Methods: We performed a retrospective study of IIM patients followed in a reference center and compared them according to the presence of ILD. Epidemiological, clinical and immunological data, pulmonary function tests (forced vital capacity and diffusing capacity for carbon monoxide), sKL-6 levels and NVC finding were retrieved. NVC findings including loss of capillary density, enlarged and giant capillaries, ramified capillaries, haemorrhages, thrombosis, avascular areas, disorganization of capillary architecture and subpapillary venous plexus presence were recollected, if present. Statistical analysis was performed by T-test and Fisher's exact test to compare qualitative and/or quantitative variables and multiple logistic regression modelling to identify correlation between pulmonary function tests, NVC findings and sKL-6 levels. Values of p<0.05 were considered statistically significant.

Results: 95 patients were included, 47 patients (49%) with ILD. 34% were male with a median age at inclusion of 55.3±24 years and a median disease duration of 6.8±7 years. Avascular areas and capillary loss showed a significant association with the presence of ILD (OR 2.43, 95% CI 1.3-5.7, p 0.004) and (OR 1.7, 95% CI 1.48-3.1, p 0.04). A negative correlation between capillary loss and enlarged capillaries was also found with FVC% (β=-0.46, p 0.001 and β=-0.57, p <0.0001) and DLCO% (β=-0.32, p 0.04 and β=-0.23, p 0.03), respectively. When we studied the correlation between sKL-6 levels, positive correlations with the presence of ILD (β=0.77, p 0.0004), the presence of hemorrhages (β =0.21, p 0.04) and avascular areas in NVC (β =0.64, p 0.03) and negative correlations with FVC% (β=-0.47, p 0.001) and DLCO% (β=-0.59, p, 0.005) were found. Multiple logistic regression identified as predictors for developing IIM-ILD are summarized in Table 1 and represented in the scatter plot in Figure 1. Male sex, respiratory symptoms, %FVC and %DLCO, sKL-6 levels, anti-Jo1 positivity and the presence of avascular areas and enlarged capillaries in NVC were identified as IIM-ILD predictors (R^2=0.974, p =0.006).

Conclusion: Capillary loss and avascular areas showed a significant association with the presence of ILD, worse FVC and DLCO values and sKL-6 levels. We identified 9 predictors for developing ILD in IIM. NVC assessment and sKL-6 levels can have a predictive role for studying pulmonary function and assessing the prognosis of IIM-ILD.

Table 1. Significant logistic regressions for predictors for IIM-ILD

Predictor	B value	P value
Male sex	0.186	0.036
Respiratory symptoms	0.40	0.002

CLINICAL FEATURES AND PREDICTORS OF MYOCARDIAL INVOLVEMENT IN ANTI-SYNTHETASE SYNDROME PATIENTS

Keywords: Heart, Myositis, Biomarkers

C. Campochiaro[1], G. De Luca[1], M. B. Cilona[1], G. Mancuso[1], L. Dagna[1]. [1]*IRCCS San Raffaele, Vita-Salute San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Anti-synthetase syndrome (ASS) is a rare systemic connective tissue disease with protean clinical manifestations. Myocarditis is one of the most worrisome organ involvement[1].

Objectives: To investigate the features associated with myocardial involvement and the predictors of myocarditis in ASS patients.

Methods: ASS patients followed up at our Myositis Clinic were identified. Patients were classified as having myocarditis whether they had a positive cardiac magnetic resonance (CMR) and/or a positive endomyocardial biopsy (EMB). All patients underwent troponin T, NTproBNP and echocardiography at first evaluation at our

Table 1. Baseline features of ASS patients with and without myocarditis

centre. Those with palpitations and/or evidence of arrhythmias also underwent 24-hour Holter-ECG. Patients with abnormalities in one the above mentioned parameters underwent CMR +/- EMB. The presenting features and the prevalence of traditional cardiovascular risk factors were compared between the 2 groups. Univariate and multivariate logistic regression analyses were performed.

Results: 43 ASS patients were identified, 13 (30%) with myocarditis and 30 (70%) without myocarditis; of these baseline echocardiography data and troponin T and NTproBNP levels before immunosuppressive treatment introduction were available for all myocarditis patients and for 22 ASS patients without myocarditis. The clinical characteristics of patients are summarized in Table 1. At baseline myocarditis patients were more frequently male, had more raised levels of troponin T (although not always with values > 5 times upper limits of normality), NTproBNP, liver enzymes and CRP. Of note, for what concerns clinical features, only fever was more frequently observed in ASS patients with myocarditis (69% versus 17%, p = 0.001). At multivariate logistic regression analysis only the presence of fever at baseline (OR 7.707, 95%CI 1.026 – 57.917, p =0.047) was associated with myocarditis.

Conclusion: Myocarditis is not a rare, but likely, an overlooked manifestation in ASS. Myocarditis in ASS can be subtle as shown by the presence of only slightly raised cardiac enzymes in some patients and the absence of striking echocardiographic or clinical features. The presence of fever might suggest that a more inflammatory phenotype is associated with myocarditis in ASS.

Background: Idiopathic inflammatory myopathies (IIM) constitute a heterogeneous group of diseases with systemic inflammation. Inflammation has previously been associated with poor subjective health appraisal in both acute and chronic inflammatory diseases [1-5].

Objectives: To explore if the patient-reported outcome measure "patient global assessment" (PGA) is associated with markers of inflammation over time and if associations could be explained by functional measures in patients with IIM.

Methods: PGA and inflammatory markers longitudinally collected over 5 years were retrieved for 1333 patients with IIM from the international MyoNet registry. Associations between PGA, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and creatine kinase (CK) were analyzed with mixed effect regression analyses. Mediation analysis was used to test if the associations between PGA and inflammatory markers could be explained by disease-associated symptoms and signs.

Results: PGA improved and inflammatory markers decreased during the first year of observation. High levels of ESR and CRP were associated with worse PGA in both men (ESR:*b*=0.21, 95%CI 0.10-0.32, p<0.001, CRP:*b*=0.16, 95%CI 0.04-0.29, p=0.012) and women (ESR:*b*=0.34, 95%CI 0.25-0.42, p<0.001, CRP:*b*=0.26, 95%CI 0.14-0.37, p<0.001) across time points, and CK was associated with PGA in women (*b*=0.70, 95%CI 0.48-0.93 p<0.001) but not in men (*b*=0.07, 95%CI -0.54-0.68, p=0.831). In men, the association between elevated inflammatory markers and poorer PGA was explained by disability and extra-muscular disease activity whereas in women this association could not be explained by any of the included functional measures. With a few exceptions, the association between reduced inflammatory markers and improved PGA during the first year of observation was partially mediated by improvements in all functional measures.

Conclusion: Higher levels of systemic inflammation were associated with poorer PGA in patients with IIM. In addition to known benefits of lowered inflammation, these findings emphasize the need to reduce systemic inflammation to improve subjective health.

Background: Cardiovascular (CV) risk due to accelerated atherosclerosis and impaired metabolism can be increased in idiopathic inflammatory myopathies (IIM) on behalf of systemic inflammation, limited mobility, and glucocorticoid therapy.
Objectives: This study aimed to evaluate CV risk in patients with IIM in comparison to healthy controls (HC) and to assess its association with disease-specific features.
Methods: 90 patients with IIM (70 females; mean age 56.6; mean disease duration 5.95 years; dermatomyositis: n=29, polymyositis: n=12, immune-mediated necrotizing myopathy (IMNM): n=20, anti-synthetase syndrome: n=29) and 180 HC (130 females, mean age 54.3) were included. In both groups, subjects with a history of CV disease (angina pectoris, myocardial infarction, cerebrovascular, and peripheral arterial vascular events) were excluded. Muscle involvement, disease activity, and tissue damage were evaluated (by MMT-8, MITAX, MDI, respectively). Comorbidities and current treatment were recorded. All participants underwent examinations of carotid intima-media thickness (CIMT), pulse wave velocity (PWV), ankle-brachial index (ABI), and body composition (by densitometry (DXA) and bioelectrical impedance analysis (BIA)). The risk of fatal CV events was evaluated by the Systematic COronary Risk Evaluation (SCORE, charts for the European population) and its modifications: SCORE multiplied by the coefficient 1.5 (mSCORE), and SCORE2.
Results: Compared to HC, IIM patients had a significantly higher prevalence of traditional CV risk factors, carotid artery disease (CARD), abnormal ABI, and PWV ($p<0.05$ for all). After propensity score matching (PSM) using traditional CV risk factors, the prevalence of CARD and pathologic PWV remained significantly higher in IIM than HC ($p<0.05$ for all), but no significant difference in SCORE was observed. Overall CV risk based on calculated risk (modifications of SCORE) and ultrasound (US) examinations was comparable between IIM ad HC after PSM (CVR-SCORE $p=0.457$, CVR-SCORE2 $p=0.130$, CVR-US $p=0.126$). IMNM patients had the most unfavorable CV risk profile among IIM subtypes. The calculated CV risk scores by SCORE and SCORE2 (in both IIM and HC), and mSCORE (in IIM only) were reclassified according to CIMT and the presence of carotid plaques. SCORE was demonstrated to be the most inaccurate in predicting CV risk in IIM, while there was a significantly higher proportion of reclassified patients with underestimated CV risk evaluated by SCORE compared to SCORE2 and mSCORE ($p=0.020$). Age, disease activity, lipid profile, body composition parameters, and blood pressure were the most significant predictors of CV risk in IIM patients ($p<0.05$ for all variables in bivariate analysis). Moreover, the length of glucocorticoid therapy was positively associated with an increased count of carotid plaques and overall CV risk estimated by US examination ($p<0.05$ for both).
Conclusion: This cross-sectional cohort study in IIM patients demonstrated a significantly increased risk of subclinical atherosclerosis and CV risk, and also an increased prevalence of traditional CV risk factors compared to HC with comparable age and gender distribution. The most unfavorable findings were seen in patients with IMNM. All scoring systems for CV risk screening underestimated the CV risk in IIM when using the CV risk according to ultrasound findings. SCORE2 appeared to be the most accurate tool in IIM.

Background: Antisynthetase syndrome (ASSD) is an autoimmune disease characterized by the presence of antiaminoacyl tRNA-synthetase antibodies (ARS) and clinical manifestations that may include interstitial lung disease (ILD), myositis, arthritis, Raynaud´s phenomenon (RP), fever and mechanic's hands (MHs). The incidence rate is unknown and no population epidemiological studies have been published.
Objectives: To determine the incidence and epidemiology of ASSD between 2016 and 2019 in Catalonia. Diagnostic criteria considered were: the positivity of ARS associated with at least one major clinical manifestation (myositis, ILD or arthritis)
Methods: Restrospective multicentrical observational study. All patients with a first ARS (Jo1, PL7, PL12, OJ, EJ) positive during the period study were selected. Patient identifacation was carried out through the immunology laboratories of all the hospitals of the public catalan network. We estimed the cumulative incidence in the average population of Catalonia betwen 2016-2019 (7.526.982 individuals) and collected demographic, epidemiologic, clinical and immunologic data.
Results: We identified 201 patients with ARS, 125 of them met ASSD criteria. The estimated cumulative incidence was 1.66 cases per 100,000 inhabitants. Most were women (62.9%) with a mean age at diagnosis of 59.8 years (DE 15.4) and 78.3% southern european caucasians. Sixty three per cent worked in the tertiary sector and 20.5% in the secondary. Some environmental exposure were recognized in 17.9%, being contact with animals and asbestos the most common, and 38.8% were smokers or ex-smokers. Anti-Jo1 was the most frequent ARS (39.2%), followed by PL7 (28.8%), PL12 (21.6%), EJ (5.6%) and OJ(4.8%). ANA were positive in 74%, mostly with a cytoplasmic pattern (59,3%). Another specific ANA was present in 58.4%, predominantly Ro52 (48%). Rheumatoid factor, ACPA and ANCA were positive in 13.6%, 4.6% and 4.3% respectively. The mean age at first symptom was 58.5 years (DE 15.6). All patients presented at least one major manifestation: 45.6% one, 40.8% two and 13.6% three. ILD was present in 90.3%: subacute/chronic dyspnea 39.3%, cough 22.3%, rapidly progressive dyspnea 18.8% and 17% asymptomatic. HRCT patterns observed were: NSIP 50.5%, OP 15.3%, NSIP+OP 11,7%, UIP 11.7% and unclassifiable pattern 9.9%. Myositis was present in 64 cases (51.6%). Muscle biopsy was available in 34 cases: 50% dermatomyositis pattern, 36% polymiositis pattern, 20% indeterminate pattern and 1% necrotizing myositis. Arthritis was present in 27.2% (polyarthritis 78.6%, oligoarthritis 21.4%), RP 11.2%, fever 25.4% and skin manifestations 49,6% (71% MH's, 27.4% Gottron'n papules, 12.9% heliotrope rash and 3.2% shawl rash). First manifestation was ILD in 58.9% of patients, followed by myositis (21.4%) and arthritis (19.6%). Fifteen patients (12%) presented cancer, 8 of them less than 3 years from AS diagnosis. Breast cancer was the most common. In 14 cases (11.2%) another autoimmune disease was associated, highlighting 6 cases with Sjögren's syndrome.
Conclusion: The estimated cumulative incidence of ASSD between 2016 and 2019 in Catalonia was 1.66 cases per 100,000 inhabitants. Despite the absence of diagnostic criteria for ASSD, the presence of ARS is a necessary condition to

establish it. We believe that identification of cases based on positive results of anti-ARS antibodies is a useful strategy to determine the incidence of ASSD in our territory.

POS1228 DETERMINANTS OF PATIENT GLOBAL DISEASE ACTIVITY IN ADULT MYOSITIS

Keywords: Myositis, Patient reported outcomes

S. Keret[1], D. Saygin[2], C. V. Oddis[2], S. Moghadam-Kia[2], R. Aggarwal[2]. *[1]Bnai Zion Medical Center, Rheumatology, Haifa, Israel*; *[2]University of Pittsburgh Medical Center, Division of Rheumatology and Clinical Immunology, Pittsburgh, Pennsylvania, United States of America*

Background: Myositis is a heterogeneous rare autoimmune disorder with muscle weakness and many systemic features that contribute to morbidity and mortality. The myositis core set measures (CSM) were developed to capture myositis disease activity, and are useful in clinical practice and therapeutic trials [**1].** However, the CSM are primarily subjective physician assessments. Understanding the drivers of the patient global (PT global) disease activity assessment and the difference between the physician and patient perception of their disease activity is important to elucidate [**2].**

Objectives: To examine the determinants of the PT global, and the discordance between PT global and physician-global (MD global) disease activity in myositis.

Methods: Adults with myositis were enrolled at the University of Pittsburgh Myositis Center and the following outcome measures were collected: Manual muscle testing (MMT), HAQ, creatine kinase (CK), fatigue, pain, PROMIS physical function (PF-20), Short Form-36 (SF-36), sit-to-stand, timed up-and-go, six-minute walk, and Actigraph step per min/day count. PT- and MD global scores (10cm visual analog scale [VAS]) were recorded, and discordance was defined as ≥3 point difference between the scores based on published literature in other rheumatic diseases [**3].** The difference in both scores was also analyzed in myositis subjects with active vs inactive disease. A linear regression model was used to determine the contribution of each measure to the PT global.

Results: Fifty patients (60% females; mean age 51.6 [±14.9] years) with probable/definite myositis (24 dermatomyositis [DM], 6 polymyositis [PM], 9 necrotizing myositis [NM] and 11 anti-synthetase syndrome [ASyn]) according to the ACR/EULAR Classification Criteria were enrolled prospectively. PT global correlated strongly with muscle disease activity, MD global, MMT, HAQ-DI, PROMIS physical function, pain VAS, fatigue VAS, SF36 physical function, health, fatigue, social functioning, and pain subdomains, 6MWD and step per min/day count (r=0.57-0.75), moderately with STS, TUG and CK levels (r=0.36-0.46), and poorly with cutaneous, pulmonary, and extra-muscular disease activity (r=0.02-0.17). Correlations of PT global with pain, physical function, fatigue, quality of life and physical activity measures were overall stronger than the MD global, as opposed to muscle and extra-muscular disease activity which correlated better with the MD global. Physical function and fatigue measures contributed most to the PT global, followed by measures of pain, physical activity, quality of life, and muscle disease, while the MD global was primarily driven by muscle disease activity (**Figure 1**). The PT global was discordant with MD global in 30% (n=15) of the patients, where the PT global was higher than the MD global in 66% (n=10). Patients with a discordantly high PT global suffered from significantly higher levels of pain (p=0.03), fatigue (p=0.05), and more functional limitation as reflected by the HAQ (p=0.04).

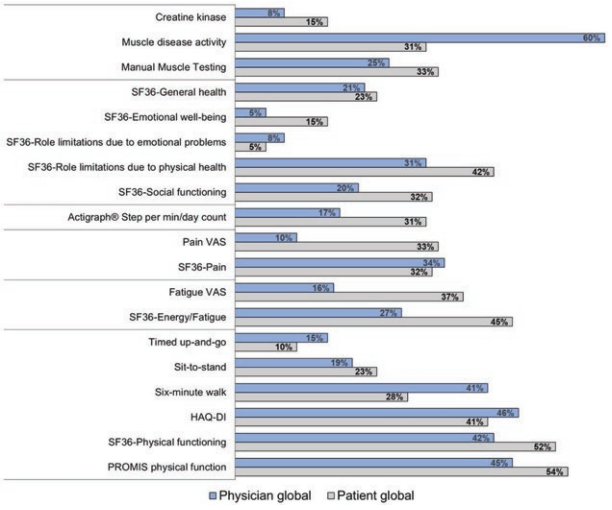

Figure 1. The determinants of patient-reported global disease activity (PT global) and physician-reported global disease activity (MD global).

Conclusion: Fatigue, pain, and physical activity are important driving factors of the differences observed in the patient vs. physician assessment of myositis disease activity. Understanding the gap between patient-physician perspectives may help provide patient-centered care.

POS1229 DO MYOSITIS AUTOANTIBODIES PREDICT RESPONSE TO IVIG IN DERMATOMYOSITIS? A POST-HOC ANALYSIS OF THE PRODERM TRIAL

Keywords: Myositis, Randomized control trial, Autoantibodies

C. Charles-Schoeman[1], J. Schessl[2], E. Clodi[3], R. Aggarwal[4], A. T. Proderm Investigators[5]. *[1]University of California Los Angeles, Rheumatology, Los Angeles, United States of America; [2]Friedrich-Baur-Institute, Ludwig-Maximilians University of Munich, Department of Neurology, Munich, Germany; [3]Octapharma Pharmazeutika Produktionsges.m.b.H., GLobal Medical & Scientific Affairs, Vienna, Austria; [4]University of Pittsburgh School of Medicine, Rheumatology and Clinical Immunology, Pittsburgh, United States of America; [5]Different Insitutions in Europe and USA, Departments of Neurology, Rheumatology and Dermatology, VIenna, Austria*

Background: Dermatomyositis (DM) is an immune-mediated idiopathic inflammatory myopathy (IIM). Two subsets of autoantibodies have been identified in patients with IIM. The first includes myositis-specific antibodies (MSA) such as anti-Jo-1, anti-TIF-1 and anti-MDA-5. The second includes myositis-associated antibodies (MAA) such as anti-PM-SCL, anti-Ku and anti-Ro, which are also found in patients with other autoimmune diseases. MSA are highly specific for IIMs and represent a unique clinical phenotype and prognosis, and have also been associated with the pathogenesis of various subsets of IIM. The ProDERM study recently demonstrated the efficacy and safety of intravenous immunoglobulin (IVIg) in DM patients (1) but the potential role of MSA and MAA in the treatment responses of these patients has not yet been determined.

Objectives: Autoantibody status at baseline and its relationship to treatment response to IVIg were investigated in a post-hoc analysis of the randomized, placebo-controlled ProDERM study.

Methods: In the ProDERM study, dermatomyositis patients received 2 g/kg IVIg treatment (n=47) or placebo (n=48) every 4 weeks for 16 weeks. From week 16 onwards eligible patients (n=91) received IVIg for a further 24 weeks. The primary endpoint was a Total Improvement Score (TIS) of at least 20 (indicating at least minimum improvement) at week 16 and no confirmed deterioration up to week 16. Serum samples were taken at baseline and analysed for MSA (anti-Jo-1, PL-12, SRP, Mi-2, TIF-1, MDA5, MJ, SUMO) and MAA (anti-PM-SCL, Ku, U1RNP, Ro/SSA) by the Oklahoma Medical Research Foundation. Patients were stratified according to their antibody status as MSA-positive (including patients who were also MAA-positive), MAA-positive only, or antibody negative at baseline. The association of antibody status with treatment response measured by TIS was evaluated.

Results: At baseline, a total of 49 (52%) patients were MSA-positive, 13 (14%) were MAA-positive, and 33 (35%) were antibody negative. Demographics of patients in each group are shown in Table 1. Of patients who were MSA-positive, 10 were also positive for MAA. The numbers of patients from the ProDERM study with each specific MSA and MAA are shown in Figure 1.

In the MSA group, 71% (35/49) of patients had TIS response (score ≥20) at week 16, compared to 55% (18/33) in the autoantibody-negative group. In the MSA group 24 patients were randomized to IVIg and of these 83% (20/24) showed TIS response (score ≥20) at week 16 compared to 60% (15/25) in the group of MSA-positive patients receiving placebo. Additional analyses (including results for specific subgroups in the MSA-positive group) will be presented at the EULAR 2023 congress.

Conclusion: Myositis-specific antibodies were commonly identified in patients with dermatomyositis in the ProDERM study. Further analyses will determine if specific MSA, such as anti-TIF-1 and others, play a role in treatment response to IVIg.

Background: Idiopathic inflammatory myopathies (IIM) are rare and heterogeneous conditions, associated with cancer in 10 to 30% of cases. While some features have been associated with cancer (age, male sex, dermatomyositis, anti-TIF1-γ antibodies), the association with cancer is more debated in antisynthetase syndrome (ASS). Few studies have assessed the prevalence of cancer during ASS meeting the criteria of cancer-associated myopathy (CAM)(cancer diagnosed within 3 years before or after the diagnosis of ASS) [1].

Objectives: The main objective was to assess the prevalence of CAM in patients with ASS. Secondary objectives were to describe clinical features, biological features and prognosis associated with CAM in ASS patients.

Methods: In this retrospective multicenter study, we included patients of the main tertiary care centers of Grand-Est and Bourgogne-Franche Comté regions (MyositEst network). Inclusion criteria were age ≥ 18 years old, and Connors criteria fulfilment. Patients with low antisynthetase antibodies levels were excluded.

Results: Among 212 patients screened, 122 patients were included, with a median age of 53.5 ± 14.5 years old, and a female predominance (68%) (Figure 1). The most frequent manifestations of ASS were interstitial lung disease, myositis, skin involvement and inflammatory rheumatism (81%, 69%, 65% and 57%, respectively), followed by fever and cardiac involvement (16% and 4%, respectively). The most frequent specific antibodies were anti-JO1, anti-PL12 and anti-PL7 antibodies (61%, 17% and 10%, respectively), followed by anti-EJ and anti-OJ antibodies (7% and 1.6%, respectively). Four patients were positive for both anti-JO1 and anti-PL12 antibodies, and 1 was positive for both anti-JO1 and anti-PL7 antibodies. Among patients included, 15 (12.3%) met CAM criteria. The diagnosis of cancer was made following whole-body imaging (n=10, either CT-scan or ^{18}FDG-positron emission tomography), systematic cancer screening (n= 3) and physical examination (n= 2). Patients with cancer were older (63.5 ± 8.27 *vs.* 52.1 ± 14.7 years-old, p = 0.0001), had lower CPK levels (541 ± 962 *vs.* 1628 ± 2404 U/L, p = 0.004), less frequently myalgia (20% *vs.* 46.7%, p = 0.05) and a higher MRC muscle scale (4.93 ± 0.25 *vs.* 4.6 ± 0.7, p = 0.0014). CAM patients had more frequent history of cancer (46.6% *vs.* 2.7%, p = 0.004) and had a higher mortality rate (33% *vs.* 5%, p = 0.003). Age above 55 years-old, fever and CPK below 500 U/L were associated with CAM both on bivariate and multivariate analysis (logistic regression model, entry p valule threshold of 0.2,

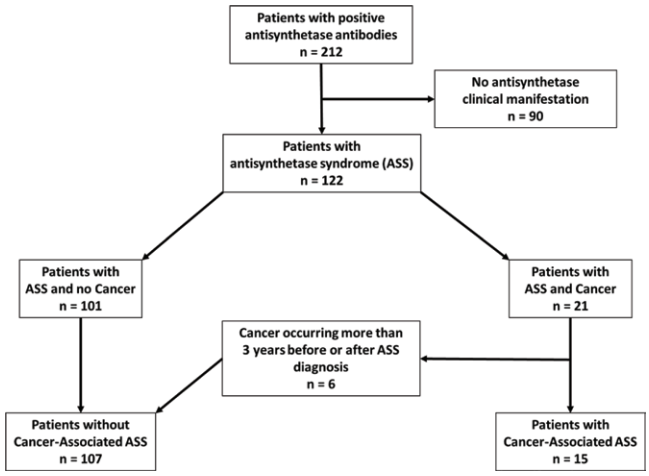

Figure 1 : Flow chart

OR = 7.3 [1.72 – 50.6], p = 0.01; OR = 4.12 [1.03 – 16.6], p = 0.04; and OR = 4.2 [1.1 – 21.1], p = 0.04, respectively)(Table 1).

Conclusion: In our study, CAM in ASS were more prevalent compared to literature data. CAM were independently associated with age, fever and low CPK levels. CAM patients had higher mortality. Careful physical examination, age and sex-based cancer screening, and whole-body imaging could be a relevant screening strategy.

Background: Comprehensive and large-scale assessment of health-related quality of life in patients with idiopathic inflammatory myopathies (IIMs) worldwide is lacking. The second COVID-19 vaccination in autoimmune disease (COVAD-2) study [1] is an international, multicentre, self-reported e-survey assessing several aspects of COVID-19 infection and vaccination as well as validated patient-reported outcome measures (PROMs) to outline patient experience in various autoimmune diseases (AIDs), with a particular focus on IIMs.

Objectives: To investigate physical and mental health in a global cohort of IIM patients compared to those with non-IIM autoimmune inflammatory rheumatic diseases (AIRDs), non-rheumatic AIDs (NRAIDs), and those without AIDs (controls), using Patient-Reported Outcome Measurement Information System (PROMIS) global health data obtained from the COVAD-2 survey.

Methods: Demographics, AID diagnoses, comorbidities, disease activity, treatments, and PROMs were extracted from the COVAD-2 database. The primary outcomes were PROMIS Global Physical Health (GPH) and Global Mental Health (GMH) scores. Secondary outcomes included PROMIS physical function short form-10a (PROMIS PF-10a), pain visual analogue scale (VAS), and PROMIS Fatigue-4a scores. Each outcome was compared between IIMs, non-IIM AIRDs, NRAIDs, and controls. Factors affecting GPH and GMH scores in IIMs were identified using multivariable regression analysis.

Results: A total of 10,502 complete responses from 1582 IIMs, 4700 non-IIM AIRDs, 545 NRAIDs, and 3675 controls, which accrued as of May 2022, were analysed. Patients with IIMs were older [59±14 (IIMs) *vs*. 48±14 (non-IIM AIRDs) *vs*. 45±14 (NRAIDs) *vs*. 40±14 (controls) years, p<0.001] and more likely to be Caucasian [82.7% (IIMs) *vs*. 53.2% (non-IIM AIRDs) *vs*. 62.4% (NRAIDs) *vs*. 34.5% (controls), p<0.001]. Among IIMs, dermatomyositis (DM) and juvenile DM were the most common (31.4%), followed by inclusion body myositis (IBM) (24.9%). Patients with IIMs were more likely to have comorbidities [68.1% (IIMs) *vs*. 45.7% (non-IIM AIRDs) *vs*. 45.1% (NRAIDs) *vs*. 26.3% (controls), p<0.001] including mental disorders [33.4% (IIMs) *vs*. 28.2% (non-IIM AIRDs) *vs*. 28.4% (NRAIDs) *vs*. 17.9% (controls), p<0.001]. GPH median scores were lower in IIMs compared to NRAIDs or controls [13 (interquartile range 10–15) IIMs *vs*. 13 (11–15) non-IIM AIRDs *vs*. 15 (13–17) NRAIDs *vs*. 17 (15–18) controls, p<0.001] and PROMIS PF-10a median scores were the lowest in IIMs [34 (25–43) IIMs *vs*. 40 (34–46) non-IIM AIRDs *vs*. 47 (40–50) NRAIDs *vs*. 49 (45–50) controls, p<0.001]. GMH median scores were lower in AIDs including IIMs compared to controls [13 (10–15) IIMs *vs*. 13 (10–15) non-IIM AIRDs *vs*. 13 (11–16) NRAIDs *vs*. 15 (13–17) controls, p<0.001]. Pain VAS median scores were higher in AIDs compared to controls [3 (1–5) IIMs *vs*. 4 (2–6) non-IIM AIRDs *vs*. 2 (0–4) NRAIDs *vs*. 0 (0–2)

controls, p<0.001]. Of note, PROMIS Fatigue-4a median scores were the highest in IIMs [11 (8–14) IIMs *vs*. 8 (10–14) non-IIM AIRDs *vs*. 9 (7–13) NRAIDs *vs*. 7 (4–10) controls, p<0.001]. Multivariable regression analysis in IIMs identified older age, male sex, IBM, comorbidities including hypertension and diabetes, active disease, glucocorticoid use, increased pain and fatigue as the independent factors for lower GPH scores, whereas coexistence of interstitial lung disease, mental disorders including anxiety disorder and depression, active disease, increased pain and fatigue were the independent factors for lower GMH scores.

Conclusion: Both physical and mental health are significantly impaired in patients with IIMs compared to those with non-IIM AIDs or those without AIDs. Our results call for greater attention to patient-reported experience and comorbidities including mental disorders to provide targeted approaches and optimise global well-being in patients with IIMs.

POS1232

EFFECT MODIFICATION OF CANCER ON THE ASSOCIATION BETWEEN DYSPHAGIA AND MORTALITY IN EARLY IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Epidemiology, Malignancy, Myositis

V. Leclair[1,2,3], M. Holmqvist[1,2], A. Notarnicola[1], O. Krysturfkova[4], H. Mann[4], H. Andersson[5], L. P. Diederichsen[6,7], J. Vencovský[4], I. E. Lundberg[1,8], R. Steele[9], M. Hudson[3]. *[1]Karolinska Institutet and Karolinska University Hospital, Department of Medicine, Division of Rheumatology, Stockholm, Sweden; [2]Karolinska Institutet, Clinical Epidemiology Unit, Stockholm, Sweden; [3]McGill University and Jewish General Hospital, Department of Medicine, Division of Rheumatology, Montreal, Canada; [4]Charles University, 1st Medical Faculty, Institute of Rheumatology and Department of Rheumatology, Prague, Czech Republic; [5]Oslo University Hospital, Department of Rheumatology, Oslo, Norway; [6]Copenhagen University Hospital, Rigshospitalet, Center for Rheumatology and Spine Diseases, Copenhagen, Denmark; [7]Odense University Hospital, Department of Rheumatology, Odense, Denmark; [8]Karolinska Institutet, Center for Molecular Medicine, Stockholm, Sweden; [9]McGill University, Department of Mathematics and Statistics, Montreal, Canada*

Background: The complex interactions amongst dysphagia, cancer, and mortality in idiopathic inflammatory myopathies (IIM) have never been studied.

Objectives: The aim of this study was to investigate the hypothesis that cancer can modify the effect of early dysphagia exposure on all-cause mortality in IIM patients.

Methods: A cohort of adult IIM patients with documented dysphagia exposure within 6 months of disease onset were identified from clinical registries in five countries (Sweden, Canada, Czech Republic, Denmark, and Norway). Mortality rates including 95% CI were calculated. Crude and adjusted mortality rates in IIM patients exposed to dysphagia or not were compared with Kaplan Meier curves and Cox proportional hazard models. To explore possible effect modification of cancer on the association between dysphagia and mortality, an adjusted Cox proportional hazard model stratified on cancer status and including an interaction term between dysphagia and cancer was performed.

Results: This study included 230 IIM adult individuals with a mean±SD age at diagnosis of 57±15 years and a mean±SD disease duration of 3±2 months. Of those, 146 (64%) were women, 122 (54%) had severe disease at baseline, 29 (13%) had cancer in the 3 years preceding IIM onset or within 6 months after IIM onset and 112 (49%) had dysphagia. When comparing the subjects unexposed or exposed to dysphagia, interstitial lung disease was less frequent (25 vs 58%), with more dermatomyositis (56 vs 28%) and less anti-synthetase syndrome (10 vs 36%) in the group exposed to dysphagia. Mortality rates per 100 person-years for IIM patients exposed to dysphagia were 2.3 (95%CI 1.0-4.5) in those without cancer compared to 33.3 (95%CI 16.6-59.2) in those with cancer. Crude survival curves for dysphagia exposure stratified by cancer status were significantly different (p <0.0001). The main effect of dysphagia exposure in IIM patients without cancer was HR 0.6 (95%CI 0.2-1.8) compared to HR 2.9 (95%CI 0.7-12.4) in those with cancer. Dual exposure to dysphagia and cancer significantly increased the risk of mortality relative to patients with neither condition (p-value interaction 0.05).

Conclusion: This is the first study to demonstrate effect modification of cancer on the association between dysphagia and mortality in IIM. This suggests that IIM patients with and without cancer are very different and that separate analyses for the 2 groups should be considered when the outcome of interest is mortality.

POS1233

CLINICAL, SEROLOGICAL AND MUSCLE SHEAR WAVE ELASTOGRAPHY ASSESSMENT IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Ultrasound, Myositis, Imaging

Y. Xin[1], J. Gao[1], Y. LI[2], F. Liu[1], J. Zhu[1]. [1]*Peking University People' s Hospital, Department of Ultrasound, Beijing, China;* [2]*Peking University People' s Hospital, Rheumatology and Immunology, Beijing, China*

Background: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of systemic autoimmune disorders characterized by various degrees of muscle weakness and inflammation. Shear wave elastography may be as a potential noninvasive quantitative imaging biomarker.

Objectives: The objective of this work was to describe the demographic, clinical and serological characteristics of IIM patients, and to evaluate the role of shear wave elastography in detecting muscle damage.

Methods: We enrolled 14 patients with IIM fulfilling the EULAR/ACR 2017[1] and having muscle involvement. Shear wave elastography were performed on rectus femoris (RF), deltoid (DEL), biceps brachii (BB) and sternocleidomastoid (SCM) muscles in these patients and 20 healthy controls along the transverse and longitudinal axes, respectively. Demographic, clinical, and serological characteristics were collected from patients' medical records.

Results: The study included 14 patients with IIM (5 dermatomyositis, 7 immune-mediated necrotizing myopathy, 2 anti-synthetase syndrome). The mean age at diagnosis was 52.93 (±12.99) years, with 9 females (64.3%). The demographic, clinical, serological characteristics of the patients were summarized in Table 1. Muscle ultrasound of IIM patients revealed increased muscle and fascia echogenicity, indicating obvious edema (Figure 1). The shear wave velocity and dispersion slope of RF (1.39 vs. 1.60 m/s, 6.70 vs. 7.59 kHz/[m/s]; 1.82 vs. 1.95 m/s, 7.95 vs. 10.10 kHz/[m/s]), DEL (1.28 vs. 1.41 m/s, 7.01 vs. 7.37 kHz/[m/s]; 2.20 vs. 2.57 m/s, 11.05 vs. 14.39 kHz/[m/s]) and BB (1.29 vs. 1.43 m/s, 7.12 vs. 7.54 kHz/[m/s]; 2.28 vs. 2.60 m/s, 11.74 vs. 13.49 kHz/[m/s]) in myositis patients are significantly lower than those in healthy controls on transverse and longitudinal axes, while SCM (6.94 vs. 7.25 kHz/[m/s], 9.49 vs. 10.51 kHz/[m/s]) only has differences in the dispersion slope ($p < 0.05$). We further calculated the sum of viscoelasticity of these four groups of muscles. The overall shear wave velocity (10.82 vs. 11.83 m/s, 16.72 vs. 18.6 m/s) and dispersion slope (55.54 vs. 59.49 kHz/[m/s], 80.46 vs. 96.99 kHz/[m/s]) of myositis patients were lower than that of the healthy controls, which was consistent across transverse and longitudinal axes ($p < 0.05$). Correlation analysis identified significant negative correlation between CK and LDH and muscle viscoelasticity, with correlation coefficients of -0.56 to -0.60 and -0.57 to -0.71, respectively ($p < 0.05$).

Conclusion: The viscoelasticity of muscle in IIM patients was significantly decreased, which was moderately to strongly correlated with muscle injury markers. Shear wave elastography can quantitatively evaluate muscle injury, it may serve as an imaging marker for the diagnosis and activity evaluation of myositis.

POS1234 CEREBROVASCULAR AND CARDIOVASCULAR RISK OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES IS INCREASED AND CAN BE PREDICTED BY ENA POSITIVITY

Keywords: Biomarkers, Cardiovascular disease, Myositis

K. Triantafyllias[1,2], S. Gauch[2], L. Cavagna[3], A. Schwarting[1,2]. [1]*Rheumatology Center Rhineland-Palatinate, Rheumatology, Bad Kreuznach, Germany;* [2]*Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany;* [3]*University and IRCCS Policlinico S. Matteo Foundation of Pavia, Rheumatology, Pavia, Italy*

Background: Patients with idiopathic inflammatory myopathies (IIM) are under increased cardiovascular (CV) and cerebrovascular (CVB) risk [1-3]. Nevertheless, data on diagnostic tools that could assist CV and CVB patient screening in IIM are scarce. Surrogate markers of CV and CVB risk have been shown to improve risk stratification in the general population and have thus been endorsed by the European Society of Cardiology (ESC) for use in clinical practice. In particular, stiffness of the aortic vasculature and sonography of the carotid arteries are associated with high levels of evidence regarding their CV- and CVB-risk predicting value.
Objectives: Therefore, aim of this study was to examine an oscillometric marker of aortic stiffness and sonographic indices of carotid atherosclerosis and rigidity in a cohort of IIM patients. Moreover, we sought to investigate their relationships with patient- and disease-associated parameters.
Methods: Patients from two large Rheumatology Departments, who have been diagnosed with IIM according to the ACR/EULAR criteria, were recruited. Carotid-femoral pulse wave velocity (cfPWV; gold standard) was used for the examination of aortic stiffness. Moreover, B-mode and Doppler sonography examinations of the common- and internal carotid arteries (CCA, ICA) were performed to assess plaque presence and/or possible abnormalities of carotid intima media thickness (cIMT), as well as vascular resistance and pulsatility indices (RI, PI). The ESC-SCORE (Systematic Coronary Risk Evaluation) was also assessed in all eligible patients.
Results: 73 IIM patients [58.9%♀; age 58 (50-65, IQR)] and 88 healthy subjects [84.1%♀; age 51 (37-57, IQR)] underwent cfPWV examinations in the context of the study (Table 1). A subgroup of the patients (n=63) was additionally evaluated via carotid sonography. IIM patients showed statistically significantly higher cfPWV-[7.92 m/s (6.49-9.26, IQR), vs. 6.72 m/s (6.0-7.69, IQR); p<0.001] and cIMT-values [0.92 mm (0.77-1.1, IQR), vs. 0.8 mm (0.66-0.88, IQR); p<0.001], compared to controls. CCA- and ICA- resistance and pulsatility indices were also statistically significantly higher in the patient group (all; p<0.01). Almost all of these differences remained significant after adjusting for confounding factors, such as age, smoking, BMI, hypertensive treatment and cholesterol [cIMT (p_{adj}<0.001), CCA-PI (p_{adj}=0.002), CCA-RI (p_{adj}=0.004), ICA-PI (p_{adj}=0.02), ICA-PI (p_{adj}<0.001)]. Interestingly, patients with ENA positivity showed higher CCA-RI values compared to their counterparts [0.85 (0.765-0.88, IQR) vs. 0.77 (0.72-0.82, IQR), p=0.044].
Conclusion: Hereby, we could show that IIM patients have a higher level of carotid atherosclerosis, as well as increased vascular resistance and pulsatility, compared to healthy subjects. Thus, a higher CVB and CV risk can be postulated. To our knowledge, this is one of the largest surrogate marker studies in the field of IIM and the first one to show that positivity of myositis associated antibodies (MSA) can be an independent predictor of a higher carotid resistance index. Therefore, MSA-status should be taken into account during CV/CVB risk-stratification of IIM.

Background: IIM-ILD follows a varied clinical course. Serological profile can help predict clinical phenotype, but impact on ILD prognosis is less clear.
Objectives: This multicentre UK cohort study examines whether serological profile can predict mortality and change in lung function over time.
Methods: Patients with IIM-ILD were identified in 3 NHS trusts from local databases. Adults with ILD meeting IIM diagnostic criteria or Interstitial Pneumonia with Autoimmune Features (IPAF) with Myositis Specific Antibodies (MSA) were included. Baseline characteristics from time of presentation were compared across antibody groups and across survivors/deceased at 2 years. Survival analysis looking at time to death (or lung transplant) for duration of available follow-up was modelled by Cox-Proportional Hazards comparing each antibody individually to all others. Models were adjusted for age, gender, ethnicity, presence of overlap CTD/malignancy, smoking and site. Regression models were also used to observe trends in lung function parameters over time.
Results: Of 430 included patients, 68% were female, 46% were of White ethnicity. 81% met IIM criteria, 19% were IPAF. Mean follow up duration was 4.3 years. Common antibodies were to Ro52, Jo1, PL12, MDA5 (n=195, 126, 44 & 32 respectively). 10% had evidence of pulmonary hypertension within 1 year of diagnosis, 4% had malignancy within 3 years. Baseline characteristics of survivors vs fatal cases at 2 years showed survivors were younger (51.4 vs 61.7 years), more likely to have never smoked (69% vs 44%), less likely to have been hospitalised at diagnosis (15% vs 52%) and had a lower Charleson Comorbidity Index. Survivors had lower CRP, higher CK & higher baseline FEV1/FVC/TLCO. Imbalance in age, BMI, CK and comorbidity status were seen across antibody groups. MDA5 had the highest adjusted hazard ratio (HR) for mortality of 4.59 (95%CI 2.10-10.01). Kaplan-Meier curve shows high early mortality in this group. Anti-synthetase antibodies (ARS) carried a reduced risk of mortality (HR 0.63), however individually Jo1 had low HR (0.61, 95%CI 0.4-0.87)

** counts of < 5 suppressed for anonymity*

and PL7 had high HR (2.07, 95%CI 1.44-2.99). RNP showed worse prognosis on adjusted analysis (HR 1.88, 95%CI 1.25-2.84) (Table 1). Regression models suggest that compared to other antibodies, %pred FVC in MDA5 improves over the first 3 years, in PL7 it drops, and in Jo1 it is no different (Figure 1). MDA5 % pred FEV1 also showed improvement, but in Ku it was lower than other antibodies from 21 months. There were no significant differences in % pred TLCO between antibodies.

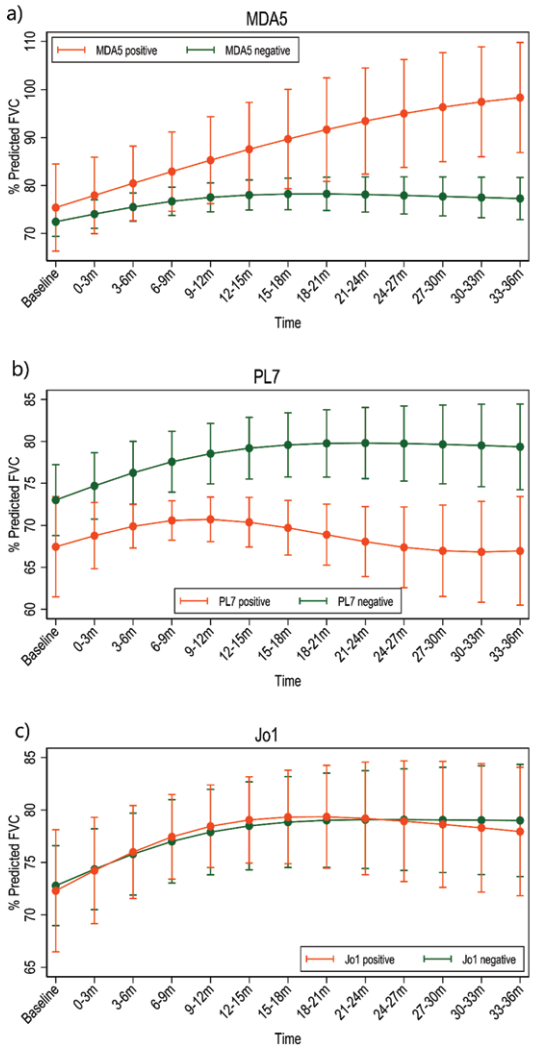

Figure 1.

Conclusion: There is strong evidence that antibody status associates with clinical outcomes, both in terms of progression of lung disease and mortality, suggesting pathogenetic differences. MDA5 predicts a high risk of death early on in disease course, whilst Jo1 associates with lower mortality. PL7 and RNP were additional antibodies associating with higher mortality. Difference between Jo1 and PL7 highlights variation within anti-synthetase syndrome. Paradoxically, if an MDA5 positive person survived the early disease phase, there was evidence that lung function can recover, which may reflect different MDA5 subpopulations.

TREATMENT TRAJECTORIES IN IDIOPATHIC INFLAMMATORY MYOPATHIES

Keywords: Myositis, Registries

K. Wipfler[1], U. Sbarigia[2], F. Zazzetti[3], A. Sheahan[4], I. Lin[5], E. Alemao[6], K. Michaud[1,7]. *[1]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, United States of America; [2]Janssen, Pharmaceutica NV, Beerse, Belgium; [3]Janssen, Pharmaceutical Companies of Johnson & Johnson, Horsham, PA, United States of America; [4]Janssen, Global Research and Development Epidemiology, Titusville, NJ, United States of America; [5]Janssen, Scientific Affairs, Horsham, PA, United States of America; [6]Janssen, Global Services, Horsham, PA, United States of America; [7]University of Nebraska Medical Center, Division of Rheumatology, Omaha, United States of America*

Background: Idiopathic inflammatory myopathies (IIM) are a group of rare, heterogeneous diseases in which the hallmark feature is chronic inflammation of skeletal muscle leading to muscle weakness. Initial conventional therapy is based on expert opinion and includes glucocorticoids in combination with methotrexate, azathioprine, or mycophenolate. If this therapy is not sufficiently effective, second line therapy (calcineurin inhibitors or IVIG) may be considered. If still insufficient, escalation to rituximab or cyclophosphamide is considered. Agents not included in conventional recommended therapies have also been used and are being studied in the management of IIM.

Objectives: To characterize real-world treatment trajectories among individuals with IIM.

Methods: Data were provided by adults with IIM enrolled in FORWARD, The National Databank for Rheumatic Diseases. Participants with a co-occurring RA, SLE, or SSc diagnosis were excluded. Participant characteristics were assessed at baseline (study entry) by treatment category and significance was assessed by one way ANOVA and Fisher's exact tests, as appropriate ($p<0.05$). Treatment category (none, steroid alone, first line without steroid, first line, second line, third line, and other DMARD) was assessed at baseline and for ultimate line of treatment reported during observation. First, second, and third line treatments were considered "conventional" and others were considered "nonconventional."

Results: A total of 126 participants met inclusion criteria. At baseline, 43% of participants were on first line therapy. Most of the remaining participants were either on a corticosteroid alone (23%) or were on first line therapy but without a corticosteroid (17%). A relatively small number of participants (2%) were on second line therapy, and none were on third line therapy at baseline. About 9% reported use of a nonconventional DMARD, and the remaining 6% reported no treatment. Those who reported no therapy were more likely to be male and had higher global severity scores. Across 504 person-years of observation, 47% reported first line treatment, 10% reported second line, and 3% reported third line as the most advanced conventional therapy received. The remaining 40% reported either nonconventional or no treatment.

Conclusion: Despite published recommendations to combine glucocorticoids with another immunosuppressive drug as part of first line therapy for IIM, many individuals with IIM are not prescribed concomitant DMARDs. In this cohort, there were no significant differences in IIM subtype, disease duration, or calendar year by conventional vs nonconventional therapy at study entry. A relatively small number of individuals with IIM reported receiving no treatment during observation, which may be due to significantly shorter follow up time in that subgroup. Future work should examine treatment response and changes in disease activity with changing lines of treatment.

Table 1. Characteristics of included participants at study entry by baseline treatment category.

	Conventional Therapy	Nonconventional Therapy	No Therapy

POS1237 MICROVASCULAR DAMAGE IN AUTOIMMUNE CONNECTIVE TISSUE DISEASES: A CAPILLAROSCOPIC ANALYSIS FROM 20 YEARS OF EXPERIENCE IN A EULAR TRAINING AND RESEARCH REFERRAL CENTER FOR IMAGING

Keywords: Diagnostic Tests, Myositis, Systemic sclerosis

E. Hysa[1], S. Sammorì[1], C. Pizzorni[1], E. Gotelli[1], A. Cere[1], C. Schenone[1], G. Ferrari[1], R. Campitiello[1], V. Gerli[1], S. Paolino[1], A. Sulli[1], V. Smith[2], M. Cutolo[1]. *[1]Laboratory of Experimental Rheumatology and Academic Division of Clinical Rheumatology, Department of Internal Medicine and Specialties, University of Genova, IRCCS San Martino Polyclinic Hospital, Genova, Italy, Genova, Italy; [2]Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Centre (IRC), Department of Internal Medicine, Ghent University, Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, Ghent, Belgium*

Background: Nailfold videocapillaroscopy (NVC) safely allows the detection of microvascular damage which can vary in terms of extent and severity (validated NVC patterns) in patients with Raynaud's phenomenon (RP) secondary to autoimmune connective tissue diseases (CTDs).
Objectives: The prevalence of the morphological capillary findings was retrospectively evaluated in a wide cohort of patients with RP secondary to a CTD at the time of the first single NVC analysis, independently from their current treatment, autoantibody profile and comorbidities.
Methods: One-thousand-one-hundred-eighty-one (1181) patients affected by CTDs (1065 females, mean age 54.1 ± 16.2, mean disease duration 4.5 years ± 3) were analysed from 2001 to 2021. The considered CTDs, diagnosed through the classification criteria available at the time of the enrollment, included: systemic sclerosis (SSc, 51%), undifferentiated connective tissue disease (UCTD, 26%), mixed connective tissue disease (MCTD, 6%), dermatomyositis (DM, 3%), systemic lupus erythematosus (SLE, 9 %), Sjögren's syndrome (SS, 3%) and primary anti-phospholipid syndrome (aPS, 2%). The capillaroscopic parameters were classified according to the CAP Fast Track Algorithm and distinguished between scleroderma-pattern (specific NVC alterations) and non-scleroderma patterns (non-specific NVC alterations) [1]. The presence of specific NVC findings detectable with a progressive microangiopathy in SSc patients ("early", "active", "late" patterns) have been searched also in other CTDs, beyond SSc. The "scleroderma-like pattern" was defined when a concomitant mix of the specific abnormalities of the SSc-patterns (namely: giant capillaries, loss of capillaries, capillary dilations, microhaemorrhages, abnormal shapes) was detected without fitting the single definition of "Early", "Active" or "Late" pattern [2].
Results: Among CTDs, the mean capillary density (1 linear mm) was significantly lower in SSc, DM and MCTD (respectively, 7.04 ± 0.18 vs 6.5 ± 0.75 vs 7.7 ± 0.48) compared with other CTDs. "Early", "Active" and "Late" NVC scleroderma patterns were detected in 34%, 38% and 16% of SSc patients, whereas the scleroderma-like pattern was found significantly more frequent in DM (63 %) and MCTD (37%). Giant capillaries, capillary dilations and microhaemorrages were significantly more frequent in SSc and DM compared with other CTDs (respectively in 73%, 99% and 70% of SSc patients e in 73%, 96% e 70% of DM patients, Figure 1). The non-specific abnormalities of capillary morphology, such as the ramifications (abnormal shapes as expression of neoangiogenesis) were significantly more frequent in SSc, MCTD and APS among all the CTDs (respectively, in 48%, 41% and 36% of cases). Moreover, giant capillaries and abnormal shapes were detected in 61% and 41% of MCTD patients. In APS, the most significant prevalence of microhaemorrages (50%) was observed compared with other CTDs, to the exclusion of SSc and DM being detectable in 70% of cases. No significant damages were observed in SS and SLE patients (Figure 1).
Conclusion: This large sample size of CTDs patients, collected over 20 years of analysis, confirms the highest specificity and severity of the NVC microvascular damage respectively in SSc and DM patients, when compared to other CTDs. Those data will be used to implement easy algorithms to distinguish scleroderma patterns, from non-scleroderma and scleroderma-like patterns.

Universitätsklinik für Hämatologie und Onkologie, Magdeburg, Germany*

Background: We previously reported that deep B cell depletion using a single infusion with autologous CD19 chimeric antigen receptor (CAR) T cells induced drug-free clinical remission in patients with severe systemic lupus erythematosus [1,2]. Whether other forms of severe autoimmune disease are sensitive to treatment with CD19 CAR-T cells has been unknown to date. Antisynthetase syndrome (ASS) is a autoimmune disease that affects muscles, joints, skin and lung. ASS can be very severe and life-threatening needing effective and fast treatment. This abstract presents the first evidence that severe ASS is highly sensitive to treatment autologous CD19 CAR-T cells.
Objectives: To test whether administration of CD19 CAR-T cells is tolerable and effective in patients with severe refractory Antisynthetase syndrome.
Methods: Autologous CD19 CAR-T cells were prepared from leukapheresis specimen after enrichment of T cells and transfection with MB-CART19.1

lentiviral vector (Miltenyi) encoding for a 4-1BB based CAR targeting CD19. Cells were expanded for 12 days and 1 million CAR-T cells/kg body weight were administered as a single intravenous infusion after standard conditioning therapy with cyclophosphamide/fludarabine, as described previously [1,2]. All disease related treatments were stopped before CAR-T cell administration. Patients were followed up in inpatient care for the first 10 days after CAR-T cell administration, thereafter weekly until the end of the first month, then monthly for three months and every three months later. Tolerability was assessed by monitoring for Cytokine-Release Syndrome (CRS) and Immune-related effector Cell Neurotoxicity Syndrome (ICANS). Efficacy was assessed by CK levels, good response according 2016 ACR/EULAR total improvement score (TIS), imaging of muscles and lungs and successful cessation of all immunosuppressive treatments including glucocorticoids.

Results: Two anti-Jo1 ASS patients (patient 1: 41year old male, patients 2: 43year old female) were treated with CD19 CAR-T cells. Both patients presented with active myositis with CK levels of 9305 U/l (normal value <190U/l), and 3055U/l, respectively. Patient 1 showed involvement of the muscles, skin and lungs, patient 2 showed involvement of muscles, skin, joints and lungs. Patient 1 did not respond to 5 different immunosuppressive treatments including cyclophosphamide and rituximab, patient 2 did not respond to 10 treatments including cyclophosphamide, rituximab and ocrelizumab. CAR-T cell treatment was well-tolerated. Only mild CRS (grade I) was observed in both patients. Patient 2 had signs of mild self-limited ICANS (grade I discrete ataxia for a few days) two weeks after CAR-T treatment. In patient 1, CAR-T cells expanded to a maximum of 60cells/µl on day 8, in patient 2 to 1524cells/µl on day 8. Expansion of CAR-T cells paralleled with the complete depletion of circulating B cells. B cell aplasia lasted for 119 days in patient 1, while patient 2 is still in B cell aplasia (day 60). Both patients experienced normalization or significant reduction in CK levels (patient 1: CK+120 days: 70 U/l, patient 2: CK+60 days: 311 U/l), major clinical improvement according to the 2016 TIS and could stop all immunosuppressive therapy. Follow-up CT scans of the lung and MRI of the thigh muscles done in patient 1 showed resolution of alveolar inflammation as well as abrogation of inflammatory changes in the thigh muscles and the hamstrings. At the latest follow up (120days and 60days) both patients were in drug-free remission. Also, the highly positive anti-Jo1 antibodies (331 U/l) disappeared after CAR-T cell treatment (5 U/l; cut-off 25U/l, Orgentec ELISA, Mainz, Germany) in patient 1, while patient 2 awaits follow up measurement.

Conclusion: Taken together, these data suggest that CD19 CAR T-cell therapy provides a possibility to intercept with severe ASS leading to drug-free remission, resolution of muscle and lung inflammation and abrogation of disease-associated autoimmunity.

POS1239

TYPE I INTERFERON SCORE IS ASSOCIATED WITH THE SEVERITY AND POOR PROGNOSIS IN ANTI-MDA5 ANTIBODY-POSITIVE DERMATOMYOSITIS PATIENTS

Keywords: Prognostic factors, Myositis

J. Qian[1], L. Zhi[1], Z. Cao[2], L. Lu[1], Q. Fu[1]. [1]*Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Department of Rheumatology, Shanghai, China;* [2]*Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Institute of Molecular Medicine, Shanghai, China*

Background: Anti-MDA5 antibody-positive dermatomyositis (anti-MDA5+DM) is a rare autoimmune disease associated with a high mortality rate due to rapid-progressive interstitial lung disease (RP-ILD), particularly in East Asia[1]. MDA5, acts as a cytoplasmic sensor of viral RNA, thus activating antiviral responses including the type I interferon (IFN) signaling pathway[2]. The involvement of type 1 IFN in the pathogenesis of MDA5+DM has been proposed based on the significantly elevated expression of its downstream stimulated genes(ISG) in muscle, skin, lung, and peripheral blood[3; 4]. Janus kinase inhibitor, which targets the IFN pathway, combined with glucocorticoid could improve the survival of early-stage MDA5+DM-ILD patients[5]. In clinical practice, there is still an urgent demand for sensitive biomarkers to facilitate clinical risk assessment and precise treatment.

Objectives: This study aimed to investigate the clinical significance of interferon score, especially IFN-I score, in patients with anti-MDA5+DM.

Methods: Different subtypes of idiopathic inflammatory myopathy, including anti-MDA5+DM(n=61), anti-MDA5-DM(n=20), antisynthetase syndrome(ASS,n=22),polymyositis(PM,n=6) and immune-mediated necrotizing myopathy(IMNM,n=9), and 58 healthy controls were enrolled.. A multiplex quantitative real-time PCR(RT-qPCR) assay using four TaqMan probes was utilized to evaluate two type I ISGs (IFI44, MX1, which are used for IFN-I score), one type II ISG (IRF1), and one housekeeping gene (HRPT1). Clinical features and disease activity index were compared between high and low IFN-I score groups in 61 anti-MDA5+DM patients. The association between laboratory findings and the predictive value of baseline IFN-I score level for mortality was analyzed.

Results: The IFN scores were significantly higher in patients with anti-MDA5+DM than in HC (Figure 1A). The IFN-I score correlated positively with serum IFN α(r = 0.335, P =0.008), ferritin (r = 0.302, P = 0.018), and Myositis Disease Activity Assessment Visual Analogue Scale (MYOACT) score(r=0.426, P=0.001). Compared with patients with low IFN-I scores, patients with high IFN-I scores showed increased MYOACT score, CRP, AST, ferritin, and the percentages of plasma cells (PC%) but decreased lymphocyte count, natural killer cell count, and monocyte count. The 3-month survival rate was significantly lower in patients with IFN-I score > 4.9 than in those with IFN-I score ≤ 4.9(72.9% vs. 100%, P=0.044)(Figure 1B).

Conclusion: IFN score, especially IFN-I score, detected by multiplex RT-qPCR, can be a valuable biomarker for monitoring disease activity and predicting mortality in anti-MDA5+DM patients.

Background: Interstitial Lung Disease (ILD) is the most common cause of mortality in myositis and there is lack of randomized clinical trials for myositis-associated ILD (MA-ILD). A T-cell mediated pathogenesis has been postulated for MA-ILD, and abatacept (ABA) is a T cell co-stimulatory modulator.

Objectives: Our primary objective was to evaluate the efficacy, safety and tolerability of ABA (125 mg SQ weekly) combined with standard of care (SOC) vs. placebo/SOC in MA-ILD patients in a multi-center, double-blind, randomized placebo-controlled proof of concept clinical trial.

Methods: 20 patients (pts) with anti-synthetase antibody (Anti-Syn Ab) were enrolled across 5 centers for 24 weeks in a randomized placebo-controlled phase (RCT) followed by an open label extension (OLE) for 24 weeks. Active myositis was not required but pts must have had active ILD (new onset or worsening requiring treatment) and previously failed ≥1 SOC drug for ILD. Pts were required to be on stable SOC [glucocorticoids (GC)/1 immunosuppressive (IS) agent (azathioprine or mycophenolate) prior to the trial as well as stable SOC IS throughout the trial]. A recommended GC taper was instituted. The primary endpoint was the change in Force Vital Capacity (FVC) (in ml) change from baseline to week 24. Secondary endpoints included FVC changes over 48 weeks, patient reported outcomes (PRO) of dyspnea (UCSD-shortness of breath questionnaire; range 0-120, MCID of 8) and DLCO corrected % predicted (DLCO) at 24 and 48 weeks. Mixed effect modeling was used for analysis and the study was not powered for primary or secondary outcomes.

Results: A total of 20 anti-Syn Ab positive pts (mean age of 57, 45% female and 85% Caucasian, Jo-1, 55%) were randomized to ABA (n=9) and placebo (n=11). All but 1 pts completed 48 weeks of the trial. There was no significant or clinically relevant difference in median FVC (ml) from baseline to week 24 between ABA (-40 ml) and placebo (30 ml), p = 0.97. However, the median FVC (ml) change from baseline to week 48 was 140 ml and -40 ml, in ABA vs. placebo (p=0.15), with a 180 ml difference in favor of the ABA group. FVC% predicted remained stable (±5%) or improved (>5%) without death or drug rescue in 75% (6/8) and 45% (5/11) at week 24 and week 48, in ABA vs. placebo, respectively. The median DLCO change from baseline was -4.5 and -10.5 at week 24; 6.5 and -2.7 at week 48, in ABA vs. placebo group, respectively. DLCO remained stable (±5%) or improved (>5%) without death or rescue in 57% (4/7) and 45% (5/11) at week 24; 62.5% (5/8) and 40% (4/10) at week 48, in ABA vs. placebo, respectively. Dyspnea improved by median of 1 and 3 at week 24; 13 and 5 at week 48 in ABA vs. placebo, respectively. Dyspnea improved by an MCID of 8 without requiring drug rescue or death in 22% (2/9) and 45.5% (5/11) at week 24; 50% (4/8) and 18% (2/11) pts at week 48 in ABA vs. placebo, respectively. There were 3 severe adverse events (1 in RCT, 2 in OLE) in 2 pts requiring hospitalization in the ABA group for progressive respiratory failure and 1 died (at 24 weeks). There were 36 and 23 adverse events among 9 placebo and 9 treatment group pts. ABA was well tolerated.

Conclusion: MA-ILD ABA-treated subjects showed similar FVC, DLCO and dyspnea PRO trends compared to placebo at 24 weeks but clinically and numerically meaningful trends were observed in ABA-treated subjects at week 48. These results suggest the need for a larger randomized study of ABA in MA-ILD. Abatacept was relatively safe and well tolerated in the cohort.

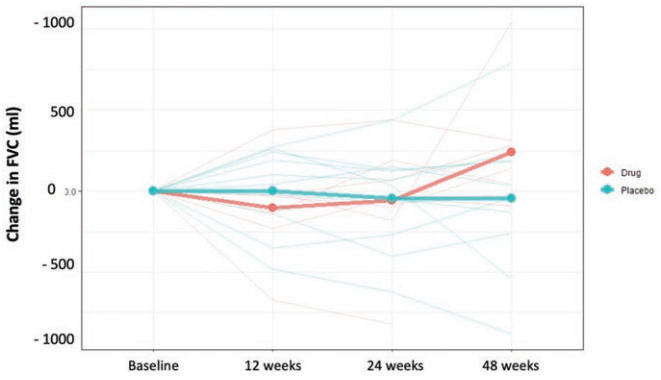

Figure 1 : Change from baseline in Forced Vital Capacity (FVC) in ml by treatment groups.

Table 1. Baseline demographics and clinical variables by treatment groups:

Clinical variable	Placebo (N=11)	Abatacept (N=9)
Age	57.7 [47.8-64.5]	49.7 [46.6-59.3]
Female	4 (36)	5 (56)
Non-Hispanic	11 (100)	9 (100)
Caucasian	10 (91)	7 (78)
Anti-synthetase antibody		
Jo-1	7	4
Non-Jo1	4	5
ILD status		
New onset	3 (27)	2 (22)
Chronic	8 (73)	7 (78)
Myositis status		
Inactive	5 (45)	2 (22)
Active	4 (37)	5 (56)
Not present	2 (18)	2 (22)
FVC%	61 [53-78]	66 [49-69]
DLCO%	49 [41-64]	47 [38-52]
Prednisone	11 (100)	8 (88)
Mycophenolate	8 (73)	8 (88)
Azathioprine	0 (0)	1 (11)

Scleroderma, myositis and related syndromes

POS1241 IMAGING OF INFLAMMATION IN THE CONTEXT OF MYOPATHIES USING A NEAR-INFRARED FLUORESCENCE-BASED METHOD - A POSSIBILITY FOR THE DIAGNOSTIC SUPPORT OF POST-ACUTE SYMPTOMS AFTER VIRUS-RELATED DISEASES?

Keywords: Inflammatory arthritides, Imaging, Myositis

P. Welker[1], D. Franke[2], A. Briel[2], V. Failli[2]. [1]*Charité - University Medicine Berlin, Functional Anatomy, Berlin, Germany;* [2]*nanoPET GmbH, Imaging, Berlin, Germany*

Background: Myopathies with main symptoms of muscle pain and weakness can have a wide variety of triggers, be characterized by different courses and localizations, and occur as side effect of rheumatic diseases. They have also recently come into focus as sequelae after systemic viral infections, for example as post-acute Covid-19 syndrome. Inflammatory reactions (Polymyositis, PM) are often difficult to differentiate from non-inflammatory myalgias. Clinical examinations and analysis of serum parameters are helpful, but do not always lead to clear results due to overlapping syndromes. In addition to pathogen-related myositis (Lyme disease, LD), muscle inflammation can also occur in autoimmune-caused rheumatic diseases such as systemic sclerosis (SSc), rheumatoid arthritis (RA), or polymyalgia rheumatica (PMR). Furthermore, overexertion, degeneration, or psychosomatic influences (fibromyalgia, FM) can lead to the symptom of muscle pain.
Objectives: The present work investigates the potential of NIR-FOI feature assessment in diagnosing patients with muscle weakness and muscle pain to better explore therapy options.
Methods: NIR-FOI analyses of patients (n = 200) without clinical symptoms (Ref, n = 31), or the diagnosis of osteoarthritis (OA) (n = 35) were compared with PM patients (n = 9), and patients diagnosed with autoimmune RA (n = 35), SSc (n = 34), Sjögren Syndrome (SS, n = 20), or PMR (n = 5). In addition, patients with diagnoses of LD or primary FM (n = 31) were examined. Indocyanine green as fluorescence dye was injected and the FOI images of both hands were evaluated from 0-240s (Prima Vista Image, PVI), or in the late period P3 (150-240s). Signal intensities (SI) were created from the summation images. For characterization of the cohorts, serum parameters were determined.
Results: Since the detection of serum JO-1 antibodies can be considered as reliable evidence of myositis, patients with this verification were examined first. In addition to increase of SI in PVI ($p<0.0001$), 8/9 PM patients show stronger accumulation in P3 in the anatomical position of hand muscles, and in the tendon-muscle junction of the forearm compared to the Ref group (Figure1). In the cohort of patients with PMR, the PVI SI was also increased ($p<0.0001$). Stronger P3 accumulation was observed in 3/5 patients. However, besides accumulation in the joints as the main site of inflammation in this disease, signal increase was detected mostly in the muscle-tendon transition, which could be also attributed to degenerative changes due to the high age of this cohort. That is also true for the patients in the OA cohort, but with lower SI both in PVI and P3. In addition, increased PVI SI was detected in all other disease cohorts ($p<0.01$). However, increased accumulation in P3 can only be detected in some of the patients of these cohorts and predominantly in the muscle-tendon transition. Most frequently, patients with increased accumulation in P3 were identified in the groups of RA and SS. However, increased accumulation in P3 was also detected in 48% of patients diagnosed with fibromyalgia, but only in the muscle-tendon junction.
Conclusion: The study demonstrates that changes in the microcirculation in inflammatory processes in the context of myositis correlate with a late phase dye accumulation during a NIR-FOI examination. This could provide valuable information for differential diagnoses of inflammatory versus non-inflammatory myopathies to optimize therapy. NIR-FOI could also potentially be used for the screening of myositis in virus-related diseases (e.g., Covid-19).

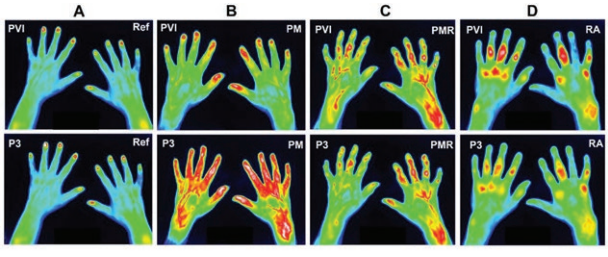

Figure 1: Examples of NIR-FOI images in patients: A. without clinical symptoms (Ref), B. JO-1 positive Polymyositis (PM), C. Polymyalgia rheumatica (PMR), or D. Rheumatoid arthritis (RA). Analysis of fluorescence dye distribution 0-240s (summations image, PVI), or in late phase 150-240s (P3). The figure demonstrates significant dye accumulations in inflammatory tissues with a focus in the areas of the muscles and tendons in PM, and in the joints in PMR and RA.

Background: Lung imaging findings vary among subtypes of connective tissue disease-associated interstitial lung disease (CTD-ILD), leading to both diagnostic and therapeutic challenges.
Objectives: We performed a comprehensive assessment of ILD morphology across CTD-ILD subtypes by examining the presence of overall imaging patterns and specific morphological features.
Methods: High-resolution chest computed tomography (HRCT) of patients with CTD-ILD enrolled in the multicentre Canadian Registry for Pulmonary Fibrosis from their first ILD clinic visit were re-reviewed in standardized multidisciplinary discussion. All CTD diagnoses were rheumatologist-confirmed. An experienced chest radiologist blinded to clinical data quantified the percentage of lung parenchyma affected by honeycombing, reticulation, ground glass opacity (GGO), hypoattenuating lobules, consolidation, and emphysema. Gas trapping was evaluated on expiratory CT. Each case was categorized into an overall disease pattern including usual interstitial pneumonia (UIP), non-specific interstitial pneumonia (NSIP), fibrotic hypersensitivity pneumonitis (fHP), lymphocytic interstitial pneumonia (LIP), and unclassifiable.
Results: 615 patients with CTD-ILD were assessed with 215 (33%) having systemic sclerosis (SSc), 127 (20%) rheumatoid arthritis (RA), 100 (16%) idiopathic inflammatory myopathy (IIM), 61 (9%) mixed connective tissue disease (MCTD), 40 (6%) Sjogren's syndrome (SS), 19 (3%) lupus (SLE), and 83 (13%) undifferentiated connective tissue disease (UCTD). NISP was most predominant in SSc (76%), IIM (62%), and MCTD (66%), while UIP was most common in RA (47%) and SS (33%). A fHP pattern was most common in RA (15%), SLE (21%), and MCTD (12%) (Figure 1a). There was substantial variability in the extent of fibrotic (honeycombing, reticulations) and non-fibrotic (pure GGO, consolidation) parenchymal features within and across each CTD (Figure 1b).
Conclusion: There is considerable variation in imaging features across subtypes of CTD-ILD, with NSIP generally most common, UIP most frequent in RA and SS, and fHP less frequent but most common in RA, SLE, and MCTD. This variability highlights the need for additional data on management of CTD-ILD that considers the potential for variable treatment responses across major CTD-ILD subtypes and phenotypes.

THE ROLE OF TAPSE/SPAP RATIO IN PREDICTING PULMONARY HYPERTENSION AND MORTALITY IN THE SYSTEMIC SCLEROSIS EUSTAR COHORT

Keywords: Heart, Lungs, Systemic sclerosis

Background: Early pulmonary arterial hypertension (PAH) diagnosis and treatment are crucial to improve systemic sclerosis (SSc) patients' outcomes. In PAH the progressive pulmonary vascular remodelling leads to an increasing load on the contracting RV and an altered right ventricular - pulmonary arterial (RV-PA) coupling. The RV-PA coupling describes the RV adaptation to its afterload [1]. Tricuspid annular plane systolic excursion/systolic pulmonary artery pressure (TAPSE/sPAP) ratio is the validated non-invasive estimation of RV-PA coupling [2]. In the new 2022 pulmonary hypertension (PH) guidelines, TAPSE/sPAP ratio has been included among the additional echocardiographic signs suggestive of PH and the echocardiographic parameters for 1-year mortality risk assessment [3]. However, to date, the role of TAPSE/sPAP ratio in SSc is underinvestigated [4-6].

Objectives: The primary aim of the study was to assess the predictive role of TAPSE/sPAP ratio for PH diagnosis in the SSc European Scleroderma Trials and Research (EUSTAR) cohort. The secondary aim of the study was to evaluate the prognostic role of TAPSE/sPAP ratio in predicting mortality in the SSc EUSTAR cohort.

Methods: Eligible patients were systemic sclerosis (SSc) patients registered in the EUSTAR database with at least one visit recording TAPSE and sPAP data. Individual centres were required to provide TAPSE and sPAP data at 12 ± 3 months before right heart catheterization (RHC). Logistic regression analysis was applied to analyse the predictive ability of TAPSE/sPAP ratio for PH diagnosis. Cox regression analysis was performed to evaluate TAPSE/sPAP ratio as a predictive factor for all-cause mortality.

Results: 2555 SSc patients met the inclusion criteria for this study with 355 SSc patients having available RHC data at baseline. PH was confirmed by RHC in 195 SSc patients (54.9%). TAPSE/sPAP ratio <0.55 mm/mmHg [OR 0.251 (95% CI 0.084-0.753), p<0.05] and FVC/DLCO [OR 2.568 (95% CI 1.227-5.375), p<0.05] were significantly associated with PH diagnosis. In logistic regression analysis with echocardiographic parameters at 12±3 months before RHC, TAPSE/sPAP ratio <0.55 mm/mmHg [OR 0.265 (95% CI 0.102-0.685), p<0.01] and FVC/DLCO [OR 2.529 (95% CI 1.358-4.711), p<0.01] were significantly associated with PH diagnosis. In multivariate Cox regression analysis, TAPSE/sPAP ratio ≤0.32 mm/mmHg [HR 0.310 (0.164–0.585), p<0.001] was the most significant predictive factor for all-cause mortality.

Conclusion: TAPSE/sPAP ratio <0.55 mm/mmHg is a predictive risk factor for PH. TAPSE/sPAP ratio ≤0.32 mm/mmHg is a predictive risk marker for all-cause mortality.

RESULTS OF A PHASE 2A STUDY OF CILNIDIPINE, A NOVEL DAILY ORAL CALCIUM CHANNEL BLOCKER WITH N-CHANNEL SELECTIVITY, FOR THE TREATMENT OF RAYNAUD'S AND OTHER SYMPTOMS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Clinical trials, Disease-modifying drugs (DMARDs)

A. Sternlicht[1,2], M. Shanahan[3], E. Morton[3], E. Briggs[3], I. Hunt[3], Z. Reed[3], A. Weragoda[3], L. Weerakoon[3], M. Todd[4]. *[1]Tufts Medical Center, Anesthesiology and Pain Medicine, Boston, United States of America; [2]Aisa Pharma, Inc, Clinical Development, Boston, United States of America; [3]Flinders Medical Center, Rheumatology, Adelaide, Australia; [4]Aisa Pharma Australia Pty Ltd, Clinical Operations, East Lindfield, NSW, Australia*

Background: Systemic Sclerosis(SSc) is a rare autoimmune disease with fibrosis, changes in the skin, vasculature, joints and internal organs. Diffuse disease involves lung, heart and kidney and 10-year mortality is >35%.[1] Raynaud's attacks occur in ~95% of SSc patients. Severe Raynaud's (RP) affects patients' health status more than depression, obesity, and heart disease.[2] No treatment for Raynaud's is approved, but calcium channel blockers (CCBs) are first-line treatment. Cilnidipine, a 4th generation CCB approved for hypertension in Asia, has been shown to be safer than other CCBs in treating hypertension, and has beneficial effects on the kidney and heart. Cilnidipine is more selective for N-type Ca channels, and improves analgesia, sympathetic, autonomic and endothelial function.[3] Cilnidipine might be repurposed for SSc-RP patients.
Objectives: We studied safety and preliminary efficacy of cilnidipine use in SSc-RP, dose response and co-administration of a low dose PDE-V inhibitor. Results are compared to a 2017 meta-analysis of CCB use in SSc-RP.
Methods: RECONNOITER-1 is a two-part, planned 76 patient trial. In Part 1, we evaluated safety, dose, efficacy and co-administration of tadalafil. Dose groups were cilnidipine 10mg and 20mg, alone and with tadalafil 5mg, tadalafil alone and placebo. The 1° endpoint was reduction in weekly frequency of RP. 2° endpoints included Raynaud's Condition Score (RCS), pain, severity, duration, and a validated PRO (SHAQ). The DSMB reviewed data on the first 27 patients in 8/2022.
Results: The ITT population was 27 patients, the mITT 24. Results are reported for the mITT population. Cilnidipine-only treated patients(n=7) had a reduction in weekly attacks of 42.2% versus 18.9% in placebo(n=4) Dose response was seen in weekly attack frequency and severity. Response was greater in the higher cilnidipine dose group on attack duration and RCS. Tadalafil increased treatment effect with 10 mg but not with 20 mg. Cilnidipine at either dose was well tolerated and only Grade 1 mild AEs were reported with cilnidipine (17.6%), with no treatment discontinuations due to AEs. The DSMB halted Part 1 early based on meeting study goals.
Conclusion: In this preliminary study, cilnidipine was well-tolerated and efficacy trends were seen. A published metanalysis of CCB use for RP finds AE's >46% and treatment discontinuation in >30% of patients.[4] Cilnidipine appears superior in safety to commonly used CCBs (P= 0.0247). Our results replicate the improved safety in hypertension treatment. PRO results (SHAQ) also favor the 20 mg dose of cilinidipine over placebo with significance over placebo, depsite the small numbers (p=0.0115). Increased N-type channel blockade may increase safety and efficacy with the drug. Part 2 will compare Cilnidipine 20mg daily to placebo in a crossover trial in 38 patients.

TREATMENT WITH METHYLPREDNISOLONE IN VERY EARLY SYSTEMIC SCLEROSIS: RESULTS OF THE HIT HARD AND EARLY RANDOMIZED CONTROLLED TRIAL

Keywords: Investor initiated trial, Systemic sclerosis, Randomized control trial

B. Kersten[1], J. Lemmers[1], A. Vanhaecke[2], F. Van den Hoogen[1], C. H. M. Van den Ende[1], V. Smith[2], M. Vonk[1]. *[1]Radboud University Medical Center, Rheumatology, Nijmegen, Netherlands; [2]Ghent University Hospital, Rheumatology, Gent, Belgium*

Background: Accumulating evidence indicates that inflammatory mechanisms drive vasculopathy and fibrosis in Systemic Sclerosis (SSc), mainly in very early disease [1]. Therefore, anti-inflammatory therapies, such as glucocorticoids, might be effective in this early pathophysiological phase. According to the VEDOSS criteria, patients can be classified as very early SSc when a combination of Raynaud's phenomenon, SSc associated autoantibodies, early SSc nailfold capillary pattern and puffy hands are present [2]. We hypothesize that by inhibition of the inflammatory process, treatment with glucocorticoids will induce remission in patients with very early SSc.
Objectives: We performed a double-blind, randomized, placebo controlled, multicenter trial in patients who meet the VEDOSS criteria, to analyze the efficacy of high dose methylprednisolone.
Methods: The trial was initiated between January 2017 and February 2021 at the Department of Rheumatology of the Radboud University Medical Centre in Nijmegen, The Netherlands and the Department of Rheumatology of the University Hospital Gent, Belgium. Patients were randomly assigned (2:1) to methylprednisolone 1000 mg intravenously for 3 consecutive days monthly for 3 months, or placebo. Patients were stratified by sex, age, and center. The primary endpoint was difference in nailfold capillary density, measured by nailfold microscopy at week 13. Changes in capillary density after 52 weeks, change in number of mega capillaries, signs and symptoms of disease progression, time to disease progression and general health utilities were secondary outcomes.
Results: Baseline characteristics were comparable between the 2 groups. Thirty patients were randomly assigned to receive methylprednisolone (n= 21) or placebo (n=9). No significant difference in change in nailfold capillary density was found at week 13, mean -0.5 (95% CI 1.1 – 0.2) (Table 1). Moreover, no differences between groups in secondary outcomes were observed, except for a difference in Visual Analogue Scale gastrointestinal complaints assessed by the Gastrointestinal Tract questionnaire in favor of the methylprednisolone group. Thirty-seven percent of patients, 4 in the placebo group and 7 in the methylprednisolone group, had disease progression during the 1 year follow up with no difference between groups (Figure 1). A relevant pulmonary function decline was seen in 23% of patients, 2 in the placebo group and 5 in the methylprednisolone group, respectively. No serious adverse events were reported.
Conclusion: We report data from the first ever investigator initiated randomized, multicenter, double blinded, placebo controlled trial on treatment with methylprednisolone in very early SSc. We were not able to demonstrate a beneficial effect of methylprednisolone. However, we observed that a substantial proportion of patients showed disease progression underlining the importance of early identification and tight monitoring of signs and symptoms of disease progression early in the course of the disease to consequently start potential treatment in this category of patients. This study shows that it is feasible to perform an intervention study with patients with very early disease.

EFFECTS OF NINTEDANIB IN PATIENTS WITH SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE (SSC-ILD) IN SUBGROUPS BY DISEASE ACTIVITY INDEX

Keywords: Systemic sclerosis, Lungs, Clinical trials

A. Herrick[1], J. Pope[2], P. Carreira[3], C. Miede[4], M. Alves[5], Y. Allanore[6]. *[1]The University of Manchester, Northern Care Alliance NHS Foundation Trust, Centre for Musculoskeletal Research, Manchester, United Kingdom; [2]University of Western Ontario, Schulich School of Medicine, Division of Rheumatology, London, Ontario, Canada; [3]Hospital Universitario 12 de Octubre, Servicio de Reumatologia, Madrid, Spain; [4]mainanalytics GmbH, Statistics, Sulzbach (Taunus), Germany; [5]Boehringer Ingelheim International GmbH, TA Inflammation Medicine, Ingelheim am Rhein, Germany; [6]Descartes University, APHP, Cochin Hospital, Department of Rheumatology A, Paris, France*

Background: The European Scleroderma Trials and Research group (EUSTAR) disease activity index was developed to assess disease activity in patients with systemic sclerosis (SSc).
Objectives: To assess disease activity using a modified version of the EUSTAR disease activity index, and compare outcomes in subgroups by disease activity, in patients with SSc-ILD in the SENSCIS trial of nintedanib versus placebo.
Methods: The SENSCIS trial enrolled patients with SSc with first non-Raynaud symptom in the prior ≤7 years and extent of fibrotic ILD on high-resolution computed tomography (HRCT) ≥10%. Patients were randomised to receive nintedanib or placebo. The EUSTAR disease activity index assesses SSc activity based on modified Rodnan skin score (mRSS), C-reactive protein (CRP) level, diffusing capacity of the lung for carbon monoxide (DLco), presence of digital ulcers, presence of tendon friction rubs, and worsening of skin fibrosis over the previous month (as assessed by the patient). A score ≥2.5 identifies patients with active/very active vs inactive/moderately active disease. For this analysis, a modified version of the index was developed that excluded worsening of skin fibrosis, as data prior to enrolment in the trial were not collected. The modified version had a maximum score of 8.5. We analysed the rate of decline in FVC (mL/year) and adverse events over 52 weeks in subgroups by score on the modified index (<2.5 or ≥2.5) at baseline. An exploratory interaction p-value was calculated to assess potential heterogeneity in the effect of nintedanib versus placebo between the subgroups.
Results: Among 523 patients, 55.1% and 44.9% had modified disease activity index scores of <2.5 and ≥2.5, respectively at baseline. Compared with patients with a score <2.5, those with a score ≥2.5 had a greater extent of fibrosis on HRCT (38.0% vs 34.8%) and lower mean FVC % predicted (69.1 vs 75.1); greater proportions had diffuse cutaneous SSc (70.2% vs 38.9%), were anti-topoisomerase I antibody positive (65.5% vs 56.3%) and were taking mycophenolate (54.0% vs 45.8%). In the placebo group, the rate of decline in FVC over 52 weeks was numerically greater in patients with a score ≥2.5 than <2.5 (Figure 1). The effect of nintedanib on reducing the rate of FVC decline was numerically greater in patients with a score ≥2.5 than <2.5, but the interaction p-value did not indicate heterogeneity in the effect of nintedanib between the subgroups (p=0.24). The adverse event profile of nintedanib was similar between the subgroups (Table 1).
Conclusion: Based on a modified version of the EUSTAR disease activity index, almost half of the patients in the SENSCIS trial had active/very active SSc. Nintedanib had a consistent effect on reducing the rate of FVC decline over 52 weeks in patients with low and high SSc disease activity at baseline.

Treatment-by-time-by-subgroup interaction p=0.24.

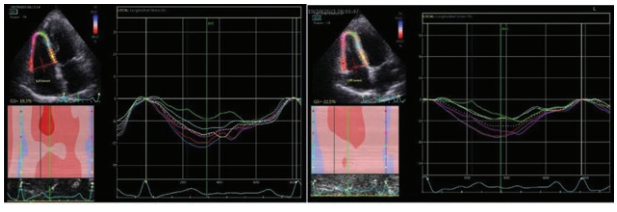
RIGHT VENTRICULAR MORPHOLOGY AND FUNCTION AFTER HIGH INTENSITY INTERVAL AND RESISTANCE TRAINING IN PEOPLE WITH SYSTEMIC SCLEROSIS: A RANDOMISED CONTROLLED PILOT STUDY

Keywords: Cardiovascular disease, Systemic sclerosis, Non-pharmacological interventions



A. Mitropoulos[1], T. Dimitroulas[2], M. Anifanti[3], E. Triantafyllidou[4], A. Teloudi[3], N. Sirakou[3], E. Pagkopoulou[2], C. Boström[5], L. P. Diederichsen[6], G. Cuomo[7], M. Klonizakis[1], E. Kouidi[3]. *[1]Sheffield Hallam University, Nursing and Midwifery, Sheffield, United Kingdom; [2]Aristotle University of Thessaloniki, Fourth Department of Internal Medicine, Thessaloniki, Greece; [3]Aristotle University of Thessaloniki, Department of Physical Education and Sports Science, Thessaloniki, Greece; [4]Hippokration University Hospital, Fourth Department of Internal Medicine, Thessaloniki, Greece; [5]Karolinska Institute, Department of Neurobiology, Stockholm, Sweden; [6]Copenhagen University, Copenhagen Research Centre for Autoimmune Connective Tissue Diseases, Copenhagen, Denmark; [7]University of Campania L. Vanvitelli, Department of Precision Medicine, Naples, Italy*

Background: The presence of left ventricular (LV) remodeling and dysfunction in systemic sclerosis (SSc) have been well studied to date [1]. Cardiac deformation and impaired right ventricular (RV) free wall contractility patterns in SSc have also been described [2]. High intensity interval training (HIIT) has demonstrated to improve microvascular function in people with SSc [3]. However, the cardiac morphology and function after exercise training in people with SSc have not been studied yet. Echocardiographic indices of RV function [4] were found to be correlated with cardiorespiratory fitness, as assessed by peak oxygen uptake (VO_2peak) in people with SSc.

Objectives: The primary objective of the present study was to assess possible exercise-induced changes in RV morphology and function. A secondary objective was to explore the relationship between VO_2 peak and RV echocardiographic indices after exercise training in people with SSc.

Methods: Twenty-eight people with SSc (24 females, mean age 57.21 ± 10.76 yrs.) were randomized into groups A (exercise) and B (control group). Baseline and three-month follow up assessments included: medical history, anthropometrics, echocardiography, and an arm crank cardiopulmonary exercise testing (CPET). Following the baseline assessments, Group A performed a 3-month supervised exercise program (twice/week) adjunctive to the usual care, while Group B received only the usual care. The supervised exercise training consisted of aerobic and resistance exercises as described previously [5]. The aerobic protocol consisted of HIIT (30s at 100% of peak power output achieved during CPET following by 30s passive recovery) on an arm ergometer.

Results: The average compliance in the exercise program was 90% with no dropouts and no adverse effects. Group A demonstrated a statistically significant increase in VO_2 peak by 25.1% ($p<0.001$), global RV free wall longitudinal systolic strain by 6.69% ($p<0.03$), RV free wall longitudinal systolic strain of the basal segment by 13.5% ($p<0.001$) and global RV four-chamber longitudinal systolic strain by 6.76% ($p<0.03$) after exercise training (Figure 1). No statistically significant difference was observed in group B.

(a) (b)

Figure 1. RV strain measurements in a SSc patient (a) at baseline (RV4CLS = −18.5%) and (b) after exercise training (RV4CLS = −22.5%).

Conclusion: Our results support the significance of 2DSTE in clinical practice for the early detection of cardiac deformation in SSc patients. In conclusion, a combined exercise training program seems to be effective in improving cardiorespiratory efficiency and RV systolic function in people with SSc with subclinical RV dysfunction.

Background: Autologous HSCT has been increasingly used for over 25 years to treat refractory autoimmune diseases (ADs). Multiple sclerosis (MS) and systemic sclerosis (SSc) cover around 80% of transplants performed for ADs[1], where HSCT has become an integral and standard-of-care part of treatment algorithms. In a first European Society for Blood and Marrow Transplantation (EBMT) analysis of HSCT performed between 2010 and 2015, there was chronological improvement in outcomes (i.e., progression-free survival, relapse/progression, and transplant-related mortality), strictly connected to the transplant center experience, patient selection and progress with supportive care.[2] Here, trends and outcomes have been updated to include HSCT performed for ADs between 2015 and 2020.

Objectives: To describe outcomes of autologous HSCT for ADs, 2 and 5 years from transplant.

Methods: This is a retrospective study on data routinely reported to EBMT's Autoimmune Diseases Working Party (ADWP) registry, based on 247 centers in 40 countries and others (Italy, Germany, Sweden, United Kingdom, Netherlands, Spain, France, and Australia account for ~75% of cases). We included adult patients (≥18 years) undergoing autologous HSCT for ADs between 2015-2020. Patients without information on follow-up after HSCT were excluded. The date of the transplant was the starting point for all time-to-event analysis, and individuals with no event were censored at the date of the last follow-up. Successful initial engraftment was defined as achieving a neutrophil white cell count ≥ 0.5×10^9/L for three consecutive days. We used Kaplan-Meier curves to evaluate overall survival (time until death) and progression-free survival (PFS) - defined as time to either relapse/progression or death. We also determined the cumulative incidence of AD relapse.

Results: We studied 1,389 individuals with ADs undergoing autologous HSCT from peripheral blood cell sources. The median follow-up was 26 months. Individuals were mostly female (58%), at a median age of 40 years (interquartile range

32.4-48.6). The main indications for HSCT included MS (68%) and SSc (21%). Successful initial engraftment occurred in the vast majority (98.5%), most times within 30 days from transplant. We observed 70 deaths (5% of 1,389), most (57, 81%) occurring within 2 years. Deaths were most often caused by AD relapse/progression (27%) or infection (24%). At 2 years post-transplant, overall survival was 95.5% (95% CI 94.2-96.5%), PFS was 82% (95% CI 79.6-84.2%), and relapse of AD occurred in 14.8% (95% CI 12.7-17.0%). Non-relapse mortality was 3.2% (2.3 - 4.3) at 2 years. Similar overall survival, PFS, and relapse rates were found for females versus males (biological sex at birth) at both 2 and 5 years post-HSCT (Table 1). Multivariate analysis was not done due to the heterogeneity of the population and the limited number of events.

Conclusion: Autologous HSCT for autoimmune disease results in high survival and moderately low relapse. Limitations include inadequate precision to stratify by autoimmune disease and transplant regimens.

POS1249 LUNG ULTRASOUND CHANGES COMPARED WITH AUTOMATED QUANTITATIVE COMPUTED TOMOGRAPHY FOR DETECTING SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Ultrasound, Systemic sclerosis, Lungs

D. M. Reza Beigi[1], G. Pellegrino[1], N. Landini[2], M. Mattone[2], G. Paone[3], S. Truglia[1], F. R. DI Ciommo[1], I. Bisconti[1], M. Cadar[1], K. Stefanantoni[1], V. Panebianco[2], F. Conti[1], V. Riccieri[1]. Background: B-lines and pleural line (PL) changes represent lung ultrasound (LUS) findings for detection of systemic sclerosis-associated interstitial lung disease (SSc-ILD). The ≥10 B-lines cut-off was found to be closely related to moderate ILD on high-resolution chest tomography (CT). Recently proposed Fairchild's criteria for PL evaluation resulted in high accuracy and reproducibility and a low spending time. Semi-quantitative PL irregularity score by Pinal-Fernandez proved to be superior to total B-lines number to detect SSc-ILD. Although several evidence-based LUS scores have been presented, there is currently a lack of studies involving a comprehensive LUS assessment and comparing different LUS scores with CT, particularly with automated quantitative CT (qCT) assessment.

Objectives: To evaluate the accuracy of quantitative and qualitative LUS B-lines and PL changes for SSc-ILD detection compared to CT with qCT assessment.

Methods: Consecutive SSc patients according to 2013 ACR/EULAR classification criteria underwent LUS by two certified blinded operators using a 14-scans method. The ≥10 B-lines cut-off and Fairchild's criteria fulfilment were selected as qualitative findings. From quantitative point of view, total B-lines number and the sum of the PL score adapted from Pinal-Fernandez were collected. CT scans performed over a ±6 months period were recorded and evaluated by two thoracic radiologists, with further processing by automated texture analysis software.

Results: The study population consisted of 29 SSc patients (Table 1). Agreement between the two operators was almost perfect for Fairchild's criteria [Cohen's kappa (k) 0.84] and substantial for ≥10 B-lines cut-off (k 0.78). Both qualitative LUS scores were predictive of ILD presence on CT, with Fairchild's criteria resulting in slightly more accuracy (Figure 1A). Results were confirmed on multivariate analysis, introducing confounders like age, disease duration, ongoing immunosuppressant therapy, and current/ever smoking (Fairchild's criteria: p 0.0003 and B-line cut-off: p 0.03). All qualitative and quantitative LUS findings were found to be significantly associated with ILD extension on qCT ($p<0.05$). Total B-lines number correlated with extension of reticulations and PL quantitative score correlated with extension of both ground-glass and reticulations (Figure 1B and C). Lung bases PL quantitative score, but not B-lines number of the same site, was found to correlate with basal ILD extension on qCT (Figure 1D).

Conclusion: This study highlights the reliability and good accuracy of a comprehensive and systematic LUS assessment for SSc-ILD detection, compared to automated qCT. LUS is increasingly emerging as an accurate, feasible, low-cost, and radiation-free pre-CT screening tool. For these reasons, standardisation of LUS appears to be required, in order to achieve its wider use in clinical practice.

Elhai[2], S. Jordan[2], E. Langballe[1], Ø. Midtvedt[1], C. Mihai[2], Ø. Molberg[1], O. Distler[2]. [1]*Oslo University Hospital, Rheumatology, Oslo, Norway;* [2]*University Hospital Zurich, University of Zurich, Rheumatology, Zurich, Switzerland;* [3]*Hospital of Southern Norway, Rheumatology, Kristiansand, Norway;* [4]*Oslo University Hospital, Oslo Centre for Biostatistics and Epidemiology, Oslo, Norway;* [5]*Oslo University Hospital, Respiratory Medicine, Oslo, Norway*

Background: Interstitial lung disease (ILD) is a major cause of morbidity and mortality in systemic sclerosis (SSc). In clinical practice, physicians often wait for progression to initiate or escalate therapy. Similarly, progressive SSc-ILD patients

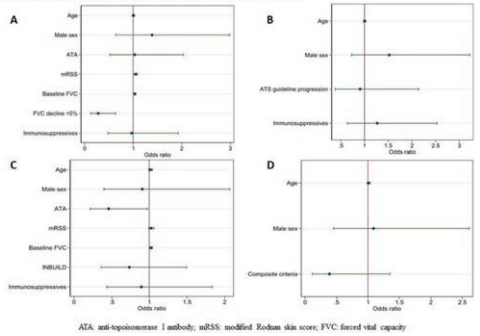
are recruited into trials to enrich for further progression. These strategies assume that patients with recent ILD progression have a higher risk for further progression. However, this has not been analyzed in SSc-ILD and there is currently no evidence to support such treatment and recruitment strategies.

Objectives: We assessed whether ILD progression predicts subsequent progression using four definitions of progressive disease in two well-characterized SSc-ILD cohorts.

