 1). Autoimmune screening revealed positive MPO-ANCA superior to 1/80 and negative c-ANCA, rheumatoid factor and anti-CCP. Thus, a diagnosis of GPA was made, and oral methotrexate 20mg weekly was started. Improvement of arthritis could be observed in four weeks.

Conclusion: GPA may present upper respiratory tract symptoms, and is considered a differential diagnosis for mucosal leishmaniasis [4]. Recurrence of the symptoms in a patient treated for mucosal leishmaniasis should prone further investigation for other conditions. The renal system was spared in our patient, however nasal septal involvement, prominent sinusopathy, joint symptoms and pulmonary typical findings strongly favored the hypothesis of GPA. A positive MPO-ANCA and good therapeutic response following methotrexate strengthened the certainty of the diagnosis. Physicians should be aware of GPA as a differential diagnosis for mucosal leishmaniasis and recognize its MPO-ANCA-positive presentation.

ARTIFICIAL INTELLIGENCE IN THE CLINICAL SETTING OF THE RHEUMATIC DISEASES; A SYSTEMATIC REVIEW OF THE LITERATURE

Keywords: Systematic review, Artificial Intelligence

K. Oku[1,1,2], B. Caffo[1], Y. Arinuma[2], K. Yamaoka[2]. [1]*Johns Hopkins School of Public Health, Department of Biostatistics, Baltimore, United States of America*; [2]*Kitasato University, Department of Rheumatology and Infectious Diseases, Sagamihara, Japan*

Background: Autoimmune Rheumatic Diseases (AIRD) are chronic multifactorial diseases that present with a variety of pathologic findings due to immune abnormalities. The pathogenesis is a complex interplay of genetic and environmental factors, and there are usually large individual differences in phenotype, imaging and blood findings, treatment response, and prognosis. As a result, clear algorithms for diagnosis and treatment are scarce, and clinicians must interpret complex disease images from a variety of data to make analogies between diagnosis, prognosis prediction, and treatment effects. Artificial intelligence, encompasses concepts such as machine learning and deep learning neural networks, is a substitute for these complex tasks, and attempts are gradually beginning to replace it in the clinical practice of AIRD. Accountability is often required for decisions in medicine that directly affect human lives, and the same is true for the black box of models used by AI. Therefore, in recent years, emphasis has been placed on the explainability of AI, and a method called explainable AI (XAI) has emerged to explain decisions made by AI models. Research in this area is still in its infancy, and it would be of significance to present an overall picture.
Objectives: To clarify the overall picture of AI/machine learning in the clinical application or research in AIRD by the systematic review of the literature.
Methods: A systematic literature review was conducted using the Pubmed and Web of Science according to the "Preferred Reporting Items for Systematic Reviews and Meta-Analyses"(PRISMA) guidelines. The search formula used Artificial Intelligence, Machine learning, Deep learning, Neural Network, AIRD and connective tissue diseases as main keywords, and selected references went through a primary/secondary screening. After screening, the literature was reviewed to validate the diseases studied, published years, the object of the study, type of training data, the algorithms, and, for XAI, the methods for algorithms explanation.
Results: The literature search yielded 1483 articles, that were published before June, 2022 and resulted in 164 articles after primary and secondary screenings. Among them, 153/163(93.9%) were published in or after 2017. The main target diseases of the articles were rheumatoid arthritis(RA) 72, systemic lupus erythematosus(SLE) 42, spondyloarthritis 11, inflammatory myositis 7, systemic vasculitis syndrome 5, systemic sclerosis 5 and others 21. The main objects of the studies were diagnosis or classification of the disease in 98, followed by the prognosis prediction in 49 and analysis of the therapeutic reagent in 19. The most common types of data used as training were demographic data in 114 articles followed by physical data 101, clinical test data 92, genomics data 40, image data 30 and pathological data 28. The most commonly used algorithms were tree-based algorithm(random forest etc.) followed by support vector machine and neural network. XAI were performed in 8 studies (3 studies with RA, 3 with SLE one with SLE/RA and 1 with AIRD in general) in which Shapley Additive exPlanations (SHAP) was the most frequently used tool (5/8; 62.5%).
Conclusion: The clinical application of AI in AIRD is mainly used as a tool for diagnosis or the prognostic prediction in RA and SLE. On the other hand, only a very small number of the study have examined the explainability of AI. The review indicates that research on the clinical implementation of AI applications is still at an early stage despite the great potential.

AB1849 AUTOIMMUNE MANIFESTATIONS OF CTLA-4 HAPLOINSUFFICIENCY IN TWO PATIENTS OF SOUTHEAST ASIAN ETHNICITY

Keywords: Rare/orphan diseases, Skin, Adaptive immunity

Y. W. Lai[1], J. Tan[1], B. Y. H. Thong[1], Y. L. Lim[2], J. Lee[2], C. G. Chua[1], X. R. Lim[1]. [1]*Tan Tock Seng Hospital, Rheumatology, Allergy, Immunology, Singapore, Singapore*; [2]*National Skin Centre, Dermatology, Singapore, Singapore*