Methods: We included all SSc patients from the Oslo and Zurich cohorts who had ILD on HRCT and at least three consecutive annual FVC measurements. For the primary analysis, ILD progression was defined as absolute FVC decline >5% over 12 months. Patients were grouped into progressors (FVC >5% decline) and non-progressors (all others). At the next annual follow up visit, all patients were again assessed for ILD progression. In secondary analyses, we applied other definitions of progression such as:

(I) 2022 ATS/ERS/JRS/ALAT guideline criteria with (1) worsening of respiratory symptoms; (2) absolute decline in FVC >5% or in DLCO >10% and (3) disease progression on HRCT over 12 months

(II) INBUILD criteria with (1) FVC decline ≥10%, (2) FVC decline >5-<10% and worsening of respiratory symptoms or an increased extent of fibrosis on HRCT, or (3) worsening of respiratory symptoms and an increased extent of fibrosis within any timeframe of 24 months.



(III) Composite criteria with absolute decline in FVC ≥10%; or FVC >5%-9% and DLCO >15%.

Multivariable logistic regression was applied, adjusting for known risk factors of ILD progression, including treatment.

Results: Here, 231 SSc-ILD patients from Oslo and Zurich were included, with mean age at onset of 48 years, 55 (24%) being males, 94 (41%) with diffuse cutaneous SSc and 83 (35%) with anti-topoisomerase I antibodies (ATA). Mean FVC was 89%, mean DLCO 64%, 59 (19%) had NYHA functional class ≥3, 35 (27%) extent of ILD >20% and 40% extent >10%. At 12 months, 71 (30.7%) showed FVC decline >5% and were classified as progressors. In multivariable logistic regression, adjusted for age, male sex, ATA, mRSS and immunosuppressive treatment, ILD progression was significantly protective for further progression at the next annual follow-up (Odds ratio 0.28, 95%CI 0.12-0.63, p=0.002, Figure1a). When other definitions of progression were applied, similar results were obtained: 44 (19%) fulfilled the guideline criteria, 89 (39%) the INBUILD criteria and 33 (14%) the composite criteria. Multivariable regression analysis adjusted for age, sex and treatment (guideline), for age and sex (composite) and for age, sex, ATA, mRSS, baseline FVC and treatment (INBUILD) showed the same direction as the primary analysis (Figure 1b-d).

Conclusion: ILD progression does not predict further progression using any ILD progression definition in SSc. These results suggest changing current treatment practices, since waiting for progression to initiate or escalate treatment does not seem to be the adequate strategy to identify patients at risk of further progression. It also has important implications for clinical trial design, since selection of progressive SSc-ILD patients does not seem to enrich for a progressive SSc-ILD study population.

Figure 1: Multivariable logistic regression for ILD progression using definitions of ILD progression (A) FVC decline >5%, (B) Guideline criteria; (C) INBUILD criteria and (D) composite criteria

ATA: anti-topoisomerase I antibody; mRSS: modified Rodnan skin score; FVC: forced vital capacity

POS1251 TREATMENT TAPERING IN SYSTEMIC SCLEROSIS: A 10-YEAR FOLLOW-UP STUDY

Keywords: Treat to target, Systemic sclerosis, Tapering

J. Ciaffi[1], S. Liem[2], N. Van Leeuwen[2], C. Allaart[2], T. Huizinga[2], J. De Vries-Bouwstra[2]. *[1]IRCCS Istituto Ortopedico Rizzoli, Medicine & Rheumatology Unit, Bologna, Italy; [2]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*

Background: In systemic sclerosis (SSc), tailoring treatment to each patient's needs is challenging and it is unclear whether and how patients need to be treated in the long-term. The feasibility of tapering and even withdrawing immunosuppressive therapies in patients with stable disease is still an open question.

Objectives: Using data from the Leiden SSc cohort, our aim was to describe how often treatment is modified during a follow-up period of 10 years, with a special interest in the possibility of tapering immunosuppressors (i.e. either tapering the dosage or switching to a less immunosuppressive regimen).

Methods: We analyzed the use and changes of immunosuppressive therapies in the whole cohort and in patients stratified for sex and autoantibody status. We included 708 SSc patients with at least one visit performed between 2009 and 2021, accounting for 2968 visits.

Results: At the time of referral to the care pathway, 31% of patients were receiving immunosuppressors and tapering was possible in 8% of them (Table 1). During the follow-up, tapering was possible in a higher proportion of patients treated with immunosuppressive medications, up to the 20% at the third-year and 26% at the sixth-year visits. No significant differences emerged in the proportions of drug tapering between males and females or between patients with anticentromere and anti-topoisomerase I antibodies. Overall, immunosuppressive medications were tapered 137 times during the 2968 visits. Of the 107 patients who tapered medications at least once during the follow-up, in 64% of cases it happened during the first three years. In 24 patients, tapering occurred at the last available visit, whereas in 83 patients the management of medications could be evaluated after tapering (246 follow-up visits). In 31 cases, therapies were not changed further. In the other 52 patients, treatment regimen was modified again and in 31 cases we had to either increase the dosage of the current therapy or to initiate a new immunosuppressive drug. Analysing the type of immunosuppressive medication used (Figure 1), we observed that treatment with methotrexate tended to decrease, while mycophenolate mofetil gained favour over the years, especially in women and in patients with anti-topoisomerase I antibodies.

Conclusion: In conclusion, tapering of immunosuppressors could be considered in 15% of cases (107 of 708) in our large prospective cohort, and this was succesful in approximately two-thirds of cases in which follow-up was available (52 out of 83). If on the one hand early therapeutic intervention might be beneficial and a window of opportunity exists in SSc, on the other hand tapering immunosuppressive treatments might become feasible in a proportion of patients with stable disease.

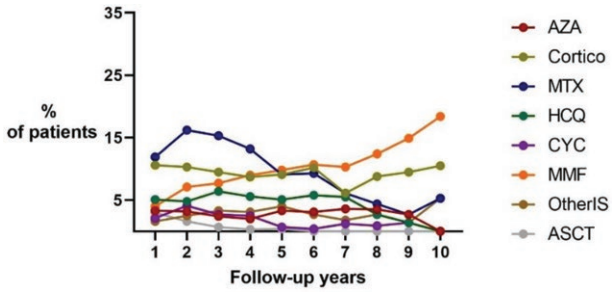

Figure 1. Medication use over time in 708 SSc patients from the Leiden SSc cohortASCT: autologous stem cell transplantation, AZA: azathioprine, Cortico: corticosteroids, MTX: methotrexate, HCQ: hydroxychloroquine, CYC: cyclophosphamide, MMF: mycophenolate mofetil, OtherIS: immunosuppressors including rituximab, tocilizumab, trial medications.

Table 1. Tapering of immunosuppressive (IS) therapies in patients from the Leiden SSc cohort

Visit year	All patients			Female patients	Male patients	ACA positive patients	ATA positive patients

POS1252

CALIPER PARAMETERS AS PREDICTORS OF MORTALITY IN SYSTEMIC SCLEROSIS: A LONGITUDINAL STUDY

Keywords: Lungs, Systemic sclerosis, Artificial intelligence

F. Godinho De Amorim[1], C. Verrastro[2], E. Santos[2], C. Kayser3. *[1]UNIFESP, Rheumatology Division, São Paulo, Brazil; [2]UNIFESP, Department of Radiology, São Paulo, Brazil; [1]UNIFESP, Rheumatology Division, São Paulo, Brazil*

Background: Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). High-Resolution Computed Tomography (HRCT) and pulmonary function tests (PFTs) are useful for the diagnosis and follow-up of ILD, but have limitations for assessing disease severity and progression, including poor reproducibility of the extent analysis by HRCT and low sensitivity of PFTs. Quantitative CT (QCT) methods, including Computed Aided Lung Informatics for Pathology Evaluation and Rating (CALIPER), are new tools that objectively measures parenchymal abnormalities and vascular features on CT images in a fully automated analysis.[1] This may bring benefits in detecting early disease and in the assessment of prognosis of patients with SSc-ILD.

Objectives: We investigated whether changes in parenchymal abnormalities measured by CALIPER are associated with mortality and their correlation with PFTs.

Methods: Seventy-one patients diagnosed with SSc (ACR/EULAR 2013 criteria) consecutively evaluated from January 2011 to October 2022 at the Scleroderma outpatients clinic at Federal University of São Paulo were retrospectively selected. To be included, patients should have volumetric HRCTs and PFTs performed at baseline and at 24 months of follow-up. All causes of death and clinical variables were collected from clinical records. HRCTs were analyzed using CALIPER. The following parameters were evaluated: ground glass opacities, reticular pattern, honeycombing, and pulmonary vascular volume (PVV), quantified and normalized to total lung volume (LV) and expressed as a percentage. The extent of ILD (ILD-extent), given by the sum of ground glass, reticular pattern and honeycombing and the fibrosis score given by the sum of the reticular pattern and honeycombing were also evaluated. The best thresholds for CALIPER measurements were calculated using ROC analysis. Factors associated with death were evaluated by Kaplan-Meier survival curves.

Results: Of the 71 SSc patients included the mean age was of 54.2 ± 11.6 years, (mean disease duration of 10 years) and 90.1% were females. Eleven patients (15.49%) died during follow-up and all had ILD. Most of the CAPILER variables remained stable over time (Table 1). All CALIPER parameters (except honeycombing), had a significant correlation with forced vital capacity (FVC) at baseline and follow-up (p<0.001). As shown by Kaplan-Meier survival curves, survival was worse among patients with ILD-extent% ≥ 6.32, fibrosis score% ≥ 1.42 and reticular pattern% ≥ 1.41 at baseline, and an ILD-extent% ≥ 4.75, a fibrosis score% ≥ 0.77, a reticular pattern% ≥ 4.34 and a PVV/LV% ≥ 2,8 at 24 months follow-up (Figure 1).

Table 1. PFTs and Caliper parameters at baseline and at 24 months of follow-up

	BASELINE (n= 71)	FOLLOW-UP (n=71)	Δ change from baseline to follow-up	p
FVC, % pred (Mean ± SD)	73.6 ± 19.1	69.6 ± 18.9	-3.93 ± 8.92	0.001
DLCO, % pred (Mean ± SD)	54.3 ± 13.7 (n=8)	51.8 ± 13.9 (n=9)	2.33 ± 8.96	0.696
CALIPER (Median [quartile range])				
Total normal volume (cm^3)	2986.5 [2236 – 3730]	2817.6 [2181 – 3503]	-81.6 [-295-112]	0.032
Reticular pattern, %	1.58 [0.671 – 2.85]	1.43 [0.666 – 3.19]	0.016 [-0.61 – 0.37]	0.720
Groundglass, %	6.06 [1.87 – 15.8]	5.96 [1.61 – 13.7]	0.239 [-2.22 – 2.75]	0.408
Honeycombing, %	0.015 [0.007-0.05]	0.017 [0.005-0.04]	0.000[-0.009– 0.01]	0.149
Fibrosis score, %	1.65 [0.68 – 3.25]	1.51 [0.67 – 3.19]	0.03 [-0.62 – 0.49]	0.920
ILD-extent, %	7.82 [3.27 – 19.1]	7.96 [2.58 – 19.7]	0.150 [-2.05 – 2.84]	0.565
PVV/LV, %	2.81 [2.09 – 4.20]	2.92 [2.00 – 4.45]	0.07 [-0.236– 0.52]	0.143

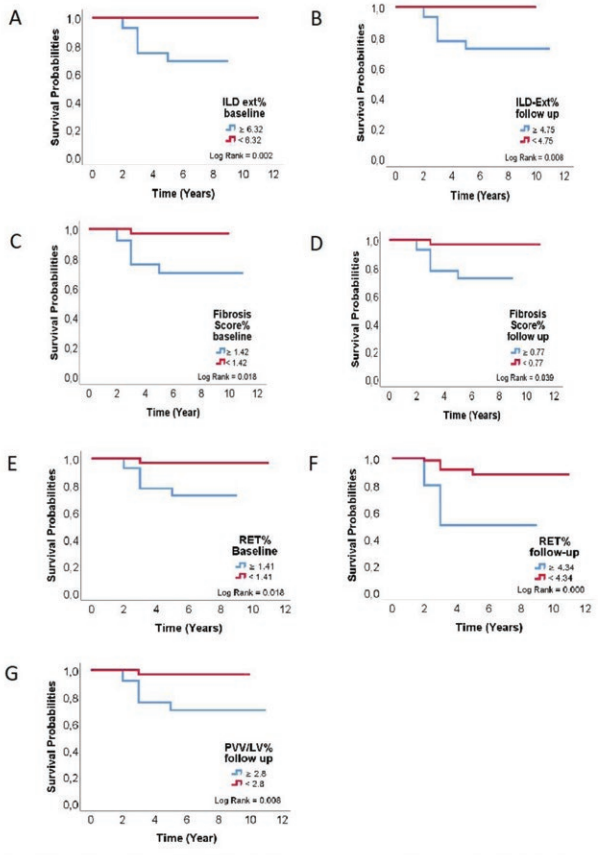

Figure 1. Kaplan-Meier survival curves according to CALIPER analysis at baseline (A, C, and E), and at follow-up (B, D, F, and G).

Conclusion: CAPILER is a useful tool for assessing lung damage and predict mortality in patients with SSc. Future studies are needed to confirm these data.

POS1253 TIMP-1 AS WELL AS IL-6 IN PULMONARY CAPILLARIES REFLECT THE COMPLICATIONS AND SEVERITY OF PH IN SYSTEMIC SCLERODERMA

Keywords: Cytokines and chemokines, Biomarkers

S. Nakashima[1], T. Kameda[1], H. Shimada[1], R. Wakiya[1], T. Miyagi[1], Y. Ushio[1], R. Mino[1], K. Chujo[1], H. Dobashi[1]. [1]*Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Kagawa, Japan*

Background: Abnormal production of various cytokines is involved in the pathogenesis of CTD, and the cytokine abnormalities vary according to the type of organ lesion. Recent reports indicate that various cytokine production abnormalities are also involved in the pathogenesis of iPAH.1) The differences between PH associated with CTD and other PH-associated cytokines, including iPAH, are not well defined. The relationship between the severity of each PH and cytokines is also not clear.

Objectives: The purpose of this study was to determine the relationship between the cytokine profile in pulmonary capillaries in CTD-PH and hemodynamic indicators of PH, and to confirm the differences in cytokine profiles between CTD-PH and other PH, including iPAH.

Methods: Patients who underwent RHC for PH diagnosis at our hospital from 2015 to 2021 years were included in the study. Serum was collected before and after pulmonary capillaries during right and left heart catheterization performed for hemodynamic analysis of PH, and cytokines were measured. TIMP-1, IL-21 MCP-1, IL-17, IL-12p70 and IL-6, which have been previously reported to be associated with the pathogenesis of CTD and PH, were included in the measurements in this study. TIMP-1, IL-21 were measured by ELISA (ABCAM UK). MCP-1, IL-17, IL-12p70 and IL-6 were measured by ELISA (Ella simple plex USA). The relationship between the measured cytokine profiles and hemodynamic parameters was compared. Statistical analyses were performed using the Spearman's rank correlation coefficient and the Wilcoxon signed-rank test in JMP software v16.1.0 (SAS, USA).

Results: Eighty-one studies were performed on 56 patients who underwent right and left heart catheterization. Forty-seven were female and nine were male, with a mean age of 64.2 years. 33 were CTD patients, including 19 SSc, 10 MCTD, 2 SLE, and 2 SS, and 23 non-CTD patients, of which 5 were iPAH. All 23 non-CTD patients were able to diagnose PH, while 11 CTD patients (8 SSc, 3 MCTD) were unable to diagnose PH. The CTD duration was 7.5 years in the PH group and 10.8 years in the nonPH group. Three of the CTDs in which PH could not be diagnosed were using pulmonary vasodilators for treatment of DU.Ten cases in the CTD-PH group were receiving immunosuppressive therapy. WHOFC found no difference in CTD-PH and non CTD-PH. Mean mPAP was 29 +/- 9.3 mmHg in CTD-PH and 32 +/- 10 mmHg in non-CTD-PH, with no significant difference. In an analysis of all patients who were able to diagnose pulmonary hypertension, IL-6 and IL-12 levels in pulmonary capillary were significantly associated with mPAP ($p < 0.05$). Furthermore, an association between IL-6 and WHOFC was found in all patients with CTD-PH, SSc-PH, and non-CTD-PH ($p<0.05$). In an analysis focused on SSc, TIMP-1 and IL-6 were markedly higher in SSc patients diagnosed with PH (TIMP-1; 134+/-42.8 vs 243+/-135, $p <0.05$, IL-6; 2.04+/-0.82 vs 21.2+/-80, $p <0.05$).In all groups examined this time, IL-17, IL-21, and MCP-1 were not significantly associated with severity of PH or with any of the hemodynamic parameter.

Conclusion: In the analysis of cytokines in pulmonary capillaries, IL-6 was found to be associated with hemodynamics in all PH patients, but TIMP-1 was found to be associated only with the PH pathogenesis of systemic scleroderma.

Background: The second COVID-19 vaccination in autoimmune disease (COVAD-2) study [1] is an international, multicentre, self-reported e-survey designed to evaluate several facets covering COVID-19 infection and vaccination as well as validated patient-reported outcome measures (PROMs) in a variety of autoimmune diseases (AIDs), including systemic sclerosis (SSc). Detailed assessment of the health-related quality of life (HRQOL) and its drivers in patients with SSc is lacking.

Objectives: To assess physical and mental health in a global cohort of SSc patients in comparison with non-SSc autoimmune inflammatory rheumatic diseases (AIRDs), non-rheumatic AIDs (NRAIDs), and those without AIDs (controls) using Patient-Reported Outcome Measurement Information System (PROMIS) global health data from the COVAD-2 survey.

Methods: The COVAD-2 database was used to extract demographics, AID diagnosis, comorbidities, disease activity, current therapies, and PROMs. PROMIS global physical health (GPH), global mental health (GMH) scores, PROMIS physical function short form-10a (PROMIS PF-10a), pain visual analogue scale (VAS), and PROMIS Fatigue-4a scores were compared between SSc, non-SSc AIRDs, NRAIDs, and controls. Outcomes were also compared between diffuse cutaneous SSc (dcSSc) vs limited cutaneous SSc (lcSSc). Multivariable regression analysis was performed to identify factors influencing GPH and GMH scores in SSc.

Results: A total of 10,502 complete responses from 276 SSc, 6006 non-SSc AIRDs, 545 NRAIDs, and 3675 controls as of May 2022 were included in the analysis. Respondents with SSc were older [SSc *vs.* non-SSc AIRDs *vs*. NRAIDs *vs*. controls: 55 (14) *vs.* 51 (15) *vs*. 45 (14) *vs*. 40 (14) years old, mean (SD), $p < 0.001$]. Among patients with SSc, 129 (47%) had dcSSc and 147 (53%) had lcSSc. SSc patients reported a significantly higher prevalence of ILD [SSc *vs.* non-SSc AIRDs *vs*. NRAIDs *vs*. controls: 30.4% *vs.* 5.5% *vs*. 1.5% *vs*. 0.2%, $p < 0.001$], and treatment with MMF [SSc *vs.* non-SSc AIRDs *vs*. NRAIDs *vs*. controls: 26.4% *vs.* 9.5% *vs*. 1.1% *vs*. 0%, $p < 0.001$].

Patients with SSc had lower GPH and PROMIS PF-10a scores [SSc *vs.* non-SSc AIRDs *vs*. NRAIDs *vs*. controls: 13 (11–15) *vs.* 13 (11–15) *vs*. 15 (13–17) *vs*. 17 (15–18), median (IQR), p < 0.001; 39 (33–46) *vs.* 39 (32–45) *vs*. 47 (40–50) *vs*. 49 (45–50), p < 0.001, respectively] and higher Pain VAS and PROMIS Fatigue-4a scores compared to those with NRAIDs or controls [SSc *vs.* non-SSc AIRDs *vs*. NRAIDs *vs*. controls: 3 (2–5) *vs.* 3 (1–6) *vs*. 2 (0–4) *vs*. 0 (0–2), p < 0.001; 11 (8–14) *vs.* 11 (8–14) *vs*. 9 (7–13) *vs*. 7 (4–10), p < 0.001, respectively]. Patients with AIDs including SSc had lower GMH scores compared to controls [SSc *vs.* non-SSc AIRDs *vs*. NRAIDs *vs*. controls: 12.5 (10–15) *vs.* 13 (10–15) *vs*. 13 (11–16) *vs*. 15 (13–17), p < 0.001]. Among SSc patients, GPH, GMH, and PROMIS PF-10a scores were lower in dcSSc compared to lcSSc [dcSSc *vs.* lcSSc: 12 (10–14) *vs.* 14 (11–15), p < 0.001; 12 (10-14) vs. 13 (10-15), p<0.001; 38 (30–43) *vs*. 41 (34–47), p < 0.001, respectively]. Pain VAS and PROMIS Fatigue-4a scores were higher in dcSSc compared to lcSSc [4 (2–6) *vs.* 3 (1–5), p < 0.001; 12 (8–15) *vs.* 9 (8–13), p < 0.001, respectively]. The independent factors for lower GPH scores in SSc were older age, Asian ethnicity, glucocorticoid use, and higher pain and fatigue scales, while mental health disorders and higher pain and fatigue scales were independently associated with lower GMH scores.

Conclusion: In a global cohort, patient-reported physical and mental health were significantly worse in patients with SSc in comparison to those with non-SSc AIDs and without AIDs. Our findings support the critical need for more attention to patient's subjective experiences including pain and fatigue to improve the HRQOL in patients with SSc.

Background: The anti-Nucleolar Organizer Region 90 antibodies (NOR90) are rare antinuclear antibodies (ANA) identified in up to 6% of patients with systemic sclerosis (SSc). However, due to the small number of available studies, the clinical relevance of NOR90 in SSc remains uncertain.

Objectives: To analyze clinical associations of NOR90 in patients with SSc in a multicentric cohort.

Methods: Post-hoc, cross-sectional study of prospectively collected data from the European Scleroderma Trials and Research (EUSTAR) group database, with additional information on NOR90 provided by participating centers (EUSTAR project CP105). NOR90 was tested using immunoassays. Differences between patients with and without NOR90 were assessed using the U Mann-Whitney and the Chi-square test, and clinical associations were tested using regression models.

Results: Overall, 1318 patients with SSc were included (mean age 58.3±13.7 years, 81.3% female), of whom 44 (3.3%) were positive for NOR90, that were also positive for other SSc-specific antibodies: anti-topoisomerase I (20.5%), anti-centromere (42.9%), and anti-RNA polymerase III (12.5%). The demographic and clinical data of NOR90-positive and -negative patients are displayed in Table 1. There was no difference in the presence of severe organ manifestations including interstitial lung disease, pulmonary hypertension, and renal crisis, but NOR90-positive patients were more frequently female, had lower modified Rodnan skin score (mRSS), and lower prevalence of upper and lower gastrointestinal symptoms compared to NOR90-negative patients. In multivariable regression models adjusted for the presence of the most frequent SSc-specific antibodies, NOR90 remained significantly associated with lower mRSS and with less frequent gastrointestinal symptoms (Figure 1).

Conclusion: To the best of our knowledge, this is the largest SSc cohort tested for NOR90 so far. Apart from negative associations with skin fibrosis and GI symptoms, which should be analyzed in further studies, we did not find any significant association of NOR90 with SSc-associated organ/ system involvement.

However, these patients had a considerable prevalence of severe organ manifestations and should therefore be carefully evaluated.

Table 1. Demographic and clinical SSc-related data of NOR90-positive and -negative patients.

Parameter	NOR90 (+)	NOR90 (-)	p-value
Age, years	61.5 (48.0; 68.0)	59.0 (50.0; 68.0)	0.663
Female, yes/total (%)	**43/44 (97.7%)**	**1029/1274 (80.8%)**	**0.005**
Disease duration, years	15.5 (9.7; 21.2)	12.0 (6.0; 21.5)	0.061
Anti-topoisomerase I, n/N (%)	9/42 (20.5%)	343/1241 (27.6%)	0.375
Anti-centromere positive, n/N (%)	18/42 (42.9%)	472/1252 (37.7%)	0.498
RNA Polymerase III positive, n/N (%)	5/40 (12.5%)	99/1186 (8.3%)	0.354
Diffuse cutaneous SSc, yes/ total (%)	6/29 (20.7%)	334/1089 (30.7%)	0.249
Digital ulcers, yes/ total (%)	4/9 (44.4%)	252/630 (40.0%)	0.101
mRSS	**2.0 (0.0; 7.0)**	**5.0 (1.2; 11.0)**	**0.001**
Pulmonary hypertension, yes/ total (%)	6/26 (23.1%)	118/850 (13.9%)	0.185
Lung fibrosis, yes/ total (%)	11/26 (42.3%)	427/897 (52.4%)	0.594
DLCO, % predicted	73.0 (44.7; 84.0)	69.5 (55.0; 83.0)	0.756
Upper gastrointestinal tract symptoms, yes/ total (%)	**17/40 (42.5%)**	**592/930 (63.7%)**	**0.007**
Lower gastrointestinal tract symptoms, yes/ total (%)	**5/40 (12.5%)**	**360/937 (38.4%)**	**0.001**
Renal crisis, yes/ total (%)	1/42 (2.4%)	34/1237 (2.7%)	0.886
Joint synovitis, yes/ total (%)	1/31 (2.3%)	138/914 (15.1%)	0.066

Data are presented as median (interquartile range) for the continuous variables and as number (percent) for the nominal ones. n = number of patients with positive results for the antibodies tested. N = total number of patients tested for the respective antibody. Significant p-values ($p < 0.05$) are marked in bold.

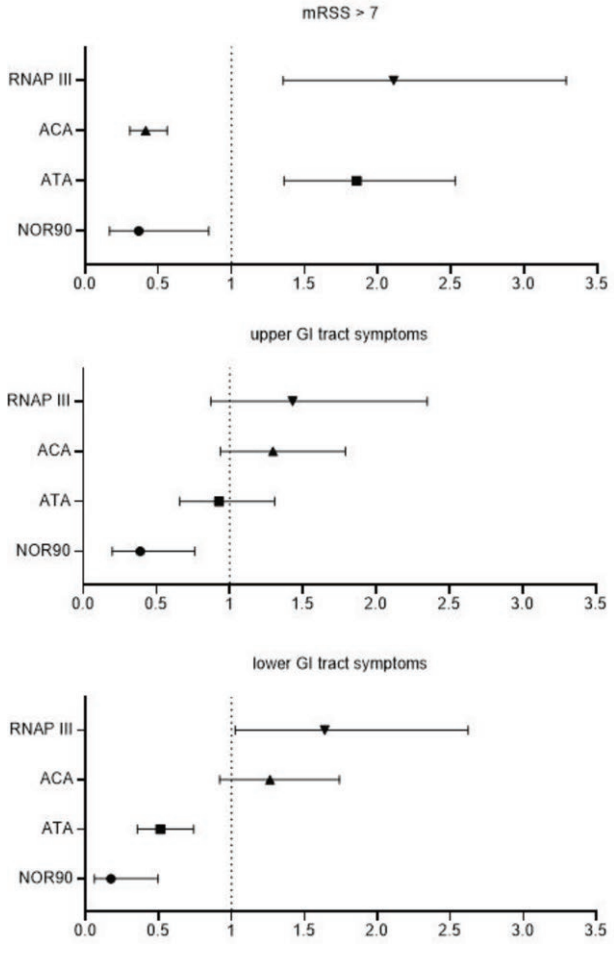

Figure 1. Association of NOR90 and SSc-criteria antibodies (ATA; ACA; RNAP III) with the mRSS and gastrointestinal (GI) manifestations.

MACROVASCULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS AND ASSOCIATIONS WITH PULMONAL ARTERIAL HYPERTENSION: CAN AORTIC STIFFNESS AND CAROTID SONOGRAPHY PLAY A PREDICTIVE ROLE?

Keywords: Biomarkers, Cardiovascular disease, Systemic sclerosis

K. Triantafyllias[1,2], A. Raetsch[2], A. Schwarting[1,2]. *[1]Rheumatology Center Rhineland-Palatinate, Rheumatology, Bad Kreuznach, Germany; [2]Johannes Gutenberg University Medical Center, Rheumatology and Clinical Immunology, Mainz, Germany*

Background: The vast majority of studies regarding vascular involvement in the context of systemic sclerosis (SSc), focus on microangiopatic manifestations, such as digital ulcers, capillaroscopic abnormalities and pulmonary arterial hypertension (PAH). On the other hand, SSc-associated macroangiopathy has not been sufficiently examined, even though a high cardiovascular (CV) and cerebrovascular (CVB) risk have been demonstrated [1,2]. Stiffness of the aortic vasculature and carotid sonography are well established markers of CV and CVB risk and their application has been shown to improve risk stratification in the general population [3].

Objectives: Thus, aim of this three-center prospective study was to investigate the presence of high aortic stiffness, subclinical carotid artery arteriosclerosis (SCAA) and carotid rigidity in a large SSc cohort and to examine their associations with clinical, laboratory and patient associated characteristics.

Methods: Carotid-femoral pulse wave velocity (cfPWV; gold standard of aortic stiffness), was examined in patients with SSc (ACR/EULAR classification) and healthy controls. Moreover, B-mode and Doppler sonography examinations of the common carotid arteries (CCA) were performed to assess plaque presence and/or possible abnormalities of carotid intima media thickness (cIMT), as well as resistance- and pulsatility-indices (RI, PI). Differences of these markers between patients and controls were statistically evaluated and subsequently controlled for the effects of possible confounding factors. Moreover, associations of the included CV and CVB surrogate parameters with clinical, laboratory and traditional CV risk factors were evaluated.

Results: *150* SSc-patients [84%♀, age 56.5 (50–65.3, IQR)] and *80* control subjects [86.3%♀, age 50.5 (35.2–57.8, IQR)] were recruited. cfPWV-values were statistically significantly higher in the patient group, compared to controls [8 m/s (6.86–9.44, IQR) vs. 6.85m/s (5.93–7.7, IQR); $p<0.001$], even after adjustment for the effect of confounding factors ($p_{adj}<0.001$). Similarly, cIMT [0.9 mm (0.65–1,

IQR) vs. 0.83 mm (0.65–0.89); p=0.001] and CCA-RI [0.76 (0.7–0.81, IQR) vs. 0.72 (0.68–0.76, IQR); p=0.02] were found to be significantly higher in the patient group. Interestingly, cfPWV was significantly higher in patients with PAH (p=0.029) and correlated moderately/poorly with erythrocyte sedimentation rate (rho=0.254; p=0.004). Moreover, cfPWV and cIMT associated among SSc-Patients significantly with several traditional CV risk factors, such as arterial pressure (p<0.001; cIMT and cfPWV) and type II diabetes (rho=0.193; p=0.018) (cfPWV).

Conclusion: This is one of the largest CV surrogate marker studies in the field of SSc and the first report of a potential diagnostic role of cfPWV in the PAH screening of SSc-patients. We were moreover able to show that patients with SSc had significantly higher aortic stiffness and more pronounced carotid atherosclerosis and resistance compared to healthy controls and thus could be under higher CV/CVB risk. In summary, cfPWV and carotid sonography may prove to be useful tools for the early identification of SSc patients under high risk for CV-events and PAH.

POS1257 CCL24 SERUM CONCENTRATION PREDICTS BOTH VASCULAR AND FIBROTIC COMPLICATIONS IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Clinical trials, Cytokines and chemokines

E. De Lorenzis[1,2], A. Mor[3], R. Ross[1], S. DI Donato[1], R. Aricha[3], I. Levi[3], I. Vaknin[3], F. Del Galdo[1,4]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Disease, Leeds, United Kingdom; [2]Catholic University of the Sacred Hearth, Fondazione Policlinico Universitario "A. Gemelli", Division of Rheumatology, Roma, Italy; [3]Chemomab, Chemomab Ltd, Tel Aviv, Israel; [4]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: CCL24 is a novel target that was found to play a dual role in advancing pro-inflammatory and pro-fibrotic processes in systemic sclerosis (SSc). Previous studies reported that skin and serum CCL24 levels are elevated in SSc and that blocking of CCL24 was effective in preventing and attenuating experimental-induced fibrosis in murine models as well as interfering with endothelial cell activation.

Objectives: Here we tested the concentration of CCL24 in an observational cohort of patients with SSc and available clinical follow-up to determine its clinical value in predicting fibrotic and vascular complications of the disease.

Methods: Consecutive patients from a single-centre observational cohort were enrolled in this analysis. Clinical data were collected according to the EUSTAR minimal essential data set. Serum Concentration of CCL24 was measured by Luminex assay (Myriad RBM) and defined as "High" for patients over the upper quartile of the Healthy control population (110 ng/ml). Interstitial Lung Disease (ILD) was defined by at least 10% parenchymal involvement at a High-Resolution CT scan of the chest while Digital Ulcer (DU) disease by the presence of current or history of DU in the previous 6 months. Progressive Fibrotic ILD was defined as previously described, according to Erice's criteria within 24 months. Clinical features were compared between CCL24 High vs Low by Chi-Square and T-student tests. R software was employed for statistical analysis.

Results: One-hundred-eighty-one SSc patients (13% males) fulfilling 2013 ACR/EULAR classification criteria were enrolled in this study. Median (IQR) disease duration was 4 (IQR 2-10) years. Thirty-seven (27%) had diffuse cutaneous SSc, 60 (32%) had ILD, and 90 (48%) had DU disease. Fifty-two patients (26%) were CCL24 High. These patients had a higher prevalence of DU (60%, p=0.042), a higher median (IQR) mRSS [4(2-7) vs 2(0-5), p=0.036) and showed a higher prevalence of ILD (42% vs 28%, p=0.055); this was more significant among patients with limited cutaneous SSc (7% vs 12%, p=0.037). Most importantly, among patients with PF-ILD (19/43 with available 24-month follow-up) 44% had significantly higher CCL24 serum concentration at baseline, compared to stable patients 1150 (817-1593) vs 725 (460-955); p=0.017. Consistent with these findings, in patients with ILD, having high CCL24 gave double the chances of progressing within 24 months (66% vs 32% of CCL24 Low; p=0.03).

Conclusion: We show here that within the context of an observational cohort of unselected patients, CCL24 serum concentration is associated with the presence of DU as well as worse skin and lung fibrotic involvement, suggesting that this molecule may be involved in both vascular and fibrotic manifestations of SSc. These results informed the rationale for a target-enriched basket randomized controlled trial to test the biological and clinical effect of CCL24 inhibition in SSc across cutaneous disease subsets.

Background: The lack of RCTs in limited cutaneous systemic sclerosis (lcSSc) is due, in part, to a paucity of relevant outcome measures to effectively evaluate this subset. This international project, supported by the World Scleroderma Foundation (WSF), Scleroderma &. Raynaud's UK (SRUK), the Scleroderma Clinical Trial Consortium (SCTC), and the US National Scleroderma Foundation, aims to create a combined response index for lcSSc for use in clinical trials; the CRISTAL index. The most bothersome symptoms from the patients' perspective were identified through lcSSc patient-centered focus groups [1] and already-identified domains and outcomes were identified through a scoping literature review [2].

Objectives: This phase of the overall CRISTAL project aimed to select candidate items for inclusion in a planned longitudinal prospective observational study assessing the psychometric properties of the selected items. We aimed to enrich the list of candidate outcomes from domains identified by the focus groups and scoping review: i) SSc-specific domains (gastro-intestinal involvement,

Raynaud's/microcirculation, musculoskeletal, digital ulcers, pulmonary involvement, cardiac involvement, hand functioning, calcinosis, skin involvement, Sicca syndrome; and ii) general domains (fatigue, pain, cognition, sleep disorder).

Methods: A two-round international online Delphi exercise was conducted to enrich the list of instruments. Experts in lcSSc were asked to suggest additional items/outcome measures for the domains. Candidate clinician-reported outcomes (ClinROs) and performance outcomes (PerfOs) were selected during a two-day meeting utilizing a nominal group technique (NGT) comprising 3 patient research partners and 8 international experts. Patient research partners received specific-training prior to the NGT meeting to become familiar with the domains, outcomes, and research processes.

Results: 100 experts were invited to the Delphi exercise and 71 provided answers for at least one round. Participants who provided answers in round 1 were invited to a second Delphi exercise, rating each item on scales (range: 1-9) for feasibility, face validity, content validity, and overall appropriateness for the CRISTAL Index. 59/71 participants provided answers to at least one survey. Items endorsed by more than 50% of the experts were included for discussion at the 2 day-NGT discussion. During the NGT meeting, for each lcSSc specific domain, the list of items selected during Delphi and their characteristics were presented and each voting member was asked to discuss the relevance of these items and to propose new items if important ones were considered missing. Voting members then ranked items from "most appropriate for the CRISTAL index" to "less appropriate". At the end of each ranking, voting members were asked if they agreed with the ranking; 80% agreement was required to move to the next domain. Across the 10 lcSSc specific domains discussed, a total of 19 items (17 ClinROs and 2 PerfOs) were identified and retained as draft items for testing in the planned observational longitudinal cohort study (Table 1).

Conclusion: These initial results from the CRISTAL initiative are essential first steps towards the development of a composite index for lcSSc. The next steps will include selection of patient-reported outcomes (PROs) from the PROMIS item bank, existing data in the reported literature, and cognitive debriefing with patients, followed by a prospective cohort study to assess and validate the draft CRISTAL index.

Background: We have previously reported short term safety of the COVID-19 vaccination in patients with Systemic sclerosis (SSc) but delayed adverse events (ADEs) (occurring >7 days post-vaccination) are poorly characterized in this rare yet vulnerable disease group.

Objectives: We analyzed delayed COVID-19 vaccine-related ADEs among patients with SSc, other systemic autoimmune and inflammatory disorders (SAIDs) and healthy controls (HC) using data from the ongoing 2nd global COVID-19 Vaccination in Autoimmune Diseases (COVAD-2) study [1].

Methods: The COVAD-2 study was a cross-sectional, patient self-reporting e-survey utilizing an extensively validated, pilot tested questionnaire, translated into 19 languages, circulated by a group of 157 physicians across 106 countries from February to June 2022.

We captured data on demographics, SSc/SAID disease characteristics (including skin subset, treatment history and self-reported disease activity), autoimmune and non-autoimmune comorbidities, COVID-19 infection history and course, and vaccination details including delayed ADEs as defined by the CDC.

Delayed ADEs were categorized into local injection site pain/soreness; minor and major systemic ADEs, and hospitalizations. We descriptively analyzed the risk factors for overall and specific ADEs in SSc and SAIDs, and further triangulated clinically significant variables in binominal logistic regression analysis with adjustment for age, gender, ethnicity, comorbidity, and immunosuppressive therapy to analyze the survey responses.

Results: From among 17 612 respondents, 10 041 patients (median age 51 (18-58) years, 73.4% females, 44.9% Caucasians) vaccinated against COVID-19 at least once (excluding incomplete responses and trial participants) were included for analysis. Of these, 2.6 % (n=258) had SSc, 63.7% other SAIDs, and 33.7% were HCs. BNT162b2 Pfizer (69.4%) was the most administered vaccine, followed by MRNA-1273 Moderna (32.25%) and ChadOx1 nCOV-19 Oxford/AstraZeneca (12.4%) vaccines. Among the patients with SSc, 18.9% reported minor

while 8.5% experienced major delayed ADEs, and 4.6% reported hospitalization. These values were comparable to those of the ADEs reported in other SAIDs and HCs. Patients with SSc reported higher frequency of difficulty in breathing than HCs [OR=2.3 (1.0-5.1), p=0.042]. Individuals receiving Oxford/AstraZeneca reported more minor ADEs [OR=2.5 (1.0-6.0), p=0.045]; whereas patients receiving Moderna were less likely to develop myalgia and body ache [OR=0.1 (0.02-1.0), p=0.047 and OR=0.2 (0.05-1.0), p=0.044 respectively]. Patients with diffuse cutaneous SSc experienced minor ADEs and specifically fatigue more frequently [OR=2.1 (1.1-4.4), p=0.036, and OR=3.9 (1.3-11.7), p=0.015] than those with limited cutaneous SSc. Self-reported active disease pre-vaccination did not confer any increased risk of vaccine ADEs in the adjusted analysis. Unlike our previous observations in myositis, autoimmune and non-autoimmune comorbidities did not affect the risk of delayed ADEs in SSc. SSc patients with concomitant myositis reported myalgia [OR=3.4 (1.1-10.7), p=0.035] more frequently, while those with thyroid disorders were more prone to report a higher frequency of joint pain [OR=5.5 (1.5-20.2), p=0.009] and dizziness [OR=5.9 (1.3-27.6), p=0.024] than patients with SSc alone. Patients with SSc-interstitial lung disease did not report increased frequency of ADEs.

Conclusion: A diagnosis of SSc did not confer a higher risk of delayed post COVID-19 vaccine-related ADEs than other SAIDs and HCs. Diffuse cutaneous phenotype and certain co-existing autoimmune conditions including myositis and thyroid disease can increase the risk of minor ADEs. These patients may benefit from pre-vaccination counselling, close monitoring, and early initiation of appropriate care in the post COVID-19 vaccination period.

POS1260 SYSTEMATIC LITERATURE REVIEW FOR THE 2023 UPDATE OF EULAR RECOMMENDATIONS FOR THE TREATMENT OF SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Systematic review, Targeted synthetic drugs

A. Lescoat[1], E. Bertoldo[2,3], J. Colic[3,4], T. Santiago[3,5], Y. A. Suliman[3,6], J. Emmel[7], P. G. Conaghan[8,9], Y. Allanore[9,10], F. Del Galdo[8,9]. *[1]University Rennes 1 - Ufr Médecine, Internal Medicine and Clinical Immunology, Rennes, France; [2]University of Verona, Rheumatology, Verona, Italy; [3]equal contribution, as second author,., France; [4]Institute of rheumatology, Rheumatology, Belgrade, Serbia; [5]Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal; [6]Assiut University, Rheumatology and Rehabilitation Department, Assiut, Egypt; [7]University of Leeds, Rheumatology, Leeds, United Kingdom; [8]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, and NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom; [9]equal supervision,.,., United Kingdom; [10]Cochin Hospital, Rheumatology, Paris, France*

Background: EULAR recommendations for the treatment of Systemic Sclerosis (SSc) were updated in 2017, informed by a systematic literature review (SLR) completed in 2014. Given the high number of SSc-related clinical manifestations and therapy-related publications in the last decade, a new SLR providing the most up-to-date literature to underpin contemporary recommendations for the management of SSc was required.

Objectives: The aim of this SLR was to provide a critical review of the updated evidence to address the questions prioritized by an international task force.

Methods: 67 clinical questions addressing 30 interventions were explored. Three categories of questions were defined: Type I Questions that were unchanged as compared to the previous set of recommendations; Type II questions exploring the efficacy/effectiveness of an intervention already mentioned in the previous recommendations but with new outcome(s); Type III questions including interventions not mentioned in the previous recommendations. Each interventions was considered independently, with 30 SLRs for 30 interventions (including several outcomes/clinical questions), and 1 dedicated SLR (with several interventions) for calcinosis (31 searches in total). Search strategies were defined with a librarian and a methodologist. Questions were divided among 5 reviewers and three databases were screened (Embase, pubmed and Cochrane Library). Full texts eligible for data extraction were selected according to the PICOS strategy. Data extraction was performed using a pre-defined template. Quality appraisal was performed using the JADAD scale. 10% of all articles were assessed by a second reviewer ensuring consistency and reliability of data extraction. The level of evidence and grade of recommendations were defined according to the CEBM criteria.

Results: For the first round of SLR, search periods were defined as follows in all three databases: new abstracts released from October 1st 2014 to March 31st 2022 for type I & type II questions and from database inception to march 31st 2022 for type III questions. 14490 abstracts were retrieved from the databases on march 31st 2022 and 18 abstracts were selected manually from march 31st 2022 to October 11th 2022 (date of the nominal group technique (NGT) exercise). 483 new full-texts were evaluated and 172 new articles were included. 187 articles from the SLR for the 2017 recommendations were included as well. For each questions and sub-questions, the reviewers provided a summary of the current knowledge, specifying the level of evidence (1 to 5) and the level of recommendations (A to D). Each summary was reviewed by task force leaders and presented during the NGT meeting to inform discussion and voting on the new recommendations. The majority of the questions covered by this SLR explored new interventions that had not been explored in previous recommendations (40% of type III questions) or with new outcomes (26% of type II questions). New interventions included targeted therapies such as abatacept, JAK inhibitors or nintedanib, and updated questions incorporated the results from key game-changing RCTs including trials on tocilizumab, mycophenolate or rituximab in SSc-interstitial lung disease.

Conclusion: This SLR provides the highest level of evidence to address questions prioritized in the 2023 update of EULAR recommendations for the treatment of SSc, providing an unprecedented comprehensive overview of recent knowledge on SSc treatments and participating in defining the future research agenda for SSc management.

Acknowledgements: The authors thank all the members of the EUSTAR SSc recommendations update task force.

POS1261

DIAGNOSTIC ACCURACY OF LUNG ULTRASOUND FOR DETECTING INTERSTITIAL LUNG DISEASE AMONG PATIENTS WITH SYSTEMIC SCLEROSIS: A COMPARATIVE STUDY OF TWO SCANNING PROTOCOLS

Keywords: Ultrasound, Lungs, Systemic sclerosis

F. Carranza-Enriquez[1], C. Soto[1], C. Pineda[1], T. S. Rodriguez-Reyne[2], A. Angeles-Acuna[1], S. Y. Solorzano Flores[1], A. Vazquez Ortega[2], I. J. Vazquez Romero[2], M. Mejia[2]. *[1]Instituto Nacional de Rehabilitación, Rheumatology, Ciudad de México, Mexico; [2]Salvador Zubirán National Institute of Health Sciences and Nutrition, Immunology and Rheumatology, Ciudad de México, Mexico*

Background: Lung ultrasound (LUS) has proven useful to detect interstitial lung disease (ILD) among patients with systemic sclerosis (SSc) when compared to high-resolution computerized tomography (HRCT) as the gold standard; owing to its accessibility and innocuity it confers several advantages over the latter, which turns it into a potential valuable tool in clinical practice. Nevertheless, a key drawback is the lack of a standardized methodology to perform LUS.

Objectives: To evaluate diagnostic accuracy of LUS for ILD by comparing the systematic evaluation of 14 intercostal spaces (ICS) against 12 postero-basal ICS.

Methods: Patients with SSc were included according to the 2013 ACR/EULAR classification criteria of the Rheumatology clinic of the National Institute of Medical Sciences and Nutrition, reference hospital in Mexico City. Demographic, clinical, serological, and imaging variables were collected, followed by LUS assessment with the simultaneous scanning of 14 predetermined ICS and 12 postero-basal ICS. "B" lines (BL) and pleural abnormalities (PA) were documented for each ICS. HRCT was performed with a maximum 3 month-interval from the time of recruitment (before or after). Descriptive statistics for categorical and continuous variables was used. A bivariate analysis was undertaken to discriminate factors associated with the presence of ILD. A Pearson correlation test was carried out to compare findings between LUS and HRCT. Diagnostic accuracy was assessed through elaboration of ROC curves.

Results: We included 73 patients, with a median age of 54.5±15.1 years and 96.1% were women. Prevalence of ILD was 43.6%. Relevant baseline characteristics are shown in Table 1. Acknowledged risk factors for ILD were pulmonary hypertension (OR 6.27, CI 95% 1.75-22.4, p=0.005) and diffuse SSc (OR 6.17, CI 95% 1.92-19.76, p=0.002). The AUC were 0.87 (95% CI, 0.78-0.96), 0.94 (95% CI, 0.88-1.00) and 0.84 (95% CI, 0.74-0.94) for the evaluation of the number of BL in 14 ICS, in 12 ICS and the number of ICS with PA (22 EIC), respectively. ROC curves are represented in Image 1.

Conclusion: Our study confirms the robustness of LUS as a tool for the detection of ILD through the quantification of BL and PA when using any of two different scanning protocols (14 and 12 ICS). However, more studies are required to elucidate the added value of pleural abnormalities identification for the diagnosis of ILD by LUS.

Table 1. Characteristics of patients according to presence or absence of ILD

POS1262

ULTRASONOGRPHIC EVALUATION OF SALIVARY GLANDS IN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Imaging, Ultrasound

A. Hafez[1], A. Moshrif[2], H. Aly[3], R. Abdelnoor[4], M. A. Mortada[5], R. Elkholi[6]. *[1]Minia University, Faculty of Medicine, Rheumatology Department, Minia, Egypt; [2]Al-Azhar University, Faculty of Medicine, Rheumatology Department, Assiut, Egypt; [3]Al-Azhar University, Faculty of Medicine, Rheumatology Department, Cairo, Egypt; [4]Tanta University, Faculty of Medicine, Internal Medicine, Rheumatology, Tanta, Egypt; [5]Zagazig University, Faculty of Medicine, Rheumatology Department, Zagazig, Egypt; [6]Tanta University, Faculty of Medicine, Rheumatology Department, Tanta, Egypt*

Background: Although dry mouth is a common symptom in systemic sclerosis (SSc), there is a lack of studies evaluating the salivary glands in this heterogenous systemic disease.

Objectives: To study the ultrasonographic changes of salivary glands in patients with systemic sclerosis and to correlate these changes with disease activity markers, clinical data and autoantibodies.

Methods: Forty-seven SSc patients and forty-three healthy age and sex matched controls were studied. Duration of illness, sicca symptoms, Schirmer's test, joint symptoms, internal organ evaluation including interstial lung disease, pulmonary artery hypertension, Raynaud's phenomenon, digital pitting scars and the modified Rodnan total skin score. Laboratory investigations included acute phase reactants, antinuclear antibody, Anti-Ro-60/SSA, anti-La/SSB, anti-Topoisomerase 1 (anti–topo I) and anticentromere (ACA). Salivary glands were evaluated by ultrasound according to the most recent guidelines.

Results: The mean age of patients was 39.6±10.8 years with a mean disease duration of 5.1±4.3 years. Sicca symptoms were obvious among patients with SSc with significant difference compared to controls. pathological changes ≥2 was seen in 31 (66%) of the involved patients. The anti-topo 1 was seen to be significantly correlated with Doppler signals in the salivary glands (p=0.049) while the ACA and anti Ro were not found to be significant with any of the glandular pathology. Anti La was significantly correlated with pathological changes of the salivary glands (p=0.023). also, a significant correlation of anti-La and pathological changes in the submandibular and total gland score (p=0.03 and 0.045 respectively).

Conclusion: Ultrasonographic changes of the salivary glands are quite frequent in patients with SSc. The abnormalities are found correlating with the disease related autoantibodies especially anti La and anti topoisomerase antibodies.

Background: The available evidence suggests that there is no correlation between smoking and disease-specific cutaneous or pulmonary manifestations in systemic sclerosis (SSc) [1]. However, three studies showed that never-smokers had a higher prevalence of anti-topoisomerase I (ATA) positivity than ever-smokers [1-3], which might be important for risk stratification.
Objectives: This study has two objectives: (1) to determine whether patients exposed to cigarette smoking present a distinct autoantibody profile; (2) to determine whether smoking confers different risk of disease progression in men and women or in patients with different autoantibodies.
Methods: Adult patients registered in the EUSTAR database fulfilling the SSc classification criteria, whose information about smoking habit was available and consistent during follow-up, were included. Patients were categorised as "ever-smokers" or "never-smokers" at the first visit. Differences in autoantibody profile were analysed using Chi-square test. Kaplan-Meier curves and log-rank tests were performed to compare outcomes between ever-smokers and never-smokers for up to 20 years of follow-up. The association between smoking habit and progression in disease domains was estimated using Cox proportional hazards models adjusted for age, antibodies (anti-centromere – ACA, and ATA), sex and disease duration. Additionally, cox models including the interaction between smoking status and sex, and between smoking status and autoantibody positivity, were built to assess effect modification. The risk of death, newly diagnosed interstitial lung disease (ILD) and cardiac involvement were evauated. Furthermore, we investigated worsening of functional impairment in patients with ILD and progression of cutaneous involvement. The study protocol was reviewed and approved by the EUSTAR board (project number CP 126).
Results: At the time of data extraction (July 5, 2022), 12314 patients met the inclusion criteria. Of these, 84.4% were female and mean age was 55.5±13.8 years. ACA was positive in 38% of patients and ATA in 32%; 4271 individuals (35%) were ever-smokers. Among never-smokers, 35% of patients was ATA positive, compared to 27% among ever-smokers (p <0.001). When stratifying for sex, this difference was accounted for by female patients: 34% of never-smoking females was ATA positive compared to 21% of ever-smoking women (p <0.001). In men, no statistically significant difference in ATA positivity was observed. Survival was significantly lower in ever-smokers than in never-smokers (46% vs 55%; log-rank test p=0.0032; Figure 1). In multivariable Cox regression analysis, ever-smoking was associated with mortality (HR 1.24; 95% CI 1.07 to 1.43). Evidence for an interaction between smoking status and sex was found (HR of interaction term 1.44, 95% CI 1.03 to 2.03). Cox proportional hazards models did not show an increased risk of developing ILD (HR 1.03; 95% CI 0.92 to 1.16) or cardiac involvement (HR 1.10; 95% CI 0.99 to 1.21), neither of functional worsening in ILD (HR 1.01; 95% CI 0.93 to 1.10) or cutaneous progression (HR 1.11; 95% CI 0.97 to 1.26) for ever-smokers.
Conclusion: Our study in a large cohort of SSc patients from the EUSTAR registry confirms that ever-smoking is associated with lower prevalence of ATA positivity among female SSc patients. Our findings indicate that ever-smoking patients have a worse survival during follow-up, while no association between smoking and development of ILD, cardiac involvement or skin progression emerged.

Background: Interstitial Lung Disease related to Systemic Sclerosis (ILD-SSc) is the first cause of mortality rate in this disease [1]. Significative functional decline in Forced vital capacity is one of the major pronostic factor in ILD-SSc and evaluation of the FCV is a key part of the follow-up of patient [2]. Nintedanib is a tyrosine kinase inhibitor that has been shown to be effective in ILD-SSc by significantly slowing decline in CVF [3]. To this day, no real-life data are available in ILD-SSc.

Objectives: Evaluation of efficacity and tolerance profile of Nintedanib in ILD-SSc patients in real life in France.

Methods: Multicentric data collection on call for observations through the GFRS, SNFMI and Orphalung. The data were obtained in an ambispective way with collection of epidemiological, clinical and paraclinical parameters including in particular CT scan, functional and cardiac data.

Results: 105 patients were included in 11 centers. 76 (74%) were female, mean age of patients was 58±11 years. 51 (48%) had diffuse SSc, 58 (60%) had anti-topoisomerase 1 antibodies. Median time from 1st non-Raynaud's sign to introduction of nintedanib was 6 years (1; 41). ILD-SSc was extensive (>20% of the lung) in 60% of cases, and CT pattern was PINS in 85% of cases. Mean FVC at nintedanib introduction was 1.96±0.47L (64±15%). Mean DLCO was 36 ±11%. Data were available at 6 months after introduction of nintedanib in 60 patients. Seven patients (12%) had discontinued treatment because of digestive intolerance (diarrhea in 5 cases, 1 significant weight loss) and including 1 death (cardiac decompensation). In the 53 remaining patients, the mean loss of FVC was 10 ± 120 mL at 6 months of nintedanib treatment versus 165 ± 225 mL in the year before the introduction of treatment. Two patients had severe infections (1 SARS CoV2 infection; 1 Clostridium difficile infection). 22 (40%) patients experienced adverse events, including 17 diarrhea, 6 abdominal pain, 4 nausea or vomiting, and 7 weight loss >5 kg.

Conclusion: ILD-SSc population in this real-life study of nintedanib has similar epidemiological characteristics to SENSCIS [3]. However, the FVC and DLCO of these patients are lower than those of the SENSCIS population (1.96± 0.47 L vs 2.46± 0.74 L and 36±11% vs 53±15%, respectively). At 6 months, there was a smaller decline in FVC in patients on nintedanib than the decline in the year before starting treatment. The current results at 6 months show a tolerance profile similar to that observed in idiopathic pulmonary fibrosis. These initial results in real-life study in a more severe ILD-SSc population than the pivotal trial suggest that nintedanib limits functional decline in FVC at 6 months. A significant number of side effects were observed, particularly related to the digestive tract, which reinforces need for better management of these side effects. Further data from this ongoing study will provide additional data at 6, 12 and 24 months.

POS1266

A PHASE IA, RANDOMIZED STUDY TO EVALUATE SAFETY, TOLERABILITY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF SINGLE ASCENDING DOSES OF RO7303509, AN ANTI-TGFB3 MONOCLONAL ANTIBODY, IN HEALTHY VOLUNTEERS

Keywords: Systemic sclerosis, Randomized control trial, Biomarkers

L. Han[1], S. Jamalian[1], L. Pan[1], X. R. Sheng[2], X. Yang[3], X. Yang[4], S. Hassan[5], S. Monemi[5], A. Stillwell[6], S. Glickstein[7], R. Kunder[7]. *[1]Genentech, Inc., Clinical Pharmacology, South San Francisco, United States of America*; *[2]Genentech, Inc., Translational Medicine, South San Francisco, United States of America*; *[3]Genentech, Inc., Bioanalytical Sciences, South San Francisco, United States of America*; *[4]Genentech, Inc., Product Development Data Sciences, South San Francisco, United States of America*; *[5]Genentech, Inc., Clinical Safety, South San Francisco, United States of America*; *[6]Genentech, Inc., Clinical Science, South San Francisco, United States of America*; *[7]Genentech, Inc., Early Clinical Development, South San Francisco, United States of America*

Background: Transforming growth factor beta (TGFβ) cytokines (TGFβ1, TGFβ2, and TGFβ3) play critical roles in tissue fibrosis.[1] However, treating fibrotic diseases with systemic pan-TGFβ inhibitors has demonstrated unacceptable toxicities.[2,3] In human lung and liver fibrotic tissue, and in the skin of patients with systemic sclerosis, elevated *TGFB3* gene expression suggests its use as a more specific therapeutic target.[2,4] RO7303509, a high-affinity, TGFβ3-specific, humanized immunoglobulin G1 (IgG1) monoclonal antibody, is being developed as a potential anti-fibrotic therapy.

Objectives: To evaluate RO7303509 safety, tolerability, pharmacokinetics, and pharmacodynamics.

Methods: This phase 1a, randomized, double-blind trial (ISRCTN13175485) in healthy adult volunteers (HVs) consisted of 6 cohorts that evaluated single doses of placebo or RO7303509, administered intravenously (IV; 50 mg, 150 mg, 240 mg) or subcutaneously (SC; 240 mg, 675 mg, 1200 mg). The follow-up period was 12 weeks. Throughout the study, we monitored frequency and severity of adverse events (AEs) and RO7303509 plasma concentrations. We also measured TGFβ pathway biomarkers, including serum periostin and cartilage oligomeric matrix protein (COMP), by immunoassay.

Results: The study enrolled 49 HVs, 18–73 years old, with a median baseline weight of 79 kg. Twenty-seven subjects (55%) were male; 8 (16%) were Black or African American, 1 (2%) was Asian, 1 (2%) was multiracial, and 39 (80%) were White; 1 (2%) was Hispanic or Latino. Ten (28%) RO7303509-treated subjects reported 24 AEs, and 6 (31%) placebo-treated subjects reported 6 AEs. All AEs were Grade 1 except for one Grade 2 AE of hyperamylasemia (unrelated) in the 1200-mg SC cohort. The most frequent AEs related to study drug were injection site reactions (1200 mg SC: 4 RO7303509, 1 placebo) and infusion-related reactions (240 mg IV: 1 RO7303509, 2 placebo). Median times to maximum plasma concentration (T_{max}) of RO7303509 after single IV and SC doses were 1–2 hours and 5–7 days, respectively. Geometric mean plasma half-lives ($t_{1/2}$) for IV and SC dosing were ~23 days. Maximum plasma concentrations (C_{max}) and area under the curve from time 0 to infinity ($AUC_{0\text{-}inf}$) values for RO7303509 appeared to increase proportionally across all doses tested after adjusting for the observed subcutaneous bioavailability of 73%. No subjects tested positive for anti-drug antibodies (ADAs) at baseline; 1 subject (2.8%; 50 mg IV) tested positive for ADAs at a single timepoint (Day 15). No clear pharmacodynamic effects were observed for the biomarkers periostin or COMP upon TGFβ3 inhibition.

Conclusion: RO7303509 was well tolerated at single IV and SC doses up to 1200 mg without any dose-limiting toxicities, Grade ≥3 AEs, serious AEs, deaths, or clinically significant vitals/ ECG changes. In addition to a favorable safety profile, the dose-proportional increase in RO7303509 exposure across the dose range after single dose administration supports further development using repeat-dosing regimens. The half-life supports SC administration every four weeks. The lack of an effect on TGFβ pathway biomarkers likely indicates that TGFβ3 is inactive during homeostasis, which suggests that targeting this pathway may have a favorable safety profile. These data support the further development of RO7303509 for the treatment of fibrotic diseases.

POS1267 IGURATIMOD AS AN ALTERNATIVE THERAPY FOR SYSTEMIC SCLEROSIS AND PREVENTION OF ISCHEMIC DIGITAL ULCER OCCURRENCE

Keywords: Disease-modifying drugs (DMARDs), Systemic sclerosis, Descriptive studies

Q. Yan[1], B. Liu[1], J. Wang[2], H. Yin[1], Q. Li[1], L. Lu[1]. *[1]Renji Hospital, Shanghai Jiaotong University School of Medicine, Rheumatology, Shanghai, China*; *[2]Renji Hospital, Shanghai Jiaotong University School of Medicine, Clinical Center for Investigation, shanghai, China*

Background: Systemic sclerosis (SSc) is not only one of the autoimmune diseases with the highest mortality but rises a severe disease burden through some not directly lethal but suffering complications such as digital ulcers (DU) [1].Iguratimod(IGU) is typically thought of as an anti-inflammatory and immunoregulatory drug [2]. On top of anti-inflammation, IGU has shown potential efficacy on fibrotic complications with autoimmune diseases[3].
Objectives: To assess the effectiveness of IGU as an alternative treatment for SSc, especially in the prevention of ischemic DU.

Table 1 Baseline Characteristics of the Study Participants with Digital Ulcers.

Characteristics	With IGU (N=11)	Without IGU (N=20)	P value
Age of Onset(years), median (IQR)	36.0(31.0-53.0)	43.0(34.0-54.0)	0.457
Sex(%)	2(18.2)	6(30.0)	0.676
Male	9(81.8)	14(70.0)	
Female			
Time since RP onset (years), median(IQR)	9.0(3.0-12.0)	7.5(3.0-14.8)	0.740
Time since first non-RP manifestation (years), median (IQR)	9.0(2.0-11.0)	5.5(2.3-12.8)	0.634
SSc subtype(%)	9(81.8)	10(50.0)	0.133
Diffuse	2(18.2)	8(40.0)	
Limited	0	2(10.0)	
Sine scleroderma			
ESR(mm/h), median (IQR)	29.0(15.5-53.8)	27.0(13.5-47)	0.880
Autoantibodies(%)	6(60.0)	12(75.0)	0.332
Anti-Scl70 antibody positive	1(10.0)	2(12.5)	
ACA positive	3(30.0)	1(6.3)	
Anti-U1RNP positive	0	1(6.3)	
Anti-Th/To positive			
Smoke(>25 pack-years)(%)	0	4(20.0)	0.269
Previous DU(s)	4(36.4)	8(40.0)	1.0
Vasodilator use (at least one agent) (%)	11(100)	20(100)	0.452
PDE5i	6(54.5)	14(70.0)	0.423
ERA	5(45.5)	5(25.0)	1
CCB	4(36.4)	6(30.0)	0.716
Beraprost	5(45.5)	11(55.0)	
Pulmonary hypertension(%)	3(27.3)	6(30.0)	1
ILD(%)	9(81.8)	13(65.0)	0.429
DU new occurrence during follow-up(%)	8(72.7)	5(25.0)	**0.021**
never	3(27.3)	15(75.0)	
new occurrence			

Methods: We constructed two cohorts from the Renji SSc registry. In the first cohort, SSc patients receiving IGU were observed prospectively with effectiveness and safety. In the second cohort, we picked up all the DU patients with at least a 3-month follow-up to investigate the prevention of IGU on ischemic DU.
Results: 1) IGU was a plausible alternative treatment for SSc with acceptable tolerance. 91.3% (21/23) of the SSc patients were disease worsening-free during IGU treatment (median follow-up: 61 weeks). 2) We unexpectedly discovered that IGU was protective against ischemic DU. Although with a limited patient number, 72.7% (8/11) of IGU-treated patients had no new DU occurrence in a median follow-up of 39 weeks; further in the second DU cohort (Table1), the protection of IGU was still true for new DU occurrence (adjusted RR = 0.25, 95% CI, 0.05-0.94, adjusted OR = 0.07, 95% CI, 0.01-0.49)(Figure 1).
Conclusion: Our study indicates IGU as a possible alternative treatment for SSc. Beyond expectation, this study for the first time describes IGU as preventative against ischemic DU occurrence and merits further investigation.

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by immune system dysregulation, endothelial dysfunction and fibrosis of skin and internal organs. Interstitial lung disease (ILD) is common in SSc and about 80% of patients will develop ILD during the disease course [1]. Although most patients have a stable or slowly progressive disease, showing a slow decline in lung function or a minimal increase in the extent of pulmonary fibrosis by high resolution computed tomography (HRCT), 25-30% of them will ultimately progress to respiratory failure or death [2]. Of the SSc-related deaths, 35% were attributed to ILD [3]. The underlying pathophysiologic mechanisms of SSc-ILD is still not completely understood [2]. The pathogenesis of SSc-ILD is initially characterized by an injury to alveolar epithelial and vascular endothelial cells which promotes the recruitment of inflammatory cells and the production of profibrotic mediators, in the attempt to repair the damage [4,5]. In this early inflammatory phase, profibrotic type 2 (Th2) cytokines, such as IL-4, IL-5, IL-13, play a key role [6,7].
Objectives: Aim of the study was to evaluate the Th2 cytokines serum levels in SSc-ILD.
Methods: Serum levels of IL-4, IL-5, IL-11, IL-13, IL-21, IL-31 and CXCL-13 were measured by Bio-Plex Multiplex Immunoassays in 60 SSc patients and 20 healthy controls (HC). Pulmonary function tests with diffusion lung capacity for carbon monoxide (DLco) and high resolution computed tomography (HRCT) were performed in SSc patients. ILD is defined as fibrotic changes (ground glass, reticular and honeycombing), assessed by Computer-Aided Lung Informatics for Pathology Evaluation and Ratings (CALIPER) software, affecting at least 10% of the lungs.
Results: Serum levels of Th2 cytokines were higher in SSc patients than HC. A linear correlation was observed between ground glass and IL-13 ($r=0.342$, $p<0.01$), IL-21 ($r=0.345$, $p<0.01$), IL-31 ($r=0.473$, $p<0.001$), IL-4 ($r=0.863$, $p<0.001$), IL-5 ($r=0.249$, $p<0.05$) and peripheral blood eosinophils ($r=0.463$, $p<0.001$). We found a negative correlation between DLco and IL-4 ($r=-0.511$, $p<0.001$) and peripheral blood eosinophils ($r=-0.446$, $p<0.001$). In the logistic regression analysis, IL-4 is associated with DLco≤ 60% of the predicted [OR 1.039 (CI 95%: 1.015-1.064), p<0.001], mRSS [OR 1.138 (CI 95%: 1.023-1.266), p<0.05] and IL-4 [OR 1.017 (CI 95%: 1-1.034), p<0.05] were associated with ILD.
Conclusion: Th2 cytokines might have a key role in early phase of ILD in SSc patients. Future large studies are needed to confirm these findings.

INVESTIGATING THE TRAJECTORY OF FUNCTIONAL DISABILITY IN SYSTEMIC SCLEROSIS: GROUP BASED TRAJECTORY MODELLING OF THE HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX

Keywords: Patient reported outcomes, Systemic sclerosis

J. Fairley[1,2], D. Hansen[1], M. Baron[3,4], S. Proudman[5,6], J. A. Sahhar[7,8], G. S. Ngian[7,8], J. Walker[6], L. Host[9], K. Morrisroe[1,2], W. Stevens[1], L. Ross[1,2], M. Nikpour[1,2]. *[1]St. Vincent's Public Hospital Melbourne, Department of Rheumatology, Fitzroy, Australia*; *[2]The University of Melbourne, Department of Medicine, Dentistry and Health Sciences, Parkville, Australia*; *[3]Lady Davis Institute at the Jewish General Hospital, Lady Davis Institute for Medical Research, Montréal, Canada*; *[4]McGill University, Department of Medicine, Montréal, Canada*; *[5]The University of Adelaide, Department of Medicine, Adelaide, Australia*; *[6]Royal Adelaide Hospital, Department of Rheumatology, Adelaide, Australia*; *[7]Monash Health, Department of Rheumatology, Clayton, Australia*; *[8]Monash University, Department of Medicine, Clayton, Australia*; *[9]Fiona Stanley Hospital, Department of Rheumatology, Murdoch, Australia*

Background: Up to 70% of people with systemic sclerosis (SSc) report impaired physical function[1,2], which can negatively impact quality of life[3]. The Health Assessment Questionnaire Disability Index (HAQ DI) is a self-administered measure of function, where higher scores (range 0-3) indicate worse function.
Objectives: To identify trajectories, clinical correlates and associations of functional disability in SSc.
Methods: Australian Scleroderma Cohort Study participants meeting ACR/EULAR criteria for SSc recruited within 5 years of SSc onset were included. Participants needed to have ≥2 HAQ DI scores available within 10 years of SSc onset. Group based trajectory modelling (GBTM) was used to identify the number and shape of HAQ DI score trajectories over 10 years. Between group comparisons were made using the chi-squared test for discrete variables and the two-sample t-test or Wilcoxon rank sum test for continuous variables. Generalised estimating equations were used to model longitudinal data involving repeated measures. Survival analyses were performed using Kaplan Meier and Cox proportional hazard modelling.
Results: 426 participants were included with incident SSc and ≥2 HAQ DI scores, with median time between HAQ DI scores of 1.1 (IQR 1.0-1.4) years. Median age at SSc onset was 53 years (IQR 44-61 years), 83% were female and 33% had dcSSc. We found two HAQ DI trajectory groups: low/stable disability (n=221, 52%), and high/increasing disability (n=205, 48%; Figure 1). Participants with high/increasing disability were older (p=0.01) and more likely to have dcSSc (p<0.01), PAH (p<0.01) and multiple cardiovascular risk factors (p<0.01; Table 1). High/increasing disability was associated with markers of poor hand function such as digital ulcers and synovitis (p<0.01), upper and lower GI involvement (both p<0.01) and proximal muscle weakness and atrophy (both p<0.001). Use of immunosuppression (p<0.001), including prednisolone (p<0.001), was more frequent in those with high/increasing disability. Those with high/increasing disability had worse survival after adjusting for age, sex, dcSSc, PAH and ischaemic heart disease (HR 1.9, 95% CI 1.0-3.8, p=0.05), as did those with increasing baseline HAQ DI scores (HR 1.8, 95%CI 1.2-2.7, p=0.01).
Conclusion: Two trajectories of functional disability in SSc were identified. Those with poorer function had a distinct clinical phenotype and survival compared to those with less functional disability. Further work is required to identify if amelioration of disease-specific features associated with higher HAQ DI scores results in a commensurate improvement in physical function.

POS1270

THE IMPACT OF OVERLAP SYNDROMES ON THE SCLERODERMA CLINICAL TRIAL CONSORTIUM DAMAGE INDEX (SCTC-DI) IN SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Organ damage

K. Filipánits[1], G. Nagy[1], D. Komjati[1], G. Kumanovics[1], C. Varjú[1], L. Czirják[1], T. Minier[1]. [1]*University of Pécs Medical School, Department of Rheumatology and Immunology, Pécs, Hungary*

Background: Systemic sclerosis (SSc) is a systemic autoimmune disease leading to tissue atrophy, vascular damage and organ failures, and therefore causing severe disability. Coexistent autoimmune diseases are called overlap syndromes. Due to the distinct clinical picture[1], the extent of damage in SSc-overlap may be affected compared to pure-SSc.

Objectives: To identify differences in the time course and characteristics of damage between pure-SSc and SSc-overlap patients by evaluating the Scleroderma Clinical Trials Consortium-Damage Index (SCTC-DI)[2].

Methods: Single tertiary care centre observational study with 160 enrolled SSc patients. Eighty-eight patients (55%) had diffuse cutaneous SSc (dcSSc), 86% were female and median disease duration was 9 years/4;16/. SSc-overlap was diagnosed based on the evaluation of the attending physicians. SCTC-DI was calculated. SCTC-DI score between 6-12 was considered as moderate and >12 points as severe damage. Damage profile of pure-SSc and SSc-overlap including subsets was compared.

Results: SSc-overlap was present in 24% of cases (n=39; 18 rheumatoid arthritis, 12 Sjögren, 12 myositis, 1 antiphospholipid syndrome). Age at enrolment and at disease onset, dcSSc/limited cutaneous (lcSSc) ratio, disease duration and gender distribution showed no difference between pure-SSc and SSc-overlap. Pure-SSc and SSc-overlap patients, including lcSSc/dcSSc subset comparison had the same damage burden (Kruskal-Wallis p>0.05). Median/IQR/ SCTC-DI was similar in pure-SSc and SSc-overlap (9/7;14/ and 9/6;13/ respectively). Moderate damage was found in around 53% and severe damage in 28% of patients in both pure-SSc and SSc-overlap. Gastrointestinal, cardiopulmonary, cardiac, vascular and renal domains of SCTC-DI did not differ between SSc-overlap and pure-SSc, whereas proximal muscle weakness was more prevalent in SSc-overlap compared to pure-SSc. ILD was scored similarly frequently in pure-dcSSc and dcSSc-overlap (82% vs 66.7%, χ^2 p>0.05), however, it was also present in 65% of pure-lcSSc and 60% of lcSSc-overlap patients. Severe damage was more prevalent in SSc-overlap patients at early stage of SSc (≤3 years duration, Fisher's p=0.029) compared to pure-SSc. Early severe damage was more frequent in dcSSc-overlap compared to pure-dcSSc (Fisher's p=0.042). Although in pure-SSc there were weak—to-moderate correlations between the SCTC-DI, age, and disease duration (Spearman's rho:.360-.498;p<0.001), no such associations were found in SSc-overlap patients. Differences in SCTC-DI items in pure-SSc and SSc-overlap are shown in Table 1.

Table 1. Differences in SCTC-DI items in SSc-overlap and pure-SSc

n (%)	**pure-SSc n=121**	**SSc-overlap n=39**	**pure-dcSSc n=67**	**pure-lcSSc n=54**	**dcSSc-overlap n=21**	**lcSSc-overlap n=18**
Small joint CC	59 (48.8)	**21 (53.8)**[d]	**41 (61.2)**[a]	18 (33.3)	14 (66.7)	7 (38.9)
Large joint CC	46 (38.0)	**19 (48.7)**[d]	**32 (47.8)** [a]	14 (25.9)	11 (52.4)	8 (44.4)
Proximal muscle weakness	12/118 (10.2)	**11/38 (28.9)**[b, c, d]	8 (11.9)	4/52 (7.7)	**7 (33.3)**[e,f]	4/17 (23.5)
Digital ulcers	45 (37.2)	13 (33.3)	**31 (46.3)**[a]	14 (25.9)	9 (42.9)	4 (22.2)
SSc-ILD	76/101 (75.2)	21/33 (63.6)	**50/61 (82)**[c]	26/40 (65)	12/18 (66.7)	9/15 (60)

CC: contracturesBold characters: p<0.05. [a] pure-dcSSc vs pure-lcSSc; [b] pure-SSc – SSc-overlap; [c] pure-dcSSc – SSc-overlap; [d] pure-lcSSc – SSc-overlap; [e] pure-SSc – dcSSc-overlap; [f] pure-dcSSc – dcSSc-overlap

Conclusion: SCTC-DI is a relevant tool to assess damage in SSc-overlap. In this cohort damage was not related to ageing and disease duration in SSc-overlap. Early dcSSc-overlap patients had higher risk to develop severe damage compared to early pure-dcSSc patients based on the SCTC-DI. Pulmonary damage was less frequent in SSc-overlap compared to pure-dcSSc, but similar in pure-dcSSc and dcSSc-overlap patients. As expected, musculoskeletal damage, especially proximal muscle weakness was present in a remarkable proportion of SSc-overlap patients.

POS1271

LONGITUDINAL TRENDS IN MULTIMORBIDITY IN SYSTEMIC SCLEROSIS: RESULTS FROM AN INCIDENT POPULATION-BASED COHORT (1980-2018)

Keywords: Comorbidities, Systemic sclerosis, Epidemiology

A. Makol[1], A. Karn[1], S. Achenbach[2], A. M. Hinze[1], C. S. Crowson[2]. *[1]Mayo Clinic, Division of Rheumatology, Rochester, United States of America*; *[2]Mayo Clinic, Department of Quantitative Health Sciences, Rochester, United States of America*

Background: Systemic sclerosis (SSc) is a chronic inflammatory autoimmune disease characterized by vascular dysfunction and widespread internal organ fibrosis. Multimorbidity (MM), defined as the co-occurrence of two or more chronic conditions, can impact life expectancy, increase risk of hospitalizations, healthcare resource utilization and reduce quality of life. The accrual of MM in SSc and its determinants are not well studied.

Objectives: To assess the longitudinal trends of MM (i.e., the presence of ≥2 morbidities) in an incident population-based cohort of patients with SSc vs. age- and sex-matched non-SSc comparators, and identify drivers of these trends.

Methods: A population-based cohort of incident physician diagnosed SSc patients between Jan 1, 1980, to Dec 31, 2018, was identified and compared to a 2:1 cohort of age- and sex-matched non-SSc comparators from the same population. Patients were followed until death, migration from the geographic area, or Dec 31, 2021. Data on 21 morbidities identified by the US Department of Health and Human Services (DHHS) and 13 morbidities included in the Charlson Comorbidity Index (CCI) was retrieved. Cumulative incidence of MM (MM2+) or substantial MM (MM5+; ≥ 5 morbidities) adjusting for the competing risk of death was estimated. Cox models adjusted for age, sex, index year and morbidity count at index date were used to compare cases and comparators. Patients who met criteria of event type before index date were excluded from respective analyses.

Results: 85 patients with SSc were compared to 170 age- and sex-matched non SSc comparators (mean age 55.4 y, 91% female, 90% white/non-Hispanic). At incidence/index date, a significantly higher prevalence of chronic obstructive pulmonary disease (COPD) (14% vs 4%, p=0.004), arthritis (33% vs 22%, p=0.054), peripheral vascular disease (40% vs 2%, p< 0.001) and liver disease (5% vs 1%, p=0.04) were noted in patients with SSc. During a mean length of follow-up of 12.4 y (SD 9.8) for SSc & 15.5 y (SD 9.8) for comparators, the development of DHHS morbidities of heart failure (HF) (HR 2.90; 95% confidence interval [CI] 1.46-5.74), cardiac arrhythmia (hazard ratio [HR] 1.60; 95% CI 1.03-2.49), stroke (HR 2.08; 95% CI 1.04-4.16), chronic kidney disease (HR 1.86; 95% CI 1.09-3.18), and COPD (HR 2.02; 95% CI 1.08-3.80) were higher in SSc vs. non-SSc comparators. While osteoporosis (HR 2.03; 95% CI 1.18-3.51) was also higher in SSc patients, it did not reach statistical significance when adjusted for baseline morbidity count at index date. Similarly, CCI morbidities of HF (HR 2.86; 95% CI 1.51-5.42), peripheral vascular disease (HR 11.32; 95% CI 6.59-19.44), cerebrovascular disease (HR 2.43; 95% CI 1.26-4.72), chronic pulmonary disease (HR 3.82; 95% CI 2.18-6.69), moderate/severe renal disease (HR 2.32; 95% CI 1.30-4.16), and any liver disease (HR 3.02; 95% CI 1.32-6.92) were also significantly higher in SSc when compared to non-SSc comparators. The cumulative incidence of DHHS MM2+ during follow-up did not differ, but the development of DHHS MM5+ was significantly higher in SSc patients vs. comparators at 10 (44% vs 32%), 15 (52% vs 45%) and 20 (64% vs 58%) years of follow up (HR 1.58; 95% CI 1.09-2.31). The development of CCI-MM2+ (HR 4.56; 95% CI 3.00-6.93) was significantly higher among SSc patients but CCI-MM5+ was not statistically significant after adjusting for morbidity count at index (HR 1.65; 95% CI 0.80-3.43).

Conclusion: Multimorbidity is significantly more prevalent in patients with SSc and adds a substantial healthcare burden on these patients. Patients with SSc have a 1.5-3 fold higher risk of developing multiple cardiopulmonary morbidities and >10 fold higher risk of developing peripheral vascular disease during longitudinal follow up than age- and sex-matched individuals without SSc. Multimorbidity assessment must be prioritized early in the disease course to reduce healthcare utilization and optimize long-term outcomes in this population.

INDUCTION OF REGULATORY T CELLS AND EFFICACY OF LOW DOSE INTERLEUKIN-2 IN SYSTEMIC SCLEROSIS: INTERVENTIONAL OPEN-LABEL PHASE 1–PHASE 2A STUDY

Keywords: Adaptive immunity, Investor initiated trial, Systemic sclerosis

F. Barde[1], R. Lorenzon[2,3], S. Riviere[1], P. Cacoub[2,4], M. Rosenzwajg[2,3], C. Cacciatore[1], A. Daguenel-Nguyen[5], O. Fain[1,2], D. Klatzmann[2,3], A. Mekinian[1,2]. *[1]Hospital Saint-Antoine Ap-Hp, Internal Medicine, Paris, France*; *[2]Sorbonne University, Faculté de Médecine, Paris, France*; *[3]University Hospitals Pitié Salpêtrière - Charles Foix, Clinical Investigation Center for Biotherapies and Inflammation-Immunopathology-Biotherapy Department, Paris, France*; *[4]University Hospitals Pitié Salpêtrière - Charles Foix, Department of Internal Medicine and Clinical Immunology, Paris, France*; *[5]Hospital Saint-Antoine Ap-Hp, Pharmacy, Paris, France*

Background: Systemic sclerosis (SSc) is a chronic autoimmune disease, with impaired immune response, increased fibrosis, and endothelial dysfunction. (1,2) Regulatory T cells (Tregs), which are essential to prevent autoimmunity, showed a decreased frequency and impaired function during SSc. (3,4) Low-dose interleukin-2 (ld-IL2) can expand and activate Tregs, but there are no data in SSc.

Objectives: We aimed to assess the in vivo biological efficacy of ld-IL2 on Tregs and its safety in patients with SSc.

Methods: We performed an interventional prospective, open-label phase I-IIa study in nine patients with SSc without severe organ involvement (eight patients with limited cutaneous subtype). This trial is a part of the TRANSREG study. All patients received 1 Million International Units (MIU)/day of IL-2 for five days, followed by fortnightly injections for 6 months. The primary endpoint was the change in the relative Tregs blood concentration identified as CD25hiCD127lo/–Foxp3+cells frequencies on day 8 among TCD4+ cells compared with baseline. Laboratory and clinical evaluations (modified Rodnan skin score (mRSS), Clinical Global Impression (CGI) activity and severity scale) were performed between day 8 and month 18.

Results: At day 8, the primary endpoint was reached with a 1.8(± 0.5) fold increase of Tregs levels among $TCD4^+$ lymphocytes (p= 0.008). Changes in concentration of effector T cells (Teffs) and $BCD19^+$ cells were not statistically significant at day 8 and during maintenance period until month 6. Patients' clinical assessments were stable throughout the follow-up with no modification on mRSS CGI activity and severity scale. Ld-IL2 was well tolerated, and no serious adverse events occurred.

Conclusion: Ld-IL2 at a dosage of 1 MIU/day for five consecutive days selectively activates and expands Tregs in SSc. Safety data were very encouraging. Phase II efficacy trials are needed to validate therapeutic potential of ld-IL2.

CHARACTERISTICS AND DISEASE COURSE OF UNTREATED PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS IN A REAL-LIFE TWO-CENTER COHORT

Keywords: Systemic sclerosis, Lungs

M. Scheidegger[1], A. Garaiman[1], I. Barua[2], M. O. Becker[1], H. J. Bjørkekjær[3], C. Bruni[1], R. Dobrota[1], H. Fretheim[2], S. Jordan[1], M. Maciukiewicz[1], Ø. Midtvedt[2], C. Mihai[1], A. M. Hoffmann-Vold[2], O. Distler[1], M. Elhai[1]. *[1]University Hospital Zurich, University of Zurich, Department of Rheumatology, Zurich, Switzerland*; *[2]Oslo University Hospital, Department of Rheumatology, Oslo, Norway*; *[3]Hospital of Southern Norway, Department of Rheumatology, Kristiansand, Norway*

Background: Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc). Current guidelines consider that some patients may not require pharmacological treatment. To date, the characteristics and disease course of untreated SSc-ILD patients remain unknown.

Objectives: To describe disease characteristics and disease course in untreated SSc-ILD patients in two well characterized SSc-ILD cohorts.

Methods: We included SSc patients from Zurich and Oslo who had a diagnosis of ILD on high-resolution computed tomography (HRCT) and available data on pulmonary function tests and treatment. The longitudinal study included patients with at least one follow-up visit. Patients were classified as treated if they had received a potential ILD modifying drug (immunosuppressive therapy or nintedanib). Treated and untreated patients were compared at baseline. ILD progression in the untreated group was defined as (i) decline in forced vital capacity (FVC) from baseline of ≥10% or (ii) decline in FVC of 5-9% associated with a decline in diffusing capacity for carbon monoxide (DLCO) of ≥15%, or (iii) start of any ILD modifying treatment during follow-up. In the untreated group, patients with ILD progression at any time point were compared with patients with no ILD progression during follow-up. Multivariable logistic regression was performed to identify (i) factors associated with no treatment of ILD at baseline and (ii) factors associated with progression in untreated patients. Covariates were selected based on clinical experience and literature evidence.

Results: The cohort included 386 SSc-ILD patients, 301 (78%) had their first visit before 2016, 82 (21.5%) were males, mean age 57±14 years, mean disease duration 12±22 years, 120 (31%) had diffuse cutaneous SSc and 127/381 (33%) positive for anti-Scl70 antibodies. Of all, 290 (75%) were untreated at baseline. Untreated patients were more often women, had a longer disease duration, more frequently a limited cutaneous form, anticentromere antibodies and lower CRP levels. They had lower NYHA functional class, limited extent (<20%) of lung fibrosis, higher FVC (96±19 % vs. 81±22%), higher DLCO (69±20 % vs. 58±21) and better performances in the 6-minute walking test. In multivariable logistic regression, a less extensive disease on HRCT (OR: 3.71 [1.66-8.53], p=0.002) and anticentromere antibodies (OR: 5.18 [1.81-18.88], p=0.005) were independently associated with no treatment of ILD at baseline in our cohort. Over mean 56 months of follow-up, 135/233 (58%) untreated SSc-ILD patients showed progression. Among them, 116 progressed on lung function parameters. Half of the patients (68) progressed at the first follow-up visit (mean 14 months). Male sex, diffuse cutaneous subtype and extensive lung fibrosis were independently associated with lung progression during follow-up in untreated patients (Figure 1).

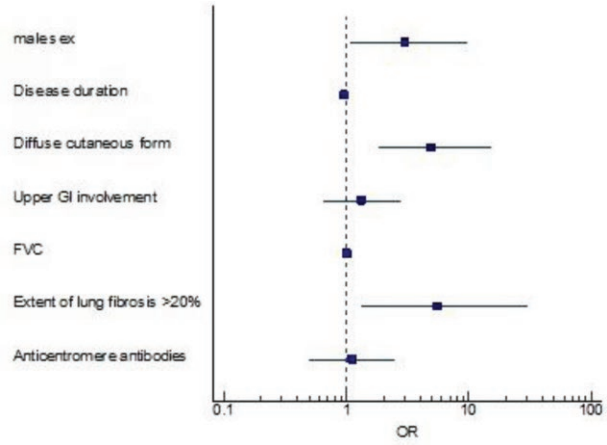

Figure 1.

Conclusion: In the past, a large number of SSc-ILD have been untreated, particularly patients with anti-centromere antibodies and overall less extensive ILD. However, during a follow-up of nearly 5 years, contrary to common belief, about 60% of untreated patients showed progression of ILD. With the development of effective and safe therapies for SSc-ILD, our results support a change in clinical practice in selecting patients for treatment.

FGF23 AND CARDIOVASCULAR STRUCTURE IN WOMEN WITH SYSTEMIC SCLEROSIS

Keywords: Cardiovascular disease, Biomarkers, Systemic sclerosis

A. Alvarez de Cienfuegos[1], M. A. González-Gay[2], N. Ortego[3]. [1]*Hospital Vega Baja, Rheumatology, Alicante, Spain*; [2]*Fundacion Jimenez Diaz, Rheumatology, Madrid, Spain*; [3]*Universidad de Granada, Facultad de Medicina, Granada, Spain*

Background: Systemic sclerosis (SSc), an autoimmune disease characterized by fibrosis of the skin and various internal organs, is associated with cardiovascular abnormalities including pulmonary hypertension, atherosclerosis, right and left ventricular dysfunction, arrhythmias, conduction defects, pericardial disease, and valvular heart disease. Fibroblast growth factor-23 (FGF23) is a circulating regulator of phosphate and vitamin D metabolism and has been implicated as a putative pathogenic factor in cardiovascular disease. FGF23 has been associated with cardiac hypertrophy and reduced left ventricular ejection fraction among patients with chronic kidney disease and cardiovascular disorders.
Objectives: The aim of this study was to examine the possible association between serum FGF23 levels and echocardiographic abnormalities in women with SSc.
Methods: This cross-sectional study was performed in San Cecilio Hospital, Granada (Spain) from November 2017 to May 2019. Sixty-two women with SSc were enrolled in this study. All patients included in this study had normal serum creatinine (Cr) levels and met the 2013 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criteria for SSc. Echocardiograms were performed at a single clinical site using Philips ie33 ultrasound machine with subjects in the left lateral decubitus position. Serum FGF23 was analyzed using ELISA.
Results: A total of 62 female patients were included in our study, with a mean (SD) age of 53 ± 10 years. The majority were Caucasian (90.5%). The mean disease duration was 8.8 ± 6.9 years. Forty-four (70.9%) patients had a limited form of the disease and 18 (29.1%) had a diffuse form. The mean left ventricular posterior wall thickness and left ventricular systolic diameter were 8.1±1.3 mm and 25.3±4.8 mm, respectively. We found a statistically significant inverse relationship between FGF23 and posterior wall thickness (r= -0.34; p= 0.03) and a statistically significant relationship between FGF23 and left ventricular systolic diameter (r= 0.5; p= 0.03) in women with SSc. Furthermore, in the linear regression model, lower FGF23 concentrations were associated with greater posterior wall thickness [β = -15.11 95% CI (-29.38, -0.848); $p < 0.05$].
Conclusion: We report an association between circulating FGF23 and left ventricular posterior wall thickness in SSc female patients, representing a novel pathway linking FGF23 to an increased cardiovascular risk.

THE HETEROGENEITY OF DEFINING SEVERITY, PROGRESSION AND OUTCOMES IN SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: RESULTS FROM A SYSTEMATIC LITERATURE REVIEW

Keywords: Outcome measures, Systemic sclerosis, Lungs

L. Petelytska[1,2], F. Bonomi[3], C. Cannistrà[3], E. Fiorentini[3], S. Peretti[3], S. Torracchi[3], P. Bernardini[3], C. Coccia[3], R. De Luca[3], A. Economou[3], J. Levani[3], M. Matucci-Cerinic[3,4], O. Distler[1], C. Bruni[1,3]. Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Milano, Italy*

Background: The course of systemic sclerosis associated interstitial lung disease (SSc-ILD) is highly variable. The SSc-ILD progression (SILPRO) project aims at developing a disease specific model to define SSc-ILD progression predicting long-term, severe SSc-ILD. The evaluation of currently used definitions of severity, progression and outcomes recorded in SSc-ILD represents the highly needed first step to achieve this aim.
Objectives: To identify definitions of progression, severity and outcomes related to SSc-ILD in the literature.
Methods: A systematic literature review was conducted according to PRISMA guidelines in Medline, EMBASE and the Cochrane Library up to 31/12/2021. Eligible papers included > 10 adult SSc patients, with ILD as primary target (at least one of population, exposure, outcome). Original papers in English were considered, while papers related to secondary lung involvement, ILD onset as an outcome or reviews were excluded. Two reviewers independently identified eligible studies and extracted data, including the abovementioned definitions used.
Results: We identified 299/8444 eligible papers, mostly reporting results of retrospective cohort studies (n=126, 42%), prospective cohort studies (n=120, 40%) and randomized clinical trials (n=24, 8%). A definition of SSc-ILD severity was included in 138 (46%) papers: it was based on high-resolution computed tomography (HRCT) data in 72 (52%) studies, on forced vital capacity (FVC) changes in 29 (21%), on combined FVC and carbon monoxide diffusing capacity (DLCO) changes in 14 (10%), on DLCO changes in 11 (8%). After combining some similar categories, 42 distinct definitions of SSc-ILD severity were identified (Figure 1 shows the most used).

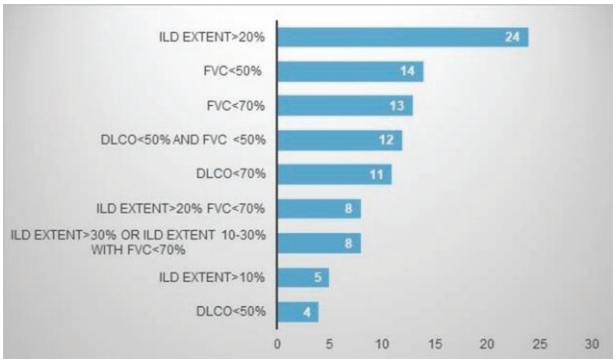

Figure 1. Most commonly used definitions of SSc-ILD severity (n papers).

Sixty-one of 169 studies (36%) provided a definition of SSc-ILD "progression" referred to combined DLCO and FVC changes, 49 (29%) to FVC changes, 23 (14%) to DLCO changes, 18 (11%) to ILD extent on HRCT, 6 (4%) to combination of pulmonary function test (PFT), clinical signs and HRCT data, 5 (3%) to vital capacity decline, 5 (3%) to combination of PFT and HRCT data and 2 (1%) to other aspects (Table 1).
Conclusion: The studies reporting a definition of SSc-ILD "progression", "severity" and "outcome" show a large heterogeneity. These results emphasize the need for developing a standardized, consensus definition of severe SSc-ILD, to link a disease specific definition of progression as a surrogate outcome for clinical trials and clinical practice.

Background: Systemic sclerosis (SSc) is an immune-mediated disease, which affects mostly women over 50 years old. Recently, single cell mRNA sequencing techniques (scRNA-seq) have contributed to establish the relevance of different immune cell types in SSc. However, little is known about the diversity of the peripheral blood monocytes, which play a central role in the early inflammatory response and in the maintenance of inflammation in SSc.
Objectives: Our aim is to analyze the composition of the peripheral blood monocyte compartment of SSc patients and to establish disease and subtype specific transcriptomic profiles at the single cell level.
Methods: CD14+ monocytes were isolated from peripheral blood mononuclear cells (PBMC) of 8 SSc diagnosed women and 8 age matched unaffected females. All the patients were between 50 and 70 years old and classified as either limited cutaneous SSc (lcSSc) or diffuse cutaneous SSc (dcSSc). ScRNA-seq libraries were generated using the 10x Genomics Chromium platform and the Chromium Next GEM Single Cell 5' Reagent Kits. After QC a total of 98,543 cells remained, with an average of ~7,000 cells per sample and 36,601 detected genes. Dimensionality reduction and cell clustering were performed using Scanpy, establishing 5,000 high variable genes and 20 principal components to implement the Leiden clustering algorithm.
Results: We identified 11 different clusters in the SSc combined analysis of the single cell transcriptomes from both the SSc patients and the controls. Using known genes and cell markers, we identified classical monocytes, non-classical monocytes and intermediate monocytes, and a dendritic cell population (Figure 1.). Non-classical monocyte populations were under-represented in SSc patients. Overall, we observed a proinflammatory profile in SSc CD14+ monocytes, which overexpressed genes related to the interferon signaling pathways, such as *IFITM2*, *IFITM3* or *IRF1*, but also *S100* family genes. This proinflammatory profile is especially enriched in the activated monocyte clusters, i.e. those with high expression of *S100A8*/*S100A9* genes. Additionally, we identified the overexpression of *TMEM176A* and *TMEM176B in* lcSSc patients compared to dcSSc patients and controls.

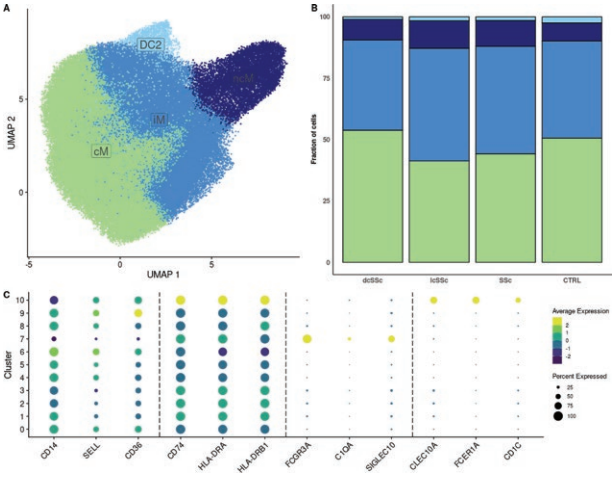

Figure 1. Monocyte subtype population in SSc. (A) UMAP visualization of monocyte CD14+ isolated from PBMCs sample of SSc and controls. (B) Proportion of cells of each monocyte subtype. (C) Dotplot of genetic and cell markers of monocyte subtype per cluster. The dot size indicates the number of cells expressing the gene in the cluster and the color the average of expression.

Conclusion: Our analysis of peripheral blood CD14+ monocytes in SSc patients showed an overrepresentation of non-classical monocytes and an increased interferon response compared to healthy controls. Moreover, we found subtype specific transcriptomic profiles, which suggested the possible use of monocyte subtypes as SSc biomarkers.

Background: Systemic sclerosis (SSc) is a severe, progressive multisystem rheumatic disease with high mortality, but without approved disease-modifying treatment to stop or reverse course of disease. Intravenous immunoglobulin G (IgG) may have a positive impact on SSc based upon available literature reports. However, to date, there have been no clinical trials evaluating subcutaneous IgG (SCIG) in SSc. In particular, the impact of pathologically altered skin in SSc on local safety and pharmacokinetics (PK) of SCIG has not been explored yet.

Objectives: The primary and secondary objectives of this trial (NCT04137224) included safety, including local infusion safety, and bioavailability of subcutaneous IgG (IgPro20) in adults with diffuse cutaneous SSc (dcSSc).

Methods: This was a randomized, open-label, crossover study. Adult subjects with dcSSc diagnosis within 5 years from first non-Raynaud's phenomenon and modified Rodnan Skin Score of 15-45 at screening were randomized 1:1 to sequence A (IgPro20, 20% normal human subcutaneous immunoglobulin followed by IgPro10, 10% normal human intravenous immunoglobulin) or sequence B (IgPro10 followed by IgPro20). Each subject was to complete two treatment periods (16 weeks each), with up to 40 weeks (including screening) study duration for an individual subject. Doses received were 0.5g/kg/week split over two sessions for IgPro20, and 2g/kg/4 weeks split over 2-5 days for IgPro10. The primary endpoint was safety of IgPro20, described as treatment-emergent adverse events (TEAEs) and changes in clinical observations.

Results: 27 subjects were randomized, with 13 subjects to sequence A and 14 subjects to sequence B. In total, 25 subjects completed the study. Of 27 treated subjects, 107 TEAEs occurred in 22 subjects (81.5%) over the 36-week study period, the majority of which were mild or moderate. The most common TEAEs (>10% of subjects) by preferred term (PT) were headache (12 events occurring in 6 subjects [22.2%]), COVID-19 (3 events occurring in 3 subjects [11.1%]), diarrhoea (3 events occurring in 3 subjects [11.1%]), and vomiting (3 events occurring in 3 subjects [11.1%]). A total of 10 serious AEs (SAEs) were reported in 6 subjects (Viral infection, Chronic gastritis, Vomiting, Dehydration, Upper gastrointestinal haemorrhage, Chest pain, Myocardial infarction, Myocardial ischemia, Breast cancer, Interstitial lung disease). Among these, one subject experienced 2 SAEs (myocardial ischemia & myocardial infarction) and was discontinued from study treatment. None of the SAEs were considered related to study treatment by the investigator, and no deaths were reported. For IgPro20, 14 infusion site reactions (ISRs) occurred in 5 subjects (19.2%), all were mild or moderate in severity. The most common ISRs were infusion site pain and infusion site swelling (3 events in 2 subjects each, 7.7%). In total, 686 IgPro20 infusions were performed, resulting in an overall ISR rate per infusion of 0.02, ie 2 ISRs per 100 infusions. No ISRs were reported for IgPro10. No clinically relevant trends in vital signs, body weight, clinical laboratory tests, electrocardiograms, or pulmonary function tests were observed. PK profiles and bioavailability in dcSSc subjects were similar to those observed in other approved indications such as Primary Immunodeficiency. Population relative bioavailability of IgPro20, based on dose-normalized, baseline-corrected $AUC_{0\text{-}tau}$ was 0.761 (90% CI: 0.7033, 0.8232), ie 76.1% compared to IgPro10 (intravenous IgG).

Conclusion: The overall safety profiles of IgPro20 and IgPro10 in subjects with dcSSc were consistent with that in approved indications such as CIDP, including a relatively low ISR rate for IgPro20. PK profiles and bioavailability were also similar to other indications. This study indicates that subcutaneous administration of IgPro20 has acceptable safety, bioavailability and PK profiles in patients with dcSSc.

Antovic[6]. *[1]Institute of rheumatology, Department of Rheumatology Unit, Belgrade, Serbia*; *[2]Karolinska Institute, Department of Molecular Medicine and Surgery, Stockholm, Sweden*; *[3]Medigroup Private Hospital, Department of Rheumatology Unit, Belgrade, Serbia*; *[4]Faculty of Medicine, University of Belgrade, Belgrade, Serbia*; *[5]Karolinska Institute, Department of Molecular Medicine and Surgery, Clinical Chemistry - Coagulation, Stockholm, Sweden*; *[6]Karolinska Institute, Department of Medicine, Rheumatology Unit, Stockholm, Sweden*

Background: Extracellular vesicles (EVs) are membrane-coated vesicles derived from virtually any cell type under different stimuli. Interstitial lung disease (ILD) is the leading cause of death in SSc. So far, only one study demonstrated elevated levels of EVs in patients with SSc-ILD (1), however the association between EVs and progressive ILD (pILD) was not previously investigated.
Objectives: To evaluate the concentration of different subpopulations of EVs in plasma from SSc patients in relation to the occurrence of pILD associated to SSc.
Methods: This was a prospective cohort study, including 59 SSc patients without any comorbidity (31 (52.5%) with ILD and 28 (47.5%) without).The median disease duration in ILD group was 3 years and 6 years in those without. ILD was defined either as X-ray positive findings or ground-glass opacification on HRCT. EVs were analyzed with flow cytometry after staining of platelet-poor plasma with fluorescent cell-specific monoclonal antibodies. The concentration of the following phosphatidylserine-positive EVs was analyzed at baseline: endothelial EVs (EEVs; $CD144^+$), platelet EVs (PEVs;$CD42b^+$), leucocyte EVs (LEVs; $CD45^+$), EVs expressing ICAM1 ($CD54^+$), TF ($CD142^+$) and HMGB1. The serum concentration of ICAM1,VEGF,and IL6 were measured by ELISA. Lung functional tests were done every 6-12 months over a 3-years period of follow-up (FU). pILD was defined by the decline of forced vital capacity (FVC) from baseline visit of ≥10%, or an FVC decline of 5-9% along with a DLCO decline of >15% [2].
Results: An inverse relation was noticed in SSc patients between EVs and FVC (EEVs r=-0.3, p<0.05; LEVs r=-0.4, p<0.01; EVsICAM1r=-0.4, p<0.01; EVsTF r=-0.4, p<0.01; EVS HMGB1r=-0.3, p<0.05). Significantly increased levels of VEGF, ICAM1, IL6, PEVs, and EVs expressing ICAM1, TF or HMGB1 were found in SSc ILD cohort compared to those without (p<0.05, respectively). There was a positive association between all explored EVs and VEGF in ILD group (p<0.05). Multivariable (Ml) logistic regression (R), adjusted for VEGF raveled that PEVs(OR 1.004, 95%CI 1.001-1.01) and EVs ICAM1 (OR 1.3, 95%CI 1.1-1.5) were independently associated with ILD. Over a FU period, 12/31ILD patients developed pILD, of which 58% had early diffuse subtype with < 1-year disease duration and were anti Scl 70 positive. Only 4/12 pILD patients have ever been treated with imunossupresive therapy. pILD occurred within 1st FU year in 50% of patients. All analyzed EVs (Figure 1), IL6 and VEGF, were found elevated in pILD (p<0.05, respectively). Moreover, the levels of PEVs, EVs expressing ICAM1 (AUC 0.9, p<0.001, respectively),TF, HMGB1, EEVs and LEVs (AUC 0.7, p<0.05, respectively) showed good validity in identifying pILD. There was only a positive correlation between VEGF and both EVs ICAM1 (r=0.8, p<0.01) and EVs HMGB1 (r=0.7, p<0.01) within pILD group. Applying Ml Cox R controlling for VEGF, EVs ICAM1 were confirmed independently significantly associated with pILD (OR 1.1, 95% CI 1.02-1.1).
Conclusion: Our results provide evidence that different circulating EV subpopulations might play a role not only in SSc ILD pathogenesis but also in the genesis of pILD. EVs expressing ICAM1 could be a novel predictive biomarker of SSc-related ILD progression, identifying patients who would potentially benefit from early aggressive treatment.

INFLAMMATORY ACTIVITY IS ASSOCIATED WITH INCREASED RISK OF SARCOPENIA IN SYSTEMIC SCLEROSIS

Keywords: Sarcopenia, Systemic sclerosis

L. Cano Garcia[1], N. Al Mashhadani[1], R. Redondo[1], M. Morales-Águila[1], G. Diaz-Cordobes[1], S. Manrique Arija[1]. [1]*Hospital Regional Universitario de Málaga; Instituto de Investigación Biomédica de Málaga (IBIMA)., Rheumatology, Málaga, Spain*

Background: Sarcopenia is a muscular condition characterized by loss of skeletal muscle mass and function. It is a condition associated with chronic diseases and aging that predicts disability, hospitalization and death.
Objectives: To describe the prevalence of sarcopenia and its associated factors in a series of patients with Systemic Sclerosis (SSc).
Methods: Design: Cross-sectional descriptive study. Participants: consecutive recruitment of patients with SSc (ACR/EULAR 2013 criteria) followed up in our unit. Follow-up of these patients is carried out every 3 to 6 months in consultation and all patients were registered in a database. 90% of the patients accepted and signed the consent, the rest refused due to travel or work difficulties. Variables: The main variable was sarcopenia defined according to the European Working Group on Sarcopenia in Older People (EWGSOPII) criteria and severe sarcopenia, which according to EWGSOPII criteria also includes physical performance in the 4-meter walk test. Clinical and analytical data were collected, as well as Mini Nutritional Assessment (MNA) nutrition questionnaires (continuous: 0-14, considering 14 better nutritional status), physical activity assessed by GPAQ, polypharmacy (if they take >3 drugs) and functional grade of Steinbrocker. Statistical analysis: descriptive and two logistic regression models to identify factors associated with sarcopenia and severe sarcopenia.
Results: 52 patients were included, of whom 51 (98.1%) were women, with a mean (SD) age of 60.8 (11.0) years. A total of 12/52 patients (23.1%) had sarcopenia and 6/52 patients (11.5%) had severe sarcopenia (Table 1). Compared to the rest, patients with sarcopenia had anti-Scl70 antibodies more frequently (41.7% vs 12.5%; p=0.030) and were polymedicated (87.5% vs 60.0%; p=0.022). Likewise, patients with sarcopenia had worse mean (SD) values in the Steinbrocker functional class (2.58 [1.24] vs 1.75 [0.89]; p = 0.040). Patients with severe sarcopenia had lower mean (SD) values of prealbumin (19.2 [3.3] vs 21.6 [4.7]; p = 0.001) and were more frequently dependent at home than the rest (16.7% vs. 2.5%; p=0.03). In addition, a greater number (%) of patients with severe sarcopenia had an inability to perform the physical function tests of the chair and the balance test compared to the rest of the sample (50% vs 13.3%; p=0.05) and (66.7% vs. 8.9%; p=0.05), respectively. The multivariate analysis identified that the only variable associated with sarcopenia in patients with SSc was CRP (OR [95% CI], 1.125 [1.037-1.220]; p=0.004) (R2=0.282). Similarly, CRP was also independently associated with severe sarcopenia (OR [95% CI], 1.240 [1.081-1.423]; p=0.002) (R2=0.314).
Conclusion: Sarcopenia is linked to inflammatory activity in SSc. This comorbidity has serious consequences for functionality and independence, which is why prevention and early detection of sarcopenia and its associated factors is important.

Table 1. Clinical-epidemiological characteristics of the 52 patients in SSc

Variable	ES n=52
Woman n (%)	51 (98,1%)
Age mean (SD)	60,8 (11,0)
Limited skin patern n (%)	40 (76,9%)
Disseminated skin patern n (%)	12 (23,1%)
DILD n (%)	17 (32,7%)
HTAP n (%)	5 (9,6%)
Anti-Centrómere antibodies n(%)	28 (53,8%)
Anti-Sl70 antibodies n (%)	10 (19,2%)
Other antibodies n (%)	9 (17,3%)
Sarcopenia n(%)	12 (23,1%)
Severe sarcopenia n(%)	6(11,5%)
MNA Normal nutritional status n (%)	34 (64,5%)
MNA Risk of malnutrition n (%)	17 (32,7%)
MNA malnutrition n (%)	1 (1,9%)
Weight loss >1kg in the last 3 months n(%)	25 (48,1%)
Polypharmacy n(%)	12(23,1%)
Steinbrocker mean (SD)	1,94 (1,03)
GPAQ mean (SD)	669,5 (666,9)
Prealbúmina mean (SD)	21,41 (4,63)

CARDIAC MAGNETIC RESONANCE IN ANTI-SYNTHETASE SYNDROME: THE ADDITIONAL VALUE OF T2 MAPPING TO DETECT MYOCARDITIS

Keywords: Heart, Imaging, Cardiovascular disease

G. De Luca[1], C. Campochiaro[1], A. Ferlito[1], G. Peretto[2], A. Palmisano[3], A. Esposito[3], L. Dagna[1]. [1]*Vita-Salute San Raffaele University & San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy & Rare Diseases, Milan, Italy*; [2]*Vita-Salute San Raffaele University & San Raffaele Hospital, Arrhythmology, Milan, Italy*; [3]*Vita-Salute San Raffaele University & San Raffaele Hospital, Radiology - CMR Unit, Milan, Italy*

Background: Myocarditis can be a subtle and underdiagnosed manifestation of anti-synthetase syndrome (ASS), and its occurrence is associated with a poor prognosis. Cardiac magnetic resonance (CMR) is the diagnostic modality of choice for the non-invasive diagnosis of myocarditis, which historically relies on the 2009 Lake Louise Criteria (LLC) [1]. LLC, however, have a low diagnostic accuracy in patients with coexisting myositis.
Objectives: To investigate the performance of the mapping techniques included in the revised LLC [2] for the identification of ASS myocarditis.
Methods: CMR data (right and left ventricular function and morphology, early and late gadolinium enhancement [LGE], T2 ratio, and T1 mapping, extracellular volume [ECV] and T2 mapping) of ASS patients diagnosed with myocarditis were reviewed. Myocarditis was clinically defined by the presence of signs and/or symptoms of ASS heart involvement with increased high-sensitive troponin T (hs-TnT) and/or NT-proBNP serum levels and at least an abnormality at 24 h ECG Holter and/or echocardiography and/or CMR.
Results: We identified 11 patients (mean age 58 ±13 years; females 45%; anti-Jo1 55%, antiPL-7 27%) with ASS myocarditis. Dyspnea was the most frequently reported symptoms (64%), 4 patients (36%) had echocardiographic abnormalities, while 24-hour-ECG Holter was normal in all patients. At baseline, troponin T levels were raised in all but 1 patient (mean value 461 ±351 ng/L), while NT-proBNP levels were raised in 45% of patients (mean value 1802 ±1484 pg/mL). All patients had at least one CMR abnormality: increased ECV in all patients, LGE in 10 (91%), and T2 mapping >50 ms in 10 (91%). Median T1 and T2 mapping were 1079 [range 906-1172] ms and 53.2 [range 48.8-57.4] ms, respectively. No statistical significant correlation emerged between CMR parameters (T1 mapping, T2 mapping and ECV) and disease parameters (troponin, NTproBNP, CPK levels and inflammatory markers). Six patients satisfied the 2009 LLC, 10 the 2018 LLC. With the new criteria including T2 mapping, the sensitivity improved from 54% to 91%.
Conclusion: The CMR mapping techniques improve the sensitivity to detect myocardial inflammation in patients with ASS-related heart involvement. The evaluation of T2 mapping increases diagnostic accuracy for the recognition of myocardial inflammation in ASS and should be always performed in ASS patients with suspected myocarditis.

Background: Heart involvement is one of the leading causes of death in systemic sclerosis (SSc). Cardiac manifestations are heterogeneous. In particular, prevalence of SSc-related cardiopathy is poorly known due to a lack of consensus in its definition.
Objectives: Our objective was to investigate the prevalence and prognosis burden of the different heart diseases in a nationwide cohort of patients with SSc.
Methods: We used data from a national multicentric prospective study using the French SSc national database. We described the characteristics of 3 different types of heart involvement: SSc-related cardiopathy, pulmonary arterial hypertension and ischaemic heart disease. We analyzed overall survival and survival according to the heart disease. Focusing on SSc-related cardiopathy, we aimed to determine its incidence and risk factors.
Results: Over the 3528 patients with SSc available for baseline analyses 312 (10.9%) had SSc-related cardiopathy at baseline. They tended to have a diffuse SSc subtype more frequently, had more severe clinical features, and presented more cardiovascular risk factors. From the 1646 patients available for follow-up analysis, SSc-related cardiopathy was associated with an increased risk of death. No significant difference of overall survival was found between SSc-related cardiopathy, ischaemic heart disease or pulmonary arterial hypertension. Concerning survival analysis, 98 patients developed SSc-related cardiopathy at 5 years (5-year event-rate: 11.15% [9.01; 13.23]). Regarding reduced LVEF < 50% and left ventricular diastolic dysfunction, the 5-year event-rate were 2.49% [CI95%: 1.13; 3.83] and 5.84% [CI95%: 4.02; 7.62], respectively. The pericarditis cumulative incidence at 5 years was 3% [CI95%: 1.91; 4.08]). Diffuse SSc subtype was a risk factor of SSc-related cardiopathy and pericarditis (adjusted HR: 1.42 [CI95%: 1.02; 1.97], p = 0.04 and adjusted HR: 1.79 [CI95%: 1.06; 3.02], p = 0.03, respectively). Female sex was associated with less diastolic dysfunction incidence (adjusted HR: 0.39 [CI95%: 0.24; 0.63], p = 0.0001).
Conclusion: Our results further describe at a large scale the incidence and prognostic burden of SSc-related cardiopathy, with gender and diffuse SSc subtype as risk factors. Further analyses should assess the potential impact of treatment on these various cardiac outcomes.

MYOCARDIAL INVOLVEMENT CHARACTERIZES EARLY SYSTEMIC SCLEROSIS WITH ANTI-SCL70 ANTIBODIES AND LONGSTANDING DISEASE WITH ANTI-CENTROMERE ANTIBODIES

Keywords: Systemic sclerosis, Autoantibodies, Heart

M. De Santis[1], A. Tonutti[1], F. Motta[1], S. Rodolfi[1], L. Monti[2], M. Francone[2], C. Selmi[1]. [1]*IRCCS Humanitas Research Hospital and Humanitas University, Rheumatology and Clinical Immunology, Rozzano, Milan, Italy*; [2]*IRCCS Humanitas Research Hospital and Humanitas University, Cardiovascular Imaging, Rozzano, Milan, Italy*

Background: Myocardial involvement is frequently asymptomatic at the early stages in systemic sclerosis (SSc) but accounts for one-third of SSc-related deaths [1]. First-line screening tools include cardiac enzymes, Holter ECG, and echocardiography [2,3], while the diagnosis relies largely on cardiac magnetic resonance [4], assessing myocardial inflammation and fibrosis [5]. The prevalence of SSc myocardiopathy and the associated factors are poorly defined [2].

Objectives: To evaluate the prevalence of myocardiopathy and the associated demographic, clinical, and instrumental features in a single center cohort of 317 SSc patients, including 49 (15%) early SSc, 66 (21%) anti-Scl70+, 178 (56%) anti-centromere (ACA)+, 45 (14%) diffuse, 99 (31%) ILD, 37 (12%) with pulmonary hypertension.

Methods: Retrospective analysis; myocardiopathy in SSc was defined as increased myocardial tissue to skeletal muscle T2 ratio, T2 TIRM or delayed enhancement areas, or increased T1 or T2 mapping native time at cardiac magnetic resonance [6].

Results: Forty-two SSc patients underwent cardiac magnetic resonance after developing symptoms (dyspnea, atypical angor, palpitations; 43%), elevated cardiac enzymes (55%), or Holter ECG alterations (38%). Myocardiopathy was detected in 29/42 patients (69%; 29/317, 9.2%). Early disease was significantly more frequent in patients with myocardiopathy (17/29, 59%; OR 7.8, 95% CI 1.45-41.7); 17/49, 35% considering early SSc in the whole cohort). Among patients with myocardiopathy, anti-Scl70 was more frequently observed in early compared to longstanding disease (9/17, 53% vs. 2/12, 17%; p = 0.05); the opposite was for ACA (4/17, 24% vs. 7/12, 58%; p = 0.06) (Figure 1). Clinical characteristics did not differ among patients with and without myocardiopathy, except digital ulcers (Table 1). Serum troponin I (TnI) was higher in patients with myocardiopathy (median 6 vs 1.6 ng/L; p = 0.049). Relevant alterations on Holter ECG, especially premature ventricular contractions (PVC) > 300/day, were observed more frequently in patients with myocardiopaty (p = 0.04 for both; Table 1).

Conclusion: We report a relevant overall prevalence of myocardiopathy in a cohort of SSc patients, similar pulmonary hypertension, affecting one third of patients with early SSc, especially with anti-Scl70. Conversely, a delayed onset of myocardiopathy was associated with ACA. Among other predictors, higher serum troponins and Holter ECG alterations, especially PVC, were significantly associated to myocardiopathy. As the early suspicion and diagnosis of myocardiopathy are crucial for promptly starting immunosuppressive treatment, we submit that the risk stratification should be performed in patients with SSc.

Background: Systemic sclerosis (SSc) is characterized by vasculopathy, inflammation and fibrosis, and carries one of the worst prognoses if patients also develop pulmonary arterial hypertension (PAH). Although PAH is a known prognostic factor, SSc-PAH patients demonstrate disproportionately high mortality, presumably due to cardiac involvement [1].
Objectives: To investigate the relation between cardiac involvement as revealed by Cardiovascular Magnetic Resonance (CMR) and systemic microvascular disease severity as measured with nailfold capillaromicroscopy (NCM) in SSc-PAH patients, compared to idiopathic PAH (IPAH) patients.
Methods: SSc-PAH and IPAH patients underwent CMR, transthoracic echocardiography (TTE), and NCM with post-occlusive reactivity hyperemia (PORH) testing on the same day [2-4]. CMR imaging included T2 mapping, native and postcontrast T1 mapping, to assess edema and fibrosis, and adenosine-stress perfusion imaging to measure the relative myocardial upslope (to determine microvascular coronary perfusion). Measures of peripheral microvascular function were related to CMR indices of edema, fibrosis and myocardial perfusion.
Results: SSc-PAH patients (n=20) had higher extracellular volume fraction (ECV) and T2 values than IPAH patients (n=5), and lower nailfold capillary density (NCD) and reduced capillary recruitment after PORH. NCD correlated with native T1, ECV, and T2 values (r=-0.431, -0.443, and -0.464, respectively, p<0.05 for all), and with markers of diastolic dysfunction on echocardiography. Furthermore, PORH-testing, but not NCD, correlated with the relative myocardial upslope by stress CMR (r=0.421, p<0.05) (Table 1).

Table 1. Nailfold capillaroscopy with post occlusive hyperemia reactivity testing

	SSc-PH (n=20)	IPAH (n=5)	p-value
Average capillary density (n/mm)	4 [3-6]	10 [10-11]	**<0.001**
Pattern (n)			
Normal	0	4 (80%)	
Non-specific	0	1 (20%)	
Systemic sclerosis: early pattern	1 (4%)	0	
Systemic sclerosis: active pattern	1 (4%)	0	
Systemic sclerosis: late pattern	18 (72%)	0	
Post-occlusive reactivity hyperemia testing			
Rest (n/mm^2)	55 [39-73]	93 [80-97]	**0.006**
Average capillaries after PORH (n/mm^2)	53 [46-77]	100 [81-120]	**0.006**
Total recruitment of capillaries (n/mm^2)	1 [-4-5)	23 [-3-27)	**<0.05**
Average capillaries at venous congestion (n/mm^2)	55 [50-78]	106 [81-126]	**0.006**
Total recruitment of capillaries (n/mm^2)	5 [1-11]	11 [-9-30]	0.613

Values are in medians [interquartile range] or number (%).*Abbreviations:* NT-proBNP, N-terminal pro-Brain Natriuretic Peptide; POHR, post-occlusive reactivity hyperemia test

Conclusion: SSc-PAH patients showed higher markers of cardiac fibrosis and inflammation, compared to IPAH patients. These markers correlated well with peripheral microvascular dysfunction, suggesting that SSc-driven inflammation and vasculopathy concurrently affect peripheral microcirculation and the heart. This may contribute to the disproportionately high mortality in SSc-PAH patients.

Department of Clinical Sciences Lund, Section for Rheumatology, Lund University and Skåne University Hospital, Lund, Sweden; [5]Karloinska Institutet, Rheumatology Division, Department of Medicine Solna, Stockholm, Sweden

Background: Systemic sclerosis (SSc) is a connective tissue disease with multiple organ manifestations including cardiac involvement. Several studies have reported arrhythmias and conduction defects to be frequent in patients with SSc, however with considerable limitations such as the lack of comparison group or of stratified analyses by arrhythmia subtypes in some studies in addition to some study populations being highly selected from tertiary care centres.
Objectives: To explore the incidence of cardiac arrhythmias and its different subtypes in an unselected national cohort of patients with SSc compared to a matched cohort from the general population in Sweden.
Methods: We used nationwide Swedish registers to identify patients with incident SSc diagnosed between 2004 and 2015 in addition to comparators from the general population (1:5), matched on sex, birth year and residential area. We excluded those with a history of arrhythmia prior to start of follow-up. The primary outcome was the first ICD-coded visit indicating arrhythmia. Follow-up started from the date of SSc diagnosis, the same date was assigned to the respective comparators, until the primary outcome, death, emigration, or the end of 2016. We estimated the incidence rate of arrhythmias overall and stratified by subtype of arrhythmia in both patients with SSc and their comparators. We estimated incidence rate ratios (IRRs) using poisson regression models and time-varying hazard ratios (HRs) using flexible parametric models.
Results: We identified 1049 patients with SSc and 5147 matched comparators with no prior history of arrhythmia. The median follow-up was 4.7 years in patients with SSc and 5.8 years for the comparators. The incidence rate of arrhythmias overall was 216.5 per 10,000 person-years (95% CI 179.8-258.5) in patients with SSc and 106.6 (95% CI 95.5-118.7) in the comparators corresponding to IRR of 2.0 (95% CI 1.7-2.5). Table 1 demonstrates the incidence rates and IRRs stratified by arrhythmia subtypes. The HR of arrhythmia overall in patients with SSc compared to the comparators decreased gradually during follow-up; 3.0 (95% CI 2.2-4.1) at the end of the first year of follow-up, 1.9 (95% CI 1.4-2.5) at the end of the fifth year of follow-up, and 1.3 (95% CI 0.8-2.3) at the end of the 10th year of follow-up.
Conclusion: Patients with SSc have higher incidence rate of arrhythmia overall compared with matched comparators from the general population.

Table 1. Incidence rates of arrhythmias in patients with SSc and in general population comparators, overall and stratified by arrhythmia subtypes. Incidence rate ratios are estimated using poisson regression models.

POS1287

KL6 AND IL-18 LEVELS ARE NEGATIVELY CORRELATED WITH RESPIRATORY FUNCTION TESTS AND ILD EXTENT ASSESSED ON HRCT IN PATIENTS WITH SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE (SSC-ILD)

Keywords: Biomarkers, Lungs, Systemic sclerosis

C. Sieiro Santos[1], S. Calleja Antolín[2], J. De la Calle Lorenzo[3], C. López Garay[4], C. Moriano[1], E. Bollo de Miguel[4], E. Diez Alvarez[1]. *[1]Complejo Asistencial Universitario de León, Rheumatology, León, Spain; [2]Complejo Asistencial Universitario de León, Immunology, León, Spain; [3]Complejo Asistencial Universitario de León, Radiology, León, Spain; [4]Complejo Asistencial Universitario de León, Pneumology, León, Spain*

Background: Interstitial lung disease (ILD) is one of the leading causes of mortality in patients with systemic sclerosis (SSc). Serum biomarkers have been suggested as indicators for pulmonary damage with clinical value in the diagnosis and prognosis of SSc-ILD.
Objectives: To investigate the role of serum biomarkers (Krebs von den Lungen-6 KL-6, IL-18 and IL-18BP) as potential biomarkers reflecting the severity of SSc-ILD as assessed through high-resolution computed tomography (HRCT) and pulmonary function tests (PFT), including forced vital capacity (%FVC) and diffusing capacity of the lung for carbon monoxide (%DLCO).
Methods: A cross-sectional study including patients with SSc fulfilling the 2013 ACR/EULAR criteria was performed. Patients were classified according to disease duration and pulmonary involvement (presence of ILD). All SSc patients underwent chest HRCT scans and pulmonary function test at baseline. Serum concentration of KL-6, IL8 and IL18BP were determined using sandwich ELISA technique (solid phase sandwich Enzyme Linked-Immunosorbent Assay), with kits from MyBiosource for KL-6 and from Invitrogen for IL18 and IL18BP. A semiquantitative grade of ILD extent was evaluated through HRCT scan (grade 1, 0–20%; grade 2, >20%). Extensive lung disease was defined as >20% of lung involvement on HRCT, and FVC <70% predicted and limited lung involvement as ≤20% of ILD involvement on HRCT, and an FVC ≥70% predicted.
Results: 74 patients were included, 27% were male. The mean age at diagnosis was 57.5±15 years. The mean time since diagnosis was 7.67±8 years. 28 patients had ILD (38%). 64 % of patients had <20% of ILD extent classified through HRCT scan. SSc-ILD patients had elevated serum KL-6 and IL-18 levels compared to patients without ILD (p=0.003 and p=0.04), and those findings were preserved after adjusting for age and sex (Table 1). Mean erythrocyte sedimentation rate (ESR) was higher in patients with SSc-ILD. A negative correlation between KL-6 levels and %FVC (β=-0.25, p 0.037) and %DLCO (β=-0.28, p 0.02) and between IL-18 levels and %FVC (β=-0.20, p 0.03) and %DLCO (β=-0.14, p 0.04) were found. Linear regression models representing correlation between KL-6 and PFT are represented in the scatter plot in Figure 1. Serum KL-6 and IL-18 levels successfully differentiated grades 1 and 2 (p = 0.028 and p=0.021). Semiquantitative grades of ILD on the HRCT scan were significantly proportional to the KL-6 (p 0.01) and IL-18 (p=0.03). A positive correlation between extensive lung disease and KL-6 (β=0.61, p 0.007) but not with IL-18 was found.
Conclusion: Serum KL-6 levels and IL-18 were increased in patients with SSc-ILD and showed a positive correlation with ILD severity as measured using a semiquantitative HRCT grading scale and a negative correlation with PFT parameters. KL-6 is positively correlated with extensive lung disease. Serum KL-6 and IL-18 could be a clinically useful biomarker in screening and evaluating SSc-ILD.

Table 1 : Demographic and clinical characteristics of patients with SSc-ILD and non-SSc-ILD.

	ILD (28)	ILD (-) (46)	P value
Mean age, years	57.3±16	57.7±28	0.97
Sex, male	6 (21%)	13 (28%)	0.51
Mean ESR (mm/h)	23±16	9±8	**0.04**
Mean CRP (mg/dL)	7.1±4.3	5.03±3.25	0.36
Serum KL-6 (U/mL)	320±68	262.5±39	**0.003**
Serum IL-18BP (U/mL)	150.46±130	123.23±90	0.21
Serum IL-18 (U/mL)	300.63±167	209.65±180	**0.03**
Pulmonary function tests	96.2±34	111±22.3	**0.01**
Mean FVC %	65.7±18	77.5±19.7	**0.001**
Mean DLCO%

PITFALLS WHEN ESTIMATING CAUSAL EFFECTS IN OBSERVATIONAL DATA: A SIMULATION STUDY BASED ON THE EUSTAR DATABASE

Keywords: Registries, Systemic sclerosis, Patient reported outcomes

E. Hensor[1], M. G. Lazzaroni[2], M. Wilson[1], M. Gilthorpe[3,4], F. Del Galdo[1].
[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; *[2]University of Brescia, ASST Spedali Civili of Brescia, Brescia, Italy*; *[3]Leeds Beckett University, The Obesity Institute, Leeds, United Kingdom*; *[4]Alan Turing Institute for Data Science and Artificial Intelligence, British Library, London, United Kingdom*

Background: To estimate the causal relationship between two variables it is important to first establish the potential causal pathways and to consider causes of bias. Omission of key confounders from the analysis, and biases introduced by selection processes and missing data, have the potential to yield coefficients that are smaller, larger, or even sign-reversed, compared to the true effect.

Objectives: To use simulation to illustrate the pitfalls of estimating causal effects in observational data, taking the relationship between forced vital capacity (FVC) and Health Assessment Questionnaire Disability Index (HAQ) in patients with Systemic Sclerosis (SSc) as an example.

Methods: We used a simplified directed acyclic graph (DAG) of the postulated causal pathways for simulation (Figure 1). The 8 nodes, some representing groups of variables, were: non-specific predisposing factors; SSc-specific predisposing factors; comorbidities; SSc; FVC; HAQ; selection; and non-missing data. Arcs (arrows) representing directed causal effects were drawn from earlier nodes in the pathway to each subsequent node. In statistical software [1] we drew the DAG and entered coefficients for each arc, informed in part by baseline descriptive data from ~17k patients in the EUSTAR registry (clinical project 96). We set a 'true' coefficient for the focal relationship between FVC and HAQ of -0.3; negative so that lower FVC would lead to higher HAQ. All variables were simulated to be continuous and all relationships were linear. We split the SSc variable at the 0.9997th and 0.9999th centiles to simulate three groups: no SSc, limited and diffuse SSc. We split the selection variable at the 1st or 3rd quartile to simulate weak selection (e.g. into the registry), or strong selection (e.g. into a clinical trial). We split the non-missing data variable at the 86th centile to simulate data missing not at random. We simulated 1000 datasets of N=76000000.

Results: Descriptive data from EUSTAR suggested that those with HAQ available were younger with shorter disease duration, higher rates of interstitial lung disease and lower rates of elevated systolic pulmonary pressure. In the simulated data, a regression model including all confounders (HAQ = FVC + SSc + Comorbidity + Specific + Non-specific) correctly estimated the coefficient for FVC in the population (median [95% simulation interval] -0.307 [-0.307 to -0.307]). Omitting confounders overestimated the coefficient by 5% to 28% depending which nodes were omitted. Including confounders, but sub-setting to include SSc only (-0.19 [-0.21 to -0.18]), to mimic weak (-0.18 [-0.20 to -0.17]) or strong selection (-0.17 [-0.20 to -0.15]) or to mimic both weak selection and missing data (-0.14 [-0.19 to -0.10]) underestimated the coefficient by 37% to 53%, although the model was correctly specified.

Conclusion: This simulation study illustrates the importance of considering the underlying causal pathways and potential biases when characterising relationships between key variables in observational datasets. Naïve analyses which do not account for confounding, selection bias and missing data can give misleading results. In this simplified example we might have concluded, in error, that the relationship between FVC and HAQ was weaker or stronger than it truly was. As we generated our own data, we knew the 'true' coefficient and the underlying data generating mechanisms. However, in practice we would know neither, but causal inference methods provide transparency as to the assumptions made during analysis and help identify any areas of concern. Careful consideration of the causal pathways to derive the appropriate model, and efforts to mitigate or remove sources of bias via study design and analysis, can improve accuracy and increase confidence in conclusions.

POS1289 MACHINE LEARNING ALGORITHM AS A USEFUL TOOL IN THE GREY AREA OF CARDIOPULMONARY MORTALITY IN SYSTEMIC SCLEROSIS

Keywords: Artificial intelligence, Cardiovascular disease, Systemic sclerosis

P. G. Cerasuolo[1], E. De Lorenzis[1,2], G. Natalello[1], L. Verardi[1], G. Alonzi[1], S. Fiore[1], A. Zoli[1], S. DI Murro[1], M. A. D'agostino[1], S. L. Bosello[1]. *[1]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy*; *[2]Scleroderma Program, Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Rheumatology Department, Leeds, United Kingdom*

Background: Prognosis of systemic sclerosis (SSc) patients is related to the presence of major internal organ involvement and specific autoantibody positivity. Cardiopulmonary complications are the leading cause of death in patients with SSc.
Objectives: The objective of the study is to evaluate the ability of an artificial intelligence algorithm based on laboratory and functional variables associated to SSc cardio-pulmonary involvement to predict the 5-year related mortality.
Methods: Laboratory and functional parameters of cardiopulmonary involvement of SSc patients symptomatic for dyspnoea, palpitations, or chest pain were recorded. Forced vital capacity (FVC), alveolar diffusion of CO (DLco), serum troponin, NT-pro-BNP, cardiac ejection fraction (EF) and pulmonary arterial systolic pressure (PAPs) were used for clustering by a partition around medoids (PAM) algorithm. The resulting clusters were compared for 5-year mortality due to SSc cardio-pulmonary causes.
Results: 216 patients were enrolled, aged 54.5±14.4 years, and with a disease duration of 7.4±7.0 years. The 12% of patients were male, 41% had a diffuse cutaneous disease, 45% were anti-Scl70 positive. With specific reference to cardiopulmonary involvement, 50% of patients had pulmonary fibrosis at HRCT, 15% pulmonary arterial hypertension, 16% a EF <55%, 11% increased levels of troponin, and 42% elevated NT-proBNP levels. During follow-up, 26 patients (12%) died because of causes related to cardiac-pulmonary involvement. The machine learning algorithm identified two different groups according to prognosis ($\chi 2(2) = 29.76$, $p<0.001$) with a 5-year mortality of 15% and 0.8%. Patients with higher mortality were characterized by lower FVC values and higher NT-proBNP and troponins compared to rest of the cohort ($p<0.001$). Furthermore, the prevalence of male gender, diffuse cutaneous disease, anti-Scl70 positivity and anti-centromere negativity were higher in the high-risk group compared with the alternative cluster ($p<0.05$ for all characteristics). Interstingly, in high mortality cluster a relevant percentage of patients apparently do not present classical risk factors for progressive SSc, in fact 40% were females, 30% of patients presented a limited cutaneous involvement, 36% were anti-Scl70 negative and 30% were anti-centromere positive, 26.4% did not presented pulmonary fibrosis, and 35% of patients did not have pulmonary hypertension.
Conclusion: An artificial intelligence algorithm based on laboratory-functional parameters of SSc cardio-pulmonary involvement was shown to be able to predict the prognosis of SSc patient more accurately than traditional predictors. Given the high mortality risk of patients with SSc, the application of dedicated prognostic algorithms could better support the clinician in the management of patients.

POS1290 INCREASED RISK OF MYOCARDIAL INFARCTION AND STROKE IN PATIENTS WITH SYSTEMIC SCLEROSIS: A NATIONWIDE COHORT STUDY

Keywords: Epidemiology, Systemic sclerosis, Cardiovascular disease

Y. Eun[1], K. D. Han[2], J. K. Ahn[1]. *[1]Kangbuk Samsung Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)*

Background: Previous studies have suggested a link between systemic sclerosis (SSc) and cardiovascular disease, but large-scale data are still lacking due to the nature of rare autoimmune diseases.
Objectives: We aimed to compare the incidence of myocardial infarction (MI) and stroke in patients with SSc and age- and sex-matched controls in a nationwide population-based cohort in Korea.
Methods: We included patients with SSc defined by the ICD-10 code (M34) and rare and intractable disease code (V138) and 1:5 age- and sex-matched controls using the Korean National Health Insurance Database. The outcomes of the study were MI and stroke. Cox proportional hazard analysis and Kaplan-Meier curve were used to compare the incidence of outcomes between patients with SSc and controls.
Results: A total of 4700 patients with SSc and 23500 controls were included in the study. The mean follow-up period was 5.6 ± 2.8 years. At baseline, patients with SSc had higher prevalent rates of comorbidities such as hypertension, hyperlipidemia, and congestive heart failure than controls. Patients with SSc had a 3-fold higher risk of MI (adjusted hazard ratio [aHR] 3.01, 95% confidence interval [CI] 2.41–3.76) and a 1.7-fold higher risk of stroke (aHR 1.65, 95% CI 1.28–2.14) compared to controls. There were no differences in the association between SSc and MI or stroke by age, sex, or comorbidities.
Conclusion: This nationwide population-based cohort study revealed an association between SSc and increased risk of MI and stroke. Therefore, careful monitoring and preventive measure for the cardiovascular diseases in patients with SSc are required.

Background: Progression of interstitial lung disease (ILD) is a candidate for long-term mortality in patients with systemic sclerosis (SSc). Different definitions of progression have been proposed. Declining lung function is often used, whereas others include composite definitions such as the 2022 ATS/ERS/JRS/ALAT guideline criteria for progressive pulmonary fibrosis (PPF) and the INBUILD criteria for progressive fibrosing ILD (PF-ILD). These different definitions have not been compared in SSc-ILD.
Objectives: To estimate the prevalence of ILD progression applying different definitions and test their performance of predicting mortality.
Methods: We included all SSc patients from the Oslo and Zurich cohorts who had ILD on HRCT and serial assessments of disease progression defined as:
(A) Absolute FVC decline >5% over 12 months
(B) PPF guideline criteria with 2/3 criteria present over 12 months of (1) worsening of respiratory symptoms; (2) absolute decline in FVC >5% or in DLCO >10% and (3) disease progression on HRCT
(C) INBUILD PF-ILD criteria within 24 months with (1) FVC decline ≥10%, (2) FVC decline >5-<10% and worsening of respiratory symptoms or increased lung fibrosis on HRCT, or (3) worsening of respiratory symptoms and increased lung fibrosis.
We assessed the prevalence of ILD progression using these competing definitions and applied multivariable cox regression models (with hazards ratios (HR) and 95%CI) adjusted for known risk factors for mortality and compared the performance using Harrels c-index.
Results: In total, 231 SSc-ILD patients from Oslo and Zurich were included, with 71 (31%) showing FVC decline >5%, 43 (19%) fulfilling the PPF guideline and 89 (39%) the INBUILD PF-ILD criteria. Most progressive patients fulfilled ≥1 definition of progression [60/107 (56%)] while 124 (54%) did not progress (Figure 1). Patient characteristics did not differ between the definitions, except for more extensive ILD and ground glass on HRCT and more frequent oxygen desaturation among those fulfilling the PPF criteria (Table 1). The number of deaths [44 (47%)] over mean 7.7 years (SD 3.9) follow up were comparable in the different groups. The progression definitions performed differently in multivariable cox models adjusted for age, sex, disease duration, SSc subtype, extent of lung fibrosis, baseline FVC and treatment using FVC decline>5% (HR1.87, 1.10-3.17

95%CI; p=0.020; c-index 0.7331), PPF guideline (HR1.42, 0.79-1.84 95%CI; p=0.231; c-index=0.7156) and INBUILD PF-ILD (HR 2.38, 1.40-4.04 95%CI: p<0.001; c-index=0.7338). The models discriminating ability was not significantly different (p=0.138).

Conclusion: The prevalence of ILD progression varies depending on which definition was applied. FVC decline alone and PF-ILD criteria predicted mortality significantly but not the 2022 PPF guideline criteria.

	FVC decline>5%	PPF	PF-ILD

Background: Patients with systemic Sclerosis (SSc) are at risk of developing pulmonary hypertension (PH) of different etiologies. Two-dimensional and Doppler echocardiography is the reference screening tool and it is recommended yearly even in the absence of symptoms; however, elevated values of systolic pulmonary artery pressure (sPAP) are not detectable at rest in the early phases of the disease.
Objectives: The aim of the study was to determine whether early signs of right ventricular or right atrial dysfunction at speckle-tracking echocardiography might identify patients who are going to develop PH during follow-up.
Methods: We studied a consecutive cohort of 113 patients with a diagnosis of SSc according to the 2013 ACR/EULAR SSc classification criteria [1], undergoing screening for PH and who were followed-up regularly at a third-level centre of reference for SSc.
All patients underwent both the baseline echocardiographic examinations and at least one echocardiographic examination during follow-up in the referral center. Standard 2-D and Doppler echocardiography was performed with a Vivid 7 or Vivid E9 ultrasound system (GE Medical Systems, Norway); images and clips were saved for offline analysis on a GE workstation (EchoPAC PC SW). Clinical, laboratory and radiographical parameters, standard in the care of SSc, such as presence of Interstitial lung disease, left-heart disease (LHD), pulmonary function respiratory tests and biomarkers as BNP were concomitantly recorded for each patient. The DETECT step 1 and 2 values were calculated according to Coghlan JG et al [2]. When indicated according to guidelines, right heart catheterization to diagnose PH was performed. Statistical analysis was performed using SPSS by IBM for mac (v13).
Results: The study enrolled 93 females and 20 males, mean age was 58±13 yrs, median disease duration was 88 months (IQR 42-168); 86 (76%) patients had limited cutaneous involvement, 21 had a diffuse disease (18,6%) and 5 (4,4%) had no skin involvement at all. At baseline, anticentromere and antitopoisomerase antibodies were present in 38 (33,6%) and in 35 (31%) patients respectively. A clinically significant ILD was present in 17 (15%) of patients of the cohort at baseline. During follow-up (44±24 months), 10 patients were diagnosed with PH (overall incidence of 8.4%) which was classified as Group 1 PH in 4 cases (40%), Group 2 PH in 1 case (10%) in Group 3 PH in 5 cases (50%). Baseline standard echocardiographic parameters including the estimated sPAP and DETECT scores for step 1 and step 2 were similar in patients who developed PH and those who did not. However, peak longitudinal right ventricular (RV) strain (RVPLS) values were significantly lower in patients who subsequently developed PH (42,13 ± 12,21 vs 33,57 ± 11,52, p=0,019). In addition, PLS values tended to decrease over time and this decrease significantly predicted PH of any etiology (HR 0.94, 0,88-0,99; p=0,049).
Conclusion: In an SSc cohort of patients at risk of developing PH, adding the evaluation of 2D-Speckle-tracking echocardiography (STE) analysis, and in particular PLS of the RV, might intercept at an early stage an alteration of the right heart to aberrantly adapt to the pulmonary vasculature overload in different extrinsic pathological settings (ILD, LHD) and also in the presence of an intrinsic pulmonary vasculopathy.

POS1294 **PREVALENCE OF PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH SYSTEMIC SCLEROSIS AND DIGITAL ULCERS TREATED WITH BOSENTAN AND SILDENAFIL: RESULTS FROM AN ITALIAN COHORT**

Keywords: Lungs, Systemic sclerosis, Cardiovascular disease

A. Damiani[1], A. R. Abate[1], F. Bonomi[1], E. Fiorentini[1], M. Orlandi[1], G. Lepri[1], S. Bellando Randone[1], S. Guiducci[1]. [1]*University of Florence, Rheumatology Unit, Florence, Italy*

Background: Systemic sclerosis (SSc) is a rare connective tissue disease where vascular damage, autoimmunity and fibrosis affect skin and organs. Among vascular manifestations, pulmonary arterial hypertension (PAH) is associated with poor prognosis accounting for about the 26% of SSc-related mortality rate [1]. Bosentan (an endothelin receptor antagonist) and Sildenafil (a selective inhibitor of phosphodiesterase 5) are approved for the treatment of SSc-related digital ulcers (DUs) and for PAH, both as mono and combination therapy.
Objectives: Evaluate the PAH prevalence in patients with SSc and DUs treated with Bosentan and Sildenafil combination therapy.
Methods: SSc patients with active or past DUs and in combination therapy for at least 3 months with Bosentan and Sildenafil were enrolled in a retrospective observational study. Demographical data, disease duration and antibody positivity were collected along with the most recent lung function test and echocardiographic esteem of pulmonary artery pressure (PAPs). Patients with a diagnosis of PAH preceding the introduction of the studied treatment were excluded. The prevalence of new onset PAH was then calculated and compared through Fisher Exact test with data from Morrisroe et al [1] whose studied population resulted homogenous to the one of the present study in term of age, sex and disease duration.
Results: Forty-seven patients were enrolled, of which 42 (89,4%) were female. Mean age was 57,87 (SD 14,87) and mean disease duration was 12,14 years (SD 5,87). Anti-Scl70 positivity was observed in 21 patients (44,7%) while anti-centromere positivity in 16 (34%). Pulmonary function tests and echocardiographic PAPs are resumed in Table 1. One out of 47 (2,1%) patients developed PAH. This was significatively lower in comparison to PAH prevalence (194 out of 1636, 11.8%) in Morrisroe et al (p 0.036)
Conclusion: The low prevalence of PAH recorded in this group of patients affected by SSc complicated by DUs suggests a protective role of the combination of Bosentan and Sildenafil against PAH, one of the most severe vascular manifestations of the disease. This data should be confirmed by prospective and controlled studies on larger populations.

POS1295 **WITHDRAWN**

survival rates were calculated. The effect of age at disease onset, gender, clinical parameters, and autoantibodies were evaluated using Kaplan-Meier analysis.
Results: A total of 226 patients (85.8% female, mean age 61.9 years) were included. The mean ± SD duration of the disease was 12.24±8.9 years. The 5-year and 10-year survival were 95.59%, and 88.1%, respectively. In the majority of patients, the cause of death was related to SSc. The two main causes of death were interstitial lung disease (ILD) and heart disease (pulmonary arterial hypertension and/or arrythmias). Older age at disease onset was independently associated with worse survival (58.9± 11.9 years vs 47.3±14.6 years, p<0.05) and male patients had statistically worse OS compared to female patients (13.1 years vs 28.4 years, p=0,001). Patients with autoAbs against Th/To (12.1 years vs 28.2 years, p=0.013) or against NOR90 had worse OS compared to autoAb-negative patients (12.1 vs 28.2 years, p=0.013, and 12.7 vs 28.8 years p=0.007, respectively). There was a trend for a better survival in patients with anti-centromere autoAbs (29.4 vs 26.2 years, p=0.064).
Conclusion: Our results show that the overall survival rates of patients with SSc have improved over the years than those reported in the past. Cardiopulmonary diseases still remain the main causes of death, while male sex is associated with worse prognosis. Additional prognostic factors have emerged from autoAb profiles.

POS1296 SURVIVAL RATES IN PATIENTS WITH SYSTEMIC SCLEROSIS ARE AFFECTED BY CONCURRENT CARDIOPULMONARY DISEASE, GENDER, AND AUTOANTIBODY PROFILE: A 15- YEAR SINGLE CENTER EXPIERENCE

Keywords: Autoantibodies, Epidemiology, Systemic sclerosis

T. Simopoulou[1], C. Katsiari[1], C. Liaskos[1], I. Alexiou[1], D. Bogdanos[1], L. Sakkas[1]. [1]University General Hospital of Larissa, University of Thessaly, Department of Rheumatology and Clinical Immunology, Larissa, Greece

Background: Systemic Sclerosis (SSc) is a systemic autoimmune disease with a high mortality rate [1-3].
Objectives: The purpose of this study was to assess long-term survival rates of patients with SSc in a single rheumatology center and identify factors affecting the survival rates.
Methods: Retrospective analysis of unselected adult patients with SSc, diagnosed and followed up in the Rheumatology Clinic of the University Hospital of Larissa in Central Greece for 15 years (2007-2022). Demographics and clinical characteristics were retrieved from medical records. while autoantibodies (autoAbs) were assessed by indirect immunofluorescence and a SSc autoantibody line blot immunoassay (Euroimmun). Overall Survival (OS), 5-year and 10-year

POS1297 PULMONARY INVOLVEMENT IN VERY EARLY SYSTEMIC SCLEROSIS (VEDOSS): REPORT FROM A SINGLE CENTER

Keywords: Lungs, Systemic sclerosis

M. Neto[1], A. Maduro[1], A. Saraiva[1], J. A. P. Da Silva[1,2], T. Santiago[1,2], M. J. Salvador[1,2]. [1]*Centro Hospitalar e Universitário de Coimbra, Rheumatology, Coimbra, Portugal*; [2]*Faculty of Medicine, University of Coimbra, Rheumatology, Coimbra, Portugal*

Background: Previous work has described interstitial lung disease (ILD) in very early systemic sclerosis (VEDOSS) [1], but its progression over time is unknown. This can contribute decisively to the delineation of screening and monitoring strategies.
Objectives: To evaluate the prevalence of ILD and its course in a cohort of patients who persist in a VEDOSS state, followed in a tertiary systemic sclerosis unit, over 10 years.
Methods: Retrospective observational study of patients persistently fulfilling VEDOSS criteria [2], with sequential measurement of diffusing lung capacity for carbon monoxide (DLCO) and forced vital capacity (FVC), at 0, 1, 5 and 10 years. Chest CT at baseline was considered, when available. A DLCO or FVC <80% of predicted values was considered indicative of lung involvement [1]. A decline of

FVC or DLCO of ≥5% and ≥15% in any of the time intervals was considered clinically relevant [3]. Demographic, clinical, and immunological variables at baseline were taken as potential independent variables, including age, gender, disease duration, arthritis, capillaroscopy pattern, and autoantibody profile. Pearson $\chi 2$ test, Fisher's exact test or independent sample t-test were used for independent measures as appropriate. Repeated-measures ANOVA was used to compare variables over time.

Results: 30 patients (86,7% women, mean baseline age 46,9±12,87 yrs) were included; median time from first symptoms to diagnosis was 4,4 (IQR 7,6) yrs.

At baseline, 4 patients had mildly decreased DLCO values (60-79% of predicted), results being normal in all remaining persons (Table 1). During the first year of follow-up, a ≥5% decrease in FVC was observed in 6/30 patients (20%) and a DLCO decrease of ≥15% in 2/30 (6,7%). There was a non-significant trend for a higher probability of FVC and DLCO decrease in males vs females (M:50,0% vs F:15,3%F and M:25,0% vs F3,8%, respectively). None of the other variables was associated with FVC or DLCO decrease. Pulmonary tests were available for the 25 and 5 patients who reached 5 and 10 years of follow-up. No association was found between any of the clinical variables and significant change of FVC and DLCO at these time points. Mean values of FVC and DLCO consistently declined overtime, without reaching statistical significance (Table 1). The incidence of significant change in FVC and DLCO between contiguous evaluations is represented in Figure 1. There is a non-significant trend for a higher probability of decline as follow-up time increased.

Table 1 FVC and DLCO measurements at baseline and at 1, 5 and 10 years

	Baseline (n=30)	1 year (n=30)	5 years (n=25)	10 years (n=5)	p-value
FVC (% predicted), mean ± SD	112,7±15,9	111,5±15,5	109,6±18,4	110,8±26,1	NS
FVC <80% predicted, % (n)	0 (0)	0 (0)	4,0 (1)	20,0 (1)	NS
DLCO (% predicted), mean ± SD	96,6±14,1	97,8±16,1	90,7±13,9	85,7±10,6	NS
DLCO <80% predicted, % (n)	13,3 (4)	16,7 (5)	20,0 (5)	20,0 (1)	NS

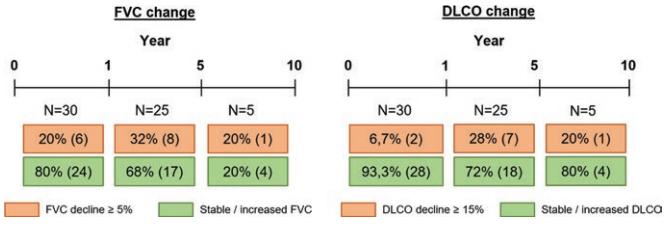

Figure 1 FVC and DLCO change at 1, 5 and 10 years

Conclusion: Our study provides data on the long-term assessment of FVC and DLCO in VEDOSS patients. There was a relevant decrease in FVC during the first year in 20% of the patients, and 20% had impaired DLCO (<80%) at 5 years, which suggests that a subset of patients who persist in VEDOSS state overtime still endure significant subclinical pulmonary involvement.

INTERSTITIAL LUNG DISEASE IN ANTI-CENTROMERE ANTIBODY POSITIVE SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Best practices, Lungs

N. Katukuri[1], A. Cherukuri[1], A. Makol[1], R. Lennon[2], C. S. Crowson[1,2], L. M. Frota Lima[3], B. Bartholmai[3], A. M. Hinze[1]. [1]*Mayo Clinic, Division of Rheumatology, Department of Internal Medicine, Rochester, United States of America*; [2]*Mayo Clinic, Division of Clinical Trials and Biostatistics, Department of Quantitative Health Sciences, Rochester, United States of America*; [3]*Mayo Clinic, Department of Radiology, Rochester, United States of America*

Background: Despite a lower risk of ILD and ILD progression in anti-centromere antibody (ACA) positive systemic sclerosis (SSc) patients, ILD may still occur and progress. Little is known regarding risk factors for ILD in ACA+ SSc patients to help guide screening with high-resolution computed tomography (HRCT), and risk of ILD progression in ACA+ SSc is understudied.

Objectives: To determine prevalence and risk factors for ILD in ACA+ SSc, to classify radiographic ILD patterns, and to evaluate rate of progression of ILD in ACA+ SSc.

Methods: A retrospective cohort of ACA+ SSc patients seen between 1/1/2007 and 12/31/2018, who met the 2013 ACR classification criteria or ≥3/5 CREST (calcinosis, Raynaud's, esophageal dysmotility, sclerodactyly, telangiectasias) criteria was identified. Subjects had to have ≥1 HRCT within 2 yrs. prior to or anytime following SSc diagnosis (dx). Two radiologists reviewed all HRCTs with interstitial abnormalities to classify by consensus into 9 radiographic patterns (1,2): confident usual interstitial pneumonitis (cUIP), probable UIP (pUIP), non-specific interstitial pneumonitis (NSIP), suggests hypersensitivity pneumonitis (sHP), lymphocytic interstitial pneumonia (LIP), organizing pneumonia (OP), not characteristic (NC) of a specific ILD pattern, too little fibrosis (LF) to characterize, and suggests sequelae of pulmonary arterial hypertension (PAH)/pulmonary venoocclusive disease (PVOD). Clinical and demographic characteristics were compared between ILD+ and no ILD (included PAH/PVOD sequelae) subjects using χ^2 tests of proportions for categorical data, and two-sample t-tests for continuous data. Kaplan-Meier curves estimated the risk of ILD progression, defined as a relative decline of 10% in forced vital capacity (FVC) from baseline PFT performed ±6 mo. of latter of SSc or ILD dx.

Results: 99/480 (21%) of subjects had interstitial changes on HRCT: 5 cUIP, 7 pUIP, 28 NSIP, 14 sHP, 6 LIP, 2 OP, 11 NC, 17 LF, and 9 PAH/PVOD sequelae. There were no differences in time between SSc dx and HRCT between ILD+ and no ILD groups (median 6 yrs. (IQR 2, 14) vs. 6 yrs. (IQR 1, 15), respectively, p=0.44) or Raynaud's phenomenon (RP) onset and HRCT (median 15 yrs. (8, 29) vs. 17 yrs. (9, 29), respectively, p=0.54). Older age at RP onset (median 55 yrs. (42, 62) vs. 44 yrs. (33, 55), ILD+ vs. no ILD, p<0.001) and at SSc dx (median 62 yrs. (55, 72) vs. 56 yrs. (45, 65), ILD+ vs. no ILD, p<0.001) were significantly associated with ILD. A positive SSA was more common in ILD+ vs. no ILD subjects (15/72 (21%) vs. 43/340 (13%), respectively, p<0.05). Sex, race/ethnicity, smoking status, cutaneous subtype, esophageal dysmotility, digital ischemia, abnormal nailfold capillaries, telangiectasias, calcinosis, and synovitis were not associated with ILD (p>0.05). In a subgroup analysis of UIP/NSIP (n=40) compared with no ILD (n=390), older age at RP onset was significantly associated with UIP/NSIP (median 55 yrs. (46, 61) vs. 44 yrs. (33, 55), p=0.042). There were no significant differences in baseline FVC% and DLCO% among ILD patterns (p>0.05). ILD progression was observed in 51% of patients with ILD by 72 mo. (Figure 1A). There was no significant difference in risk of ILD progression between the UIP/NSIP and sHP/LIP/OP/IP/LF subgroups (Figure 1B, p=0.67).

Conclusion: To our knowledge, this is the largest study characterizing radiographic ILD patterns and assessing risk factors for prevalent ILD in ACA+ SSc patients. Older age at onset of RP and SSc dx, and a positive SSA, identifies a higher risk population for HRCT screening. UIP/NSIP accounted for close to half of ILD cases. Other radiographic patterns including sHP and IP require further study to determine potential underlying factors (e.g. exposure history, aspiration). The rate of ILD progression was similar between UIP/NSIP vs. other interstitial patterns, with half of subjects experiencing progression by 6 yrs. This underscores the role of HRCT screening for ILD detection and periodic PFTs for monitoring even in lower risk SSc populations.

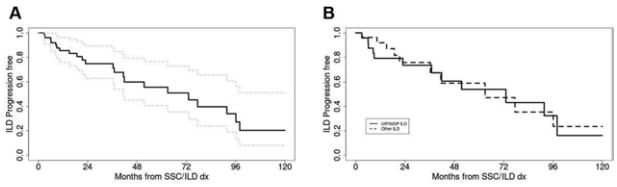

Figure 1. Kaplan-Meier Survival Curves Evaluating Time to ILD Progression in ACA+ SSc-ILD subjects. ILD progression is defined as a relative decline of 10% in FVC% predicted from baseline PFT. Baseline PFT was performed within 6 months of the latter of SSc or ILD diagnosis. The 2-year and 5-year progression free survival was 75% (95% CI 63% to 89%) and 56% (95% CI 41% to 76%), respectively (A). There were no significant differences in progression rates for the UIP/NSIP subgroup compared with the subgroup of all other ILD patterns (B, p=0.67, log-rank test).

POS1299 LONG-TERM NEURODEVELOPMENTAL OUTCOME OF CHILDREN BORN TO SYSTEMIC SCLEROSIS WOMEN: PEDIATRIC NEUROPSYCHIATRIC ASSESSMENT THROUGH A SET OF VALIDATED TOOLS

Keywords: Pregnancy and reproduction, Quality of life, Systemic sclerosis

E. Pedretti[1,2], J. Galli[2,3], L. Moschetti[1,2], C. Nalli[1], M. Bendoni[2,3], L. Visconti[2,3], A. Molinaro[2,3], F. Franceschini[1,2], A. Tincani[1,2], P. Airò[1], L. Andreoli[1,2], E. Fazzi[2,3], M. G. Lazzaroni[1,2]. *[1]Rheumatology and Clinical Immunology Unit, ASST Spedali Civili of Brescia, Brescia, Italy*; *[2]Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy*; *[3]Unit of Child and Adolescent Neuropsychiatry, ASST Spedali Civili of Brescia, Brescia, Italy*

Background: The neurodevelopmental (ND) outcome of children born to women with autoimmune disorders might be affected by factors related to maternal disease (*e.g.* the transplacental passage of maternal antibodies/drugs), as well as by mothers' coping with their disabilities during growth. These aspects have been studied in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) [1]; no data are available for Systemic Sclerosis (SSc).

Objectives: To evaluate the long-term ND outcome of children born to SSc mothers.

Methods: A pediatric neuropsychiatric evaluation was proposed to SSc mothers with at least one child ≤18 years (August 2021-June 2022). Evaluations, performed by a child neuropsychiatrist, included the assessment of the following domains:

- Developmental/Cognitive skill (Griffiths Mental Development Scales III -GMDS-III- and Wechsler Scale for corrected age)
- Adaptive behavior (Vineland Adaptive Behavior Scales-II -VABS-II-)
- Social/Behavioral problems (Child Behavior CheckList and Youth Self Report -YSR- for children ≥11 years)
- Quality of life (Pediatric Quality of Life Inventory 4.0 -PedsQL-)

A set of questions to investigate the child's ND milestones were submitted to mothers. Data about maternal disease were retrieved from medical records.

Results: 20 children (median age 8 years; F/M 1:1) born to 12 SSc mothers were evaluated: 4 were born before and 16 after SSc onset. Four preterm births (<37 gestational weeks -GW-) (one twin pregnancy) and no small for gestational age babies were recorded. One child already had a diagnosis of autism spectrum disorder (ASD) at enrollment. All the children showed a normal score for developmental or intelligence quotient (IQ) and in all VABS-II domains, except for the child affected by ASD. YSR, administered to 6 children, highlighted an impairment in social abilities (*e.g.* extra-academic/social activities). In CBCL, externalizing problems (*e.g.* aggressive behavior, hyperactivity) were reported in 3 children (15%), while internalizing problems (*e.g.* anxiety, somatic complaints) in 2 (10%). The lowest scores at PedsQL were observed in the emotional domain. Different types of sleep disorders were reported in 45% of children. No significant differences were found in maternal characteristics upon the comparison between children with/without ND abnormalities. Children and mothers' features are shown in Table 1.

Conclusion: Children born to SSc mothers displayed normal intellectual functioning. The reported impairment in social abilities, suggesting an "adult profile", possibly reflect the effect of coping with maternal disabilities. Our data did not show a specific pattern of ND alterations in the offspring of SSc mothers; however the inclusion of a child neuropsychiatrist in the multidisciplinary team dedicated to SSc patients and their families seems to be important to detect and correct any possible ND problems at an early stage.

POS1300 NAILFOLD CAPILLAROSCOPY FOR STANDARD CLINICAL PRACTICE: ARE TWO FINGERS AS ACCURATE AS EIGHT?

Keywords: Systemic sclerosis

Y. El Miedany[1], S. Ismail[2], M. Fawzy[3], M. Elgaafary[4], M. H. Abu-Zaid[5]. *[1]Canterbury Christ Church University Medway Campus, Rheumatology, Gillingham, United Kingdom*; *[2]National Research Center, Rheumatology and Rehabilitation, Cairo, Egypt*; *[3]Faculty of Medicine Kasr Al-Ainy, Cairo University, General Medicine, Cairo, Egypt*; *[4]Faculty of Medicine, Ain Shams University, Community and Public health, Cairo, Egypt*; *[5]Faculty Of Medicine - Tanta University, Rheumatology and Rehabilitation, Cairo, Egypt*

Background: Nail-fold capillaroscopy (NFC) is a non-invasive, in vivo diagnostic tool for the assessment of microvasculature of the proximal nail fold. The comprehensive approach based on assessment of four finger each hand excluding the thumbs (in total eight fingers are examined) is the gold standard for NFC evaluation and scoring. The patient is identified to have abnormal nailfold capillaries, if abnormality was present in any finger/nailbed. However, this process is time consuming and is not applicable in standard clinical practice. Therefore, a question was raised can a concise approach based on assessment of a smaller number of fingers be implemented in standard practice. The challenge to this hypothesis is that there may be marked variability in the nailfold morphology between different fingers, as abnormalities may only be seen in some but not all fingers.

Objectives: 1. To evaluate the comparability of the concise to the comprehensive approach (the gold standard) represented as the percentage of agreement of the NFC patterns recorded from each approach. 2. To assess the statistical difference on comparing the concise approach score to the gold standard score.

Methods: This was a prospective, cross sectional multicenter study. 164 Patients were recruited for this study. The patients' cohort included systemic sclerosis,

ANA: anti-nuclear antibodies, ACA: anti-centromere antibodies, GW: gestational weeks; lcSSc: limited cutaneous SSc, dcSSc: diffuse cutaneous SSc, ILD: interstitial lung disease, 0: absent, 1: present, N: normal, B: borderline, A: abnormal*ASD diagnosis, •born before SSc onset $ Twins, °Gestational diabetes, ^Preeclampsia/IUGR

rheumatoid arthritis, psoriatic arthritis, systemic Lupus erythematosus, Behcet's disease, Sjogren's syndrome and mixed connective tissue diseases. Imaging sessions were carried following the national standard for NFC [1]. NFC with 200x magnification was used to capture panoramic nailfold videocapillaroscopy images. Images were recorded from 4-fingers each hand, excluding the thumbs. For each finger 5 parameters were assessed: density, architecture, hemorrhage, neoangiogenesis and dimension. Semiquantitative scoring system was implemented to score each parameter [2].

Results: Considering the correct diagnosis using the gold standard score was 100%, the concise approach based on mean of the scores recorded from the middle and ring fingers both hands gave the correct pattern in 155/164 (94.5%) of the cases. There was no statistical difference between the comprehensive approach total score (3.5+0.76 [CI 95% 1.918 - 5.082]), when compared to the concise total score from 2 fingers both hands which was (3.25+2.87 [1.873 - 4.626], p= 0.18. There was no significant difference on comparing the right to the left hand fingers.

Conclusion: Examining the NFC from middle and ring fingers in each hand, can be time saving and not inferior to the comprehensive NFC assessment. Concise approach can be used in the standard clinical practice and, in the meantime, are able to give an overall NFC picture reflecting the real state of the nailfold capillaries.

POS1301 MORTALITY AND CAUSES OF DEATH AMONG FINNISH PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Epidemiology

S. Kortelainen[1], M. Käyrä[2], T. Rissanen[3], J. Paltta[1], L. Pirilä[1], J. Huhtakangas[4]. *[1]Turku University Hospital, Rheumatology and Clinical Immunology, Turku, Finland*; *[2]Oulu University Hospital, Rheumatology, Oulu, Finland*; *[3]University of Turku, Biostatistics, Turku, Finland*; *[4]Kuopio University Hospital, Rheumatology, Kuopio, Finland*

Background: Systemic sclerosis (SSc) is a rare rheumatic autoimmune disease, characterized by vasculopathy and fibrosis of the skin and internal organs [1]. Mortality and morbidity of systemic sclerosis is significant. The studies assessing changes in the mortality of SSc are controversial, only minor sign of improvement of prognosis is seen. Among SSc-related causes of death scleroderma renal crisis has become rare and cardiopulmonary causes have become more common. Most of the studies are conducted using either the ACR 1980-criteria or the LeRoy and Medsger -criteria.

Objectives: Aim of this study was to examine mortality and basic causes of death among Finnish patients with systemic sclerosis (SSc) during years 2000-2020 using the ACR/EULAR 2013 criteria for SSc diagnosis.

Methods: Patients with a diagnostic code of systemic sclerosis (ICD-10 codes beginning with M34) that appeared at least once in their medical records during the years 1996–2018 were identified from the hospital discharge registers of Turku and Oulu University hospitals. False diagnoses and typing errors were excluded. Using ACR/EULAR 2013 criteria and clinical findings, the diagnoses were reclassified and divided into different subsets of the disease. These subsets were diffuse cutaneous systemic sclerosis (dcSSc), limited cutaneous systemic sclerosis (lcSSc), over-lap SSc (diagnosis of other rheumatic disease fulfilled simultaneously) and sine scleroderma (SSc without skin affision). The clinical data was collected to the end of year 2020. The death certificates including the basic and imminent causes of death were obtained from Statistics Finland until August 2021. By examining patient records and death certificates the basic cause of death for each subject was re-evaluated. The study data were collected and managed using REDCap electronic data capture tools hosted at the University of Turku.

Results: Among 313 SSc patients, 91 deaths occurred between 4/2000- 9/2020. 35 deaths were caused by SSc, 20 by atherosclerosis, 18 by cancer and 18 by other causes. Majority of SSc-related deaths were due to interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH), 13 and 11 deaths respectively. Four deaths were due to scleroderma renal crisis (SRC), three deaths due to gastrointestinal tract involvement, two due to SSc-related myocardial involvement and two due to other SSc-related causes, those were vasculopathy complications. The mean age at dead of patients who died of a SSc-related cause was 65.6 years (SD 12.7, CI= 61.2-70.1) in contrast to patients who died due to other causes was 74.2 years (SD 9.6, CI= 71.5-76.9), the difference was statistically significant (p=0.0006). The median time from SSc diagnosis to death was 4.4 years [IQR 1.5, 11.8] in the SSc-related death group and 10.8 years [IQR 4.7, 17.1] for others, the difference was statistically significant (p=0.0061). Death due to renal crisis occurred fastest, in two months. An ILD related death occurred 11.8 years after and a PAH related death 3.7 years after the SSc diagnosis on average. In females, PAH and ILD were the most common causes of death, both nine of 25 subjects. In males, ILD was the most common cause of death, in four of ten subjects. In the group of dcSSc, the most common cause of death was ILD with five deaths out of twelve. In the group of lcSSc, PAH and ILD were the most common causes of death with both eight of 19 deaths. Four deaths due to SRC were all in the group of dcSSc. Twelve of 23 patients with dcSSc (52%) and nineteen of 60 patients with lcSSc (32%) died due to SSc.

Conclusion: The main finding in our study is the fact, that SSc disease itself is the major cause of death among Finnish SSc patients. Among the SSc related deaths, ILD and PAH were the leading causes of death. The patients who died due to SSc were significantly younger and the time from SSc diagnosis was significantly shorter compared to those who died due to other causes.

POS1302 SPECKLE-TRACKING GLOBAL LONGITUDINAL STRAIN AS A PREDICTOR OF CLINICAL OUTCOMES IN SYSTEMIC SCLEROSIS PATIENTS

Keywords: Prognostic factors, Systemic sclerosis

D. Benfaremo[1,2], G. Stronati[3], C. Dichiara[4], Y. Ferraioli[4], C. Tana[4], I. Paterno[4], S. Bigoni[4], S. Contegiacomo[4], M. Sistoni Pepparoni[4], N. Pacenti[4], A. Dello Russo[3], F. Guerra[3], G. Moroncini[1,2]. *[1]Marche Polytechnic University, Department of Clinical and Molecular Sciences, Ancona, Italy*; *[2]Marche University Hospital, Clinica Medica, Ancona, Italy*; *[3]Marche University Hospital, Cardiology Clinic, Ancona, Italy*; *[4]Marche Polytechnic University, Internal Medicine Residency Program, Ancona, Italy*

Background: Primary cardiac involvement occurs in up to 40% of patients affected by systemic sclerosis (SSc), and although it may be asymptomatic is associated with negative outcomes. Speckle-tracking derived global longitudinal strain (GLS) has been proven to be a cost-effective tool in the detection of left ventricular (LV) and right ventricular (RV) dysfunction in patients with SSc and no overt cardiac disease [1].

Objectives: The aim of this study was to assess whether GLS can predict clinical outcomes in patients with SSc.

Methods: We conducted a prospective observational study enrolling all consecutive patients referred to our Scleroderma Unit between June 2016 and January 2022. All patients had a definite diagnosis of SSc according to ACR/EULAR criteria and no overt cardiac disease, pulmonary arterial hypertension, or atrial fibrillation at the time of enrollment. For each patient, echocardiogram and GLS calculations were performed at baseline and at each follow-up. We also collected all data regarding clinical history, hospitalizations or adverse events and ECGs.

Results: 164 patients (148 female, 58±14 years) were enrolled. Overall, 19 (11.6%) patients died during a median follow-up of 3.2 years for mainly non-cardiovascular deaths (7.3%) while cardiovascular deaths were lower (3% non-sudden, 1.3% sudden). Left GLS at first visit was associated with all-cause death, with a 1% left GLS worsening associated with a 19% increased risk of death after adjusting for age, gender, and LVEF (adjusted HR 1.19; 95% CI 1.05-1.35; p=0.007). Similarly, right GLS at first visit was associated with all-cause death, with a 1% right GLS worsening associated with a 12% increased risk of death after adjusting for age, gender, and TAPSE (adjusted HR 1.12; 95% CI 1.03-1.21; p=0.005). Patients with a left GLS worse (i.e. higher) than -20% had a 3.5-fold increased risk of death when compared to patients with better left GLS (HR 3.55; 95% CI 1.28-9.88; p=0.015; Figure 1a). Similarly, patients with a right GLS worse than -20% had a 4.5-fold increased risk of death when compared to patients with better left GLS (HR 4.47; 95% CI 1.4-13.74; p=0.009; Figure 1b).

Conclusion: We demonstrated that GLS is associated with clinical outcomes in patients with SSc. GLS is a reproducible and cost-effective echocardiographic

based method to assess SSc primary heart involvement and its progression, therefore allowing an earlier intervention in patients with worse prognosis.

POS1303 ARTHRITIS AND RISK STRATIFICATION OF PATIENTS WITH VERY EARLY SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis, Inflammatory arthritides

S. Muraru[1], C. Mihai[1], M. O. Becker[1], M. Elhai[1], S. Jordan[1], A. Garaiman[1], C. Bruni[1], O. Distler[1], R. Dobrota[1]. [1]*University Hospital Zürich, Department of Rheumatology, Zürich, Switzerland*

Background: Regular monitoring of patients with very early systemic sclerosis (veSSc) is essential for detecting disease progression. Whereas arthritis is associated with a worse prognosis in established disease [1], knowledge about its relevance in veSSc is scarce.

Objectives: Our objective is to assess the prevalence of arthritis in patients with veSSc, its association with other disease features and its impact on progression to established SSc.

Methods: We included patients with veSSc defined as presence of Raynaud's phenomenon and at least one of puffy fingers, antinuclear antibodies (ANA), abnormal capillaroscopy, not fulfilling the ACR/EULAR 2013 classification criteria for SSc at baseline. Data about arthritis were based on clinical diagnosis of synovitis by the treating physician, and verified in the electronic records in order to exclude arthritis due to other causes. *We investigated associations between arthritis and relevant clinical parameters cross-sectionally at baseline using Fishers' and Mann-Whitney-U tests. A longitudinal analysis* using Kaplan-Meier plots and multivariable Cox regression was performed to investigate arthritis as a potential predictor of progression towards established SSc (fulfilment of ACR/EULAR criteria at any follow-up visit).

Results: Of 161 patients included, 110 had at least one follow-up visit, with a median follow-up of 2.0 years. Baseline characteristics are shown in the Table 1. SSc-related arthritis was reported in 22/161 (13.7%) patients and was mostly seronegative (20/22, 90.9%), only one patient having an overlap syndrome with seropositive rheumatoid arthritis.

Table 1. Baseline characteristics

Variable	Frequency/Median
Age, median (years) (IQR, Q1-Q3)	48 (25, 35-60)
Female	144/161 (89.4%)
2013 EULAR/ACR classification criteria fulfilled at any time during follow-up	45/161 (28%)
Disease duration since first Raynaud symptom (years; median, IQR, Q1-Q3)	3.1 (9.33, 1.08-10.42)
SSc-related synovitis (n, %)	22/161 (13.7%)
CRP elevation (n, %)	18/153 (11.8%)
ESR elevation (>25mm/1h; n, %)	16/144 (11.1%)
Anti-centromere positive (n, %)	83/155 (53.5%)
Anti-Scl-70 positive (n, %)	13/153 (8.5%)
Anti-RNA Polymerase III positive (n, %)	12/135 (8.9%)
ILD on HRCT (n, %)	10/135 (7.4%)
SSc pattern on nailfold capillaroscopy (n, %)	82/161 (50.9%)
Digital ulcers (n, %)	5/135 (3.7%)
Pitting scars (n, %)	3/136 (2.2%)
Puffy fingers (n, %)	33/147 (22.4%)
Modified Rodnan skin score (median, IQR, min-max)	0 (0, 0-4)

Abbreviations: ILD-interstitial lung disease; HRCT-high resolution tomography; CRP C-reactive protein; ESR erythrocyte sedimentation rate

We found a statistically significant association between arthritis and presence of anti-centromere antibodies (p=0.008). Arthritis was neither associated with the other SSc-specific antibodies (anti-Scl70 and anti-RNA-Polymerase III), nor with inflammatory markers. Overall, 45/161 (28%) patients progressed to established SSc during follow-up. There was no statistically significant difference in fulfilling the classification criteria at follow-up between patients with- and without arthritis (Figure 1).

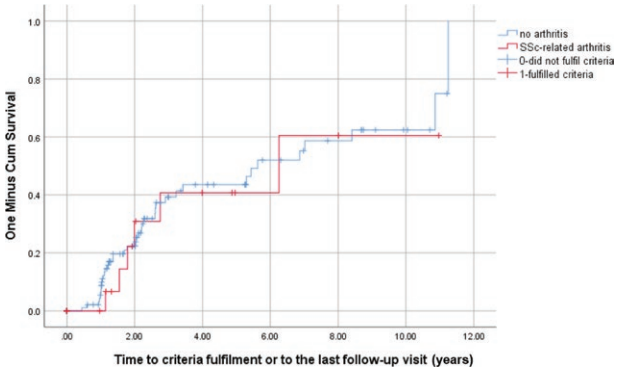

Figure 1. Kaplan Meier analysis for progression to SSc stratified by SSc-related arthritis.

Furthermore, arthritis was not a significant predictor for progression to established SSc in a multivariable Cox regression model adjusted for known predictors (specific antibodies, puffy fingers and SSc pattern on capillaroscopy [2]). In this model only the specific antibodies (p = 0.036) and puffy fingers (p = 0.045) reached significance.

Conclusion: In this first study analysing arthritis in veSSc, we found a relevant prevalence of arthritis in this mildly affected cohort. Presence of anti-centromere antibodies was significantly associated with arthritis at baseline. Arthritis was not a prognostic factor for progression towards established SSc in our cohort.

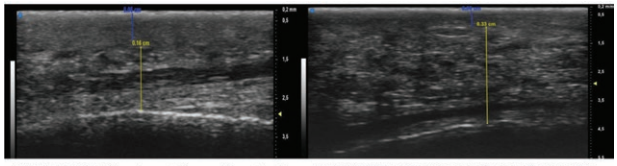
POS1304 PREDICTORS OF DISEASE ACTIVITY PERSISTENCE AND DAMAGE IN A MONOCENTRIC SYSTEMIC SCLEROSIS COHORT

Keywords: Prognostic factors, Systemic sclerosis

B. Moccaldi[1], E. Zanatta[1], M. Binda[1], S. Prete[1], M. Favaro[1], A. Martini[2], A. Doria[1]. [1]*Padova University Hospital, Department of Medicine - DIMED, Division of Rheumatology, Padova, Italy*; [2]*Padova University Hospital, Department of Medicine - DIMED, Padova, Italy*



Background: Systemic sclerosis (SSc) carries a significant burden of disease-related morbidity and life-threatening complications. Unlike other rheumatic disorders (e.g., systemic lupus erythematosus and rheumatoid arthritis), the concepts of "disease activity" and "damage" have only recently been defined in SSc.
Objectives: We aimed to identify clinical and serological predictors of persistence of disease activity and remission in a monocentric prospective cohort of systemic sclerosis patients. Our second aim was to evaluate potential predictors of persistence or new onset of moderate-to-severe damage in our cohort.
Methods: Adult patients fulfilling the ACR/EULAR 2013 classification criteria for SSc and referring to our center from 2013 to 2021 were enrolled. Clinical findings, serological indices and internal organ involvement (pulmonary, cardiac, gastrointestinal, renal and musculo-skeletal) at baseline and at each visit during follow-up were retrospectively analyzed. At least one follow-up visit was required to be included in the study. EUSTAR-AI (European Scleroderma Trials and Research group Activity Index) [1], Medsger severity scale (MSS) [2] and SCTC (Scleroderma Clinical Trials Consortium) damage index [3] were calculated at each visit, at baseline and during follow-up. Follow-up period was defined as the time between baseline and the last available visit. Active disease was defined as an EUSTAR-AI ≥ 2,5, while remission as an EUSTAR-AI <2,5; activity persistence was defined as an EUSTAR-AI ≥ 2,5 in more than 50% of follow-up visits. According to the literature, damage was classified as mild (SCTC damage index < 6) and moderate-severe (SCTC damage index ≥ 6).
Results: 173 SSc patients (87,9% females) were enrolled in our study and followed up for a median time of 3,5 years. The median disease duration at baseline was 9 years while the median age at diagnosis was 45 years; 34,6% of patients had diffuse cutaneous SSc. Patients with persistently active disease during follow up (13,2%) had at baseline a significantly higher frequency of diffuse cutaneous subset (54% vs 17%, p<0,0001) and cardiac involvement (43,4% vs 20,7%, p=0,036) than persistently inactive patients; erythrocyte sedimentation rate (ESR) values were higher (p=0,002) and total lung capacity (TLC) values were lower (p=0,034) in persistently active patients. Positive anticentromere antibodies (ACA) were associated with persistent remission (p=0,042). Persistent disease activity was associated with higher disease severity [MSS 6,3 (±3) vs 3,5 (± 1,7)], p<0,0001] and more severe damage [SCTC-DI 3,7 (±4) vs 1,3 (±1,9), p<0,0001] at baseline. At the multivariate analysis, ESR values (OR 1,04 95% CI 1,01-1,07) and MSS values at baseline (OR 1,75, 95% CI 1,29-2,37) were independent predictors of activity persistence. Patients with persistent or new onset of moderate-severe SCTC at the end of the follow up (9%) had more frequently telangiectasia (81,3% vs. 38,6%, p=0,001) and ILD (62,5% vs. 31,6%, p=0,013) at baseline than patients with mild damage; they also showed lower DLCO values (p=0,047) and lower TLC values (p<0,0001), as well as higher systolic pulmonary arterial pressure (sPAP) on transthoracic echocardiography (p< 0,0001) at baseline. Multivariate analysis showed that TLC values (OR 0,95, 95% CI 0,92-0,98) and telangiectasia (OR 4,7, 95% CI 1,18-18,54) were independent predictors of moderate-severe damage. An association was found between persistence of disease activity and moderate-severe damage at the end of follow-up (p=0,003).
Conclusion: Identifying predictors of disease activity persistence and damage accrual at baseline may help to improve the risk stratification of SSc patients, through the identification of those patients who require prompt treatment and a more thorough clinical follow-up.

POS1305 ULTRA-HIGH-FREQUENCY ULTRASOUND FOR THE EVALUATION OF SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS: PRELIMINARY RESULTS OF A MONOCENTRIC STUDY

Keywords: Ultrasound, Systemic sclerosis, Outcome measures

Y. Ferraioli[1], M. Fogante[2], D. Benfaremo[3,4], G. Argalia[2], G. Moroncini[3,4]. [1]*Marche Polytechnic University, Internal Medicine Residency Program, Ancona, Italy*; [2]*Marche University Hospital, Radiologia Materno Infantile, Senologica, Cardiologica ed Ecografica Ambulatoriale, Ancona, Italy*; [3]*Marche Polytechnic University, Department of Clinical and Molecular Sciences, Ancona, Italy*; [4]*Marche University Hospital, Clinica Medica, Ancona, Italy*

Background: Cutaneous involvement is one of the most important clinical aspects of systemic sclerosis (SSc) and is characterized by three different phases in temporal sequence: oedematous, fibrotic and atrophic. The most widely used method to evaluate skin involvement is the modified Rodnan Skin Score (mRSS), which assigns a grade from 0 (normal) to 3 (severe) in 17 different areas of the body. However, the intra- and inter-operator variability of mRSS is considerably high. Thus, a more objective, sensitive and reproducible method for measuring skin involvement in SSc would be needed, both for clinical trials and for daily clinical practice.
Objectives: To evaluate the possible role of ultra-high-frequency skin ultrasound in patients with SSc.
Methods: Consecutive SSc patients fulfilling ACR/EULAR classification criteria were enrolled in this cross-sectional study. Patients with active immunosuppressive (IS) treatment were not excluded. Subjects with idiopathic Raynaud's phenomenon (RP) and healthy controls (HC) were also evaluated upon informed consent. All subjects underwent US evaluation, using a 70 MHz ultra-high frequency (UHF) probe, by an experienced radiologist, blinded to the clinical characteristics of the patients and controls, at six anatomical sites (forearm right and left, hand right and left, second finger right and left). The thickness of the dermis, epidermis and hypodermis was measured at each site, and the mean value between the right and the left side was used (Figure 1). Differences between groups were analysed using the ANOVA. The Pearson coefficient was used to evaluated correlations between variables.
Results: Sixty-two (62) SSc patients (43 limited cutaneous (lc) and 19 diffuse cutaneous (dc) SSc), 14 RP and 16 HC were enrolled. Patients with RP were significantly younger than SSc and controls. Mean disease duration of SSc was 9.74 years. 27% of patients were on active IS treatment, 30% were using bosentan and 48% intravenous prostanoids. UHF-US allowed a precise identification and measurement of the thickness of the dermis and hypodermis of all individuals. The mean dermal thickness in the fingers was significantly higher in dcSSc patients than in lcSSc, RP and HC (p<0.001), while in the hands it was significantly higher only compared to RP (p<0.001) and in the forearm there was no difference between groups. Dermal thickness at the finger level significantly correlated with age (r 0.28, p=0.0067) and mRSS (r 0.29, p=0.01). We found no differences in dermal thickness of SSc patients according to use of IS treatment. Hypodermal thickness of the hands and fingers was higher only in patients with lcSSc compared to all other groups but was also significantly correlated to age (r 0.31 and 0.22, p<0.05, respectively) and BMI (r 0.36 and 0.32, p<0.001, respectively). Hypodermal thickness of the fingers was lower in patients using bosentan treatment (p=0.01).
Conclusion: These data show that skin UHF-US allows to measure in detail the dermal thickness and that these measurements correlate with the skin score. UHF-US could be used as an objective, sensitive and reproducible method for measuring skin involvement in SSc.

POS1306 HEALTH-RELATED QUALITY OF LIFE (HRQOL) ACROSS DIFFERENT CONNECTIVE TISSUE DISEASES (CTDS): ANALYSIS OF A MONOCENTRIC EXPERIENCE

Keywords: Systemic lupus erythematosus, Patient reported outcomes, Quality of life

E. Elefante[1], L. Gualtieri[1], C. Cardelli[1], M. DI Battista[1], L. Carli[1], A. Della Rossa[1], C. Tani[1], M. Mosca[1]. [1]*Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*

Background: patients with CTDs have a worse HRQoL compared with the general population and chronic non-rheumatic diseases. However, only few studies have compared HRQoL among CTDs that differ for age at diagnosis, type and severity of organ involvement, disease course.
Objectives: to analyze HRQoL and fatigue across different CTDs in a monocentric cohort.
Methods: a cross-sectional study that enrolls consecutive adult patients with a diagnosis of Systemic Lupus Erythematosus (SLE), Systemic Sclerosis (SSc) and Idiopathic Inflammatory Myopathies (IIM), regularly followed at the Rheumatology Unit of Pisa. For each patient, demographics, treatment, clinical and laboratory data were collected. At enrollment, each patient completed the SF-36 for HRQoL and the FACIT for fatigue.
Results: we enrolled 490 CTD patients: 255 (52%) SLE, 150 (30.6%) SSc, and 85 (17.3%) IIM. The majority were female (85.7%) and of Caucasian ethnicity (97.5%). At enrollment, patients with SLE were significantly younger (mean age: 44.6 ±12.7 years for SLE, 62.6 ±13.6 for SSc, 65.7 ±12.4 for IIM, p<0.001), with a significantly longer disease duration (14.1 ±10.1 years for SLE, 8.2 ±6.4 for SSc, 5.3 ±5.7 for IIM, p<0.001) compared to the other two groups. The rate of fibromyalgia was highest in SSc (24.7% in SSc, 15.3% in SLE, 11.8% in IIM). Among SLE patients, 79 (31%) presented a mild active disease at enrollment, with skin (35/255) and hematological (32/255) manifestations being the most frequent; only 11 patients (4.3%) presented an active renal disease. Among IIM patients, 67 (78.8%) presented an active disease according to the clinician evaluation: 31 had active myositis and 29 active skin lesions. 33 patients had an Interstitial Lung Disease (ILD). Among SSc patients, 62% presented limited skin involvement; 45 patients (30%) had an ILD and 41 (27.3%) presented a scleroderma heart involvement, while 18 patients had active digital ulcers at enrollment. As far as treatment is concerned, most patients were on Hydroxychloroquine (63.5%); almost half of patients enrolled (45.7%) were on a low dose of glucocorticoids (mean daily dose 2.12 ±2.78 mg of 6-methylprednisolone), and 43.9% were on immunosuppressants. The results of the SF-36 domains are represented in Figure 1. We compared the results of questionnaires across groups. At the univariate analysis, the domains of Physical Function (PF), Role Physical (RP) and Role Emotional (RE) resulted different between groups. In particular, the IIM patients presented the lowest scores compared with the other two groups (Table 1). However, at the multiple linear regression analysis, only the PF domain confirmed to be significantly different across the three groups, after adjusting for age at enrollment and disease duration (β-0.003, [95% CI-0.005, -0.001; p<0.01]).
Finally, the FACIT scores were not significantly different between groups.
Conclusion: in our monocentric cohort of patients with CTDs, there were no clear differences in HRQoL driven by diagnosis, except for the physical function domain which appeared more impaired in myositis patients. HRQoL appears as an independent domain of patients' health status, only marginally influenced by the clinical characteristics of the disease. This underlines the importance for clinicians managing patients with complex autoimmune diseases to develop common strategies to address and improve HRQoL, parallel to the clinical management of the disease.

Background: Interstitial lung disease (ILD) is a severe manifestation of inflammatory rheumatic diseases (IRD). Conventional treatments have shown modest and short-lived success in the control of ILD [1]. Nintedanib (Nib) was recently approved for systemic sclerosis (SSc)-associated ILD and fibrosing ILD with a progressive phenotype [1]. However, its experience in other IRD-associated ILD is still scarce.
Objectives: To describe the clinical features and outcomes of patients with IRD-ILD treated with Nib across ten national rheumatology departments.
Methods: Retrospective cohort study, with chart review of the medical records for inclusion of patients with IRD-ILD treated with Nib. Data are presented as frequencies and mean±standard deviation (range) for categorical and continuous variables, respectively.
Results: A total of 64 patients (70% women) were identified (Table 1). The mean age at IRD and ILD diagnosis was 56.2±11.7 and 59.7±10.8 years (y), respectively, and the mean time for Nib initiation after ILD diagnosis was 5.1±3.9 y. The most frequently underlying IRD were SSc (55%) and rheumatoid arthritis (28%). ILD was diagnosed prior to the IRD in only 7 patients (11%). Computed tomography (CT) identified usual interstitial pneumonia (UIP) in 36 cases (56%), fibrotic nonspecific interstitial pneumonia (NSIP) in 27 (42%) and organizing pneumonia in one (2%). Patients with UIP took longer to start Nib (5.5±4.4 y) compared to patients with NSIP (4.7±2.4 y). Before Nib, respiratory function tests (RFTs) showed a low single-breath diffusing capacity of the lungs for CO (DLCO) in all patients, with a mean predicted value of 39±18%. All patients had previously received immunosuppressive therapy, most commonly glucocorticoids (70%) and mycophenolate mofetil (50%). Patients were exposed to Nib for a mean of 18.5±15.9 months (m), 17 were treated for more than 24m. After 6m, there was a statistical improvement in DLCOc SB (p=0.041) and DLCOc/VA (p=0.029) compared to baseline, which was not observed at 12 or 24m (p>0.05). No differences were found between patients with NSIP and UIP. Nevertheless, the latter showed a trend for an overall lower benefit on RFTs

Table 1 - Clinical features of patients

UIP									

ILD	UIP	NSIP	OP
Time for Nib initiation after diagnosis (years)	5.5±4.4 (0.5-19)	4.7±2.4 (0-13)	3
Nib treatment duration (months)	16.9±16.8 (2-67)	21.9±15.1 (1-52)	16

Abbreviations DM - dermatomiositis; MCTD - mixed connective tissue disease; MPA - microscopic polyangiitis; PM - polymyositis; pSS - Sjögren's Syndrome; RA - rheumatoid arthritis; SLE - systemic lupus erythematosus

(Figure 1), mainly in the first 12m of treatment (NSIP: forced vital capacity [FVC] p=0.173 and DLCOc SB p=0.199; UIP: FVC p=0.278 and DLCOc SB p=0.267). In patients with <3y of ILD duration (n=20 [8 NSIP; 12 UIP]) a significant improvement in DLCOc SB and DLCOc/VA was observed at 24m (p=0.003 and p=0.017). Regarding tolerance: 38 (59%) patients were able to maintain a daily dose of 150 mg bid, 24 (38%) required reduction to 100 mg bid due to gastrointestinal (GI) symptoms and 2 (3%) discontinued Nib.

Conclusion: An initial benefit was observed in the DLCO of patients treated with Nib at 6m. Only 1/3 of patients were started on Nib with less than 3y of ILD duration, possibly reflecting the recent approval of Nib for these diseases. In this subset of patients, a significant improvement in DLCO was observed at 24m, suggesting that early initiation of treatment may halt ILD progression.