Background: Cytotoxic T- lymphocyte antigen 4 haploinsufficiency (CTLA4-H) is an autosomal dominant monogenetic disorder caused by heterozygous CTLA4 germline mutation.[1] Its diagnosis is complicated by a highly variable clinical phenotype including an immune dysregulation syndrome with autoimmunity, lymphoproliferation, atopy and malignancy; as well as immunodeficiency with hypogammaglobulinemia and recurrent infections.[2] CTLA4-H has been reported mainly in North America and Western Europe, whilst lipopolysaccharide-responsive beige-like anchor (LRBA) deficiency (LATAIE) mainly in East Asia.[3]
Objectives: To raise awareness of adults with CTLA4-H presenting with varied autoimmune end-organ manifestations to rheumatologists.
Methods: Case reports.
Results: A 53-year-old Malay male first developed violaceous papules and nodules on both legs and arms at the age of 44 years old. He later developed widespread lymphadenopathy, maxillary sinusitis, lung nodules, cholestatic hepatitis, splenomegaly and thrombocytopenia over the course of the next 6 years. Biopsy of the skin, lymph nodes and liver all demonstrated non necrotizing granulomas and returned negative for mycobacterial studies and malignancy. He was diagnosed with sarcoidosis and started on moderate dose corticosteroids and azathioprine. He later developed hypogammaglobulinemia, listeria meningoencephalitis and two episodes of disseminated zoster, prompting further evaluation. Genetic analysis identified a missense variant of uncertain significance (VUS) c.506C>A (p.Ala169Glu) in the CTLA-4 gene. Functional testing showed reduced expression of CTLA-4 on both unstimulated and stimulated Foxp3+T cells by flowcytometry. He is treated with regular replacement intravenous immunoglobulin (IVIg), prednisolone and ciclosporin. The second patient is a 28-year-old Chinese male with a prior history of endogenous eczema diagnosed at 13 years old. He developed recurrent sinusitis at 18 years old, followed by 3 episodes of pneumonia over a course of 2 years. He was found to have chronic rhinosinusitis, bronchiectasis, hypogammaglobulinemia, blunted post-vaccination responses to pneumococcus and tetanus. He was initially treated for Common Variable Immunodeficiency with regular IVIg while continuing to require regular prednisolone for control of eczema. 2 years later, he developed immune-mediated thrombocytopenia. He later developed photosensitive eczematous patches over his face, chest, legs and the diagnosis was revised to chronic actinic dermatitis. He was eventually found to have a novel deletion on his CTLA4 gene c.522del (p.Leu174Phefs*13) on genetic analysis, reduced CTLA4 expression on resting Treg cells by flowcytometry, with levels returning to normal with stimulation. He is treated with regular IVIg, prednisolone and methotrexate.
Conclusion: Diagnosis of adult-onset primary immunodeficiency syndromes can be a challenge when these present with autoimmune phenomena rather than recurrent infections. Genetic testing in this era of rapidly expanding knowledge of inborn errors of immunity and detection of VUS may have potential clinical and therapeutic implications.

AB1850 MICROSCOPIC POLYANGIITIS WITH CONCURRENT THROMBOTIC THROMBOCYTOPENIC PURPURA: A CASE REPORT

Keywords: Vasculitis

E. Tullis[1], C. Roy[1], J. Petkova[2]. [1]*Houston Methodist Hospital, Internal Medicine, Houston, United States of America*; [2]*Houston Methodist Hospital, Hematology, Houston, United States of America*

Background: Thrombotic thrombocytopenic purpura (TTP) and Microscopic polyangiitis (MPA) rarely occur in conjunction. Autoimmune TTP is caused by autoantibodies to the ADAMTS13 protein that cleaves von Willebrand factor. MPA is a small-vessel vasculitis that typically affects the small blood vessels of the lung and kidney [1]. We present a case of concurrent TTP and MPA which we believe could highlight a pathogenetic correlation and treatment overlap between the two diseases.
Objectives: To report a rare case of concurrent TTP and MPA and to educate physicians on optimal treatment strategies.
Methods: Case report and literature review.
Results: A 67-year-old patient with history of stroke and sickle cell trait presented to the emergency department due to altered mental status and fever. Serology on admission was notable for marked acute kidney injury and anemia requiring transfusions. Urinalysis showed hematuria and proteinuria. Autoimmune serology was remarkable for p-ANCA positivity at 1:80 with myeloperoxidase antibody > 30 pmol/L; a diagnosis of MPA was made. Patient's serology was also remarkable for thrombocytopenia with a nadir under 60 and evidence of thrombotic microangiopathy on peripheral blood smear and hemolysis labs. ADAMTS13 autoantibodies were reduced with less than 3% functionality and an inhibitor of 1/0 BU, confirming a concurrent diagnosis of TTP. Patient was initiated on high-dose steroids and therapeutic plasma exchange (TPE) with resultant normalization of platelets and improvement in renal function. TPE was discontinued, and the patient was transitioned to rituximab with continuation of high-dose steroids. The patient was ultimately discharged home with a steroid taper and maintenance rituximab dosing.
Conclusion: Per literature review, three other cases of concurrent TTP and MPA have been reported [2-4]. Further investigation into pathogenetic and treatment overlap of MPA and TTP may be warranted. Although rare, when occurring together the presentation is often severe, and urgent initiation of treatment is critical. TPE is the mainstay of treatment in TTP but is usually only recommended in MPA patients with anti-GBM antibodies, those at high risk of progression to end stage renal disease, or those unresponsive to first-line therapies [1,5,6]. Rituximab, which acts to decrease B cell activity and overall antibody production, has been shown to reduce disease activity in both conditions [1,5]. This case report suggests that, in the rare event that TTP and MPA are concurrently diagnosed, the combined use of rituximab and TPE in conjunction with steroids may induce remission more efficiently than either treatment alone.

AB1851 TERMINATION OF PREGNANCY IN LUPUS NEPHRITIS: A BIOETHICAL ANALYSIS WITH THE INTEGRATIVE METHOD

Keywords: Best practices, Pregnancy and reproduction, Systemic lupus erythematosus

T. Cano-Gámez[1], A. Lobato-Belmonte[1], I. Peláez-Ballestas[1], G. Medrano Ramirez[1], J. De León-Carbajal[2], A. Manrique de Lara[1]. [1]*Hospital General de México "Dr. Eduardo Liceaga", Rheumatology Division, Mexico City, Mexico*; [2]*Hospital General de México "Dr. Eduardo Liceaga", Maternal-Fetal Medicine Division, Mexico City, Mexico*