ASSOCIATION BETWEEN RED CELL DISTRIBUTION WIDTH AND INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS

Keywords: Descriptive studies, Biomarkers, Systemic sclerosis

L. L. Holguín Arias[1], L. Sorrentino[1], J. A. Brigante[1], D. Yucra[1], R. Gomez[2], M. D. L. P. Menendez[3], M. S. Menendez[4], M. Rivero[5], A. Benitez[2], C. Peon[2], M. J. Gamba[2], C. Soliz[1], M. Iudici[6], A. Hamaui[1], D. Dubinsky[1]. [1]*Sanatorio Güemes, Rheumatology, CABA, Argentina*; [2]*Hospital Posadas, Rheumatology, CABA, Argentina*; [3]*Hospital Alemán, Pulmonology, CABA, Argentina*; [4]*Hospital de Chivilcoy, Pulmonology, CABA, Argentina*; [5]*Hospital Municipal de Alberti, Rheumatology, CABA, Argentina*; [6]*Hospital Beau-Séjour, Rheumatology, Geneva, Switzerland*

Background: Interstitial lung disease (ILD) and pulmonary arterial hypertension (PHT) account for 60% of deaths related to scleroderma (SSc) [1]. The Red Cell Distribution Width (RDW) is a biomarker that has been used as a marker of poor prognosis in various pathologies [2-9]. In SSc, the RDW has been found to be elevated in PHT and has been proposed as a predictor of cardiorespiratory compromise [10-11].

Objectives: To evaluate the association between the increase in RDW and the presence of ILD in patients with SSc.

Methods: Observational, retrospective, multicenter, cross-sectional study of patients with SSc (ACR/ EULAR 2013) between 1/1/2011 to 8/31/2021. Other concomitant autoimmune diseases, malignancy, active infections, anemia, recent transfusions, cardiovascular, renal, or hepatic disease were excluded. The diagnosis of ILD was made by high-resolution computed tomography (HRCT) and the extension evaluated by Goh criteria[12]. A review of medical records was performed, collecting relevant clinical and demographic characteristics.

Results: Seventy-five patients were included, with a mean age of 59.4 years (SD 14.1, 95% CI 56-63), 67 (89%) were women. A median of 8 years of disease evolution was observed (IQR 8). ILD was observed in 50 (66,6%) patients while 25 (33.3%) did not. According to Leroy's classification, limited SSc (lcSSc) was observed in 50 patients (66,6%) and diffuse SSc (dSSc) in 24 (33,3%); the last classification was significantly associated with the presence of ILD, as was as MRSS (Modified Rodnan Skin Thickness Score)> 14, digital ulcers, and positive ATA (DNA topoisomerase I), unlike ACA (anticentromere antibodies) (Table 1). The most frequent HRCT pattern was NSIP (Nonspecific interstitial pneumonia) in lcSSc (66.6%). An association was found between dSSc and fibrotic patterns (fNSIP and UIP). OR 6, 95% CI 1.6-21 (p 0.009). The extension of the disease was measured in 44 patients (6 missing data), being limited in 25 (57%) and extensive in 19 (43%). The extensive form was correlated with a higher RDW mean (p < 0.0001). The MRSS was measured in 70 patients, being less than 14 in 63 (90%). 100% of the patients with mRSS > 14 had a high RDW (p 0.01). Increased RDW was evidenced in the group with ILD, with a statistically significant difference (OR 6.06 95%CI 2-17 p 0.001).

Table 1. Clinical, demographic and laboratory characteristics

ACA: anticentromere antibodies; ATA: DNA topoisomerase I; CRP: C reactive protein; dSSc: diffuse SSc; ERS: erythrocyte sedimentation rate; fNSIP: fibrotic NSIP; GERD: gastroesophageal reflux disease; HRCT: high-resolution computed tomography; ILD: interstitial lung disease; IQR: interquartile range; lcSSc: limited SSc; Me: median; MD: missing date; MRSS: modified rodnan skin thickness score; NSIP: nonspecific interstitial pneumonia; PHT: arterial hypertension; RDW: red cell distribution width; SD: standard deviation; SRC: scleroderma kidney crisis; UIP: usual interstitial pneumonia.

The median RDW in the groups with isolated ILD and ILD plus PHT was significantly higher than in patients without lung disease (p < 0.001). We found no significant difference between the ILD and ILD plus PHT groups (p 0.350) (Figure 1).

Figure 1.

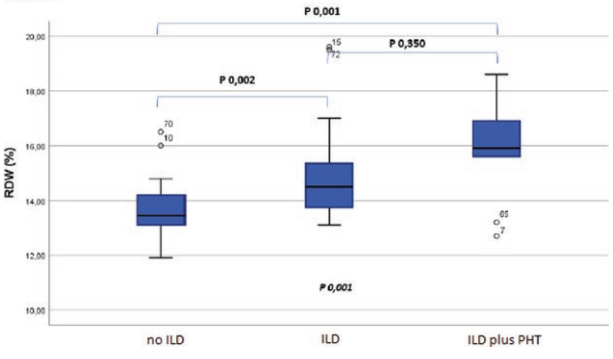

Figure 1.

Conclusion: We have been able to show that there is a significant relationship between the increase in RDW and the presence of ILD in patients with SSc; this association was more significant for the extensive forms of the disease as well as fibrotic patterns. These findings are relevant as the RDW is an easily accessible parameter that could be used in the follow-up of patients with SSc, and an elevation not explained by other causes of the RDW could be an alarming marker to search more exhaustively for the presence of cardiorespiratory compromise. The limitations of the study are those of any retrospective study, the presence of

missing data in addition to the limited number of patients. It is necessary to continue studies with a larger number of patients to grant robustness to the results.

Background: Lower gastrointestinal tract (GIT) complications are common in patients with systemic sclerosis (SSc), associate with a high disease burden, and current treatment alternatives are limited. Patients with SSc have also an altered intestinal microbiota composition. This provides a rational for the investigation of fecal microbiota transplantation (FMT) in SSc patients with lower GIT symptoms.

Objectives: To assess the safety and efficacy of a standardized intestinal microbiota infusion in SSc patients with lower GIT symptoms.

Methods: Patients with SSc and moderate to severe bloating and/or diarrhea assessed by the UCLA SCTC GIT score 2.0 were enrolled in a Norwegian multicenter, double-blind, randomized, placebo-controlled, phase 2 trial. Patients were randomized to receive an intestinal infusion of a standardized fecal microbiota culture (ACHIM) or placebo at weeks 0 and 2. At week 12, all patients received an ACHIM infusion and were followed in an open maintenance phase until week 20. The primary outcome was a change between baseline and week 12 in UCLA GIT score item diarrhea or bloating, depending on which was the worst symptom at the baseline evaluated separately for each patient, measured as the average marginal effect (AME). Secondary outcomes were safety and tolerability and total UCLA GIT score. Other outcome measures included the change in UCLA GIT score from week 12 to week 20.

Results: A total of 65 patients were randomized to receive ACHIM or placebo. Baseline characteristics in the placebo and ACHIM groups were comparable (Table 1). There was no significant difference in the change in lower GI symptoms from week 0 to week 12 between the ACHIM and placebo groups (AME=0.17 (-0.12, 0.47), p=0.25). Similarly, no significant difference was observed in the total GIT score between the two groups over the same time period (AME=0.09 (-0.04, 0.23), p=0.17). Furthermore, during the maintenance phase, there was no statistical difference in change between the ACHIM and the placebo group (AME= -0.04 (-0.32, 0.23), p=077). In ACHIM, 16 (37%) and in placebo 19 (42%) experienced any side effect. These were in general mild and short-lasting, with abdominal pain as the most frequent side effect present in 5 (15%) in ACHIM and 2 (6%) in placebo. Time to resolved pain was 2 days in both groups. One patient experienced an intramural perforation during gastroscopy and needed IV antibiotics but fully recovered.

Conclusion: We were unable to find indications that FMT improves lower GIT symptoms in SSc patients, but the treatment was found to be safe.

Table 1: Baseline characteristics

Parameter	ACHIM (N=33)	Placebo (N=34)
Age, y (SD)	58 (11.5)	60 (11.7)
Female, n (%)	33 (100)	29 (85)
Worst symptom Bloating, n (%)	22 (67)	22 (65)
Disease duration, y (SD)	9 (7)	10 (8)
Limited cutaneous SSc, n (%)	31 (94)	28 (85)
FVC% (SD)	95 (13.7)	90 (19.2)
Immunosuppressives, n (%)	3 (9)	5 (15)
PPI, n (%)	27 (82)	21 (62)
CCB, n (%)	18 (58)	20 (59)
Total GIT score	0.9 (0.5)	0.7 (0.3)
GIT scale Diarrhea	0.8 (0.7)	0.5 (0.5)
GIT scale Bloating	1.8 (0.8)	1.7 (0.7)

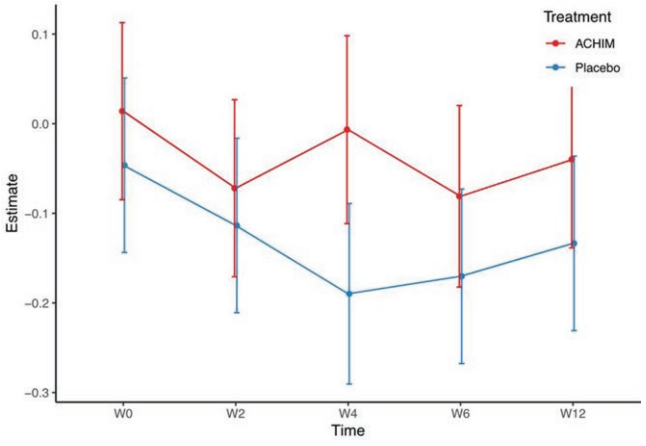

Figure: Change between baseline and week 12 in UCLA GIT score item diarrhea or bloating, depending on which was the worst symptom at the baseline in ACHIM (red) and placebo (blue), adjusted for baseline.

Background: Gastrointestinal (GI) complications are a major cause of morbidity and mortality in systemic sclerosis (SSc) [1]. Proton pump inhibitors (PPIs) are widely used to treat gastroesophageal reflux disease in SSc. However, not all patients respond adequately to these drugs, and concerns about the safety of their long-term use of PPI's exist in the general population [2].
Objectives: To identify patients' unmet needs and perspectives concerning PPI therapy.
Methods: An online survey in the English language targeting patients with SSc treated with PPI was developed and distributed through international patient associations and social media. The survey was launched on 4th November 2022 and kept open for 4 weeks.
Results: Of 416 people starting the survey, responses from 301 subjects with self-reported SSc from 14 countries (US 70.4% and UK 19.3%) were evaluable. The majority of patients were between 30-70 years of age and were female (95%). The most frequent patient-reported symptoms were acid reflux (97%), dysphagia (60%), nausea, vomiting and the regurgitation of food or phlegm (>60%). 83% of patents had undergone at least 1 invasive test to diagnose gastroesophageal reflux disease (e.g., upper endoscopy). The most commonly prescribed PPIs were omeprazole (62%), esomeprazole (24%), and pantoprazole (10%). One third of patients (35%) had only taken one PPI, whereas the use of various PPI's (in series) was required by the majority (two PPIs: 30%, three PPIs: 21%). Daily PPI (46%) vs twice daily PPI regimens (47%) were divided equally among respondents. When on PPI, the majority of patients (89%) reported an improvement of GI symptoms when taking PPI, especially for symptoms of gastroesophageal reflux disease (94%). Only 19% experienced side effects from PPIs use, weak bones (osteoporosis) and calcium formation (calcinosis) being the most frequent. Half of patients (47%) experienced a return of symptoms despite initial improvement on PPI. Combination therapy (PPI plus other medication for reflux disease) was required for the optimal management of reflux disease in 41% of patients and was often deemed more beneficial than PPI monotherapy (72%). Many patients (83%) were worried that GI symptoms would return following PPI discontinuation. Furthermore, 79% of patients were worried about side effects from long-term use PPI, particularly the development of 'weak bones (i.e., osteoporosis)' (66%), kidney problems (55%), calcium formation (i.e., calcinosis) (39%), and cardiovascular disease (38%). PPIs were prescribed by a healthcare professional in 92% of respondents (8% bought over-the counter). Financial reimbursement for PPIs was only provided in around two-thirds of patients (64%). Only 58% of patients received information on lifestyle and diet to manage GI symptoms before starting PPI. Furthermore, the majority of patients (85%) obtained information about PPIs online. In only 12% of cases, a surgical approach to manage upper GI symptoms was discussed (rheumatologist or gastroenterologist). However, 46% of patients expressed their approval to undergo surgery (e.g., fundoplication) to resolve their reflux symptoms; however, many (80%) were worried about possible complications.
Conclusion: Our study benchmarks the importance of gastroesophageal symptoms in patients with SSc and the frequent use of PPIs. There is significant heterogeneity in the use of PPI in SSc and combination therapy is not uncommon. Patients live with great uncertainty including PPI side effects. Education about PPIs is often neglected, and patients rely on online information. A surgical approach is still not widely considered as a therapeutic option.

POS1312 **PREVALENCE OF GASTROINTESTINAL SYMPTOMS AND OBJECTIVE GASTROINTESTINAL DYSMOTILITY IN PATIENTS WITH SYSTEMIC SCLEROSIS**

Keywords: Systemic sclerosis, Gastrointestinal tract, Quality of life

L. Alcala-Gonzalez[1], A. Guillen-Del-Castillo[2], A. Marin[1], L. Comas[1], C. Codina[2], I. Blazquez[2], J. Corada[2], C. Malagelada[1], C. P. Simeon Aznar[2]. Background: After the skin, the gastrointestinal tract is the most frequently affected system in systemic sclerosis (SSc). The pathophysiology of gastrointestinal symptoms is mostly secondary to gastrointestinal dysmotility. Due to the increase survival in patients with systemic sclerosis, digestive manifestations are becoming more relevant in the comprehensive management of the disease.
Objectives: To assess the prevalence of gastrointestinal symptoms, the presence of gastric and intestinal dysmotility in objective testing and to examine associations between gastrointestinal involvement and other systemic sclerosis features.
Methods: A cross-sectional study was conducted in the cohort of active SSc patients in a tertiary center. Patients who fulfilled LeRoy or ACR/EULAR 2013 classification criteria were contacted by telephone and asked to complete standardized questionnaires: UCLA-GIT 2.0, IBS-SSS (IBS symptom severity score), a gastrointestinal symptoms questionnaire and the SF-36 (quality of life). Questionnaire terminology was altered to replace references to 'IBS' with 'GI symptoms'. Demographic, clinical-immunological data and results of complementary motility tests were collected from the medical records. Gastrointestinal motility was assessed by gastric emptying scintigraphy, small intestinal manometry and/or abdominal CT scan.
Results: A total of 183 SSc patients participated in the study with a mean age ± standard deviation (SD) of 59±12 years, 103 (55%) patients had limited cutaneous SSc (lcSSc) subset, 43 (24%) diffuse cutaneous SSc (dcSSc), and 37 (21%) sine sclerosis SSc (ssSSc). 139 (77%) patients reported having at least one frequent digestive symptom (>1 day/week). The prevalence of digestive symptoms correlated negatively with overall quality of life measured by SF-36 (r= -0.503 p=<0.001). In univariate analysis, female gender (87 vs 73%; p=0.025), onset at an early age (44±7 vs 50±6 years; p=0.037) and a capillary loss pattern (23% vs 7%; p=0.023) were associated with the presence of digestive symptoms. Gastrointestinal motility assessment detected gastroparesis in 18/31 (total 58%; mild n=6, moderate n=5, severe n=7), small bowel abnormal motility patterns in 6/6 (total 100%, neuropathic n=1, myopathic n=5) and small bowel dilated loops in 6/65 patients (total 9%, CT scan). Among the patients studied by gastric emptying scintigraphy, gastric retention at 4 hours had a moderate positive correlation with IBS-SSS and UCLA GIT 2.0 scores (r=0.433 and r=407, p=<0,01 respectively).

Gastric meal retention at 4 hours measured by scintigraphy showed a moderate positive correlation with gastrointestinal symptom burden measured by UCLA GIT 2.0 (r= 0.407) and with the severity of gastrointestinal symptoms measured by the modified IBS severity symptom score (r=0.433).

Figure 1.

Moderate-severe gastrointestinal involvement (21 patients, 11%) was associated with older age at SSc onset (45 ± 9 vs 36 ± 14 years; p=0.012), dcSSc (57% vs 18%; p=0.001), myositis (24% vs 3%, p=0.011), tendon friction rubs (29% vs 3%, p=0.003) erosive esophagitis (10% vs 57%, p=0.001) despite proton bomb inhibitor treatment. Patients with moderate-severe gastrointestinal involvement had a worse (higher) UCLA GIT 2.0 score (1.05 ± 0.63 vs 0.62 ± 0.51; p=0.043) mainly due to reflux (1.07 ± 0.63 vs 0.58 ± 0.61; p=0.001) and bloating (1.85 ± 0.78 vs 1.23 ± 0.94; p=0.001) and greater severity of abdominal symptoms (IBS-SSS score, 185 ± 91 vs 146 ± 113; p=0.032). All patients (n=6) with chronic intestinal pseudo-obstruction presented dcSSc subset.

Conclusion: Patients with SSc have a high prevalence of digestive symptoms and objective gastrointestinal dysmotility that negatively impact their quality of life. Gastrointestinal dysmotility seems to worsen reflux disease. The dcSSc subset is associated with more severe gastrointestinal involvement.

POS1313 EFFICACY OF IMMUNOGLOBULIN TREATMENT ON GASTROINTESTINAL, CUTANEOUS AND VASCULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS: DATA FROM AN ITALIAN COHORT OF 65 PATIENTS

Keywords: Skin, Gastrointestinal tract, Systemic sclerosis

F. Bonomi[1], A. Damiani[1], C. Coccia[1], J. Levani[1], E. Fiorentini[1], G. Lepri[1], M. Orlandi[1], F. Bartoli[1], M. Matucci-Cerinic[1,2], S. Bellando-Randone[1], S. Guiducci[1]. *[1]Azienda Ospedaliero Universitaria Careggi, Experimental and Clinical Medicine, Division of Rheumatology, Florence, Italy*; *[2]IRCSS San Raffaele Hospital, 2. Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Milan, Italy*

Background: Systemic sclerosis (SSc) is a rare connective tissue disease characterized by autoimmunity, vasculopathy, and fibrosis involving many organs. To date, the gastrointestinal (GI) involvement accounts for few therapeutic options, while cutaneous and vascular manifestations are often refractory to standard treatments. Immunoglobulin (Ig) therapy is an interesting option as it exhibits both immunomodulatory and antifibrotic properties even though its efficacy on GI, skin and muscle involvement has been described only in case series with limited numbers of patients.

Objectives: To evaluate the efficacy of Ig therapy on GI, cutaneous, and vascular involvement in SSc.

Methods: a retrospective observational study was conducted evaluating SSc patients treated with Ig at a 2 gr/kg/month dosage either intravenously (IV) or subcutaneously (SC). Demographical data, antibodies positivity, associated therapies (vasoactive and immunosuppressants) and disease duration were collected. Moreover, the presence of diarrhea, gastroesophageal reflux (GER), dysphagia, digital edema, digital ulcers (DUs), as well as the modified Rodnan Skin Score (mRSS) and videocapillaroscopic pattern (VCP: normal, early, active, late) were assessed at baseline (BL) and after 6 (T6) and 12 (T12) months of Ig therapy. Variation of these items from BL to T6 and T12 was tested by Paired T Test, Mc Nemar test, Wilcoxon's signed rank test as appropriate. Regression analyses were than performed to assess influence of possible confounders variables (vasoactive and immunosuppressants drugs) on outcome variables (VCP, digital edema, DUs).

Results: Clinical records of 65 patients were analyzed. Mean age was 56.18 (± 12.32 SD) and median disease duration was 10.00 years (min-max 1.00-38.00). Sixty-three patients (96.9%) were ANA positive, with positivity for anti-centromeric antibodies in 23 (35.4%), SCL-70 in 27 (41.5%) and RNA polymerase III in 8 (12.3%) patients. Ig were administrated IV in 57 patients and SC in 8 patients. Table 1 summarized the trend of clinical items from BL to T12. At BL, 49.2% of patients complained diarrhea, 90.8% GER, 51.6% dysphagia, 76.9% digital edema; 38.5% presented DUs. VCP was normal in 3.1% of patients, early in 21.9%, active in 45.3%, and late in 29.7%. Also, median mRSS was 10 (min-max 0-50). At T6, median mRSS significatively improved [6 (min-max 0-34), p<0.0000001] together with VCP (normal in 15.6%, early in 15.6%, active in 35.6%, and late in 33.3%, p=0.00448). Moreover, a significative reduction of the prevalence of GER (49.2%, p<0.000001), diarrhea (19.4%, p<0.0001), dysphagia (22%, p<0.0001), digital edema (44.4%, p<0.0001), DUs (14.1%, p=0.0022) was noted. At T12, median MRSS improved even more [3 (min-max 0-23), p<0.00000001] along with VCP (normal in 19.0%, early in 23.8%, active in 28.6%, and late in 28.6%, p=0.00596). Also, the prevalence of GER was lower (25.9%, p<0.001). Regression analyses did not evidence any influence of other treatments on the tested outcome variables.

Conclusion: Our data confirms literature data on Ig therapy efficacy towards GI and skin manifestations [1]. To date, this is the first study presenting a possible positive effect on the vascular component shown by the improvement in VCP; these data should be confirmed with prospective randomized studies on bigger samples.

POS1314 AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION: LONG-TERM OUTCOMES IN A SINGLE-CENTER COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Disease-modifying drugs (DMARDs), Systemic sclerosis, Organ damage

N. Del Papa[1], A. Rindone[1], S. Cavalli[1], A. Minniti[1], F. Onida[2], G. Saporiti[2], M. Goldaniga[2], C. Iannone[1], G. Armentaro[1], S. Germinario[1], M. Sette[1], R. Caporali[3]. *[1]ASST Gaetano Pini-CTO, Rheumatology, Scleroderma Clinic, Milano, Italy*; *[2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Università degli Studi di Milano, Hematology and BMT Unit, Milano, Italy*; *[3]ASST Gaetano Pini-CTO, Department of Clinical Sciences and Community Health, Research Center for Adult and Pediatric Rheumatic Diseases, University of Milan, Milano, Italy*

Background: Although various immunosuppressive drugs are used to treat Systemic Sclerosis (SSc), no therapy has proved to be actually effective in changing the natural history of the disease. Three randomized controlled trials have demonstrated the superiority of autologous hematopoietic stem cell transplantation (AHSCT) on conventional therapies for patients suffering from severe SSc. However, data on disease activity and progression after AHSCT are really scant.

Objectives: To retrospectively evaluate the long-term effectiveness of AHSCT in a monocentric cohort of SSc patients with a severe diffuse cutaneous disease at the baseline, and every 12 months up to 60 months after transplantation. In addition, we retrospectively compared the disease outcome of transplanted patients to an age-and sex-matched group of severe SSc patients selected from our historical cohort and treated with conventional therapies.

Methods: Clinical, instrumental and laboratory data of all SSc patients who underwent AHSCT between 2003 and 2020 in our center and with a regular follow up of 60 months after transplant, have been retrospectively analyzed. AHSCT was performed by mobilisation with CTX and G-CSF, selection of CD34+ cells and conditioning regimen with CTX and rabbit ATG. Survival, skin involvement assessed by modified Rodnan skin score (mRSS), cardiac and lung involvement assessed by echocardiography and lung functional parameters, and EUSTAR disease activity (EDA) scores were recorded. All transplanted patients had a rapidly progressive cutaneous disease characterized by a mRSS>14 and were unresponsive to conventional immunosuppressive therapies. Similar evaluations were made in the control group represented by age- and sex-comparable patients suffering from an exactly comparable disease-duration and clinical characteristics in term of skin involvement and disease activity, and treated with conventional therapies. For this group, the enrolment period was 1991-2020.

Results: 35 patients underwent AHSCT, 30 females and 5 males. Patients were eligible for AHSCT when they had mRSS>14 and an EDA score>2, in the absence of severe organ involvement (renal clearance<40mL/min, DLCO<40%, ejection fraction<45%). At the baseline mean, mRSS was 21.4 ± 5, mean FVC 90.1% ±17.9 and mean DLCO 66.5%±15. We observed a sustained improvement in skin thickening and a persistent reduction of EDA scores, with p-values<0.0001 for both parameters at any follow up time. Transplant-related mortality occurred in 2 patients, one at +65 days from interstitial pneumonia and one at +2 days from myocarditis (5.7%). Three patients died during the follow up from disease progression complications, one at +3 years due to fatal cardiac arrhythmia and two due to progressive lung failure at + 5 years and +7 years. In the control group (68 patients), 25 patients received 6 monthly pulses of intravenous cyclophosphamide (750mg/m^2), 10 received mycophenolate, 10 methotrexate, 12 rituximab, and 11 received steroids and vascular therapies, in the absence of real immunosuppressive therapies. AHSCT patients experienced a better overall survival compared with control patients (p=0.001). AHSCT was also more effective than other therapies for the outcomes of skin score (p<0.0001), lung function (p=0.0004) and disease activity (p<0.0001).

Conclusion: The results of this large historical cohort study of patients with severe SSc confirm efficacy of AHSCT in terms of survival, response to treatment and disease progression rate. The improvement of skin thickening and stabilization of organ function up to 5 years after transplantation, result in a global clinical improvement, as showed by the persistent reduction in the activity score. Probably as a consequence of an accurate patient selection, transplant related mortality results to be acceptable and similar to that reported in previous studies. Despite the limitation of a retrospective study, AHSCT is more effective than conventional therapies, including the latest immunosuppressive agents.

Dobrowolski[1]. *[1]Icahn School of Medicine at Mount Sinai, Rheumatology, New York, United States of America*; *[2]Mount Sinai, Morningside-West, Internal Medicine, NYC, United States of America*; *[3]Icahn School of Medicine, Mount Sinai, Gastroenterology, NYC, United States of America*

Background: Systemic Sclerosis (SSc) is an autoimmune disease characterized by fibrosis and vascular abnormalities in the skin and internal organs, which confers high morbidity and mortality [1]. Esophageal dysmotility (EsD) and gastrointestinal esophageal reflux disease (GERD) are among the most common manifestations of SSc, occurring in up to 80% of patients and decreasing quality of life [2]. To date, treatment of SSc-associated EsD/GERD consists of symptomatic management, including the use of pro-motility agents and anti-reflux medication [3]. Despite the elevated burden of SSc-EsD/GERD, no high-quality evidence to support the use of disease modifying immunomodulatory medications exists. This study explored mycophenolate (MMF), an inosine-5'-monophosphate dehydrogenase inhibitor, which has shown efficacy for suppressing other SSc manifestations including interstitial lung disease and skin thickening [4].

Objectives: To investigate the potential relationship of MMF with SSc-associated esophageal disease.

Methods: A retrospective chart review was completed for patients with SSc at the Mount Sinai Hospital between January 1, 2000 – January 6, 2022. Individuals with Ssc were identified using a validated ICD-10 M34 code. Data gathered included demographic factors, history of MMF use and cumulative dosing, GERD/EsD diagnosis, medication use, and other relevant clinical factors. Esophageal disease was considered to be present if a patient had any of the following: a formal diagnosis of GERD, absent/ineffective contractility on manometry, or Barrett's esophagus identified on endoscopy. Descriptive statistics were conducted, and X^2 tests/t-tests were computed to compare demographic and outcome variables between patients taking MMF and those not. Multivariable logistic regression analysis was conducted to identify the relationship between MMF use and GERD/EsD prevalence.

Results: 612 participants were included in the study. 167 (27.3%) patients were prescribed MMF, with an average dose of 28.1 g/kg. 141 (84.4%) of the patients prescribed MMF were diagnosed with esophageal disease, compared to 293 (65.9%) patients who were not prescribed MMF (p<0.01). Patients taking MMF were more likely to use a PPI (p<0.01). No differences were found in vascular risk factors (i.e. smoking, coronary artery disease, stroke, hypertension diabetes), head and neck or GI malignancy (thyroid, tongue, gastric, etc.) or presence of psychiatric comorbidities. Multivariable logistic regression revealed that total cumulative MMF dosage (OR=2.99, 95% CI=1.76-5.08, p=<0.0001) was significantly associated with increased likelihood of esophageal disease.

Conclusion: This study revealed that patients with SSc who were prescribed MMF were more likely to have GERD/EsD, and that total cumulative dose of MMF was significantly associated with an increased likelihood of esophageal disease. There are many potential explanations for this result, including possible MMF side effects and bias by indication (i.e. patients taking MMF may have more severe disease to warrant such therapy). Additional studies (notably prospective trials) are needed to examine other possible disease modifying treatments for SSc-associated GERD/EsD.

POS1316 WITHDRAWN

transfusions and treatment-related mortality at 100 days. We report endoscopic and clinical results 12 months following AHSCT.

Results: Five dcSSc patients (mean age 49.2 ± 9.0 years, 4 [80%] females, 4 patients [80%] with RNA polymerase III antibodies and one [20%] with SCL-70 antibodies) were diagnosed endoscopically and histologically with GAVE 1-4 months prior to AHSCT. Two of them needed APC. The mean Hb level at baseline was 9.6±2.5 g/dl. At the AHSCT, three patients received conditioning with Cyclophosphamide 200mg/kg and 7.5 mg/Kg ATG, and two patients received "cardiac-safe" conditioning with rituximab 1000 mg, cyclophosphamide 60 mg/kg and fludarabine 120 mg/m². The mean nadir thrombocyte level was 41.2 × 10^9/L (±39.1 × 10^9/L). The mean duration of thrombocytopenia below 50× 10^9/L was 4.6±4.8 days. The mean number of blood transfusions during hospitalization for AHSCT was 4.4 ±4.0 units. Only one GI bleeding episode (melena) was noted in one patient during the transplantation. Treatment-related mortality was 0%. At the repeated upper gastrointestinal endoscopy following AHSCT (mean time after AHSCT 7.8 ± 4.4 months, range 4-12 months), all five patients (100%) had a complete resolution of the endoscopic as well as the histological findings of GAVE (**Figure 1**). The Hb level at the time of the second gastroscopy increased from baseline by 1.7 ± 1.8 g/dl, range 0-4.1 g/dl).

Conclusion: We describe the complete resolution of GAVE 12 months after AHSCT in five consecutive patients without treatment-related mortality.

COMPLETE RESOLUTION OF GASTRIC ANTRAL VASCULAR ECTASIA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN SYSTEMIC SCLEROSIS

Keywords: Gastrointestinal tract, Systemic sclerosis

S. Keret[1], T. Zuckerman[2], I. Henig[2], T. Rainis[3], S. Odeh[3], N. Artoul[3], A. Shouval[1], G. Slobodin[1], D. Rimar[1]. *[1]Bnai Zion Medical Center, Rheumatology, Haifa, Israel*; *[2]Rambam Medical Center, Hematology, Haifa, Israel*; *[3]Bnai Zion Medical Center, Gastroenterology, Haifa, Israel*

Background: Gastric antral vascular ectasia (GAVE) is a known vascular gastrointestinal (GI) complication of systemic sclerosis (SSc), characterized by a distinctive endoscopic appearance of a "watermelon stomach" [1]. In patients screened for autologous hemopoietic stem cell transplantation (AHSCT) in the "Scleroderma: Cyclophosphamide or Transplantation" (SCOT) trial, the reported prevalence was up to 22%, and even higher, 45%, specifically in patients with RNA polymerase III antibodies [2]. GAVE carries significant morbidity due to frequent and recurrent GI bleeding, requiring blood transfusions and repeated endoscopic interventions with Argon plasma coagulation (APC). There is no well-established specific therapy for GAVE in the literature. AHSCT is grade A therapy for early diffuse progressive SSc, the population at risk for GAVE. During the conditioning period, thrombocytopenia may result in bleeding from active GAVE. In the SCOT trial, patients with active GAVE were excluded from the study [3]. The data regarding the safety and efficacy of AHSCT in SSC patients with GAVE is scarce.

Objectives: To evaluate the safety and efficacy of AHSCT in SSc patients with GAVE.

Methods: We selected from our cohort of twenty adult dcSSc patients who underwent AHSCT, patients who had GAVE according to gastroscopy prior to AHSCT. We recorded the number of APC procedures before AHSCT, The complications during AHSCT: the nadir thrombocytopenia level, the need for blood

GASTRO-INTESTINAL INVOLVEMENT IN SYSTEMIC SCLEROSIS: IMPORTANCE OF AN EARLY DIAGNOSIS THROUGH POPULATION SCREENING AND THE "UCLA SCTC GIT 2.0" QUESTIONNAIRE

Keywords: Systemic sclerosis, Gastrointestinal tract

F. R. Di Ciommo[1], A. Ulian[2], G. Pellegrino[1], D. M. Reza Beigi[1], I. Bisconti[1], M. Cadar[1], S. Truglia[1], C. Severi[2], F. Conti[1], V. Riccieri[1]. *[1]Policlinico Umberto I, Sapienza University of Rome, Clinical Internal, Anesthesiological and Cardiovascular Sciences, Rome Italy, Rome, Italy*; *[2]Policlinico Umberto I, Sapienza University of Rome, Department of Translational and Precision Medicine, Rome, Italy, Rome, Italy*

Background: Gastrointestinal tract (GIT) involvement in Systemic Sclerosis (SSc), often identified late or sometimes unacknowledged, is estimated in nearly 90% of patients and can be severe in more than 10% of them. "UCLA SCTC GIT 2.0" is a validated questionnaire to assess GI symptoms, using a total score between 0 and 2.83.

Objectives: We aimed to study the role of "UCLA SCTC GIT 2.0" questionnaire in the outpatient practice, as a tool to optimize the diagnosis of GIT disorders and to characterize the specific manifestation for each patient. We also investigated the GIT prevalence in our population to identify predictors of more severe involvement.

Methods: We carried-out a prospective study in patients with SSc, according to the 2013 ACR/EULAR criteria, attending our "Scleroderma Clinic". GIT involvement was investigated through history and administration of "UCLA SCTC GIT 2.0" questionnaire. Patients were stratified according to the severity of 6 items (gastroesophageal reflux disease-GERD, distension/bloating-D/B, fecal

incontinence, bowel movements such as diarrhea or constipation, social activities, emotional well-being) into 3 subgroups: "none to mild", "moderate", "severe to very severe". GIT involvement and its severity have been compared with clinical-demographic and laboratory features.

Results: Study population consisted of 87 patients (M/F 7/80), median age [IQR] of 64 [54;70] years. 81(93%) cases presented GIT disorders where GERD symptoms showed the highest prevalence followed by the B/D ones. The descriptive analysis of the main characteristics is summarized in Table 1. The "UCLA SCTC GIT 2.0" questionnaire revealed a median Total score [IQR] of 0.41 [0.21;0.84]. Median scores and trend of each item are reported in Figure 1. The median D/B score 1 was the statistically highest among all the other reported GIT scores (p=0.0030; p=<0.0001; p=<0,0001 respectively). The analysis of the collected data showed a positive association between GERD and D/B (r=0.4144; p=<0.0001), while positive correlations were found for both total score and GERD with smoking habit (r= 0.2735; p= 0.0104) (r=0.2117; p= 0.0490) and with PPI therapy (r= 0.2270; p= 0.0345) (r= 0.2269; p= 0.0346) respectively. Diarrhea was positively associated with PPI treatment (r= 0.2765; p= 0.0095), while Total score (r= -0.2181; p= 0.0424), GERD (r= -0.2327; p= 0.0301), and diarrhea (r=-0.2386; p= 0.0261) were negatively associated with vascular therapy. D/B score was positively associated with the limited form of the disease (r= -0.2158; p=0.0447) but negatively with mRSS > 7(r=-0.3067; p=0.0039) and disease duration (r=-0.2602; p=0.0149). We didn't find any correlation between GIT involvement and specific autoantibody presence.

Conclusion: Although the results of the present study confirm the higher prevalence of GERD in SSc, they also highlight the highest median score of D/B, often underestimated, whereas its negative correlation with the disease duration, rather than with the extension of the cutaneous involvement, seems to point at an early phenomenon not to be disregarded at the beginning of the patient follow-up. Of interest is to investigate the effective role of vascular therapy for GIT involvement. These findings underline that timely diagnosis and early treatment could provide the opportunity to implement clinical action as well as improvement in the GIT prognosis in SSc, encouraging wider and longer studies.

OUTCOMES IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH RITUXIMAB AND MYCOPHENOLATE MOFETIL COMBINATION THERAPY COMPARED TO HEMATOLOGICAL STEM CELL TRANSPLANTATION

Keywords: Safety, Systemic sclerosis, Lungs

S. Keret[1], L. Kaly[1], A. Shouval[1], T. Zuckerman[2], I. Henig[2], A. Awisat[1], I. Rosner[1], N. Boulman[1], M. Rozenbaum[1], A. Dortort Lazar[3], G. Slobodin[1], D. Rimar[1]. *[1]Bnai Zion Medical Center, Rheumatology, Haifa, Israel; [2]Rambam Medical Center, Hematology, Haifa, Israel; [3]Rabin Medical Center, Rheumatology, Petah Tikva, Israel*

Background: Autologous hematological stem cell transplantation (AHSCT) is a grade A therapy for early diffuse progressive systemic sclerosis (SSc), that has been validated in three randomized controlled trials (RCT) compared to cyclophosphamide (CYC) [**1**]. CYC, however, is no longer considered the gold standard therapy for SSc and does not provide long-term benefit [**2**]. The efficacy of rituximab on skin and lung involvement in SSc has recently been demonstrated in an RCT, the DESIRES study. The combination of rituximab with mycophenolate mofetil (MMF) is a potential potent regimen for progressive SSc, that has not been evaluated compared to AHSCT.

Objectives: To retrospectively compare the outcomes of SSc patients in our cohort, fulfilling eligibility criteria for AHSCT studies, who received a combination therapy of MMF and rituximab, with patients who underwent AHSCT.

Methods: Repeated longitudinal assessments at baseline and every 6 months for 24 months, including modified Rodnan Skin Score (mRSS), forced vital capacity (FVC), and diffusing capacity of the lung for carbon monoxide (DLCO) values, were compared between groups using a linear mixed model regression. Clinical improvement (CI) was defined as a decrease in mRSS by more than 25% or an increase in FVC by more than 10%. Event-free survival (EFS) was defined as the occurrence of death or the development of persistent major organ failure (heart, lung, kidney). Hazard ratios (HRs) and 95% CIs were calculated by Cox regression.

Results: Twenty-one SSc patients in the combination group were compared to sixteen in the AHSCT group. There were no significant differences in the demographic or clinical variables, except for Nintedanib treatment (**Table 1**). CI at 12 months was seen in 86% of patients in the combination group, compared to 81% in the AHSCT group (p=0.7). The hazard ratio (HR) for EFS at 24 months favored the combination group (HR=0.09, 95% CI 0.009 to 0.9; P =0.04). In both groups, a statistically significant and similar increase in FVC values, but not in DLCO, was demonstrated at each time point during follow-up. The inclusion of Nintedanib usage in the mixed model did not influence these results. In both groups, there was a significant and similar reduction in mRSS at 12 and 24 months compared to baseline (**Figure 1).**

Conclusion: In our cohort, combination therapy of MMF and rituximab compared to AHSCT in SSc patients eligible for AHSCT, resulted in similar skin and lung clinical improvement with a better safety profile after 24 months.

Borangiu[1,2], M. M. Negru[1,2], C. Cobilinschi[1,2], D. Mardale[1,2], C. L. Constantinescu[1,2], M. Duna[1], V. Vlad[1], M. Abobului[1,2], R. Ionescu[1,2], A. Balanescu[1,2]. [1]*St. Mary's Clinical Hospital, Internal Medicine and Rheumatology, Bucharest, Romania*; [2]*University of Medicine and Pharmacy "Carol Davila", Internal Medicine and Rheumatology, Bucharest, Romania*

Background: The significance of anti-Ro antibodies in systemic sclerosis (SSc) is still unclear as their presence could represent an epiphenomenon of the strong immune response in severe visceral involvement or directly participate in tissue damages in SSc patients. Recent data suggest that the presence of anti-SSA/Ro antibodies is an independent risk factor for worse pulmonary outcome and higher all-cause mortality in patients with SSc [1].
Objectives: To determine the frequency of anti-SSa/Ro antibodies in a cohort of SSc patients and its association with clinical, serological features and survival, in order to analyze the diagnostic utility of their separate detection.
Methods: This was a single-center retrospective study of a SSc cohort followed over a 10-year period in our rheumatology department. Duration of disease progression, symptoms and parameters related to a specific organ involvement according to MEDS evaluation sheets, were evaluated in all patients.
Results: 270 SSc patients were selected, from which we identified a final population of 28 (10%) anti-Ro-positive patients. The anti-SSA/Ro group included more women (26/28) with a mean age of 47.9 ± 13.7 years, most of them with diffuse subset (16/30). The presence of anti-SSA/Ro antibodies was positively correlated with presence of anti-Scl 70 antibodies (p=0.012), elevated modified Rodnan score (p=0.041), myositis (p=0.013), and lower DLCO (p=0.019). Moreover, associations were strongest for elevated CRP levels (p<0.001) and calcinosis cutis (p<0.001). Compared to non-anti-SSa/Ro patients, both groups were similar regarding demographic data, age at diagnosis, disease duration and type of skin involvement. As expected, the anti-SSa/Ro group had significantly more frequent erosive synovitis (p=0.002), myopathy (p=0.010), gastrointestinal involvement and interstitial lung disease (ILD) (p=0.001). No statistically significant differences were found regarding frequencies of Raynaud's phenomenon, pulmonary hypertension, renal, vascular and cardiac involvement, nor neoplasia. There was a greater proportion of digital ulcers and calcinosis in the anti-SSa/Ro group (42% vs 17% and 58% vs 14%), but without statistical significance. Again, among those patients, a much higher proportion (64% vs 42%) was treated with immunosuppressive agents. No differences in mortality were found between the groups.
Conclusion: Anti-SSA/Ro antibodies seem to characterize a distinct group of SSc patients who are almost exclusively female, express elevated CRP levels, have a high prevalence of ILD, myositis, joint involvement and calcinosis, and commonly receive immunosuppressants.

Background: In systemic sclerosis (SSc), a specific nailfold videocapillaroscopy (NVC) pattern is observed in 90% of cases and seems to be associated with severity and progression of the disease. Data about SSc patients with normal/nonspecific NVC are scarce [1].
Objectives: This study aims to investigate the clinical and immunologic characteristics of SSc patients with normal or nonspecific NVC and to compare them to those with a scleroderma NVC pattern.
Methods: This was a single-center retrospective study which enrolled 270 SSc patients referred for NVC since January 2000, in our rheumatology department. Demographic and clinical features, symptoms and parameters related to a specific organ involvement according to MEDS evaluation sheets and survival were evaluated.
Results: 270 SSc patients were selected in the database, from which we identified a final population of 19 (7%) patients with normal/nonspecific NVC pattern. The group comprised 14 females and 5 males, with a mean age of 52.7 (±17.4) years, most of them with diffuse subset (12/19). Among the cases, 8 (42%) had normal NVC and 11 (58%) had nonspecific NVC changes, characterized by isolated ramified capillaries in 42%, curved capillary limbs in 33%, giant capillaries in 16% and focal microhemorrhages in 9 % of patients. The mean Raynaud phenomenon's (RP) duration was longer (18.4 ± 14.4 years) compared to the other cases (10.2 ± 1.5 years). The difference was not significant (p=0.107). Significantly higher percentages of cases had lower overall frequency of digital ulcers (28% vs 51%, p=0.04). Presence of synovitis (p=0.010) and myositis (p<0.001) was positively correlated with normal/nonspecific NVC changes. Regarding other organ involvement, the cases also had less severe pulmonary involvement, less frequent digestive involvement and/or pulmonary arterial hypertension than controls, but these differences did not reach significance. No differences in mortality were found between the groups.
Conclusion: SSc patients with normal/nonspecific NVC changes have less organ involvement and less overall disease severity than those with a typical SSc specific NVC pattern, with no between-group differences. Musculoskeletal involvement was the only factor independently associated with normal/nonspecific NVC. It is possible that SSc with normal NVC may be at lower risk of progression to severe visceral and skin involvements, but prospective studies are required.

Background: Abberations of B cells have been implicated in the pathogenesis of systemic sclerosis(SSc) [1] and CD21^{low} B cells, which express high levels of activation markers, have recently been associated with vascular manifestations in SSc [2]. CD32 (FcγRII), comprised of three isoforms A, B and C, is involved in B cell regulation and antibody production. B cells do not express FcγRIIA and mainly express the inhibitory FcγRIIB isoform [3].

Objectives: The aim of our study was to assess the expression of CD32 in CD21^{low} B cells in SSc patients with digital ulcers (DUs).

Methods: Thirty patients, 23 women (median age 56 years. Interquartile range 32 -81) and 7 men (median age 60 years, Interquartile range 52-79) fulfilling the ACR/EULAR 2013 criteria for SSc were included in the study. Peripheral blood mononuclear cells from patients were analyzed with multicolor flow cytometry using anti-CD19 monoclonal antibody (moAb), anti-CD21 moAb, and anti-CD32 moAb, that recognizes both the FcγRIIA and FcγRIIB isoforms.

Results: The percentage of CD21^{low} B cells was significantly increased in patients with DUs compared to patients without DUs (difference between means: 24.6, 95% CI 5.37-43.8, p = 0.014). The percentage of CD21^{low}CD32^{low} B cells were significantly increased in patients with DUs compared to patients without DUs (difference between means: 23.24 ± 7.364, 95% CI 8.152-38.32, p = 0.0038) (Figure1A). The percentage of CD21^{low}CD32^{high} B cells was significantly decreased in the DUs group (difference between means: -26.61 ± 9.312, 95% CI -45.69 to -7.539, p = 0.0080) (Figure 1B).

Conclusion: Our study suggests that low expression of CD32 accounts for the association of CD21^{low} B cells with DUs in SSc and implies that CD32 may have an inhibitory effect on CD21^{low} B cells.

POS1323 BODY COMPOSITION IN PATIENTS WITH SYSTEMIC SCLEROSIS: RESULTS OF A COMPUTED TOMOGRAPHY STUDY

Keywords: Imaging, Systemic sclerosis

M. Binda[1], G. Fichera[2], B. Moccaldi[1], L. Pilati[2], A. Doria[1], C. Giraudo[2], E. Zanatta[1]. *[1]Padova University Hospital, Department of Medicine - DIMED, Division of Rheumatology, Padova, Italy*; *[2]Padova University Hospital, Department of Medicine - DIMED, Division of Radiology, Padova, Italy*

Background: Subclinical primary muscular involvement and malnutrition may occur in a significant percentage of patients with systemic sclerosis (SSc), and they are potential risk factors for the development of sarcopenia [1]. Sarcopenia is defined as age-associated loss of muscle mass, strength, and function, and unlike other chronic rheumatic inflammatory disorders, it has been poorly investigated in SSc patients. In recent years, some imaging methods have emerged for the identification of sarcopenic markers such as altered muscle composition and fat infiltration (myosteatosis).

Objectives: To evaluate the occurrence of myosteatosis and the prognostic role of body composition, assessed by computed tomography, in patients affected with SSc.

Methods: Patients affected with SSc (2013 EULAR/ACR criteria) referring to our tertiary center from 2015 to 2021 who underwent chest computed tomography to assess pulmonary involvement were included. A semi-automatic segmentation of the subcutaneous fat and paravertebral muscle was performed at the level of the 12th dorsal vertebra using a software and the following body composition variables (BCV) were collected: subcutaneous fat area, subcutaneous fat Hu, paravertebral muscle area, paravertebral muscle Hu. Myosteatosis was considered as Hu values <30. The Student's t-test was used to evaluate if any difference regarding BCV occurred between males and females. Logistic regression analysis was applied to assess the role of the BCV on the overall survival while the Spearman correlation coefficient was used to evaluate the relationship between the BCV and the skin score. For all the analyses the applied significance level was p<0.05.

Results: Sixty SSc patients were included (51 females; mean age 55.63±14 years). Most patients were positive for anti-nuclear antibodies (ANA, 90%), with anti-topoisomerase I specificity in 61.6% of them; twenty-nine patients (48.3%) were affected by the diffuse cutaneous form. At baseline, the mean modified Rodnan skin score (mRSS) was 10.22 (±8.8) and the mean revised EUSTAR activity index was 2.08 (±1.4). Signs of myosteatosis were detected in forty-seven (78.3%) SSc patients. Males showed significantly greater muscle areas (males 9732±3019 vs. females 6599±1328 mm^2; p<0.001) and less hypodense subcutaneous fat (males 76±18 vs. females 88±16 Hu; p=0.027). Overall, seven patients deceased at a 5-year follow-up. No correlation was found between BCV and the mRSS. None of the radiological variables emerged as a predictor of survival.

Conclusion: Most patients with SSc are affected by myosteatosis, even those without symptoms of muscle involvement, while overall body composition does not appear to predict survival. The results of our pilot study may open the door to evaluating the role of body composition in SSc patients: larger longitudinal studies looking at different time-points in the disease course may provide further insights.

Background: Mycophenolate mofetil (MMF) is the most widely used immunosuppressant in Systemic Sclerosis (SSc) since the Scleroderma Lung Study II demonstrated the safety and efficacy of this drug. Real-life evidence about long early and long-term adverse events (AEs) associated to the use of MMF is lacking, and SSc predictors of drug's discontinuation are not identified yet.
Objectives: To evaluate the long-term persistence of MMF treatment and the adverse events (AEs) incidence in a multicentric cohort of SSc patients.
Methods: Medical records of SSc patients treated with MMF and followed up in 9 tertiary centers were retrospectively collected and evaluated. AEs occurrence (i.e. infections, gastrointestinal (GI) intolerance, laboratory abnormalities, new cancer diagnosis), and reasons for dosage reduction or discontinuation in the 5 five years after the MMF prescription were recorded. Infections were reported and classified according to the organ involved, the etiology, and the severity.
Results: Data from 494 SSc patients observed for 3.1 years (IQR 1.4-4.9) were analyzed. Combination therapy with steroids was reported in 37.0% of patients, while in 14.8% of cases MMF was associated with Rituximab or Tocilizumab treatment. Raw MMF therapy persistence at 12, 24 and 60 months was 91.37%, 88.37%, and 66.34%, respectively. MMF discontinuation incidence was 7.65 per 100 patient years due to any cause, 4.69 per 100 patient years due to drug-related AEs, 1.8 per 100 patient years due to GI intolerance, 1.01 per 100 patient years due to severe or recurrent infections, 0.79 per 100 patient years due to laboratory abnormalities, and 0.65 per 100 patient years due to new cancer diagnosis. Longer disease duration (p=0.003), low diffusing capacity for carbon monoxide (DLco) (p=0.003), late pattern at video-capillaroscopy (p=0.02), esophageal involvement (0.002), and intestinal involvement (p<0.001) were associated with MMF discontinuation. Of note, the most frequent recorded infections had a viral non-COVID19 and non-HZV etiology (21.7%), mostly affecting upper airways (7.1%), and were characterized as mildly severe (13.4%). During follow-up, 127 severe or moderately severe infections were reported, and they were associated with baseline low DLco (p=0.01), late capillaroscopy pattern (p=0.005), esophageal involvement (p=0.01), intestinal involvement (p=0.04), and smoking (p=0.005).

Table : Clinical characteristics of multicentric cohort

Clinical characteristics	N = 494
Age, years, mean±standard deviation	53±14
Female gender, n (%)	406 (82.3)
Diffuse cutaneous subset, n (%)	291 (58.9)
Disease duration, median (interquartile range)	2.0 (0.0, 6.0)
Anti-centromere antibody positive, n (%)	56 (17.6)
Anti-topoisomerase I antibody positive, n (%)	250 (50.6)
Late pattern on capillaroscopy, n (%)	125 (25.3)
Digital ulcers, n (%)	224 (45.3)
Severe gastroesophageal reflux n (%)	316 (64.0)
Chronic diarrhea, n (%)	57 (11.5)
Intestinal dysmotility (chronic constipation, incontinence), n (%)	54 (10.9)
Interstitial lung disease, n (%)	386 (78.1)

Conclusion: This real-life analysis of our multicenter cohort demonstrated that MMF is well tolerated with a high treatment persistence rate. The main reasons of MMF discontinuation were GI intolerance followed by infections and laboratory abnormalities. Advanced SSc microvascular damage on capillaroscopy and GI SSc involvement characterized the patients at higher risk of AEs during treatment.

POS1325

TREATMENT WITH NINTEDANIB IN SYSTEMIC SCLEROSIS ASSOCIATED WITH INTERSTITIAL LUNG DISEASE: SAFETY AND EFFECTIVENESS AFTER ONE YEAR IN A REAL-LIFE COHORT

Keywords: Safety, Systemic sclerosis, Lungs

J. Corada[1], A. Guillen-Del-Castillo[1], I. Blazquez[1], C. Codina[1], A. Antón[1], J. Mestre[1], A. Gil[1], J. Perurena-Prieto[2], I. Ojanguren[3], A. Villar[3], C. P. Simeon Aznar[1]. *[1]Vall d'Hebron University Hospital, Internal Medicine Department. Systemic Autoimmune Diseases Unit, Barcelona, Spain*; *[2]Vall d'Hebron University Hospital, Immunology Department, Barcelona, Spain*; *[3]Vall d'Hebron University Hospital, Pneumology Department, Barcelona, Spain*

Background: Interstitial Lung Disease (ILD) is detected in 80% of the high resolution CT scans (HRCT) of patients with Systemic Sclerosis (SSc). ILD is responsible for 60% of the mortality related to SSc. Although classic treatment is based on immunosuppressant therapies, nintedanib has recently been approved for SSc-ILD as disease modifying antifibrotic drug.
Objectives: To describe the safety and effectiveness of nintedanib over one year follow-up in a cohort of SSc-ILD patients.
Methods: Basal characteristics of SSc patients, concomitant therapy, adverse events, and pulmonary function test after one year of nintedanib treatment were collected in a cohort with SSc-ILD from a tertiary hospital. SPSS 20.0 was used for descriptive statistics.
Results: Twenty-two patients were treated with nintedanib for SSc-ILD, 17 (77.3%) of the patients were women, with a median (interquartilic range, IQR) age at ILD diagnosis of 45.7 (39.4 – 56.8) years, and with a median extent of ILD features in the HRCT at the beginning of the treatment of 29.7% (20.0% - 39.9%). The median period from the ILD diagnosis to nintedanib initiation was 46.5 months. As concomitant therapies, 17 (77.3%) were under mycophenolate acid, 7 (31.8%) received previously intravenous cyclophosphamide, and 8 (36.4%) had taken rituximab previously or during nintedanib treatment. In terms of security profile, 17 out of 22 (81.4%) patients presented some infection –severe infections were described only in 3 cases-, taking into account that among them 14 (82.4%) patients were under concomitant immunosuppressant treatment. Nine (40.9%) patients suffered from diarrhea, and 5 (22.7%) presented elevation of liver enzymes, which required dose reduction in 2 (9.1%), temporary interruption of nintedanib in another 2 (9.1%), and permanent withdrawal in 1 (4.5%) patient. During a median period of follow-up of 29.5 months, 3 (13.6%) patients died, 13 (59.1%) required a nintedanib dose reduction, 4 (18.2%) temporary interruption, and 5 (22.7%) a permanent withdrawal. The absolute forced vital capacity (FVC) percentage after the first 12-month follow-up increased in 0.15 % (-3.8 – 5.5), which meant a relative increase in FVC of 2.3% (-4.7 – 7.9).
Conclusion: Nintedanib treatment for SSc-ILD showed a satisfactory safety profile, constituting diarrhea and elevated liver enzymes the most common adverse events related with the drug. An increase in infection rates cannot be established as the majority of the patients were under concomitant immunosuppressant therapies. FVC was stable during follow-up, which supports the effectiveness of nintedanib for SSc-ILD in real-life cohorts.

POS1326 LONG TERM TREATMENT WITH RITUXIMAB IN PROGRESSIVE SYSTEMIC SCLEROSIS: A MONOCENTRIC RETROSPECTIVE STUDY

Keywords: Systemic sclerosis, Safety

G. Alonzi[1], G. Natalello[1], S. Fiore[1], L. Verardi[1], E. De Lorenzis[1,2], P. G. Cerasuolo[1], A. Zoli[1], S. Di Murro[1], M. A. D'agostino[1], S. L. Bosello[1]. *[1]Università Cattolica del Sacro Cuore, Policlinico Universitario Agostino Gemelli IRCSS, Roma, Italy., Rheumatology Department, Roma, Italy*; *[2]Scleroderma Program, Leeds Institute of Rheumatic and Musculoskeletal Medicine University of Leeds, Rheumatology Department, Leeds, United Kingdom*

Background: Treatment of Systemic Sclerosis (SSc) remains challenging and some clinical studies reported the efficacy of Rituximab (RTX) in skin disease and in stabilizing lung involvement. Recently 2 randomized clinical trial demonstrated the efficacy of RTX in SSc and in lung involvement in connective tissue diseases (1,2), however current data are limited by the small number of samples examined and the short duration of follow-up.
Objectives: We aimed at retrospectively evaluate the efficacy, safety, and long-term persistence of RTX therapy in a monocentric SSc cohort.
Methods: All clinical records of SSc patients (pts) treated with RTX in our center were retrospectively analyzed. Demographic, clinical and disease characteristics, treatment approach, combination therapies, and adverse events during RTX were considered. Every 6 months, skin score, pulmonary function test and swollen joint count (SJC) modifications as well as digital ulcer occurrence were recorded.
Results: Fifty-two SSc pts (pts) have been treated with RTX in our center since 2005. The mean age of the pts was 55.3±24.3 years and 21.5% were male. The disease duration at the time of the first treatment with RTX was 4.4±2.8 years and the mean reached follow-up was 6.6±2.2 years (range 2-17 years). Forty pts (77.0%) had a diffuse cutaneous involvement, 33 pts (63.6%) had anti-topoisomerase positivity, 45 (88.2%) an interstitial lung disease on high resolution chest CT, 30 pts (59.2%) arthritis or tenosynovitis, and finally 38 pts (73.1%) presented any history of digital ulcers. Twenty-three (44.2%) pts had been previously treated with cyclophosphamide. During RTX treatment, 39 pts (75.0%) received an immunosuppressive combination therapy, most with mycophenolate mofetil (53.8%). Concomitant glucocorticoids treatment was assumed by the 53.8% of pts. Twenty-five pts (48.1%) were treated with Rituximab for only one clinical involvement, 27 pts (51.9%) received treatment for more than one organ involvement including skin, lung or joint. Overall, 82.7% were treated for progression of skin disease, 50.0% for lung involvement deterioration and 23.1% for active arthritis. Treatment showed improvement in the skin score, arthritis, and/or stabilization of the pulmonary functional status in 44 pts (84.6%), while in the remaining 8 pts, therapy was stopped because of worsening of the disease over the 6 months of follow-up. Among responders, skin score improved from 17.3±8.9 to 10.3±8.6 (p=0.04), while FVC and DLco remained stable (87.4±3.5% to 86.2±20.5% and 66.3±23.9% to 64.3±22.1%, respectively). As expected, there was an improvement in DAS28 (4.9±0.8 to 1.9±0.5, p<0.01). Finally, there was a reduction in the rate of ulcer occurrence (46.15% to 21.70%, p=0.04). Twenty-two pts (42.3%) were treated with one single cycle of therapy (1 gr two weeks apart), while the remaining 30 pts were treated with repeated cycles of RTX, with a mean number of cycles of 4.3±2.0. Among the re-treated pts, 50% were treated every year and 50.0% at the time of new clinical worsening, and retreatment was done every 60.5±31.4 months. All pts re-treated with RTX on demand responded to the therapy. Nineteen percent of pts developed adverse events (5.7% leukopenia, 7.7% infusion reactions, 1.9% sepsis, 3.8% pneumonia). Ten pts (19.2%) died during follow-up: 8 deaths were related to organ complication of SSc and 2 to cancer.
Conclusion: Our data suggest long-term efficacy and safety of RTX in pts SSc. Further real world studies will be necessary to evaluate the best therapeutic approach with RTX (regular cycles or retreatment when clinical worsening occurs) and/or the combination with other immunosuppressant drugs.

POS1327 HORMONE REPLACEMENT THERAPY INCREASES THE RISK OF SYSTEMIC SCLEROSIS: RESULTS FROM LARGE POPULATION-BASED CASE-CONTROL STUDY

Keywords: Epidemiology

K. Patasova[1], M. Dehara[1], E. Arkema[1], M. Holmqvist[1]. *[1]Karolinska Institute, Department of Medicine, Stockholm, Sweden*

Background: Systemic sclerosis (SSc) exhibits, similarly to other autoimmune diseases, a strong female preponderance. Estrogen has been found to activate signaling pathways involved in immune response and promote autoimmunity [1]. Several studies on cultured SSc skin fibroblasts have reported fibrinogenic role of female sex steroids, but the hormonal impact on the risk of SSc remains underexplored. In a recently published pharmacovigilance report, hormone replacement therapy (HRT) was highlighted as potentially implicated in SSc development [2].
Objectives: In this case-control study, we aimed to assess the relationship between HRT and risk of SSc in a population-based cohort of SSc patients and matched controls.
Methods: Participants with newly diagnosed SSc and their matched controls were identified from nationwide registers. Definition of SSc required a first-time diagnosis of SSc (ICD10 codes: M34.0, M34.1, M34.9, M34.8, as a primary diagnosis) in specialist care, with a second visit listing SSc within 12 months We included visits between Jan 1, 2009 and December 31, 2017 with the first visit representing the index date. Controls were sex, age and region-matched to SSc cases in 1:5 ratio. Study sample was restricted to women aged 40 or older at index date. Participants on progestogen in monotherapy and those with history of thromboembolism, stroke, ischemic heart disease, endometrial and breast cancer before index date, were excluded. Dispensations of HRT were extracted from Prescription register, using The Anatomical Therapeutic Chemical classification system codes. Study participants with a history of ever taking HRT (estrogen, estrogen and progestogen combination and tibolone) at least three years before the index date were considered exposed. The relationship between HRT and SSc was assessed using conditional logistic regression models adjusted for socioeconomic factors and polypharmacy. The impact of underlying comorbidities was evaluated by identifying the most common ICD-10 codes among the users of HRT and sequentially excluding cases and controls with a history of these comorbidities from the analyses.
Results: In total, 553 SSc cases and 2,696 controls were included. Twelve percent of cases and 9% of controls were taking HRT at any time ≥3 years before the index date was associated with a 42% increased risk of SSc (95% CI: 1.1,1.9; p=0.02, Figure 1 a). Combination of estrogen and progestogen showed statistically significant associations with SSc (OR=1.5; 95% CI: 1.0,2.05; p=0.03) (Figure 1 a). Subsequent sensitivity analyses indicated that underlying comorbidities did not influence the observed relationship between HRT and SSc (Figure 1 b).
Conclusion: The findings of this study implicate HRT in the development of SSc and add to a growing body of evidence pointing to the proinflammatory role of female sex steroids in the pathogenesis of immune-mediated disorders.

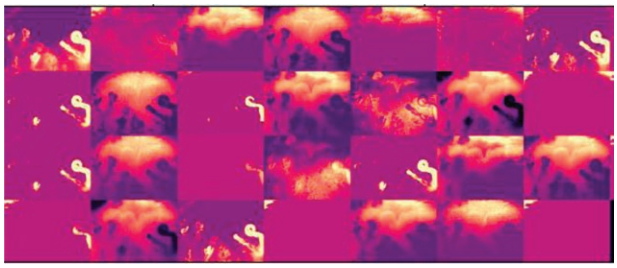
POS1328

DIFFERENTIATING "SCLERODERMA" WITH "NON-SCLERODERMA" PATTERNS IN NAILFOLD CAPILLARY MICROSCOPY USING A DEEP LEARNING MODEL



Keywords: Systemic sclerosis

V. Korendovych[1], P. Korsten[1]. [1]*University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*

Background: Nailfold capillary microscopy is used for diagnostic purposes in rheumatology since many years. Abnormal nailfold capillaries are also listed in the 2013 ACR/EULAR classification criteria for systemic sclerosis (SSc) [1]. A fast-track algorithm to differentiate between "scleroderma" and "non-scleroderma" patterns of capillary microscopy was published in 2019, and is being applied in clinical routine as a useful decision algorithm [2]. Artificial intelligence is being increasingly implemented in many spheres of everyday life, including medicine. Keras is a publicly available deep learning framework, which is widely used for research purposes, in particular for constructing artificial neural networks [3].
Objectives: To estimate the ability of a deep learning model, to differentiate between scleroderma and non-scleroderma capillary microscopy patterns.
Methods: Capillary microscopy was performed using Optilia Digital Capillaroscope. We analyzed capillary microscopy images, which were equally subdivided into two groups, including scleroderma and non-scleroderma patterns. Subsequently the pictures were assigned to training, validation and test sets. Each set contained the same number of images with scleroderma- and non-scleroderma patterns. Then we trained a deep learning model using training and validation datasets to differentiate between the aforementioned capillaroscopy patterns. A test set was applied to estimate the model performance in an independent data set. The technical side of the study was performed using a 2D convolutional neural network, which was constructed based on Keras deep learning libraries (example Picture 1).
Results: A total of 1076 capillaroscopy images from 70 patients were analyzed the study: 780, 196 and 100 pictures in the training, validation and test sets accordingly. Each image dataset contained an equal amount of pictures from scleroderma- and non-scleroderma patterns. The trained model showed an accuracy of 87,8% with sensitivity of 94.9% (95% CI 0,905 to 0,99), specificity of 80,6% (95% CI 0,73 to 0,88) and an area under the curve (AUC) of 0.9326 in the validation set. In the test set, there was a slightly better model performance with an accuracy of 92%, a sensitivity of 96% (95% CI 0,91 to 1), a specificity of 88% (95% CI 0,79 to 0.97) and an AUC of 0,9742.
Conclusion: Despite the relatively small image dataset, the developed deep learning model could successfully discriminate scleroderma- vs. non-scleroderma capillaroscopy patterns, which may be applied in an automated assessment of capillaroscopy pictures in the future.

KG, Pulmonology, Ingelheim am Rhein, Germany*; [14]*Cornell University, Department of Medicine, New York City, United States of America*

Background: Progressive pulmonary fibrosis (PPF) includes any diagnosis of progressive fibrotic interstitial lung disease (ILD) other than idiopathic pulmonary fibrosis (IPF), and occurs in a range of disorders such as connective tissue diseases or hypersensitivity pneumonitis. Patients with PPF have comparable disease progression, lung function decline and mortality as patients with IPF. It is therefore hypothesised that they share underlying pathobiology and may respond to the same treatments, as was also seen in the Phase III INBUILD trial of nintedanib. BI 1015550, a preferential phosphodiesterase 4B inhibitor, prevented lung function decline in a Phase II study in IPF and may provide an additional treatment option, alone or with nintedanib, in patients with PPF.
Objectives: This Phase III trial (FIBRONEER-ILD™) will investigate the efficacy and safety of BI 1015550 in patients with PPF.
Methods: This double-blind, randomised, placebo-controlled trial (NCT05321082) is underway at approximately 400 sites in 45 countries. It is planned that 1041 patients will be randomised in a 1:1:1 ratio to either 18 mg BI 1015550 twice daily (BID), 9 mg BI 1015550 BID or placebo, in addition to standard of care, over at least 52 weeks (Figure 1). Similar to the INBUILD trial, patients are stratified by high-resolution computed tomography pattern (usual interstitial pneumonia-like vs other fibrotic patterns), and by baseline use of nintedanib (yes/no). Patients are enrolled if they meet the predefined criteria for PPF and other criteria (Table 1).
Results: The trial initiated and began enrolment in October 2022. Enrolment is expected to complete by the end of 2023. The primary endpoint is absolute change from baseline in forced vital capacity (FVC) (mL) at Week 52. The key secondary endpoint is the time to first acute exacerbation, first hospitalisation for respiratory cause or death (whichever occurs first) over the duration of the trial.
Conclusion: The FIBRONEER-ILD™ trial is designed to investigate the potential use of BI 1015550 as a treatment option for patients with PPF, with and without background nintedanib treatment.

*Randomisation will be stratified by the presence of background nintedanib use (with or without nintedanib) and high-resolution computed tomography imaging pattern (usual interstitial pneumonia pattern vs other fibrotic patterns). In Part B, patients will continue treatment with blinded trial medication and have trial visits every 12 weeks, until the last randomised patient reaches 52 weeks of treatment. EOS is expected to be up to 130 weeks with an assumed recruitment period of 18 months. †Day 1. BID, twice daily; EOS, end of study; EOT, end of trial (i.e. last randomised patient reaches 52 weeks of treatment); R, randomisation.

Figure 1. Trial design

Table 1 . Main inclusion and exclusion criteria

Inclusion criteria
• ≥18 years old
• FVC ≥45% predicted
• DLco corrected for haemoglobin (Visit 1) ≥25% and <90% predicted
• Patients are on stable treatment with nintedanib for at least 12 weeks or not on treatment with nintedanib for at least 8 weeks
• Patients treated with permitted immunosuppressive agents for an underlying systemic disease (e.g. methotrexate, azathioprine) need to be on a stable treatment for at least 12 weeks prior to the initial screening period (Visit 1) and during the screening period
• Presence of fibrotic lung disease on HRCT, defined as reticular abnormality with traction bronchiectasis with or without honeycombing, with disease extent >10% on HRCT (confirmed by central review) within 12 months of Visit 1
• Patients must fulfil at least one of the following criteria within 24 months of Visit 1:
– Clinically significant decline in FVC% predicted based on a relative decline of ≥10%
– Marginal decline in FVC% predicted based on a relative decline of ≥5–<10% with worsening of respiratory symptoms
– Marginal decline in FVC% predicted based on a relative decline of ≥5–<10% with increasing extent of fibrotic changes on chest imaging
– Worsening of respiratory symptoms and increasing extent of fibrotic changes on chest imaging
Exclusion criteria
• Patients with airway obstruction (pre-bronchodilator FEV_1/FVC ratio <0.7) (Visit 1)
• Acute ILD exacerbation (investigator-determined) within 3 months prior to Visit 1 and/or during the screening period
• Treatment with oral corticosteroids >15 mg/day within 4 weeks; cyclophosphamide, tocilizumab, mycophenolate within 8 weeks; rituximab within 6 months
• Suicidal behaviour in the past 2 years

DLco, diffusing capacity of the lung for carbon monoxide; FEV_1, forced expiratory volume in 1 second; FVC, forced vital capacity; HRCT, high-resolution computed tomography; ILD, interstitial lung disease.

POS1330 LUNG ULTRASOUND FOR THE FOLLOW-UP OF SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE TREATED WITH NINTEDANIB: OUTCOMES AND COMPARISONS WITH OTHER ASSESSMENT TOOLS

Keywords: Systemic sclerosis, Ultrasound, Lungs

M. Di Battista[1,2], A. Della Rossa[1], M. Da Rio[1], C. Romei[3], A. Delle Sedie[1], M. Mosca[1]. [1]*University of Pisa, Rheumatology Unit, Pisa, Italy*; [2]*University of Siena, Department of Medical Biotechnologies, Siena, Italy*; [3]*University of Pisa, Radiology Unit, Pisa, Italy*

Background: Nintedanib (NIN) is an antifibrotic drug used to slow the progression of systemic sclerosis-related interstitial lung disease (SSc-ILD), reducing the decline in forced vital capacity (FVC). High-resolution chest tomography (HRCT) is the gold standard imaging technique to assess SSc-ILD, whereas lung ultrasound (LUS) is a useful and repeatable non-invasive tool which is increasingly used in clinical practice.

Objectives: The aim of this work was to investigate the usefulness of LUS during the follow-up of SSc-ILD patients treated with NIN.

Methods: Adult SSc patients starting NIN for ILD were enrolled and followed for 12 months. LUS was performed at baseline and quarterly on 55 antero-posterior spaces, evaluating pleural line irregularities (PLI; semi-quantitative score 0-1-2) and the number of B-lines (BL), according to OMERACT definition. FVC was investigated every six months, whereas HRCT was performed at baseline and at 12 months. The following patient-reported outcomes were administered quarterly: Leicester cough questionnaire and St.George respiratory questionnaire. During follow-up, all of the aforementioned investigations were assessed for stability, improvement, or worsening from baseline, then evaluating the concordance with LUS variations.

Results: Ten SSc-ILD patients (70% female, mean age 62±10.9 years) starting NIN were enrolled. One patient had to prematurely discontinue NIN due to unbearable gastrointestinal adverse effects. The other 9 patients were followed for 12 months, achieving FVC stabilization in 87.5% of the cases. The mean PLI score and the mean BL number both showed a declining trend over time (Figure 1), with a 12-months significant overall reduction (p=0.02 for PLI; p<0.01 for BL). At the final evaluation, both PLI and BL were improved in 55.5% of the cases and stable in the rest, whereas HRCT resulted worsened in 62.5% of patients and stable in the rest. The concordance of these two imaging techniques was very low (12.5%). LUS concordance with FVC was quite good (61.5% for PLI and 46.1% for BL). Moreover, PLI variations showed a greater concordance for Leicester cough questionnaire and St.George respiratory questionnaire (69.2% and 42.3%, respectively) than BL variations (35.7% and 28.5%, respectively).

Conclusion: We performed LUS for the follow-up of SSc-ILD patients treated with NIN. Changes in PLI and BL fairly closely reflected the functional and subjective trend of the patients. PLI variations showed a good correlation with the outcomes of FVC and cough questionnaires. HRCT seems to progress regardless of the efficacy of NIN on lung function, therefore LUS could be used for monitoring SSc-ILD patients receiving NIN.

POS1331 DEVELOPMENT AND VALIDATION OF A CLINICAL SCORE FOR MORTALITY PREDICTION IN SYSTEMIC SCLEROSIS: THE SSCORE STUDY

Keywords: Prognostic factors, Systemic sclerosis, Systematic review

L. Dullius[1], A. Ribeiro[1], M. Spier Borges[2], M. Gubert[2], M. Loporchio[2], V. Lovison[2], A. Azeredo-Da-Silva[3], V. Hax[1], M. Bredemeier[4], R. Chakr[1]. [1]*Hospital de Clínicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil*; [2]*Federal University of Rio Grande do Sul, School of Medicine, Porto*

Alegre, Brazil; [3]*Hospital de Clínicas de Porto Alegre, Division of Internal Medicine, Porto Alegre, Brazil*; [4]*Nossa Senhora Conceição Hospital, Division of Rheumatology, Porto Alegre, Brazil*

Background: Systemic sclerosis (SSc) is one of the most lethal systemic autoimmune diseases. Considering recent advances in drug therapy and safety concerns, predicting mortality may contribute to a personalized treatment decision [1,2].
Objectives: Our goal was to develop and validate a clinical score for mortality prediction in SSc patients (SScore)
Methods: For SScore development, a systematic literature review (SLR) in PubMed and EMBASE (up to July 2022) was performed by two independent reviewers and hazard ratios (HR) from clinically relevant and statistically significant 5-year SSc mortality predictors were meta-analyzed. Considering heterogeneity (I2 test) and publication bias (Egger's test and funnel plots), we selected the most representative HR of each predictor. The weighted risk of death was estimated by Poisson's regression model, and the final SScore was the sum of each predictor score, varying from 0 to 1. For SScore validation, 91 SSc patients (ACR-EULAR 2013 or LeRoy and Medsger classification criteria) were consecutively included in a prospective cohort and followed-up between 2019 and 2022 in the outpatient clinics of two tertiary hospitals. Death was confirmed by medical records and phone calls.
Results: Out of 6,893 studies (2,539 in PubMed; 4,354 in EMBASE), 33 were included in the meta-analysis [3,449 deaths in 15,403 SSc patients over 8.6 years (mortality 22.4%)]. Six predictors were included in SScore: age, dyspnea, malignancy, renal impairment, anti-Scl70 and scleroderma renal crisis (Table 1). In the validation cohort, there were 13 deaths (mortality 14.3%) among the 91 SSc patients over 2.6 years [age 60.5 (±10.3) years-old; women 92.3%; 81.2% white; SSc duration 13.0 (±8.1) years; diffuse cutaneous SSc 22.0%]. The best SScore cut-off was 0.18 (sensitivity 61.5%, specificity 87.2%, positive and negative predictive values 44.4% and 93.2%, respectively, and accuracy 79.1%). The area under the receiver operating characteristic curve (Figure 1) was 0.78 (95%CI 0.64-0.92). SScore was higher among those who died (p<0.001).

Table 1 : Clinical score for mortality prediction in systemic sclerosis.

Predictor	Relative risk (95%CI)	Score
Age ≥ 60 anos	1.85 (0.61-5.56)	0.10
NYHA functional classes III and IV	2.18 (0.60-7.96)	0.15
Malignancy	5.33 (2.02-14.1)	0.30
Renal impairment	3.60 (1.28-10.1)	0.20
Anti-Scl70	1.89 (0.50-7.06)	0.10
Scleroderma renal crisis	2.44 (0.45-13.2)	0.15

NYHA (New York Heart Association) functional classes III and IV: dyspnea, palpitation or exhaustion with mild physical activity/at rest; renal impairment: creatinine elevation/proteinuria.

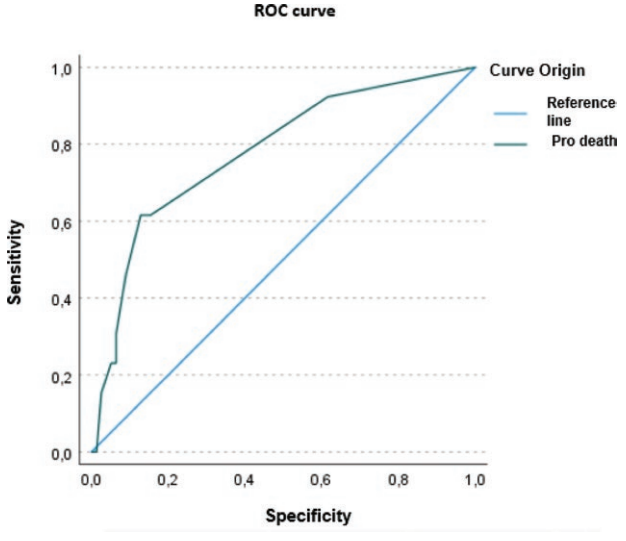

Figure 1 : Receiver operating characteristic curve for death prediction by SScore.

Conclusion: An accessible score for SSc mortality prediction (SScore) was developed from a SLR and validated in a real-life scenario with high specificity and negative predictive value and acceptable accuracy. Larger cohort studies are needed to clarify SScore usefulness in clinical practice, including treatment individualization.

POS1332

ANTI-NUCLEAR VALOSIN-CONTAINING PROTEIN-LIKE AUTOANTIBODIES ARE ASSOCIATED WITH A NEW CLINICAL PHENOTYPE IN SYSTEMIC SCLEROSIS PATIENTS: LIMITED CUTANEOUS SUBSET WITH RECALCITRANT CALCINOSIS AND HIGHER RISK OF CANCER

Keywords: Systemic sclerosis, Autoantibodies, Malignancy

J. Perurena-Prieto[1,2,3], L. Viñas-Giménez[1,2], M. T. Sanz-Martínez[1,2], A. Selva-O'callaghan[4], E. L. Callejas-Moraga[5], R. Colobran[1,2,3,6], A. Guillen-Del-Castillo[4], C. P. Simeon Aznar[4]. [1]*Vall d'Hebron University Hospital (HUVH), Immunology Division, Barcelona, Spain*; [2]*Vall d'Hebron Research Institute (VHIR), Translational Immunology Group, Barcelona, Spain*; [3]*Autonomous University of Barcelona (UAB), Department of Cell Biology, Physiology and Immunology, Bellaterra, Spain*; [4]*Vall d'Hebron University Hospital (HUVH), Systemic Autoimmune Diseases Unit, Internal Medicine Department, Barcelona, Spain*; [5]*Hospital Público de Monforte, Internal Medicine Department, Lugo, Spain*; [6]*Vall d'Hebron University Hospital (HUVH), Department of Clinical and Molecular Genetics, Barcelona, Spain*

Background: It has been reported that 80-85% of established systemic sclerosis (SSc) patients present anti-nuclear autoantibodies (ANAs) [1]. However, in a group of clinically heterogeneous patients with high-titer ANAs no SSc-specific autoantibodies are found. It is likely that these patients present autoantibodies that have not been previously described. Protein immunoprecipitation (IP) followed by mass spectrometry (MS) has the potential to identify these new autoantibodies.
Objectives: To identify novel autoantibodies through a new protein IP assay based on bioorthogonal non-canonical amino acid tagging (BONCAT) combined with MS and to describe the clinical associations of these novel autoantibodies.
Methods: Sera samples and clinical data of 307 SSc patients from Vall d'Hebron University Hospital were collected. All patients met the LeRoy and Medsger criteria and 84.0% fulfilled the 2013 ACR/EULAR classification criteria of SSc. ANAs were tested in all patients by indirect immunofluorescence (IIF) on HEp-2 cells and positive reactions were categorized according to the International Consensus on ANA Patterns (ICAP) classification. Specific autoantibodies (anti-Scl70, -centromere, -RNA-polymerase III, -fibrillarin, -NOR-90, -Th/To, -PM/Scl, -Ku, -U1-RNP, -U11/U12-RNP) were evaluated by a commercial immunoblot and chemiluminescence immunoassay and traditional RNA IP. Patients negative for all tested autoantibodies (n=51) were further studied by an IP assay based on BONCAT. Protein IP was performed by incubation of sera of these patients with protein A-sepharose beads in IP buffer, and subsequent incubation with labelled K562 cell extracts. Obtained immunoprecipitates were fractionated by 10% SDS-polyacrylamide gel electrophoresis (SDS-PAGE). Protein bands detected on SDS-PAGE were further analysed by Liquid Chromatography-MS.
Results: Five patients tested by protein IP showed a band with a molecular weight of 110-115kDa on SDS-PAGE and a homogeneous nucleolar pattern (AC-8) by IIF. These bands were identified as nuclear valosin-containing protein-like (NVL) by MS. All anti-NVL positive patients fulfilled the 2013 ACR/EULAR classification criteria of SSc and presented the limited cutaneous (lcSSc) subtype. Anti-NVL positive patients were characterised by higher age at SSc onset (51.7 vs. 39.9 years, p=0.041) and higher prevalence of calcinosis (100% vs 10.9%, p<0.001). More importantly, anti-NVL positive patients presented higher risk for malignancy (60.0% vs 4.3%, p=0.005; OR 33.0; 95% CI 3.4-323.4) and synchronous cancer (40.0% vs 2.2%, p=0.023; OR 30.0; 95% CI 2.1-433.1).
Conclusion: We have identified NVL as a novel autoantibody target on SSc patients by a new protein IP assay. Anti-NVL positive patients presented a lcSSc phenotype characterized by high prevalence of calcinosis and higher risk of cancer, including synchronous cancer. Further work is required to confirm the clinical associations that were found in this cohort of SSc patients and to evaluate the presence of anti-NVL in other autoimmune diseases and conditions.

POS1333 ASSOCIATION BETWEEN SYSTEMIC SCLEROSIS AND CACNER: A NATIONWIDE COHORT STUDY

Keywords: Systemic sclerosis, Epidemiology, Malignancy

Y. Eun[1], K. D. Han[2], J. K. Ahn[1]. [1]*Kangbuk Samsung Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)*

Background: Previous studies have shown an association between systemic sclerosis and cancer. However, because the disease is rare, large-scale studies are lacking, especially in Asians.
Objectives: We aimed to compare the incidence of cancer in patients with SSc and age- and sex-matched controls in a nationwide population-based cohort in Korea.
Methods: We included patients with SSc defined by the ICD-10 code (M34) and rare and intractable disease code (V138) and 1:5 age- and sex-matched controls using the Korean National Health Insurance Database. The outcomes of the study were incidence of cancer. Cox proportional hazard analysis and Kaplan-Meier curve were used to compare the incidence of cancer between patients with SSc and controls.
Results: A total of 5,145 patients with systemic sclerosis and 25,725 controls were included in the study. During the study period, the overall cancer incidence rate was 11.07 per 1,000 person-years in patients with systemic sclerosis and 7.59 per 1,000 person-years in controls. Overall cancer risk was 1.5 times higher in patients with systemic sclerosis (adjusted hazard ratio 1.46, 95% confidence interval 1.28–1.67). Lung cancer and lymphoma had a high risk in both male and female patients with systemic sclerosis, and colorectal cancer had a high risk only in male patients with systemic sclerosis. The risk of biliary cancer, skin cancer, and cervical cancer was high in female systemic sclerosis patients.
Conclusion: This nationwide cohort study showed that patients with systemic sclerosis were associated with increased cancer risk. Clinicians should be aware of cancers that may increase the risk in patients with systemic sclerosis and apply appropriate screening measures.

POS1334 WORK PARTICIPATION AND WORK DISABILITY IN BELGIAN PATIENTS WITH SYSTEMIC SCLEROSIS

Keywords: Systemic sclerosis

I. Desimpele[1], A. S. De Craemer[1,2,3], L. Delmez[1], D. Elewaut[1,2,3], P. Carron[1,2,3], F. Van den Bosch[1,2,3], V. Smith[1,2,3]. [1]*Ghent University, Internal Medicine and Pediatrics, Faculty of Medicine and Health Sciences, Ghent, Belgium*; [2]*Ghent University Hospital, Rheumatology, Ghent, Belgium*; [3]*VIB-UGent, Center for Inflammation Research, Ghent, Belgium*

Background: Systemic sclerosis (SSc) is an immune-mediated connective tissue disease that potentially affects multiple organ systems. Besides health-related complications, patients often describe work-related difficulties (e.g. productivity loss, sick leave, work disability) that may result in a major individual burden and the rise of indirect costs for society.
Objectives: Despite the rheumatology community's growing interest, work participation and its influencing factors is still an underrecognized and underexplored field of research in SSc patients. This study therefore aims to provide up-to-date data about work status and its determinants in SSc patients.
Methods: Adult SSc patients were questioned on their socio-economic status at the occasion of an outpatient visit at the rheumatology clinic of Ghent University Hospital, a tertiary hospital in the Flemish region (February 2020 to March 2021). All patients were included in a SSc clinical care path (Belgian Systemic Sclerosis Cohort) and fulfilled the LeRoy and Medsger's classification criteria. Employment rate was compared with general Flemish population after adjustment for age and sex. Comparative data on the average duration of working life in Belgium were derived from Eurostat (reference year 2020).
Results: Among the 108 participants, 81 (75%) belonged to the working age category (18-65 y/o). The crude employment rate in SSc patients of work-productive age was 64%, resulting in a standardized employment ratio of 0.90 (95%CI 0.69-1.17). About half of these patients worked full time (53%), with a mean±SD of 41.7±8.7 weekly working hours. The median duration of labor force participation in SSc patients was 40.0 years, while the average career duration in the Belgian population amounted 33.4 years. Long term work disability was reported as the most common reason for leaving the labor market (20%). Patients on work disability were significantly older, less highly educated, more functionally disabled and reported a lower quality of life than patients having a paid job. Job characteristics did not differ significantly between patients with and without a paid job (Table 1).
Conclusion: Our data refute the common perception that SSc patients show a significantly lower work participation grade compared to the general population. Socio-demographic but not job-related characteristics are associated with work disability in this population. Quality of life is remarkably better in patients who perform a paid job, reinforcing the importance to support active labor force participation.

Table 1: Patients characteristics according to working status.

	SSc patients with a paid job N= 52	*SSc patients with work disability N=16*	*P-value*

POS1335 ASSOCIATION BETWEEN LIPID PROFILE AND RISK OF INCIDENT SYSTEMIC SCLEROSIS: A NATIONWIDE POPULATION-BASED STUDY

Keywords: Epidemiology, Systemic sclerosis, Real-world evidence

O. C. Kwon[1], K. D. Han[2], M. C. Park[1]. [1]*Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; [2]*Soongsil University, Department of Statistics and Actuarial Science, Seoul, Korea, Rep. of (South Korea)*

Background: Lipid metabolism is altered in patients with systemic sclerosis (SSc), mediating activation of immune cells and fibroblasts. However, it is unclear whether altered lipid profile in individuals without SSc is associated with a risk of future development of SSc.

Objectives: To assess the association between lipid profile and future development of SSc.

Methods: Individuals without SSc who underwent national health check-ups in 2009 were selected and followed up through 2019 from a nationwide database of the Korean National Health Insurance Service. Serum levels of total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and triglyceride, measured on the date of health check-up in 2009, were each categorized into quartiles (Q1 [lowest], Q2, Q3, and Q4 [highest]). Individuals who developed SSc during follow-up were identified. Cox regression analyses adjusted for multiple covariates were performed to estimate the adjusted hazard ratios (aHRs), and 95% confidence intervals (CIs) according to the quartiles of levels of TC, HDL-C-, LDL-C, and triglyceride, respectively, using Q1 as the reference.

Results: Of the 9,894,996 individuals selected, 1,355 individuals developed SSc during a mean follow-up of 9.2 years, accounting for an incidence rate of 1.49 per 100,000 person-years. Compared with Q1 levels, Q4 levels of TC (aHR 0.691, 95% CI 0.592–0.806), HDL-C (aHR 0.611, 95% CI 0.521–0.716), and LDL-C (aHR 0.735, 95% CI 0.630–0.856) were associated with a lower risk of incident SSc, while Q4 levels of triglyceride (aHR 1.060, 95% CI 0.896–1.254) were not. Higher quartiles of TC (p for trend<0.001), HDL-C (p for trend<0.001), and LDL-C (p for trend=0.001) were associated with a larger effect size.

Conclusion: Serum levels of TC, HDL-C, and LDL-C were inversely associated with the risk of incident SSc. Our findings provide new insights that altered lipid profile could be considered a risk factor for incident SSc.

MRI DIGITAL ARTERY VOLUME INDEX (DAVIX©) AS QUANTITATIVE, CONTINUOUS IMAGING OUTCOME MEASURE OF VASCULAR DISEASE IN SYSTEMIC SCLEROSIS

Keywords: Clinical trials, Outcome measures, Imaging

M. Hughes[1,2], S. Di Donato[3], K. Gjeloshi[4], G. Abignano[5], F. Danzo[6], G. Lettieri[5], E. De Lorenzis[3,7], D. Bertham[8], P. O'connor[8], O. Kubassova[9], J. Dehmeshki[9,10], F. Del Galdo[3,8]. Gemelli", Division of Rheumatology, Roma, Italy*; [8]*Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*; [9]*Image Analysis Group, Imaging, London, United Kingdom*; [10]*Kingston University, Department of Computer Science, London, United Kingdom*

Background: In Systemic Sclerosis, beyond the value of Nailfold capillaroscopy, there is still a deeply unmet need in quantitative imaging surrogate outcome measures to assess activity and/or severity of peripheral vascular disease. This has been halting the implementation of trials targeting vascular disease beyond crude endpoints such as number of digital ulcers (DU). Quantitative MRI based scores have boosted the implementation of new trials in inflammatory arthritis.

Objectives: To determine the value of MRI-based Digital Artery Volume Index (DAVIX©) score in predicting the burden of DU disease as well as other vascular endpoints including clinical manifestation and patient reported outcomes (PROs).

Methods: Consecutive patients with Raynaud's phenomenon were enrolled in two independent discovery and validation cohorts. Data collected included: pulmonary function tests, nailfold capillaroscopy, modified Rodnan Skin Score (mRSS), history/presence of DU (defined as DU Disease), sHAQ-DI, Cochin hand function and Borg scales. Discovery cohort had clinical follow up data at 12 months, Validation cohort had only baseline data. DAVIX© (dominant hand) was calculated by MRI time of flight based, digital artery volumetric assessment over the volume of each finger, as %mean of the 4 fingers [1, 2]. Mann-Whitney test was used to compare DAVIX© between patients' subgroups. Correlations between DAVIX© and clinical variables/PROs were performed using Pearson's and Spearman's tests, as appropriate. Data analysis was conducted using R software.

Results: 233 patients were recruited in discovery (D=91) and baseline validation (V=142) cohorts. 139 patients fulfilled 2013 SSc classification criteria (62 in discovery cohort and 77 in validation cohort), 94 were patients with VEDOSS (2013 ACR/EULAR SSc classification criteria <9) and not included in further analysis. Median (IQR) disease duration was 5.9 (7) and 4.7 (6) years in the two cohorts (P=0.618). DAVIX was significantly lower in patients with DUs disease in both cohorts (0.34% and 0.49% vs 0.65% and 0.75%) compared to patients with no DUs (D, P=0.0018; V, P=0.003). DAVIX© correlated with baseline DLCO% in both cohorts (r= 0.368 and 0.315; P=0.004 and 0.038, respectively). There was no correlation with mRSS or FVC% whereas, DAVIX© correlated with FVC/DLCO ratio (r=-0.337, P=0.009). The analysis of PROs showed that DAVIX correlated best with VAS DUs (r=-0.291 and -0.243, P<0.05 for both cohorts) and VAS Raynaud (r=-0.270, P=0.048 for the discovery cohort), whereas there was no significant correlation with the other PROs. Importantly, DAVIX© correlated inversely with disease duration in both cohorts (r=-0.415 and -0.441, P<0.001 for both). In the discovery cohort, 12 patients developed new (7) or their first (5) DUs during follow-up and their mean DAVIX© was 0.23% vs 0.66% of 73 patients who did not develop any new DUs (p=0.02). Standard Receiver Operating Curve indicated that DAVIX© <0.36% conferred a 4 times higher risk of new DUs, independently of any other clinical variable.

Conclusion: DAVIX© is a feasible, automated, contrast-free imaging outcome measure that reflects worse vascular disease as far as DU disease, DLCO% and patient reported burden of Raynaud's and DU disease. DAVIX© validation in Randomized Controlled Trials would offer a novel imaging based surrogate outcome measure of vascular disease in Systemic Sclerosis.

Pain in rheumatic diseases, including fibromyalgia

POS1337 LONG-TERM OPIOID USE AMONG PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES: IMPACT OF VARYING DEFINITIONS

Keywords: Pain, Fibromyalgia, Inflammatory arthritides

J. Y. T. Huang[1], D. Jenkins[2,3], B. Birlie Yimer[1], C. Ramirez Medina[1], N. Peek[2,4], M. Lunt[1], W. Dixon[1,4], M. Jani[1,4]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, Manchester, United Kingdom*; [2]*University of Manchester, Division of Informatics, Imaging and Data Science, Manchester, United Kingdom*; [3]*University of Manchester, NIHR Greater Manchester Patient Safety Translational Research Centre, Manchester, United Kingdom*; [4]*Manchester Academic Health Science Centre, NIHR Manchester Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, United Kingdom*

Background: People living with rheumatic and musculoskeletal diseases (RMD) are frequently prescribed opioids for non-cancer pain. A proportion of RMD patients newly prescribed an opioid will transition to long-term opioid use, and represent a high-risk subgroup for opioid dependence, abuse and harms. However, definitions of long-term opioid use in the literature vary considerably, making it difficult to characterise the scale of the issue and design future interventions to address it [1,2].
Objectives: (1) To evaluate the proportion of patients transitioning to long-term opioid use in new users across 6 RMD conditions using varying definitions used in the literature (2) To assess the proportion of long-term opioid users who transition to opioid dependence.
Methods: Patients aged ≥18 years with a diagnosis of rheumatoid arthritis (RA), psoriatic arthritis (PsA), axial spondyloarthritis (AxSpA), systemic lupus erythematosus (SLE), osteoarthritis (OA) and fibromyalgia and without prior cancer, with a new episode of opioid use between 01/01/2006 and 31/10/2021 and at least a 1-year follow-up in the Clinical Practice Research Datalink (CPRD) were included. CPRD is a database of anonymised UK primary care electronic health records representative of the national population. Long-term opioid users were defined using 3 different definitions: 1) *Standard* (most commonly used): ≥3 opioid prescriptions issued within a 90-day period, or ≥90 days opioid supply, in the first year of follow-up (excluding the first 30 days). 2) *Stringent*: ≥10 opioid prescriptions filled over >90 days, or ≥120-day opioid supply in the first-year follow-up. 3) *Broad*: ≥3 monthly prescriptions (no need to be consecutive) in the first 12 months. Opioid dependence was defined as RMD patients who had relevant Read Codes within 5 years after a new episode of opioid use. The proportions of long-term opioid use and opioid dependence for RMDs were calculated.
Results: This study included 841,047 patients of whom 12,260 had a code for RA, 5,195 PsA, 3,046 AxSpA, 3,081 SLE, 796,276 OA, and 21,189 fibromyalgia. The highest proportion of long-term opioid users among the 6 RMDs was patients with fibromyalgia (27.4% for *Standard*, 20.9% for *Stringent*, and 33.7% for *Broad*), followed by RA (25.7%, 18.5%, and 32.3% respectively) and AxSpA (23.8%, 17.3%, and 29.6% respectively) (Figure 1-stacked bar chart). On average, using *Broad* definition showed 10-13% higher than *Stringent* definition for all RMDs. As the Venn diagram in Figure 1, 241,727 patients met any of the definitions of long-term use, of which half fulfilled all 3 definitions. The *Broad* definition was able to identify additional half of long-term users, with 24.0% overlapping with the *Standard* definition. In total, 685 (0.06%) RMD patients were diagnosed with opioid dependence within 5 years after starting opioids. Similar proportions of opioid dependence were observed in long-term opioid users across all definitions: 332 (0.18%) for *Standard*, 281 (0.23%) for *Stringent*, and 355 (0.15%) for *Broad* definitions. Moreover, 323 out of 685 RMD patients (47.2%) who had a diagnosis of opioid dependence were not classified as long-term opioid users by the 3 definitions.
Conclusion: Around 1 in 3 fibromyalgia patients and 1 in 4 RA/ AxSpA patients fulfilled definitions for long-term opioid use within 12 months after starting an opioid. The low prevalence of opioid dependence across all RMDs, defined using Read Codes alone is likely to be considerably underrepresented in clinical practice. This reflects both coding practises in primary care and under recognition of the issue in those on long-term opioids.

POS1338 PHARMAKON OR THE ART THAT HEALS: TRANS-DISCIPLINARY ARTISTIC-TRANSFORMATIVE WORKSHOPS FOR FIBROMYALGIA SYNDROME

Keywords: Non-pharmacological interventions, Patient reported outcomes, Fibromyalgia

C. Villani[1], M. Sapio[2], V. Giorgi[3], P. Sarzi-Puttini[3]. [1]*Transdisciplinary Designer of Artistic-cultural Experiences, Freelance, Palermo (PA), Italy*; [2]*Ospedale Buccheri La Ferla FBF, Pain Medicine, Palermo (PA), Italy*; [3]*IRCCS Istituto Galeazzi - Sant'Ambrogio. Milan State University School of Medicine, Rheumatology Department, Milan, Italy*

Background: Fibromyalgia syndrome (FMS) is a widespread chronic pain syndrome with many associated symptoms. It is frequently related to a traumatic event (1), strong and of short duration, or slight but protracted over time. A multidisciplinary therapeutic approach is recommended by international guidelines. The transformative experience (TE) allows for a profound and immediate change that differs from linear and gradual psychological change; this helps create novel responses to the same initial thoughts and actions, thereby breaking the maladaptive emotional/behavioral loop elicited by chronic stress and trauma (2), creating a sort of "virtuous" cycle, adaptive rather than maladaptive and long-lasting. In this study, TE was specifically elicited through transformative art (TA), an intrinsically transdisciplinary tool, in different ways in the three arms of the study.
Objectives: Validation of the efficacy (in terms of quality of life and sleep, self-esteem, self-efficacy) of transdisciplinary TA workshops in patients with FMS.
Methods: Prospective observational study lasting 8 months (February-October, 2021), in which the effectiveness of three different TA workshops in patients with FMS was evaluated: in group 1 participants were encouraged to review their autobiography and illness in a humorous sense; in group 2 participants were guided to express their own realities of chronically ill patients in poetry; group 3 was based on the guided narration of works of art according to visual thinking strategies integrated with the principles of narrative medicine. Patients were divided into the three laboratories according to their preference. Tests were administered at baseline and post-workshop. The activities took place entirely online.
Results: 109 FM patients completed the study (n=3 males, mean age 52.9, mean years from diagnosis 11.2 [SD 8.6]). No differences were found among the three groups at baseline in terms of clinimetric variables. Data analysis made by a Wlicoxon non-parametric test (WNPT) of the three groups in conjunction showed a statistically significant improvement of the Pittsburgh Sleep Quality Index (PSQI) ($p<0.05$), Response to Stressful Experiences Scale (RSES) ($p<0.05$), World Health Organization- Five Well-Being Index (WHO-5) ($p<0.001$) and Global Health scale (GH) ($p<0.05$). No significant difference was found for The Mindful Attention Awareness Scale (MAAS) ($p=0.2663$). A WPNT was performed to compare baseline and final results of the three groups separately. The best performance was seen in Group 1, since patients ameliorated in almost all parameters: PSQI ($p<0.05$), GH ($p<0.05$), SAP dimension 1 ($p<0.05$), 2 ($p<0.05$) and 4 ($p<0.05$), WHO-5 ($p=0.0013$). MAAS ($p=0.895$), RSES ($p=0.0673$) and SAP dimension 3 ($p=0.0573$) resulted nonsignificant, although very close to significance. Sleep ($p<0.05$) and the 3rd dimension of SAP ($p<0.05$) improved in patients of Group 2; whilst self-esteem ($p<0.05$) and WHO-5 ($p<0.05$) did in Group 3.
Conclusion: Our research shows that art, experienced as TA, leads to significant improvements of the psychophysical condition of FMS patients. TA can be seen as a crucial mediator for overcoming the trauma/stressors, probably through the generation of "pivotal mental states" (PIMS), defined as a "hyper-plastic state aiding rapid and deep learning that can mediate psychological transformation" [3].

POS1339

EFFICACY OF VERY LOW-CALORIE KETOGENIC DIET IN OBESE PATIENTS WITH FIBROMYALGIA: PRELIMINARY RESULTS FROM A MONOCENTRIC INTERVENTIONAL STUDY

Keywords: Diet and nutrition, Pain, Fibromyalgia

J. Ciaffi[1], L. Lisi[1], A. Mari[1], L. Mancarella[1], V. Brusi[1], E. Quaranta[1], S. Ricci[2], G. Vitali[2], N. Stefanelli[2], F. Ursini[1,3]. *[1]IRCCS Istituto Ortopedico Rizzoli, Medicine & Rheumatology Unit, Bologna, Italy*; *[2]IRCCS Istituto Ortopedico Rizzoli, Dietetic Service, Bologna, Italy*; *[3]Alma Mater Studiorum - Università di Bologna, DIBINEM, Bologna, Italy*

Background: Obesity can worsen fibromyalgia (FM) and very low-calorie ketogenic diet (VLCKD) is a potential therapeutic option in diseases that share clinical and pathophysiological features with FM [1].

Objectives: In this pilot interventional study, we investigate the effects of VLCKD in obese patients with FM.

Methods: Adult FM patients with a BMI ≥ 30 kg/m [2] and who had failed standard low-calorie diets, were eligible for VLCKD. The weight-loss program was preceded by 4 weeks of free-diet (W-4 to W0). During the first period of VLCKD (W1 to W4), patients could eat protein preparations and vegetables. In the next phase (W5 to W8), natural proteins were gradually integrated in the dietary regimen. Ketosis was assessed weekly with urine strips. Carbohydrates were then progressively reintroduced (W9 to W20). Changes in BMI, FM impact questionnaire (FIQ) and Hospital Anxiety and Depression Scale (HADS-A for anxiety and HADS-D for depression) were evaluated at established timepoints. As previously reported, a change of 14% in FIQ was considered clinically relevant [2]. This interim analysis evaluates patients who reached the final visit after 20 weeks from the beginning of VLCKD (W20).

Results: At data cut-off, 20 patients, all females, were enrolled in the study. Two patients discontinued the intervention while 4 are currently in the maintenance phase. Mean age of the 14 patients who reached W20 was 50.4 years and BMI was 36.9. Baseline characteristics are summarized in Table 1. No significant difference in BMI, FIQ, HADS-A and HADS-D was observed from W-4 to W0. All patients lost weight during the first period of VLCKD and this achievement was maintained through W20 (Figure 1, panel A). Mean BMI decreased from 36.9 at W0 to 34.5 at W4, 33.3 at W8 and 32.2 at W20 (all p <0.001 compared to W0). Compared to W0, a significant reduction of mean FIQ (Figure 1, panel B) from 64.3 to 35.2 was observed at the end of W4 (p <0.001) and was maintained also at W8 (mean FIQ of 38.8; p =0.004) and at W20 (mean FIQ of 39.1; p =0.007). Analysing the trend in each participant, at W4, all 14 patients showed a reduction in FIQ, which was clinically relevant in 13 (93%). Compared to W0, a meaningful improvement in FIQ was still observed at W20 in 12 cases (86%). However, change in BMI was not significantly correlated with change in FIQ at any timepoint. HADS-A and HADS-D improved significantly from W0 to W4, W8 and W20. (Figure 1, panels C, D). Mild constipation was reported by 8 patients (57%), fatigue by 4 (29%) and headache by 3 (21%). No major safety concern emerged.

Conclusion: These are the first data on the efficacy of VLCKD in FM. All patients achieved improvement in disease activity outcomes during the ketogenic phase, which was maintained also after carbohydrate reintroduction. Our data suggest that ketosis might exert beneficial effects in FM which extend beyond the promotion of rapid weight loss.

POS1340 VALIDATION OF QUALISEX QUESTIONNAIRE TO EVALUATE SEXUAL DYSFUNCTION IN WOMEN AFFECTED BY FIBROMYALGIA

Keywords: Quality of life, Lifestyles, Fibromyalgia

C. Gioia[1], G. Dolcini[1], M. Favretti[1], D. Franculli[1], F. Giardina[1], C. Iannuccelli[1], R. Priori[1,2], F. Conti[1], M. Di Franco[1]. [1]*Sapienza University, Division of Rheumatology, Department of Clinical Internal, Anaesthesiologic and Cardiovascular Sciences, Rome, Italy*; [2]*UniCamillus, Saint Camillus International University of Health Science, Rome, Italy*

Background: Fibromyalgia (FM) is a common chronic widespread pain condition, also characterized by fatigue, sleep and mood disorders, with higher prevalence in women. Sexual function is an important feature in people's well-being; its alterations include decreased sex drive, sexual satisfaction, orgasm, and arousal, as well as increased genital pain. Emerging but still too few studies observed a higher prevalence of sexual dysfunction in FM, especially related to depression.
Objectives: The aim of this study was to evaluate sexual dysfunctions in a large cohort of FM women through Qualisex questionnaire, used in other rheumatic diseases but not yet validated for FM.
Methods: We consecutively enrolled women affected by FM (ACR 2016) referring to our out-patient clinic. Demographic and clinical examination as well as evaluation of severity of FM symptoms (R-FIQ, SSS and WPI) were assessed for each patient. Moreover, Hospital Anxiety and Depression Scale (HADS) and questionnaire for sexual dysfunction-Qualisex were anonymously administered. Qualisex questionnaire is composed by 10 questions on different items of sexual life with higher scores suggestive of greater negative impact of FM on sexual life.
Results: The cohort was composed by 373 FM female patients, median age 49,1. Qualisex questionnaire was validated with Cronbach's alpha test (0,878), median value 5,3. Women with lower grade of education (p=0,002), married (p<0,001) and with lower sexual feeling with partner (p<0,001) showed higher values of Qualisex. Menopause status, drug assumption and comorbidity did not influence patients' sexual quality. High values of HADS-A and HADS-D showed a positive correlation with Qualisex Total (p<0,001 r=0,312; p<0,001 r=0,542 respectively) as well as high values of VAS pain, VAS fatigue and VAS dryness (p<0,001 r=0,438; p<0,001 r=0,375; p<0,001 r=0,70 respectively). Relationship duration also presented a positive correlation (p<0,001 r=0,202). Multivariate analysis observed a significantly influence of relationship duration, VAS pain, fatigue and dryness, HADS-A/D, R-FIQ and all specific items of Qualisex, on Qualisex Total correcting for patients' age (p<0,001).
Conclusion: Qualisex questionnaire represents a good test to evaluate sexual disorders in FM women. Different aspects contribute to sexual dysfunction both from a psychological (anxiety, depression, loss of self-esteem, decreased sexually attraction) and a physical (pain, fatigue etc..) point of view with an important impact of FM on sexual life and consequently a worsening of FM symptoms. Over a demotivation feeling, inability to live a "normal everyday life", the reduced sexual function contributes to a bad quality of life. Other studies are needed to analyze which interventions, pharmacological and non (physical activity, psychotherapy), could improve the sexual aspect in the global contest of FM and to investigate this important aspect in FM male patients.

POS1341 GENDER DIFFERENCES IN THE REVISED FIBROMYALGIA IMPACT QUESTIONNAIRE (FIQR) A PILOT STUDY

Keywords: Patient reported outcomes, Gender/diversity issues, Fibromyalgia

M. Favretti[1], G. Dolcini[1], C. Iannuccelli[1], D. Franculli[1], C. Gioia[1], F. Conti[1], M. Di Franco[1]. [1]*Sapienza University, Rheumatology Division, Department of Clinical Internal, Anaesthesiologic and Cardiovascular Sciences, Rome, Italy*

Background: Fibromyalgia (FM) is a chronic syndrome clinically characterized by widespread musculoskeletal pain associated with symptoms like fatigue, sleep disturbances and cognitive impairment. Prevalence is higher in females but the 2010/2011 and 2016 revisions of the American College of Rheumatologist (ACR) criteria reduced prevalence differences and the actual female:male ratio is approximately 3:1. Even if in the last years some studies have been conducted regarding gender differences in FM, disease severity is still assessed using questionnaires, such as the Revised Fibromyalgia Impact Questionnaire (FIQR), designed for female patients and validated through a predominantly female sample.
Objectives: Aim of this pilot study was to compare the 21 items of the FIQ-R among male and female patients in order to evaluate the possible existence of a gender bias.
Methods: In this case control study, all the consecutive patients with a diagnosis of FM (2016 ACR criteria) referring to our out-patients *Fibromyalgia Clinic* between May 2020 and December 2022 were asked to answer an online survey, including demographic characteristics, disease variables and the Italian version of the FIQR. Among the 544 patients that compiled the questionnaire, 78 patients, 39 males and 39 females matched for age and disease duration, were consecutively enrolled in order to compare their total FIQR score and the different domains scores.
Results: The univariate analysis of the FIQR scores, taking account of the total score and of the different domains of FIQR, showed that total scores and physical function domain scores were significantly higher in females compared to males. No significant differences emerged between the two groups regarding overall impact domain score and symptoms domain score. Among the 21 items of the FIQR, the female group obtained significantly higher scores answering the questions FIQR1 (brush or comb your hair), FIQR4 (vacuum, scrub, or sweep floors), FIQR5 (lift and carry a bag full of groceries), FIQR7 (change bed sheets), FIQR9 (go shopping for groceries) and FIQR21 (sensitivity to loud noises, bright lights, odors, cold).
Conclusion: The results of our pilot study showed that female patients obtain significantly higher scores in the FIQR total score and in the physical function domain score, in particular in 5 out of the 9 sub-items of the FIQR physical function domain. These preliminary results indicate that the use of the FIQR as a severity index in male patients probably underestimates the disease impact in this group. In order to confirm these results the sample needs to be increased but it seems reasonable to conclude that the assessment of disease impact should be diversified, taking gender differences into account.

POS1342 COGNITIVE DYSFUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RELATIONSHIP WITH BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF)

Keywords: Cognitive function, Spondyloarthritis, Fibromyalgia

I. Shapoval[1], H. Vyshar[1], L. Perebetiuk[1], V. Khomenko[1], L. Shvets[1], M. Stanislavchuk[1]. *[1]National Pirogov Memorial Medical University, Vinnytsya, Ukraine, Chair of Internal Medicine #1, Vinnytsya, Ukraine*

Background: Normal cognitive status is essential for daily activities, but many people with chronic autoimmune rheumatic diseases are impaired in this function. This is probably related to the age of the patients, the education level, the duration of the disease, the disease activity. Pronounced pain syndrome in ankylosing spondylitis (AS) patients is a risk factor of cognitive dysfunction [1, 2]. There are also literature data regarding the involvement neurotrophins, namely brain-derived neurotrophic factor (BDNF), in the mechanisms of pain regulation and psychoemotional disorders [3].
Objectives: Our study aimed to evaluate the cognitive status in patients with AS and the relationship with BDNF.
Methods: We examined 143 patients (81.8% male) with AS according to modified New York criteria. The mean age of the examined patients was 42.1±11.3 years. The Mini Mental State Examination MMSE (Folstein M.F. et al., 1975) was used to assess the psychological and cognitive status. The level of BDNF in plasma was determined twice a day (at 8:00 and 20:00) by the ELISA method, also we calculated the ratio between morning and evening BDNF level (BDNF index "8:00/20:00"). The study was conducted in compliance with bioethical standards. All data were analyzed using IBM Statistics SPSS 23 software.
Results: Cognitive dysfunction, according to MMSE, was diagnosed in 90 (62.9%) AS patients. The values of the MMSE scale in AS patients ranged from 25 to 30. It should be noted, that 57.4% had mild cognitive impairment (MMSE - 26-27 points) and only seven patients (4.9%) had moderate (MMSE - 24-25 points) cognitive impairment.
Plasma levels of BDNF (pg/ml) in AS patients shown in Table 1.

Table 1 Value of the plasma levels of BDNF (pg/ml) in AS patients

Group	BDNF			
	Morning level	Evening level	BDNF index "8:00/20:00"	Daily average level
AS with normal cognitive status	970.6±302.0	758.3±448.26	1.75±1.12	864.46±314.3
AS with cognitive dysfunction	957.8±387.2	879.7±357.2	1.59±1.25	918.7±416.1
P	0.836	0.077	0.444	0.413

We established the circadian rhythm of BDNF production during the day. It was revealed in patients with normal cognitive status, as well as in patients with cognitive dysfunction. The BDNF level in the morning was significantly higher than in the evening. We compare BDNF levels in patients with normal cognitive status and in patients with cognitive dysfunction. Patients with cognitive dysfunction showed a trend toward higher evening BDNF level compare patients with normal cognitive status (P=0.077). We established a negative correlation between cognitive status and the evening BDNF level - with an increase in evening BDNF level cognitive dysfunction deepens (P <0.05).
Conclusion: Cognitive dysfunction is a frequent condition in patients with AS. Our study results demonstrate circadian rhythm of BDNF production during the day and relationship between BDNF production and cognitive status – cognitive dysfunction in AS patients is associated with high evening BDNF levels.

POS1343 INFLUENCE OF REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION OF CNS ON FIBROMYALGIA PATIENTS - A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY (INTERIM ANALYSIS)

Keywords: Patient reported outcomes, Fibromyalgia, Non-pharmacological interventions

Z. Veličković[1], S. Radovanović[2,3], G. Radunovic[1,3]. *[1]Institute of Rheumatology, Internal Medicine - Rheumatology, Belgrade, Serbia*; *[2]Institute for Medical Research, Neuroscience, Belgrade, Serbia*; *[3]University of Belgrade, School of Medicine, Belgrade, Serbia*

Background: Fibromyalgia syndrome (FMS) is a chronic disorder characterized by diffuse pain, sensitivity to sensory stimuli, fatigue, cognitive impairment, mood and sleep disorder. The side effects of drugs used in treatment (i.e. antiepileptics) can mimic certain symptoms of fibromyalgia (i.e. impaired balance, dizziness), so there is a huge need for alternative treatment. Repetitive transcranial magnetic stimulation (rTMS) is a non-invasive therapy utilizing a magnetic field to stimulate different brain structures. rTMS is registered as adjuvant therapy for major depressive disorder, migraine, and obsessive-compulsive disorder, and its efficacy is being investigated for other conditions.
Objectives: The main aim was to evaluate the influence of rTMS in alleviating the symptoms in patients with fibromyalgia.
Methods: Sixteen patients were randomized to rTMS (n=10) or sham treatment (n=6). rTMS was applied in 10-day sessions with a frequency of 10 Hz and an intensity of 130% of the predetermined motor threshold over the left dorsolateral prefrontal cortex (DLPFC). One session of rTMS consisted of 5 seconds of stimulation (frequency of 10 Hz, for a total of 50 stimuli) and a 10-second pause. Patients received 2000 stimuli per day (50 stimuli in 40 repeated sessions). The placebo was applied with an inactive "sham" coil which resembles active treatment. The intensity of symptoms was assessed with Tender Point Examination (TPE), Visual Analog Scale of Pain (VAS), Brief Pain Inventory (BPI), Beck Depression Inventory II (BDI II), Beck Anxiety Inventory (BAI), Montreal Cognitive Assesment (MoCa), Medical Outcome Studies Sleeping Scale (MOS SS), Functional Assesment of Chronic Illness Therapy – Fatigue (FACIT-F), 36-item Short Form Survey (SF-36), and Revised Fibromyalgia Impact Questionnaire (FIQR).
Results: There was no difference between groups in any of the characteristics at baseline. There was a decrease in BDI score after the treatment period, but the change was more prominent in the rTMS group compared to the placebo (p=0.064). rTMS was also superior in a decrease in FIQR score (p=0.054) (Table 2.) and an increase in vitality through SF-36 (p=0.003). Moreover, placebo treatment led to a significant reduction in sleep disturbances (p=0.035). There were no differences between groups in delta values before and after treatment regarding the rest of investigated characteristics (Table 1., p> 0.05).
Conclusion: Preliminary results suggest a reduction in the impact of the disease and depression, as well as an increase in the vitality of participants who have been treated with rTMS. The placebo effect on a reduction of sleep disturbance can be partly explained by the stimulating effect of rTMS. Because this was an interim analysis, the presented results should be taken with caution.

Gemelli IRCCS, Immunology Research Core Facility – Gemelli Science and Technology Park (GSTeP), Rome, Italy*

Background: Rheumatoid arthritis (RA) is a chronic disease characterized by a high degree of disability and pain. Remission is the optimal goal but, even when it is reached, the pain can persist as "residual pain".
Objectives: The aims of the study were (i) to characterize the size and perception of residual pain and (ii) to evaluate the possible impact of residual synovitis on pain perception in remission RA patients.
Methods: One hundred twenty-seven RA patients (defined by 2010 ACR/EULAR criteria), of which 68 in clinical and ultrasound remission (REM-RA) and 29 in high disease activity (HDA-RA) defined by DAS28-CRP were enrolled in the study. Thirty fibromyalgia patients (2016 ACR criteria) were enrolled as a control group (FIBRO). Upon enrolled, demographic, clinical and ultrasound features were collected for each patient and an assessment of pain symptom was performed for each patient according to the RAID, FACIT, GHQ and VAS-pain questionnaires. Patients with RA underwent minimally invasive ultrasound-guided biopsy of the synovial membrane of the knee in order to assess the degree of synovitis, according to the Krenn Score (KSS).
Results: Considering the RA group, the synovitis degree is directly correlated with the life quality and disability, as demonstrated by the inverse correlation between FACIT and DAS28-CRP (R2=-0.506, p<0.0001). Furthermore, considering the pain mental aspects, the total GHQ score (R2=0.407; p<0.0001) and the VAS-pain scale (R2=0.402, p<0.0001) are instead directly correlated to the DAS28-CRP in RA patients. Since GHQ value ≥24 identifies a subject requiring psychiatric attention, a higher score was found in 26% of REM-RA patients compared to 52% (p=0.004) and 77% (p<0.0001) in the HDA-RA and FIBRO groups respectively while, considering the VAS-pain, the REM-RA patients had lower values (20) compared to HDA-RA (50; p<0.0333) and FIBRO (70; p<0.0001), suggesting how the underlying pathology could affect psychological well-being and pain perception. Further confirmation was obtained with the RAID questionnaire: REM-RA patients presented lower scores (3.34) than HDA-RA (5.56; p = 0.0003) and FIBRO patients (7.63; p <0.0001). Finally, considering the synovitis degree, the presence of subclinical synovitis (KSS≥2) in REM-RA patients (50%) was not associated with a higher pain score, assessed by VAS-pain, suggesting the possible non-inflammatory nature of residual pain.
Conclusion: Remission status in RA is associated with a better psycho-physical state than in HDA patients but, despite that, there is the persistence of a certain degree of residual pain, regardless of the subclinical synovitis degree. It emerges that the features of pain in patients in remission is different from other conditions (high disease activity or fibromyalgia), suggesting different underlying biological mechanisms.

POS1345 PAIN OVER 5 YEARS IN OUR EARLY RHEUMATOID ARTHRITIS UCLOUVAIN BRUSSELS COHORT: RESULTS AND CORRELATION WITH CLINICAL RESPONSE, QUALITY OF LIFE

Keywords: Quality of life, Rheumatoid arthritis, Patient reported outcomes

C. Desmet[1], E. Sapart[1], M. Lauras[2], B. Joly[2], T. Cayrol[2], T. Sokolova[1], A. Avramovska[1], P. Durez[1]. *[1]Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC)., Rheumatology, Brussels, Belgium*; *[2]Institute of Experimental and Clinical Research (IREC), UCLouvain, Health Sciences Division, Brussels, Belgium*

Background: Pain is a major patient reported outcome in early rheumatoid patients (ERA). Pain is associated with disease activity but could be also related to non-inflammatory conditions. Chronic pain has a negative impact on quality of life in ERA patients. The main treatment objective in ERA is remission or low disease control, but relief of pain is a priority of patient.
Objectives: To evaluate the pain course and the proportion of unacceptable pain (VASp >4) during a five-years follow-up in ERA patients and to investigate correlation with clinical response and quality of life.
Methods: 474 ERA patients fulfilling the 2010 EULAR/ACR criteria included in our ERA UCLouvain Brussels cohort were retrospectively analyzed. All were naïve to csDMARDs (MTX), b- or tsDMARDs with symptoms duration < 12 months. Pain was assessed using a visual analogue scale (0-100 mm) and unacceptable pain was defined as a VAS pain > 40mm (VASp>4) based on the patient acceptable symptom state. VASp, HAQ and DAS28-CRP scores were assessed at baseline (BL), 6, 12, 36 and 60 months in order to correlate the % of ERA with an unacceptable pain (VASp>4), non clinical response (DAS28-CRP> 3.2) and no restored quality of life (HAQ >0.5).
Results: Data from 474 eligible ERA patients were collected. The average age of the population is 48.5 years, and the BMI is 25.3. 70.5% of the patients are women. 27.1% are smokers and 68.8% are positive for anti-citrullinated protein antibody (ACPA). The evolution of VAS pain over 5 years of follow-up is shown in Figure 1:

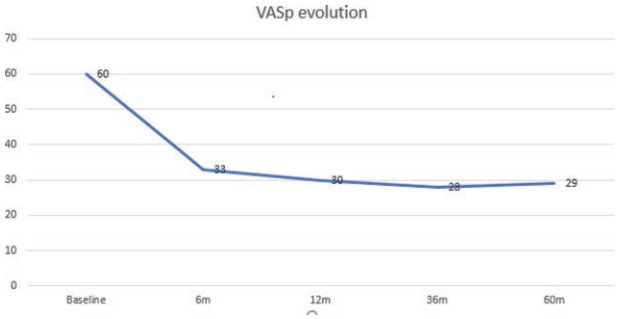

Figure 1.

At BL, the mean VAS pain at the baseline was at 60.2 +/- 26.5mm (range 0-100mm). VASp pain was reduced by 45% (mean 33.1+/- 28.5 mm) at 6 months and remained stable with 51,7% reduction (mean 29.0 +/-27.6mm) at 5 years. 78% of patients (n=308) reported an unacceptable pain at diagnosis which was reduced to 40.4% (n=163) at 6 months and 33% at year 5 (Figure 2):

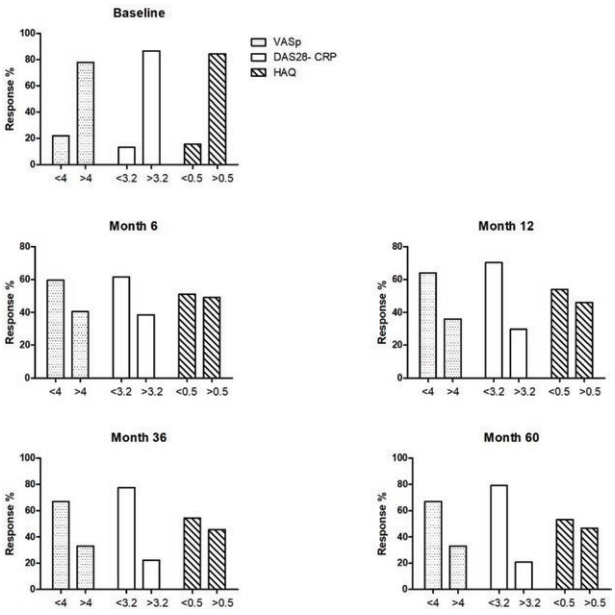

Figure 2. Clinical response: VASp, DAS28-CRP and HAQ throughout the follow-up

No statistical difference was observed for age, sex ratio, BMI, ACPA, or RF except for smokers (27.3% vs 15.6%) between patients with unacceptable pain or not.
A strong correlation was observed between the decrease of VAS pain, DAS28-CRP and HAQ at all-time points. Among the patients with an unacceptable pain at 6 months, HAQ BL score was statistically higher (1.30 +/- 0.69 vs 1.15 +/- 0.67), while the BL DAS28-CRP scores were similar (4.66 +/- 1.41 vs 4.67 +/-1.24). We identified also 20 patients with unacceptable pain throughout the 5 years follow-up, BL DAS28-CRP and HAQ values were statistically increased (5.4 +/- 1.1 vs 4.7 +/- 1.4 and 1.41 +/- 0.86 vs 1.21 +/- 0.62). By contrast, 31 patients reached a complete response defined by a VAS pain <4 + DAS28-CRP<3.2 + HAQ< 0.5 throughout the 5 years follow up). Baseline VAS pain, DAS28-CRP and the HAQ scores assessed at diagnosis were statistically lower in this group. (38.9 +/- 28.4 vs 61.9 +/- 25.7, 4.3 +/- 1.1 vs 4.8 +/- 1.4 and 0.86 +/- 0.60 vs 1.2 +/- 0.71). All patients were treated according the standard of care, mainly with Methotrexate.
Conclusion: We demonstrate that control of pain is achieved in a majority of ERA patient in our cohort. Decrease of pain was correlated with decrease of the disease activity score, meaning that the positive effect is mainly related to inflammation in ERA.

POS1346 CHASING PAIN: EXPLORING SOMATOSENSORY PROFILES IN PATIENTS WITH RHEUMATOLOGICAL DISEASES THROUGH QUANTITATIVE SENSORY TESTING

Keywords: Diagnostic tests, Pain, Clinical trials

C. J. Bauer[1], R. Schrapper[1], S. Petzinna[1], C. Behning[2], T. Bender[3], P. Brossart[1], M. Mücke[4], V. Schäfer[1]. [1]*University Hospital Bonn, Clinic of Internal Medicine III, Department of Oncology, Hematology, Rheumatology and Clinical Immunology, Bonn, Germany*; [2]*University Hospital Bonn, Department of Medical Biometry, Informatics and Epidemiology, Bonn, Germany*; [3]*University Hospital Bonn, Center for Rare Diseases Bonn (ZSEB), Bonn, Germany*; [4]*University Hospital RWTH Aachen, Institute for Digitalization and General Medicine, Aachen, Germany*

Background: Pain reflects a major symptom in many rheumatological diseases. To assess nociceptive and non-nociceptive submodalities of different afferent nerve fiber groups and central pathways, and to examine the presence of sensitive plus or minus signs such as hyperalgesia or hypesthesia, the "Quantitative Sensory Testing" (QST) approach was developed. QST, established by the German Neuropathic Pain Research Network (DFNS), is meant to be used for the generation of somatosensory profiles [1]. These can then be used as a guidance to improve a targeted pain medication.
Objectives: The goal of this study is to explore whether patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), axial spondyloarthritis (axSpA) and systemic sclerosis (SSc) show differences in somatosensory profiles between each other and in contrast to a healthy control group.
Methods: In this monocentric five-armed study (ethical approval under Institutional Review Board #065/20), four groups of each 20 patients with RA, PsA, axSpA or SSc, and one control group consisting of 20 healthy individuals were collected and a somatosensory profile using the standardized procedure of QST was created for each one of the 100 participants. QST included both small fiber mediated stimuli and large fiber mediated stimuli, via all categories shown in Figure 1. The vibration detection threshold where the detection of vibration is ranked on a scale from zero to eight, with '8' being normal perception of vibration, serves as an example for large fiber mediated stimuli. Additionally, standard questionnaires incorporating laboratory parameters, joint manifestations and pain condition were used to determine disease activities (BASDAI, PASDAS, CDAI and mRSS).
Results: A preliminary data analysis of all 100 study participants found occurrence of allodynia in 5% of patients with SSc, 15% of RA, 25% of PsA, and 15% of all axSpA patients, compared with 0% in the control group. Considering the vibration detection threshold, there was little difference between all disease groups, also in comparison to the control group: SSc (mean ± SD: 7,79 ± 0,34), RA (mean ± SD: 7, 66± 0,4), PsA (mean ± SD: 7,76 ± 0,34), AxSpA (mean ± SD: 7,69 ± 0,57) and control group (mean ± SD: 7,98 ± 0,16).
Conclusion: The analysis for allodynia occurrence indicates the presence of sensory gain towards small fiber mediated stimuli in all four disease groups studied. Until now, our vibration detection threshold studies do not suggest a loss or gain of sensory function for large fiber mediated stimuli. The full analysis completion is expected in March 2023.

POS1347 EVALUATING THE EFFICACY OF LOCAL CORTICOSTEROID INJECTION, PLATELET-RICH PLASMA, AND EXTRACORPOREAL SHOCKWAVE THERAPY IN PATIENTS WITH PES ANSERINE BURSITIS: A PILOT RANDOMIZED, COMPARATIVE CLINICAL TRIAL

Keywords: Pain, Osteoarthritis

W. A. Gouda[1], A. S. Abbas[1], T. M. Abdel-Aziz[1], M. Z. Shoaeir[1], A. Moshrif[1], A. Mosallam[1]. [1], *Faculty of Medicine, Al Azhar University, Rheumatology Department, Assiut, Egypt*

Background: Pes anserine bursitis is one of the causes of painful knee syndromes. It limits physical activity and impairs the quality of life of a patient. Obesity and osteoarthritis (OA) of the knee are common predisposing factors for pes anserine bursitis. It is treated with non-steroidal anti-inflammatory drugs (NSAIDs), physiotherapy, injections of local anesthetics, and corticosteroids. This study examines the efficacy of local corticosteroid injection, Platelet-rich plasma (PRP) injection, and extracorporeal shock wave therapy (ESWT) as different modalities to alleviate pain and improve function in patients with pes anserine bursitis.
Objectives: This study examines the efficacy of local corticosteroid injection, Platelet-rich plasma (PRP) injection, and extracorporeal shock wave therapy (ESWT) as different modalities to alleviate pain and improve function in patients with pes anserine bursitis.
Methods: This randomized comparative clinical trial was performed between July 2021 and June 2022 in the rheumatology and rehabilitation department at Al-Azhar University hospitals in Egypt on 180 patients diagnosed with chronic pes anserine bursitis according to Larson and Baum criteria. The enrolled patients were divided into three groups, each including sixty patients. Group I received a local corticosteroid injection of 40 mg of methylprednisolone acetate/1 ml (n = 60); Group II received a PRP injection (n = 60); and in Group III, ESWT (n = 60) was used. The Visual Analog Scale (VAS), Western Ontario and McMaster Universities (WOMAC) pain score, WOMAC physical function score, and Ritchie score for tenderness were recorded at the baseline, after 1 week, and after 8 weeks.
Results: There are significant differences between the corticosteroid group compared to the PRP group (10.6± 2.5) and the ESWT group (9.7 ±2.6) regarding the WOMAC pain score and WOMAC physical function score one week after the application of procedures. There is a highly statistically significant (p= 0.001) decreased 8-week WOMAC pain score in the corticosteroid group (5.7 ± 2.7) when compared to the PRP group (9.4± 2.4) and ESWT group (7.1± 1.5) **Table [1].** As regards VAS, there isn't a statistically significant difference (p = 0.636) between the studied groups as regards baseline VAS or 8-week VAS after the procedure.
Conclusion: An examination of Pes anserine bursitis is essential and shouldn't be missed in knee OA patients complaining of pain. Our findings show that local corticosteroid injection is more effective than PRP injection and ESWT for pain relief.
Declarations: The authors declare that they have no competing interests.

Table (1): Post hoc analysis for multiple comparisons between studied groups as regard 1-week WOMAC score (pain & physical function) after the application of procedures.

1 week		Corticosteroid vs PRP	Corticosteroid vs ESWT	PRP vs ESWT
WOMAC pain score	**LSD**	**3.06**	**2.1**	0.93
	p-value	**< 0.001 HS**	**0.001 S**	0.126 NS
WOMAC physical function score	**LSD**	3.2	**9.1**	**6.0**
	p-value	0.120 NS	**< 0.001 HS**	**0.004 S**

S: p-value < 0.05 is considered significant.HS: p-value < 0.001 is considered highly significant.LSD: Least sig. difference. NS: p-value > 0.05 is considered non-significant.

Background: People with knee osteoarthritis (OA) (KOA) desire therapies which delay disease progression [1] supporting the need for disease-modifying OA drugs (DMOADs). Sprifermin, truncated recombinant human fibroblast growth factor-18, promotes chondrocyte proliferation and extracellular matrix production [2], improves cartilage biomechanical properties [3], and in the Phase 2 FORWARD study [4], dose-dependently increased knee cartilage thickness. In FORWARD, improvement from baseline in the Western Ontario and McMaster Universities OA Index (WOMAC) symptom subscales occurred in all study arms, but lack of differentiation from placebo (PBO) was thought to be due to inclusion of participants not at risk of KOA progression. A subsequent post-hoc analysis identified a subgroup at risk (SAR) enriched for disease progression [5]. Clinically meaningful change in WOMAC Pain and Function has been defined as ≥10 points (0-100 scale) [6,7], with this degree of worsening pain predictive of structural progression and knee replacement in KOA cohorts [8-10]; this endpoint has not been applied to evaluate symptomatic progression in DMOAD studies to date.
Objectives: Evaluate the effect of sprifermin on symptomatic progression of KOA.
Methods: In FORWARD, participants were randomized 1:1:1:1:1 to intra-articular PBO or sprifermin 30 µg or 100 µg every 6 or 12 months (Q6M or Q12M) for 18 months. WOMAC was collected Q3M and MRI performed Q6M. In the current Kaplan-Meier analysis, time to symptomatic progression (i.e., first occurrence of worsening [increase] of WOMAC Pain of ≥10 points with no improvement [≤9 point decrease] in WOMAC Function) was evaluated over 3 years. The individual treatment arms of the intent-to-treat population (ITT) and the SAR (i.e., baseline WOMAC Pain 40-90, mJSW of 1.5-3.5 mm) were analyzed, as well as the sprifermin 100 µg groups combined for additional power. Time to symptomatic progression was also analyzed by changes in cartilage thickness (decrease or no change/increase) for the populations with an evaluable MRI, i.e., the modified (m) ITT and SAR.
Results: The FORWARD ITT and SAR sprifermin individual treatment arms (Table 1) showed dose-dependent benefits in the time to symptomatic progression compared to PBO, with clinically meaningful and statistically significant separation from PBO for the sprifermin 100 µg groups combined (logrank p-value ITT=0.0282, SAR=0.0099) (Figure 1); separation from PBO was more pronounced in the SAR compared to the ITT. The sprifermin 100 µg groups combined also demonstrated less symptomatic progression than PBO regardless of an increase or no change/decrease in cartilage thickness in the mSAR and mITT.

Table 1: FORWARD Study Populations

Population (n)	Placebo	Sprifermin					Total (N)
		30 µg x 2	30 µg x 4	100 µg x 2	100 µg x 4	100 µg groups combined	
ITT	108	110	111	110	110	220	549
Modified ITT	96	99	99	99	101	200	494
SAR	34	36	27	31	33	64	161
Modified SAR	32	32	26	29	32	61	151

x 2=Q12M; x 4 = Q6M; ITT=intent-to-treat; SAR=subgroup at risk.

Conclusion: These post hoc results support the hypothesis that sprifermin may prevent symptomatic progression of KOA, with benefits seen in both ITT and SAR populations for the sprifermin 100 µg groups combined. As differences between the sprifermin- and PBO-treated groups were detectable in a 3-year time frame, time to symptomatic progression of KOA could be a meaningful endpoint for an

investigational DMOAD trial. Symptomatic and structural benefits of sprifermin need to be confirmed in the planned Phase 2b SPRING study.

POS1349 A BIOMARKER APPROACH TO DATA-DRIVEN IDENTIFICATION OF ENDOTYPES IN KNEE OA PATIENTS

Keywords: Biomarkers, Osteoarthritis

Z. Lisowska-Petersen[1,2], M. Toft Hannani[2], M. Karsdal[2], C. Bager[3], A. C. Bay-Jensen[2], C. Thudium[2]. [1]*Danish Technical University (DTU), Department of Applied Mathematics and Computer Science, Kgs. Lyngby, Denmark*; [2]*Nordic Bioscience, Immunoscience, Herlev, Denmark*; [3]*Nordic Bioscience, Data Science, Herlev, Denmark*

Background: Osteoarthritis (OA) is a heterogeneous and multifactorial disease. Despite its high prevalence, the underlying mechanisms of disease are not fully understood, and treatment options are limited. One of the challenges in understanding OA is the lack of clear subgroups or "endotypes" within the disease, which could help to identify specific causes and point to more targeted treatments. Recent research has suggested that molecular biomarkers may be able to help identify different endotypes of OA. For example, certain biomarkers may be elevated in OA patients with inflammation, while others may be elevated in patients with more severe cartilage degeneration.
Objectives: The objective of the study was to identify endotypes of OA using soluble biomarkers reflecting tissue turnover by applying unsupervised machine learning approaches.
Methods: Biomarkers of cartilage remodeling (CTX-II, C2M, T2CM, PRO-C2), bone remodeling (N-MID, UCTX-I, SCTX-I), and tissue inflammation (CRPM, VICM, C1M, C3M) were measured at baseline in the phase III clinical trials SMC01 (n=1176) and SMC02 studies (n=1030), testing efficacy and safety of oral salmon calcitonin in knee OA patients. Only patients from the placebo group with more than 5 biomarkers available were included (n=528). Approximately 4% of data was missing data and imputed using Random Forest. K-Means clustering was applied on UMAP dimensionality reduced data. The association of change in symptomatic and radiographic parameters over 2 years with the identified clusters was compared with Kruskal Wallis test for numerical variables and chi-square test for categorical variables.
Results: K-Means clustering identified three distinct clusters; 1) a low tissue turnover endotype, 2) a systemic inflammation endotype and 3) A structural damage endotype (Figure 1). The structural damage endotype was characterized by higher levels of bone remodeling markers CTX-I, N-MID and the cartilage degradation marker CTX-II. The systemic inflammation endotype presented with higher levels of C1M, C2M, C3M, CRPM and VICM related to tissue inflammation. Finally, the low tissue turnover endotype showed overall lower levels of both tissue-related and inflammatory markers. We observed a difference in JSW change over two years between the three groups (Cluster 1: -0.28 mm, Cluster 2: -0.16 mm, Cluster 3: -0.32 mm; p=0.049), but this difference was not significant in the corrected analysis. Overall, the three endotypes progressed similarly.
Conclusion: These findings suggest that distinct biomarker-based endotypes exist in OA and highlight that multiple mechanistic avenues may lead to joint deterioration. By identifying these endotypes we may enable the development of more targeted treatments that are tailored towards the underlying cause of OA in individual subgroups of patients.

POS1350 FACTORS ASSOCIATED WITH SEDENTARY BEHAVIOR IN KNEE OSTEOARTHRITIS PATIENTS

Keywords: Lifestyles, Osteoarthritis, Physical therapy/Physiotherapy

A. Adnine[1], F. Z. Taik[1], N. Soba[2], N. Takhrifa[1], F. Z. Aharrane[1], M. Fourtassi[2], F. E. Abourazzak[1]. [1]*Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco*; [2]*Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Sedentary behavior is linked to poor physical and mental health outcomes. Despite of the known benefits of physical activity in patients with knee osteoarthritis, many individuals remain physically inactive.
Objectives: We aimed at investigating the socio-demographic and clinical factors associated with sedentary behavior (SB) in patients with knee osteoarthritis.
Methods: A cross-sectional study was performed among patients with knee osteoarthritis Aged between 40 and 75 years old who visited the outpatient clinic between April 2022 and October 2022. Patients with knee osteoarthritis were included then classified on the basis of the Kellgren and Lawrence radiograph scale. Socio-demographic and clinical findings were collected. Participants were assessed for pain and disability using visual analogic scale (VAS) and LEQUESNE scale. SB was assessed using the international physical activity questionnaire (IPAQ-SF). Furthermore the participants underwent screening for anxiety and depressive disorders using Patient health questionnaire (PHQ-9) and General anxiety disorder (GAD-7) respectively.
Results: The final study simple was made up of 178 patients with a mean (±SD) age of 58.48 ± 9.9 years, 88.2% of them were females, and 69.1% had comorbidities. Mean (±SD) of pain VAS score upon walking was 4.78 ± 2.21. According to the Kellgren and Lawrence classification, 64.4% of the patients had OA grade 2 and 25.6% had grade 3. Mean of Lequesne scale was 9.8 ± 3.8. The average daily duration of sedentary behavior was 151.02 ± 105.04 minutes.
The results of uni and multivariate analysis of associated factors with SB are showed in Table (1):

Table 1 : *Multiple regression with the duration of sedentary behavior as the dependent variable.*

	Univariate analysis OR (95%) P value	Multivariate analysis OR (95%) P value
Age	1.992 [0.354, 3.630] 0.017	1.445 [0.176, 3.066] 0.052
BMI (kg/m2)	-0.024 [-0.098, 0.049] 0.517	_____ _____
Educational level	-27.544 [-45.411, -9.676] 0.003	-27.544[-45.411, -9.676] 0.048
Socioeconomic status	-13.745 [-26.263, -1.227] 0.032	-13.108 [-25.417, -0.799] 0.037
Comorbidities	10.955 [-9.276, 31.185] 0.287	_____ _____
Disease duration (in Years)	-1.321 [-3.971, 1.971] 0.326	_____ _____
VAS Pain level	1.327 [-5.971, 8.626] 0.720	_____ _____
LEQUESNE Scale	-1.334 [-6.351, 3.684] 0.599	_____ _____
Kellgren and lawrence grading scale	-11.661 [-38.703, 15.381] 0.396	_____ _____
Anxiety scale (GAD-7)	-2.221 [-4.891, 0.449] 0.102	_____ _____
Depression scale(PHQ-9)	-1.181 [-1.965, -0.396] 0.002	-0.890 [-1.576, -0.205] 0.011

Conclusion: In the literature few studies discuss factors associated with sedentary behavior in patients with knee osteoarthritis. Our study shows that level of pain and disability are not associated with SB, on the contrary, educational level, socioeconomic status and depressive disorders are the principal factors associated with SB. Our study highlights the importance of therapeutic education and assessment of mental health to improve the management of patients with knee osteoarthritis.

POS1351 A PHASE 2, 104-WEEK STUDY OF REPEAT LORECIVIVINT INJECTIONS EVALUATING SAFETY, EFFICACY, AND BONE HEALTH UTILIZING QUANTITATIVE COMPUTED TOMOGRAPHY (QCT) IN KNEE OSTEOARTHRITIS (OA-06)

Keywords: Osteoarthritis, Imaging, Clinical trials

Y. Yazici[1], C. Swearingen[2], H. Ghandehari[2], J. Britt[2], S. Kennedy[3], J. Tambiah[3], N. Lane[4]. *[1]NYU Grossman School of Medicine, Rheumatology, New York, United States of America*; *[2]Biosplice Therapeutics, Biostatistics, San Diego, United States of America*; *[3]Biosplice Therapeutics, Clinical development and external innovation, San Diego, United States of America*; *[4]University of California Davis, Medicine and Rheumatology, Davis, United States of America*

Background: Knee osteoarthritis (OA) is a common joint disorder associated with pain, disability, and damage. There is unmet need for safe and efficacious treatments for symptoms and structural modification. Lorecivivint (LOR), an intra-articular (IA) CLK/DYRK inhibitor thought to modulate Wnt and inflammatory pathways, is in development as a potential knee OA treatment.

Objectives: To assess the safety and tolerability of repeated 6-month dosing of LOR in a 104-week trial (OA-06, NCT03727022). Additionally, to characterize juxta-articular bone health with quantitative computed tomography (qCT) and regional bone health via dual energy x-ray absorptiometry (DXA).

Methods: Participants with ACR-defined clinical and radiographic knee OA, aged 40-80, and Kellgren-Lawrence (KL) grades 2-3 were randomized 1:1 to receive IA injections of 2 mL 0.07 mg LOR or vehicle PBO at baseline, 24, 52, 72 weeks. The trial was conducted in two 52-week phases, part A (baseline to week 52) and part B (week 53 to week 104), with part A completers invited into part B. Safety was assessed by collection of adverse events (AEs), and serious AEs (SAEs). Bone safety assessments included qCT to assess target and non-target knee BMD, DXA to assess spine and hip BMD and bone/ cartilage biomarkers. Exploratory efficacy was assessed by patient-reported outcomes (PROs). For bone imaging endpoints, change from baseline was estimated using baseline-adjusted ANCOVA.

Results: 101 participants (mean age 60.9±9.1 years, BMI 28.6±3.7 kg/m^2, female 59.4%, KL2 52.5%) were enrolled. 77 participants completed part A and 53 completed part B. AE rates were similar between PBO and LOR, and no SAEs were deemed treatment related. There were no clinical bone health signals (no fractures, accelerated OA, osteoporosis) observed for LOR. Observed target knee qCT BMDs were similar between LOR and PBO (Figure 1). Change from baseline in BMD at Week 104 was -7.08 (12.34) mg/cm^3 in LOR and -2.95 (8.65) mg/cm^2 in PBO, (estimated difference -4.05 [95% CI -11.21, 3.11], not significant). Trends in target knee BMDs for those with higher risk of decreasing BMD, (female and age 65-80), showed no meaningful differences between LOR and PBO. There were no significant differences in total hip or spine BMD between LOR and PBO. Potential confounding factors included baseline imbalances in sex (PBO 68.0% vs. LOR 51.0% female), KL grade (PBO 62.0% vs LOR 42.1% KL 2), and site randomization. There were no meaningful differences in PRO changes between LOR and PBO groups. A trial conduct limitation was the small number of qCT-enabled sites available in the US.

Conclusion: The incidence of AEs was similar between treatment groups and not affected by repeated injections of LOR. Multiple injections of LOR over 2 years did not appear to lead to any bone health adverse effects locally around the knee or regionally at spine or hip.

Background: Hand pain is a common symptom in hand osteoarthritis (OA). Questionnaires are used to measure and to monitor this pain over time. However, it is unknown whether these measurements reliably reflect patients' experience.

Objectives: This study aimed to compare pain development scored by a validated questionnaire with pain development scored by a direct question to the patient.

Methods: Data from the first four years of the ongoing HOSTAS (Hand OSTeoArthritis in Secondary care) cohort were used. HOSTAS consists of patients with primary hand OA diagnosed by a rheumatologist. Pain was measured with the Australian/Canadian hand Osteoarthritis index (AUSCAN) pain subscale (range 0-20) at baseline and annually afterwards. Partway through the study, an annual anchor question was added asking participants whether pain had worsened, improved, remained stable or if they had never had pain, compared with the year before. Patients were included in the current analysis when change in AUSCAN pain and the anchor question were available for at least one year. Change in pain measured with AUSCAN was categorized according to the minimal clinical important difference (MCID) of 1.49 between the yearly visits. Changes between annual visits on AUSCAN and the anchor questions were described and Cohen's kappa was calculated for each category (increase, stable and decrease). Annual results were comparable between years, and so the years were pooled.

Results: In 307 patients, the mean age was 61.0 (SD 8.2), with 82% women and a mean BMI of 27.3 (SD 4.8). The baseline AUSCAN pain was 9.1 (SD 4.2). Over 4 years, 708 annual intervals with both change in AUSCAN and anchor questions were available. Of the 309 patients, 95 provided one interval, 74 provided two intervals, 87 provided three and 51 provided four. Results are described in Table 1. In 203 intervals 172 patients reported an increase in AUSCAN pain (of which in 151

intervals patients (74%) indicated their pain had worsened on anchor questions), in 293 intervals 199 patients reported a stable level of pain (of which in 96 intervals (33%) indicated their pain had not changed) and in 212 intervals 176 patients reported a decrease in pain (of which 39 (19%) indicated their pain had improved) (Table 1). The most frequent answer was a worsening of pain, regardless of AUSCAN change. In total, in 286 out of 704 (40%) of the intervals, the anchor question was in accordance with the AUSCAN pain, with a Cohen's kappa of 0.12.

Conclusion: There are large differences between changes in AUSCAN pain and experienced changes in pain when reported by the patient. The patient experiences worsened pain more often than is reflected in the AUSCAN pain. Although recall bias may play a role in the answers to the anchor questions, they are close to the real-world clinical practice, in which patients are often asked how the symptoms compare to last visit. This indicates a difference between change in pain perceived in the clinical setting and in research setting, which should be addressed in order to improve research on pain development.

Table 1. ***Change in AUSCAN pain vs anchor questions.*** **Data presented as number (%), with the % calculated over the vertical columns. Change in AUSCAN pain horizontally, anchor questions vertically. The number and % of concordant answers in bold.**

		Change in AUSCAN pain			
		Worsening	Stable	Improvement	Total
Anchor question	Worse – more pain	**151 (74)**	173 (59)	98 (46)	422 (60)
	No change	41 (20)	**96 (33)**	74 (35)	211 (30)
	Better – less pain	11 (5)	20 (7)	**39 (19)**	70 (10)
	Never had this symptom	0 (0)	4 (1)	1 (0)	5 (1)
	Total	203 (100)	293 (100)	212 (100)	708 (100)

Background: Knee Osteoarthritis (KOA) is one of the most frequent causes of pain and disability, representing a relevant clinical burden. Although it was largely considered a mostly mechanical-based pathology, low-grade synovial inflammation was found to contribute to radiographic progression and pain chronicity [1].

Objectives: To evaluate the histological characteristics of synovial membrane inflammation in KOA patients compared to chronic inflammatory diseases as Rheumatoid (RA) and Psoriatic Arthritis (PsA) across disease phases.

Methods: 170 patients with KOA, 240 patients with RA, 92 patients with PsA naive to pharmacological treatments and 200 patients with RA in sustained clinical and ultrasound remission (RA-r) underwent ultrasound-guided synovial biopsy of the knee and conventional X-rays. None of enrolled KOA patient had evidence of inflammatory condition (including chronic inflammatory diseases and crystal related arthritis). Synovial membrane samples were processed for histology (hematoxylin-eosin staining) for the semiquantitative assessment of synovitis degree (Krenn synovitis score [2] - KSS). Moreover, this analysis was implemented with the semiqualitative assessment of presence/absence of synovial lymphocytes, plasmacells, myxoid degeneration and inflammatory perivascular aggregates. X-rays were scored for Kellgren-Lawrence score [3] (KLs) assessment.

Results: RA and PsA patients naive to pharmacological treatment showed higher degree of synovial inflammation than patients with KOA as well as more likely presence of lymphocytes and plasmacells aggregates. Considering the whole KOA population, total KSS directly correlated with age (R^2=0.041; p=0.008), thickness of synovial membrane (R^2=0.115; p<0.001) and Power Doppler score (R^2=0.142; p<0.001) at ultrasound evaluation, VAS pain (R^2=0.025; p=0.039) and KLs (R^2=0.54; p<0.0001). Stratifying KOA patients based on age categories, KOA patients aged ≥70 years had higher KSS (mean ±SEM, 2.46 ±0.179) and KLs (2.14 ±0.17) than younger KOA patients (KSS 1.98 ±0.113, p=0.0182 and KLs 1.25 ±0.101, p<0.001). To distinguish residual inflammation from osteoarthritis-related synovitis, we compared KOA-derived synovial tissues with the ones of RA-r patients, showing that the degree of KOA-related synovitis is significantly higher (mean ±SEM, 2.10 ±0.09) than the subclinical residual synovitis detected in RA-r patients (1.77 ±0.08, p=0.0103).

Conclusion: KOA-related synovitis represents an unmet clinical need due to still uncovered pathogenetic mechanisms. The severity of KOA-related synovitis impacts on bone structural damage and is related to age, supporting the role of inflammageing in KOA pathogenesis.

POS1354 REGRESSION TO THE MEAN FOR PAIN OUTCOMES IN CLINICAL TRIALS FOR KNEE OSTEOARTHRITIS

Keywords: Epidemiology, Osteoarthritis, Pain

M. Englund[1], A. Turkiewicz[1]. [1]*Lund University, Clinical Sciences Lund, Lund, Sweden*

Background: Improvements in pain in clinical trials for osteoarthritis (OA) are largely contextual.(1) Given known fluctuations of osteoarthritic pain, a substantial proportion of contextual response could be explained by the regression-to-the-mean (RTM) phenomenon.

Objectives: To estimate the size of RTM for a typical OA trial with pain as outcome.

Methods: We included participants of Osteoarthritis Initiative who fulfilled inclusion criteria typically required for enrolment in a clinical trial. These included: age 40-79 years, symptomatic knee OA, Kellgren-Lawrence grade 2-3, use of pain medication more than half the days of a month in past 12 months, numerical rating scale (NRS) pain of 4 to 9 in the target knee. We studied observed changes in the mean levels of pain with respect to conditioning on current knee pain.

Results: We identified 459 subjects who fulfilled inclusion criteria on at least one annual follow-up between year 1 and year 8. In these subjects, the mean NRS pain level at each follow-up time point was similar, ~4.6, but at the time of fulfilling the inclusion criteria, the mean level of pain in the same subjects was 6.2 (Figure 1). The difference in NRS pain between the theoretical point of inclusion in a trial and one year after was -0.8 (95% confidence interval -0.6, -0.9).

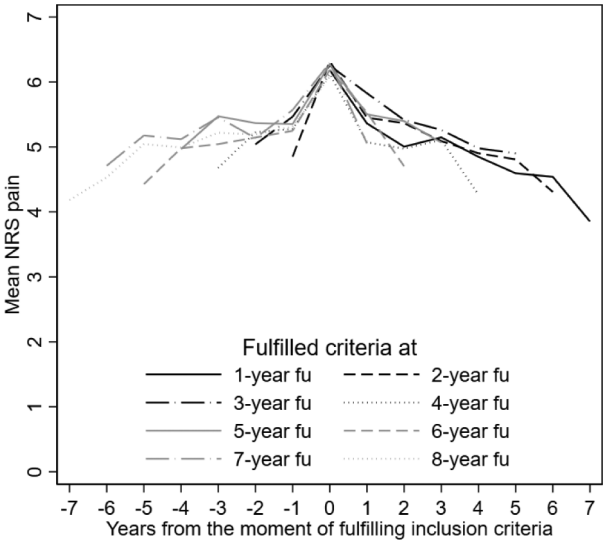

Figure 1. Mean levels of pain among 459 persons fulfilling criteria for inclusion in a hypothetical knee osteoarthritis trial. Time 0 means the moment when fulfilling the criteria. Each line represents a cohort of subjects fulfilling criteria at one follow-up occasion (between year 1 and year 8 post baseline). Each person can be included multiple times.

Conclusion: RTM in a typical osteoarthritis trial is likely to explain as much as about 0.8 NRS point improvement on a 0 to 10-point scale. RTM is a powerful phenomenon that may mislead interpretation of effectiveness as it neither represents improvement from the intervention nor placebo response.

POS1355 COMBINED ASSESSMENT OF CARTILAGE AND SUBCHONDRAL BONE IN OSTEOARTHRITIC AND NON-OSTEOARTHRITIC KNEE COMPARTMENTS: A ULTRA-HIGH FIELD MRI STUDY

Keywords: Imaging

A. Bourara[1], M. A. Hostin[2,3], E. Soldati[2,4,5], F. Suzanne[2,6], J. P. Mattei[1,2], W. Theo[1], M. Guye[2], C. Chagnaud[2,7], D. Bendahan[2], S. Guis[1,8,9]. Background: Knee osteoarthritis (OA) is one of the most common degenerative diseases causing disability in elderly people. Although X-ray radiography is widely used as a diagnostic tool, several limitations have been identified *[1]*. MRI is a non-invasive imaging method widely used in order to assess articular and periarticular structures of the knee joint *[2]*. However, the image resolution provided by conventional MRI is not high enough to assess subchondral bone so that ultra-high field MRI (7 Tesla) has been proposed as an alternative of interest to compute bone microarchitectural parameters *[3]*.

Objectives: We used ultra-high field MRI (UHF 7 Tesla MRI) to assess cartilage and subchondral bone microarchitecture in patients with mild and severe OA. For each patient, compartments classified as osteoarthritic were compared with non-osteoarthritic compartments.

Methods: Twenty-four patients were divided into 3 groups according to the Kellgren Lawrence staging and 12 volunteers were recruited as controls. UHF MRI was used to calculate cartilage thickness (Tc), volume (Vc), and T2*. MRI sequences used were T1 3D gradient recalled echo sequence (T1 3D GRE) and sagittal T2* mapping. Bone microarchitecture was assessed on the basis of trabecular thickness (TbTh), trabecular number (TbN), trabecular space (TbSp), and bone volume fraction (BVF).

Results: For the medial tibial plateau, while Tc was unchanged between the two OA groups, Vc was decreased in patients with severe OA (Δ= -49%, $p < 0.05$). For the patella, Vc was decreased in patients with mild OA (Δ = -36%, $p<0.05$), while Tc was unchanged. Similar results were found for the lateral femoral condyle. The study of T2* cartilage relaxation (T2* mapping) revealed no statistically significant changes in all knee joint compartments. Computed TbSp in the lateral tibial plateau and patella was significantly higher in the mild OA group (Δlateral tibial plateau = +25%; Δpatella = +31.5, $p<0.05$), whereas most subchondral bone parameters were unchanged. Medial femoral condyle cartilage volume was significantly correlated with patellar cartilage thickness r=0.46 ($p = 0.01$). Medial tibial plateau cartilage thickness and patellar cartilage thickness were linearly related r = 0.587 ($p < 0.05$). Medial tibial plateau cartilage volume was significantly correlated with patella TbTh, r = 0.41 ($p = 0.02$)

Conclusion: Cartilage volume seems to be more sensitive than thickness for the assessment of cartilage changes in OA. TbSp would be a sensitive marker of subchondral bone degradation. Cartilage degradation in a given OA compartment would be accompanied by changes in subchondral bone and cartilage in the opposite healthy compartments. UHF MRI can provide interesting information for the analysis of cartilage and subchondral bone and could be considered as a tool of interest for the subtle evaluation of changes associated to therapeutic strategies.#8232;#8232;

POS1356 ASSESSMENT OF THE EFFICACY OF COMBINATION OF ORAL ACETAMINOPHEN AND TOPICAL DICLOFENAC IN OSTEOARTHRITIS PAIN: INSIGHTS FROM A MODEL-BASED META-ANALYSIS

Keywords: Osteoarthritis, Pain

V. Sood[1], L. Qin[2], E. Cox[2], I. Trocóniz[3], O. Della Pasqua[4,5]. [1]*Haleon (formerly GlaxoSmithKline Consumer Healthcare), Medical Affairs, Singapore, Singapore*; [2]*Certara, Modeling & Simulation, Princeton, United States of America*; [3]*University of Navarra, School of Pharmacy and Nutrition, Pamplona, Spain*; [4]*GlaxoSmithKline, Clinical Pharmacology Modelling and Simulation, Brentford, United Kingdom*; [5]*University College London, Clinical Pharmacology & Therapeutics Group, London, United Kingdom*

Background: Osteoarthritis (OA) is a major cause of chronic pain and disability in older adults and currently affects approximately 300 million people worldwide [1]. In the absence of curative therapy, symptomatic drugs comprise the backbone of pain management in OA. However, acetaminophen provides inadequate relief and oral non-steroidal anti-inflammatory drugs (NSAIDs) exhibit significant gastrointestinal and cardiovascular toxicity which prohibit their long-term use in the elderly [2,3]. Although opioids can be an effective alternative in patients experiencing insufficient pain relief with other analgesics, concerns have been raised about the risk of side effects, addiction, and overdose deaths [4]. Therefore, there is a significant unmet need for effective and well-tolerated treatments. Acetaminophen and topical diclofenac exhibit complementary mechanisms of action targeting pain and inflammation, respectively, and are therefore attractive candidates for use in combination analgesia in OA pain [5,6,7]. Although ample clinical evidence exists on the monotherapy of acetaminophen or topical diclofenac in OA, there is a data gap for evidence on their combination.

Objectives: The present study aims to assess the effect of the combination of acetaminophen and topical diclofenac in OA and compare its performance to acetaminophen and diclofenac monotherapy using a model-based meta-analysis (MBMA) leveraging published summary-level data on the combination from OA as well as other acute pain indications [8].

Methods: Randomized controlled trials (RCTs) investigating the combination of acetaminophen and diclofenac in OA and acute pain settings were identified through systematic literature searches. MBMA was implemented to infer the efficacy of the combination in the population of interest. Pain score reduction on numerical rating scale (NRS), visual analogue scale (VAS) and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale along with opioid sparing effect (defined as reduced opioid dose without loss of analgesic efficacy) were selected as the clinical endpoints.

Results: In the absence of RCTs on the combination in OA, MBMA was implemented in conjunction with extrapolation principles on trials in acute pain setting (11 RCTs, n=1396 patients). The combination demonstrated greater reduction in pain scores versus acetaminophen monotherapy in 8 of the 11 RCTs. Moreover, a parsimonious MBMA was developed on 5 RCTs allowing PCA, which revealed a statistically significant 32% lesser opioid use with the combination than with acetaminophen monotherapy (Figure 1). However, the combination effect was less conclusive versus diclofenac monotherapy.

Conclusion: The current analysis demonstrates greater pain reduction and opioid sparing efficacy for the combination versus acetaminophen monotherapy in the treatment of acute pain. Considering the overlap in pain transmission pathways between acute and chronic OA pain, the combination may be anticipated to exhibit similar performance on extrapolation to chronic OA pain. Overall, our research tries to bridge the gap in pharmacological and clinical evidence supporting the use of combination of acetaminophen and topical diclofenac in mild-to-moderate OA pain.

BURDEN OF OSTEOARTHRITIS IN CHINA FROM 1990 TO 2019 AND PREDICTIONS OF THE BURDEN IN FUTURE 25 YEARS: FINDINGS FROM THE GLOBAL BURDEN OF DISEASE STUDY 2019

Keywords: Osteoarthritis, Epidemiology

H. Chen[1], Z. Zhou[2], X. Fang[1], D. Hunter[1,3,4], C. Ding[1,5,6,7], Z. Zhu[1]. *[1]Zhujiang Hospital of Southern Medical University, Clinical Research Centre, Orthopedic Centre, Guang Zhou, China*; *[2]Zhujiang Hospital of Southern Medical University, The Second Clinical Medical School, Guang Zhou, China*; *[3]Royal North Shore Hospital, University of Sydney, Department of Rheumatology, Sydney, Australia*; *[4]Kolling Institute, University of Sydney, Sydney Musculoskeletal Health, Sydney, Australia*; *[5]Guangzhou First People's Hospital, Department of Rheumatology, Guang Zhou, China*; *[6]Affiliated Hospital of Youjiang Medical University for Nationalities, Department of Orthopaedics, Bai Se, China*; *[7]University of Tasmania, Menzies Institute for Medical Research, Hobart, Australia*

Background: China has the world's largest population and a high prevalence of osteoarthritis (OA), accompanying by a rapidly ageing and increasingly obese population [1-2]. However, the disease burden and secular trend of OA in China have not been well described nor predicted.
Objectives: To describe and predict the epidemiological features and secular trends attributable to OA in China from 1990 to 2044 in a comprehensive manner.
Methods: Data from the Global Burden of Disease (GBD) Study 2019 were used to estimate the incidence, prevalence, disability-adjusted life years (DALYs) and the related age-standardized rates (ASRs) of OA, as well as the burden of OA due to a high body mass index (BMI). The estimated annual percentage change (EAPC) in the ASRs was used to describe the temporal trend of OA changes and the Norpred age-period-cohort (APC) model was used to predict the disease burden over the next 25 years.
Results: The prevalence of OA in China increased from 51.76 (45.95-58.26) million in 1990 to 132.81 (118.00-149.08) million in 2019. The ASR of OA incidence increased from 472.53/100,000 in 1990 to 509.84/100,000 in 2019, with an EAPC of 0.36 (0.29-0.44); the ASR of OA prevalence increased from 5880.58/100,000 in 1990 to 6330.06/100,000 in 2019, with an EAPC of 0.35 (0.28-0.42), and the ASR of OA DALYs increased from 206.38/100,000 in 1990 to 224.78/100,000 in 2019, with an EAPC of 0.40 (0.32-0.48). The ASR of OA DALYs associated with high BMI increased rapidly from 1990 to 2019, especially in male and hip OA (Table 1). The projections suggested that there will be an increasing trend in the incidence (male 27.92%; female 15.51%), prevalence (male 71.08%; female 50.30%) and DALYs (male 71.93%; female 50.02%) of OA from 2020 to 2044, and the prevalence and DALYs of OA in China would increase by approximately 1.5 times in future 25 years. (Figure 1).
Conclusion: The disease burden of OA has increased in China in the past 30 years and will continue to rise over the next 25 years. Therefore, prevention and early intervention are pivotal to mitigating the growing burden of OA.

POS1359 SURGICAL DENERVATION TO TREAT PAIN IN HAND OSTEOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

Keywords: Systematic review, Osteoarthritis, Pain

C. Van der Meulen[1], L. Van de Stadt[2], A. Claassen[3], F. Kroon[4], M. Ritt[5], F. Rosendaal[6], S. Terpstra[1], A. Vochteloo[7], M. Kloppenburg[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Reade, Rheumatology, Amsterdam, Netherlands*; [3]*Dutch Society for Rheumatology, N/A, Utrecht, Netherlands*; [4]*Zuyderland Medical Center, Rheumatology, Heerlen, Netherlands*; [5]*Amsterdam UMC, Plastic, Reconstructive and Hand Surgery, Amsterdam, Netherlands*; [6]*Leiden University Medical Center (LUMC), Clinical epidemiology, Leiden, Netherlands*; [7]*OCON Orthopedic Clinic, Orthopedic Surgery, Hengelo, Netherlands*

Background: Surgical denervation has been proposed as a treatment for pain in hand osteoarthritis (OA).
Objectives: We performed a systematic literature review to summarize the available evidence and propose a research agenda.
Methods: A systematic literature search was performed up to September 2022. Two investigators identified studies that reported on denervation for OA of the proximal interphalangeal joint (PIPJ), distal interphalangeal joint (DIPJ), metacarpophalangeal joint (MCPJ) or first carpometacarpal joint (CMCJ). Reviews, comments, letters or editorials, studies in languages other than English and studies investigating other interventions, joints or conditions were excluded. Quality of studies was assessed with the Joanna Briggs Institute checklist for case series and the Risk of Bias in Non-randomized Studies of Interventions (ROBINS-I), where applicable. Study characteristics, patient characteristics, details of the surgical technique and outcomes of the surgery were extracted. Due to the nature of the data, no meta-analysis was performed. Data from the studies were pooled and minimal and maximal scores were estimated.
Results: The search yielded 212 articles from the Pubmed, OVID and Cochrane databases. From these, 17 articles (reporting on 384 denervation surgeries in 351 patients) were selected. Twelve studies described CMCJ denervation, three described PIPJ denervation, and the others described DIPJ (n=1), MCPJ (n=1) or a mixture of MPCJ, PIPJ and DIPJ denervation (n=1). The surgical techniques varied greatly, both in incisions and in the nerves severed, even between studies investigating denervation of the same joint. The innervation of the joints in the hand is still subject to debate. Most of the studies were case series (n=16), and one was a non-randomized clinical trial. Sample size ranged from 3 to 60 participants. All studies had significant risk of bias. The studies consisted of patient groups with average age ranging from 55 to 65 and 60-75% female participants. The sixteen case series reported positive outcomes with respect to pain, function and patient satisfaction. Average pain decrease ranged from 3 to 8.1 on a 10-point numeric rating scale (NRS) (n=8 studies), with a 56-92% patient satisfaction rate (n=5) and mean increase in range of motion of 3.5-27 degrees (n=3). The non-randomized clinical trial reported no differences in outcome when comparing denervation to trapeziectomy. Adverse event rates ranged from 0-75% of denervation procedures. Sensory abnormalities occurred most, followed by the need for revision surgery and infections of the area of the surgery.
Conclusion: Surgical denervation for pain in hand OA shows promise, but the available evidence does not allow conclusions, as for example regression to the mean can strongly influence the observations in case series. More and higher quality evidence is needed before it can be recommended as part of standard care. On the research agenda are 1) the innervation of the joints, 2) the best surgical technique to sever all relevant nerves, and 3) perform high-quality randomized clinical trials to investigate the efficacy of surgical denervation in comparison to sham, 4) to investigate other interventions targeted at the innervating nerves, and finally 5) the safety of the different surgical denervation techniques.

POS1360 PATIENTS ARE ALWAYS RIGHT! ASSOCIATION BETWEEN HUMIDITY LEVEL AND PAIN EXPERIENCE IN HAND OSTEOARTHRITIS

Keywords: Pain, Osteoarthritis

M. Pezot[1], R. Lacoste Badie[2], S. Tuffet[2], A. Rousseau[2], P. Richette[3], B. Fautrel[4], F. Berenbaum[1], A. Courties[1], J. Sellam[1]. Background: While many patients with joint disease report pain changes according to meteorological factors (1), this common belief has not been clearly demonstrated and never been documented in hand osteoarthritis (HOA).
Objectives: We aimed to investigate the cross-sectional association between meteorological factors that are ambient temperature and humidity on HOA symptoms.
Methods: We used the baseline data from the prospective DIGICOD HOA cohort including patients with established symptomatic HOA. The clinical outcomes were AUSCAN-pain, AUSCAN-stiffness and AUSCAN-function subscores, VAS-scale for pain during activity, number of spontaneous tender joints and tender joints at palpation. Meteorological data (from Météo France), ambient temperature and humidity, are defined as the mean value observed during the 3 days before inclusion (day of inclusion, D-1 and D-2). Considering non-normal distribution, each outcome was binarized by the median value, in order to define high and low symptoms intensity. Association between each outcome and meteorological data were studied using two logistic regression models (separate models for temperature and humidity), adjusted for age, sex, sum of Kellgren-Lawrence score of all hand joints and Hospital Anxiety Depression scale. Assumption of linearity between temperature or humidity and the logit of the outcomes being not verified, those two parameters were introduced in the models as categorical variables according to quartiles. Results are presented as odds ratio (OR) with 95% confidence intervals (CIs). The reference groups were respectively lower humidity and lower temperature quartile.
Results: We have studied 377 patients in whom all variables of interest were available (mean age ± standard deviation (SD) 66.5 ± 7.4 years, 85% women). Median AUSCAN-pain subscore was 20/100 (IQR [8; 38]), median AUSCAN-stiffness subscore was 22/100 (IQR [7; 53]), median AUSCAN-function subscore was 32/100 (IQR [13; 55]), median VAS-pain during activity was 42/100 (IQR [22; 66]), median number of spontaneous tender joints was 0/30 (IQR [0; 2]), median

number of tender joints at palpation was 3/30 (IQR [2; 6]). Results of models for humidity are presented in Table 1. There was an association between humidity percentage and AUSCAN pain ≥ 20 for third quartile vs. first quartile (OR [79-85%] vs. [43-68%] = 1.99 (1.08 to 3.68), p = 0.03) and between humidity and VAS pain during activity ≥ 42 for second quartile vs. first quartile (OR [68-79%] vs. [43-68%] = 1.97 (1.06 to 3.63) p = 0.03). Considering patients with at least 1 spontaneous hand joint pain, an association was found for all 3 higher quartiles of humidity ([68-79%], [79-85%] and [85-96%]) compared to the lower one ([43-68%]), but without dose-effect. There was no effect of humidity on AUSCAN stiffness or function, or number of tender joints at palpation. Temperature was not associated with any clinical outcomes (pain, function or stiffness).

Conclusion: This is the first study about impact of meteorological factors in HOA. While we did not find any association between temperature and symptoms, we found an association between humidity and pain. Although we cannot conclude on any causality between humidity and pain, our results support patient's belief about influence of humidity on joint pain.

POS1361 THE INFLUENCE OF BASELINE DEMOGRAPHICS ON VARIABILITY OF OA PAIN ASSESSED BY WOMAC PAIN CHANGE FROM BASELINE IN INTERVENTIONAL TRIALS

Keywords: Biomarkers, Osteoarthritis, Randomized control trial

A. R. Bihlet[1], P. Alexandersen[2], J. R. Andersen3, Y. Li3, M. Karsdal3, C. P. Miller[4]. [1]*Nordic Bioscience, Clinical Development, Søborg, Denmark*; [2]*Sanos Clinic Syddanmark, Clinical, Vejle, Denmark*; [1]*Nordic Bioscience, Clinical Development, Søborg, Denmark*; [4]*Nordic Bioscience, Clinical Development, 2860, Denmark*

Background: Development of new products for OA treatment is difficult, partly due to excessive placebo response and high variability in patient-reported pain outcomes, and exclusion of trial subjects with potentially confounding pain from non-target joints may increase the effect size. This may in part be due to reductions in variability, and hence in standard deviation (SD) of the mean changes in pain scores, which improves the statistical power to detect differences between study groups. The impact of refining the study population in terms of added benefit to the SD and statistical power vs. added screen failures is poorly described.

Objectives: To investigate the impact of common demographic and pain characteristics on the SD of mean pain change from baseline in a large interventional OA trial database.

Methods: Data from 2 randomized controlled trials of oral salmon calcitonin in OA (1) were analyzed post-hoc. The SD of the mean change from baseline (SD-CFB) to Year 2 in the WOMAC knee pain score (0-100) was calculated. The SD-CFB was also calculated for subgroups (e.g. demographics, pain of the target and non-target knee). The sample size required to identify a statistically significant difference of at least 8 out of 100 between groups (with 80% power) was calculated, and the additional proportion of eligible subjects to be screen-failed if the particular subgroup was excluded was calculated to quantify the potential impact on the study feasibility.

Results: A total of 1,487 subjects had WOMAC pain data throughout the trial period. Results are shown in Table 1. Few clinical characteristics influenced the SD and hence the required sample size, except for Asian race, associated with a lower SD compared to Caucasians (19.71 vs. 21.85), to detect a significant difference. Exclusion of those with high BMI (≥ 35 kg/m^2) led to a reduced sample size required of 113. Subjects with non-target knee pain above the median had higher pain variability and thus a larger sample sizes required to detect differences vs. those with pain scores below the median. However, exclusion of these groups required screen failing approx. extra 50 % of the eligible population to achieve this. A less exclusive method was excluding subjects with non-target knee pain not exceeding that of the target knee. Radiographic characteristics did not influence the SD, except for those with a KL grade 3 or 4 of the non-target knee (Table 1). This observation requires further scrutiny.

Table 1.

	SD of mean WOMAC pain change	n	Sample size per group to detect mean WOMAC pain difference of 8 out of 100 (n)	Proportion of eligible subjects screen failed if subgroup was excluded (%)
All study completers	21.58	1,487	115	0
Male	21.12	516	110	34.7
Female	21.82	971	117	65.3
Age < 64 yrs	21.49	799	114	53.7
Age ≥ 64 yrs	21.68	688	116	46.3
BMI < 35 kg/m^2	21.45	1,316	113	88.5
BMI ≥ 35 kg/m^2	22.53	171	125	11.5
Subgroups by **Non-Target knee characteristics** at Baseline				
KL grade 0	20.79	60	107	4.0
KL grade I	21.19	271	111	18.2
KL grade II	20.83	766	107	51.5
KL grade III	23.80	346	139	23.3
KL grade IV	17.55	42	76	2.8
WOMAC Pain ≤ 35 (0-100)	20.08	731	99	49.2
WOMAC Pain > 35 (0-100)	22.96	722	130	48.6
Low VAS (0-100, ≤ 37)	19.39	714	93	48.0
High VAS (0-100, > 37)	23.54	722	136	48.6
Nontarget knee WOMAC pain ≥ Target knee WOMAC pain	22.64	408	126	27.4
Nontarget knee WOMAC pain < Target knee WOMAC pain	20.84	1,024	107	68.9

Conclusion: High BMI and high baseline pain of the non-target knee may contribute negatively to the study power, however, the added study cost in terms of additional screened subjects required to replace those excluded based on these parameters should be carefully evaluated. The potential impact of these parameters on the magnitude of the difference between study groups was not evaluated and may also differ, with additional statistical implications.

POS1362 THE OA TRIAL BANK: UPDATE OF INDIVIDUAL PATIENT DATA META-ANALYSIS OF INTRA-ARTICULAR GLUCOCORTICOIDS IN PERSONS WITH KNEE AND HIP OSTEOARTHRITIS

Keywords: Osteoarthritis

S. Yu[1,2], M. Van Middelkoop[3], M. Ferreira[4], L. Deveza[1,2], S. M. A. Bierma-Zeinstra[3], V. Venkatesha[5], D. Hunter[1,2]. [1]*Royal North Shore Hospital,*

Rheumatology, St Leonards, Australia; [2]*Sydney Musculoskeletal Health, Kolling Institute, University of Sydney, School of Medicine, Faculty of Medicine and Health, St Leonards, Australia*; [3]*Erasmus MC, Department of General Practice, Rotterdam, Netherlands*; [4]*Sydney Musculoskeletal Health, Kolling Institute, University of Sydney, School of Health Sciences, Faculty of Medicine and Health, St Leonards, Australia*; [5]*Royal North Shore Hospital, Northern Sydney Local Health District, St Leonards, Australia*

Background: Intra-articular (IA) glucocorticoid injections are often employed in the management of osteoarthritis (OA) patients, but in whom to best target treatment is unclear. OA clinical guidelines have advocated for the identification of predictors of response to different treatments, but no reliable subgroups with treatment effect have been found.

Objectives: This study aims to conduct an individual patient data (IPD) meta-analysis to evaluate the efficacy of IA glucocorticoid for knee or hip OA in specific subgroups of patients according to the baseline pain severity and inflammatory signs. This is an update on an IPD meta-analysis on IA glucocorticoid by the OA Trial Bank [1].

Methods: Randomised trials evaluating one or more IA glucocorticoid preparations in hip and knee OA, published from 2012 to May 2018, were selected from the literature. IPD of participant and disease characteristics and outcome measures were acquired. The primary outcome was pain severity at short-term follow-up (around 4 weeks). A two-stage IPD analysis was performed. Potential interaction effect of baseline severe pain (≥70 points, 0-100 scale) and signs of inflammation were studied using linear mixed-effects models. Analysis of trend was conducted, assessing if a baseline pain cut-off was associated with the threshold for clinically important treatment effect of IA glucocorticoid compared to placebo.

Results: Four out of 16 eligible randomised clinical trials (n=641) were combined with the existing OA Trial Bank studies (n=620), yielding n=1261 from eleven studies. Participants with severe baseline pain compared to those with less severe pain had greater pain reduction at mid-term (around 12 weeks) (mean reduction: -6.90 (95%CI -10.91; -2.90)), but not at short- or long-term follow-up. No interaction effects were found between inflammatory signs and IA glucocorticoid injections compared to placebo at all follow-up time-points (Table 1). Analysis of trend showed treatment response to IA glucocorticoid injections from baseline pain levels >50 (0-100 scale) and above (Figure 1).

Conclusion: This IPD meta-analysis demonstrated that in participants with severe baseline pain, clinically relevant response is seen at mid-term follow-up, suggesting that sustained response to IA glucocorticoid injection may be seen in a subgroup of OA participants. As baseline pain score increases, treatment response is seen in participants from moderate pain levels onwards. No concrete conclusions can be made on baseline inflammatory signs. Ongoing IPD studies with an increased number of studies are required.

CIRCULATING GALECTIN-1 LEVELS IN INDIVIDUALS WITH KNEE AND/OR HAND OSTEOARTHRITIS – A HALLOA STUDY

Keywords: Biomarkers, Osteoarthritis

M. Andersson[1,2,3], M. Zimmerman[4,5], E. Brogren[5,6], S. Bergman[7,8], E. Fryk[9], L. Strinberg[9], P. A. Jansson[9]. [1]*Spenshult Reserach and Development Center,., Halmstad, Sweden*; [2]*Halmstad University, Department of Environmental and Biosciences School of Business, Innovation and Sustainability, Halmstad, Sweden*; [3]*Lund University, Department of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; [4]*Helsingborg Hospital, Department of Orthopaedics, Helsingborg, Sweden*; [5]*Lund University, Department of Translational Medicine - Hand Surgery, Lund, Sweden*; [6]*Skane University Hospital, Department of Hand Surgery, Malmö, Sweden*; [1]*Spenshult Reserach and Development Center,., Halmstad, Sweden*; [8]*University of Gothenburg, The Sahlgrenska Academy, Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Gothenburg, Sweden*; [9]*University of Gothenburg,The Sahlgrenska Academy, SU Sahlgrenska, Department of Molecular and Clinical Medicine, Institute of Medicine, Gothenburg, Sweden*

Background: Circulating galectin-1 levels are associated with metabolic diseases including obesity, diabetes type II, and subclinical inflammation [1]. These medical conditions are often seen as comorbidities of osteoarthritis (OA) in the knees and hands.

Objectives: The aim was to study longitudinal associations between circulating galectin-1 levels and radiographic knee OA (RKOA), radiographic hand OA (RHOA), and general OA (GOA, RKOA and RHOA).

Methods: This longitudinal study included 232 individuals from the Halland osteoarthritis cohort (HALLOA) (2) with knee radiographs at inclusion and at a two-year follow-up. Of the included individuals, 211 had hand radiographs at the two-year follow-up. Body mass index (BMI), and waist circumference (WC) were measured. Visceral fat area (VFA) was assessed by bioimpedance (InBody 770). Serum/plasma levels of HbA1c, glucose, and C-reactive protein (CRP)≥1.0 mg/L were measured according to the current laboratory standards in Sweden. CRP below 1.0 mg/L, was further analysed with a sensitive CRP ELISA method (Abnova). Insulin resistance was assessed by the triglyceride glucose index (TyG). Galectin-1, IL-1 beta, IL-6, and TNF alfa using Quantikine, ELISA (biotechne, United Kingdom). RKOA was defined according to Ahlbäck, as grade 1 or more in at least one knee at two years follow-up; RHOA was defined according

to Kellgren and Lawrence as grade 2 or more in at least one joint at two years follow-up. GOA was defined as having RKOA and RHOA. Comparisons between groups at inclusion were performed using Mann-Whitney U test, chi-2, and univariate Logistic regression models for associations.

Results: At the two-year follow-up, 34% of the included individuals had RKOA, 42% had RHOA, and 50 individuals had GOA. Individuals with RKOA were older, more obese, and had higher median serum levels of HbA1c, CRP, and IL-6, but no increased serum level of galectin-1, Table 1. Age (OR 1.12; 95% CI 1.06-1.17) obesity (WC OR 1.04; 95% CI 1.01-1.06) and galectin-1 (OR 1.04; 95% CI 1.003-1.08) were associated with RKOA. Those with RHOA were older and had increased serum levels of HbA1c, galectin-1, TyG index, and IL-6, Table 1. Age (OR 1.21; 95% CI 1.14-1.28), HbA1c (OR 1.11; 95% CI 1.01-1.21), and galectin-1 (OR 1.05; 95% CI 1.01-1.10) were associated with RHOA. Individuals with GOA were older, more obese, had more inflammation, and increased levels of HbA1c and galectin-1, table 1. Age (OR 1.30; 95% CI 1.18-1.45) and galectin-1 (OR 1.06; 95% CI 1.01-1.12) were associated with GOA.

Conclusion: Circulating galectin-1 seems to associate with OA, especially RHOA. More studies are needed to assess a potential underlying pathophysiological mechanism of galectin-1 in OA.

A COMPARISON OF SEMI-QUANTITATIVE AND QUANTITATIVE CARTILAGE LOSS ASSESSMENTS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

Keywords: Cartilage, Imaging, Osteoarthritis

A. Ray[1], B. Dube[2], M. A. Bowes[3], A. Brett[4], E. Rowbotham[5], P. G. Conaghan[2].

[1]York, York and Scarborough Teaching Hospitals: NHS Foundation Trust, York, United Kingdom; *[2]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[3]Stryker, Imorphics, Manchester, United Kingdom*; *[4]Stryker, Imorphics, Austin, United States of America*; *[5]University of Leeds, Leeds Musculoskeletal Biomedical Research Centre, Leeds, United Kingdom*

Background: In Disease Modifying Osteoarthritis Drug (DMOAD) trials, cartilage loss may be assessed semi-quantitatively or quantitatively, although the latter is higher cost and more technically challenging. The MRI Osteoarthritis Knee Score (MOAKS) is the most commonly used semi-quantitative knee OA scoring system that assesses thickness of MOAKS cartilage morphology loss (tMCM) and denudation (dMCM) on the articulating subregions of femur and tibia.

Objectives: This study aimed to compare the cross-sectional relationship and longitudinal responsiveness of MOAKS with the more accurate quantitative cartilage assessment.

Methods: Images and MOAKS scores from 297 participants with radiographic progression (groups 1 and 2) from the OAI FNIH sub-cohort were included. Quantitative cartilage thickness was measured using Active Appearance Models (AAMs). To facilitate direct comparison with MOAKS, novel quantitative measures of cartilage loss were matched to MOAKS regions (Q-MOAKS). Mean normative cartilage thickness was computed for each subregion (Figure 1) using FNIH controls (group 4). Q-MOAKS thickness loss score (tQCM) was based on the proportion of cartilage thickness over a subregion that was <95% normative thickness and denudation score (dQCM) was based on <5% normative thickness. Q-MOAKS area proportions were categorised into scores as for MOAKS (0: none, 1: 0-10%, 2: 10-75% and 3: >75%). Quantitative cartilage thickness (ThCtAB) was also measured in the central medial femur (cMF) and tibia (cMT). We compared MOAKS against Q-MOAKS and ThCtAB. Cross-sectional relationships between measures were assessed using Spearman's rank correlation. Responsiveness was assessed at 1 and 2 years using bootstrapped standardised response means (SRM).

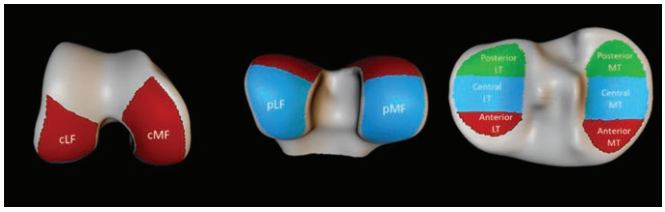

Figure 1: Cartilage regions definitions consisting of the medial and lateral central and posterior femur (cMF, cLF, pMF, pLF) subregions and the medial and lateral tibial anterior, central, posterior (aMT, cMT, pMT, aLT, cLT, pLT) subregions.

Results: Cross-sectionally, there was moderate correlation between MOAKS and Q-MOAKS denudation in the central medial femur (cMF r = 0.42, (95%CI: 0.32, 0.51)) and tibia (cMT r = 0.51, (0.42, 0.59)). There was a poor correlation between MOAKS and Q-MOAKS thickness loss and denudation scores in all other regions. In the tibia (cMT), 61% (96/159) of knees with thickness loss tMCM = 2 (the 10-75% score) were also tQMC = 2 and 66% of denudation dMCM = 2 were also dQCM = 2. In the femur (cMF), the figures were 56% and 23%. MOAKS tMCM and dMCM were less responsive than Q-MOAKS tQCM and dQCM in most subregions (selected SRMs presented in Table 1). Q-MOAKS tMCM in pMT demonstrated the most responsiveness for all the scores (SRM=+0.76 vs SRM = +0.20 for MOAKS tMCM). Quantitative cartilage thickness (ThCtAB) measures were most responsive. In the cMF region, the SRM= -0.46 (95% CI: -0.56, -0.33) at 1-year and 0.82 (-0.94, -0.72) at 2-years while the cMT SRM = -0.4 (-0.5, -0.28) at 1-year and -0.71 (-0.80, -0.60) at 2-years.

Table 1. Responsiveness of cartilage scores at follow up. Values are SRM (95% CI).

	YEAR ONE				YEAR TWO			
AREA	**tMCM**	**tQCM**	**dMCM**	**dQCM**	**tMCM**	**tQCM**	**dMCM**	**dQCM**
cMF	+0.28 (0.13,0.41)	+0.32 (0.20,0.43)	+0.07 (-0.05,0.18)	+0.20 (0.11,0.28)	+0.46 (0.32,0.57)	+0.53 (0.40,0.63)	+0.37 (0.26,0.48)	+0.44 (0.38,0.51)
cLF	+0.07 (-0.07.0.17)	+0.20 (0.09,0.33)	+0.02 (-0.09,0.14)	+0.14 (0.05,0.23)	+0.13 (0.02,0.20)	+0.24 (0.12,0.36)	+0.11 (-0.03,0.19)	+0.30 (0.24,0.36)
cMT	+0.32 (0.27,0.37)	+0.36 (0.24,0.47)	+0.23 (0.11,0.32)	+0.25 (0.13,0.33)	+0.45 (0.37,0.52)	+0.61 (0.49,0.72)	+0.42 (0.29,0.53)	+0.44 (0.36,0.51)
cLT	+0.18 (0.12,0.24)	0.22 (0.10,0.34)	+0.11 (-0.03,0.18)	+0.15 (0.04,0.24)	+0.23 (0.17,0.29)	+0.14 (0.02,0.26)	+0.17 (0.08,0.23)	+0.29 (0.20,0.37)

Conclusion: Quantitative measures or derived Q-MOAKS scores were more responsive than MOAKS. MOAKS appears to have better concordance with quantitative cartilage denudation than thickness loss, which might be explained by diagnostic accuracy for full thickness lesions being better than earlier grade lesions.

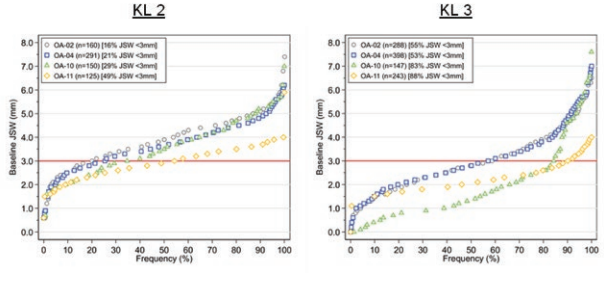
POS1365 STRUCTURAL SEVERITY IN KNEE OSTEOARTHRITIS IMPACTS TREATMENT RESPONSE: A POST HOC POOLED ANALYSIS OF LORECIVIVINT CLINICAL TRIALS

Keywords: Imaging, Osteoarthritis, Clinical trials

Y. Yazici[1], C. Swearingen[2], H. Ghandehari[2], I. Simsek[3], S. Kennedy[4], J. Tambiah[4], T. Mcalindon[5]. [1]*NYU Grossman School of Medicine, Rheumatology, New York, United States of America*; [2]*Biosplice Therapeutics, Biostatistics, San Diego, United States of America*; [3]*Alpine Immunesciences, Clinical Development, Seattle, United States of America*; [4]*Biosplice Therapeutics, Clinical Development and External Innovation, San Diego, United States of America*; [5]*Tufts Medical Center, Rheumatology, Boston, United States of America*

Background: Osteoarthritis (OA) is a leading cause of disability globally, with disease burden expected to rise [1]. Unmet needs remain for safe and efficacious treatments for symptoms and structural modification. Difficulties assessing pain and joint structure in clinical trials exist due to disease heterogeneity. This post hoc analysis of lorecivivint (LOR), an intra-articular (IA) CLK/DYRK inhibitor thought to modulate Wnt and inflammatory pathways, examined the structural heterogeneity of participants enrolled in Phase 2 and 3 LOR trials and associated treatment responses within KL grade subgroups.



Objectives: To identify potential relationships between OA pain and knee joint structural damage which may aid future clinical trial design.

Methods: Data was analyzed from two Phase 2 (OA-02, NCT02536833; OA-04, NCT03122860), and two Phase 3 trials (OA-10, NCT04385303; OA-11, NCT03928184) trials. In all trials, participants had ACR-defined (clinical and radiographic) knee OA, Kellgren-Lawrence (KL) grades 2-3. For OA-04, OA-10 and OA-11, additional pain inclusion criteria included Pain Numeric Rating Scale (NRS) [0-10] ≥4 and ≤8 in the target knee and <4 in the contralateral knee. Baseline JSW for each study was compared using cumulative frequency distribution plots by KL grade; percentages of subjects with JSW < 3mm for each study was also summarized to provide a surrogate for loss of ~50% healthy JSW (Deep et al. *JBJS* 2003). For the trials which captured Pain NRS outcomes, treatment responses were assessed according to KL grade. For all treatment-related outcomes, change from baseline was estimated using baseline-adjusted ANCOVA at each timepoint.

Results: KL 2 participants with baseline mJSW < 3 mm comprised 16% (OA-02), 21% (OA-04), 30% (OA-10) and 49% (OA-11). KL 3 participants with baseline mJSW < 3 mm comprised 55% (OA-02), 53% (OA-04), 81% (OA-10) and 88% (OA-11) (Figure 1) Beneficial treatment effect of LOR vs. PBO was seen for KL 2 subgroup in OA-04 and OA-10, but not in OA-11. Beneficial treatment effect of LOR was seen only in OA-04 for KL 3 at week 12.

Conclusion: In this post hoc analysis, substantial heterogeneity in baseline mJSWs existed across LOR clinical trials within the KL grade 2-3 inclusion criteria. Participants with less structurally advanced knee OA showed greater pain treatment responses to 0.07 mg LOR compared to those with more advanced disease. These data support the hypothesis that the amount of OA structural damage is associated with the pain of knee OA and that earlier LOR intervention may improve outcomes.

Figure 1. Cumulative frequency of baseline mJSW by KL grade across LOR trials

POS1366 EFFICACY OF DULOXETINE COMPARED TO NONSTEROIDAL ANTI-INFLAMMATORY DRUGS IN THE TREATMENT OF KNEE OSTEOARTHRITIS IN IRAQI KURDISTAN REGION

Keywords: Randomized control trial, Clinical trials, Osteoarthritis

A. Jalal[1], N. Albarzinji[2]. [1]*Kurdistan Board for Medical Specialities, Rheumatology, Erbil, Iraq*; [2]*Hawler Medical University/College of Medicine, Rheumatology, Erbil, Iraq*

Background: Osteoarthritis (OA) is the most common degenerative joint disease [1]. Knee OA is an insidious disease related to structural changes in the joint over many years. Duloxetine, a selective serotonin, and norepinephrine reuptake inhibitor, seems to be effective in treating neuropathic and chronic pain conditions [6].