Background: Termination of pregnancy in patients with rheumatic diseases is controversial due to current lack of evidence. Around one fourth of pregnancies in patients with rheumatic diseases are terminated due to medical reasons. Only 0.026% of articles in Rheumatology relate to bioethics despite the high frequency of ethical dilemmas in the treatment of pregnant patients with autoimmune diseases. [1]
Objectives: To analyze from a bioethical perspective the case of a pregnant patient with lupus nephritis unresponsive to treatment, for whom termination of pregnancy is considered as a therapeutic measure.
Methods: The integrative model was applied combining different normative ethical theories. The central moral dilemma and main stakeholders were identified. The case was analyzed from utilitarian, deontological and virtue ethics perspectives, followed by integration to establish a global conclusion.
Results: *Case presentation.* A 30-year-old woman was diagnosed with systemic lupus erythematosus in 2019 in Mexico. Induction therapy for lupus nephritis was started; however, it was interrupted due to COVID-19 pandemic. When she returned for follow-up, despite treatment was reinstated, she persisted with proteinuria without achieving complete remission criteria. Multi-target therapy was started; however, patient stopped treatment for economic reasons and became pregnant shortly after. She presented for prenatal control follow-up at 20 gestational weeks with edema in the lower extremities and hypertension, for which she was hospitalized in intensive care. Renal replacement therapy was initiated without further response to treatment. A multidisciplinary team suggested pregnancy termination as a therapeutic option, which the patient refused. *Bioethics analysis.* Figure 1 shows the background factors and initial steps for defining and analyzing the bioethical dilemma. Three different normative ethical theories were used. *Utilitarianism*. The consequences of the action are the central component, and the decisions made must be profitable and effective for the majority. Terminating the pregnancy would seek to protect the mother's life, since saving one life represents a greater benefit than losing two. For the patient's family, the costs of continuing with the pregnancy would be unsustainable. For the institution, the termination of the pregnancy would lead to a more efficient use of human and material resources. Therefore, interrupting the pregnancy is justifiable. *Deontology*. Duty-based ethics center the action itself regardless of consequences, as well as valuing autonomy. Seeking all therapeutic alternatives, including termination of pregnancy, is a good action itself. However, considering the patient's autonomy, her desire to continue pregnancy must be taken into account. Therefore, both terminating and continuing the pregnancy are justifiable. *Virtue ethics.* Aretology centers the importance of decisions in the person who performs the action. Core values involve enabling flourishing and personal growth. For both the family and the institution, flourishing would imply preserving the life of the patient. Therefore, the termination of pregnancy is justifiable.
Conclusion: Using the integrative method, we conclude that termination of the pregnancy is justifiable from the three ethical theories and is an appropriate resolution to the ethical dilemma. However, considering the patient's desire to continue pregnancy, health professionals should offer psycho-emotional support. The lack of recommendations about medically indicated termination of pregnancy in rheumatology leads to complex moral decisions, making the bioethical analysis of paradigmatic cases essential to ensure the best possible action and as a precedent for future similar situations.

AB1852 DERMATO-NEURO SYNDROME PRECIPITATED BY COVID-19 INFECTION IN THE SETTING OF SCLEROMYXEDEMA

Keywords: Skin, COVID

C. G. Hobayan[1], J. Lin[2]. [1]*The Ohio State University, College of Medicine, Columbus, Ohio, United States of America*; [2]*The Ohio State University Wexner Medical Center, Division of Rheumatology and Immunology, Department of Internal Medicine, Columbus, Ohio, United States of America*

Background: A black female in her 40s presented with a nonpruritic rash for 10 months consisting of bumps on the face, hands, forearms, and thighs. She had no prior treatment. Past medical history was significant for pulmonary embolism (PE) 6 years prior. She had no personal or family history of autoimmune disease. Physical exam revealed numerous smooth 2-3 mm skin-colored papules over the bilateral forearm dorsa, hands, anterior thighs, and face. Serum protein electrophoresis revealed monoclonal IgG lambda gammopathy. Skin biopsy of her left elbow showed dermal fibroplasia with mucin deposition. IgG was less than 1.5 grams/deciliter; bloodwork was otherwise stable. The diagnosis of scleromyxedema was rendered.
Objectives: The objective of this clinical case was to evaluate a neurologic sequela of COVID-19 infection in a patient with scleromyxedema.
Methods: One month following diagnosis of scleromyxedema, our patient was diagnosed with COVID-19 five days before admission to the emergency department with altered mental status and aphasia. Rheumatology was consulted due to malignant hypertension and acute kidney injury with question of scleroderma-like renal crisis in the setting of recently diagnosed COVID-19 infection, although she had no other features of systemic sclerosis. The infectious disease team was consulted due to COVID-19-induced inflammatory reaction.
Results: The patient's creatinine kinase and brain natriuretic peptide were elevated. Creatinine and potassium trended upwards. She developed seizures and became hemodynamically unstable with rapidly declining clinical status. She was transferred to the intensive care unit, where she developed respiratory arrest, shock, hyperkalemia, and acidemia. She received escalating doses of pressors but experienced frequent arrhythmic disturbances and developed asystole. Resuscitation efforts were unsuccessful; she expired within 24 hours of consultation.
Conclusion: Dermato-neuro syndrome (DNS) is a potential complication of scleromyxedema associated with confusion, dysarthria, seizures, and coma. The patient's clinical presentation is consistent with DNS in the setting of scleromyxedema likely precipitated by COVID-19. Intravenous immunoglobulins are first-line treatment for scleromyxedema; however, it is associated with risk of venous thromboembolism. The patient was considered for treatment as an outpatient but deferred due to history of PE. She was reevaluated for treatment upon presentation to the hospital, but given the severity and rapidity of her condition, it was already too late. This is the second reported case of COVID-19 induced DNS in a patient with scleromyxedema. Given the severity, we recommend early initiation of treatment in patients with scleromyxedema and aggressive treatment for those contracting COVID-19.

SPONTANEOUS ABORTION AS DIFFERENTIAL DIAGNOSIS OF INTERMITTENT GLOMERULAR PROTEINURIA IN CLINICALLY AND SEROLOGICALLY INACTIVE SLE

Keywords: Systemic lupus erythematosus, Pregnancy and reproduction, Kidneys

F. Ullrich[1], A. Skapenko[1], H. Schulze-Koops[1]. *[1]LMU Clinic Munich, Division of Rheumatology and Clinical Immunology, Munich, Germany*