Objectives: The objective of this study was to assess the efficacy of duloxetine tablet compared to nonsteroidal anti-inflammatory (NSAID) for the reduction of pain in Osteoarthritis.

Methods: A Randomized open labelled clinical trial of a 13-weeks done in Rizgary Teaching and CMC (Consultant Medical City) hospitals in Iraqi Kurdistan Region. From 5th of September 2022 to 2nd of January 2023 with Trial Registration ID (NCT05486026). Those eligible to enter the study their ages were ≥ 40years, both Genders were included, who will meet the American College of Rheumatology clinical and radiographic criteria for the diagnosis of osteoarthritis of the knee [8]. Patients were divided into two groups, The first group received Duloxetine tablet 30 mg for two weeks then titrated up to 30 mg BID. were compared to control group that received NSAID (nonsteroidal anti-inflammatory drug). End points were recorded at baseline then 2nd visits at 13 weeks. Measurement of pain severity was done by the weekly mean of the 24-h average pain scores in patients with osteoarthritis knee pain by Brief pain inventory (BPI). Another tool is (WOMAC) WESTERN ONTARIO AND MCMASTER OSTEOARTHITIS INDEX used for evaluation of pain in knee Osteoarthritis which involve three categories. The Patient Global Impression of Improvement (PGI-I) scale measured patients' perceived change in overall well-being (in response to therapy/treatment) and even side effects.

Results: Out of two hundred patients, forty-six participants were excluded: one hundred fifty-four were enrolled in the study. Their mean ages ±SD (57.38 ±10.58, 58.47±12.03) in Duloxetine, NSAID group Respectively. BPI-Severity average pain improved significantly after treatment with Duloxetine were 4.64 (95%CI:4.25 to 5.02) and P value was 0.00. BPI during 24-hour pain interfere with (activity, Mood, walking ability, work, relations with other people, sleep, enjoyment of life) were lower in Duloxetine group after treatment in comparison to control group (NSAID) 4.45 (95% CI:4.01 to 4.87), 5.47 (95%CI:5.11 to 5.82) respectively p value was significant ‹ 0.001. The total WOMAC score after treatment in Duloxetine group decreased 31.74 (95%CI:27.05 to 36.42) while in NSAID groups were 42.46(95%CI:38.05 to 46.86). about (PGI-I) scale, the patients who treated with Duloxetine was generally better than those treated with NSAID group; as the response and cure rate were higher in the Duloxetine(34.2%,30.3%,7.9%) much improve, very much improved, minimally improved respectively so; total (72.4%) were improved in comparison to the control group(28.2%, 6.4%, 11.5%) much improved, much improved,minimally improved respectively so; total (46.1%) were improved, the p value were significant 0.002 and about adverse effect in Duloxetine group most common side effects were epigastric pain and headache(3,3), with one patient with nausea, one with tremor and one fatigability, the symptoms were mild they continue study with symptomatic treatment of side effects, and 4 in NSAID developed side effect.

Conclusion: Duloxetine reduced pain and improved function in patients with knee osteoarthritis, by reducing BPI inventory and WOMAC score, with much improvement on PGI scales in comparison to NSAID.

Table 1: primary outcomes by BPI and WOMAC scales

	scales	Duloxetine(case) 76(49.4%) N. 95%CI	NSAID(Control) 78(50.6%) N. 95%CI	P value

POS1367 **WITHDRAWN**

POS1368 **THE LONGITUDINAL ASSOCIATION OF HAND OA WITH PAID AND UNPAID WORK IMPAIRMENT AND RELATED COSTS: THE HOSTAS COHORT**

Keywords: Patient reported outcomes, Epidemiology, Work-related issues

S. Terpstra[1,2], L. A. Van de Stadt[1], A. Boonen[3], F. Rosendaal[2], M. Kloppenburg[2,3].
[1]*Leiden University Medical Center, Rheumatology, Leiden, Netherlands*; [2]*Leiden University Medical Center, Clinical Epidemiology, Leiden, Netherlands*; [3]*Maastricht University Medical Center, Rheumatology, Maastricht, Netherlands*

Background: Hand osteoarthritis (OA) is associated with impairment in paid and unpaid work and contributes to societal burden and costs of OA. However, the longitudinal development of hand OA-related work impairment and related societal costs are unknown.
Objectives: To investigate the association of hand OA with paid and unpaid work productivity loss, hinder and societal costs longitudinally.
Methods: We used annual data of the Dutch Hand OSTeoArthritis in Secondary care (HOSTAS) cohort, consisting of patients with primary hand OA primary hand OA defined by the treating rheumatologist. Data from baseline to four years of follow-up was used. The Health and Labour Questionnaire (HLQ) was assessed over the last two weeks on (i) hand OA-related limitations and hours of productivity loss while at work, (ii) hours of sick leave, and (iii) limitations and hours of unpaid work replacement. Patients with HLQ data on >1 timepoint were included in this study. Societal costs of paid work productivity loss (=all hourly costs in order to employ a worker, such as salary and premiums) were estimated by multiplying the number of unproductive and sick leave hours due to hand OA by the estimated hourly costs of paid work in The Netherlands based on age and sex. Costs of unpaid work were estimated by multiplying the hours of unpaid work replaced by others by the Dutch gross average hourly salary of a household help (2021:€12.50). Costs were adjusted to 2021 values using conversion factors provided by the Dutch government, and to yearly values.
Results: 470 patients had data on more than one timepoint. Baseline data was available for 381 patients, of whom 256 patients (67%) completed four years of follow-up, and 215 (56%) completed all five follow-up moments. Of 256 patients

with baseline and four years follow-up, 113 (52%) had paid work at baseline and 104 (41%) at four years (**Table** 1 for patient characteristics). Unproductive hours at any timepoint were present for 85/470 patients (18%), for whom unproductive hours fluctuated over time (**Figure 1**). Median paid work hinder score (score range: 6-24) remained stable at 7 (interquartile range (IQR): 6;8) over the study period. Unproductive hours at any timepoint were present for 85/470 patients (18%). Regarding unpaid work, 105/256 (41%) required unpaid task replacement by others due to hand OA at baseline, which remained stable over time (108/256 at four years (42%)). Unpaid work hinder was reported by 100/256 patients (39%) at baseline and 97/256 (36%) at four years. Costs related to loss of paid and unpaid productivity were incurred at baseline by 136/256 patients, with a median of €63 per patient ((IQR) 38;125) per two weeks (€1630 per patient (978;3261 per year). At four years, these costs were present for 120/256 patients, with a median of €50 (38;100) per two weeks (€1304 (978;2609) per year).

Conclusion: Patients with hand OA experience significant impairment in paid and unpaid work participation over the years, which translates into substantial societal costs. Impairment and costs fluctuate on individual level but seem to remain stable over four years on group level.

CHANGES IN PAIN AND REACHING THE PATIENT ACCEPTABLE SYMPTOM STATE IN HAND OSTEOARTHRITIS OVER 4 YEARS

Keywords: Osteoarthritis, Pain

C. Van der Meulen[1], L. Van de Stadt[2], S. Buck[1], F. Rosendaal[3], M. Kloppenburg[1]. [1]*Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; [2]*Reade, Rheumatology, Amsterdam, Netherlands*; [3]*Leiden University Medical Center (LUMC), Clinical Epidemiology, Leiden, Netherlands*

Background: Hand pain is common in hand osteoarthritis (OA).

Objectives: This study aimed to characterize patients with an increase or decrease in pain, and to investigate which patients are likely to achieve a good clinical outcome after four years.

Methods: Four year data from the ongoing HOSTAS (Hand OSTeoArthritis in Secondary care) cohort were used, consisting of 538 consecutive patients with primary hand OA diagnosed by their rheumatologist. Hand pain was measured with the pain subscale of the Australian/Canadian hand osteoarthritis index (AUSCAN, range 0-20) annually. Demographics, disease characteristics and patient characteristics were collected, as were the Short Form (SF)-36 and Hospital Anxiety and Depression Scale (HADS). Change in pain was categorized as increase, stable or decrease according to the AUSCAN pain minimal clinical important difference (MCID, 1.6) between baseline and year 4. Good clinical outcome was defined as an AUSCAN pain score below the Patient Acceptable Symptom State (PASS) of 8.2 (Bellamy 2015). All patients with measurements at baseline and year 4 (MCID analysis) and at year 4 (PASS analysis) were included. Associations between determinants and change in pain or PASS were investigated using multinomial or binary logistic regression, respectively.

Results: Of 356 patients included in the MCID analysis, 83% were female, mean age was 60.6 years and mean AUSCAN pain score was 9.1. Over 4 years, pain decreased in 137, increased in 106, and 113 remained stable. In the decrease group, mean (SD) change in pain was -4.8 (2.8), in the stable group -0.1 (0.8), and in the increase 3.8 (1.9). Baseline BMI was positively associated with increase in pain. Health-related quality of life (HR-QoL) at baseline was positively associated with decrease in pain. Employment was positively associated with both increase and decrease in pain. HADS scores were negatively associated with decrease in pain (Table 1). Of 361 in the PASS analysis, 155 were below the PASS at baseline, and 177 were below the PASS after 4 years. Patient characteristics and disease characteristics at baseline were not associated with PASS after 4 years. Higher physical HR-QoL and lower pain level at baseline were associated with a higher chance of reaching PASS (data not shown).

Conclusion: Change in pain is associated with BMI, HR-QoL, mental wellbeing and employment status. Good clinical outcome is associated with physical health-related quality of life. These factors can help identify patients likely to achieve good clinical outcome and may aid stratified patient selection for trials.

Table 1. Associations with increase or decrease in pain

POS1370 METABOLIC SYNDROME IS ASSOCIATED WITH MORE PAIN IN HAND OSTEOARTHRITIS: RESULTS FROM THE DIGICOD COHORT

Keywords: Comorbidities, Pain, Osteoarthritis

A. Charton[1], R. Lacoste Badie[2], S. Tuffet[2], A. Rousseau[2], E. Maheu[1], B. Fautrel[3], M. Dougados[4], F. Berenbaum[1], A. Courties[1], J. Sellam[1]. Background: While association between metabolic syndrome (MetS) (combining central obesity, diabetes, dyslipidemia and/or hypertension) and the risk of osteoarthritis (OA) disease risk remains controversial at the structural level, MetS could be involved in OA-related pain. To analyze such an association, investigating hand OA is more relevant than knee OA to avoid the strong influence of weight on bearing joints.
Objectives: To determine whether the presence of MetS is associated or not with a higher pain level in hand OA.
Methods: This cross-sectional study involved patients included in the hospital-based hand OA DIGICOD cohort, for whom all baseline variables of interest were available (NCT01831570). The characteristics were described and compared according to the presence or absence of MetS (Adult Treatment Panel III criteria). We searched for an association between MetS and several outcomes measuring different aspects of OA-related pain (hand pain intensity using visual analog scale (VAS) on activity, VAS pain at rest, hand pain in various situations using the self-reported Australian Canadian Osteoarthritis Hand Index (AUSCAN) pain subscore, Arthritis Impact Measurement Scale (AIMS2) pain subscore assessing the OA pain nonspecifically related to hands, number of painful hand joints on pressure) using 2 logistic regression models: model 1: adjustment for age, sex, and the radiological Kellgren-Lawrence (KL) total sum score. model 2: model 1 + hospital anxiety and depression (HAD) scale. All pain outcomes were binarized by their median values defining thus high and low pain levels. Results are presented as odds ratios (OR) with 95% confidence intervals (CIs). The reference group was "no MetS" (MetS-).
Results: A total of 359 patients (85% women, 66.3±7.4 years) were analyzed out of 425 included, including 128 (36%) patients with MetS (MetS+). The 2 groups (MetS+ and MetS-) did not differ in their demographic characteristics except for BMI (27.1±4.5 and 24.0±3.8 kg/m^2, p<0.0001), age (67.9±7.1 and 65.5±7.5, p=0.003), KL sum score (48.9±17.7 and 44.5±17.5, p=0.03), and HAD (13.7±6.7 and 12.1±5.7, p=0.02) (Table 1). MetS was associated with a higher VAS pain at activity (median: 44/100) in model 1 (OR=1.63, 95%CI (1.04; 2.56), p=0.03) but this association was attenuated with further adjustment on HAD scale (OR=1.48, 95%CI (0.94; 2.35), p=0.09) (Table 1). MetS was also associated with a higher AUSCAN pain (median: 20/100) in non-adjusted analysis but this did not persist in adjusted model 2. No association was found with VAS pain at rest or the number of painful joints on pressure. MetS was associated with a higher AIMS2 pain subscore (median: 33/100) in both models (OR=1.70, 95%CI (1.06;2.74), p=0.03).

Table 1. Association between metabolic syndrome and pain in hand osteoarthritis according to various measurement tools*

	Unadjusted model	Adjusted for age, sex, KL total sum score	Adjusted for age, sex, KL total sum score and HAD
AUSCAN Pain subscore ≥ 20	1.59 (1.03; 2.46)°	1.51 (0.97; 2.37)	1.40 (0.89; 2.21)
AIMS 2 pain score ≥ 33	1.89 (1.21; 2.95)°	1.90 (1.20; 3.01)°	1.70 (1.06; 2.74)°
VAS at rest ≥ 15	1.39 (0.90; 2.15)	1.39 (0.89; 2.17)	1.30 (0.82; 2.04)
VAS at activity ≥ 44	1.64 (1.06; 2.54)°	1.63 (1.04; 2.56)°	1.48 (0.94; 2.35)
Number of painful joints ≥3	1.38 (0.88; 2.17)	1.38 (0.87; 2.20)	1.32 (0.83; 2.12)

° Statistically significant*Data are OR (95% CI) given for Mets+ versus Mets-.

Conclusion: MetS was associated with more hand pain in hand OA, partly mediated by anxiety-depression. MetS also increased the risk of OA pain nonspecifically related to hands suggesting a higher susceptibility to joint pain in general in patients with MetS.

POS1371 THE ASSOCIATION BETWEEN X-RAY PROGRESSION AND CLINICAL OUTCOMES IN PATIENTS WITH HAND OSTEOARTHRITIS WITH 5-YEAR FOLLOW-UP

Keywords: Pain, Quality of life, Imaging

O. Sleglova[1], J. Baloun[2], J. Gatterova[1], X. Svec3, O. Růžičková[1], K. Pavelka[1], L. Šenolt[1]. [1]*Instutute od Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Praha 2, Czech Republic*; [2]*Instutute od Rheumatology, Department of Experimental Rheumatology, Praha 2, Czech Republic*; [2]*Instutute of Rheumatology, Department of Experimental Rheumatology, Praha 2, Czech Republic*

Background: Hand osteoarthritis (HOA) is a heterogeneous disorder with two main subtypes, non-erosive and erosive. The progression of HOA is assessed by various radiographic scoring methods, including the Kallmann scale, and the understanding of the association between radiographic changes and clinical symptoms might help improve the monitoring of disease progression.
Objectives: This study aimed to investigate the association of the Kallman scale with clinical assessment parameters and the erosive subtype in a Czech population of HOA patients over 5 years.
Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. All patients were evaluated at baseline and follow-up examinations over 2 and 5 years. Clinical examinations were performed by qualified rheumatologists. The number of clinically tender and swollen joints was recorded. Pain, stiffness, and function were assessed by the Australian/Canadian (AUSCAN) hand osteoarthritis index. Hand disability was evaluated based on the Algofunctional index. The visual analogue scale (VAS-pain) and the health assessment questionnaire (HAQ) was used for the assessment of pain and function/disability. Postero-anterior plain radiographs of both hands were examined, and radiographs were scored by two trained readers (rheumatologists) according to the Kallman scale. The inter-rater reliability was computed using weighted Cohen's Kappa for two ratters.
Results: Of 154 patients enrolled in this study, 129 subjects (89.3% females; mean age at baseline = 64.6±8.0 years) met the ACR classification criteria for HOA and were followed up over 5 years at the outpatient department of the Institute of Rheumatology in Prague. Out of these patients, 57 were diagnosed with the non-erosive form (87.7% females; mean age at baseline = 63.8±7.7 years) and 72 with the erosive form (90.3% females; mean age at baseline = 65.7±8.1 years), where erosive HOA was defined by at least one interphalangeal joint with radiographic signs of erosion. Firstly, we analysed each examination separately and found that the Kallman scale was both significantly increased in patients with the erosive subtype (2.95 – 3.12-fold, p<0.001 for all) and associated with age in all examinations (β = 1.27 – 1.57; p<0.001 for all). Next, we used generalized additive modelling (GAM) to analyse data collected over five years and discovered the association of the scale with HOA subtypes and age (p < 0.01 for both). GAM also revealed associations of the Kallman scale with HAQ (edf=2.5, p=0.016) in all patients and patients with non-erosive HOA (edf=1.7, p=0.027). Similarly, the scale was associated with the number of clinically swollen joints in all HOA patients (edf = 1, p = 0.041) and patients with non-erosive HOA (edf=4, p=0.046). Eventually, Algofunctional index (edf=1.9, p=0.02) was associated with the scale only in all patients with HOA. Other parameters (e.g., AUSCANs) were insignificant.
Conclusion: Our 5-year longitudinal study revealed the associations of structural progressions with both subtypes and age at each time point. In contrast, functional impairments were associated with the progression only in non-erosive subset and all HOA patients. Further studies in a larger cohort of patients are needed to validate these data.

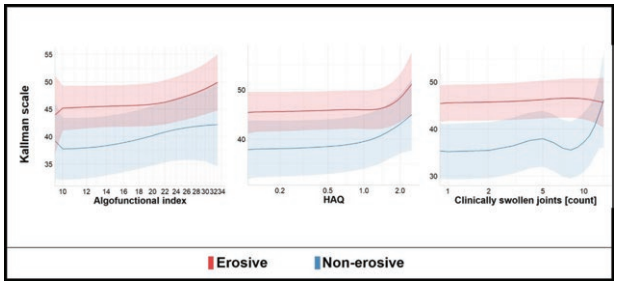

Figure 1. Associations of the Kallman scale with Algofunctional index, HAQ and the number of clinically swollen joints in patients with erosive and non-erosive HOA.

Background: Osteoarthritis (OA) is one of the most common chronic health conditions. Painful and very disabling, it affects about 500 million people worldwide. For its management, the different guidelines recommend a combination of non-pharmacological and pharmacological treatments [1]. However, 90% of the patients in the stop osteoarthritis I and II survey feel that they are poorly managed in terms of their OA pain and we currently lack effective means to do so [2]. We propose to assess an innovative medical device (MD) for neuromodulation of pain in patients with peripheral OA. This MD is a wristband and consists of a very low-power millimetre wave transmitter. The application of these waves on the wrist, a highly innervated area, has neuromodulatory effects thanks to the synthesis and release of endorphins and the activation of the parasympathetic system.

Objectives: We conducted a clinical trial to evaluate if the regular use of this MD would reduce the pain felt by the patient as well as his consumption of analgesics and if it would improve quality of life (QoL).

Methods: This prospective study was performed between December 2020 and august 2022. Sixty patients with a peripheral OA and a pain score ≥4 on the visual analogic scale (VAS) was included and randomised in one of the two cross-over group. The randomization is stratified on the most painful OA localisation (upper/lower limbs). Patients of group A followed a 3-month period with their conventional treatment (CT) and after they get the device in add on for 3 months. Those of group B started by using for 3 months the MD added on CT and after they took only CT for 3 months. Between the 2 periods, there was a one-month wash-out with only CT. Patients were instructed to perform 1 to 3 sessions/day with the wristband. The duration of each session was 40 minutes. The intern memory of the MD allowed to measure this frequency of use. After 7 days of wristband use, a phone call was performed to ensure that patient had no difficulties with the wristband. A follow-up phone call was also made once a month to remind the patient to use wristband, to report data and to collect potential adverse events. The primary outcome was the difference of pain score between the period with and without the wristband use. The primary endpoint was collected on the VAS every day during the last two weeks of each month of follow-up (i.e. months 1 to 3 and 5 to 7). The other parameters, collected at the inclusion and follow-up visits are specific QoL of OA (WOMAC questionnaire/DREISER index), generic QoL with EuroQuol5D-5L, anxiety-depression questionnaire (HADS), antalgics and cares consumption, the sleep quality on VAS, usability questionnaire (meCUE), patient use of the MD and adverse events. In the aim of a personalized medicine a comparison is made for each patient between the real evolution of their pain score and the decreases in the pain score that they felt having a relevant impact.

Results: All analyses were performed in intention to treat. The mean age of patients was 65.78±7.2 years old. At baseline all parameters were similar between the two groups except the number of male (group A: 5M; group B: 1M) and the body max index (group A: 24.29±4.01 kg/m^2; group B: 27.80±4.7 kg/m^2). The mean pain score at baseline was 6.17±1.43. For this cross-over study, there were no carryover, no sequence, and no period effect. The two groups difference on the pain score was significative ($p<0.05$) with a VAS of 4.57±2.0 in the MD group and 5.32±1.77 in the conventional treatment group. The effect size of the MD, calculated with the Cohen's D formulae, was of 0.42. No serious adverse effect occurs.

Conclusion: We have demonstrated in this world first study the efficacy of this new medical device to reduce peripheral OA pain. Easy to use, discreet and safe, this free drug therapy opens a new field of OA pain treatment.

POS1373

EROSIVE OR INFLAMMATORY HAND OA (HOA): A MORE SEVERE DISEASE? CROSS-SECTIONAL STUDY OF BASELINE ASSOCIATED RISK FACTORS IN PATIENTS FROM THE DIGICOD COHORT

Keywords: Osteoarthritis, Epidemiology, Descriptive studies

E. Maheu[1], T. Sophie[2], A. Rousseau[2], M. Crema[3], K. Margreet[4], F. Rannou[5], F. Berenbaum[1], J. Sellam[1]. *[1]Sorbonne Université - Assistance Publique - Hôpitaux de Paris (AP-HP), Saint-Antoine Hospital, Rheumatology, Paris, France*; *[2]Hospital Saint-Antoine Ap-Hp, Clinical Pharmacology and East Paris Clinical Research Unit (URCEST, CRB, CRC), Paris, France*; *[3]Institute of Sports Imaging, INSEP, Sports Medicine Department, Paris, France*; *[4]Leiden University Medical Center (LUMC), Rheumatology, Leiden, Netherlands*; *[5]University of Paris-Center, Cochin Hospital, AP-HP, Physical and Readaptation Medicine of Musculoskeletal Diseases Unit, Paris, France*

Background: Erosive HOA (EHOA), defined by an erosive radiographic joint and inflammatory HOA (IHOA) defined by the presence of clinical synovitis are frequent in HOA. The association with specific risk factors and a more severe disease, remains still debated.

Objectives: To identify demographic, disease-related and clinical factors as risk factors for EHOA or IHAO.

Methods: Clinical and radiographic data were extracted from baseline data of the 6-years prospective longitudinal HOA French cohort DIGICOD [1]. Demographic and hand OA clinical and radiological data were compared at baseline between EHOA (≥1 erosive joint in E- or R-phase according to Verbruggen scoring) versus non EHOA, and IHOA (≥ 1 joint with clinical synovitis) vs non IHOA groups. A model of logistic regression analysis was performed for each demographic and clinical HOA-related studied parameter to identify factors associated with EHOA and/or IHOA. Analyses were adjusted for age, sex and body mass index. Results are expressed as Odd Ratios and their 95%Confidence Interval (OR (95%CI)).

Results: 425 patients were analyzed, 195 EHOA (46%), 185 IHOA (43%), with 113 both EHOA and IHOA (27%). The risk of EHOA was reduced by a half in case of current/past professional occupation involving hands (OR 0.6; 95%CI: 0,4; 0.9) and by at least 0.6 (0.3;1.0) if grip strength ≥ 19kg. It was increased by at least 2.0 (1.1; 3.5) if OA duration was ≥6 years, by 2.6 (1.7; 3.9) if aesthetic damage scored ≥40 on a 0-100 mm VAS, by 2.2 (1.4; 3.5) if ≥2 painful joints on pressure, by 2 (1.3; 3,1) if the AUSCAN stiffness subscale scored ≥20 (0-100 VAS), by 2.3 (1,5; 3,5) if the Functional Index for HOA (FIHOA) scored ≥20 (score normalized to 0-100). The risk of IHOA was increased by 2.4 (1.4; 4.0) if OA duration was ≥11 years versus < 6 years, by 1.8 (1.1; 3.0) if pain at rest VAS was ≥40 and by 2.1 (1.4; 3.2) if pain on activity was ≥40, by 2.5 (1.6; 3.8) if aesthetic damage scored ≥40, by 2.5 (1.5; 4.1) if ≥2 painful joints on pressure and by 1.9 (1.2; 2.9) if ≥2 spontaneous painful joints, by 1.9 (1.2; 3.0) if AUSCAN stiffness subscale ≥40, by 1.8 (1.2; 2.7) if the FIHOA was ≥20. Structural damage was higher in both EHOA and IHOA than in those without EHOA and IHOA, respectively: the mean ±standard deviation number of joints at a Kellgren-Lawrence grade ≥2 was 18±5 in erosive vs 13±6 in non-erosive patients and 18±6 vs 13±6 in IHOA vs non IHOA.

Conclusion: There was a high prevalence of EHOA and IHOA in our cohort, partly due to a tertiary-care recruitment. Structural damage was more severe in both phenotypes than in those without erosive or inflammatory signs.

There was an inverse correlation between hand use and EHOA, confirming that EHOA is rather linked to systemic factors. Risk factors for both EHOA and IHOA were a longer disease duration, a higher aesthetic damage (notably in IHOA), number of painful joints on pressure, stiffness, and functional impairment (FIHOA). IHOA was also associated with more pain. Prospective longitudinal studies are needed to confirm these risk factors.

POS1374 RELATIONSHIP BETWEEN POSSIBLE TIBIOFEMORAL OSTEOPHYTE AND CREPITUS AND EFFUSION IN PATIENTS WITH KNEE SYMPTOMS BUT WITHOUT JOINT SPACE NARROWING

Keywords: Pain, Osteoarthritis

A. Mahmoudian[1,2], M. Englund[2]. [1]*University of West Florida, Movement Sciences and Health, PENSACOLA, United States of America*; [2]*Lund University, Department of Clinical Sciences, Orthopedics, Lund, Sweden*

Background: Osteophytes are common structural sign identified to be associated with knee osteoarthritis (OA) and has been included as a criterion for presence and progression of knee OA.

Objectives: Our aim was to investigate the association of possible tibiofemoral osteophyte with knee-joint-related physical examination in symptomatic knees without radiographically detected joint space narrowing.

Methods: We used the Osteoarthritis Initiative (OAI) open access database (http://www.oai.ucs.edu), approved by the local institutional review boards. The OAI comprises data of 4796 men and women aged 45–79 years at baseline. We selected subjects, from the following two sub-cohorts: 1) progression cohort, individuals with symptomatic knee OA (n=1390); 2) incidence cohort, individuals at risk for knee OA (n=3284). Crepitus was examined at baseline by placing the palm of the hand over the patella to detect the presence of a continuous grinding sensation during passive knee flexion-extension movement in the supine position. A positive bulge sign was considered as presence of knee joint effusion. We included subjects with no joint space narrowing but no or doubtful osteophyte in either knee at baseline based on fixed-flexion posteroanterior knee radiographs. We further required subjects to have answered YES to the following question at baseline: "*Do you have knee pain, aching or stiffness for more than half the days of a month during the past 12 months?*" We used unconditional logistic regression to evaluate the association between the presence of knee crepitus and effusion possible tibiofemoral osteophyte. Only one knee per subject was randomly included if both knees were eligible. In the first model the outcome was structural OA development irrespective of knee symptoms at 4 years, and in the second model we required the presence of knee pain, aching or stiffness also at the 4-year follow-up (i.e., the subjects remained symptomatic).

Results: We included 726 subjects with no or little radiographic evidence of OA and a symptomatic knee (60% women, mean [SD] age 58.9 [8.5], BMI 29.6 [4.9]. Our results indicated that presence of crepitus and/or effusion on physical examination were (statistically) significantly associated with possible tibiofemoral osteophyte (**Table 1**).

Conclusion: Presence of both crepitus and effusion at examination in subjects with no or minimal radiographic OA of their symptomatic knee showed moderate association with possible osteophyte in the tibiofemoral joint. An important limitation is that radiographic changes in the patellofemoral joint was not systematically evaluated within the OAI.

Table 1. The association between crepitus and effusion and possible tibiofemoral osteophyte in 726 subjects with a symptomatic knee but without joint space narrowing

	Crude odds ratio (95% CI)	Adjusted* odds ratio (95% CI)

POS1375 RELIABILITY AND VALIDITY OF THE LIE-TO-SIT-TO-STAND-TO-WALK TRANSFER TEST IN HIP OSTEOARTHRITIS

Keywords: Safety, Outcome measures, Osteoarthritis

B. Unver[1], K. S. Kacmaz[1], V. Karatosun[2]. [1]*izmir Katip Celebi University, Physical Therapy and Rehabilitation, Izmir, Turkey*; [2]*dokuz Eylul University, Orthopedics and Traumatology, Izmir, Turkey*

Background: Falls represent a major health problem for older adults and often lead to disability and mortality. Each year 30% to 50% of community-dwelling older adults report a fall and almost 75% of falls occur in bedrooms or bathrooms, and 41% of all falls occur during transfers [1,2]. Patients with hip osteoarthritis (OA) have many hip and age-related dysfunctions including muscle weakness, sensory loss, gait and balance deficits, which all increase the risk of falls [3]. Task-specificity has been shown to be a critical factor in the effectiveness of fall-reducing interventions [4]. The Lie-to-Sit-to-Stand-to-Walk Transfer Test (LSSWT) was created to measure complicated transfer abilities in older people [5]. However, the LSSWT's reliability and validity are not known in patients with hip OA.

Objectives: The aim of this study was to investigate the reliability, validity, and minimal clinically important difference (MCID) of the LSSWT in patients with hip OA.

Methods: Twenty-seven patients with hip OA were included in this study. Patients performed trials for the LSSWT and the Timed up-and-go (TUG) test. Between the trials, patients rested for an hour to prevent fatigue.

Results: The relative (ICC coefficient) and absolute (SEM and SRD95) reliability of the LSSWT were 0.95, 0.49, and 1,35 respectively. The Pearson correlation coefficient between the LSSWT and the TUG was 0.69.

Conclusion: The analysis showed that the LSSWT has excellent reliability and high validity in hip OA. ($p<0.001$). The low MCID of the LSSWT (1.35) shows its sensitivity and can be used as a responsive outcome measure of interventions and fall risk. the LSSWT also can be valuable in determining independent transferring ability, admissions, or discharges from/to healthcare/residential facilities.

POS1376 PARACETAMOL PRESCRIPTION PATTERNS IN LOW BACK PAIN AND OSTEOARTHRITIS IN REAL-WORLD GENERAL PRACTICE IN FRANCE

Keywords: Pain, Osteoarthritis, Real-world evidence

J. Cittee[1], P. Lemire[2], A. Annenkova[3], J. Y. Milon[3], S. Perrot[4]. [1]*University Paris-Est Créteil Val de Marne, Department of General Medicine, Paris, France*; [2]*IQVIA, Real World Solutions, Paris, France*; [3]*UPSA SAS, Medical Affairs, Rueil-Malmaison, France*; [4]*Cochin Hospital, Université Paris Cité, INSERM U987, Paris, France*

Background: Lower back pain (LBP) and osteoarthritis (OA) are the most frequent musculoskeletal disorders in the general population significantly impacting patients' quality of life. An adequate pain management is key. General practitioners (GPs) are the front-line decision-makers in the French primary care system. In France, paracetamol remains a first-line analgesic in LBP and OA, according to the national guidelines. Few data on the real-world paracetamol prescriptions in LBP and OA are available.
Objectives: This observational retrospective cohort study aimed to identify the paracetamol prescription patterns in LBP- and OA-related pain in real-world GP practice.
Methods: Prescription data from IQVIA's French EMR database with a representative panel of approximately 1,200 GPs. Data collection was systematic, non-interventional, reflecting the daily clinical practice. Patients aged more than 18 years old presenting with LBP- and OA- related pain and receiving a paracetamol prescription during a GP consultation over a 10-month period were included in the analyses.
Results: A total of 18,677 LBP and 8,882 OA patients were included. In more than 90% of these patients, the paracetamol prescriptions were not preceded by any other analgesic for the same diagnosis within the previous month. Paracetamol was mainly prescribed alone (57% LBP, 78% OA). The most frequent associations were NSAIDs and grade II analgesics. Treatment discontinuation at Month 1 was the most frequent event (67% LBP and 52% OA). In case of treatment restart, paracetamol was prescribed again in 57% LBP and 81% OA patients. At Month 3, 78% LBP and 71% OA patients discontinued treatment.
Conclusion: Paracetamol remains a pivotal analgesic and is prescribed first line in the majority of the patients in both indications. Paracetamol is the treatment of the given painful episode, with more than a half of patients discontinuing treatment at Month 1.

POS1377 HAND OSTEOARTHRITIS: CORRELATION BETWEEN HAND ULTRASOUND AND CONVENTIONAL RADIOGRAPHY

Keywords: Osteoarthritis, Diagnostic tests, Ultrasound

H. Boussaa[1], S. Bouzid[1], S. Miladi[1], A. Fazaa[1], M. Yasmine[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], C. Selma[1], K. Ben Abdelghani[1], A. Laatar[1]. [1]*Mongi Slim Hospital, Rheumatology, Tunis, Tunisia*

Background: Hand osteoarthritis (OA) is among the most prevalent OA phenotypes. The simultaneous involvement of multiple hand joints makes hand OA a heterogeneous disorder that is complex to study [1]. It is widely accepted that radiography is the gold standard for the diagnosis of hand OA [2].
Objectives: We aimed to investigate the correlation between ultrasound (US) and X-ray findings in hand OA.
Methods: We conducted a cross-sectional study, including patients with hand OA, fulfilling American College of Rheumatology criteria. All patients underwent a physical examination followed by an US exam. US was performed in all metacarpophalangeal, proximal interphalangeal, and distal interphalangeal joints, and features were quantitatively scored (0/1). Recent (less than six months old) posterior-anterior view X-rays of the hands were analyzed. Pearson correlation coefficient was calculated.
Results: We examined 280 joints in a total of 10 patients with hand OA (9 women and one man). The mean age was 66±11 years [46–78]. The mean duration of hand OA symptoms was 4±3 years. The mean tender and swollen joints were 1.5 [0-5] and 0.1 [0-1], respectively. X-rays showed joint space narrowing and osteophytes in all patients. Sclerosis was found in 2,4 [0-8] joints. A significant correlation was found between the number of osteophytes in both US and X-rays ($p<0.001$). Joint space narrowing was correlated to calcifications ($p=0.003$) and enthesophytes ($p=0.039$). X-rays subchondral cysts correlated with osteophytes ($p=0.015$) and calcifications ($p=0.04$) in US. No significant association was noted between sclerosis and US findings.
Conclusion: Despite the small study population, our results showed a significant match between US and X-ray in hand OA. This finding is likely to have practical implications for facilitating the diagnosis and the monitoring of hand OA.

POS1378 PERCEIVED BENEFITS AND BARRIERS TOWARDS EXERCISE AMONG PATIENTS WITH KNEE OSTEOARTHRITIS

Keywords: Mental health, Osteoarthritis, Rehabilitation

A. Adnine[1], F. Z. Taik[1], N. Soba[2], N. Takhrifa[1], F. Z. Aharrane[1], M. Fourtassi[2], F. E. Abourazzak[1]. [1]*1Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Rheumatology, Tangier, Morocco*; [2]*Abdelmalek Essaidi University, Faculty of Medicine of Tangier-Tetouan- Al Hoceima, University Hospital Center Tangier-Tetouan-Al Hoceima, Physical Medicine and Rehabilitation, Tangier, Morocco*

Background: Physical activity (PA) is highly recommended in patient with osteoarthritis. Despite the major benefits of PA and exercise, patients with knee osteoarthritis report low level of PA and engage more in sedentary behavior (SB). Understanding the perception of these patients towards exercise is essential to help find better interventions.
Objectives: The Aim of this study is to assess the perception of benefits and barriers towards exercise among patients with knee osteoarthritis and analyze the associated factors.
Methods: This is a cross-sectional study that was conducted from April to September 2022. Patients with knee osteoarthritis were included then classified on the basis of the Kellgren and Lawrence radiograph scale. Socio-demographic and clinical characteristics were collected. Level of PA was assessed using (IPAQ-SF). Perceived benefits and barriers towards exercise was assessed using Perceived benefits and barriers to exercise scale (PBBS). Participants were also assessed for anxiety and depression (GAD-7) and (PHQ-9) scales respectively.
Results: A Total of 178 patients were enrolled in the study, with a mean (±SD) age of 58.48 ± 9.9 years, 88.2% of them were females, and 69.1% had comorbidities. Mean (±SD) VAS pain score upon walking was 4.78 ± 2.21. According to the Kellgren and Lawrence classification, 64.4% of the patients had OA grade 2 and 25.6% had grade 3. Mean of Lequesne scale was 9.8 ± 3.8. The mean of PBBS benefits scale was 94.35 ± 20.25. The Mean of PBBS barriers scale was 27.01 ± 8.23. Top three ranked perceived benefits to exercise were (Mean ± SD): «Exercise improve my mental health» 3.53± 0.62, «My disposition is improved with exercise » 3.48 ±0.63 and «Exercise decreases feelings of stress and tension for me » 3.43± 0.65. Top three ranked perceived barriers to exercise were

(Mean ± SD): «Exercise tires me» 2.42± 1.18, «I'm fatigued by exercise » 2.32 ± 1.17 and «Exercise is hard work for me» 2.27± 1.17.

Table 1: ***uni and multivariate analysis of associated factors with PBBS benefits/barriers scale.***

	Perceived benefits of exercise (PBBS)		Perceived barriers of exercise (PBBS)

PHQ-9:	-4.998 [-7.784, -2.211] p=0.001	-0.839 [-1.376, -0.302] p=0.002	0.967[0.366,1.665] p=0.002	0.979[0.212,1.508] p=0.015

Conclusion: In Our study, the most highly ranked perceived barriers to exercise reported were items related to physical exertion. Some studies have found similar findings in patients with multiple sclerosis (1) and HIV female patients [2]. Pain and handicap related to knee osteoarthritis were not associated with the perception of barriers to PA. The most highly rated perceived benefits to exercise were those related to improvements in mental health. Regular PA have shown to improve mood and fight depression, in addition depression often alter the perception of benefits and barriers to exercise as shown in our study. Screening and treating Depressive disorders is essential to help patient break the cycle.

POS1379

A NOVEL MEASURE OF END-STAGE KNEE OSTEOARTHRITIS REDUCES THE DURATION AND SAMPLE SIZE REQUIRED FOR OBSERVATIONAL STUDIES AND TRIALS

Keywords: Outcome measures, Osteoarthritis, Clinical trials

Z. Salis[1], J. Driban[2], T. Mcalindon[2], A. Sainsbury-Salis[3]. [1]*The University of New South Wales, Centre for Big Data Research in Health, Kensington, Australia*; [2]*Tufts Medical Center, Division of Rheumatology, Boston, United States of America*; [3]*The University of Western Australia, School of Human Sciences, Perth, Australia*

Background: Total knee replacement (TKR) has been used as an outcome measure in research into the causes and possible treatments for knee osteoarthritis (KOA). However, because KOA progresses slowly, and because TKR has a low incidence, research using TKR as an outcome measure necessitates long duration and/or large sample sizes. Moreover, TKR is influenced by multiple factors (such as education and income) besides the progression of KOA.

Objectives: We defined a novel outcome measure that signifies end-stage KOA (esKOA); and determined whether esKOA was sensitive enough to detect the effect of an exposure that is known to have a modest effect on reducing TKR, namely weight loss.

Methods: A knee was considered to have esKOA if any of the following two conditions were met: 1) moderate, intense, or severe KOA symptoms (i.e., the sum of the pain and disability scores on the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) ≥ 12) and severe radiographic knee osteoarthritis (RKOA), defined as a Kellgren and Lawrence Grade (KLG) of 4); or 2) intense or severe KOA symptoms (i.e., the sum of the pain and disability scores on the WOMAC ≥ 23) and frequent knee pain (i.e., knee pain on most days of one or more months in the past 12 months) and mild or moderate RKOA (KLG = 2 or 3). We used data from two prospective cohort studies: the Osteoarthritis Initiative (OAI) and the Multicenter Osteoarthritis Study (MOST). We analyzed the data in two ways: as an observational study; and as an emulated trial. In the emulated trial, participants who lost ≥ 5% of their weight between baseline and 1 - 1.25 years (weight loss group) were matched with participants who gained ≥ 5% of their weight in that same period (weight gain group), using 1:1 nearest-neighbour matching on propensity scores. In both analyses, we used a multilevel mixed-effects generalized linear model. In the observational study, we investigated the association of weight loss between baseline and the following time points with esKOA and TKR at these time points: 1 - 1.25 years; 2 - 2.5 years; and 4 - 5 years. In the emulated trial, we compared the odds of incidence of esKOA and TKR between the weight loss and weight gain group at the following time points: 2 - 2.5 years; and 4 - 5 years.

Results: The observational study included 7107 participants (58.4% female, mean ± SD age and BMI 61.4 ± 8.8 years and 29.2 ± 5.1 kg/m^2 at baseline, and an incidence of esKOA of 2.9, 6.8, and 10.4% at 1 - 1.25 years, 2 - 2.5 years, and 4 - 5 years, respectively, and a corresponding incidence of TKR of 0.1, 0.5, and 1.6%. While weight loss was associated with a reduced adjusted odds ratio (aOR) for both esKOA and TKR at 4 - 5 years (for 5% weight loss: 0.85 [95% CI 0.79 - 0.92] for esKOA and 0.79 [0.67 - 0.93] for TKR), weight loss was only associated with a reduced aOR for esKOA - and not TKR - at the earlier time point of 2 - 2.5 years (for 5% weight loss: 0.80 [0.72 - 0.90] for esKOA and 1.05 [0.76 - 1.45] for TKR). At 1 - 1.25 years, there was no association between weight loss and esKOA or TKR. The sample size required to detect a 50% reduction in the odds of esKOA was 6% to 13% of the sample size required for that of TKR (236 versus 3990 at 2 - 2.5 years; 162 versus 1286 at 4 - 5 years). In the emulated trial, compared to the weight gain group (367 participants), the weight loss group (also 367 participants) had significantly lower odds of esKOA but not TKR at 4 - 5 years (0.43 [0.22 - 0.84] for esKOA and 0.39 [0.06 - 2.67] for TKR). There was no difference between groups in the odds of esKOA or TKR at the earlier time point of 2 - 2.5 years in the emulated trial.

Conclusion: Given that our novel measure of esKOA could detect an association with weight loss at a time point 1.5 - 3 years earlier than TKR in an observational study, and in a sample size that was too small to detect an association with TKR at 4 - 5 years in an emulated trial, esKOA is recommended as an outcome measure for observational studies and trials investigating causes and possible treatments for KOA. Our powerful novel measure of esKOA enables shorter and smaller – hence cheaper – studies, which can boost the research on effective treatment for KOA.

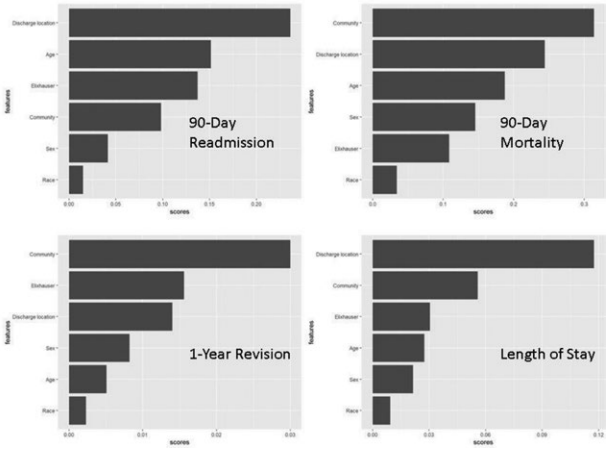
Background: With total hip arthroplasty (THA) utilization rising rapidly, [1] it is important to understand social determinants of health (SDOH) that contribute to disparities in THA outcomes.

Objectives: We sought to explore the relationship of multiple community-level SDOH with 90-day readmission, 90-day mortality, 1-year revision post-THA, and length of stay (LOS) using prediction modelling.

Methods: Our retrospective study using the Pennsylvania Health Care Cost Containment Council Database included 105,336 patients undergoing THA 2012-2018. Community-level variables include walkability index; median household income; and percent unpaid family workers, without health insurance and not in the labor force, above high school, above college, foreign-born, speaking languages other than English, with computer access, and with internet access. They were extracted from US census via geocoding. We trained explainable boosting machine using Generalized additive models to predict readmission, mortality, LOS, and revision. Resulting mean absolute scores (MAS) were aggregated to measure collective importance of the above "community-factors."



Results: Predictive performance was best for mortality (AUROC=0.76); it was moderate for readmission (AUROC=0.66), revision (AUROC=0.58), and LOS (RMSE=0.41, R^2=0.2). Community factors relatively contributed more to adverse outcomes than race in all models. The top 3 predictors of readmission were discharge location, age, and comorbidities (MAS =0.24, 0.15, 0.13, respectively). The top 3 predictors of mortality were community factors, discharge location, and age (MAS=0.31, 0.24, 0.19, respectively). The top 3 predictors of revision were community factors, discharge location, and comorbidities (MAS=0.03, 0.01, 0.005, respectively). Lastly, the top 3 predictors for LOS were discharge location, community factors, and comorbidities.

Conclusion: In all THA outcome models, aggregated community factors were more important than individual race in predicting 90-day readmission, 90-day mortality, 1-year revision, and length of stay.

Clinical cases

POS1381 TRANSIENT PERIVASCULAR INFLAMMATION OF THE CAROTID ARTERY (TIPIC) SYNDROME: A RARE CAUSE OF CAROTIDYNIE

Keywords: Vasculitis, Ultrasound, Rare/orphan diseases

C. Porpaczy[1], C. Zimmermann[1], R. Steinbach[2], K. Redlich[1]. [1]*Klinik Hietzing, 2nd Dept of Medicine, Wien, Austria*; [2]*Klinik Hietzing, Dept. of Radiology, Wien, Austria*

Background: Carotidynie defines localised, unilateral neck pain in the region of the carotid bifurcation and is a relatively frequent event with a myriad of causes. Differential diagnosis include mainly arterial dissection, large vessel vasculitis or local inflammation or surrounding structures (e.g. lymphadenitis). We herein describe a patient with carotidynie caused by a TIPIC syndrome under follow up by ultrasound imaging.
Methods: The logiq S8 from GE2 with 2 different linear probes was used.
GE L8-18i-D Hockey Stick probe. ML 6-15-D Matrix probe.
Case presentation: A 36 year old male patient was referred to our rheumatological outpatient department because of localized pain in the left lateral part of the neck, which persisted over two days. Swallowing of fluids or solid food was painful, but unimpaired. The patient mentioned no recent trauma, but he reported symptoms of an upper respiratory tract infection, without fever, two weeks before. Clinical investigation showed no signs of local swelling or palpable lymph nodes. ENT consultation ruled out inflammatory processes causing the symptoms including tonsillitis, pharyngitis or laryngitis. Analgesic treatment with tramadol was not effective. Laboratory investigations revealed slightly increased CRP and Erythrocyte Sedimentation Rate (ESR) values. ANA and subsets, as well as ANCA were negative. An ultrasound of the region showed a localized swelling of the media and adventitia of the left common carotid artery, involving half of the circumference over a length of 4 mm. Multiple lymph nodes with signs of inflammation were present on both sides of the vessel. No dissection or stenosis was detectable. Due to a typical clinical presentation and ultrasound appearance without carotid stenosis, typical lokalisation at the distal part of the carotid communis artery the diagnosis of carotidynie or TIPIC was made. Treatment with nonsteroidal antirheumatic drugs was initiated without any effect. Therefore, we initiated a treatment with steroids (0,3mg/kg body weight). 3 days after the beginning of the therapy the before unbearable pain nearly resolved. A MRI angiography of the vessel performed 5 days after the inition of the steroid treatment showed an eccentric wall thickening with diameter of 5 mm near the bifurcation of the common carotid artery, with a slightly increased enhancement of the carotid wall, but no further inflammatory structures. Awareness of this syndrome and its excellent visualization for diagnosis, exclusion of other pathologies and follow up by high resolution ultrasound could be useful to reassure patients about the benign nature of this syndrome and help the clinician to avoid more invasive imaging modalities.
Conclusion: The disease is first reported by Fay in 1927. Despite only a few case reports are available in the last 20 years and mostly one case only is reported. Usually an inflammatory process is suspected. Although a rare event sonography is capable to diagnose such vessel abnormality with high precision. Treatment with NSAIDs and, if not sufficient, eventually steroids are required.

POS1382 DON'T TURN A BLIND EYE - ANTERIOR CIRCULATION STROKE IN GIANT CELL ARTERITIS

Keywords: Remission, bDMARD, Vasculitis

S. M. Lao[1], U. Dhamrah[1], W. Chi[1]. [1]*Icahn School of Medicine at Mount Sinai, Rheumatology, New York, United States of America*

Background: Giant cell arteritis (GCA) is a form of systemic vasculitis involving large and medium sized vessels. It is more common in women and affects adults greater than 50 years old. Typical presentations include insidious onset of headache, scalp tenderness, jaw claudication, visual changes, and constitutional symptoms. Stroke is an uncommon complication of GCA with an incidence rate of 3% - 7% and usually occurs between the onset of arteritis symptoms and one month after initiating steroid therapy. GCA related strokes usually involve the vertebrobasilar artery and less commonly the carotid artery.
Objectives: To discuss a patient with GCA progression to strokes despite steroid therapy.
Methods: A 77 year old female with a history of hypertension, diabetes, uterine and breast cancer in remission presented to the hospital with right eye vision loss. She reported two weeks of blurry vision in her right eye, bilateral temporal headache, jaw claudication, weight loss, and loss of appetite. She denied prior similar episodes. Exam revealed scalp and right temporal artery tenderness, right eye vision loss. She had equal radial and brachial pulses, and 5/5 strength in bilateral upper and lower extremities. Labs showed sedimentation rate >120 (ESR 0-38mm/hr) and C-reactive protein 62 (CRP 0-5 mg/L). Patient was started on intravenous (IV) methylprednisolone 1g daily for presumed GCA, then tapered and discharged on oral methylprednisolone 48mg (1mg/kg) daily. Temporal artery biopsy confirmed GCA showing patchy moderate chronic inflammation in the intima and media with small lymphocytes, macrophages, and rare giant cells. On follow up, she continued to have right eye vision loss but improvement of other GCA symptoms. Within one month of her initial presentation, she returns to the hospital for left sided weakness, facial droop, and dysarthria.
Results: She endorsed compliance with methylprednisolone, aspirin, and atorvastatin. Computerized tomography angiography (CTA) showed interval worsening of the severe stenosis of the clinoid segment of the right internal carotid artery (ICA) now with near occlusion. Labs with ESR 33, CRP <0.2. Exam with 4/5 strength in the left upper extremity (LUE) and left lower extremity (LLE). On hospital day 3, she had fluctuating weakness in the LUE and methylprednisolone was increased to 1g daily. Repeat CTA with stable severe focal stenosis of the right clinoid ICA. Cerebral angiogram showed multiple vessels in the anterior and posterior circulation with evidence of irregularity in the lumen suggestive of diffuse vasculitis but no evidence of atherosclerosis in the right ICA. On hospital day 6, weakness worsened in the proximal and distal LUE to 1/5 strength and LLE to 3/5 strength. Given concern for GCA progression she was started on IV tocilizumab 6mg/kg and had emergent angiography with right ICA angioplasty. Patient completed 5 days of IV methylprednisolone 1g and was tapered and discharged on methylprednisolone 48mg daily and tocilizumab 162mg subcutaneous weekly. On follow up she continues to improve; exam without facial droop, 5/5 upper extremity strength, and 3/5 lower extremity strength.
Conclusion: This highlights a rare case of GCA related stroke within the ICA territory despite being on high dose steroids. There was a diagnostic dilemma and the initial suspicion for GCA related stroke was low because the patient had been on high dose steroids for 3 weeks with normal inflammatory markers, but cerebral angiography confirmed the evidence of vasculitis. Progression of symptoms despite high dose steroids called for aggressive therapy with angioplasty until therapeutic effect of tocilizumab was achieved. Patient's response to therapy suggests that tocilizumab is effective for GCA related stroke.

POS1383 ANTI-TIF-1-Y DERMATOMYOSITIS IN OVERLAP WITH GREAT VESSEL VASCULITIS: A CASE REPORT

Keywords: Vasculitis, Myositis

F. D'alessandro[1], F. Fattorini[1], L. Carli[1], M. Cazzato[1], M. Mosca[1]. [1]*Santa Chiara Hospital, Rheumatology, Pisa, Italy*

Background: Dermatomyositis (DM) are systemic autoimmune diseases that are part of Idiopathic inflammatory myopathies. The peak incidence is at the age of 50–60 years. The DM-related autoantibodies Anti-TIF-1γ are found in DM associated with aggressive skin lesions. However, in adults above the age of 40, anti-TIF-1γ antibodies are strongly associated with malignancy [1].
Objectives: The aim of the work is to illustrate a difficult management of anti-TIF1-y dermatomyositis in overlap with great vessel vasculitis.
Methods: In January 2022 a 79-year-old woman suffering only from arterial hypertension was beginning to develop heliotropic and occipital rash, initially interpreted as an allergic reaction to an antihypertensive drug and treated with antihistamines without clinical benefit. Over the following weeks rhinolalia, mixed dysphagia, and Gottron's papules developed simultaneously. She performed a laryngoscopy excluding a deficit of the vocal cords. In the suspicion of esophageal diverticulosis performed X-ray with gastrografin, showing no alterations of the esophageal tract. The picture was related to a major depressive episode and antidepressant therapy was initiated. In May 2022 worsening of muscle symptoms led the patient to go to the hospital again, with subsequent transfer to our rheumatological department. She was cachectic, dysphagic, with hypostenia (MMT8 35/80) and skin rash typical for DM. Therefore, some investigations were ordered, showing:

- High titer positivity for anti-TIF1y, PL-12, SSA-Ro52
- Significant retention in the oro-pharyngeal region at swallowing study

- Edema of the pelvic girdle muscles, compatible with a picture of myositis in the phase of activity on magnetic resonance
- Increase CPK and inflammation indices in blood chemistry tests

Hence, a diagnosis of DM was performed. Because the recent onset of the disease, and for the association described in the literature between Anti-TIF1y and neoplastic disease, further investigations were required to exclude the paraneoplastic nature of the clinical picture. While waiting to conclude the investigations, therapy with intravenous pulse of glucocorticoids has been started (1.5mg/kg) with progressive decalage. Despite a predominantly cutaneous improvement, the symptoms progressively worsened by reducing the steroid below the threshold dose of 1mg/kg, with the appearance of a new cutaneous flare. During hospitalization, the patient showed a gradual increase in inflammation indices, associated with pancytopenia. After excluding an underlying hematological cause, FDG-PET was performed. It showed uptake of the drug in the ascending and arch of the thoracic aorta, and both subclavian arteries. In order to exclude infectious causes of aortitis, in-depth examinations were performed, with negative results (HIV, syphilis).

Results: The finding of vascular uptake despite therapy with intravenous pulse of glucocorticoids, the absence of infections and the clinical symptoms led us to diagnose dermatomyositis overlapping with vasculitis of the great vessels.

Conclusion: Our case represents the first description of overlap between these two diseases within 5 months of clinical onset. Therefore, we decided to initiate therapy with intravenous pulse of glucocorticoids (2mg/kg) with progressive tapering, associating it with IntraVenous ImmunoGlobulin (IVIG) and periodic intravenous immunosuppressive therapy with Cyclophosphamide (CFX), since the efficacy of these drugs was demonstrated both on systemic vasculitis and on DM. After the first days of combination therapy, the patient showed marked improvement in the muscles and skin, regaining the ability to eat and being able to resume daily activities (MMT8 70/80).

HPR Professional education, training and competencies

POS1384-HPR THE FUTURE OF PATIENT EDUCATION: DESIGN FOR A WEB PLATFORM FOR EDUCATION IN RHEUMATOID ARTHRITIS

Keywords: Education, Patient information and education, Patient reported outcomes

G. S. Rodríguez-Vargas[1], F. Rodriguez[2], N. Pinto-Florez[3], L. Realpe[3], A. Rojas-Villarraga[4], P. Santos-Moreno[1]. [1]*BIOMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia*; [2]*BIOMAB - Center for Rheumatoid Arthritis, Patients Education, Bogotá, Colombia*; [3]*UniversitAR, Expert Patient, Bogotá, Colombia*; [4]*Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: In 2018, a multi-component educational program called UniversitAR was launched. This program was aimed at patients diagnosed with Rheumatoid Arthritis. In the process of training the patients, topics such as clinimetry, comprehensive treatment of the disease, healthy lifestyles, and the enhancement of personal and interaction skills were included. After 3 years of implementation of this program, the certification of 91 expert patients in rheumatoid arthritis was achieved. However, there is a major challenge for health education to have a greater reach for the entire population.

Objectives: The objective of this study is to design a digital education platform, with reach for patients in any country in Latin America and the Caribbean and with a thematic content that is effective for the care of their disease and the improvement of their quality of life.

Methods: A review and digital adaptation of the 3 educational levels of UniversitAR was made. It was considered feasible to maintain the 3 levels of education to respect the criteria of social inclusion, which is a fundamental principle of the multicomponent educational program (Level 1: Basic Knowledge of the Disease Program, Level 2: Patient Empowerment Program for Effective Self-Management of the Disease and Level 3: Expert Patient Program). Contents were updated, the total training time was reduced and evaluation and measurement criteria were added for each educational level. A total of 104 educational sessions were reviewed, as well as the measurements included in the training process in aspects such as: the level of disease activity, autonomy and independence, quality of life and satisfaction with the educational program.

Results: The multicomponent educational program was reconstructed, reducing the educational program from 104 to 84 educational sessions and minimizing the academic intervention times in each session. The total estimated training time for the patient went from 22 months to be carried out in a period between 8 months and 1 year, considering that it will be the patient who will decide the number of sessions they want to see per day. In December 2022, an event for patients with Rheumatoid Arthritis was held and a demo of the platform was presented. The official launch of this digital educational program will be in the third quarter of 2023 and the training of 600 patients is expected this year.

Figure 1. Description of the multi-component educational program web platform

Conclusion: The creation of alternatives that facilitate the education of patients, such as digital platforms, are very important strategies that allow reaching the population, since this breaks down access barriers such as: the geographical location of the patient with respect to their place of training, mobility limitations and out-of-pocket expenses incurred to attend your training sessions.

POS1385-HPR ARTIFICIAL INTELLIGENCE APPROACHES FOR RHEUMATOLOGY PRACTICE: RESULTS FROM AN INTERNATIONAL E-SURVEY OF THE DIGITAL RHEUMATOLOGY NETWORK

Keywords: Artificial intelligence

V. Venerito[1], L. Gupta[2,3,4], V. Agarwal[5], J. Knitza[6], T. D. R. N. [7], T. Hügle[8]. [1]*University of Bari, Rheumatology Unit - Department of Precision and Regenerative Medicina and Ionian Area, Bari, Italy*; [2]*Royal Wolverhampton Hospitals NHS Trust, Department of Rheumatology, Wolverhampton, United Kingdom*; [3]*City Hospital, Sandwell and West Birmingham Hospitals NHS Trust, Department of Rheumatology, Birmingham, United Kingdom*; [4]*The University of Manchester, Division of Musculoskeletal and Dermatological Sciences, Centre for Musculoskeletal Research, School of Biological Sciences, Manchester, United Kingdom*; [5]*Sanjay Gandhi Postgraduate institute of medical sciences, Department of Clinical Immunology and Rheumatology, Lucknow, India*; [6]*Friedrich-Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3 - Rheumatology and Immunology, Erlangen, Germany*; [7]*The Digital Rheumatology Network, Working Group, Lausanne, Switzerland*; [8]*University Hospital Lausanne (CHUV), Switzerland, Department of Rheumatology, Lausanne, Switzerland*

Background: Artificial Intelligence (AI) is emerging as a promising tool to improve clinical decision-making and enhancing patient care. In rheumatology, AI may enable precision medicine, allowing patient profiling, prediction and treatment personalization [1]. Healthcare professionals' (HPs') perceptions regarding implementation of AI in rheumatology have been not investigated sufficiently so far.

Objectives: This international e-survey aimed to evaluate healthcare professionals' attitudes towards AI's potential benefits in managing patients with rheumatic diseases.

Methods: An online self-reported questionnaire (August 2022-December 2022) promoted using social media platforms was used to capture data on the knowledge of state-of-the-art AI methods. We evaluated attitudes, perceptions and expectations related to AI-powered clinical prediction modelling, computer vision and natural language processing (NLP) on e-health records (EHR). Univariate logistic regression was used to explore associations between demographic

characteristcs of participants and their trust in machine learning and AI (Figure 1, panel A, expressed as a boolean.variable).

Results: Fifty-nine HPs (male n.36/58 respondents, 37.93%, 1 skipped) of mean age (±SD) 37.55 ± 10.12 years at a mean of 12.33 ± 10.54 years since graduation were considered for the analysis. Fifty-two out of 59 were specialists (88.14%), the largest part working in University Hospitals (45/58, 77.59%, 1 skipped). Thirty-seven out of 59 (62.71%) declared an open attitude in adopting machine learning tools for clinical prediction modelling for rheumatoid arthritis patients (Figure 1, Panel B). More than half of the respondents were interested in a prediction horizon of ≥1 year (33/59, 55.93%, Figure 1 Panel C). The vast majority (51/59, 86.44%) liked having an AI-powered clinical prediction embedded in EHRs, preferring disease activity scores as the target outcome (54/59, 91.53%). Consistently, most of the participants considered that clustering algorithms assigning patients to phenotypes have room in clinical practice, (45/59, 76.27%) especially in treatments selection (46/58, 79.31%, 1 skipped) and early arthritis management (37/59, 63.79%). Computer vision algorithms were considered of particular interest for the detection of erosions (39/59, 66.1%). Most of the participants agreed that machine learning could be beneficial to extract information from EHR (52/58, 89.66%). In particular, NLP was seen as a tool for capturing longitudinal changes among critical patient outcomes (36/54, 66.67%, 4 skipped) and for Reducing diagnostic delay by promptly identifying symptoms in primary care EHRs 36/58, 62.07%, 1 skipped). In general about an half of respondents (33/58, 56.90%), considered machine learning-based prediction as more powerful than conventional statistics in terms of clinical predictive modelling, especially for the potential of providing more sensitive analysis and identify smaller contributing variables (39/57, 68.42%). Neither age, gender, and time from degree were associated with trust in machine learning.

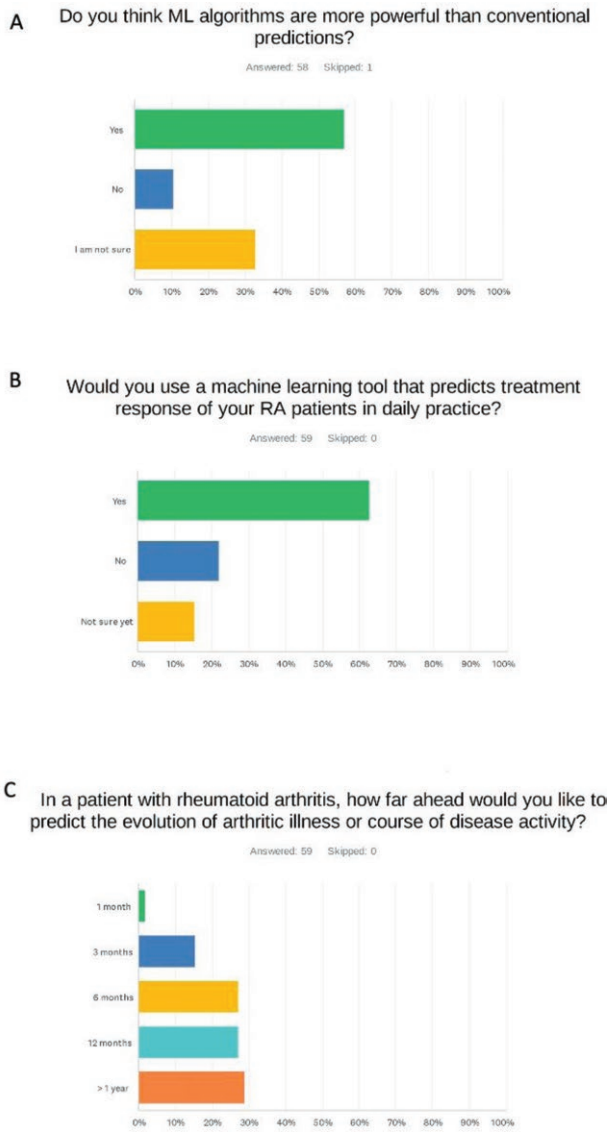

Figure 1. Participants answers to relevant questions.

Conclusion: The participants of this international survey showed an open and optimistic attitude regarding AI implementation in clinical rheumatology. Expectations were mainly centered on improving patient management by allowing for accurate mid-to-long term prognosis.

POS1386-HPR

EFFECTIVENESS OF SUBCUTANEOUS METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS PERSISTENCE IN THE LONG TERM

Keywords: Rheumatoid arthritis, Disease-modifying drugs (DMARDs)

L. Villarreal[1], N. Gutiérrez[2], P. Rodríguez-Linares[3], M. Cardozo[4], A. Rojas-Villarraga[5], P. Santos-Moreno[3]. *[1]BIOMAB - Center for Rheumatoid Arthritis, Asistencial Direction, Bogotá, Colombia*; *[2]BIOMAB - Center for Rheumatoid Arthritis, Clinical Reports, Bogotá, Colombia*; *[3]BIOMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia*; *[4]Pharmalab Laboratories, Medical Direction, Bogotá, Colombia*; *[5]Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: Methotrexate (MTX) has been established as the headstone of treatment for rheumatoid arthritis (RA). However, many patients treated with oral MTX experience adverse events. For this reason, new forms have been developed, such as the subcutaneous presentation in a prefilled syringe, which improve tolerance, adherence and response to treatment.

Objectives: The aim of this study is to describe the effectiveness of treatment with subcutaneous MTX (SC MTX) in a prefilled syringe in a reference center for the management of patients with RA and the persistence of treatment during 5 years of follow-up.

Methods: Retrospective observational cohort study (1-Jan-2018 and 31-Dec-2022) in patients with RA, with more than one year of treatment with MTX SC; Patients <12 months with MTX SC and those who had concomitant biological therapies were excluded. Response to treatment was analyzed by DAS28.

Results: 1062 patients treated with MTX SC were analyzed. At the time of analysis, 877 patients persisted in treatment and 185 abandoned due to adverse events (17.4%). 190 received it as monotherapy, 285 in combination with other conventional DMARDs, 184 with a corticosteroid, and 218 with cDMARDs and a corticosteroid. 368 (42%) started therapy due to intolerance to the oral formulation, 20 (2.3%) received the 7.5 mg dose, 114 (13%) 10 mg and 234 (26.7%) 15 mg, while 509 patients (58%) did so to optimize the dose, 259 (29.5%) with 20mg and 250 (28.5%) with 25mg. At one year of follow-up, there was an increase in the number of patients who achieved low disease activity [573 (65.3%) remission and 139 (15.85%) low activity] and there was a decrease in patients with moderate activity and high (Figure 1). Of the 877 patients, 27.6% have remained in treatment between 12 and 24 months, 18.8% between 25 and 36, 19% between 37 and 48, and 34.5% for more than 48 months. Over the 5 years, a gradual increase in the percentage of patients achieving low disease activity is observed (Figure 2).

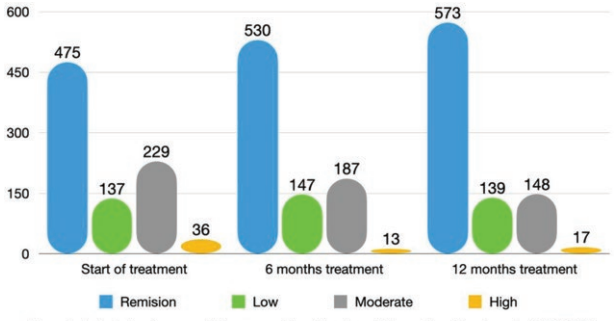

Figure 1. Patients by disease activity group at baseline, 6, and 12 months of treatment with MTX SC

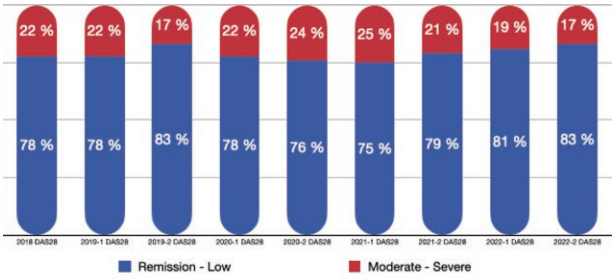

Figure 2. Persistence of the effectiveness of subcutaneous methotrexate over 5 years

Conclusion: This study shows high effectiveness of treatment with MTX SC in patients with RA; an increase in the percentage of patients who achieved remission was observed, with low treatment abandonment rates. After 5 years of follow-up, high persistence rates are observed. This makes MTX SC an excellent alternative for patients with intolerance or insufficient response to oral MTX.

POS1387-HPR THE IMPACT OF PSYCHOEMOTIONAL MOOD DISORDERS ON MUSCULOSKELETAL PAIN IN PATIENTS WITH INFLAMMATORY JOINT DISEASES

Keywords: Pain, Prognostic factors, Quality of life

S. Bogdanova-Petrova[1], T. Shivacheva[1], T. Georgiev[1], S. Dimitrov[1], R. Moraliyska[2], S. Hristova[3], G. Gerganov[4], M. Dimova-Mileva[5], P. Petrov[6]. *[1]Medical University Varna, First Department of Internal Medicine, Varna, Bulgaria; [2]Medical University Varna, Clinical Medical Sciences, Varna, Bulgaria; [3]Medical University Varna, Family Medicine, Varna, Bulgaria; [4]Medical University Varna, Propedeutic of Internal Medicine, Varna, Bulgaria; [5]Medical University Varna, Propedeutic of Internal Medicine, Varna, Bulgaria; [6]Medical University Varna, Psychiatry and Medical Psychology, Varna, Bulgaria*

Background: Chronic inflammatory joint diseases such as rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) are most common rheumatic diseases that may cause musculoskeletal pain [1]. The genesis of pain is very complex and many different mechanisms are involved. It is the result of multiple biochemical reactions and is influenced to varying degrees by biological, physiological and social factors. (2) The presence of pain is largely determined by the inflammatory activity of the underlying disease, but subjective factors that depend on the psycho-emotional state of the patient are involved in the assessment of the severity of pain symptoms [3].

Objectives: The aim of the study is to assess the intensity of musculoskeletal pain - arthralgia and myalgia and its correlation with anxiety and depressive mood disorders among a Bulgarian cohort of patients with chronic inflammatory diseases.

Methods: A single-center, observational study including patients with RA, AS and PsA, dispensary in the Rheumatology clinic, "St. Marina" UMBAL - Varna. All the patients were diagnosed according to the criteria for the specific inflammatory joint disease and were treated with a biological medication. Visual analogue scales (VAS) to assess pain intensity (muscular and joint) and Zung self-report scales for depression (SDS) and anxiety (SAS) were used. Laboratory acute phase indicators were investigated in all patients. Descriptive statistics, one-Sample T test, correlation and linear regression analyses were used. A significance level of p<0.01 was accepted.

Results: 130 patients with inflammatory joint disease (RA, AS, PsA), were included in the study. The average age of the study population was 56.37 years (from 21-76 years). 41.5% (n=54) of them were women, 58.5% (n=76) were men. No significant differences were found in evaluating the visual-analog scales for assessing joint and muscle pain between men and women (p=0.177 for joint pain and p=0.717 for muscular pain). On the other hand women scored higher on the anxiety and depression scales, and the difference was again significant (p<0.001 for the depression scale and p=0.001 for the anxiety scale). The self-assessment on the depression scale (SDS) shows a significant correlation with the self-assessment of muscle and joint pain, but the self-reported anxiety scale (SAS) showed a significant correlation only with the self-reported joint pain (SDS and VASm, p=0.008; SDS and VASa, p<0.001; SAS and VASm, p=0.031, SAS and VASa, p=0.004 respectively). Inflammatory indicators (predictors) determine about 8% of the variation of the two pain indicators - for joint pain - R square 7.8%, for muscle pain - R square 8.1%

Conclusion: Musculoskeletal pain is one of the most common clinical presentations of inflammatory join diseases. Chronic pain can lead to mood disorder. The intensity of the pain correlates with anxiety and depressive symptoms in these patients.

POS1388-HPR RELATIONSHIP BETWEEN CENTRAL SENSITIZATION AND PSYCHOLOGICAL FACTORS IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL, MULTICENTER STUDY

Keywords: Rheumatoid arthritis, Quality of life, Patient reported outcomes

F. R. Spinelli[1], L. Quartuccio[2], S. Farah[3], C. Bazzani[4], F. Nacci[5], M. Fornaro[6], D. Iacono[7], C. Baldi[8], S. Perniola[9], S. Longhino[2], F. Salaffi[3]. *[1]Rheumatology Unit, Sapienza Università di Roma, Dipartimento di Scienze Cliniche Internistiche, Anestesiologiche e Cardiovascolari-Reumatologia, Roma, Italy; [2]Division of Rheumatology, Academic Hospital "Santa Maria della Misericordia", ASUFC, Department of Medicine (DAME), Udine, Italy; [3]Rheumatology Clinic, Università Politecnica delle Marche, Dipartimento Di Scienze Cliniche e Molecolari, Ospedale "Carlo Urbani", Jesi, Italy; [4]U.O. Reumatologia e Immunologia Clinica, ASST Spedali Civili di Brescia, Brescia, Italy; [5]SODc Reumatologia, Dipartimento di Medicina Sperimentale e Clinica Azienda Ospedaliero Universitaria Careggi, Firenze, Italy; [6]Rheumatology Unit, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy; [7]Unità Operativa di Reumatologia, Dipartimento di Medicina di precisione, Università degli Studi della Campania, Napoli, Italy; [8]Rheumatology Unit - Siena University Hospital, Department of Medicine, Surgery and Neurosciences, Siena, Italy; [9]Division of Clinical Immunology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy*

Background: Affective distress (clinically significant depression, anxiety and stress) and central sensitization (CS) are consistently associated with the reported sensitivity and severity of pain, physical disability, poor treatment outcomes, and inflammatory disease activity, and potentially with early mortality in rheumatoid arthritis (RA).

Objectives: We aimed to explore affective distress in patients with RA and determine how they connected to CS.

Methods: Used the CSI to measure CS and the Depression, Anxiety and Stress Scale - 21 Items (DASS-21) to evaluate the negative emotional states of depression, anxiety and stress. The total CSI score ranges from 0 to 100, and a score of 40 or greater has been established to indicate CS. Each of the three DASS-21 scales contains 7 items, divided into subscales with similar content. Multiple regression analysis was used to find out which factors were most likely to be linked to CS.

Results: Overall we included 192 RA patients (age ranging from 22 to 86 years) with a mean disease duration of 5.95 (SD 13.75) years. The CSI score was ≥ 40 in 70/192 patients (36.5%). In our RA cohort, the DASS-21 total score was 32.3 (SD29.8). The mean Anxiety score (Mean=10.68 and SD=8.92 was in the moderate range (10-14), whereas the mean Depression (Mean = 10.11 and SD = 11.66) and Stress (Mean = 15.8 and SD=12.05) scores were in the mild range (10-13 and 15-18, respectively). In the 70 patients with CSI score > 40, the mean Anxiety score (Mean=12.20 and SD=10.01) and the mean Depression (Mean = 14.01 and SD = 13.83) and Stress (Mean = 19.51 and SD=12.77) scores were all in the moderate range (10-14, 14-20 and 19-25, respectively).

Conclusion: Affective distress symptoms (clinically significant depression, anxiety and stress) and CS are common in RA patients. Screening and recognition of such psychosocial disorders may help patients achieve optimal disease control and a good outcome. Overall, our findings have implications for health policy and emphasize the significance of identifying high-risk fibromyalgia (FM) patients by monitoring CS as an indicator of severe disease.

HPR Epidemiology and public health (including prevention)

POS1389-HPR AGE-SUBSET INCIDENCE AND PREVALENCE ANALYSIS OF JUVENILE SYSTEMIC SCLEROSIS IN THE UNITED STATES

Keywords: Real-world evidence, Systemic sclerosis, Epidemiology

J. Mattson[1], H. Bao[2], M. Flack[3], K. Coeytaux[2]. [1]*Boehringer Ingelheim Pharmaceuticals Inc., Clinical Development Medical Affairs, Connecticut, United States of America*; [2]*Boehringer Ingelheim Pharmaceuticals Inc., Global Epidemiology and RWE Center of Excellence, Connecticut, United States of America*; [3]*Boehringer Ingelheim Pharmaceuticals Inc., Medicine, Inflammation, Connecticut, United States of America*

Background: Juvenile systemic sclerosis (jSSc) is an extremely rare orphan disease. To date, there is very limited published data regarding incidence and prevalence of jSSc. Specifically, there are no published data on jSSc incidence rates by age group and only one Columbian report of jSSc prevalence rates by age group. These data are important given the significant developmental differences between age subsets.
Objectives: To evaluate jSSc age-subset incidence and prevalence using U.S. administrative claims data.
Methods: Children <18 years old with medical claims for SSc and who received methotrexate, mycophenolate mofetil, or cyclophosphamide at a pediatric age (<18 years old) were identified from the OPTUM Clinformatics claims database 2007-2021. jSSc patients were identified using ≥2 medical claims (710.1, 517.2 for ICD-9-CM codes and M34, M34.x for ICD-10-CM codes) for SSc on different dates within a 1-year period. Incidence and prevalence were estimated overall, by age group, and were age and sex adjusted using 2020 US census data.
Results: Adjusted incidence and prevalence estimates are presented in the table below. Overall, jSSc incidence and prevalence rates among children in the US were 1.4 per million person-years (PY) and 7.3 per million, respectively. Both incidence and prevalence rates increased with age.

Table 1.

Age	Adjusted incidence per 1,000,000PY	Adjusted prevalence per 1,000,000
Overall (0-≤18)	1.4 (0.9, 1.9)	7.3 (5.5, 9.1)
0-<6	0.6 (<0.01, 1.4)	0.6 (<0.01, 1.4)
6-<10	0.5 (<0.01, 1.1)	3.1 (0.6, 5.6)
10-<12	1.7 (0.03, 3.3)	5.2 (0.6, 9.7)
12-<18	2.7 (1.5, 3.8)	16.6 (12, 21.3)

Conclusion: jSSc is an extremely rare disease with incidence and prevalence rates increasing with age. Specifically, incidence and prevalence rates vary dramatically for different age subsets, with increasing rates at 10 years and older. To our knowledge, this is the first study to estimate jSSc incidence and prevalence rates by age group.

POS1390-HPR LUPUS NEPHRITIS PROFILE IN TUNISIAN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Keywords: Systemic lupus erythematosus, Autoantibodies, Clinical trials

M. Cherichi[1], Y. Boussoukaya[1], M. Elghali[2], N. Sakly[2], M. Jguirim[3], S. Hammami[1]. [1]*Fattouma Bourguiba University Hospital, Internal Medicine Department, Monastir,Tunisia*; [2]*Fattouma Bourguiba University Hospital, Immunology Laboratory Depatment, Monastir,Tunisia*; [3]*Fattouma Bourguiba University Hospital, Rhumatology Department, Monastir,Tunisia*

Background: Lupus Nephritis(LN) is associated with morbidity and worse survival and its clinical, the immunological and the follow-up profile varies between studies due to race and ethnicities differences. Previous studies have evaluated clinical and immunological factors associated with LN. only few studies were done in the north African region.
Objectives: To define clinical, immunological and treatment differences according to the presence of lupus nephritis (LN) in tunisian Systemic Lupus Erythematosus (SLE) patients.
Methods: We studied SLE 141 patients. A clinical examination and a laboratory evaluation were performed in all SLE patients at the onset of the disease.
Results: Of all patients, 26.24% presented LN. The mean age of patients with LN was lower than patients without LN (34.3 ±14.61 years vs 40.46 ±14.94 years). LN was associated with pleural effusion, pericarditis, higher SLEDAI score, higher levels of creatinine and proteinuria, lower rate of glomerular filtration, anemia, leukopenia, thrombocytopenia, necessity of immunosuppressive drugs, antibodies such as anti-dsDNA, anti-Sm, anti-Sm/RNP and anti-SSA/La. In terms of renal histopathological findings, when we combined class IV and V (profilerative nephritis), we found that this form was more prevalent (56.8%) and associated with higher rate of proteinuria, C-reactive protein and necessity of immunosuprissive drugs.
Conclusion: The north African studies in the term of Lupus Nephritis are scarce. Nonetheless, severe forms seem to be frequent with a high prevalence of proliferative nephritis in our study. Pleural effusion, anti-dsDNA positivity, leukopenia and thrombocytopenia are the predective factors to develop LN.

POS1391-HPR HEALTH PROFILE AND QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A BRAZILIAN CITIZENS SURVEY

Keywords: Epidemiology, Systemic lupus erythematosus, Quality of life

P. Santana[1], I. M. B. De Souza[1], M. Antunes[1], M. Pinheiro[1], A. Cruz[1], P. Januário[1], A. Pasqual Marques[1]. [1]*University of São Paulo, Department of Physical Therapy, Audiology and Speech Pathology and Occupational Therapy, Medical School at University of São Paulo., Sao Paulo, Brazil*

Background: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory disease, multisystemic, of unknown cause, autoimmune, with periods of exacerbations and remissions, which may generate limitations in functional and occupational capacity. Brazil has high prevalence rates of SLE (20 to 150 cases per 100,000 inhabitants). The survival rate of these patients has increased in the last century (from 50% to 95%). This context raises questions about the social, health, and quality of life profile of the patient.
Objectives: To profile and evaluate the quality of life of patients with SLE residing in Brazil.
Methods: This is a cross-sectional study, in subjects aged ≥18 years, diagnosed with SLE and residing in Brazil. We applied online form through Google Forms and collected sociodemographic (age, sex, marital status, years of study, occupational activity, and self-reported race), clinical (Body Mass Index (BMI), duration of disease, presence of comorbidities and use of corticosteroids) and quality of life data through the Systemic Lupus Erythematosus Quality of Life (SLEQOL). Data analysis was descriptive (mean, sample standard deviation, and percentage).
Results: 642 volunteers were female (98.29%), aged between 18 and 73 years, and BMI of 27.3 ± 45.8. Greater representation from the Southeast region (60.12%); self-reported white race (54.98%); married marital status (39.88%), education with ≥12 years of schooling (64.64%), have already withdrawn from occupational activity (74.92%) and changed profession after SLE diagnosis (37.85%). The duration of SLE was ≥ 5 years (45.64%) and they have other diagnosed comorbidities (63.24%), and they use corticoid (62.62%). Quality of life had a score of 137.72 ± 51.89, closer to the minimum score (minimum score = 40 and maximum = 280; whereby, higher values correspond to worse quality of life).
Conclusion: Most of the sample are female as already pointed out in other studies; the most recurrent self-reported race was white, unlike studies that the Afro-descendant race was more frequent. Throughout their illness, patients encounter physical, psychological, and social challenges, reflecting on their functional capacity, interfering with occupational activity (leaves of absence and sometimes changing professions) even with education ≥12 years of study. These changes can interfere with health-related quality of life. Care strategies aimed at decreasing the impact of the disease for the patient and his family are needed; as

well as, future studies to explore non-drug therapeutic resources for an integral care of the patient.

HPR Interventions (educational, physical, social and psychological)

POS1392-HPR EFFECTS OF DIGITAL-BASED HIGH-INTENSITY TRAINING INTERVENTION IN INDIVIDUALS WITH AXIAL SPONDYLOARTHRITIS – A RANDOMIZED CONTROLLED PILOT STUDY (RCT)

Keywords: Spondyloarthritis, Non-pharmacological interventions

A. Torell[1], M. C. Olsson[2], Å. Andersson[2], K. Malm[3], I. Åberg[3], E. Wiking[3], E. Haglund[2,4,5]. *[1]Ängelholm Hospital, Dept. of Rehabilitation, Ängelholm, Sweden*; *[2]Halmstad University, Dept. of Environmental and Biosciences, School of Business, Innovation and Sustainability, Halmstad, Sweden*; *[3]Capio Movement, Dept. of Rheumatology, Halmstad, Sweden*; *[4]Lund University, Dept. of Clinical Sciences, Section of Rheumatology, Lund, Sweden*; *[5]Spenshults Research and Development Centre,., Halmstad, Sweden*

Background: Physical exercise is an important treatment for individuals with axial spondyloarthritis (axSpA). Although high-intensity training (HIT) has been shown to reduce disease symptoms and risk of comorbidity without exacerbating disease activity (1), compliance tends to decrease over time. Increased knowledge is needed on how to optimize and tailor individual exercise programs for continued regular exercising and improved health.

Objectives: To study the effects of HIT on aerobic capacity, body composition, disease activity, physical function, health status and fatigue in individuals with axSpA after a 12-week intervention supported by digital coaching.

Methods: Twenty-two individuals (women, n=12), recruited from two rheumatology clinics in southern Sweden, were randomized to a HIT intervention group (HG; n=11) or a control group (CG; n=11). The HG completed three HIT sessions/week, including two interval training sessions (4x4 min), in self-selected activities for 12 weeks. The individuals in the HG were individually coached and had regular support from a physical therapist primarily by digital coaching. The CG continued exercising as usual. Assessment of aerobic capacity (VO2max), body composition (BMI and visceral fat area [cm2]), disease activity (CRP [µg/ml], BASDAI, 0-10 best-worst), physical function (BASFI, 0-10 best-worst), health status (EQ5D, 0-1 worst-best, ASAS health index [ASAS-HI], 0-17 best-worst), and fatigue (fatigue severity scale [FFS], 0-7 best-worst) were sampled at baseline and after 12 weeks. Mean and standard deviation (SD) were used for descriptive statistics. Repeated measures analysis of variance (ANOVA) was used to investigate effect of group (HG*CG) and time (PRE*POST), with a post-hoc analysis using t-tests when ANOVA indicated a significant difference in main effects or interactions. A significance level of $p \leq 0.05$ was used. Fisher´s exact test was used to study the effects over time for CRP (as dichotomized variable, > or < 4 µg/ml).

Results: Results presented are part of an ongoing RCT based on 19 individuals (women n=11) that have completed the 12-week follow-up analyses. The participants mean (SD) age was 48 (10) years, BMI 25 (4), VO2max 37 (6) mlO2/kg/min, and BASDAI 2.6 (0.3). No differences were present between the HG (n=9) and the CG group (n=10) at baseline for the studied variables. After 12 weeks of HIT an ANOVA interaction ($p<0.05$ showed that HG increased their VO2max (6.4 [3.6] mlO2/kg/min; $p<0.001$) but CG did not. For BMI, visceral fat area, disease activity (BASDAI), physical function (BASFI), fatigue (FFS) no differences in main effects or interactions were found ($p>0.05$). Health status (EQ5D) showed an ANOVA time main effect ($p=0.007$) where the HG increased their health status (0.10 [0.06] units; $p=0.02$) after 12-weeks, but CG did not. For health status measured with ASAS-HI no differences between groups were found. For dichotomized CRP-values no differences were found in either of the group's pre-post.

Conclusion: This pilot RCT shows that after 12 weeks of digital-based HIT intervention, the HG increased their aerobic capacity and EQ5D health status compared to CG, while body composition, disease activity, physical function, and fatigue did not show any significant differences between the groups.

POS1393-HPR THE INTERVENTION OF AN EXPERT PATIENTS GROUP IN RHEUMATOID ARTHRITIS IN AN INTEGRAL HEALTH MANAGEMENT MODEL

Keywords: Rheumatoid arthritis, Self-management, Patient information and education

F. Rodriguez[1], G. S. Rodríguez-Vargas[2], N. Pinto-Florez[3], L. Realpe[3], P. Rodríguez-Linares[2], A. Rojas-Villarraga[4], P. Santos-Moreno[2]. *[1]BIOMAB, Patients Education, Bogotá, Colombia*; *[2]BIOMAB, Scientific Direction, Bogotá, Colombia*; *[3]UniversitAR, Expert Patient, Bogotá, Colombia*; *[4]Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: Education for patients is a powerful tool that allows them to participate more efficiently in the relationship with their medical teams and to generate high adherence to their therapy. However, there is a high possibility of establishing lasting relationships between medical teams and patients thanks to the intermediation of expert patients. An expert patient is a person who has received education for the care of their health condition, the improvement of the relationship with their medical team and has been trained to educate, guide and support other patients who have the same health condition.

Objectives: The objective of this study is to implement a participation model that integrates expert patients into healthcare teams so that they can help other patients to learn about the benefits of a correct relationship between doctor and patient and to be more adherent to their treatment, becoming thus in a support axis in the medical care model.

Methods: After the training and certification of 50 expert patients in Rheumatoid Arthritis, a review of the literature was carried out to demonstrate intervention strategies in which expert patients have leadership roles and are integrated into comprehensive medical care models. Then, the patients received training dedicated to: knowledge of the health care model, the algorithm used for the intervention of the interdisciplinary team, the importance of therapeutic adherence in the treatment of a chronic disease, clinimetry and the characterization of patients. to determine a treatment by objectives (Treat to Target Strategy). Finally, expert patients were trained so that they can establish effective communication strategies with other patients in real time.

Results: The intervention will be carried out in groups between 2 and 3 patients and they will be able to interact with other patients in the medical center in a group or individual way. Expert patients will exchange experiences, resolve concerns, conduct literacy, and provide feedback to the medical team and other relevant information (see Figure 1). Likewise, a data collection will be carried out in each interaction to determine through a qualitative study the impact of the support of the expert patients. The duration of each day of intervention will be 6 hours, which denotes a reach of 72 patients per day and an impact on nearly 1,400 patients who come to the medical center per month.

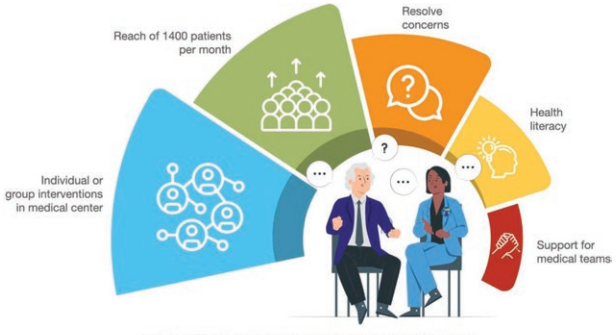

Figure 1: Intervention method of expert patients in care model

Conclusion: It is important to create strategies that allow the education of patients towards therapeutic adherence and integrate them into healthcare teams, since the inclusion of expert patients in medical care models can generate high impacts on the doctor-patient relationship and improve the degrees of adherence in the population, thanks to the relationship between peers that will lead to a better understanding of the role of patients in their treatment.

POS1394-HPR **WITHDRAWN**

POS1395-HPR **EMOTIONAL INTELLIGENCE: A NOVEL OUTCOME ASSOCIATED WITH QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS**

Keywords: Systemic sclerosis, Quality of life

D. Karagianni[1], D. Bogdanos[1], L. Sakkas[1]. *[1]Faculty of Medicine, University of Thessaly, Department of Rheumatology and Clinical Immunology, University General Hospital of Larissa, Larissa, Greece*

Background: Health related quality of life (HrQoL) in patients with systemic sclerosis (SSc), a systemic autoimmune disease, is severely impaired. Patients suffer from Raynaud's phenomenon, stiff hands, tight skin, pruritus, difficulty in swallowing, gastrointestinal disturbances, dyspnoea on exertion, and depression, significantly affecting their HrQoL. While several studies have addressed HrQoL in patients with SSc, no studies so far have investigated the trait emotional intelligence (TEI) of these patients.

Objectives: To investigate for the first time whether HrQoL of SSc patients is influenced by TEI in a cross-sectional study.

Methods: Sixty patients with SSc (Female: 86.67%) completed three questionnaires: TEI Questionnaire Short-Form (TEIQue-SF); Short-Form Health Survey (SF-36); and demographic characteristics. A series of multiple linear regression models were used to analyze the data with dependent variables (DV) every dimension of SF-36 (Physical Functioning, Role-Physical, Bodily Pain, General Health, Vitality, Social Functioning, Role-Emotional, Mental Health) and independent variables TEI total and every TEI factor (Well-being, Self-control, Emotionality, Sociability).

Results: The average age of participants was 56.4±13.4 years and the mean disease duration was 7.7±7.5 years. TEI total was found to affect both physical and mental component summaries ($p<0.001$) and all 8 dimensions of the HrQoL ($p<0.001$). Well-being appeared to have a positive effect on Role-Physical, General Health, Vitality, Social Functioning and Mental Health. Self-control appeared to influence Physical Functioning and Pain, and Emotionality appeared to influence Role-Emotional. Sociability was not an important factor for any dimension of HrQoL (Table 1).

Conclusion: Understanding the relationship between TEI and HrQoL dimensions is important for the support and empowerment of SSc patients, as well as the establishment and implementation of appropriate psychotherapeutic interventions.

Table1. Multiple linear regression analyses results for elements of the TEI and HrQoL dimensions

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

POS1396-HPR **DOES FIBROMYALGIA WORSEN CATASTROPHIZING IN PATIENTS WITH RHEUMATOID ARTHRITIS?**

Keywords: Fibromyalgia, Rheumatoid arthritis

H. Boussaa[1], O. Hamdi[1], S. Miladi[1], H. Ben Ayed[1], L. Souabni[1], K. Ouenniche[1], S. Kassab[1], S. Chekili[1], K. Ben Abdelghani[1], F. Alia[1], A. Laatar[1]. *[1]Mongi Slim hospital, Rheumatology, Tunisia, Tunisia*

Background: Pain is a cardinal symptom of several rheumatic conditions such as rheumatoid arthritis (RA) and fibromyalgia. Catastrophizing incorporates an amplification of symptoms associated with pain, and therefore contributes to its sustainability.

Objectives: We aimed to assess the impact of RA-associated fibromyalgia on catastrophizing.

Methods: We conducted a cross-sectional study including RA patients meeting the 2010 ACR/EULAR criteria. Patients were divided into two groups: group 1 (G1) including patients with fibromyalgia associated to RA, and group 2 (G2) including patients with RA. Fibromyalgia screening was based on the Fibromyalgia Rapid Screening Tool (FIRST). RA activity was assessed using the Disease Activity Score (DAS_{28} ESR). Quality of life was assessed using the Health Assessment Questionnaire (HAQ). Catastrophizing was assessed using the Pain Catastrophizing Scale (PCS), which is composed of 13 items. The PCS total score varies between 0 (absence of catastrophizing) to 52 (significant tendency to catastrophizing). The cognitive and emotional representation of pain was assessed by the Brief

Perception Illness Score (BPIS). It consists of 9 items: 8 quantitative questions on a numerical scale ranging from 0 to 10, and one last item in the form of a qualitative question. The total score varies from 0 to 90, without predefined thresholds. The higher the score, the more threatening the patient's perception of the disease is. The significance threshold was set at a p value of 0.05.

Results: Our study included 80 patients (G1: N= 40 and G2: N=40), 76 women and 4 men, with an average age of 59±9 years [42-77] in G1 and 53±10 years in G2 [37-74]. The mean disease duration was 11.29±6.24 years. RA was erosive in 90% of cases. Rheumatoid factor and/or ACPA were positive in 85% of cases. The mean delay between fibromyalgia and RA diagnosis was 49±7 months. Seventy five percent of patients were on corticosteroids with an average dose of 10 mg per day of Prednisone equivalent. All patients were receiving a DMARD: methotrexate 85%, leflunomide 11.2%, and biologics 37.5%. The mean VAS pain was 6.3±1.8 cm in G1, and 5±1.1 cm in G2. The mean VAS fatigue was 6±2.3 cm in G1, and 4 ±0.9 cm in G2. The mean global patient assessment was 5.9±2 in G1, and 3±0.5 in G2. The mean morning stiffness duration was 30 minutes in G1, and 55 minutes in G2. The mean DAS_{28} ESR was 5±0.7 in G1, and 3.97±0.5 in G2. The mean HAQ was 1±0.3 in G1, and 0.7±0.1 in G2. Catastrophizing was greater in patients with RA-associated fibromyalgia with a mean PCS of 41± 8.2 in G1 vs 32±4.4 in G2 (p=0.01). Cognitive and emotional impact was also greater in G1 compared to G2: the mean BPIS was 71±9 in G1 vs 55±7.5 in G2 (p=0.05).

Conclusion: Our study showed that fibromyalgia aggravates catastrophizing and illness perception in patients with RA. It is important to remind the place of cognitive therapy in the management of these chronic conditions.