Background: In SLE, new-onset proteinuria and albuminuria raise concern for renal involvement, even when isolated and subnephrotic. In women of childbearing age, pregnancy-related complications are other causes of renal protein loss. Distinguishing renal disease from pregnancy-related complications of SLE is difficult because SLE is associated with adverse maternal and fetal events, while pregnancy is also a cause of disease relapses. Common to all causes of pathologic proteinuria in SLE is that they are related to disease activity and/or the need for intervention, as proteinuria does not normalize on its own.
Objectives: We report a case of a patient with inactive SLE who intermittently developed significant isolated proteinuria and albuminuria of glomerular origin that was directly related to spontaneous abortion in early (possibly twin-) pregnancy.
Methods: A 39-year-old female with SLE on hydroxychloroquine presented at our clinic for a routine check-up. Physical examination and laboratory tests were performed. To that date, SLEDAI-2K during most visits had a score of 0, indicating inactive disease.
Results: The patient reported feeling well, and the physical examination was unremarkable. Stable low-grade thrombocytopenia was the only relevant abnormality in recent years. On the current examination, the urine showed significant proteinuria and A3 albuminuria in the protein/albumin to creatinine ratio (uPCR 724 mg/g, uACR 488 mg/g). IgG/creatinine was markedly elevated (74.4 mg/g), and α1-microglobulin was normal, indicating nonselective glomerular proteinuria without tubular impairment. There were no other abnormalities suggestive of SLE activity. After she recalled having vaginal spotting a week earlier, a pregnancy test was performed and was positive. Subsequently, the βHCG level increased insufficiently, and ultrasound detection of a live embryo was not successful, but the presence of two amniotic cavities was suspected. An early incomplete miscarriage was diagnosed, and the gestational age was calculated to be 6+5 weeks. Shortly thereafter, a planned suckling curettage was performed. One week later, she had a final vaginal bleed. At this time, the urine showed a decrease in proteinuria of over 50% (uPCR 317 mg/g, uACR 210 mg/g, IgG 26.9 mg/g). Three weeks later, urine protein was completely normalized, which proved stable 12 weeks after initial diagnosis. Throughout the follow-up period, she did not show any SLE relapse.
Conclusion: After exclusion of differential diagnoses (chart), causality of the miscarriage with the urinary findings seems evident. To date, there have been no reports of the concomitant occurrence of early pregnancy miscarriage, possibly LN-indicative glomerular proteinuria, and its spontaneous regression in a clinically and serologically inactive SLE patient. Recently, observations were confirmed that a large proportion of patients with a uPCR <1g/g had LN histology, whereas a relevant proportion had inactive sediment or normal serology like our patient. As the kidney is the organ most affected in SLE pregnancy, it is important to be aware of intermittent proteinuria, as the consequences may be very different from persistent proteinuria as would be expected in nephritis.

Diagnostic algorithm of intermittent glomerular proteinuria. *Clustering in probability of etiology. Arrow labeling indicates diagnostic steps leading to "rule-out" or "rule-in" of diagnosis.*

MM: Medic measures; PM: Patient measures. Group A: Patients with educational training in RA. Group B: Patients without training.**. The correlation is significant at the 0.01 level (bilateral). *. The correlation is significant at the 0.05 level (bilateral).

Colombia; [4]*Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: The level of adherence to treatment in patients with rheumatoid arthritis (RA) is important to achieve control of the disease. In turn, educational strategies in self-care and knowledge of RA help improve adherence and promote knowledge for self-measurement of clinimetry.

Objectives: The purpose of this work was to evaluate the correlation of the clinimetry measurements made by the doctor (MM) with those made by the patient (PM) in a group of patients with education in their disease and to compare it with another group of patients without specific education, according to the level of adherence.

Methods: A cross-sectional study was carried out that included adult patients with RA. Two groups were included, Group A: Patients with educational training in RA (12-14 months, face-to-face and virtual modules developed by an expert health group), Group B: Patients without training. Both groups measured their PM by means of a digital form and after one week they were evaluated (blind MM). Both PM and MM included global VAS, Fatigue, MDHAQ, RAPID 3 and EQ5, additionally the physician evaluated the DAS28, CDAI and the Morisky Green Levine Medication Adherence Scale. Correlations were made using the Pearson coefficient. The project was approved by the ethics committee.

Results: All the participants were women (Group A: 28, Group B: 63). Group A had a significantly higher proportion of higher than secondary schooling, erosivity, nodularity, polyautoimmunity, anti-CCP positivity, treatment with biologics, older age, and disease duration. The total group had a low level of disease activity (DAS28). A significant correlation (Table 1) was found in all the MM variables with corresponding ones PM, with the highest coefficients in group A (except in MDHAQ). There was a significantly higher proportion of adherent patients in group A (78.5%) than in group B (42.8). When analyzing the correlations in the subgroup of adherent patients, all the coefficients increased (except global VAS), maintaining the same ratio of superiority of correlation coefficients in group A compared to group B.

Conclusion: MM has a higher correlation with PM in patients with educational training in RA. These correlations are even greater in the group that is adherent to the treatment, persisting higher in the group with training. The results deserve to be replicated in patients with different levels of severity to those studied here.

SUSAC SYNDROME: CASE SERIES FROM ADULT & PEDIATRIC TERTIARY ACADEMIC MEDICAL CENTERS

Keywords: Vasculitis, Rare/orphan diseases

N. Couette[1], S. Gagne[2], J. Paul[3]. [1]*Genesis HealthCare System, Rheumatology, Zanesville, United States of America*; [2]*Nationwide Children's Hospital, Department of Rheumatology & Immunology, Columbus, United States of America*; [3]*The Ohio State University Wexner Medical Center, Department of Rheumatology & Immunology., Columbus, United States of America*

Background: Susac Syndrome (SS) is a rare autoimmune endotheliopathy that affects the brain, retina, and inner ear, characterized by a clinical triad of encephalopathy, branch retinal artery occlusion (BRAO), and sensorineural hearing loss (SNHL)[1]. Brain MRI, fluorescein angiogram (FA), and audiometry help to establish a diagnosis[2]. The clinical presentation of SS is often variable leading to a delay in the diagnosis.

Objectives: This study aims to compare clinical features and therapeutic strategies in adult and pediatric populations with Susac Syndrome.

Methods: This was a retrospective chart review of cases with a diagnosis of SS from December 2010 to December 2020 at The Ohio State University Wexner Medical Center (OSUWMC) and Nationwide Children's Hospital in Columbus, Ohio, USA (tertiary care centers). We analyzed the following: age, gender, ethnicity, symptoms at the time of presentation, diagnostic studies, autoimmune serologies, brain MRI, FA, audiometry, treatment approaches, and outcomes.