SHARED DECISION MAKING ON SUBCUTANEOUS METHOTREXATE OPTIONS FOR RHEUMATOID ARTHRITIS PATIENTS, WHAT DOES THIS LOOK LIKE FOR PATIENTS AND HEALTHCARE PROFESSIONALS?

Keywords: Disease-modifying drugs (DMARDs), Rheumatoid arthritis, Best practices

L. West[1], J. Painter[2], H. Smith[3], A. Davies[4], F. Brown[5], P. Livermore[6], G. Zabate[7], C. Jacklin[8], A. Kent[9]. [1]*Nordic Pharma, -, Reading, United Kingdom*; [2]*Royal Wolverhampton Hospital Trust, Rheumatology Dept., Wolverhampton, United Kingdom*; [3]*University Hospital Sussex, Rheumatology Dept., Brighton, United Kingdom*; [4]*Cardiff & Vale University Hospitals, Pharmacy Dept., Cardiff, United Kingdom*; [5]*Noah's Ark Hospital, University Hospital Wales, Paediatric Unit, Cardiff, United Kingdom*; [6]*Great Ormond St Children's Hospital, Rheumatology and Clinical Academic Dept., London, United Kingdom*; [7]*NHS Lothian, Rheumatology Dept., Edinburgh, United Kingdom*; [8]*Clinical Director National Rheumatoid Arthritis Society, -, Berkshire, United Kingdom*; [9]*Salisbury NHS Foundation Trust, Rheumatology Dept., Salisbury, United Kingdom*

Background: Methotrexate (MTX) is the most commonly used rheumatoid arthritis (RA) drug and will often be the first drug prescribed to treat RA [1]. Enhanced bioavailability of subcutaneous (SC) administration of MTX and improved tolerability compared to oral MTX may make this route of administration preferable to the oral route in certain patients [2]. RA patients with 'dexterity' issues have physical challenges impacting their ability to use their SC MTX device, therefore making the need to offer choice of device to the individual patient to suit their needs are important. Single device policy within hospitals is a major issue as it results in an inability for health care professionals (HCP) to offer a choice, deliver shared decision making and limits the ability to provide optimal disease management [3].

Objectives: The aims of this study were to quantify the cohort of UK RA patients with impairments affecting their ability to self-administer SC MTX, to explore whether such patients are treated any differently or experience inequity of care due to restrictions in device choice, and to identify the challenges facing prescribers and patients of only having one device available for RA patients.

Methods: A 30-minute computer-assisted telephone interview (CATI) was performed during 16 May-24 June 2022. Twenty-nine UK HCPs (22 rheumatology nurses and 7 consultant rheumatologists) were included. CATI included questions categorised in 4 sections including how to choose a device and importance of patient choice (8 questions), impairments (7 questions), impairment management (5 questions), and challenges and progression (4 questions). Data was further validated using a virtual expert panel meeting with another group of HCPs working within rheumatology on 11 June 2022.

Results: 31% of HCPs feel there are significant challenges for some patients using a SC device specifically, those with reduced hand function or with active or significant disease, which results in being unable to self-inject leading to non-adherence to treatment. It was estimated that 23% of RA patients have impairment (mostly reduced manual dexterity) impacting their ability to self-administer. HCPs feel patients with impairments have different needs which are mostly identified during the patient assessment or device observation. 90% of HCPs stated they rely on patients telling them of any issues, however patients do not always raise their challenges with their device to their HCP. 90% of HCPs defined patient choice in terms of facilitating patients to make an informed decision. 83% of HCPs mentioned ability to use a device as the most important factor for choosing a device. ~70% of hospitals only have one SC MTX device available (Figure 1), and this is due to formulary restraints. To be able to offer patient choice, HCPs believed that >1 device should be available (76%), and patients should be informed on benefits of different devices (55%). HCPs consider single device policy is a big issue in the ability to offer a choice (59%) and to manage the disease (50%). Main challenges are difficulties physically using the device and accurately administering drug. 31% of HCPs feels that the impaired patients have poorer compliance and progress to biologics more quickly (8.5 vs. 11.5 months) and 52% of HCPs feel these patients require more frequent visits. The subsequent expert panel meeting essentially confirmed the results.

Conclusion: A significant number of patients (23%) have challenges using SC MTX devices impacting both clinical and non-clinical outcomes. These patients have different needs, thus different devices may offer different benefits. Most rheumatology units in hospitals (69%) have only one SC MTX device on their formulary. Current perception of 'one device fits all' is inconsistent with the Royal College of Nursing guidelines on SC MTX and the NHS Long Term plan (regarding patient choice) [3].

SUPPORT NEEDED BY PEOPLE WITH SYSTEMIC SCLEROSIS TO REMAIN IN THE WORKFORCE

Keywords: Work-related issues, Systemic sclerosis

J. L. Poole[1], K. Carandang[2], M. Thelander-Hill3, A. Koch[4], P. Rogers[5], D. Lacaille[6]. [1]*University of New Mexico, Occupational Therapy Graduate*

Program, Albuquerque, United States of America; [2]*University of Wisconsin-River Falls, Young Patients' Autoimmune Research & Empowerment Alliance, River Falls, United States of America*; [1]*University of New Mexico, Occupational Therapy Graduate Program, Albuquerque, United States of America*; [4]*New Mexico Highlands University, Rehabilitation Counseling, Rio Rancho, United States of America*; [5]*Arthritis Research Canada, Research, Richmond, Canada*; [6]*University of British Columbia, Rheumatology, Vancouver, Canada*

Background: Systemic sclerosis (SSc) severely limits one's ability to participate in paid employment, which may threaten an individual's economic, social, physical, or mental well-being. No programs and very little resources exist to help people with SSc remain in the work force despite the high prevalence of work disability. The few programs that do exist were developed for persons with other rheumatic conditions. One evidence-based program, Making it Work™ (MIW), has the potential to be adapted to meet the specific work related problems faced by people with SSc.
Objectives: This study identified challenges in the work environment and supports received or desired by persons with SSc as a preliminary step to identify adaptations that could make the MIW™ more relevant to people with SSc.
Methods: Participants were recruited through virtual communication from the National Scleroderma Foundation and word of mouth to participate in one 2-hour virtual focus group. Participants were >18 years of age, currently employed or stopped work in the past 5 years, United States residents, English-speaking, and self-reported a diagnosis of SSc and that SSc affected their work ability. Participants were first asked about difficulties working with SSc. The facilitator created a list of challenges based on initial discussion, then participants identified the top five most important challenges according to their experience. Participants were then asked about supports received or desired to help maintain employment. Focus group notes and transcripts were analyzed to determine challenges and supports that must be addressed in an employment intervention for people with SSc.
Results: The sample included 14 participants (85.7% women, mean age 48.8±10.1 years, mean disease duration 7.7±7.4 years; 78.6% had diffuse SSc). 71.4% had college degrees and 71.4% were employed full time. 42.9% described their jobs as having mostly mental demands while 35.7% had both physical and mental demands. Important challenges prioritized by the most participants were: 1) challenges with physical tasks, particularly related to hand use [11, 78.6%] –"*My hands are pretty messed up; typing is a challenge*"; 2) fatigue [9, 64.3%]-"W*hen you say fatigue, people are like, "Well, go take a power nap," but that's not what it is. I could sleep 12-hours and still be exhausted";* 3) mental and emotional health, related to coping with how the unpredictability of SSc affects the body, identity, and employment [8, 57.1%]-"*This disease does not just knock us down one time or challenge us on one level. It's like one body system after another.*""*You have to deal with the issues of your self-esteem, feeling like you're different than everybody else, mourning that loss of ability or career or work ethic that you had prior to your diagnosis"* Participants identified a variety of individualized strategies that enabled them to overcome challenges with SSc at work, including ways to plan ahead, adaptive equipment, and strategies to adapt job tasks. However, participants emphasized that in order to use these tools, it is most helpful to: 1) have the knowledge and advocacy skills to know what to ask for; 2) feel confident that asking for support or accommodations in the workplace will lead to a beneficial change; and 3) be able to problem solve with others (e.g., clinicians, work-related program, therapists, support group).
Conclusion: This study identified the prominent barriers and supports to employment from the perspectives of patients with SSc. While there is some overlap with issues reported by persons with other rheumatic conditions, there are also SSc-specific concerns. This information will be used to adapt the MIW™ intervention, and warrants further consideration for how to incorporate better supports in healthcare, workplaces, and vocational counseling for people with SSc.

POS1399-HPR ONLINE SCHOOL AS A METHOD OF INCREASING THE MEDICAL LITERACY OF PATIENTS WITH RHEUMATIC DISEASES

Keywords: Patient information and education

A. Nurmamedov[1], N. Shuvalova[2], S. Lezhenina[3], E. Guryanova[3]. [1]*Mary Central Clinic, Department Internal Diseases, Mary, Turkmenistan*; [2]*I.Ya. Yakovlev Chuvash Pedagogical State University, Department of Theoretical Foundations of Physical Education, Cheboksary, Russian Federation*; [3]*Chuvash State University by I. N. Ulianov, Department of Healthcare Management and Economics, Cheboksary, Russian Federation*

Background: Today, most of the population of Kazakhstan have access to the Internet. Due to this fact, the use of online schools for patients with rheumatic diseases seems to be a promising direction [1,2].
Objectives: The purpose of the study is to analyze whether online rheumatology schools can be used as one of the methods to improve the medical literacy of patients.
Methods: A survey was conducted with 90 patients IN the city of Astana attending an online school on RH from September 2021 to September 2022 after graduation. The online questionnaire included 20 questions (part A and part B). The questions in Part A concerned the age of patients, gender, bad habits, heredity, sources of information about the school, and the desire to study at an online school. In part B, the questions concerned the novelty and quality of the information received. Patients had to choose one/several of the presented answer options. In some questions, a differentiated assessment was used on a 5-point scale, where 0 points is the minimum, and 5 is the maximum positive assessment. The lecture course consisted of 36 lectures and 6 practical exercises on rheumatic diseases. The questionnaire data were processed in Statistical Analysis Software15.0. Statistical significance was handled using Analysis of variance.
Results: Part A. The number of patients under the age of 30 was 9 (10%) respondents, 31-40 years old - 41 (45.6%) respondents, 41-50 years old - 12 (13.3%) respondents, 51-60 years old - 17 (18.9%) respondents, over 60 years old - 11 (12.2%) respondents. 75 (83.3%) patients were women. 26 (28.8%) patients had bad habits. 17 patients (18.8%) knew about rheumatic diseases FROM relatives. Most of the participants received information about the online school from the clinic staff - 42 (46.7%) or FROM the clinic website - 27 (30.0%), from other sources - 21 (23.3%) respondents. 72 (80%) respondents noted their desire to attend such classes in the future. These data indicates on the interest of respondents of different age groups in improving the level of medical literacy in rheumatic diseases. Part B. 77 (85.5%) and 82 (91.1%) respondents learned about new risk factors for RD (the role of infection and stress), respectively. 39 (43.3%) patients understood the need to correct their lifestyle. A total of 26 (28.8%) respondents realized that they could independently control treatment. 92% of respondents rated the quality of the information received by the maximum score.
Conclusion: The online school can be used as one of the methods to improve the medical literacy of patients with rheumatic diseases.

POS1400-HPR COMPARISON OF BODY AWARENESS, PHYSICAL ACTIVITY, KINESIOPHOBIA, PAIN CATASTROPHIZING, AND PSYCHOSOCIAL STATUS IN INDIVIDUALS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

Keywords: Rheumatoid arthritis, Spondyloarthritis, Patient reported outcomes

G. I. Kinikli[1], N. B. Karaca[1], S. Sezer[2], B. Keleşoğlu[3], G. Kınıklı[4]. [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Department of Musculoskeletal Rehabilitation, Ankara, Turkey*; [2]*Ankara Training and Research Hospital, Department of Rheumatology, Ankara, Turkey*; [3]*Dışkapı Yıldırım Beyazıt Training and Research Hospital, Department of Rheumatology, Ankara, Turkey*; [4]*Ankara University, Faculty of Medicine, Department of Rheumatology, Ankara, Turkey*

Background: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are among the most common rheumatic (joint) conditions. RA and AS are different types of arthritis. Living with RA or AS can significantly affect your quality of life, mental health, and emotional well-being.
Objectives: We report the preliminary results of an ongoing prospective observational study that compare the body awareness, physical activity, kinesiophobia, pain catastrophizing and psychosocial status in individuals with RA and AS.
Methods: A total of 78 individuals (RA=48; AS=30; women/men=48/30) recruited from two university hospitals in Turkey. All individuals were assessed regarding physical characteristics (age, BMI, duration of disease, BASDAI, DAS-28); body awareness by Body Awareness Questionnaire, physical activity level by International Physical Activity Questionnaire Short Form, fear of movement by Tampa Scale of Kinesiophobia, pain catastrophizing by Pain Catastrophizing Scale and psychosocial status by Beck Depression Inventory.
Results: Individuals' characteristics and outcome measures are presented in Table 1. As expected, there were statistical differences between age and gender in study groups ($p<0.001$). However, disease duration and disease activity, mild depression level were similar between groups. Individuals with AS were

significantly more physically active compared to individuals with RA (p<0.005). Body awareness, kinesiophobia, pain catastrophizing and psychosocial status were similar between groups (p>0.05). In addition, disease activity was moderately correlated with body awareness, pain catastrophizing and kinesiophobia individuals with AS (r=-0.529; r=0.613; r=0.427, p<0.05).

Conclusion: Treatment of RA and AS is similar, but there are key differences. According to our results, individuals with AS is more physically active than individuals with RA regardless of disease duration and disease activity. Health professionals can also focus on correlation between disease activity and higher body awareness, pain catastrophizing and kinesiophobia in individuals with AS.

POS1401-HPR LIVED EDUCATIONAL EXPERIENCE OF YOUNG ADULTS WITH CHILDHOOD- AND ADULT-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: A MULTI-CENTER CANADIAN QUALITATIVE STUDY

Keywords: Qualitative research methods, Systemic lupus erythematosus, Work-related issues

M. Golding[1], F. Nishat[2,3], K. Merrill[1,4], R. Kaur[1,4], J. Stinson[2,3], J. Protudjer[1,4], R. Woodgate[1,5], C. Peschken[6], D. Lacaille[7], U. Oguzoglo[8], Z. Touma[9], L. Lim[1,4]. *[1]Children's Hospital Research Institute of Manitoba, Paediatrics, Winnipeg, Canada*; *[2]University of Toronto, Paediatrics, Winnipeg, Canada*; *[3]University of Toronto, Child Health Evaluative Sciences, Winnipeg, Canada*; *[4]University of Manitoba, Paediatrics, Winnipeg, Canada*; *[5]Canada Research Chair, Tier 1, Paediatrics, Winnipeg, Canada*; *[6]University of Manitoba, Medicine, Winnipeg, Canada*; *[7]University of British Columbia, Medicine, Vancouver, Canada*; *[8]University of Manitoba, Economics, Winnipeg, Canada*; *[9]University of Toronto, Medicine, Toronto, Canada*

Background: Education and employment established in young adulthood predict future lifetime socioeconomic achievements. Young adults with Systemic Lupus Erythematosus (SLE) have physical, cognitive and mental health issues and other comorbidities that may impact employment.

Objectives: To understand the lived experiences of young adults with SLE (YASLE), as students, and to assess their perceived barriers from SLE.

Methods: YASLE were recruited from two Lupus clinics in Toronto and Winnipeg. Semi-structured qualitative interviews were conducted individually via secure video conferencing. As this study was conducted during the coronavirus pandemic, participants were also asked about the pandemic impacts on their education experiences. All interviews were transcribed verbatim, double-coded and analysed using a reflexive thematic approach.

Results: Twelve participants (2 males), 9 of childhood- and 3 adult-onset SLE (cSLE, aSLE) were interviewed. Nine participants (82%) were <25 years old. Five also worked while studying. Five were Asians, 5 were White, 2 of other ethnicities. Half have severe disease (central nervous system or renal involvement). Median duration of disease was 4.0 (25th-75th percentile, 1.8- 5.3) years. The impacts of SLE on their education experience emerged in 5 themes:

1) *Challenges imposed by SLE:* Difficulties adjusting to the diagnosis, physical and cognitive symptoms of SLE. While most participants disclosed their diagnosis to their schools, some expressed hesitation.
2) *Changes in aspirations:* Education/career goals were modified by reducing course load or shifting to more sedentary or less cognitively demanding careers.
3) *Coping and acceptance*: More adaptive than maladaptive coping strategies were used to manage their SLE, including self-acceptance, pacing, planning and avoidance. All strived to do well in their studies despite SLE and were hopeful for their futures.
4) *Facilitating factors for education success:* Family and friends' social support, individualized accommodations from school and parental financial support were identified.
5) *Pandemic impacts*: Virtual learning and flexible schedules enabled participants to adapt their schedules according to their physical conditions (e.g. pain, fatigue). However, fewer opportunities to interact in-person were viewed as challenges. Participants want hybrid options to continue even after the pandemic.

Conclusion: SLE affected students' performance through physical symptoms, fatigue and cognitive dysfunction. Ongoing social and school supports help to support them. Maintaining the remote learning options may increase accessibility for them. These results identified opportunities for developing future supportive interventions for YASLE patients in their schooling which then better prepare them for future employment.

POS1402-HPR BODY MASS INDEX MAY HAVE A ROLE IN THE PROGRESSION OF STRUCTURAL DAMAGE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

Keywords: Lifestyles, Spondyloarthritis

E. Erpek[1], E. Durak Ediboglu[1], K. A. Sinci[2], E. Otman Akad[1], H. Kocaayan[1], G. Alp[1], H. Cinakli[1], A. Özkan[1], İ. Kurut Aysin[1], M. Ozmen[1], S. Gucenmez[1], O. Tosun[2], D. Solmaz[1], S. Akar[1]. *[1]İzmir Katip Çelebi University Atatürk Training and Research Hospital, Department of Internal Medicine, Division of Rheumatology, izmir, Turkey*; *[2]İzmir Katip Çelebi University Atatürk Training and Research Hospital, Department of Radiodiagnostics, Izmir, Turkey*

Objectives: To examine the association between basline body mass index (BMI) and progression of radiographic damage in axial spondyloarthritis (ax-SpA) patients. We also assessed the correlation between baseline BMI and baseline radiographic damage in terms of mSASSS score and the presence of syndesmophytes.

Methods: In total 657 (431[65.6%] r-axSpA and 226 nr-axSpa; 243 [37%] female and mean age of 39.9 ± 11.7 years) patients classified as axSpA according to the "Assessment of Spondyloarthritis International Society [ASAS]" criteria were

included in the study. mSASSS progression was defined as at least 2 units mSASSS score increase on radiographs taken at least two years apart. An increase in mSASSS score and/or the development of new syndesmophyte was considered as radiolographic progression.

Results: Age, age at diagnosis, symptoms duration and education level were significantly different between the patients with BMI<30 and BMI≥30. BASDAI, C-reactive protein and erythrocyte sedimentation rates were similar between groups. BASFI, BASMI, fasting blood glucose, triglyceride, total cholesterol, low-density lipoprotein levels and aspartate aminotransferase values measured in the same period were significantly higher in axSpA patients with BMI≥30. While baseline total and lumbar vertebrae mSASSS scores were similar between the groups, cervical mSASSS scores were significantly high in the BMI≥30 group. In our study group baseline BMI was positively correlated with radiographic progression (r=0.201; P=<0.005) and the development of new syndesmophyte (r=0.134; P=<0.05).

Conclusion: The results of this study showed that BMI was associated with both basline and the progression of structural damage in axSpA patients. The effect of high BMI on structural damege may be related to mechanical factors. However, BMI was found to be associated with cervical, but not lumbar syndesmophyte at baseline. Thse findings might be the results of increase in proinflammatory cytokines such as TNF-alfa and IL-6 and the reduction of anti-inflammatory cytokines such as IL-10 and adiponectin secreted from dysfunctional adipose tissue.

Table 1. Demographic and clinical characteristics of patients with axial spondyloarthritis categorized according to body mass index.

LONGITUDINAL PILOT-STUDY EXPLORING CHANGES IN EDUCATIONAL NEED AMONG PATIENTS WITH NEWLY DIAGNOSED AAV USING ENAT

Keywords: Vasculitis, Patient information and education

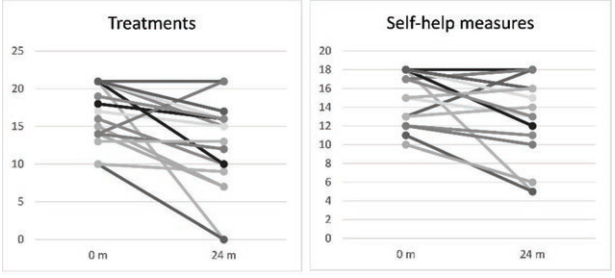
S. Brolin[1,2], I. Gunnarsson[1,2], S. Pettersson[1,2]. [1]*Karolinska University Hospital, Department of Rheumatology, Stockholm, Sweden*; [2]*Karolinska Institutet, Medicine, Stockholm, Sweden*

Background: Previous studies have shown that disease duration associate with an increased need of educational support in ANCA associated vasculitis (AAV) [1]. Shorter disease duration showed to significantly increase educational needs although not yet investigated whether the disease duration or time itself is the deciding factor. Longitudinal studies using the Educational Needs Assessment Tools (ENAT) are in general scarce.

Objectives: The aim of this pilot study was to explore how educational needs changes over two years among newly diagnosed patients with AAV using ENAT.

Methods: This pilot study included longitudinal data from the Rheumatology and Nephrology clinics at the Karolinska University Hospital in Sweden during 2009-2022. Inclusion criteria were being diagnosed with AAV (GPA, MPA and EGPA), minimum age of 18 years and literate in Swedish. Exclusion criterion was cognitive impairment interfering with literate capabilities. Disease activity was estimated using Birmingham Vasculitis Activity Score version 3 (BVAS). Educational needs were captured by patients' answers to the ENAT questionnaire at baseline and after 24 months. The ENAT consists of 39 questions, presented as total ENAT and seven domains (managing pain, movement, feelings, disease process, treatment, self-management and, support) each containing 4-7 items (item answers ranging from 'not at all important' = 0, to 'extremely important' = 3). Paired samples t-test was used to compare means between the two timepoints.

Results: 17 individuals (47% men) with GPA (n=15) and MPA (n=2) completed the questionnaire. At baseline mean age was 51 years, ranging from 20-66, and mean years of education 14.6. Mean disease duration at baseline was 0.2 years. All but three were newly diagnosed at baseline and 3 was diagnosed the year before inclusion. All individuals had an active disease, with a mean BVAS of 15.2, range 1-25. The mean total ENAT score decreased from 83.5 at baseline to 72.6 at 24 months (p=0.04) (Table 1). Change in individuals total ENAT scores ranged from +10 to -73. Educational needs decreased within two of the seven domains, 'Self-help measures' 15.4-12.9 (p=0.03) with individual score change ranging from +5 to -13 and 'Treatment' 16.8-12.1 (p=0.005) with individual score change ranging from +7 to -21 (Graph 1). Domains indicating lower educational needs at baseline were still low after 2 years. Over time the domain with highest educational needs shifted from 'Self-help measures' at baseline to 'Disease process' at follow-up.



Conclusion: This pilot study demonstrates that patients newly diagnosed with AAV expressed high educational needs at baseline compared to previous studies on both patients with established and newly diagnosed AAV [1]. The educational need decreased over time in total and within two of the domains but was still high after 24 months. Our findings point to the fact that patients need continuous educational support during the first years of diagnosis. To further explore patterns and clusters of changes in educational needs more data is needed, including data on what and how information and patient education is received.

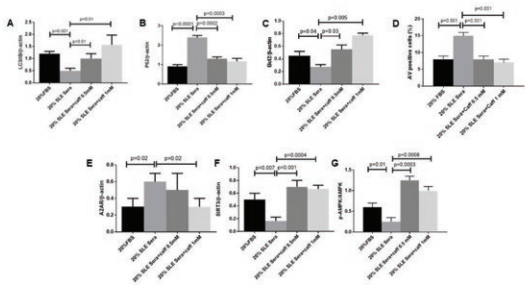
SLE, Sjön's and APS - aetiology, pathogenesis and animal models



POS1404 **CAFFEINE IMPROVES SYSTEMIC LUPUS ERYTHEMATOSUS ENDOTHELIAL DYSFUNCTION BY PROMOTING ENDOTHELIAL PROGENITOR CELLS SURVIVAL**

Keywords: Systemic lupus erythematosus, Diet and nutrition, Cardiovascular disease

V. Orefice[1], F. Ceccarelli[1], C. Barbati[1], G. Buoncuore[1], C. Alessandri[1], C. Pirone[1], F. Conti[1]. [1]*Lupus Clinic, Reumatologia, Dipartimento di Scienze Cliniche Internistiche Anestesiologiche e Cardiovascolari, Sapienza Università di Roma, Roma, Italy*

Background: Circulating endothelial progenitor cells (EPCs) are widely demonstrated biomarkers of endothelial function. Their frequency and function varied in systemic lupus erythematosus (SLE) patients, with a significant association with subclinical atherosclerosis [1]. Caffeine, one of the most widely consumed products in the world, seems to improve endothelial cells number and EPCs migration in coronary artery disease both in mouse models and in patients [2]. We recently demonstrated the impact of caffeine on SLE disease activity status, in terms of SLE Disease Activity Index 2000 (SLEDAI-2K) values and serum cytokine levels [3].
Objectives: The aim of this study was to evaluate the possible role of caffeine intake on endothelial function in SLE patients, by assessing its effect on number and function of EPCs both *ex vivo* in SLE patients and *in vitro* in healthy donors (HD) treated with SLE sera.
Methods: We performed a cross-sectional study enrolling SLE patients, excluding patients with history of traditional cardiovascular risks factors. Caffeine intake was evaluated using a 7-day food frequency questionnaire. At the end of questionnaire filling blood samples were collected from each patient to assess circulating EPC percentage. EPCs were detected by using a flow cytometry analysis defined as KDR CD34 double positive cells. Subsequently, EPCs pooled from 6 HD were co-cultured with caffeine at 0.5 mM and 1 mM with and without SLE sera. After 7 days, we evaluated the cells morphology and the ability to form colonies; moreover, we analyzed for the percentage of annexin V-positive (AV) apoptotic cells by flow cytometry analysis and for levels of autophagy and apoptotic markers LC3-II, p62 and Bcl2 by western blot, alone or in the presence of protease lysosomal inhibitors E64d and Pepstatin A. Finally, we performed a WB analysis to assess the A2AR/SIRT3/AMPK pathway.
Results: We enrolled 31 SLE patients (F:M 30:1, median age 43 years, IQR 18; median disease duration 144 months, IQR 180). We found a EPCs median percentage of 0.03% (IQR 0.04) observing a positive correlation between caffeine intake and circulating EPCs percentage (p=0.03, r=0.4). Moving on *in vitro* experiments, HD EPCs treated with SLE sera and caffeine showed an improvement in morphology and in number of EPCs-CFU in comparison with those incubated without caffeine (p=0.0003). The colonies treated with SLE sera were poorly organized in comparison with HD; the addition of caffeine restored the colony structure. After treating HD-EPCs with SLE sera we observed an increase in AV positive cells and p62 values and a reduction of LC3-II and Bcl2 values; the addition of caffeine was able to significantly reduce AV positive cells and p62 values and to significantly increased LC3-II and Bcl2 values, without any significant differences between caffeine 0.5 mM and 1 mM (Figure 1 A-D). After E64d and pepstatin A treatment, both LC3IIB and p62 trend didn't change, compared to untreated cells. Finally, we observed after caffeine treatment, in comparison with SLE sera alone, a significantly reduction in A2AR levels leading to an increase in protein levels of SIRT3 and subsequently AMPK phosphorylation (Figure 1 E-G).

Figure 1. A-D. Percentage of LC3IIB, p62, Bcl2, AV positive cells in HD-EPC co-coltured with caffeine 0.5 mM and 1 mM with and without SLE sera
E-G. A2AR, SIRT3, p-AMPK/AMPK levels in HD-EPCs co-coltured with caffeine 0.5 mM and 1 mM with and without SLE sera

Conclusion: We demonstrated, for the first time, a protective role of caffeine on endothelial function in SLE patients. Caffeine intake positively correlated with the percentage of circulating EPCs in SLE patients; moreover, caffeine in vitro treatment was able to improve EPCs survival and vitality through the inhibition of apoptosis and the promotion of autophagy via A2AR/SIRT3/AMPK pathway.

POS1405 **FERROPTOSIS OF CD163+ TISSUE INFILTRATING MACROPHAGES IN LUPUS NEPHRITIS**

Keywords: Systemic lupus erythematosus, Kidneys, Cell biology

Q. Cheng[1], L. Mou[2], W. Su[3], H. Wu[1], Y. Du[1]. [1]*The Second Affiliated Hospital of Zhejiang University School of Medicine, Rheumatology, Hangzhou, China*; [2]*The Second Affiliated Hospital of Zhejiang University School of Medicine, Nephrology, Hangzhou, China*; [3]*Shandong Provincial Hospital Affiliated to Shandong First Medical University, Pathology, Jinan, China*

Background: Lupus nephritis (LN) is one of the most common complications of systemic lupus erythematosus (SLE), with high morbidity and mortality. Despite a better understanding of the pathogenesis of LN, treatment progress is still insufficient. Dysregulation of cell death and deficient clearance of dying cells lead to the production of autoantigens, induction of autoantibodies, deposition of circulating immune complexes, and other abnormal immune responses in SLE and LN patients [1]. Ferroptosis, a recently discovered PCD, has hardly been reported in detail in LN [2]. Thus, the purpose of this study was to investigate the role of ferroptosis and its associated metabolic pathways in the pathogenesis of LN.
Objectives: The purpose of this study was to investigate the role of ferroptosis and its associated metabolic pathways in the pathogenesis of LN.
Methods: Transcriptome datasets containing LN and Living donors was obtained from GEO database, and gene sets associated with different PCD modes and different metabolic pathways was extracted from the signaling pathway database or literature search. Composite gene expression scores were calculated by averaging z-scored transformed log2 expressed genes within the pathway. Immunohistochemistry and immunofluorescence were used to detect the expression of 4-HNE and CD163 in LN.
Results: We found that ferroptosis was significantly increased in LN, especially in the glomeruli, while ferroptosis of tubulointerstitial compartment was different in two datasets (Figure 1A, B, C). By immunohistochemistry, we found that the expression of 4-HNE (key medium for ferroptosis) was significantly increased in both glomerulus and tubules (Figure 1D). Next, we explored changes in LN of eight metabolic pathways associated with ferroptosis. In the glomerular compartment, iron metabolism and oxidative phosphorylation pathways were significantly enhanced, while fatty acid synthesis pathway was significantly reduced. In the tubulointerstitial compartment, fatty acid synthesis and oxidative phosphorylation pathways were significantly reduced (Figure 1E). Only iron metabolism and ferroptosis were positively correlated in glomerulus and tubules (Figure 1F). By intersecting differentially expressed genes and metabolism-related genes, we finally obtained one up-regulated gene (CD163) and two down-regulated genes (PC and ATP6V0A4) in glomerulus (Figure 1G, H). The expression of CD163 in glomerulus was positively correlated with ferroptosis (Figure 1I). Meanwhile, immunofluorescence showed that CD163 and 4-HNE co-located in the glomerulus (Figure 1J).
Conclusion: In conclusion, this study reveals that different PCD modes, especially ferroptosis, markedly elevated in LN. In addition, we provided the first in-depth analysis of the changes of different ferroptosis-related metabolic pathways in LN and found that enhanced iron metabolism pathway may be the most important factor in ferroptosis of glomerular. Finally, we identified an upregulated iron metabolism gene, CD163, that was significantly associated with ferroptosis. Due to the lack of studies on the mechanism of CD163+ tissue infiltrating macrophages in LN, we believe that ferroptosis is a very novel and promising option and direction.

UNBALANCED LEVELS OF CIRCULATING NEUROACTIVE STEROIDS IN NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS: A PILOT STUDY FOR AN UNEXPLORED SCENARIO

Keywords: Gender/diversity issues, Systemic lupus erythematosus, Mental health

M. M. Angioni[1], E. Chessa[1], A. Perra[2], E. Pintus[2], A. Floris[1], M. Congia[1], M. G. Carta[2], A. Cauli[1], M. Piga[1]. *[1]Rheumatology Unit, AOU and University of Cagliari, Department of Medical Sciences and Public Health, Monserrato, CAGLIARI, Italy*; *[2]University of Cagliari, Department of Medical Sciences and Public Health, Monserrato, CAGLIARI, Italy*

Background: Sex hormones have effects on the development, progression and severity of SLE, prevalently affecting women (F:M=9:1). The neuroprotective, neurotrophic and anti-inflammatory properties of a class of progesterone-derived NeuroActive Steroids (NASs), prompted numerous investigations about the potential of these GABAA receptor allosteric modulators. However, no data about NASs on neuropsychiatric SLE (NPSLE) are available.
Objectives: This exploratory pilot study aims to delve into a new unexplored landscape by assessing circulating NASs levels in NPSLE patients.
Methods: A cohort of 16 SLE patients without NP manifestations and 16 with new onset NP diffuse symptoms was enrolled. Mood disorders and cognitive dysfunction were defined according to the Center for Epidemiologic Studies Depression Scale (CES-D) and a battery of neuropsychological tests, respectively, interpreted by a neuropsychologist. A group of 8 healthy controls (HCs) matched for mean age and gender ratio was also recruited. Exclusion criteria: ongoing contraceptive or hormonal treatment; glucocorticoid pulse or treatment variations 6-month before blood collection; anxiolitic, anticonvulsivant, antiepilettic drug intake; gonadal-adrenal surgical intervention or pathologies. Data regarding demographics, SLEDAI andSLICC organ damage index (SDI) were collected. NASs serum levels and their precursor were measured by ELISA assay, as listed: Progesterone, Diidroepiandrosterone (DHEA), Diidroepiandrosterone-Sulphate (DHEA-S), Allopregnanolone. To appreciate differences between groups, women's fertile or menopausal subgroups were formed and p-value <0.05 has been set.
Results: Table 1 reports on data from the whole cohort. Progesterone levels in fertile women were significantly higher in the NPSLE versus HCs group (p=0.011). The Progesterone-direct metabolite, Allopregnanolone, was significantly increased in NPSLE compared to both groups of fertile SLE (p=0.026) and HCs females (p=0.027). Inversely, low levels of DHEA and DHEA-S in SLE patients versus HCs (p=0.025 and p=0.005) were found. Looking for NP symptoms, DHEA titer inversely correlates with cognitive deficit diagnosis (p=0.04), while depression diagnosis (62.5% of NPSLE cohort) correlates with Allopregnanolone levels (p=0.042). Moreover, depression severity measured by the CES-D score correlates with Progesterone (r=0.550, p=0.041) and Allopregnanolone (r=0.712, p=0.004; Figure 1). At multivariate analysis after correction for age, disease duration, SLEDAI and SDI, Allopregnanolone confirmed its independent correlation (β=0.712, p=0.004) with depression severity.
Conclusion: In this pilot study, we describe for the first time the unbalanced levels of the most potent neuroactive steroid Allopregnanolone in SLE fertile patients with new onset neuropsychiatric diffuse manifestations. Moreover, in NPSLE patients, the diagnosis of cognitive deficit associates with circulating DHEA low levels and that of depression associates with Allopregnanolone high levels, significantly correlated also with the severity of this manifestation. Since the appropriate NASs balance is needed for optimal brain and neuroimmune function, our preliminary observations – that needs to be validated in an extended cohort - open a new perspective in the field, where the circulating NASs assessment in NPSLE patient could be a new promising diagnostic and preclinical research strategy.

Table 1. Demographic and clinical characteristics of the participants

	NPSLE (16)	SLE (16)	HC (8)
Age mean (DS)	48.2 (15.9)	42.1 (10.8)	49 (16)
Gender (F, %)	100	100	100
Fertile (%)	50	50	50
Menopausal (%)	50	50	50
Disease duration, yrs median (IQR)	6(2.3-9.3)	6.7(3.0-10.4)	-
SLEDAI median (IQR)	5 (1.8-11)	2 (0-4)	-

INTEGRATED METABOLOMICS AND PROTEOMICS NETWORK ANALYSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS HIGHLIGHTS METABOLIC AND IMMUNITY PATHWAYS ASSOCIATED WITH DISTINCTIVE CLINICAL PROFILES

Keywords: Biomarkers, -Omics, Systemic lupus erythematosus

T. Cerdó[1], C. Perez-Sanchez[2], M. A. Aguirre[1], P. Seguí Azpilcueta[3], I. Sanchez-Pareja[1], L. Muñoz-Barrera[1], C. Merlo[1], P. Ortiz Buitrago[1], D. Ruiz[1], M. C. Ábalos-Aguilera[1], F. U. Pilar[1], N. Barbarroja Puerto[4], E. Collantes Estevez[1], R. Ortega Castro[1], C. Lopez-Pedrera[1]. *[1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Rheumatology, Córdoba, Spain*; *[2]IMIBIC/Reina Sofia Hospital/University of Cordoba, Cell Biology, Physiology and Immunology, Córdoba, Spain*; *[3]IMIBIC/Reina Sofia Hospital/University of Cordoba, Radiology, Córdoba, Spain*; *[4]IMIBIC/Reina Sofia Hospital/University of Cordoba, Medical and Surgical Science, Córdoba, Spain*

Background: Systemic lupus erythematosus (SLE) is a severe multisystem disease, notably heterogeneous in terms of clinical course and therapeutic response, which converts it into a significant challenge at the diagnostic and treatment levels.
Objectives: This study investigated the serum proteomic and metabolomic profiles of SLE, in order to identify new mechanisms underlying relevant clinical patterns.
Methods: Proteomic and metabolomic approaches were used to assess the serum levels of 184 inflammation and organ damage-related proteins [by proximity extension immunoassay (PEA, Olink)] and 250 metabolic markers [by nuclear magnetic resonance (NMR) covering glycolysis metabolites, amino acids and 130 lipid measures (NMR, Nightingale)] in consecutive SLE patients (n = 133) and age-matched healthy donors (HD) (n = 27). In parallel, an extensive clinical and analytical profile of recruited subjects was performed. To evaluate the contribution of molecular profiles to the disease severity, unsupervised clustering analyses were developed.
Results: Thirty-six proteins related to inflammation and organ damage, and 17 metabolites were coordinately altered in the serum of SLE patients in relation to HD. Unsupervised clustering analyses differentiated 2 patient clusters (C1 and C2) presenting different proteomic profiles. Clinically, although no differences were found in terms of age or disease duration, patients belonging to C1 were characterized by a significantly higher status of disease activity (SLEDAI > 6) and prevalence of positivity for anti-ENA and anti-dsDNA antibodies than patients belonging to C2, along with a preponderance of patients with biopsy diagnosed lupus nephritis (LN), abnormal creatinine and proteinuria. Besides, this cluster comprised SLE patients with higher CV risk, revealed by an elevated incidence of atheroma plaques, dyslipidemia, and hypertension. Statistical analysis between clusters revealed 67 serum proteins deregulated, among which C1

displayed elevated well-recognized inflammatory cytokines and regulatory proteins of leukocyte activity [(IFN, IL, CSF-1, LIF-R, MCP-1, MCP-4, CCL, CXCL, MMP, PDL, 4E-BP1), accompanied by proteins involved in renal damage (KIM1, LAT2, NPPC, ERBB2IP). Regarding metabolomic profile, comparative analysis between proteome clusters characterized increased levels of proatherogenic VLDL and LDL lipoprotein subsets in C1, and reduced levels of anti-atherogenic HDL lipoproteins subsets, total cholesterol, ketone bodies (acetate) and glycolysis related metabolites (lactate). Interestingly, statistical analyses showed that proteins and metabolites markers correlated significantly, suggesting potential interconnections related to different aspects of lupus pathology.

Conclusion: The present study showed a multi-omics landscape identifying molecular patterns that distinguished patients with high disease activity and lupus nephropathy, including several novel candidate proteins and metabolites markers. The study of the specific role and suitability of these mediators as SLE biomarkers would provide insights for the management of this complex autoimmune disorder.

POS1409 NEW INSIGHTS INTO THE ANTIPHOSPHOLIPID SYNDROME SPECTRUM: FROM ANTIPHOSPHOLIPID ANTIBODIES POSITIVE SUBJECTS PROFILING TO IDENTIFICATION OF SYSTEMIC APS SUBSET THROUGH TYPE I INTERFERON PATHWAY ACTIVATION

Keywords: Autoantibodies, Anti-phospholipid syndrome

I. Cecchi[1], M. Radin[1], A. Barinotti[1], S. G. Foddai[1], E. Rubini[1], A. Suárez[2], D. Roccatello[1], S. Sciascia[1], J. Rodríguez-Carrio[2]. *[1]University of Turin, Department of Clinical and Biological Sciences, Turin, Italy*; *[2]Area of Immunology, Faculty of Medicine, University of Oviedo and Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Department of Functional Biology, Oviedo, Spain*

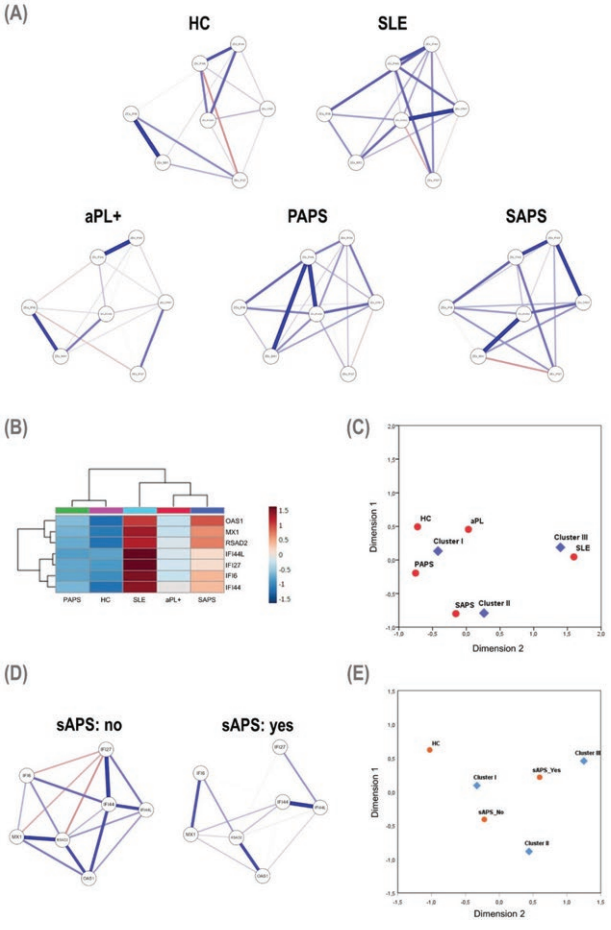

Figure 1.

Background: Type I Interferon (IFN) pathway activation plays a central role in the pathogenesis of several autoimmune conditions. However, limited evidence is available on the IFN pathway activation in antiphospholipid antibody (aPL) positive subjects, including aPL carriers and antiphospholipid syndrome (APS) patients. In addition, recent evidences have highlighted the existence of a bridging condition between pure primary APS (PAPS) and defined systemic lupus erythematosus (SLE) with higher general features, such as cytopenia and arthritis, which is known as *systemic APS* [1] and needs further clarification.

Objectives: The aim of this study was to evaluate the differential expression of IFN stimulated genes (ISG) among different subsets of aPL positive subjects.

Methods: For the purpose of this study, 31 primary APS, 25 secondary APS (SAPS), 27 SLE patients without aPL, 29 aPL carriers [2,3] and 19 healthy controls (HCs) were recruited. Complete demographic, clinical, and laboratory data were collected at the time of the inclusion. *Systemic APS* was defined as in previous papers [1]. IFI6, IFI44, IFI44L, MX1, IFI27, OAS1 and RSAD2 gene expression was evaluated by RT-PCR in whole blood. Normalized gene expression levels (Z-scores) were averaged into a global IFN signature (IFN score). Differences were measured by Kruskal-Wallis tests, and associations among genes were studied by cluster, correspondence and network analyses.

Results: An overall IFN pathway activation was noted across APS subsets, but certain differences were noted among genes. Some genes were already upregulated in the aPL-positive group compared to HC (IFI44, IFI44L, MX1, IFI27, OAS1 and RSAD2, all $p<0.050$), while others were only increased in SLE (IFI6). MX1 differed between SLE and SAPS, whereas IFI27 and OAS1 showed differences between PAPS and SAPS. The composite IFN score revealed quantitative differences across APS subsets, being elevated in aPL carriers/PAPS groups compared to HCs (both $p<0.050$) and increasing in SAPS ($p<0.010$) and SLE ($p<0.001$). Network analyses (Figure 1A) revealed qualitative differences in the gene-gene correlation networks: (i) weaker structures were found in HCs and aPL carriers, compared to stronger and higher-degree networks in SAPS and SLE; and (ii) the influence of each node was different across groups. Unsupervised cluster analysis revealed 3 clusters (Figure 1B), whose usage differed across APS subsets, thus correlating clinical status (Figure 1C). *Systemic APS* (n=51) was hallmarked by a higher IFN pathway activation ($p=0.032$) which was attributed to the expression of certain genes (IFI6, IFI44, IFI44L and IFI27; all $p<0.050$), compared to those without *systemic APS*. Gene-gene interactions also showed differences between subsets (Figure 1D). Individuals with *systemic APS* were more likely to use cluster III ($p=0.042$) (Figure 1E).

Conclusion: IFN pathway activation is a common hallmark among aPL-positive individuals as well as in *systemic APS*, in which a differential and unique expression of ISG has been observed. Qualitative and quantitative differences across the APS spectrum can be identified, leading to the identification of distinct IFN signatures with different clinical value beyond traditional categorization.

POS1410 PROTEOMIC ANALYSIS OF CUTANEOUS LUPUS ERYTHEMATOSUS AND DERMATOMYOSITIS DERMAL INFILTRATE REVEALS DIFFERENTIALLY EXPRESSED CANONICAL PATHWAYS

Keywords: Skin, Systemic lupus erythematosus, Myositis

A. Häyry[1], T. Niewold[2], A. Meves[3], J. Lehman[3,4], K. Popovic-Silwerfeldt[5], C. Charlesworth[6], B. Madden[6], E. Svenungsson[1,7], V. Oke[1,8]. *[1]Karolinska Institutet, Division of Rheumatology, Department of Medicine, Stockholm, Sweden*; *[2]Hospital for Special Surgery, Rheumatology, New York, NY, United States of America*; *[3]Mayo Clinic, Department of Dermatology, Rochester, MN, United States of America*; *[4]Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, MN, United States of America*; *[5]Karolinska Institutet, Department of Clinical Science and Education, Södersjukhuset, Stockholm, Sweden*; *[6]Mayo Clinic, Mayo Clinic Medical Genome Facility - Proteomics Core, Rochester, MN, United States of America*; *[7]Karolinska University Hospital, Rheumatology, Stockholm, Sweden*; *[8]Stockholm Region, Center for Rheumatology, Academic Specialist Center, Stockholm, Sweden*

Background: Cutaneous lupus erythematosus (CLE) and dermatomyositis (DM) are autoimmune diseases with characteristic cutaneous rashes. Both are histopathologically characterized by interface dermatitis and they are difficult and sometimes impossible to differentiate based on skin biopsies. The specific pathogenesis of both conditions remains enigmatic.

Objectives: To systematically identify patterns of protein expression in CLE and DM dermal infiltrate that differentiate the two conditions from each other.

Methods: Punch biopsies were obtained from lesional skin from 6 patients with CLE and 5 patients with DM. Healthy or unaffected skin from 6 individuals was used as control material. Laser capture microdissection was used to isolate 1,000,000µm2 of tissue within the LE and DM dermal inflammatory infiltrates or control dermis. The samples were analyzed by nano-LC tandem mass spectrometry. Qiagen Ingenuity pathway analysis was performed based on the obtained proteomic database, and identified canonical pathways were compared between CLE, DM, and controls.

Results: Comparing CLE vs controls we identified 246 pathways, while 51 of them were enriched (threshold $p<0.05$). Comparing DM vs controls 200 pathways were identified, while 72 were enriched. Canonical pathways enriched in both CLE and DM were those involved in antigen presentation, protein ubiquitination, acute phase response, interferon signaling, GP6 signaling, tRNA charging, and B cell development. Analysis of CLE vs DM showed 237 pathways, 70 of which were enriched ($p<0.05$). The top differentially enriched canonical pathways in CLE compared to DM included EIF2 signaling, complement system, LXR/RXR and FXR/RXR activation, acute phase response signaling, mTOR and granzyme A signaling, clathrin mediated endocytosis signaling, and coagulation system.

Conclusion: Canonical pathways enriched in both CLE and DM skin are associated with activation of innate and adaptive immune systems, including the interferon system. A major difference between CLE and DM was that the EIF2 pathway, involved in cellular stress and induction of cell death, was enriched in CLE. Enriched granzyme A signaling indicates cytotoxic T lymphocyte activity in CLE, which is in line with that the top differentially upregulated cytokine in CLE in the proteomics was IL-16 (1), as CD8 T lymphocytes are well-described expressors of IL-16. Further, results indicate differentially activated metabolic pathways and deposition of complement and coagulation components in CLE dermal infiltrate.

Albani[1,3,5]. *[1]SingHealth Duke-NUS Academic Medical Centre,Translational Immunology Institute, Singapore, Singapore*; *[2]Duke-NUS Medical School, MD-PhD Programme, Singapore, Singapore*; *[3]Duke-NUS, Medical School, Singapore, Singapore*; *[4]KK Women's and Children's Hospital, Rheumatology and Immunology Service, Singapore, Singapore*; *[5]Singapore General Hospital, Department of Rheumatology & Immunology, Singapore, Singapore*; *[6]KK, Women's and Children's Hospital, Singapore, Singapore*

Background: Systemic lupus erythematosus (SLE) is a complex, systemic autoimmune disease. Disease presentation is heterogeneous and characterized by alternating flares and remissions. Recent treatment developments have been made with FDA approval of anifrolumab for adult SLE in 2021 [1] but there are many patients with inadequate therapeutic response. Furthermore, with lack of specific molecular therapeutic targets, current therapy relies mainly on general immunosuppression. This can adversely affect bone health and impede growth of childhood-onset SLE patients. Treatment for paediatric patients is extrapolated from adult studies with the assumption that underlying immunopathogenic mechanisms are similar. However, children are not little adults and a better

understanding of underlying disease mechanisms using a holistic and multiparametric approach is needed to improve current theragnostics.

Objectives: We aim to use a high-dimensional approach to characterise and compare immune signatures of adult-onset and childhood-onset SLE patients, as well as compare their immunological profiles with age-matched healthy controls. In the process, we hope to study the roles of B and T cells in SLE to better understand the adaptive immune response.

Methods: Peripheral blood mononuclear cells from adult-onset and childhood-onset SLE patients underwent mass cytometry. The adult-onset SLE group consists of 26 SLE (timepoints: 40, median age: 40 years) and 23 age-matched healthy subjects. The childhood-onset SLE group consists of 30 SLE (53, 14 years) and 17 age-matched healthy subjects. Data was analysed and visualized using the Extended Polydimensional Immunome Characterisation (EPIC) machine learning platform [2]. Normalization and FlowSOM clustering were performed with 43 functionally and phenotypically important immune markers. Mann Whitney U test identified significantly different cluster frequencies.

Results: Unsupervised analysis revealed multiple significant differences ($p<0.05$) between the adult-onset and childhood-onset SLE immunomes. Of note, an activated $CD11c^+Tbet^+CD21^-$ B cell subset was significantly enriched in childhood-onset SLE (median: 0.42%, interquartile range 0.16-0.72% of $CD45^+$ PBMCs) versus adult-onset SLE (0.15%; 0.09-0.31%; $p<0.001$). These age-associated B cells (ABCs) increase in prevalence with age and presence of autoimmune disease. A significant increase in childhood-onset SLE may offer us insights into the differences with adult-onset SLE; the former group tends to have more active disease over time. Transitional B cells ($CD24^+CD38^+$) were also significantly increased in childhood-onset SLE (0.91%; 0.41-1.84%) compared to their adult counterparts (0.3%; 0.043-0.65%; $p<0.001$). In the T cell compartment, an activated $CD4^+IL21^+$ subset was expanded in childhood-onset SLE (0.41%; 0.23-0.68%) compared to adult-onset SLE (0.19%; 0.1-0.38%; $p<0.001$). IL21 plays a key role in B cell activation and this cell subset is therefore of mechanistic interest. Another $CD8^+CD45RA^+BAFF^+$ T cell subset was enriched in adult-onset (1.95%; 1.24-2.86%) versus childhood-onset SLE (0.88%; 0.45-1.37%; $p<0.001$). B-cell activating factor (BAFF) supports autoreactive B cell survival in autoimmune disease and an anti-BAFF drug (belimumab) is FDA-approved for SLE. Despite increasing use of belimumab, not all patients respond equally, so BAFF inhibition alone may not adequately alter disease activity.

Conclusion: With a multiparametric unbiased approach comparing adult and paediatric SLE patients, we identified cell subsets that may be of immunopathogenic importance. Studying these cell interactions in further detail may identify pathological pathways to facilitate improvements in SLE theragnostics.

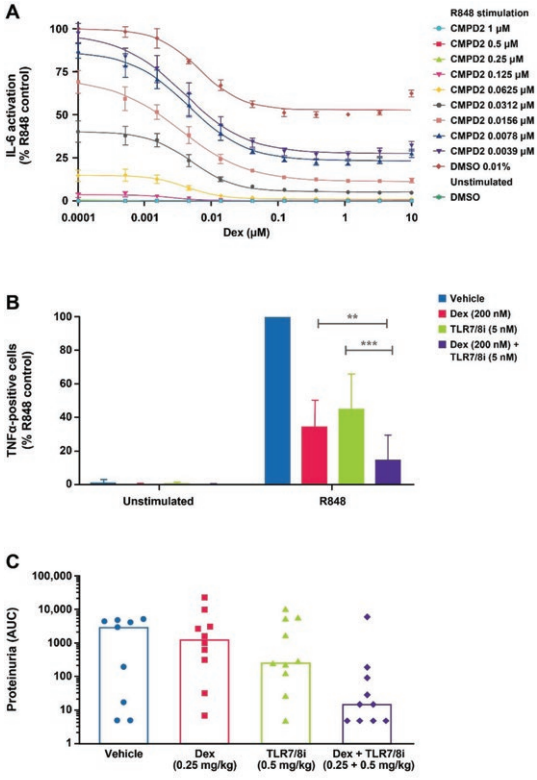
POS1413

PRECLINICAL EVIDENCE FOR THE GLUCOCORTICOID-SPARING POTENTIAL OF A DUAL TLR7/8 INHIBITOR IN AUTOIMMUNE DISEASES

Keywords: Tapering, Cytokines and chemokines, Systemic lupus erythematosus

A. Deshmukh[1], A. Pereira[1], N. Geraci[1], E. Tzvetkov[1], M. Przetak[1], M. Catalina[1], E. F. Morand[2], A. Bender[1], B. Vaidyanathan[1]. *[1]EMD Serono Research & Development Institute, Inc., an affiliate of Merck KGaA, Research Unit – Neuroscience & Immunology, Billerica, United States of America*; *[2]Monash University, School of Clinical Sciences at Monash Health, Melbourne, Australia*



Background: Toll-like receptor 7 (TLR7) and TLR8 are single-stranded RNA-sensing endosomal pattern recognition receptors that evolved to defend against viral infections, however their dysregulation and activation by endogenous ligands has been implicated in autoimmune diseases including lupus. While glucocorticoids (GC) are effective, they have many undesirable effects that limit their use. In addition, resistance to GC, which was recently shown to be imparted by TLR activation and Type I interferon (IFN), is a major challenge for the treatment of patients with autoimmune diseases including lupus. New treatment approaches that allow for the use of lower doses of GC would be highly beneficial.

Objectives: To evaluate the GC-sparing effects of a dual TLR7 and TLR8 inhibitor (TLR7/8i).

Methods: Human peripheral blood mononuclear cells (PBMC) from healthy donors were treated with TLR7/8i, dexamethasone, or both. Cytokine production was measured using an AlphaLISA immunoassay, gene expression was analyzed by NanoString and single-cell RNA sequencing, and effects on protein markers were evaluated by flow cytometry. In addition, the efficacy of combined TLR7/8i and dexamethasone treatment was evaluated in the MRL/*lpr* mouse model of lupus.

Results: Studies in human PBMCs revealed synergistic effects of TLR7/8i and GC on inflammatory cytokine production resulting in increased GC potency in the presence of TLR7/8i (Figure 1A), an effect that was most pronounced in myeloid cells, especially monocytes (Figure 1B). Gene expression analysis revealed that the combination of TLR7/8i plus GC substantially impacted myeloid cell clusters, particularly modules for IFN and GC response genes, as well as nuclear factor-kappa B-regulated cytokines. Treatment with TLR7/8i and GC *in vivo* was more efficacious then either agent alone, as evidenced by reduced proteinuria (Figure 1C) and improved survival.

Conclusion: These results demonstrate that TLR7/8 inhibition increases the potency of GC by alleviating TLR activation-dependent GC resistance in a cell type-specific manner. Our findings suggest a GC-sparing potential for TLR7/8i compounds and indicate that TLR7/8 inhibition may offer a new therapeutic strategy for the treatment of autoimmune diseases. The safety, efficacy and GC-sparing effect of the TLR7/8i enpatoran is being evaluated in patients with systemic and/or cutaneous lupus erythematosus in the randomized, double-blind, placebo-controlled Phase II WILLOW study (NCT05162586), which has a mandatory GC tapering schedule.

POS1414 TYPE I INTERFERONS INDUCE TIE2-MEDIATED ENDOTHELIAL CELL DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Cytokines and chemokines, Cardiovascular disease

C. Rafael Vidal[1], B. Malvar Fernández[1], S. Martínez-Ramos[1], C. Mouriño Rodríguez[1], I. Altabás González[1], A. Floudas[2], D. Veale[3], U. Fearon[2], J. M. Pego-Reigosa[1], S. García[1]. Background: Endothelial cell (EC) dysfunction is a hallmark of Systemic Lupus Erythematosus (SLE) and has been generally accepted to be one of the important factors contributing to the higher risk of thrombosis and atherosclerotic events observed in SLE patients. Although the presence of traditional factors (smoking, diabetes, increased age, obesity) and the presence of autoantibodies are associated with atherosclerosis and thrombotic events, they do not completely explain the higher risk of these events in SLE, suggesting the existence of other mechanism/factors. Tie2 is a tyrosine kinase receptor essential for vascular development and blood vessel remodeling through interaction with its ligands angiopoietin-1 (Ang-1) and Ang-2. In homeostatic conditions, both Ang-1 and Ang-2 activate Tie2 signaling and induce vascular stabilization in a Tie1-dependent manner. However, inflammatory processes induce Tie1 cleavage, leading to the inhibition of Ang-1-induced Tie2 activation, and to the increase of Ang-2 now acting as a Tie2 antagonist, culminating in vascular dysfunction and EC activation [1,2]. Importantly, this process has been implicated in both atherosclerosis and thrombosis.
Objectives: As type I Interferons (IFN-α and IFN-β) are key cytokines in the pathogenesis of SLE, the aim of this study is to determine whether these cytokines induce Tie2 signaling-mediated endothelial cell dysfunction.
Methods: Serum levels of Ang-1, Ang-2 and sTie1 in SLE patients (n=48) and healthy control (HC, n=29) were measured by ELISA. Human Umbilical Vein EC (HUVEC) were stimulated with SLE serum (20%), IFN-α and IFN-β (1000 IU) for 5, 15, 30 min and 1, 2, 4, 6, 8, 12, 24, 48 and 72 hours and mRNA and protein expression of Ang-1, Ang-2, Tie1 and Tie2 were determined by quantitative PCR (qPCR) and ELISA, respectively. The phosphorylation of Tie2 was determined by *Western Blot* and HUVEC viability by calcein assay. The angiogenic capacity was measured by tube formation assay. Silencing assays were performed with siRNAs addressed to IFNAR1 and Tie1 receptors.
Results: Type I IFNs, mainly IFN-β, significantly reduced *TIE1* and *TIE2* levels. IFN-β stimulation significantly increased the secretion of the Tie1 ectodomain (sTie1). Both IFNs significantly reduced protein secretion of Ang-1 after 24h of stimulation. Also, IFN-β induced Ang-2 secretion at early time points (<4h). Furthermore, IFN-α and IFN-β stimulation reduced Tie2 activation (Figure 1). Both type I IFNs significantly reduced the viability of HUVEC. SLE serum increased Ang-2 and sTie1 secretion levels in HUVEC at early time points (<1h). We found reduced levels of Ang-1 and elevated Ang-2 and sTie1 in SLE patients compared to HC. Also, IFN-β induced tube formation at short times (4h) and decreased at 24h. Remarkably, this effect was reversed by silencing the receptors Tie1 and IFNAR1.

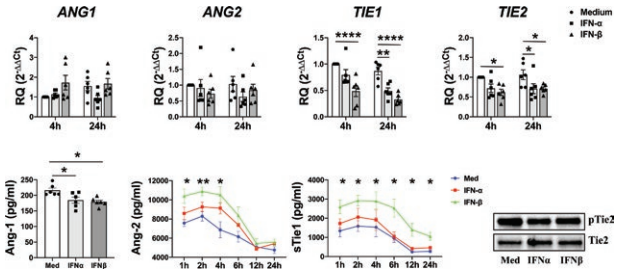

Figure 1. Ang-1, Ang-2, Tie1 and Tie2 mRNA expression and protein secretion in HUVEC stimulated with IFN-α or IFN-β (1000 IU/ml) for the indicated time points. Means and SEM are shown. * p<0.05, ** p<0.01 and **** p<0.0001. Also, representative immunoblot of Tie2 phosphorilation in HUVEC stimulated with IFN-α or IFN-β (1000 IU/ml) for 24 h is shown.

Conclusion: Our results demonstrate that type I IFNs play a relevant role in the stability of endothelial cells by inhibiting Tie2 signaling, suggesting that these processes may be implicated in the cardiovascular events observed in SLE patients.

POS1415 ENDOTHELIAL INFLAMMAGING AND MITOCHONDRIAL DYSFUNCTION IN THE ANTIPHOSPHOLIPID SYNDROME

Keywords: Anti-phospholipid syndrome, Cardiovascular disease

C. Pericleous[1], R. Maughan[1], L. Kabir[1,2], A. Dabrowska[1], K. Paschalaki[1], D. Carling[2], A. Randi[1], D. Arachchillage[3,4], J. Mason[1,5]. [1]*Imperial College London, National Heart & Lung Institute, London, United Kingdom*; [2]*Imperial College London, MRC London Institute of Medical Sciences, London, United Kingdom*; [3]*Imperial College London, Department of Immunology & Inflammation, London, United Kingdom*; [4]*Imperial College Healthcare NHS Trust, Haematology, London, United Kingdom*; [5]*Imperial College Healthcare NHS Trust, Rheumatology, London, United Kingdom*

Background: Inflammageing, vascular ageing and mitochondrial dysfunction are important contributors to cardiovascular risk in the rheumatic diseases. In antiphospholipid syndrome (APS), endothelial dysfunction is underpinned by a thrombo-inflammatory state mediated by antiphospholipid antibodies (aPL). The contribution of endothelial senescence and metabolic disturbances is not known.
Objectives: To assess senescence, inflammation and metabolic function in *ex vivo* blood derived endothelial colony forming cells (ECFC), a novel source of patient endothelium.
Methods: ECFC were isolated from PBMC of 17 thrombotic APS and 11 healthy control (HC) donors, cultured in endothelial growth media containing 20% FBS. ECFC frequency, days from PBMC seeding to first colony appearance and days to initial passage (from P0 to P1) were similar between APS and HC. ECFC were phenotyped at P4 by flow cytometry (CD31+/CD144+/CD146+/CD14-/CD45-) and assayed at P4-P5. Proliferation was measured by fluorescent EdU incorporation. Senescence was determined by staining for senescence-associated β-galactosidase activity (SA-βgal) and nuclear DAPI, expressed as % senescent cells against total cell number. Mitochondrial function and glycolysis were assessed in live cells using extracellular flux assays (Seahorse). Molecular analysis was informed by RNA-seq (5 APS, 5 HC) and targets validated in the extended cohort at the mRNA and protein level. Data was analysed by non-parametric Mann-Whitney, ANOVA and Spearman's correlation tests.
Results: Impaired proliferative capacity and a greater proportion of senescent cells were observed in APS *vs* HC ECFC (median % senescent, 13.1% *vs* 7.9%) (p=0.02). RNA-seq analysis revealed 266 differentially expressed genes in APS ECFC (188 up, 78 down) primarily representing elevated inflammatory cytokines, chemokines, cell adhesion and fibrosis-remodelling molecules. Target validation at the mRNA level confirmed a hypoproliferative inflammatory phenotype in APS; elevated genes included *CDKN2A*/p16 (late senescence), *GADD45B* (growth arrest, DNA damage); *IFNA1* (cytokine), *CXCL10* (chemokine), *CD274*/PDL1 (exhaustion), *PTX3* (fibrosis-remodelling), *SERPINE1* (fibrinolysis-remodelling), *EDN1* (vasoconstrictor), all p<0.05. A positive correlation was noted between senescent and inflammatory gene expression (e.g. *p16 vs CXCL10*, r=0.4,

p=0.03). Upregulation of selected targets was confirmed at the protein level (e.g. p16 and PDL1 by flow cytometry, APS *vs* HC p=0.002 and p=0.03 respectively). Diminished mitochondrial respiration and ATP production (p<0.01) coupled with elevated glycolysis (p=0.02) was seen in APS *vs* HC ECFC. Mitochondrial parameters positively correlated with proliferative capacity (r≥0.5, p<0.01) and negatively correlated with senescence and inflammation (r≤-0.4, p<0.05), indicating a relationship between endothelial health and mitochondrial function. Glycolysis negatively correlated with proliferation (r=-0.6, p<0.01). Comparing ECFC from patients with previous cardiovascular events (CVE, n=9) *vs* those without (no-CVE, n=8) revealed more pronounced senescence and mitochondrial dysfunction in CVE, while greater loss of proliferative capacity was observed in no-CVE. Inflammatory markers varied between the two patient groups e.g. PTX3 was higher in CVE and CXCL10 in no-CVE. Collectively, these observations suggest different underlying biological processes in patients with severe thrombotic complications compared to those without.

Conclusion: We propose APS as a paradigm disease for immune-mediated endothelial ageing, defined by a hypoproliferative-senescent, inflamed and metabolically perturbed phenotype. Evidence for a more severe dysfunctional phenotype in ECFC from patients with CVE compared to no-CVE, agrees with published studies associating vascular ageing and mitochondrial damage with cardiovascular risk. Ongoing work is assessing the impact of *ex vivo* treatment with IgG aPL, cytokines and relevant drugs capable of modulating senescence and immunometabolic processes.

POS1416 IL-6, IL-8, TNF-A ARE SIGNIFICANTLY INCREASED IN CEREBROSPINAL FLUID AND ASSOCIATED WITH ALTERATIONS OF EYE SIGN IN PATIENTS WITH NEUROPSYCHIATRIC LUPUS ERYTHEMATOSUS

Keywords: Biomarkers, Systemic lupus erythematosus, Cytokines and chemokines

J. L. H. Shi[1]. [1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, China*

Background: Several pro-inflammatory cytokines such as interleukin (IL)-6, IL-8 have been implicated in the pathogenesis of in patients with neuropsychiatric systemic lupus erythematosus (NPSLE) [1]. The alterations of eye sign has been reported and correlated with disease activity in NPSLE [2].

Objectives: To ascertain whether the intrathecal levels of cytokines/chemokines relative to serum levels is associated with microvacular changes of eye sign in the patients with neuropsychiatric systemic lupus erythematosus (NPSLE).

Methods: SLE Patients (>18 years) were consecutively enrolled, for whom the cerebrospinal fluid (CSF) and serum samples were collected at the same time, 6 kinds of cytokine/chemokine concentrations in the CSF and serum samples were measured by Chemiluminescent Immunoassey. The diagnosis of NPSLE was evaluated and based on the consensus from rheumatologist, neurologist, radiologist and psychiatrist. Bulbar conjunctival microvascular changes in eye sign were performed and scored for all SLE patients by rheumatologist using our criteria. NP assessments were evaluating in all SLE patients by psychiatrist, including the mini-mental state examination (MMSE), self-rating anxiety scale (SAS), self-rating depression scale (SDS). Demographic and clinical data were compared between two groups and to identify potential predictors for NPSLE by using multivariable logistic regression analysis.

Results: 120 SLE patients were recruited (30 [24-41] years) including 30 NPSLE and 90 non-NPSLE. In multivariable logistic analysis, total score of eye sign in model 1 and ramified loops, microangloma and wound spot of eye sign in model 2 were predictors for NPSLE after adjusting SLEDAI (Table 1). A significant positive correlation between IL-6, IL-8, TNF-α in CSF and total score microangioma in eye sign and between TNF-α in CSF and ramified loops, wound spot in eye sign were found (Figure 1), moreover, significant positive correlation between IL-6, IL-8, TNF-α in CSF and SLEDAI were also observed (r=0.35, p<0.001, r=0.43, p<0.001, r=0.22, p=0.027, respectively), while no significant positive correlation was observed between CSF levels and serum levels of each cytokine/chemokine in these 120 SLE patients.

Conclusion: In NPSLE the production of IL-6, IL-8, TNF-α in CSF might take place in the nervous system, especially in active disease state. These increased CSF cytokines/chemokines along with ramified loops, microangioma and wound spot in eye sign might have an interaction and prerequisite role in the pathogenesis of NPSLE.

POS1417 CATEGORIZATION OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS USING DISEASE ACTIVITY, PATIENT-REPORTED OUTCOMES AND TRANSCRIPTOMIC SIGNATURES

Keywords: Systemic lupus erythematosus

R. Arcani[1], E. Jouve[2], L. Chiche[3], N. Jourde-Chiche[4]. [1]*La Timone University Hospital of Marseille, Internal Medicine and Therapeutics, Marseille, France*; [2]*La Conception University Hospital of Marseille, Service Evaluation Médicale, Marseille, France*; [3]*Hôpital Européen, Internal Medicine, Marseille, France*; [4]*La Conception University Hospital of Marseille, Nephrology, Marseille, France*

Background: Patients with systemic lupus erythematosus (SLE) display symptoms that are not always related to disease activity and may distort clinical trial results. Recently, a clinical categorization based on the presence of type 1 (inflammatory manifestations) and/or type 2 (widespread pain, fatigue, depression) symptoms has been proposed in SLE (1) and tested in a cohort of 212 patients [2]. This allowed the categorization of patients at the time of clinical assessment into four distinct groups: “type 1”: patients displaying only type 1 symptoms; “type 2”: patients displaying only type 2 symptoms; “mixed”: patients displaying both type 1 and type 2 symptoms; “minimal”: patients with no symptoms. This classification was built upon the SLEDAI score (type 1 symptoms), which is widely available in SLE studies, and on American College of Rheumatology fibromyalgia criteria (type 2 symptoms), which are less commonly used in SLE and are rarely available.

Objectives: Our aim was to develop a type 2 score derived from the Short-Form health survey (SF-36) to categorize SLE patients and to compare immunological and transcriptomic profiles between groups.

Methods: Seventeen items from the SF-36 were selected to build a type 2 score for 50 SLE patients (100 visits; LUPUCE cohort) and the SLEDAI was used to define type 1 symptoms. Patients were categorized in four groups: minimal (no symptoms), type 1, type 2 and mixed (both type 1 and type 2 symptoms).

Clinical, immunological and transcriptomic profiles (3) were compared between the groups. The PSY-LUP cohort (from a study evaluating the psycho-social consequences of SLE) (4) was an independent cohort used to confirm the results found in the LUPUCE cohort.

Results: Type 2 scores ranged from 0 to 31, with a cut-off value of 14 (75th percentile) that was the chosen threshold to define the type 2 symptoms. The sample categorization was: minimal in 39%, type 1 in 37%, type 2 in 9% and mixed in 15%. The type 2 score was calculated in an independent cohort of 100 SLE patients (PSY-LUP cohort). This showed a similar pattern of values to the LUPUCE cohort: the score ranged from 0 to 33, and 23% of patients were above the threshold of 14. Type 2 patients were older than minimal patients (52 vs. 31 years, p=0.016) and had a longer disease duration than type 1 and mixed patients (10 vs. 5 years and 10 vs. 2 years, p=0.011, respectively). Immunological data (elevated anti-dsDNA antibodies, anti-dsDNA level, low C3 and/or C4) and modular interferon (IFN) signatures (modular IFN score, number of activated IFN modules and level of regulation of each IFN module) did not differ between the groups.

Conclusion: Patients with SLE can be categorized into four clinical groups using the SLEDAI score and our SF-36-derived type 2 score. This categorization is non-redundant with immunological or transcriptomic profiles and could prove useful to stratify patients in clinical trials.

Background: Systemic lupus erythematosus (SLE) is associated with autoimmune and allergic events along with impaired defensive responses. Dysregulated T-cell responses might account for this evidence but antigen-specific T-cell behaviour in SLE has not been characterised.

Objectives: To test for clinical/pathophysiological correlates of SLE immune dysfunction by characterising CD4+ T-cells selectively recognising key SLE-related, major histocompatibility complex (MHC)-restricted epitopes.

Methods: Human leukocyte antigen (HLA) DRB1*03:01 or 11:01-positive subjects were selected from a cohort of 222 patients with SLE and compared with patients with Takayasu's arteritis (TAK) and healthy controls (HC). *In silico* analyses through the Immune Epitope Database identified suitable HLA-peptide epitope pairs from a shortlist of autoantigens (histone H3 and H4), allergens (penicilloylated albumin) and pathogen-derived antigens (Epstein-Barr virus, EBV, nuclear antigens) based on the cohort clinical/serological profile. Fluorochrome-conjugated epitope-bound MHC tetramers were eventually built and used to detect antigen-specific CD4+ T-cells through flow cytometry. T-cell differentiation was assessed by CD45RA, CD62L and CD95 and polarisation by CD25, CD127, CD183, CD196 and CD194 staining. Epitope-specific reactivity was validated by multi-cytokine release assays and measurement of CD40L, CD137, OX40 and CD69 expression upon T-cell stimulation with the study peptides. SLE disease activity index 2000 (SLEDAI-2K) and lupus low disease activity state (LLDAS) were used to assess activity and remission.

Results: Total stem-cell memory T-cells (T_{SCM}) were expanded in SLE compared to control groups. Histone-specific CD4+ T-cells were selectively found in SLE and clustered with anti-DNA antibodies. Only patients with beta-lactam allergy had anti-penicilloylated albumin T-cells. Anti-EBV-specific T cells were found in patients and controls (**Figure 1A-C**). Antigen-specific T-cell counts were reciprocally correlated. Histone-specific regulatory T-cells (Treg) were inversely correlated with SLEDAI-2K. Circulating histone- and EBV-specific effector memory T-cells (T_{EM}) and Treg were lower in active SLE (**Figure 1D-F**). EBV-specific T_{SCM} decreased in patients transitioning from remission to active SLE. Immunosuppressive treatment was associated with expanded CD4+ histone-specific T-cells. *In vitro* T-cell reactivity assays to study epitopes were consistent with *ex vivo* evidence. Higher IL17F and IL5 were released in response to histones and higher IL5 and IL22 in response to penicilloylated albumin-peptides in SLE. Defective anti-EBV IFNγ, TNF and IL22 release was observed in active SLE compared to HC.

Conclusion: Histone-specific T-cell responses constitute a hallmark of SLE and might defectively be regulated during active disease, promoting autoreactive effector peripheralisation into target tissues. Dysfunctional T-cell reactivity to EBV might also subtend a constitutional defect in the control of endogenous or exogenous viral stimuli and possibly contribute to autoreactivity through misdifferentiation of precursors. Aberrant responses to beta-lactam might also synergise with autoreactive responses and can accurately be detected through penicilloylated-albumin peptide T-cell reactivity. Antigen-specific (rather than total) T-cell dynamics might faithfully reflect the occurrence of key pathogenic events accounting for SLE immune dysfunction in response to multiple types of antigens and efficiently be used to track SLE phenotype heterogeneity.

SINGLE CELL ANALYSIS REVEALING THE LECTIN BINDING PATTERN OF T-CELLS, NKT-CELLS, NK CELLS, B-CELLS AND MONOCYTE SUBSETS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus

E. Szabo[1], G. Bodor[2], L. Kovács[2], G. Szebeni[1,3]. [1]*Biological Research Centre, Laboratory of Functional Genomics, Szeged, Hungary*; [2]*Albert Szent-Györgyi Medical School and Health Centre, University of Szeged, Department of Rheumatology and Immunology, Szeged, Hungary*; [3]*University of Szeged, Department of Physiology, Anatomy and Neuroscience, Faculty of Science and Informatics, Szeged, Hungary*

Background: Cell surface glycosylation serves as a binding platform for endogenous lectin families such as galectins (Gals) or sialic acid immunoglobulin-like lectins (Siglecs) with well-known immunoregulatory functions. Several studies, including our own work [1], have shown that Gals play an important role in pathogenesis of systemic lupus erythematosus (SLE) in animal models but their contribution to human SLE must be better elucidated. For these lectins to act, the appropriate glycan structures should be available on the target cells and should not be masked by alpha-2,6-sialylation which prevents binding of Gal-1, but not Gal-3. Although cancerous diseases are well-characterized by an altered glycome, limited information regarding cell surface glycosylation is gathered for autoimmune diseases like SLE.
Objectives: In the current study, we aim to analyse the ability of certain immune subsets to bind Gal-1, Gal-3, sialic acid binding C-type lectin (Siglec-1), the fucose binding *Aleuria aurantia* lectin (AAL), the sialic acid binding *Sambucus nigra* Agglutinin (SNA) lectin in SLE patients versus healthy controls.
Methods: We collected peripheral blood mononuclear cells (PBMCs) from 19 new or relapsing SLE patients with active disease (mean age: 47.5, SLEDAI-2K:15.8, anti-dsDNA level: 76.4 IU/ml) with no or minimal immunosuppressive therapy and 19 healthy age-matched controls. Multicolor antibody panel was designed to identify the main peripheral immune subsets: CD4+T-cells, CD8+ T-cells, CD4-/CD8- T-cells, CD4+/CD8+ T-cells; CD4+NKT-cells, CD8+NKT-cells, CD4-/CD8-NKT-cells, CD4+/CD8+NKT-cells; CD56+ NK cells; naive B-cells, memory B-cells, plasmablasts; classical monocytes, non-classical monocytes and intermediate monocytes. The five lectins (Gal-1, Gal-3, Siglec-1, AAL, SNA) were conjugated with different fluorophores for FACS. The binding of fluorochrome labelled lectins to each of these populations was assessed simultaneously by flow cytometry directly after thawing (resting state) and following activation. In case of T-cells, activation was achieved by a polyclonal activator (CytoStim), while B-cells and monocytes were activated by LPS.
Results: In our experiments with control PBMCs, titration and compensation of both antibodies and lectins were carried out and gating strategies were built to identify the above-mentioned immune subsets and their lectin binding characteristics. There were remarkable differences in lectin binding among different immune populations, e.g. classical and intermediate monocytes outperformed non-classical monocytes and lymphocytes in all lectin binding. Interestingly, naive B-cells were more sialylated (Median Fluorescence Intensity(MFI_{SNA}:2737) and bound less Gal-1 (MFI_{Gal-1}:5730) than both memory B-cells (MFI_{SNA}:2368; MFI_{Gal-1}:16189) or plasmablasts (MFI_{SNA}:1263; MFI_{Gal-1}:16515). Similarly, highest SNA (MFI_{SNA}:144) and lowest Gal-1 (MFI_{Gal-1}:3658) binding was observed for CD4+ T-cells among the analysed T-cell subsets (MFI_{SNA} range:12-120; MFI_{Gal-1} range: 4201-5460) or NK cells (MFI_{SNA} not detectable; MFI_{Gal-1}:14288) or NKT-cells (MFI_{SNA} range: not detectable-108; MFI_{Gal-1} range:3580-6327).
Conclusion: The focus of this study is to identify relevant changes in the cell surface glycosylation of SLE immune subsets which is a unique approach and could contribute to a better understanding of the glycobiology of lupus.

INCREASED INTERLEUKIN-6 (IL-6) RECEPTOR SHEDDING UNDER INTERFERON-α AND IL-6 EXPLAINS LOW C-REACTIVE PROTEIN (CRP) LEVELS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Keywords: Cytokines and chemokines, Systemic lupus erythematosus, Biomarkers

M. Hempel[1], E. Klapproth[2], B. Heschel[1], N. Leuchten[1], A. El-Armouche[2], M. Aringer[1]. [1]*University Medical Centre and Faculty of Medicine TU Dresden, Division of Rheumatology, Department of Medicine III, Dresden, Germany*; [2]*University Medical Centre and Faculty of Medicine TU Dresden, Department of Pharmacology, Dresden, Germany*

Background: In active SLE, CRP levels are disproportionally low for increased IL-6 levels. While a molecular explanation is lacking, these low CRP levels have been found associated with increased type I interferon signature in SLE. IL-6 signalling requires gp130 and IL-6 receptor-α (IL-6R). Leukocytes and hepatocytes carry surface IL-6R (CD126). Other cells express only gp130 and require soluble IL-6R receptor (sIL-6R) for IL-6 signalling. This sIL-6R derives from membrane-bound CD126 shedded by metalloproteinases.
Objectives: To comprehensively analyze IL-6 and its signal transduction via signal transducer and activator of transcription (Stat) 3 in patients with SLE and in healthy individuals (HC).
Methods: We analyzed peripheral blood mononuclear cells (PBMC) and sera of 41 SLE patients and 71 HC. IL-6 and soluble IL-6 receptor (sIL-6R) were measures by ELISA. CD126 was stained with phycoerythrin (PE)-labelled antibodies. PBMC were stimulated with recombinant human IL-6, fixed, permeabilized and stained with PE-labelled antibodies to phosphorylated Stat3 (pStat3) or control antibodies. Healthy PBMC were incubated for 24 hours with or without the addition of IL-6, IL-10, tumor necrosis factor (TNF), interferon-α (IFNα), or combinations of these cytokines. Flow cytometry was performed on a Becton Dickinson FACSCalibur fluorocytometer, determining percentages of CD126+ lymphocytes or the increase in pStat3 mean fluorescence intensity (Δmfi). sIL-6R in supernatants was detected by immunoprecipitation (IP) and immunoblotting.
Results: IL-6 was increased in SLE (median 3.64 vs 0.89 pg/ml in HC, p<0.0001). Significant correlations with SLE disease activity by ECLAM were found for serum IL-6 (Spearman r=0.40, p<0.01), but not CRP (r=0.29). CD126+ lymphocytes were decreased in SLE (median 46% vs. 61% for HC, Mann Whitney p<0.0001), in line with reduced IL-6 induced phosphorylation of Stat3 in SLE (median Δmfi 14.2 vs. 18.8 in HC, p=0.0044). In a mirror image of CD126, sIL-6R serum levels were increased in SLE (median 42.2 ng/mL vs. 38.6 ng/mL in HC, p=0.02). Stimulation of healthy PBMC with the combination of IL-6 and IFNα led to a reduction in CD126+ cells by 39±13% (p<0.0001)(A) and to an increase in sIL-6R (normalized for IgG) (p=0.0055)(B) detected by IP and Western blotting, mimicking the in vivo situation.

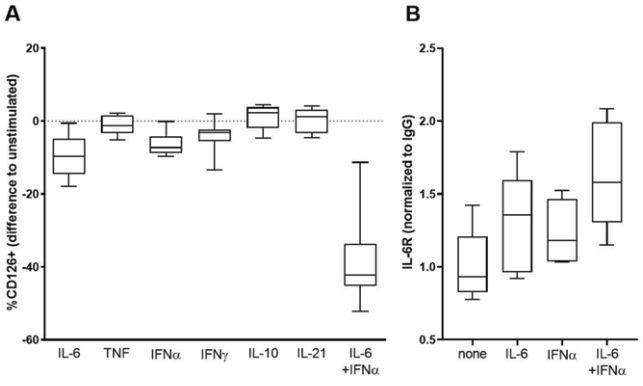

Figure 1.

Conclusion: The combination of type I interferon and IL-6, both of which are well known to be increased in SLE, leads to shedding of membrane bound CD126 to sIL-6R. This moves IL-6 effects from the liver, which produces CRP, to other cells, effectively increasing IL-6 inflammatory effects while limiting CRP levels.

SINGLE-CELL RNA SEQUENCING OF HAEMATOPOIETIC STEM/PROGENITOR CELLS IN HUMAN SLE: EVIDENCE FOR A CHRONIC IFN EXPOSURE AFFECTING EARLY HAEMATOPOIETIC PROGENITORS IN SLE, AND DRIVING THEIR PROLIFERATION AND MYELOID SKEWING

Keywords: Descriptive studies, Systemic lupus erythematosus, -Omics

A. Filia[1,2], M. Grigoriou[1,2], A. Banos[1], I. Mitroulis[2], I. Kokkinopoulos[1], D. Boumpas[1,3]. *[1]Biomedical Research Foundation of the Academy of Athens, Autoimmunity and Inflammation laboratory, Athens, Greece*; *[2]Democritus University of Thrace, University Hospital of Alexandroupolis, Laboratory of Molecular Hematology, Alexandroupolis, Greece*; *[3]Attikon Hospital, National & Kapodistrian University of Athens Medical School, Department of Medicine, Athens, Greece*

Background: All immune cells that contribute to the pathogenesis of systemic lupus erythematosus (SLE) derive from adult haematopoietic stem and progenitor cells (HSPCs) within the bone marrow (BM). We reasoned that the fundamental abnormalities in the disease can be traced back to HSPCs.
Objectives: I) To delineate human haematopoietic CD34+ progenitor subpopulations that may be involved in the pathogenesis of the disease and II) to identify deregulated pathways in each subpopulation in SLE as compared to healthy controls.
Methods: BM samples from 6 SLE patients and 5 healthy controls and 2 umbilical cord blood (CB) samples were used. CD34+ cells were isolated from BM and CB samples and single cell capture and RNA extraction were performed on Fludigm C1 IFC. Libraries were prepared and 75bp or 150bp paired-end sequencing was performed. Cells were excluded if total reads were <25,000, alignment rate was <50%, the number of detected genes (at least 1 count) was <200 and >6,000 and the percentage of reads mapping to mitochondrial genes was >20%. The Seurat and harmony R packages were used for normalization, marker identification and graph-based clustering. Pseudobulk differential expression (DE) analysis was performed using edgeR R package. Enrichment analysis was performed using EnrichR.
Results: A total of 426 out of 836 cells and 24,473 genes were used in the analysis. There was a statistically significant difference in the total number of detected genes between the three sample types (Kruskal-Wallis chi-squared=14.9, p<0.001) with CB samples expressing more genes compared to the other two sample types. The top 3,000 highly variable genes across cells were identified and loaded into a PCA and the top 10 principal components were provided as the input for the UMAP visualization which resulted in seven distinct clusters of cell types (Figure 1). Mutually exclusive markers, which were characteristic of each cell type were identified. Cluster 0 cells (T-like progenitors) uniquely expressed IL32 and CD3E, whereas cluster 1 (Myeloid-1 progenitors) uniquely expressed MMP8. Of note, there was a significantly lower proportion of SLE BM B-like progenitor cells (3.5% of total SLE BM cells) and SLE BM HSCs-3, characterized by primitive progenitors with low expression of the cell cycle gene MKI67 (4% of total SLE BM cells) compared to 10% B-like progenitors and 21% HSCs-3 of total healthy BM cells respectively. Following DE analysis between SLE and healthy BM there were statistically significant differences (FDR<0.1) in Myeloid-2 progenitors, with differentially expressed genes (DEGs) enriched for TNF signaling and DNA repair pathways, and in HSCs-1, with DEGs enriched for IFN alpha-beta signaling and heme metabolism. Interestingly, we observed an upregulation in the expression of IFN inducible genes, such as IFI44, IFI44L, in SLE compared to healthy in all three HSC subpopulations.
Conclusion: Single-cell RNA sequencing analysis from CD34+ progenitor cells from patients with SLE revealed both quantitative- as evidenced by decreased numbers of non-proliferating early progenitors, and qualitative differences- characterized by an IFN signature, which is known to drive loss of function and attrition of HSPCs. Chronic IFN exposure affects early hematopoietic progenitors in SLE, driving their proliferation and myeloid skewing and may account for the immune abberancies and the cytopenias in SLE.

Background: Lupus nephritis is a severe and life-threatening manifestation of systemic lupus erythematosus. Tubulointerstitial hypoxia is a key factor in the progression to end-stage renal disease. Numerous aquaporins are expressed by renal tubules and are essential for their proper functioning. Several mouse models have shown their involvement in the regulation of renal inflammation during acute stress episodes. However, the expression of aquaporins (AQP) in human lupus nephritis has been poorly studied.
Objectives: The aim of this study is to characterise the tubular expression of AQP1, AQP2 and AQP3 which could provide a better understanding of tubulointerstitial stress during lupus nephritis.
Methods: This retrospective monocentric study was conducted at Erasme-HUB Hospital, Brussels with the approval of the ULB-Erasme Ethical Committee (P2020/710). A total of 37 lupus nephritis samples and 9 healthy samples collected between 2000 and 2020 were obtained from the biobank of the pathology department. Kidney biopsy sections were reviewed according to the ISN/RPS 2018 classification. Immunohistochemistry was performed to detect AQP1, AQP2 and AQP3 and followed by digital image analysis. Digital image quantification analysis was performed using ImageJ software.
Results: We observed weak expression of AQP1 in glomeruli and strong expression on the apical side of proximal convoluted tubules in the cortex. In the medulla, it was confined to the descending loop of Henle and the vasa recta. AQP2 was exclusively expressed on the apical side of collecting tubules in both the cortex and the medulla. AQP3 was not detected in glomeruli, weakly expressed on the basolateral side of proximal convoluted tubules, and strongly expressed on the basolateral side of distal convoluted tubules and collecting tubules. No difference in staining location was found between healthy and lupus nephritis kidney biopsies. By digital quantitative analysis, we observed a significant decrease in AQP1 expression in the renal cortex ($p<0.0001$), a non-significant trend towards a decrease in AQP2 expression and a significant cortical and medullary decrease in AQP3 expression ($p<0.001$). This decrease was more pronounced in the subgroup of membranoproliferative glomerulonephritis (class III/IV), particularly for AQP3 ($p<0.05$). Within the subgroup of membranoproliferative glomerulonephritis, there was a strong negative correlation between both cortical and medullary AQP2 expression and interstitial inflammation ($r=-0.5238$; $p<0.01$). Decreased cortical AQP3 expression was strongly negatively correlated with interstitial fibrosis ($r=-0.6651$; $p<0.001$) and tubular atrophy ($r=--0.6651$; $p<0.001$).
Conclusion: We found a significant decrease in the expression of several AQPs in the parenchyma of lupus nephritis. We believe that this decrease is a feature of tubulointerstitial damage. Immunohistochemical analyses of AQPs on lupus nephritis samples could help to assess the tubulointerstitial hypoxia and cell damage and therefore renal prognosis.

Background: NETosis has been described to play a role in the pathogenesis of APS. IgG and sera of APS patients are known to induce NETosis [1], however the direct role of aβ2GPI on NETosis is not fully known.
Objectives: The aim of this study is to evaluate the interplay between NETosis and aβ2GPI antibodies.
Methods: HD neutrophils were stimulated either with polyclonal aβ2GPI isolated from a serum pool of primary APS, with immunoglobulin isolated from HD (IgHD) or PMA. NETs were stained with anti-neutrophils elastase, SYBR green and DAPI. NET quantification was performed with NETQUANT, an automated approach. To evaluate the ability of aβ2GPI to bind to NET, HD neutrophils were stimulated with PMA and stained with anti-neutrophil elastase, SYBR green and with aβ2GPI and, as a control, with IgHD instead of aβ2GPI. Colocalization of aβ2GPI and NET signal was performed with Just Another Co-localization Plugin (JACoP). In order to evaluate the ability of aβ2GPI to bind to NETs and prevent DNA degradation, incubation with DNase I was also performed.
Results: Stimulation of HD neutrophils with aβ2GPI was able to induce a significantly higher number of NETs compared to stimulation with IgHD (77.6% vs 20%, $p<0.0001$). The prevalence of NETs in stimulated IgHD and unstimulated neutrophils was similar (20% vs 16%, p=ns). Two different shapes of NET were identified in neutrophils stimulated with aβ2GPI: "cloudy-like" and "spiky-like". Unlike IgHD, aβ2GPI binds to NETs (Figure 1), and the aβ2GPI signal colocalized with the anti-neutrophil elastase signal at 93.6%. In addition, we showed that aβ2GPI binding to NETs did not prevent NETs degradation by DNase.
Conclusion: Aβ2GPI antibodies are able to induce NETosis and to bind to NETs.

Background: In a systemic lupus erythematosus (SLE) murine model, the translocation of a gut pathobiont induced an autoimmune response and death, which were prevented by antibiotics and a vaccine [1]. These findings suggest that the gut microbiota modulates SLE phenotype. Previously, we found increased circulating lipopolysaccharide (LPS) in SLE patients, which could be associated with decreased gut barrier integrity and translocation from the gut to the bloodstream [2]. We hypothesize that dysbiosis, impaired intestinal barrier integrity, and endotoxemia are crucial to the chronic activation of the immune system seen in SLE.
Objectives: To study diet, physical activity, body composition, gut microbiota, and gut permeability in SLE patients in comparison with healthy controls (HC).
Methods: Evaluation of HC and SLE patients (children and adults) who fulfill the 2019 EULAR/ACR SLE classification criteria. Individuals with inflammatory bowel disease, celiac disease, irritable bowel syndrome, diabetes, malignancy, or other immune-mediated diseases were excluded. The SLEDAI-2K score was used to evaluate disease activity. Diet and physical activity were assessed by three-day diet recall, PREDIMED, KIDMED, and the International Physical Activity questionnaires. Body composition was analysed by whole-body air-displacement plethysmography. Gut microbiota was studied by Next Generation Sequencing, with amplicon sequencing-based 16S rRNA analysis. The lactulose/mannitol test, which directly assesses intestinal permeability, was quantified by mass spectrometry (LC-MS/MS). Serum markers of gut permeability and inflammation (zonulin, sCD14, IFABP) were measured by ELISA. The biological activity of LPS was assessed through serum-induced toll-like receptor 4 (TLR4) stimulation in a reporter cell line.
Results: We studied 16 HC (median age 35.5Y **[**14-50Y**]**; 88% females) and 45 SLE patients (11 children and 34 adults; median age 32Y **[**11-57Y**]**; 87% females; median age at diagnosis 19Y **[**8-43Y**]**; median disease duration 7Y **[**3M-29Y**]**; 64% had lupus nephritis; median SLEDAI-2K at sample collection 4].
SLE patients had lower physical activity and higher sitting time, lower adherence to the Mediterranean diet, and higher fat mass than HC ($p<0.05$). In addition, SLE patients had a lower intake of α-linolenic acid and manganese ($p<0.05$). A decreased α-diversity of gut microbiota ($p<0.05$) was identified in SLE patients, reflecting dysbiosis. Lower adherence to the Mediterranean diet, higher zonulin levels, and longer SLE disease duration were significantly associated with decreased gut diversity in this cohort ($p<0.05$). The lactulose/mannitol ratio was significantly higher in SLE patients compared to HC ($p<0.05$), reflecting greater gut permeability. Patients with lupus nephritis had a higher lactulose/mannitol ratio than SLE patients without renal involvement ($p<0.05$). Interestingly, we found that zonulin was significantly increased in SLE patients ($p<0.05$). We also found significantly increased levels of sCD14 in SLE patients ($p<0.05$) and increased levels of IFABP, but only in adult patients ($p<0.05$). No significant correlation was observed between any evaluated biomarker and SLEDAI-2K.
The serum of SLE patients induced a significantly higher TLR4 response compared to HC ($p<0.05$), which may reflect endotoxemia.
Conclusion: Our data support the hypothesis that gut dysbiosis and higher intestinal permeability contribute to SLE pathogenesis, being two promising therapeutic targets in this disease.