Results: All the patients (seven adult- patients and two pediatric-onset patients) identified as females, and the majority (78%) were Caucasian. The age at presentation ranged from 10 to 45 years old with a mean age of 38 years. The time to diagnosis ranged from 3 to 17 months with a mean of 7.8 months. The most common symptoms at onset included dizziness, hearing loss, and visual change. ESR was elevated in 50% with a range of 23 to 52 mm/hr (normal<30 mm/hr). CRP was elevated in 22% of patients with a range of 11 to 22 mg/dl (normal <10 mg/dL). Low to medium titer ANA was positive in 30%. FA detected unilateral or bilateral BRAO in seven patients (78%). Sensorineural hearing loss was confirmed on audiogram testing in 7 of 9 patients, and 44% of patients had bilateral hearing loss. 88% of our patient population had evidence of corpus callosal involvement ("snowball lesions") in the brain MRI. CSF study was done in 5 patients - 4/5 had elevated CSF protein at 77 mg/dL (range 15-45 mg/dL) and the mean cell count was <3 (normal), without any oligoclonal bands. One patient had a brain biopsy. The most common initial treatment was high-dose steroids followed by a taper. Oral immunosuppressive therapy with mycophenolate mofetil (MMF) was initiated in 78% and was maintained in 56% of patients, who remained stable. Intravenous immunoglobulin (IVIG) was initially used in 56% of patients. Two patients transitioned from MMF to azathioprine due to pregnancy. Due to the severity of the disease, one patient transitioned from MMF to tacrolimus and Rituximab. 20% had a disease flare after the initial therapy requiring additional immunosuppression.

Conclusion: Our series highlights the rarity of SS. A neurologic exam, brain MRI, fluorescein angiogram, and audiogram should be performed in every case. A brain biopsy is not necessary for the diagnosis, unless for exclusion. BRAO was detected in 75% of our patients, highlighting the importance of an ophthalmology evaluation with FA, even in the absence of visual symptoms. In our series, only 20% presented with the full clinical triad of visual, auditory, and central nervous system symptoms, indicating that presentation of SS is often incomplete and diagnosis relies on a high index of suspicion[3]. Treatment depends on the severity of the presentation and involves the use of high-dose corticosteroids along with immunosuppression including mycophenolate, IVIG, tacrolimus, rituximab, and cyclophosphamide[4].

AB1856 IDENTIFYING THE ADULT-ONSET FAMILIAL COLD-ASSOCIATED AUTOINFLAMMATORY SYNDROME TYPE 2

Keywords: Genetics/Epigenetics, Innate immunity

N. Garvin Grande[1], C. Zamora Ramos[1], P. Turiel[1], E. Álvarez[1], P. Collado[1].
[1]*Hospital Universitario Severo Ochoa, Rheumatology Service, Leganés, Spain*

Background: Autoinflammatory syndromes encompass a group of diseases caused by dysregulation of the innate immune system that classically present with periodic fevers and usually debut in childhood.
Objectives: An unusual case of an autoinflammatory syndrome with adult onset is presented.
METHODS:
Results: This is a 57-year-old adult woman, ex-smoker, and ex-alcoholic, with no other personal history of interest. She was referred to internal medicine in 2017 for weight loss of 10-15 kg for two months, without other symptoms. Complementary test ruled out autoimmune aetiology and viral infections (hepatotropic and HIV), and a thoracoabdominal-pelvic CT scan identified micronodular millimetric liver lesions and sclerosing lesions in the vertebral and in the iliopubic bones, with no pathological data in a subsequent bone scan. The follow-up showed new symptoms, such as Raynaud's phenomenon, right carpitis (calcium pyrophosphate crystals in synovial fluid), and once again weight loss, and episodes of profuse sweating, predominantly in the evening, without thermometric fever. Studies at that time highlighted massive splenomegaly, retroperitoneal and mesenteric lymphadenopathy. Serologies HBV, HCV, HIV, Leishmaniasis, Rose Bengal, LUES and Mantoux were negative. Acute phase reactants changed from normal to sustained elevation: erythrocyte sedimentation rate (ESR) up to 120 mm/h, C-reactive protein (CRP) up to 136 mg/L and ferritin to 1380 ng/ml. In addition, she began to present progressive cytopenia (red and white series), with normocellular bone marrow biopsy. Given the suspicion of probable tumour origin, a liver biopsy was indicated, splenectomy with excision of abdominal lymphadenopathy with corresponding anatomopathological studies that ruled out tumours such as splenic lymphoma, tricholeukaemia and lymphoproliferative syndromes. After splenectomy, she presented clinical improvement interrupted by febrile episodes lasting a week with self-limited peaks (4-5 hours/day). Coinciding with one of the episodes, she presented with diffuse abdominal pain, vomiting and diarrhoea for which she was admitted. Gastrointestinal examination revealed evidence of hypertensive gastropathy and oesophageal varices, as well as liver fibrosis grade F4 (possible enolic origin). In the current year, an urticarial rash appeared on her legs, arms, trunk, and face, with a biopsy compatible with vasculitis-urticaria, which required treatment (prednisone 30 mg/day and colchicine 0.5 mg/day) getting remission but maintaining the febrile peaks and elevated ESR y CRP. A next-generation sequencing (NGS) genetic study was requested, which detected a c.753C>G p. (Asn251Lys) variant in the NLRP12 gene, a missense-type change. This mutation is associated with familial cold-associated autoinflammatory syndrome type 2.
Conclusion: Although the diagnosis of autoinflammatory syndrome is strongly linked to paediatric age, we should not forget to include this diagnosis in the study of an adult patient with recurrent febrile episodes after ruling out infectious processes before performing invasive techniques.

AB1857 A FIRST CASE REPORT OF SCHNITZLER SYNDROME PRESENTING WITH ACROPACHY AND LITERATURE REVIEW

Keywords: bDMARD, Imaging, Inflammatory arthritides

X. Sun[1], Z. Zhang[1]. [1]*Peking University First Hospital, Department of Rheumatology and Clinical Immunology, Beijing, China*

Background: Schnitzler syndrome (SchS) is a rare and easily misdiagnosed autoinflammatory disease. The misdiagnosis not only delays proper treatment, but also leads to the unreasonable use of immunosuppressants or even chemotherapeutic agents which results in needless financial and physical burdens.
Objectives: The objective of this study was to summarize the clinical features and help physicians to avoid more misdiagnosis.
Methods: Here we report a 52-year-old female with SchS, who suffered from chronic pruritic urticaria, fever, and arthralgia for over 10 years. Then we systemically reviewed 471 patients, 470 from 138 previous case reports and 1 from our case report.
Results: Most of the patients were middle-aged or elderly women from European and American countries. There were limited number of cases coming from Asia, and no cases from Africa had yet been identified. The main clinical manifestations included chronic urticaria with or without pruritus, fever, arthralgia, ostealgia/myalgia, fatigue, and weight loss. Some cases also presented with lymphadenopathy, hepatomegaly, and splenomegaly. The presence of monoclonal immunoglobulin was the main diagnostic criteria, and the most common was IgMκ. Laboratory examinations also showed elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Neutrophil infiltration was the most common pathological results in the skin tissue of SchS patients. Currently, anti-IL-1 therapy seems to be the best choice, followed by anti-IL-6 therapy. Glucocorticoid and traditional immunosuppressants seemed to be ineffective to SchS.
Conclusion: As the diversity and variability of clinical symptoms, clinicians should pay more attention to the features of SchS to avoid misdiagnosis. Nearly half a century has passed since the first case of SchS was reported. Exploring its pathogenesis is still on the way. More Research is warranted for individualized therapy.

RHEUMATOID MENINGITIS - A RARE PRESENTATION OF RHEUMATOID ARTHRITIS

Keywords: Rheumatoid arthritis, Diagnostic Tests

S. Subasinghe[1], S. Wijesooriya[1]. *[1]Medway NHS Foundation Trust, Rheumatology, Gillingham, United Kingdom*

Background: Rheumatoid arthritis (RA) is a multisystem autoimmune disease mainly affecting the joints. Rarely it can present with extra articular manifestations without any joint symptoms. Rheumatoid meningitis (RM) is an uncommon extra articular manifestation of the disease and can be the first presentation of RA very rarely.
Objectives: A 76 year old Caucasian lady was presented with aphasia of 10 minutes duration with frontal headache. Furthermore she complained of gradual onset difficulty in walking for the last 10 months and jerky legs. She was on treatment for hypothyroidism, hypertension, anxiety and denied any joint pains. Examination showed normal cranial nerves and spastic quadriparesis with limb power of 4/5, global hyperreflexia and extensor plantar reflexes. She was also observed to have focal clonic seizures of the left lower limb. Lungs were clear. 10 days later she developed painful left wrist and metacarpophalangeal joints with swelling and tenderness.
Methods: MRI of the brain with contrast showed right fronto-parietal leptomeningeal enhancement. Cerebrospinal fluid (CSF) tested repeatedly showed lymphocytic pleocytosis, normal glucose, mildly elevated proteins (0.6g/l). CSF was negative for flow cytometry, TB PCR, TB culture, antineuronal antibodies, cryptococcal antigen, viral PCR, fungal cultures, fungal studies and beta D glucan. Rheumatoid factor (141 iu/ml) and anti CCP antibodies (447u/ml) were strongly positive. CSF anti CCP antibody titre was 8 u/l. Rest of the autoimmune serology was negative. ACE level was normal. Inflammatory markers were raised. X ray of the hands showed degenerative changes only. CT chest abdomen and pelvis and FDG PET scan showed left sided axillary lymphadenopathy of which the biopsy showed reactive changes. CT also showed possible early interstitial lung disease (ILD).
Results: Patient was managed with the collaboration of the neurology team, rheumatology team and input from a tertiary care center. Meningeal biopsy was not done due to the risks involved and delay in starting treatment. RM was diagnosed after exclusion of other differential diagnosis. Patient was treated with IV methyl prednisolone 1g 3 pulses and started on a tailing off regime of oral prednisolone. Hydroxychloroquine and sulfasalazine were started as disease modifying treatment. Methotrexate was avoided due to the suspicion of ILD. Patient had good recovery clinically and radiologically in 6 months.
Conclusion: RM can be the first presentation of RA rarely. Hence it is important for rheumatologists to be aware of this rare manifestation. Usually patients develop joint symptoms within a year of presentation of RM [1]. Most of the patients are strongly sero positive [2]. Clinical symptoms can be diverse with focal neurological deficit, focal seizures, neuropsychiatric symptoms, stroke like episodes and headache. MRI characteristically shows meningeal enhancement. It can be confirmed with a meningeal biopsy. However RM can be diagnosed with confidence as in patient by thorough exclusion of other inflammatory, infective and paraneoplastic causes of chronic meningitis. It is postulated that anti CCP antibody levels in CSF is raised in patients with RM. Direct measurement of these values and calculation of intrathecal anti CCP antibody production based on these values are useful in diagnosing RM in patients, unable to go ahead with a meningeal biopsy [3]. Acute treatment of RM is immunosuppression with steroids that can be combined with cyclophosphamide or rituximab.

CERVICAL INVOLVEMENT IN CALCIUM PYROPHOSPHATE DEPOSITION DISEASE - DISEASE SPECTRUM

Keywords: Education, Imaging, Crystal Arthritis

E. Costa[1], C. Campinho Ferreira[1], A. M. Gomes Correia[1], D. Esperança Almeida2, P. Pereira2, J. Silva[1], M. Cerqueira[1], J. Redondo Costa[1], A. R. Ribeiro[1], J. Neves[1]. *[1]Hospital de Braga, Rheumatology, Braga, Portugal*; *[1]Hospital de Braga, Rheumatology, Braga, Portugal*

Background: Calcium pyrophosphate deposition disease (CPPD) is microcrystalline arthropathy that affect space joints and fibrocartilage, leading to inflammation and structural damage. CPPD affects predominantly the appendicular skeleton. For this reason, CPPD has several pseudonyms such as pseudogout, pseudo-rheumatoid arthritis, and pseudo-osteoarthritis. The involvement of the axial skeleton is less common or recognized but may have a broad spectrum of clinical presentations.
Objectives: To describe the clinical spectrum of axial manifestations of CPPD.
Methods: Case report and discussion.
Results: 1–Asymptomatic deposition of calcium pyrophosphate (CPP) in C1-C2: 68-year-old woman, diagnosed with CPPD with a pseudogout-like presentation. Previously, a knee arthrocentesis has been performed during an episode of monoarthritis. Blunt crystals with weak birefringence and positive elongation were identified in the synovial fluid analysis by polarized light microscope, compatible with CPP crystals. Later, the patient underwent a brain computed tomography (CT), after a head trauma, and it was observed the presence of calcification of the atlas transverse ligament (figure A), without associated symptoms.
2–Crowned Dens Syndrome: A 59-year-old woman, with a definitive diagnosis of CPPD secondary to iatrogenic hypomagnesemia by proton pump inhibitor, requested urgent evaluation due to inflammatory neck pain with 2 days of evolution. She reported sudden onset during the night, limitation of cervical mobility, and fever (38.1ºC). Moreover, the patient had suspended her medication (colchicine and oral magnesium) 1 month before the onset of complaints, without

medical advice. Analytically, she presented acute phase reactants elevation. Cervical spine CT showed mineralization of the transverse atlas and alar ligaments (figure B). The patient completed a low-dose corticosteroid regimen and restarted the usual medication, with rapid and complete recovery.

3–Retro-odontoid pseudotumor: An 85-year-old woman followed by neurosurgery for clinical signs suggestive of cervical myelopathy was referred to rheumatology. From the imaging study carried out, she had CT and MRI of the cervical spine and skull, where calcification and marked thickening of the atlantoaxial ligament complex and peri odontoid soft tissues were identified, with anterior dislocation of the odontoid and stenosis of the vertebral canal at the medullary bulb transition (figure C). Clinically, she reported longstanding episodes characterized by mixed rhythm cervicalgia. She denied a previous history of peripheral arthritis. Radiographic and ultrasound studies evidenced triangular fibrocartilage of the carpus and knee menisci chondrocalcinosis, and intracartilaginous hyperechoic images in multiple locations, suggestive of CPP deposition. The patient started therapy with colchicine 1mg/day and cervical orthosis for symptomatic control.

4–Inflammatory discitis: 78-year-old male, hospitalized for inflammatory neck pain, wrist and metacarpophalangeal joints arthritis, dysphagia, dyspnea, urinary incontinence, and fever. The laboratory analysis showed acute phase reactants elevation, without leukocytosis. After an exhaustive investigation of infectious etiology and refractoriness to multiple antibiotics, the patient started high-dose corticosteroid therapy with rapid resolution of complaints. The CT image showed C4-C5 and C5-C6 discitis with osteophytosis leading to pharyngeal anatomical distortion and periodontal and posterior longitudinal ligament calcification (figure D).

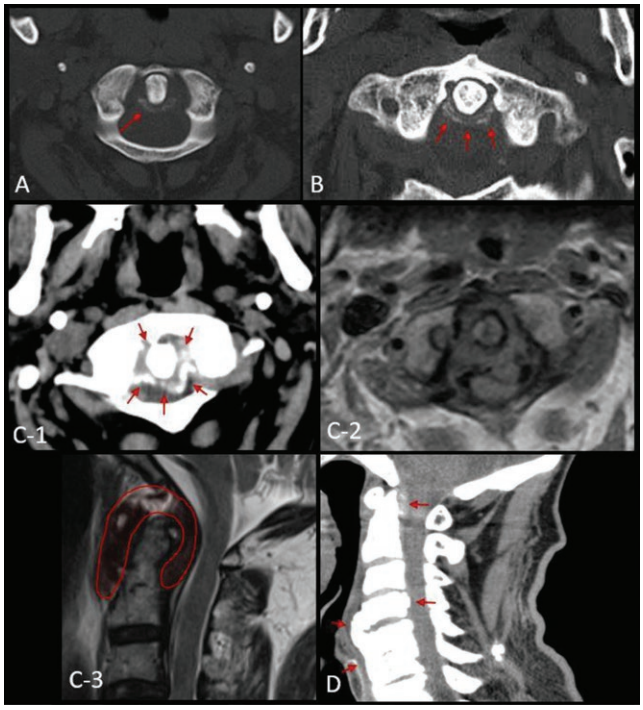

Figure 1.

Conclusion: The axial involvement of CPPD can have several clinical presentations, from asymptomatic to acute presentation with manifestations of other organ systems. The imaging findings of axial involvement are distinctive and can be crucial in the diagnosis. The differential diagnosis with other etiologies in situations of acute presentations, namely infectious, is imperative. Recognition of this potential clinical manifestation is essential to avoid underdiagnosis.

AB1860 **CHARACTERISTICS OF IMMUNE CHECKPOINT INHIBITOR INDUCED SICCA SYNDROME**

Keywords: Sjögren syndrome, Real-world evidence

T. Cox[1], A. Desai[1], R. M. Brown[2], T. Bates[2], S. Nayar[1], A. Olson-Brown[3], L. Pallan[4,5], N. Steven[4,5], B. A. Fisher[1]. [1]*Institute of Inflammation and Ageing, University of Birmingham, Rheumatology, Birmingham, United Kingdom*; [2]*University Hospitals Birmingham NHS Trust, Department of Histopathology, Birmingham, United Kingdom*; [3]*The Clatterbridge Cancer Centre - Wirral, Medical Oncology, Birkenhead, United Kingdom*; [4]*Institute of Immunology and Immunotherapy, College of Medical and Dental Sciences, University of Birmingham, Immunology and Immunotherapy, Birmingham, United Kingdom*; [5]*Cancer Centre, University Hospitals Birmingham NHS Foundation Trust, Oncology, Birmingham, United Kingdom*

Background: Immune checkpoint inhibitors (ICIs) have revolutionised management of certain cancers and significantly improved mortality. They work by blocking specific checkpoint proteins or ligands: CTLA-4 (ipilimumab), PD-1 (pembrolizumab and nivolumab) and PDL-1 (durvalumab and atezolizumab). This augments anti-tumour immunity through improved T cell function. Unfortunately the augmented immune function can lead to immune related adverse events (irAEs). One of these irAEs is sicca syndrome, which is a discrete entity from Sjogren's syndrome and was first reported by Cappelli in 2017[1].

Objectives: To report on a supra-regional cohort of patients with immune checkpoint inhibitor induced sicca syndrome, exploring clinical and pathological features.

Methods: We evaluated data from patients who were referred with new onset sicca symptoms to Queen Elizabeth Hospital Birmingham's Sjogren's service, between 2017 and 2022.

Results: 22 patients were identified (male =12, median age = 66) with underlying cancers (metastatic melanoma =16, renal cell carcinoma = 4, small cell lung cancer =1, hepatocellular carcinoma =1) who were being treated with various ICIs (atezolizumab =2, durvalumab =3, pembrolizumab = 5, nivolumab and ipilimumab combination = 11 and monotherapy nivolumab =1). 4 patients had pre-existing autoimmune disease (autoimmune thyroiditis =2, coeliac disease =1, type 1 diabetes mellitus =1). 21 patients reported xerostomia, with 15 of the 16 patients who performed salivary flow tests having very low unstimulated flow rates. Xeropthalmia was reported by 10 patients; interestingly 4 patients did not report dry eye symptoms but had significantly reduced tear production on Schirmer's testing. Glandular swelling was only seen in 2 patients. ANA was positive in 3 patients, none had a positive ENA. One patient was rheumatoid factor positive (38.8 IU/ml). 4 had IgG levels >16 g/L. No cases of hypocomplementaemia were seen. The median time to symptom onset, after ICI initiation, was 3 months, with varied intensity of onset. The mean oral dryness score, on initial assessment, was 6.5 out of 10 (SD ±2.5). ICI Therapy was stopped in 5 patients due to severity of symptoms. 3 required temporary discontinuation, due to sicca syndrome with an average pause of 9.3 weeks. 13 of the 22 patients had a history of additional irAEs, most commonly arthritis, colitis and endocrine issues (new onset diabetes, hypothyroidism, hypercalcaemia). Systemic steroids were required in 12 patients to alleviate their symptoms (starting doses 10-30mg), and 6 of these subsequently started hydroxychloroquine. Mean oral dryness score, following treatment (ICI cessation or aforementioned treatments) had reduced by over half, to a mean of 3.1 (SD ±2.9) at last clinical assessments. Labial salivary gland biopsy was performed in 15 patients; 4 showed focal lymphocytic sialadenitis (FLS; a biopsy finding also associated with Sjogren's syndrome). None of the patients with FLS had autoimmune disease or dryness symptoms predating ICI. The other 12 samples showed nonspecific chronic sialadenitis, with characteristic atrophy and fibrotic changes. Immunohistochemistry typically showed lightly dispersed CD3+ T cells with an even mixture of CD4+ and CD8+ cells.

Conclusion: We have presented the clinicopathological features of a supra-regional ICI induced sicca syndrome cohort. Our findings mirror those from the US cohort described by Warner et al[2] with significant oral symptoms which occur soon after treatment initiation and may respond to withholding or stopping ICI, steroids and hydroxychloroquine. ICI induced sicca syndrome significantly impacts quality of life and should be recognised as an irAE that in certain cases requires treatment.

Neupane[4]. *[1]Advanced Centre for Immunology and Rheumatology, Immunology & Pediatric Rheumatology, Kathmandu, Nepal*; *[2]Government Medical College, Srinagar, Kashmir, India, Pediatrics, Kashmir, India*; *[3]All India Institute of Medical Sciences, Patna, India, Pediatric Rheumatology, Patna, India*; *[4]Advanced Centre for Immunology & Rheumatology, Kathmandu, Nepal, Data & statistics, Kathmandu, Nepal*

Background: Monogenic causes are increasingly being detected in pediatric rheumatological diseases (PRDs).[1] Monogenic disorders are inborn errors of immunity resulting into innate immune disturbance and autoinflammation. With increasing awareness and diagnostics, PRDs are diagnosed with increasing frequency and accuracy in Nepal.

Objectives: To describe the profile of children diagnosed with PRDs and monogenic causes explored on them at a tertiary care center in Nepal during 2020-2022.

Methods: Case records of patients diagnosed with PRDs during Aug 2020-November 2022 were analysed. The lead author (DB) collated data from all patients. Diagnosis and treatments were based on internationally acclaimed guidelines. Genotyping was done by whole exome sequencing and/or sanger sequencing.

Results: The availability of subspecialists, diagnostics, and therapeutics has shifted the paradigm of PRDs in developing countries. A total of 454 patients with PRDs were diagnosed. Mean duration from initial presentation to diagnosis was 12.5 months. Juvenile idiopathic arthritis (JIA) (including systemic JIA) (n = 131), connective tissue disorders (n = 113) and vasculitides (n = 104) constituted the largest proportion of PRDs. Arthritis related to infection was observed in 42 cases whereas autoinflammatory disorders were diagnosed in 29. Monogenic causes were detected in 19 patients (**Table 1**). Majority were of non-inflammosome related conditions. Causative genes were *CECR1, ARPC1B, TNFAIP3, NLRP3, TNFRSF1A, MVK, PSTPIP1, NOD2, NLRP3, STX11, TNFRSF6, XIAP, BMPR2, PIK3CD, CTLA4, GATA2* and *C1QA*. Clinical features included recurrent fever, rashes, edema, lymphadenopathy, arthritis, vasculitis, ear and ocular issues, organomegaly, and various multisystemic symptoms. Treatment of polyarteritis nodosa with mycophenolate mofetil and idiopathic calcinosis with methotrexate and pamidronate were notable reports from our cohort. Oligoarthritis in X-linked agammaglobulinemia was a peculiar finding. One child with the monogenic PRD has undergone hematopoietic stem cell transplantation.

Conclusion: We present first and largest cohort of PRDs from Nepal. Noticeable number of unique monogenic causes of PRDs were diagnosed for the first time in the country. There are significant challenges in diagnosis and treatment of PRDs in resource-limited settings. Various socioeconomic and environmental factors coupled with lack of awareness, fewer referrals, and inexpedient treatment accounted for a late presentation, missed diagnosis, increased morbidity, disability, and mortality.

Table 1. Details of monogenic causes of pediatric rheumatological diseases from Nepal (2020-2022)

Diagnosis	Number of patients	Gene affected
Deficiency of Adenosine deaminase 2 (DADA2)	2	*CECR1*
ARP2/3-mediated filament branching defect	2	*ARPC1B*
Haploinsufficiency of A20	1	*TNFAIP3*
Familial cold autoinflammatory syndrome	1	*NLRP3*
Tumor Necrosis Factor Receptor Associated Periodic Syndrome (TRAPS)	1	*TNFRSF1A*
Hyperimmunoglobinemia D with periodic fever syndrome	1	*MVK*
Pyogenic sterile arthritis, pyoderma gangrenosum, and acne syndrome (PAPA) syndrome	1	*PSTPIP1*
Juvenile systemic granulomatosis (Blau syndrome)	1	*NOD2*
Neonatal-onset multisystem autoinflammatory disease	1	*NLRP3*
Familial hemophagocytic lymphohistiocytosis	1	*STX11*
Autoimmune lymphoproliferative syndrome	1	*TNFRSF6*
X-linked inhibitor of apoptosis protein deficiency	1	*XIAP*
Primary pulmonary hypertension	1	*BMPR2*
Activated Phosphoinositide 3-kinase δ syndrome (APDS)	1	*PIK3CD GOF*
CTLA4 haploinsufficiency (ALPS-V)	1	*CTLA4*
GATA2 deficiency	1	*GATA2*
C1Q deficiency (early complement defect lupus)	1	*C1QA*