POS1428 AMLEXANOX INHIBITS PRODUCTION OF TYPE I INTERFERON AND SUPPRESSES B CELL DIFFERENTIATION AND IMMUNOGLOBULIN PRODUCTION IN VITRO: A POTENTIAL NOVEL THERAPEUTIC OPTION FOR SLE

Keywords: Systemic lupus erythematosus

A. Björk[1,2,3], M. J. Wahadat[3,4], M. Braams[3], C. G. Van Helden-Meeuwsen[3], M. Versnel[3]. *[1]Karolinska Institutet, Department of Medicine, Stockholm, Sweden*; *[2]Academic Specialist Center, Center for Rheumatology, Stockholm, Sweden*; *[3]Erasmus MC, University Medical Center Rotterdam, Department of Immunology, Rotterdam, Netherlands*; *[4]Sophia Children's Hospital, Erasmus MC, University Medical Center Rotterdam, Department of Paediatric Rheumatology, Rotterdam, Netherlands*

Background: The immunopathology of systemic lupus erythematosus (SLE) is characterized by production of autoantibodies and aberrant activation of the type I interferon (IFN) system. In SLE, type I IFNs directly and indirectly affect differentiation and survival of autoreactive B cells, partly by IFN induced release of B cell activating factor (BAFF). TANK-binding kinase 1 (TBK-1) is an important upstream mediator of type I IFN production, which has been implicated in several systemic autoimmune diseases [1]. Additionally, B cell intrinsic TBK-1 was recently shown to be essential for germinal center (GC) formation and proper B cell development in mice [2]. Amlexanox (AMX), a small molecule TBK-1 inhibitor, has been used to treat aphthous ulcers and asthma. Systemic administration of AMX has indicated that the drug is well tolerated with little evidence of safety concerns [3]. Therefore, we hypothesize that AMX, by inhibition of TBK-1, could be a novel therapeutic option in SLE.
Objectives: To determine whether AMX can inhibit type I IFN and IFN induced BAFF production, and to unravel its potential direct effects on B cells in human in vitro culture systems.
Methods: Cultured PBMC from healthy donors were stimulated with Imiquimod, CpG-A, Poly:IC, G3-YsD or 3p-hpRNA to induce type I IFN production through various routes, with or without presence of AMX. Production of type I IFN was assessed by a HEK IFN-α/β reporter cell line and the ability of supernatants to induce transcription of the BAFF and MX1 genes was measured by real-time quantitative PCR. Sorted CD19+ B cells were cultured for 6 or 9 days under GC-like conditions with CD40L and IL-21 (4), as well as IFN, BAFF, and AMX at various concentrations. Viability and differentiation into CD38highCD27highCD138+/- cells was assessed by spectral flow cytometry. Immunoglobulin M and IgG were measured in supernatants by ELISA.
Results: Amlexanox significantly inhibited production of type I IFN through all investigated endosomal and cytosolic routes (p=0.03 to p=0.001). Likewise, supernatants from cells treated with AMX were unable to induce expression of BAFF and MX1. The inhibiting capacity of AMX in this setting was comparable to blocking of the interferon alpha/beta receptor (IFNAR) with a monoclonal antibody. As could be expected, AMX did not affect expression of BAFF and MX1 upon IFNAR ligation, indicating no effect on signaling downstream of the receptor. To mimic an autoimmune setting, IFN and BAFF was added to the CD40L/IL-21 B cell culture system, resulting in increased B cell differentiation. Addition of AMX resulted in significantly decreased differentiation into CD38highCD27highCD138+/- cells (p<0.0001) without affecting cell viability. Correspondingly, production of IgM and IgG was lower in the AMX condition.
Conclusion: Our data demonstrate *in vitro* inhibitory effects of AMX on type I IFN production and B cell differentiation in primary human cells. Inhibition of TBK-1 is a promising therapeutic target for treatment of SLE warranting further investigations.

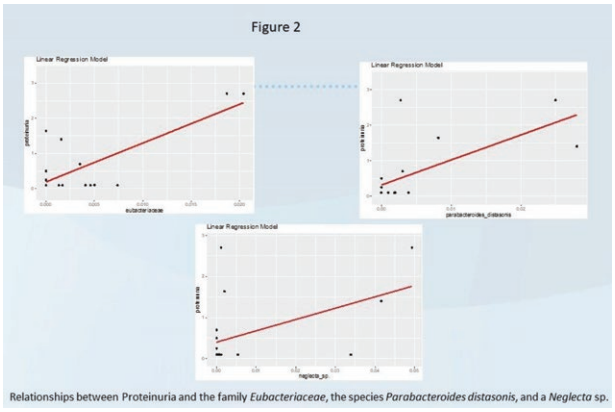
POS1429 AN ANALYSIS OF THE GUT MICROBIOTA IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS REVEALS THE RELATIONSHIPS BETWEEN GUT BACTERIA AND DISEASE SEROLOGY

Keywords: Autoantibodies, Systemic lupus erythematosus, Kidneys



A. Bankole[1], X. Cabana-Puig[2], J. Michaelis[2], M. Pop[3], Z. Lin[4], S. Church[4], X. Luo[2]. *[1]Virginia Tech Carilion School of Medicine, IM, Roanoke, United States of America*; *[2]Virginia tech, Biomedical Sciences and Pathobiology, Blacksburg, United States of America*; *[3]The University of Maryland Center for Bioinformatics and Computational Biology, Bioinformatics and Computational Biology, College Park, United States of America*; *[4]Virginia Tech, Department of Statistics, Blacksburg, United States of America*

Background: Systemic lupus erythematosus (SLE) is the prototypical systemic autoimmune rheumatic disease and is characterized by hyperactive B cells leading to autoantibody production. Changes in gut microbiota are associated with autoimmune disease including SLE. We theorize that changes in the gut microbiota seen in patients with SLE relate to both serological, clinical manifestations as well as disease activity in SLE. A better understanding of the gut microbiota may lead to its use as a biomarker, part of disease activity scoring in SLE, or a potential future therapeutic target.
Objectives: The objective was to determine the relationship between changes in the gut microbiota and the patient reported outcomes using patient global health assessment (PG) and overall disease assessment using Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDI). Secondary objective including the relationship between serological markers of SLE, and proteinuria was also investigated.
Methods: A total of 36 patients were enrolled, and 20 patients who met the Systemic Lupus Collaborating Clinics (SLICC) criteria for SLE each provided a stool sample. Table 1 demonstrates some of the patient and disease related information collected. The stool samples were homogenized, and the DNA was extracted. The V4 region of 16S rRNA gene was amplified using PCR. The purified amplicons were sequenced bi-directionally. Samples were analyzed using the R package phyloseq. Reads were processed and amplicon sequence variants (ASVs) were generated using DADA2 in R. Taxonomy was assigned using the SILVA 138 rRNA database training set using the DADA2 functions, assignTaxonomy and addSpecies. Two samples with fewer than 1000 reads were removed from the dataset, resulting in 18 samples and 1311 ASVs used for downstream microbiota and statistical analyses.
Results: There was also no statistical relationship between the gut microbiota and patient global health assessment or SLEDI. We found no statistical correlation between the gut microbiota and lymphopenia, complement C3/C4, ANA titers, SSA/SSB results or the presence of lupus nephritis. There was an inverse relationship between the family of Ruminococcaceae and dsDNA antibody levels (Figure 2). We also noted significant positive correlation between the level of proteinuria and the genus Eubacterium (family Eubacteriaceae) and the species Parabacteroides distasonis and a Neglecta sp. (Figure 2).
Conclusion: There were significant changes in gut microbiota in SLE that correlated with the levels of dsDNA antibodies and proteinuria. The findings are suggestive that there may be a direct relationship between lupus nephritis serology, clinical symptoms, and the gut microbiota.

POS1430 ROLE OF IL-10 -SECRETING CELLS IN THE PATHOGENESIS OF SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Cell biology, Adaptive immunity, Systemic lupus erythematosus

M. Gerosa[1,2], C. Iannone[1], C. Vasco[3], L. M. Argolini[2], N. Pulvirenti[3], G. Carrea[1], I. Suardi[1], R. Caporali[1,2], J. Geginat[1,3]. *[1]University of Milan, Clinical Sciences and Community Helath, Milan, Italy*; *[2]ASST PINI CTO, Lupus Clinic Department of Clinical Rheumatology, Milan, Italy*; *[3]Fondazione Istituto Nazionale di Genetica Molecolare "Romeo ed Enrica Invernizzi", Immunity Lab, Milan, Italy*

Background: Systemic Lupus Erythematosus (SLE) is characterized by great clinical heterogeneity. Its complex pathogenesis has not been fully understood and factors influencing the development of different clinical phenotypes are still to unveil. A better understanding of these aspects could help in identifying new potential biomarkers and possible therapeutic targets to manage different disease subsets. Interleukin-10 (IL-10) has two opposite effects: it inhibits pro-inflammatory cytokine production but can also exert stimulatory effects by promoting B cell growth and differentiation [1-3]. Consequently, follicular and extrafollicular IL-10 producing B Helper T cells could play a pathogenic role. In SLE patients an increased frequency of circulating extrafollicular CCR6+ B Helper T cells have been reported especially in patients with active disease [1,4]. CRR6+ B helper T cells produce IL-10 and spontaneously induce IgG in SLE patients, including the pathogenic anti-dsDNA autoantibody [4].

Objectives: Our aim was to evaluate the role of IL-10 -secreting cells in the pathogenesis of SLE and to highlight differences in the expression of these cells in different disease stages and clinical phenotypes.

Methods: We analyzed the percentages of IL-10-producing lymphocytes either ex vivo (a standard negative control) or after brief stimulation with PMA and ionomycin, which activates all T-cells to produce cytokines. Surprisingly, 4 patients had very high levels of IL-10 production ex vivo, while the remaining patients produced some IL-10 only upon stimulation, similarly to healthy controls. We then divided our population into 2 groups according to disease activity: patients with SLEDAI ≥ 4 displayed significantly higher IL-10 production than inactive patients. To assess which cells were responsible for spontaneous IL-10 production, we analyzed the phenotype of IL-10+ cells. Spontaneously IL-10 secreting lymphocytes were mainly CD4+ helper T-cells that expressed high levels of CCR6, CXCR5 and IL-7R.

Results: We looked at the percentage frequency of IL-10 -producing cells out of total lymphocytes under two conditions: ex vivo and after stimulation with PMA and ionomycin. Surprisingly, 4 patients had high levels of IL-10 production ex vivo, while the remaining patients produced IL-10 only following stimulation as expected. We then divided the test population into two groups according to disease activity: patients with SLEDAI ≥ 4 displayed significantly higher IL-10 levels than inactive patients. To assess which cells were responsible for IL-10 production, we analyzed the percentage of CD4 and CD8 cells in two populations of lymphocytes, those that expressed IL-10 and those that did not (Figure 1). Spontaneosly IL-10 secreting cells were mainly CD4+ helper T-cells that expressed high levels of CCR6, CXCR5 and IL-7R.

Conclusion: IL-10 was reported to be spontaneously produced by B-cells and monocytes, but this is to our knowledge the first evidence that also T-cells spontaneously produce Il.-10 in SLE. IL-10 levels were higher in active disease and produced mainly by B helper T-cells, suggesting that it stimulates autoreactive B cells to produce pathogenic autoantibodies: the ex vivo production of IL-10 by B helper T cells in selected patients suggest that they are continuously activated by autoantigens and contribute to the aberrant production of autoantibodies. However, further analysis are needed to better characterize the spontaneously IL-10 producing lymphocytes in these patients.

POS1431 IMMUNE CELLS AND THEIR EFFECTOR FUNCTIONS IN NEONATES BORN TO ANTI-RO/LA POSITIVE WOMEN

Keywords: Autoantibodies, Sjögren syndrome, Pregnancy and reproduction

C. Gerstner[1], L. Rudolph[1], G. E. Thorlacius[1], V. Ottosson[1], L. Meneghel[1], F. Nordenstam[2], G. Bergman[2], S. E. Sonesson[1,2], M. Hedlund[1], M. Wahren-Herlenius[1]. *[1]Karolinska sjukhuset Solna, Department of Medicine, Solna, Stockholm, Sweden*; *[2]Karolinska sjukhuset Solna, Department of Women's and Children's Health, Stockholm, Sweden*

Background: Neonatal lupus, including autoimmune congenital heart block, is a passively acquired autoimmune condition dependent on placental transfer of maternal Ro/La autoantibodies to the fetus. The mothers are commonly diagnosed with Sjögren's syndrome or systemic lupus erythematosus, and present with elevated plasma interferon (IFN) levels and signs of immune activation. Recent studies demonstrate both a correlation between the maternal and neonatal IFN-scores, as well as elevated plasma IFNα levels in the neonates. Whether IFNα can be produced by the fetus or whether it originates from the mother is not known.

Objectives: To characterize immune cells in Ro/La autoantibody-exposed neonates with regard to phenotypes, effector functions and cytokine production.

Methods: We used full spectrum multi-color flow cytometry staining for an array of cell phenotype, activation and proliferation markers combined with intracellular cytokine staining to cover the most important innate and adaptive immune cell populations in cord blood cells of anti-Ro/La-exposed (n=12) and non-exposed (n=6) newborns.

Results: We confirmed an increased surface expression of Sialic acid-binding Ig-like lectin-1 (Siglec-1) on CD14+ monocytes and further show increased Siglec-1 expression also on CD14-CD16+ non-classical monocytes and conventional dendritic cells in anti-Ro/La-exposed compared to healthy control neonates. We did not observe any major differences in general populations such as CD4+, CD8+ or gamma delta T cells. However, we found a decreased frequency of regulatory CD4+ FoxP3+ T cells in the autoantibody-exposed newborns. In line with this, we observed an increase in conventional CD4+ FoxP3- T cells and that these cells have less of a naïve phenotype with significantly lower frequency of CD62L+ and more CD69-expressing cells in the CD4+ FoxP3- population. Interestingly, Ro/La-exposed newborns also had less CD5-expressing CD19+ B cells compared to healthy newborns, while the frequency of CD19+ CD5- B cells was not affected. Further, we noted a decreased surface expression of CD19 and CD11b on both these CD19+ subpopulations. Interestingly, for neonates born to mothers with high levels of all three of Ro52, Ro60 and La autoantibodies, we also found intracellular cytokine IFNα and TNFα production in B cell, dendritic cell, and monocyte populations.
Conclusion: Together, our data provide valuable insight into the effects of Ro/La autoantibody exposure *in utero* on immune activation of both innate and adaptive immune cell populations in exposed fetuses, enhancing our understanding of the immunological basis of neonatal lupus.

POS1432 CAR-TREGS FOR SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Adaptive immunity, Animal models

M. Doglio[1], A. Ugolini[1], B. Camisa[1], C. Toma[1], R. Norata[2], S. Del Rosso[3], F. Ciceri[4], F. Sanvito[2,5], M. Casucci[6], A. Manfredi[7], C. Bonini[8]. *[1]San Raffaele Scientific Institute, Experimental Hematology Unit, Milano, Italy*; *[2]San Raffaele Scientific Institute, GLP Test Facility, SR-Tiget, Milano, Italy*; *[3]San Raffaele Hospital, Autoimmunity Lab, Milan, Italy*; *[4]San Raffaele Hospital, Haematology and Bone Marrow Transplantation Unit, Milan, Italy*; *[5]San Raffaele Scientific Institute, Pathology Unit, Milan, Italy*; *[6]San Raffaele Scientific Institute, Innovative Immunotherapies Unit, Milan, Italy*; *[7]San Raffaele Scientific Institute, Autoimmunity and Vascular Inflammation Unit, Milan, Italy*; *[8]San Raffaele Scientific Institute, Experimental Hematology Unit, Millan, Italy*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by an abnormal inflammatory response against nuclear antigens with consequent tissue damage. Autoreactive B cells and auto-antibodies have a fundamental role in SLE pathogenesis. Regulatory T cells (Tregs) physiologically maintain the immune tolerance and are impaired in SLE. Polyclonal Treg trnasfer obtained unsatisfactory results due to the low number of disease-relevant antigen-specific cells. Chimeric Antigen Receptors (CARs) are molecules capable of redirecting T cell specificity. CAR-Tregs proved effective in pre-clinical mouse models of autoimmunity.
Objectives: We aimed at developing a CAR-Treg based product to be employed in SLE.
Methods: We isolated Tregs from Healthy Donors Peripheral Blood Mononuclear Cells (PBMCs) and expanded them with IL-2 and rapamycin. We transduced Tregs with a Lentiviral Vector encoding for a second-generation anti-CD19 CAR, considering the relevant role of autoreactive B cells and autoantibodies in SLE.
Results: Engineered cells retained their immune suppressive capabilities upon polyclonal stimulation. Noticeably, they acquired new antigen-specific suppressive capacities, being able to block autologous B cell proliferation. We set up a humanized mouse model of SLE. In vivo, CAR-Tregs delayed the occurrence of B cell lymphopenia, producing immunomodulatory cytokines and without showing toxicity or reprogramming towards Th17 pro-inflammatory cells. In inflamed organs, CAR-Tregs restored the normal composition of the immune system.
Conclusion: In conclusion, we efficiently generated anti-CD19 CAR-Tregs and proved their efficacy both in vitro and in an in vivo humanized mouse model of lupus.

POS1433 RELATIONSHIP BETWEEN THE EFFECT OF BELIMUMAB ON IMMUNOPHENOTYPE AND THE DISCONTINUATION OF GLUCOCORTICOIDS IN PATIENTS WITH SLE: LOOPS REGISTRY, FLOW STUDY

Keywords: Systemic lupus erythematosus, Real-world evidence

Y. Miyazaki[1], S. Nakayamada[1], S. Kubo[2], K. Sonomoto[3], H. Tanaka[1], K. Hanami[1], S. Fukuyo[1], A. Yamaguchi[4], Y. Todoroki[1], H. Miyata[1], Y. Tanaka[1]. *[1]University of Occupational and Environmental Health, Japan, First Department of Internal Medicine, Kitakyusyu, Japan*; *[2]University of Occupational and Environmental Health, Japan, Department of Internal Medicine (Molecular Targeted Therapy), Kitakyusyu, Japan*; *[3]University of Occupational and Environmental Health, Japan, Department of Adult and Geriatric Nursing, Faculty of Nursing, Kitakyusyu, Japan*; *[4]Hospital of the University of Occupational and Environmental Health, Japan, Department of Laboratory and Transfusion Medicine, Kitakyusyu, Japan*

Background: The efficacy of belimumab (BEL) for maintenance therapy in patients with systemic lupus erythematosus (SLE) remains unclear. Furthermore, the effects of BLM on the peripheral blood immunophenotype in patients with SLE are unknown.
Objectives: Patients with SLE in the maintenance phase were analyzed to determine the relationship between the efficacy of BEL and peripheral immunophenotypes. This study aimed to identify patients with SLE for whom belimumab was optimal by clinical findings and peripheral immunophenotypes.
Methods: In this retrospective observational study, patients with SLE (n=110) in the maintenance phase (SELENA-SLEDAI < 10, glucocorticoid [GC] dose ≤ 0.2 mg/kg/day) were assessed. Based on the standard human immune cell subset classification protocol by NIH/FOCIS, peripheral immunophenotypes were analyzed in SLE patients and age/gender-matched healthy controls (n=76), and were compared. The efficacy of BEL combined with standard-of-care (BEL+SoC group, n=64) was compared with SoC alone (SoC group, patients using either mycophenolate mofetil or hydroxychloroquine, n=46). Selection bias was adjusted by propensity score-based inverse probability of treatment weighting (PS-IPTW). Peripheral immunophenotypes were also compared between the baseline and after six months for the SoC group and BEL+SoC group.
Results: The proportion of naïve-CD4 T-, -CD8 T-, and -B cells were lower, and that of the memory CD4 T-, memory CD8 T-, class-switched memory B-, and IgD^-CD27^-B cells, and plasmocytes was higher in the SLE patients than in controls. No significant difference was observed in the patient background between the two groups after adjustment by PS-IPTW. Compared with the SoC group, the GC dose after one year was significantly lower (BEL+SoC, 1.7±2.3 vs. SoC, 5.4±4.8 mg/day, p<0.0001) in the BEL+SoC group. In the BEL+SoC group, 31.3% (20/64) of patients discontinued GC, significantly more than the SoC group (BEL+SoC, 31.3% vs. SoC, 5.0%, p=0.0012). The relapse rate (BEL+SoC, 6.1% vs. S oC, 22.4%, p=0.0128) was significantly lower in the BEL+SoC group than in the SoC group. The incidence of infections was significantly lower in the BEL+SoC group compared to the SoC group before and after PS-IPTW. No significant difference between the two groups was observed in peripheral immunophenotypes at baseline. The proportion of activated Tfh cells (p=0.0323), IgD^-CD27^-B cells (p<0.0001), and plasmocytes (p=0.0370) was significantly decreased six months after BLM introduction. In the BEL+SoC group, 18 (28.1%) who discontinued GC had no relapse for one year and showed a significantly lower proportion of IgD^-CD27^-B cells six months after BLM introduction (p=0.0387). These changes were not observed in the SoC group.
Conclusion: In maintenance-phase SLE, administration of BLM was able to achieve a reduction or discontinuation of GC dose while suppressing flare-ups. A reduction in IgD-CD27-B cells due to BLM may help to control disease activity and enable the reduction/discontinuation of GC in SLE patients in the maintenance phase.

Vasculitis - aetiology, pathogenesis and animal models

POS1434 ABERRANT PHENOTYPE OF CIRCULATING ANTIGEN PRESENTING CELLS IN GIANT CELL ARTERITIS AND POLYMYLAGIA RHEUMATICA

Keywords: Innate immunity, Vasculitis

R. Reitsema[1], B. C. Hesselink[2], K. Van der Geest[2], W. Abdulahad[2], A. Boots[2], E. Brouwer[2], P. Heeringa[2], Y. Van Sleen[2]. *[1]Örebro University, Faculty of Medicine and Health, Örebro, Sweden*; *[2]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Giant Cell Arteritis (GCA) and Polymyalgia Rheumatica (PMR) are overlapping diseases occurring exclusively in people older than 50 years. Antigen-presenting cells (APCs), including monocytes and dendritic cells (DCs), are main contributors to the immunopathology of GCA and PMR. In GCA tissues, DCs may be prone to activation, leading to chemokine production and recruitment of CD4+ T-cells and monocytes to the arterial wall. However, little is known about APC phenotypes in the peripheral blood at the time of GCA/PMR diagnosis.
Objectives: We aimed to investigate the phenotype of the circulating monocytes and DCs in GCA and PMR patients.
Methods: APCs among peripheral blood mononuclear cells (PBMCs) of treatment-naive GCA and PMR patients were compared to those in age- and sex-matched healthy controls (HCs) using flow cytometry (n=15 in each group). Using a 13-colour panel, we identified three monocyte subsets: classical (CD14+CD16-), intermediate (CD14+CD16+), and non-classical (CD14lowCD16+) monocytes. DC subsets were subdivided in CD303+CD11c- plasmacytoid DCs (pDCs), CD11c+CD141+ conventional DCs (cDC1) and CD11c+CD1c+ conventional DCs (cDC2). Each of these subsets was analysed for expression of pattern recognition receptors (Toll-like receptor 4 (TLR4), TLR2) and activation markers (CD86, Programmed Death- Ligand 1 (PD-L1), CD40, HLA-DR, CD11c) by assessing the mean-fluorescence intensity of these markers. Data were analysed by conventional gating strategies and by unsupervised tSNE.
Results: GCA and PMR patients displayed a monocytosis, which was due to increases in classical and intermediate monocyte counts, whereas the proportion of non-classical monocytes was reduced. Intermediate monocytes of GCA patients had significantly higher TLR2 expression, a similar trend was observed in non-classical monocytes of GCA and PMR patients. A divergent pattern was observed in the expression of activation markers on classical versus non-classical monocytes: classical monocytes of GCA/PMR patients appeared to be less activated, whereas non-classical monocytes showed an increased marker expression compared to HCs (Figure 1). Even though no differences were observed in DC counts in the peripheral blood, cDC2 counts correlated negatively with CRP levels (r=-0.60 for GCA, r=-0.55 for PMR).
Conclusion: Circulating non-classical monocytes, but not DCs, display an activated phenotype in GCA and PMR patients at diagnosis. These cells are thought to be pro-inflammatory, representing the end stage of monocyte maturation in the blood. In contrast, classical monocytes show reduced expression of activation markers in GCA and PMR patients, potentially signalling either an immature or exhausted phenotype.

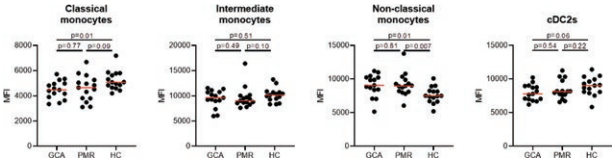

Figure 1. CD11c expression on monocyte subsets and cDC2 for GCA patients, PMR patients and HCs

Shown is the mean fluorescence intensity (MFI) of CD11c on the surface of monocyte subsets and CD1c+ conventional dendritic cells (cDC2). Data are shown for patients with giant cell arteritis (GCA) or polymyalgia rheumatica (PMR) and age-matched healthy controls (HCs), n=15 for each group. Statistics by Mann Whitney U. CD11c expression data for pDCs (no CD11c expression) and cDC1 (too small population) are not shown.

POS1435 A GM-CSF AND IFN-γ-DRIVEN PRO-INFLAMMATORY MACROPHAGE SIGNATURE IN POLYMYALGIA RHEUMATICA

Keywords: Cytokines and chemokines, Innate immunity, Biomarkers

W. F. Jiemy[1], A. Zhang2, M. Sandovici[1], P. Heeringa[3], A. Diepstra[3], E. Brouwer[1], K. Van der Geest[1]. *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[1]University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[3]University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands*

Background: Polymyalgia rheumatica (PMR) is a common, rheumatic inflammatory disease. Synovial inflammation of the shoulder bursae and tendon sheaths is a hallmark feature of PMR. Data on the immune pathology of PMR are scarce, with glucocorticoid treatment remaining the mainstay treatment for this condition. An earlier study reported that macrophages dominate the inflammatory infiltrates in the synovium of PMR patients [1]. Recently, macrophages were identified as potent producers of IL-6 and GM-CSF in PMR bursa tissue [2,3], while a strong IFN-γ signature was observed among bursa T cells [4]. GM-CSF and IFN-γ might potentially skew macrophages towards a pro-inflammatory phenotype. To what extent bursa macrophages in PMR also produce other pro-inflammatory cytokines remains unknown.
OBJECTIVES:
1) To investigate the pro-inflammatory cytokine signature of bursa tissue macrophages in PMR.
2) To determine whether GM-CSF and IFN-γ stimulated monocytes adopt a pro-inflammatory macrophage phenotype.

Methods: Ultrasound-guided bursa tissue biopsies were obtained from 12 PMR patients with active disease. Immunohistochemistry staining for proinflammatory cytokines (IL-6, IFN-γ, IL-1β, TNF-α, IL-12, IL-23 and GM-CSF) and homeostatic cytokines M-CSF was scored quantitatively. Double immunofluorescence staining was performed linking cytokine expression to CD68+ macrophages. *In vitro* studies were performed with monocytes isolated from peripheral blood mononuclear cells of 8 patients with active PMR and 8 healthy donors. Monocytes were differentiated into macrophages during a 7-day culture in the presence of GM-CSF, with or without 24 hours co-incubation with IFN-γ on day 7 for additional polarization. Real-time qPCR was performed to determine expression of IL-6 in the cultured cells.
Results: CD68+ macrophages were the predominant immune cells in PMR bursa biopsies. IHC staining showed high expression (>60% of positive cells) of proinflammatory cytokines (IL-6, IL-12, IL-23, TNF-α and GM-CSF) and the homeostatic cytokine M-CSF throughout the bursal tissue, while IFN-γ and IL-1β were moderately expressed (>35% of positive cells). Double immunofluorescence staining confirmed the expression of these cytokines by the bursa tissue macrophages. *In vitro* experiments showed a slight upregulation of IL-6 expression when monocytes were differentiated into macrophages by GM-CSF. In the presence of IFN-γ, a substantially stronger upregulation of IL-6 was observed. In essence, similar *in vitro* findings were observed for monocytes/macrophages obtained from PMR patients and healthy controls.
Conclusion: Macrophages are the predominant immune cells in PMR bursa tissue and produce a wide array of pro-inflammatory cytokines. GM-CSF and IFN-γ may contribute to the pro-inflammatory phenotype of macrophages in PMR, as indicated by their strong ability to promote IL-6 expression *in vitro*. This study provides the first glance on the complex cytokine network present in key tissues affected by PMR.

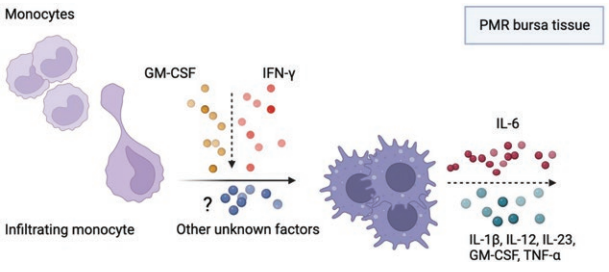

Figure 1. Hypothetic pathogenesis of PMR in bursa tissue. GM-CSF and IFN-γ, together with other factors in the bursa tissue steer monocytes to differentiate into macrophages that produce pro-inflammatory cytokines such as IL-6.

POS1436 IMMUNE CELLS ARE HIGHLY DISTURBED IN POLYMYALGIA RHEUMATICA PATIENTS

Keywords: Adaptive immunity, bDMARD

G. Carvajal Alegria[1,2], S. Boukhlal[3], S. Hillion[4], P. Pochard[4], E. Porchet[4], A. Saraux[3,4], S. Jousse-Joulin[3], T. Marhadour[3], D. Guellec[3], D. Cornec[4], V. Devauchelle-Pensec[3,4]. *[1]Université de Tours, EA6295 NMNS, Tours, France*; *[2]CHRU de Tours, Rheumatology, 37000, France*; *[3]CHRU de Brest, Rheumatology, Brest, France*; *[4]Université de Bretagne occidentale, UMLR1227 LBAI, Brest, France*

Background: Polymyalgia rheumatica (PMR) is an inflammatory disease. But it's pathophysiology and the impact of the treatments on immune cells are poorly known.
Objectives: Our objectives were to describe the immune cells of patients with PMR dependent from glucocorticoids and to analyze their evolution under tocilizumab.
Methods: The SEMAPHORE trial (NCT02908217, (1)) was a randomized control trial including patients with PMR dependent from glucocorticoids. Between inclusion and week 12, patients were blindly treated with either tocilizumab infusion or placebo infusion every 4 weeks associated to a tapering of glucocorticoids. Age and sex-matched healthy controls (HC) were recruited in the rheumatology department of the Brest University Hospital. HC did not have any history or presence of cancer, auto-immune disease or active infection and did not received treatment with a known impact on the immune system. We analyzed immune cells on whole fresh blood after red cell lysis on flow cytometry (Navios, Cytoflex, Beckmann Coulter) after staining for CD16, CD56, CD19, CD14, CD4, CD8, CD3, CD45, IgD, IgM, CD21, CD27, CD24, CD38, CD5 CD126, CD62L, CD45RA, CD127, CD25, in four different panels.
Results: Samples were obtained for 40 PMR patients and 34 HC. At inclusion, in PMR patients, compared to HC, CD14+CD16- classical monocytes were increased (82±1% vs 77±2%, p=0.01), CD14-CD16+ non-classical monocytes were decreased (4±0.3% vs 7±0.6%, p<0.0001), granulocytes were increased (63±2% vs 52±2%, p<0.0001), natural killer cells were decreased (8±1% vs 13±1%, p=0.007). B cells were decreased (8±0.6% vs 10±0.8%, p=0.03), but with an enrichment in CD27-IgD- senescent B cells (p<0.0001) and in $CD21^{low}$ B cells (p=0.04). T cells were increased (70±2% vs 64±2%, p=0.02) with an enrichment in CD4+ T cells (p=0.02) and in $CD4+CD25^{high}CD127-$ regulatory T cells (p<0.0001). At week 12, in PMR patients receiving tocilizumab therapy, compared to PMR patients receiving placebo, granulocytes were lower (58±5% vs 73±2%, p=0.006) and monocytes were higher (8±1% vs 5±0.5%, p=0.02).
Conclusion: In patients with a PMR dependent from glucocorticoids, immune cells homeostasis is disturbed. Tocilizumab has an impact more pronounced on granulocytes and monocytes. Knowledge about immune disturbance in PMR might help to choose to use a targeted therapy when glucocorticoids are not sufficient.

POS1437 INTERSTITIAL ANCA-ASSOCIATED VASCULITIS ASSOCIATES WITH SEVERE KIDNEY INJURY INDEPENDENT OF GLOMERULONEPHRITIS

Keywords: Kidneys, Vasculitis

B. Tampe[1]. *[1]University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany*

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a small vessel vasculitis affecting multiple organ systems, including the kidney. Small vessels in the kidney include small-sized arteries (interlobular artery, afferent and efferent arteriole), capillaries (glomerular and peritubular capillary) and venules.
Objectives: Although crescentic ANCA glomerulonephritis (GN) is a common histological finding reflecting glomerular small vessel vasculitis, it is reasonable that manifestation of AAV could also contribute to interstitial small vessel vasculitis. Therefore, we here aimed to expand our current knowledge focusing on interstitial vasculitis in ANCA GN by systematic histological scoring of vascular lesions analogous to Banff.
Methods: A total number of 49 kidney biopsies with confirmed renal involvement of AAV at the University Medical Center Göttingen were retrospectively included between 2015 till 2020. A renal pathologist evaluated all biopsies and was blinded to clinical data collection and analysis.
Results: Since previous studies established that crescentic ANCA GN associates with severe kidney injury and acute deterioration of kidney function in AAV, we first systematically scored interstitial vasculitis in association with requirement of renal replacement therapy (RRT). Among all active and chronic tubulointerstitial lesions analogous to the Banff scoring system, the only association between severe kidney injury requiring RRT was observed for interstitial vasculitis in AAV reflected by peritubular capillaritis (ptc, p=0.0002) and arteritis (v, p=0.0069), affecting 5/49 (10.2%) and 11/49 (22.4%) of renal biopsies, respectively. Since it is known that severe deterioration of kidney function also correlates with crescentic ANCA GN, we next directly compared glomerular and tubulointerstitial lesions. The fraction of normal glomeruli was inversely associated with interstitial fibrosis (ci), total (ti) and inflammation in IFTA (i-IFTA), whereas glomerular crescents were associated with interstitial inflammation (i), tubulitis (t) and total inflammation (ti). In contrast, global glomerular sclerosis associated with less interstitial inflammation (i) but correlated with interstitial fibrosis (ci) and tubular atrophy (ct), confirming established mechansim that chronic glomerular injury leads to tubular atrophy and interstitial fibrosis. Interestingly, no association between interstitial vasculitis (ptc and v correlating with severe kidney injury) and any glomerular lesion in ANCA GN (also correlating with severe kidney injury) was observed, thereby confirming that interstitial vasculitis contributes to severe kidney injury independent of ANCA GN. By contrast, short-term renal recovery from RRT was equal in both groups, suggesting a distinct association with acute decline of kidney function at disease onset.
Conclusion: Taken together, by using the Banff scoring system we here expand our current knowledge of renal interstitial lesions in AAV revealing peritubular capillaritis and arteritis as important histological alterations associated with severe kidney injury in a considerable subset of AAV. Furthermore, our findings that interstitial vasculitis did not correlate with crescentic ANCA GN implicate that the characteristics of each vasculitis manifestation are independent and could further improve our understanding of mechanisms contributing to renal injury. These observations suggest that interstitial vasculitis in AAV may also affect long-term prognosis requiring further investigation.

ANALYSIS OF THE PLASMA PROTEOME PROVIDES MECHANISTIC INSIGHTS INTO THE PATHOPHYSIOLOGY OF ANCA-ASSOCIATED VASCULITIS

Keywords: -Omics, Vasculitis

E. Hellbacher[1], V. Van Hoef[2], A. Johansson[1], A. Knight[1], I. Gunnarsson[3], A. Bruchfeld[4], P. Eriksson[5], S. Olsson[6], A. J. Mohammad[6], A. Soderbergh[7], E. Berglin[8], S. Rantapää Dahlqvist[8], J. Dahlqvist[1]. *[1]Uppsala University, Department of Medical Sciences, Uppsala, Sweden*; *[2]Uppsala University, NBIS Science for Life Laboratory, Uppsala, Sweden*; *[3]Karolinska Institutet, Department of Medicine, Stockholm, Sweden*; *[4]Linköping University, Department of Medical and Health Sciences, Linköping, Sweden*; *[5]Linköping University, Department of Biomedical and Clinical Sciences, Linköping, Sweden*; *[6]Lund University and Skåne University Hospital, Department of Clinical Sciences, Lund, Sweden*; *[7]Örebro University Hospital, Department of Rheumatology, Örebro, Sweden*; *[8]Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden*

Background: The pathogenesis of ANCA-associated vasculitis (AAV) remains largely unknown. Proteinase 3 (PR3)- and myeloperoxidase (MPO)-AAV are two cateogories of AAV with distinct genetic background, but mechanistic differences between the two are poorly characterized. We hypothesized that in-depth studies of the plasma proteome in patients with active AAV would provide clues to the molecular and cellular mechanisms behind these disorders.
Objectives: To improve our understanding of the disease mechanisms behind AAV and pathophysiological differences between PR3- and MPO-AAV.
Methods: Plasma samples were collected at six Swedish rheumatological and/or nephrological centers from 42 PR3-AAV- and 25 MPO-AAV patients with active disease prior to commencement of therapy and from 138 healthy matched controls. All patients were classified into granulomatosis with polyangiitis or microscopic polyangiitis according to the European Medicines Agency algorithm. Samples were analysed for the relative levels of 181 proteins associated with inflammation or cardiovascular disease, using proximity extension assay (OLINK Proteomics). Differentially expressed proteins (DEPs) between groups were analyzed using ANOVA, where proteins with a fold change ≥ 1.5 and adjusted P value < 0.05 were considered as significant DEPs. Partial least square discriminant analysis (PLS-DA) was used to identify proteins contributing most to PR3-AAV/MPO-AAV separation from healthy controls. The STRING database was used to analyse protein–protein interaction networks. Gene ontology, KEGG and Reactome databases were used for pathway enrichment analyses using ClueGO.
Results: In comparison with healthy controls, 63 DEPs were identified for PR3-AAV and 62 for MPO-AAV; of these, 49 DEPs were common to both AAV groups. Pathway enrichment analysis of the 49 common DEPs identified IL-17-, IL-10-, TNF-α- and NF-kappa B signaling and neutrophil chemotaxis among the significantly enriched processes. The 14 DEPs unique for PR3-AAV formed a functional and physical protein-protein interaction network in STRING analysis, with significant enrichment for regulation of B cell proliferation, activation of matrix metalloproteinases, collagen degradation and IL-17- and TNF-α signaling pathways. The 13 DEPs unique for MPO-AAV did not show any significant functional enrichment. Of the top 15 proteins contributing most to group separation in the PLS-DA analysis, 11 proteins where common to both PR3- and MPO-AAV and 4 proteins were unique for PR3-AAV and MPO-AAV, respectively (Table 1).
Conclusion: Combining quantitative proteomics and bioinformatics analyses, we have identified a large group of DEPs characterizing both active PR3- and MPO-AAV and have determined their associated biological mechanisms. DEPs unique for PR3-AAV formed an interconnected protein network associated with biological processes of high relevance for AAV-pathogenesis. In conclusion, these findings may provide new insights into similarities and differences in the pathogenesis of MPO- and PR3-AAV.

Table 1. PLS-DA results showing the top 15 proteins contributing most to separation of PR3-AAV and MPO-AAV patients, respectively, from healthy controls.

DEREGULATION IN ADULT IGA VASCULITIS SKIN AS THE BASIS FOR THE DISCOVERY OF NOVEL SERUM BIOMARKERS

Keywords: -Omics, Vasculitis, Biomarkers

M. Bajželj[1,2], M. Hladnik[3], T. D. Toluay[3], S. Sodin-Šemrl[1,4], A. Hocevar[1,2], K. Lakota[1,4]. *[1]University Medical Centre Ljubljana, Department of Rheumatology, Ljubljana, Slovenia*; *[2]University of Ljubljana, Faulty of Medicine, Ljubljana, Slovenia*; *[3]Faculty of Mathematics, Natural Sciences and Information Technologies, University of Primorska, Department of Applied Natural Sciences, Koper, Slovenia*; *[4]Faculty of Mathematics, Natural Sciences and Information Technologies, University of Primorska, Department of Biodiversity, Koper, Slovenia*

Background: Immunoglobulin A vasculitis (IgAV) is a small vessel leukocytoclastic vasculitis, characterized by vascular IgA deposits, and a variable clinical presentation. While IgAV might be self-limiting with a complete recovery, the severe acute form of the disease with gastrointestinal tract (GIT) and renal involvement may lead to significant morbidity, especially in adults. A skin or renal biopsy is still the golden standard for diagnosis. Currently, clinically used markers for IgAV cannot predict patients at risk for severe renal involvement and GIT complications with long-term consequences and which patients will exhibit a mild and self-resolving course limited to skin.
Objectives: This study aimed to use deregulated biological processes in patients' skin to identify potential serum biomarkers in adult IgAV, enabling stratification of patients with different clinical presentation.
Methods: Skin biopsy samples were collected from treatment-naïve adult IgAV patients at the time of diagnostic procedure: 1) skin-limited disease (n=3), 2), IgAV with renal involvement (n=3), and age-/sex-matched HC (n=3). RNA was isolated and 100 bp paired-end sequenced using the Illumina HiSeq 4000 platform (25.9 to 30.8 million reads were obtained per sample). Reads were mapped with Salmon tool against the human transcriptome (Ensemble Release 104). Differentially-expressed genes (log2 fold change ≥ $\left|1\right|$, padj < 0.05) were computed using the R package DESeq2. Potential serum biomarkers were measured in sera of 59 IgAV patients and 22 healthy controls by magnetic bead-based multiplex assay using the Luminex platform. Statistically significant differences between groups were determined by the Mann-Whitney U test (for 2 groups) and the Kruskal-Wallis test followed by Dunn's post-test for multiple comparisons (≥ 3 groups). Spearman's rank correlation was calculated to measure the correlation between parameters.
Results: Based on differentially-expressed genes and deregulated biological pathways in IgAV patients' skin, we identified adipokines (fatty acid binding protein 4 (FABP-4), adiponectin, leptin, serpin A12 and angiopoietin-like protein 4 (ANGPTL4)), extracellular matrix associated proteins (osteopontin and matrix metalloproteinase-1 (MMP1)) and acute phase protein lipopolysaccharide binding protein (LBP) that were measured in patients' sera. We detected significantly higher serum levels of FABP-4 ($p < 0.001$), leptin ($p = 0.002$), ANGPTL4 ($p < 0.001$), osteopontin ($p < 0.001$), MMP1 ($p = 0.007$) and LBP ($p < 0.001$) in adult IgAV patients, as compared with healthy controls. Most highly enriched biological pathways identified only in skin of IgAV patients with renal involvement were the Regulation of lipolysis in adipocytes (padj 9.066×10^{-4}) and ECM-receptor interaction (padj = 4.2882×10^{-3}). Among the top 30 most differentially-expressed genes identified specifically in the skin of IgAV patients with renal involvement were LBP, LEP, SPP1, ADIPOQ, HP and RBP4. Serum levels of adiponectin ($p=0.0043$) and FABP-4 ($p=0.049$) were significantly higher in patients with renal involvement as compared to those with gastrointestinal involvement. The level of adiponectin ($p=0.018$) was significantly higher in patients with skin-limited IgAV compared to patients with gastrointestinal involvement. LBP positively correlated with the levels of two already routinely measured acute-phase proteins, C-reactive protein (CRP) (correlation coefficient = 0.550, $p < 0.001$) and serum amyloid A (SAA) (correlation coefficient = 0.545, $p < 0.001$), established markers of inflammation. Among adipokines, the level of ANGPTL4 positively correlated with CRP (correlation coefficient = 0.514, $p < 0.001$) and SAA (correlation coefficient = 0.528, $p < 0.001$).
Conclusion: We identified novel biomarkers of deregulated lipid metabolism and inflammation in adult patients with IgAV that are associated with internal organ involvement. Further analysis of their involvement in disease pathogenesis is warranted.

POS1440 EVIDENCE FOR INCREASED RESPONSIVENESS TO INTERFERON TYPE I IN CD8+ T CELLS IN PATIENTS WITH GIANT CELL ARTERITIS

Keywords: Innate immunity, Cytokines and chemokines, Vasculitis

M. Van Nieuwland[1,2], I. Esen[2], R. Reitsema[2], W. Abdulahad[2], Y. Van Sleen[2], M. Sandovici[2], E. Brouwer[2], L. Van Bon[1]. [1]*Hospital Group Twente, Rheumatology and Clinical Immunology, Almelo, Netherlands*; [2]*University Medical Center Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) is a vasculitis which can lead to severe complications when not timely recognized and treated. There is a need for the discovery of biomarkers to expedite the diagnostic process. Interferon type I (IFN-I) is increasingly recognized as a key player in a range of autoimmune diseases and might play a role in GCA pathogenesis [1]. However, evidence for IFN-I potentially linking innate and adaptive immune responses in GCA is limited. IFN-I activates the Janus kinase/signal transducers and activators of transcription (JAK-STAT) pathway, leading to an increased expression of interferon stimulated genes (ISGs).
Objectives: In this study, IFN-I involvement in GCA pathogenesis is explored.
Methods: Phopho-STAT1 (pSTAT1) expression was investigated in IFN-α-stimulated peripheral mononuclear cells (PBMCs) gated separately for CD8+ T-cells of patients with GCA (n=18), healthy controls (HC, n=15) and infection controls (n=11) by fluorescent cell barcoding and flow cytometry. Also, in 3 GCA patients and 3 HCs, single cell RNA sequencing was performed on PBMCs focusing on ISG expression. Furthermore, IFN-I induced myxovirus-resistance protein A (MxA) and CD8+ expression was investigated in temporal artery biopsies (TAB) of GCA patients (n=20) and GCA mimics (n=20) by immunohistochemistry.
Results: pSTAT1 expression was increased in IFN-α stimulated CD8+ T-cells from patients with GCA compared to both HC ($p<0.05$) and infection controls. Furthermore, Interferon Induced Transmembrane Protein 1 (IFITM1) mRNA expression was upregulated in peripheral blood CD8+ T cells ($p<0.001$). MxA was present in TABs of 13/20 GCA patients compared to 2/20 mimics and MxA location co-localized with CD8+ expression in the tissue.
Conclusion: Our results provide evidence for IFN-I involvement in GCA pathogenesis, with CD8+ T cells as IFN-I responding effector cells. Increased pSTAT1, IFITM1 and MxA expression may reflect increased IFN-I responsiveness in CD8+ T-cells of GCA patients, both locally and systemically. These findings warrant further investigation regarding IFN-I induced biomarkers and IFN-I related novel therapeutic options.

Background: Cellular immunity of Behçet's Disease (BD) remains poorly understood. Previous work has provided clues pointing to most innate and adaptive immune cell types in BD, but strong signals from non-immunogenetic studies are rare and often inconclusive.
Objectives: Here we aimed to identify BD/HD discriminant single immune cell profiles in semi-biased and targeted approaches and determine their significance at a BD relevant effector site.
Methods: We utilized multi-parametric flow cytometry to dissect cellular phenotypes in PBMC of untreated BD patients (n=27) and HD (n=22) consisting predominantly of active ocular and major vascular BD subjects. Data were subjected to supervised machine learning (CITRUS) and results verified with targeted gating. We also analyzed anterior chamber (AC) fluid cells and autologous PBMC from BD uveitis subjects with scRNA seq.
Results: CITRUS identified CD16+, CD14low, CD4low, CD3-, CD19- cells as a BD/HD distinguishing cellular expression pattern at an FDR of >0.05. Targeted gating confirmed highly significant differences with large effect sizes in PBMC of BD vs HD for "non-classical" (CD14lowCD16hi) and "intermediate" (CD14+CD16+) monocytes at decreased frequencies compared to peripheral blood. "Classical" (CD14++CD16-) monocytes were more abundant in BD PBMC than in HD. CD16+ dendritic cells (DC) were significantly decreased in BD PBMC. CD14+ cells showed high abundance in the AC during BD uveitis and co-expressed CD16 far more frequently than CD14+ cells in autologous peripheral blood.
Conclusion: Significantly lower frequencies of CD16+ monocyte and DC subsets in PBMC of untreated active BD vs HD strongly point to their importance in BD. The high abundance of CD14+ cells with CD16 co-expression in the eye during uveitis relative to their frequency in autologous peripheral blood, suggests their transmigration or post-migrational interconversion within the eye during BD uveitis rather than a stochastic process.

POS1442 AMELIORATION OF IGA VASCULITIS BY SUPPRESSION OF THE PATHOLOGICAL EXPANSION OF TFH17 CELLS

Keywords: Vasculitis, Animal models, Treat to target

X. MA[1], Q. Jiang[2], Y. Shan[3], X. Chi[1], H. Jiang[1]. [1]*The First Hospital of China Medical University, Department of Pediatrics, Shen Yang, China*; [2]*Zhongshan City People's Hospital, Department of General Pediatrics, Zhong Shan, China*; [3]*University of Occupational and Environmental Health, Japan, The First Depatment of Internal Medicine, Kitakyushu, Japan*

Background: Immunoglobulin A vasculitis (IgAV), also named Henoch–Schönlein purpura, is a systemic vasculitis characterized by the deposition of IgA1-dominant immune complexes in small vessels that often involves the skin, joints, gastrointestinal tract, and kidney [1-3]. Research indicated increased frequencies of circulating activated B cells and plasmablasts in IgAV, which may serve as the source of the rising IgA levels [4]. T follicular helper (Tfh) 17 cells are considered to support the activation of B cells and help germinal center (GC) B cells switch to high-affinity IgA production. In human, Tfh17 cells prompt naive B cells to produce higher concentrations of IgA [5]. T cell-deficient mice that receive an adoptive transfer of Th17-Tfh cells show induced development of IgA-expressing GC B cells and an increase in the concentration of IgA. Transfer of non-Tfh17 phenotype $CD4^+$ T cells leads to higher amounts of IgG in serum but fails to increase the serum IgA level [6]. Therefore, targeted therapy against Tfh17 cells may specifically inhibit the secretion of IgA and thereby ameliorate IgAV condition.
Objectives: Our previous study has confirmed that Tfh17 cells increase in the peripheral blood of IgAV patients [7]. However, there is no further study on the pathogenesis of IgAV. To evaluate the pathological role of Tfh17 cells in IgAV, we investigated the mechanism responsible for the differentiation of Tfh17 and the production of IgA in IgAV patients and IgAV rats respectively, and explored how to ameliorate IgAV by modulating Tfh17 generation.
Methods: Peripheral blood mononuclear cells from IgAV patients were analyzed by flow cytometry. In vitro culture was performed to assess the modulation of

cytokine-induced phenotypes. IgAV rat model was established by intragastric administration of mixed solution, intraperitoneal injection of ovalbumin and Freund's adjuvant. IgAV rats were used to explore the therapeutic effects of IL-6 blockade and the regulatory functions of IL-6 and TGF-β-producing dendritic cells in Tfh17 cells. Serum cytokine and IgA levels were measured by ELISA while histopathological changes were evaluated by H&E and PAS staining. Flow cytometry and immunofluorescence staining were used to detect T cell and GC B cell phenotypes in circulation and tissues of IgAV rats.

Results: Frequency of $CD4^+CXCR5^+CCR6^+$ Tfh17 cells were increased in IgAV patients and associated with disease severity. IL-6 promoted the dendritic cell production of TGF-β and Tfh17 differentiation. Blockade of IL-6 signaling using tocilizumab inhibited Tfh17 differentiation, resulting in reduction of the germinal center and IgA production. Suppression of Tfh17 cells using IL-6 blockade greatly ameliorated clinical symptoms such as hemorrhagic rash and bloody stool and decreased IgA deposition and mesangial proliferation in the kidney in IgAV rats.

Conclusion: Our findings suggest that suppression of Tfh17 differentiation can alleviate IgA-mediated vasculitis and may permit the development of tailored medicines for treating IgAV.

SLE, Sjön's and APS - clinical aspects (other than treatment)

POS1443 CORRELATION BETWEEN SAXON TEST AND UNSTIMULATED SALIVARY FLOW RATE IN PATIENTS WITH SUSPECTED SJÖGREN´S SYNDROME

Keywords: Sjögren syndrome, Diagnostic tests

M. Fernandez Castro[1], M. J. Santos-Bornez[1], C. Merino Argumánez[1], J. Sanz[1], J. Campos Esteban[1], N. De la Torre Rubio[1], P. Navarro Palomo[1], M. Pavía Pascual[1], M. Machattou[1], H. Godoy[1], M. C. Sánchez Fernández[1], P. D. Briongos Díaz[1], B. García Magallón[1], C. Barbadillo[1], L. F. De Villa[1], C. Isasi Zaragoza[1], J. L. Andréu Sánchez[1], A. Sánchez[1]. *[1]Hospital Universitario Puerta de Hierro Majadahonda, IDIPHISA, Rheumatology, Majadahonda (Madrid), Spain*

Background: Sjögren syndrome (SS) is a chronic systemic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands, which alters their function producing dryness of the mouth, eyes and other mucous membranes. The method used to quantify glandular hypofunction is by whole saliva flow stimulated and unstimulated (UWSF) [1], which takes between 5 and 15 minutes (min).The Saxon test (St) [2], is another tool with the same objective but requires less time: 2 minutes. In the literature, we only have found one study that compared the Saxon test with other diagnostic methods although it is developed in patients without SS [3].

Objectives: To compare the Saxon test and UWSF in a cohort of patients with suspected SS.

Methods: In a consecutive cohort of patients who attended the rheumatology department for suspected SS, UWSF was measured (mL/5 min) and the Saxon test (gr/2 min) was performed. The Index Reported by Patients with SS of the EULAR (ESSPRI) was collected too. This is a patient-reported index designed to assess the severity of patients' symptoms (dryness, pain, somatic and mental fatigue) in SS through an average of single 0–10 numerical scale for each domain. To measure the UWSF, patients were asked to swallow their saliva before the start of the test and then to spit into a container for 5 min. The St was performed by calculating the difference in the weight of two pieces of sterile gauze that the patient chews for two minutes. A UWSF >0.25 mL/min and a St >2.75 g/2min were considered normal, as well as and ESSPRI<5. Spearman's rank correlation coefficient (rs) was used to determine the correlation between both quantitative variables. The Chisquare test and the Gamma test were used in the comparisons between the groups (altered and normal) and the Mann-Whitney U in the comparisons of the quantitative variables based on the groups (altered and normal) previously defined. *P* values <0.05 were considered statistically significant.

Results: We enrolled 199 patients (166 women), with a mean age ± standard deviation of 55,1±13,7 years. The medians (Me) and interquartile ranges (IQR) obtained were 1,50 (0.70 – 2.50) mL/5min for the UWSF, 2,31 (1,60-3,10) g/2min for the St, 6,33 (3.67- 7.67) for ESSPRI and 7,00 (5,00-8,00) for ESSPRI-dryness score. A direct and significant correlation between the St and the UWSF (rs=0,391; $P=2{,}236x10^{-7}$) was observed; 76 patients (38,2 %) presented an altered UWSF and 107 patients (65,2 %) had an altered St. When we analysed the intensity of the association between the different groups (altered/normal) of both variables, we observed a direct and significant association (Gamma value=0,4, *P*=0,019) between both tools. We also detected differences in the St between patients with altered UWSF (Me: 1,72gr/2min; IQR: 1,04-2,50) and those with normal UWSF (Me: 2,62 gr/2 min.; IQR: 1,95-3, 54) ($P=3{,}9x10^{-6}$). Similarly, we observed significant differences in UWSF values between patients with altered St (Me: 1,50 mL/5min IQR: 0,60-2,50) and those with a normal St (Me: 2,00 mL/5min IQR: 1,00-3,00) (*P*=0,014). Regarding the ESSPRI, 129 (65,8 %) patients presented an altered ESSPRI and 153 (78,1%) had an altered ESSPRI-dryness score. The group patients with ESSPRI-dryness score≥5 obtained significantly lower scores on the St (Me: 2,10 g/2min IQR: 1,39-3.01), on the UWSF (Me: 1,5 ml/5min IQR: 0,6-2,0), and on the ESSPRI (Me:7,00 IQR:5,33-8,00) than the normal ESSPRI-dryness score group: Me:2,98 g/2min, IQR:2,22-3,75, on St (*P*=0,001); Me:2,45 ml/5min, IQR:1,50-3,50, on UWSF ($P=6{,}547x10^{-5}$); Me: 3,17 IQR:1, 00-4.08, on the ESSPRI ($P=1{,}17x10^{-15}$).

Conclusion: In patients with suspected SS, there is a direct and significant correlation between the St and the UWSF. Therefore, the St could be useful in the initial assessment of oral gland dysfunction, to save time and/or to select patients who require performing the UWSF.

POS1444 EXTRAGLANDULAR INVOLVEMENT AND AUTOANTIBODY STATUS AS RISK FACTORS FOR CARDIOVASCULAR DISEASE IN PRIMARY SJÖGREN'S SYNDROME (PSS): A 20-YEAR FOLLOW-UP STUDY

Keywords: Autoantibodies, Sjögren syndrome, Cardiovascular disease

C. Sieiro Santos[1], R. Rego Salgueiro[2], P. Pérez-García[1], J. Ordas Martínez[1], C. Moriano[1], C. Álvarez Castro[1], I. González Fernández[1], E. Diez Alvarez[1]. *[1]Complejo Asistencial Universitario de León, Rheumatology, León, Spain*; *[2]ULS Guarda, Internal Medicine, Guarda, Portugal*

Background: Primary Sjögren's syndrome (pSS) is an autoimmune disorder characterized by chronic multisystem inflammation with shared pathophysiology with SLE and RA. Cardiovascular events have emerged as major causes of morbidity and mortality in patients with autoimmune diseases however, the clinical significance of cardiovascular disease in patients with pSS remains unclear.

Objectives: To study the association between cardiovascular disease and primary Sjögren's syndrome (pSS) and analyze the risk of cardiovascular disease accordingly to glandular/extraglandular involvement and anti-Ro/SSA and/or Anti-La/SSB autoantibody status.

Methods: pSS patients fulfilling the 2016 ACR/EULAR classification criteria for pSS was consecutively evaluated and followed in our department between 2000 and 2022. We evaluated the prevalence and clinical significance of cardiovascular risk factors with primary Sjögren's syndrome (SS), focusing on the possible association with clinical and immunological features, the therapies administered, and the impact on cardiovascular disease. A two-tailed value of p<0.05 was taken to indicate statistical significance. Potential risk factors associated with cardiovascular involvement were determined by multivariate regression analyses.

Results: A total of 102 pSS patients were included. 90% were female, with a mean age of 65±24 years and a disease duration of 9.9 ±7 years. The baseline prevalence of comorbidities was 59% for hypertension, 29% for cardiovascular diseases, 34% for dyslipidemia, 15% of diabetes, 29% for obesity, 12% had history of stroke and 17% had arterial/venous thrombosis. 39% of patients had a history of smoking. Patients with extraglandular involvement had a higher

prevalence of cardiovascular risk factors, including arterial hypertension (OR 2.28 95% CI (1.01-5.09), p 0.04), dyslipidemia (OR 4.4 95% CI (1.67-11.6), p 0.003), LDL mean values (116±48 vs 99±44, p 0.038), uric acid (6.58±1.7 vs 4.3±1.03, p 0.04) and higher risk for myocardial ischemia (OR 4.09 95% CI (1.46-11.4), p 0.01) after adjustment for age, sex, disease duration, and the significant variables in the univariate analysis. Patients positive for both Ro/SSA and La/SSB autoantibodies had a substantially higher risk of arrythmia (OR 3.4 95% CI (1.01-10.6), p 0.04), arterial and venous thrombosis (OR 5.5 95% (1.18-25.7), p 0.03) and stroke (OR 3 95% (1.02-8.8), p 0.04). In the multivariate logistic regression analysis, extraglandular organ involvement (p=0.008), beta2microglobulin levels (p=0.001), the use of glucorticoids (p=0.02), hypergammaglobulinemia (p=0.02), ESR levels (p=0.007) and an ESSDAI (Sjögren's syndrome disease activity index)>13 (p=0.02) were found to be risk factors associated with cardiovascular events in pSS patients, meanwhile C3 levels (p=0.01) and treatment with HCQ (p=0.03) were protective factors. Anti-Ro/SSA and anti-La/SSB were significant predictors in univariate but not in multivariate analysis.

Conclusion: pSS patients are more vulnerable to cardiovascular diseases (CVDs). In addition to traditional CVD risk factors, we identified risk factors independently associated with cardiovascular involvement in pSS patients, which suggests the need for early detection and prevention measures to improve the prognosis in those patients.

Table 4. Significant logistic regressions for predictors for CV risk

	OR 95% IC	P value
Extraglandular involvement	16.5 (4.51-28.5)	0.008
Beta2microglobulin (mg/dL)	7.83 (3.16-12.5)	0.001
C3 (mg/dl)	0.92 (0.24-0.98)	0.01
Glucocorticoids	7.2 (2.34-15.7)	0.02
Hypergammaglobulinemia	10.2 (4.5-21.2)	0.02
ESSDAI >13	1.2 (0.23-4.52)	0.02
ESR (mm/h)	1.1 (0.42-3.45)	0.007
HCQ	0.82 (0.26-0.92)	0.03

Background: Within the group of inflammatory myopathies, Inclusion-Body Myositis (IBM) is a distinct pathology with clinical and histological features very different from other entities. In the literature, an association between primary Sjögren's syndrome (pSS) and IBM has been previously reported.

Objectives: The aim of our study was to compare the inflammatory infiltrates between IBM associated or not with pSS and, among patients with pSS, between muscle and salivary gland.

Methods: We conducted a translational research project, from formalin-fixed and paraffin-embedded muscle biopsies of patients with IBM, associated with Sjögren's syndrome (IBM-pSS) and sporadic (sIBM) forms, from 6 French expert centers, and salivary glands were collected when available. Imaging mass cytometry (IMC) multiplex immunostaining (37 markers) was used to quantify and decipher the composition of the inflammatory infiltrates within samples (Figure 1). Supervised and unsupervised statistical analyses were performed to compare IMC data between IBM-pSS and sIBM patients and muscle and salivary glands among patients with pSS.

Results: No statistically significant difference was encountered in our comparisons between IBM-pSS and sIBM muscle biopsies. Nevertheless, some trends were pointed and could merit further work in larger case series. Indeed, IBM-pSS samples (14 patients) tended to have more widespread inflammatory infiltrate than sIBM samples (7 patients) involving on average 4.8% versus 1.6% of muscle biopsy surface respectively (p=0.12). Macrophages and T cells were the predominant populations in both IBM-pSS and sIBM patients' groups. Among T cells, CD8+ cells predominated compared to CD4+ cells in both groups. The proportion of plasma cells (CD138+ CD38+ CD27+) was higher in IBM-pSS than in IBMs patients (medians of 14.7% and 8.5%, respectively, p=022), as was the proportion of B cells (median of 3.1% and 0.5%, respectively, p=0.14). Comparing salivary gland and muscle biopsies in patients with pSS, the plasma cells were predominant in the salivary gland with more numerous plasma cells and B cells and less numerous macrophages and T cells in salivary glands than in muscle samples. Nodular inflammatory infiltrate pattern containing B cells appeared to be restricted to pSS patients both in muscle and salivary gland biopsies.

Conclusion: Using for the first time IMC on muscle biopsy and salivary gland has allowed us 1) to point difference between IBM-pSS and sIMB and 2) similarities between salivary and muscle inflammatory infiltrates in patients with pSS samples. These differences suggest that IBM associated with pSS has a distinct pSS-related pathophysiology compared to sIBM, which could raise potential diagnostic and therapeutic applications.

POS1446 VARIATION IN SYSTEMIC DISEASE ACTIVITY MEASURED WITH ESSDAI IN A PROSPECTIVE LONGITUDINAL COHORT OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME WITHOUT IMMUNOSUPPRESSIVE TREATMENT

Keywords: Outcome measures, Sjögren syndrome

L. De Wolff[1], G. M. Verstappen[1], A. J. Stel[1], G. S. Van Zuiden[1], J. F. Van Nimwegen[1], A. Vissink[2], F. G. M. Kroese[1], S. Arends[1], H. Bootsma[1]. *[1]University of Groningen, University Medical Centre Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]University of Groningen, University Medical Centre Groningen, Oral and Maxillofacial Surgery, Groningen, Netherlands*

Background: The EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) has been used as primary endpoint in many recent randomised clinical trials (RCTs) in patients with primary Sjögren's syndrome (pSS). In multiple RCTs, a large placebo effect (>50%) was observed with the ESSDAI. Since patients are often included with a moderate or high disease activity (ESSDAI ≥5), this placebo effect may partly be due to regression to the mean [1]. Little data is available on the natural course of the ESSDAI in patients who are not treated with immunosuppressives in daily clinical practice.

Objectives: To assess the variation in ESSDAI up to five years of follow-up in a cohort of pSS patients without immunosuppressive treatment.

Methods: This prospective longitudinal study included consecutive outpatients with pSS from the ongoing Registry of Sjögren Syndrome LongiTudinal (RESULT) cohort who fulfilled the ACR/EULAR classification criteria for pSS and who reached at least two years of follow-up with available ESSDAI until December 2022. Patients who received immunosuppressive treatment (biological DMARDs, conventional synthetic DMARDs, including hydroxychloroquine, or prednisone) were excluded. Patients visited the outpatient clinic once a year, or on clinical indication more often, and at each visit the ESSDAI was recorded. All

available visits from baseline up to five years of follow-up were used for analyses. For the analysis at group level, yearly visits were used, defined as the nearest available ESSDAI within a time frame of ±6 months from the yearly visit. For analyses at individual patient level, all available ESSDAI scores were used. The largest change (Δ) in ESSDAI was calculated for each patient by subtracting the lowest ESSDAI from the highest ESSDAI score during follow-up.

Results: In total, 247 pSS patients fulfilled ACR/EULAR classification criteria and reached at least two years of follow-up with available ESSDAI. Of these, 142 patients did not receive immunosuppressive treatment and were included. 126 (89%) of these patients were female, median age was 53 years (IQR 43-65), median disease duration was 6 years (IQR 2-10) and 122 (87%) were anti-SSA positive. Median ESSDAI at baseline was 3 (IQR 1-6) and 93 (67%) patients had a low disease activity according to ESSDAI (score<5). At group level, ESSDAI remained stable during five-year follow-up (Figure 1A). At individual patient level, the ESSDAI varied in the majority of patients (Figure 1B). The median largest Δ (worsening or improvement) in ESSDAI was 4 (IQR 2-8, range 0-22). In total, 93 (65%) patients had a Δ of ≥3 points in ESSDAI, and 65 (46%) patients a Δ of ≥5 points at some point during follow-up. Of the 93 patients with an ESSDAI<5 at baseline, 50 (54%) patients remained in a low disease activity state during follow-up (median follow-up 40 months). Of the 46 (89%) patients who had a moderate or high disease activity (ESSDAI≥5) at baseline, 41 (89%) improved to a low disease activity for at least one visit (Figure 1B) and 37 (80%) patients reached the previously defined minimal clinically important improvement of ≥3 points improvement at some point during follow-up compared to baseline.

Conclusion: In this prospective longitudinal cohort of pSS patients without immunosuppressive treatment, a large variation in ESSDAI was observed during follow-up in individual patients, despite the median ESSDAI scores remaining stable at group level. This study underlines that natural variation in systemic disease activity measured with ESSDAI should be taken into account when using ESSDAI as study endpoint.

Background: In recent years, rheumatology research focused on first-degree relatives of people with rheumatic diseases, mainly rheumatoid arthritis, since they have a higher risk of developing the disease compared with the general population and offer a potential source of insight into the preclinical phase of the disease. However, evidence on preclinical Sjögren's syndrome is still lacking.

Objectives: To explore the perspective of first-degree relatives of people with SS and inform the Pre-Sjögren's Syndrome Targeted Immunology Evaluation (PreSStige) study, conducted under the auspices of the EULAR Study Group on Sjögren's Syndrome (eSSential).

Methods: An online survey targeting first-degree relatives of people with SS was developed in English and translated into 11 languages (Italian, German, French, Spanish, Portuguese, Greek, Swedish, Finnish, Romanian, Norwegian and Maltese). The survey was launched on social media on December 15, 2022 and distributed via patient associations, forums, support groups, and in 3 Rheumatology participating centres (Austria, Italy and Portugal). Respondents without a diagnosis of SS were confronted with a scenario where they were offered a free rheumatology examination to assess whether they had symptoms suggestive of pSS. If so, they are advised to undergo additional exams (within a variable range of costs) to ascertain whether they have pSS. Surveys were accepted until January 10, 2023.

Results: Of 1064 people starting the survey, 677 respondents from 32 countries fulfilled the entry criteria (age >18 years, being a first-degree relative of a person living with pSS). 90% of respondents were siblings, 7% were offspring, and 3% were parents of pSS patients. Respondents were mainly females (80%), aged 30-49 years (31%) and 50-70 years (38%). 155 (23%) of respondents already had a diagnosis of SS, while 119 (17%) had a diagnosis of other autoimmune diseases (AD) (23/119, 19% had more than one AD). When asked about their perceived risk of developing SS or another AD, several respondents did not feel to be at higher risk being first-degree relatives of affected people (Figure 1). When confronted with an hypothetical scenario, over half of the respondents without a diagnosis of pSS (N=522) mentioned feeling either worried, sad or scared about the possibility of being diagnosed with pSS. Nonetheless, the majority of them (86% of 522) were keen on accepting a preclinical rheumatology consultation, with the main reason for that being, "If I have pSS/other autoimmune diseases, I want to know it as early as possible" (82%). Conversely, those that would decline a free rheumatology examination mainly justified their decision based on the absence of symptoms suggestive of pSS (56%). Among respondents that would accept a free rheumatology consultation, 84% would proceed further and perform additional exams if advised by the rheumatologist based on the detection of symptoms/signs suggestive of pSS. As above, the main reason was the possibility of achieving an early diagnosis. The respondents that accepted the free rheumatology consultation but would not proceed further even if the rheumatologist would identify red flags for pSS mentioned the economic aspect as the main barrier (specifying they would accept performing additional exams if free of charge).

Conclusion: Our study explored, for the first time, the perspective of first-degree relatives of people with SS highlighting an overall willingness to undergo preclinical examinations for an early SS diagnosis. Economic challenges (namely,

paying for diagnostic exams) have been identified as a barrier. The survey is still open and is being translated into additional languages to increase its reach.. The results of the survey will inform the next steps of the Pre-Sjögren's Syndrome Targeted Immunology Evaluation (PreSStige) study.

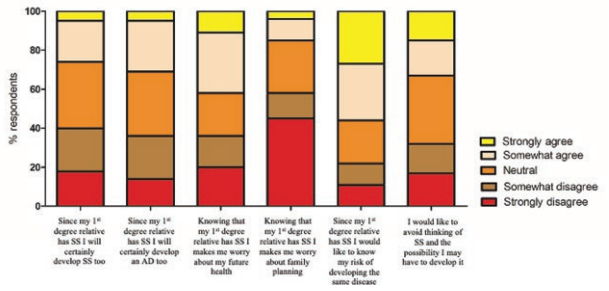

Figure 1. Respondents' level of agreement with statements related to their perceived risk and attitude towards the development Sjögren's Syndrome or other autoimmune diseases

POS1448 INDIVIDUALS AT RISK FOR SJÖGREN'S SYNDROME – TWO-YEAR DATA OF THE PRESSTIGE (THE PRE-SJÖGREN SYNDROME TARGETED IMMUNOLOGY EVALUATION) STUDY

Keywords: Sjögren syndrome, Autoantibodies

S. Zenz[1], P. Javorova[1], L. Erlacher[1], B. Dreo[1], A. Lackner[1], D. Cornec[2], J. Thiel[1], M. Stradner[1]. *[1]Medical University of Graz, Department of Rheumatology and Immunology, Graz, Austria*; *[2]University of Brest, Department of Rheumatology, Brest, France*

Background: Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease often diagnosed years after appearance of the first symptoms. Therefore, little is known about initial development of the disease. Anti-Ro antibodies can be found years before the first symptoms appear.
Objectives: To identify individuals at risk for pSS and follow up over 10 years to examine symptoms and immunopathology before and during the development of pSS.
Methods: This ongoing longitudinal study enrolled individuals at risk for developing pSS but have not met the ACR-EULAR classification criteria. We recruited three groups: A.) Anti-Ro positive individuals without any symptoms for an underlying systemic autoimmune disease; B.) First degree relatives of patients with a diagnosis of pSS AND an abnormal immunologic laboratory value (ANA ≥ 1:160 and/or anti-Ro$^+$ and/or rheumatoid factor$^+$) C.) Individuals with at least one feature of the ACR-EULAR classification criteria for pSS, but not fulfilling the criteria. At screening and at annual follow-up visits, demographic data, blood, urine and saliva samples were obtained. Salivary flow, Schirmer's test, and salivary gland ultrasonography (SGUS) using Hocevar-Score were performed. A lip salivary gland biopsy (LSB) was obtained at the screening visit and repeated once when typical symptoms appeared within the follow-up visits. The primary endpoint was the development of definite pSS according to the ACR-EULAR classification criteria or a diagnosis of another systemic autoimmune disease.
Results: After two years, 53 subjects were recruited from all three groups, of whom 31 were enrolled in the study (Anti-SSA$^+$ n=25, relatives n=4, incomplete n=2). Most of the 22 screening failures were relatives who did not have an abnormal immunologic laboratory value. 28 individuals were female, they had a mean age of 49.6 ± 12.7 years (SD; standard deviation) and a mean body weight of 71.4 ± 15 kg. 11 individuals reported having a relative with an underlying autoimmune disease. The median ESSDAI was 0 (0-5; min-max). individuals had a pathological stimulated whole saliva flow (mean 3.7 ± 1.4 g) and eight had pathological Schirmer's test (left eye: mean 13.6 ± 13.1 mm; right eye: 13.2 ±12.2 mm). Three of 14 individuals had a pathological SGUS score. All three individuals were recruited in the Anti-Ro$^+$ group. At screening visit, 11 LSB were performed (mean focus score of 0.53 ± 1.2) and one individual reached a focus score ≥ 1. So far, 18 individuals have completed the two-year visit. Two of them had pathological stimulated whole saliva flow (mean 3.85 ± 1.4 g) and five of them a pathological Schirmer's test (left eye: mean 15.4 ± 13 mm; right eye: 14.5 ± 13). The median ESSDAI was 0 [0-4]. Eight SGUS were performed with a mean Hocevar-Score of 5.6 ± 8. Within two years, four patients (13%) were diagnosed with pSS, one (3%) with systemic lupus erythematosus and one (3%) with rheumatoid arthritis.
Conclusion: This longitudinal study for the first time provides us with data on the evolution of pSS. Future recruitment at multiple centers and longer follow-ups will shed light on the earliest phase of pSS.

POS1449 CARDIOVASCULAR DISEASE IN PRIMARY SJÖGREN SYNDROME

Keywords: Sjögren syndrome, Cardiovascular disease

C. L. Zippel[1], S. Beider[2], E. Kramer[2], F. F. Konen[3], T. Seeliger[3], T. Skripuletz[3], S. Hirsch[2], A. Dopfer-Jablonka[2], T. Witte[2], K. Sonnenschein[4], D. Ernst[2]. *[1]Hannover Medical School, Department of Rheumatology and Immunology, Hannover, Germany*; *[2]Hannover Medical School, Department of Rheumatology and Immunology, Hannover, Germany*; *[3]Hannover Medical School, Department of Neurology, Hannover, Germany*; *[4]Hannover Medical School, Department of Cardiology, Hannover, Germany*

Background: Primary Sjögren's syndrome (pSS) is associated with an increased prevalence of traditional risk factors and cardiovascular diseases (CVDs).
Objectives: The study aimed to identify specific risk factors for CVD in pSS patients.
Methods: PSS patients with and without CVD were compared. All patients fulfilled the EULAR/ACR classification criteria. Patients with CVD presented at least one of the following manifestations: myocardial infarction, transient ischemic attacks, ischemic or hemorrhagic stroke, peripheral artery disease, coronary artery disease and carotid plaques. Data were collected by a standardized protocol and review of medical records.
Results: 61/312 (19.6%) pSS patients presented with CVD. Traditional risk factors such as hypertension, hypercholesterinemia and diabetes (p<0.05), pSS manifestations, in particular vasculitis (p=0.033) and Raynaud's phenomenon (p=0.018) were associated with CVD. Among patients with ischemic events (28/312, 9%), particularly cerebrovascular disease (n=12/28, 42.9%), correlations with increased EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) (p=0.039) and EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) (p=0.048) were observed. Age at first cerebrovascular event was 55.2 [48.9 – 69.6] years. Multivariate analysis confirmed hypertension (odds ratio (OR) 3.7, 95% confidence interval (CI) 1.87–7.18, p<0.001), hypercholesterinemia (OR 31 3.1, 95% CI 1.63–5.72, p<0.001), male gender (OR 0.4, 95% CI 0.17–0.78, p=0.009), Raynaud's phenomenon (OR 2.5, 95% CI 1.28–4.82, p=0.007) and CNS involvement (OR 2.7, 95% CI 1.00–33 7.15, p=0.048) as independent CVD predictors.
Conclusion: Raynaud´s phenomenon as well as vasculitis and high ESSDAI have shown a significant association to CVD. PSS patients with cerebrovascular events were younger than expected. Knowledge about risk factors may help clinicians to identify pSS patients at risk for CVD. After diagnosis of pSS, patients should be screened for risk factors such as hypertension and receive appropriate therapy to prevent or at least reduce sequelae such as infarction. However, further investigations are necessary in order to achieve a reliable risk stratification for these patients.
Acknowledgements: We would like to express our gratitude to the staff of the Rheumatology Outpatients Department at Hannover Medical School for their continual help in organization of patients Reference styles.
Disclosure of Interests: None Declared.

POS1450 3-YEAR ANALYSES OF AT-RISK ANA-POSITIVE COHORT: PROGNOSTIC VALUE OF CLINICAL AND INTERFERON BIOMARKERS TOWARDS AUTOIMMUNITY

Keywords: Biomarkers, Sjögren syndrome, Systemic lupus erythematosus

M. Y. MD Yusof[1,2], S. U. Hassan[2], Z. Wigston[1], A. Psarras[1], J. Arnold[1], L. M. Carter[1], P. Emery[1,2], E. Vital[1,2]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Autoimmune connective tissue disease (AI-CTD) arise from a common "At-Risk" ANA-positive population in which clinical phenotype does not reliably predict progression. We previously showed that higher IFN-Score-B and family history were predictive of progression to meeting classification criteria at 12-months[1]. However, classification criteria may undergo revision and not capture all significant outcomes. There is limited data on longer-term outcomes since some may progress at later time-points.

Objectives: To describe the 3-year outcomes of At-Risk individuals; to assess discriminative ability of baseline clinical and IFN-Score-B in predicting various progression endpoints at 1 and 3 years.

Methods: We conducted a prospective cohort study in At-Risk individuals (ANA-positive, non-specific symptoms of ≤1 year and treatment naïve). Patients were assessed at baseline, then annually for 3 years. We used multiple RMD classification criteria, including the revised 2019 EULAR/ACR for SLE, and need for therapy, to group patients as below:

1. Absolute non-progressors (ANP) (no clinical criteria)
2. Undifferentiated CTD (U-CTD) (≥1 clinical criteria but not fulfilling RMD criteria). This group was subdivided into those requiring an immunosuppressant (IS) excluding antimalarials only and those who did not)
3. Year 1 progressors (meeting criteria for RMD by 1 year)
4. Late progressors (meeting criteria for RMD in Years 2-3)
5. Clinically significant disease (CSD) (progressors OR U-CTD on IS)

Bloods were analysed for two IFN-stimulated gene expression scores previously described[2]. Discrimination of single or combined clinical and IFN-Score-B markers were assessed using ROC curve analyses.

Results: Of 148 patients, 132 (89%) were female, 107 (72%) were Caucasians, 48 (32%) had a family history of RMD, 56 (38%) were anti-dsDNA+ and 8 (6%) had low C3 and/or C4 level. Number of established clinical criteria at baseline were 0 (30%), 1 (64%) and 2 (6%). Outcomes were: Year 1 progressors: 21 (14%) [SLE=14; pSS=6; AS=1]; Late progressors: 12 (8%) [SLE=10; pSS=1; AS=1]; U-CTD on IS: 8 (5%); U-CTD on antimalarials only: 20 (14%); U-CTD not on therapy: 52 (35%) and ANP: 35 (24%). Thus, 41 (28%) patients were classified as CSD. Only 2/148 (1%) patients progressed after the first 2 years. For the prediction of Year 1 progressor, in addition to baseline IFN-Score-B and family history, multivariable logistic regression showed total number of any established clinical criteria was associated with increased risk, OR 6.8 (95% CI 1.8-25.4). Table 1 showed that the combined baseline markers (IFN-Score-B, family history and number of clinical criteria) had good accuracy in predicting various definitions of progression at Years 1 and 3 as per AUROC.

Conclusion: Just over a quarter of At-Risk individuals developed into CSD (progressors and patients who did not meet criteria but needed IS therapy) by 3-year follow-up. Combined baseline clinical and IFN biomarkers could be used to risk stratify ANA-positive referrals to rheumatology at the first visit to exclude imminent or future disease/requirement of immunosuppressant. A validation study with cost-effectiveness analysis of these markers is in progress and would help translate their use in clinical practice and inform early therapy trials in the "High Risk" individuals.

Background: The most important diagnostic test in Sjogren's syndrome is the minor salivary gland test (MSGB). Immunohistochemical staining of the MSGB may provide prognostic value for organ affection.

Objectives: To compare the lymphocytic composition of the MSGB and major organ affection in patients with Sjogren's syndrome during 3 years of follow-up. To compare the lymphocytic composition of the MSGB and worsening of SSDDI index more than 2 points.

Methods: A retrospective cohort study was conducted. Inclusion criteria was patients ≥18 years that met 2016 ACR/EULAR criteria for Sjogren's Syndrome with focal lymphocytic sialadenitis (≥1 infiltration of ≥50 lymphocytes) by MSGB. CD45, CD4, CD8, CD20 staining was carried out for all samples. Infection, amyloidosis, IgG4 related diseases or head radiation therapy were excluded. Finally, 78 patients from the systemic autoimmune diseases division between September 2017 – October 2018 were included. Patients were followed up for 3 years. The outcomes evaluated were: 1. Severe organ affection (defined as lymphoma, interstitial lung disease, central or peripheral nerve system, renal involvement or arthritis) that required steroids or disease modifying drugs; 2. Worsening of SSDDI index ≥ 2 points.

Results: The mean age was 60.6 (SD 12.7) and 8 (10.3%) of the patients were men. There was overlap with other SAD in 13 (16.7%) patients. Severe organ damage was present in 16 (20.5%) and moderate or high ESSDAI in 6 (7.7%) at baseline. Ro52/60 was present in 15 (19.3%). Steroid treatment was used in 6 (7.8%). The baseline characteristics of patients with severe organ affection was compared with patients that did not present severe organ affection. Patients with severe organ affection had a significantly higher proportion of male sex (56.3% vs 35.7%), higher median baseline ESSDAI (3.81 vs 1.06, p=0.00) and SSDDI (1.88 vs 1.02, p=0.04). Higher proportion of lymphoma (18.8% vs 3.2%, p=0.024), higher proportion of steroids (37.5% vs 0, p=0.00) and higher proportion of disease modifying drugs (37.5% vs 3.2%, p=0.00) were observed as well. The comparison of lymphocytic composition of the BGSM according to outome 1 and outcome 2 are summarized in Table 1.

Table 1.

Variable, mean (SD)	Stable disease	Severe organ affection	p-value	SSDDI ≤ 2	SSDDI > 2	p-value
Number of infiltrates	1.44 (0.88)	1.88 (1.15)	**0.049**	1.46 (0.87)	1.68 (1.13)	0.18
Total lymphocytes	121.05 (112.52)	191.56 (256.17)	**0.051**	124.91 (117.56)	162.5 (222.27)	0.17
T cells	58.95 (38.77)	115 (157.06)	**0.0062**	60.27 (38.98)	96.36 (137.57)	**0.038**
CD4+ cells	41.4 (3.39)	82.11 (27.58)	**0.046**	42.39 (25.21)	70.25 (93.61)	**0.027**
CD8+ cells	24.69 (2.38)	49.32 (17.94)	**0.0084**	23.59 (17.10)	46.97 (59.56)	**0.007**
B cells	62.10 (84.06)	76.56 (132.71)	0.30	64.64 (88.66)	66.14 (112.45)	0.48
Limfos aïllats	0.18 (0.39)	0.19 (0.40)	0.46	0.19 (0.40)	0.13 (0.35)	0.27

Conclusion: There were significantly increased number of total lymphocytes and number of infiltrates in the MSGB of patients that presented severe organ affection within 3 years of follow up. Also a significantly increased number of T cells, both CD4+ and CD8 cells, were observed in patients with severe organ affection.

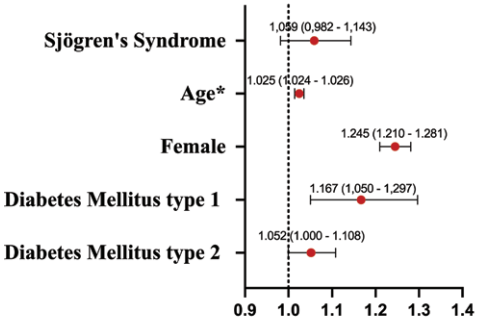
POS1452

PERIODONTITIS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME: A NORWEGIAN NATION-WIDE REGISTER STUDY OF 10 086 PATIENTS

Keywords: Sjögren syndrome, Registries, Epidemiology

O. O. Aga[1], A. Bolstad[2], S. Lie[3], B. T. Svanes Fevang[4]. [1]*The Faculty of Medicine, University of Bergen, Bergen, Norway*; [2]*Department of Clinical Dentistry, University of Bergen, Bergen, Norway*; [3]*Department of Clinical Dentistry, University of Bergen, Bergen, Norway*; [4]*Haukeland University Hospital, Bergen, Department of Rheumatology, Bergen, Norway*



Background: Primary Sjögren's syndrome (pSS) is a systemic autoimmune disorder characterized by focal lymphocytic infiltration of the exocrine glands causing dry eyes and dry mouth. Immunological mechanisms in pSS have similarities with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), which have increased risk for periodontitis [1]. Patients with pSS already have inferior oral health and information regarding a possible connection between periodontitis and pSS is sparce. There is a need to explore this further in a large-scale study.
Objectives: To investigate the association between periodontitis and primary Sjögren's syndrome in a large national cohort.
Methods: We conducted a population-based study, where the cohorts were identified based on International Classification of Disease (ICD)-10-codes registered in the Norwegian Patient registry (NPR) during the period January 2011 – December 2017. The outcome was the manifestation of periodontitis defined by either at least one registration of periodontal surgery or 6 or more registrations of systematic treatment of periodontitis in the Norwegian Control and Payment of Health Reimbursement (KUHR). To be included in the pSS cohort (n=10 086) patients had to have 4 or more registrations with M35.0 as the main diagnosis in NPR. This limit was set to minimize the risk of miscoding. The comparative cohort (n=310 573) entailed patients treated for assumed non-osteoporotic fracture or having undergone hip- or knee replacement due to osteoarthritis during the study period. Only patients between 20 – 80 years of age were included, and patients with RA or SLE was excluded from the study population. Odds Ratio (OR) for periodontitis was calculated using logistic regression analyses adjusting for sex, age, diabetes mellitus (DM) 1 and 2, myocardial infarction (MI) and death. Lastly, similar regression analyses were performed for 6 age categories.
Results: A total of 760 (7.5%) patients in the pSS cohort had periodontitis, compared to 22 178 (7.1%) in the control cohort (p = 0.13), **Table 1**. When adjusting for age, sex, DM1 and DM2, the presence of pSS had no significant association to periodontitis (OR: 1.06, 95% CI: 0.98 – 1.14), **Figure 1**. In the age group 50 – 60 years the presence of pSS was statistically significantly associated periodontitis (OR: 1.22, 95% CI: 1.06 – 1.40). The same association could not be seen in any other age group. Furthermore, increasing age was associated with increased risk of periodontitis (OR: 1.025, 95% CI: 1.024 – 1.026.)
Conclusion: These results indicate that patients with pSS age 50-60 years have a significant increased risk of periodontitis compared to a control population. However, we observed no association between periodontitis and pSS in any of the other age groups in this large nationwide study.

PROGRESSIVE PULMONARY FIBROSIS ACCORDING TO THE NEW ATS DEFINITION IS NOT UNCOMMON IN THE CONTEXT OF SJÖGREN'S SYNDROME-ASSOCIATED INTERSTITIAL LUNG DISEASE

Keywords: Sjögren syndrome, Lungs

G. La Rocca[1], F. Ferro[1], S. Fonzetti[1], G. Fulvio[1], I. C. Navarro García[1], C. Romei[2], M. Mosca[1], C. Baldini[1]. [1]*University of Pisa, Department of Rheumatology, Pisa, Italy*; [2]*Pisa University Hospital, 2nd Radiology Unit, Department of Radiology, Pisa, Italy*

Background: Interstitial Lung Disease is relatively frequent in Primary Sjögren's Syndrome patients (SS-ILD), however, data on its prognosis are heterogenous. The American Thoracic Society (ATS) recently provided clinical-instrumental criteria for the definition of Progressive Pulmonary Fibrosis (PPF) (1), based on the assumption that this clinical phenotype is associated with worse prognosis and may benefit from treatment with the novel antifibrotic agents. Frequency and characteristics of PPF, defined according to ATS, have not been investigated in the context of SS-ILD.
Objectives: 1. To describe the outcome of SS-ILD in terms of ILD progression according to the recent definition of PPF in our cohort. 2. To identify specific factors associated to PPF in well characterized SS-ILD patients.
Methods: Demographic, clinical, biological and imaging data of SS patients attending our center were retrospectively analyzed. SS-ILD was defined based on clinical history, pulmonary function tests (PFT) and HRCT assessed by an expert thoracic radiologist for all patients. She also defined ILD pattern, extension (by Warrick score) and progression on HRCT. The new ATS definition of PPF was applied to all SS-ILD patients in follow-up in the last 4 years, who presented at least 2 clinical-instrumental evaluations at 1 year of distance. PPF was defined in the presence of 2/3 among: worsening symptoms, significant functional decline (FVC ≥5% or DLCO ≥10%) and radiological progression, within 1 year. PPF and non-PPF SS-ILD patients, with complete imaging and functional follow-up data available, were then compared in terms of clinical, biological, functional and imaging features. For statistical analysis, we used the Fisher test for categorical data and the ANOVA t-test or Mann-Whitney test for continuous data.
Results: Out of 620 primary SS patients attending our center, 52 (8.4%) were diagnosed with SS-ILD (F:M=46:6). Mean age at diagnosis was 61 (±13) years, positive SSA were present in 44/52 (84.6%), and the mean follow-up time was 8 (±7) years. ILD was the first manifestation of SS in 32/52 (61.5%) and followed SS diagnosis in 20/52 (38.5%) cases, with a mean latency of 8.5 (±6) years. The distribution of ILD patterns was in line with recent literature, with 24/52 (46.2%) patients presenting NSIP, 9/52 (17.3%) UIP, 7/52 (13.5%) LIP, 8/52 (15.4%) NSIP+OP, 2/52 (3.8%) OP, and 2/52 (3.8%) an unclassifiable pattern. Out of 46 SS-ILD patients with available follow-up data: 13/46 (28.3%) presented worsening clinical symptoms; 13/42 (31%) experimented significant decline of FVC (≥5%) and/or DLCO (≥10%), while 4 patients were unable to perform PFT due

to desaturation; 3/46 (6.5%) patients died because of ILD progression. Complete seriate evaluations including HRCT at 1-year distance were available for 17 patients: 8/17 (47.1%) were defined as PPF and 10/17 (58.8%) as non-PPF according to the ATS definition. The former group exhibited older age at diagnosis (p=.001) and a UIP pattern in 5/8 vs 0/9 cases (p=.06). Standard of care immunosuppressive treatment did not differ significantly between the two groups, while no patients were treated with antifibrotics.

Conclusion: The clinical phenotype of PPF is relatively common among SS-ILD patients and is associated with older age at diagnosis and a UIP pattern on HRCT. These characteristics may aid in the selection of patients eligible for antifibrotic therapy.

Background: Salivary gland ultrasonography (SGUS) is commonly used in primary Sjögren Disease (pSD) as a diagnostic tool [1]. It could also be used to monitor disease activity, but severity of SGUS parenchymal abnormalities in relation to disease duration is not well characterized.

Objectives: To assess transversally the severity of ultrasound salivary parenchymal abnormalities in relation to pSD duration.

Methods: In this prospective cross-sectional international multicentric study, patients with pSD according to 2002 or 2016 ACR/EULAR classification criteria were included. Parenchymal abnormalities assessed by ultrasound within both parotid and sub-mandibular glands were reported on a standardized form and classified according to the semi-quantitative score of the OMERACT (global score and each item evaluated separately) [2]. Reliability between experts was measured after online training. Demographic, clinical and paraclinical data were also collected and patients were separated into 4 groups according to disease duration from the first buccal dryness symptoms (group A: < 5 years, group B: between 5 and 10 years, group C: between 10 and 20 years, group D: > 20 years of evolution).The association between disease duration groups and SGUS parenchymal abnormalities was quantified in terms of odds ratio and its 95% confidence interval.

Results: 247 patients were consecutively included between May 2019 and February 2022 in 12 international centers. They were 47, 69, 78 and 53 in groups A, B, C and D, respectively. Women represented 94.7% of patients, with a median age of 58 [range 19-89] years old. Oral and ocular dryness were reported by 99.6% and 95.1% of patients, respectively. Salivary flow was abnormal in 74.7% of patients and Schirmer's test in 82.1%. The focus score was ≥1/4mm2 in 89% of patients. 85% of patients had positive anti-SSA and 59.6% had rheumatoid factor. The median ESSDAI score was 3 [0-48]. Considering for each patient the gland with the highest US OMERACT score, there was a global significant association between disease duration and OMERACT score (OR for 5 years duration: 1.23 [IC95% 1.04; 1.47], p=0.02). When comparing groups A+B versus C+D on the OMERACT score, the OR was 1.95 [IC95% 1.10; 3.46], p=0.02, while no significant difference was found when comparing group A versus B+C+D. Considering each item of the OMERACT score, there was not any statistical difference between the 4 groups in relation to the proportion of an/hypoechoic areas in the gland nor homogeneity or posterior border visibility. The only statistical difference between groups was found regarding the proportion of hyperechoic bands (p = 0.0009). When comparing group A versus B+C+D on this item, the OR was 2.55 [95%CI 1.30-5.01], p=0.006).

Conclusion: This large international transversal study in patients with pSD found a positive association between global SGUS lesions evaluated by the OMERACT score and disease duration, with a significant difference only observed in the proportion of hyperechoic bands, when considering separately each item of the score. This may suggest a progressive fibro-adipous evolution of the gland across disease duration. The presence of diffuse hyperechoic bands (grade 3 in the OMERACT scoring system), corresponding to a higher disease duration group, could be useful in the future to stratify patients in clinical trials and to interpret SGUS modifications after treatment.

Kwok[2]. *[1]Uijeongbu St. Mary's Hospital,The Catholic University, Division of Rheumatology, Department of Internal Medicine, Euijeongbu, Korea, Rep. of (South Korea)*; *[2]The Catholic University of Korea Seoul St. Mary's Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[3]The Catholic University of Korea Yeouido St. Mary's Hospital, Division of Rheumatology, Department of Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[4]Bucheon St. Mary's hospital, the Catholic Univ. of Korea, Pulmonary, Allergy and Critical Care Medicine, Bucheon, Korea, Rep. of (South Korea)*; *[5]Bucheon St. Mary's Hospital, the Catholic university of Korea, Division of Rheumatology, Department of Internal Medicine, Bucheon, Korea, Rep. of (South Korea)*

Background: Interstitial lung disease (ILD) is a potentially serious yet underdiagnosed manifestation of primary Sjogren's syndrome (pSS).

Objectives: This observational study aimed to investigate the clinical, functional, and imaging characteristics of ILD in pSS, together with treatment and prognosis.

Methods: Longitudinal clinical and laboratory data of patients with pSS were extracted from three hospitals of the Catholic Medical Center through a clinical data warehouse, between March 1, 2012, and February 28, 2022. Predisposing factors for the development of ILD and acute exacerbation were identified using a logistic regression model.

Results: A total of 1,402 patients with pSS were included in this study (Female, 98%; median age, 55 years). Among them, 92 patients with pSS (7%) were comorbid with ILD (21 biopsy-proven cases). Fibrosing nonspecific interstitial pneumonia (NSIP) was the most prevalent CT pattern in pSS-ILD (58%), followed by usual interstitial pneumonia (20%), and organizing pneumonia (16%). At the diagnosis with pSS-ILD, 64% of patients showed reduced diffusion capacity, and 54.3% of patients with pSS-ILD showed a restrictive functional pattern. The median follow-up period was 3.2 years. During follow-up, six patients died (6.5%) and 26 patients (28.3%) experienced acute exacerbation (AE). However, 64% of patients showed no AE without treatment. Lower baseline forced vital capacity (FVC) (Odds ratio (OR), 0.962, P = 0.026) and high neutrophil-to-lymphocyte ratio (OR, 3.59, P = 0.046) were significant predisposing factors for AE.

Conclusion: ILD accounted for 7% of the comorbidity of SS, and 64% showed stable lung function without treatment. AE was associated with NLR and baseline FVC.

POS1456 DIAGNOSTIC ACCURACY OF THE LABIAL SALIVARY GLAND BIOPSY INCREASES WHEN OTHER HISTOPATHOLOGICAL PARAMETERS BESIDES FOCUS SCORE ARE TAKEN INTO ACCOUNT IN PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Diagnostic tests

M. S. Van Ginkel[1], U. Nakshbandi[1,2], S. Arends[1], E. A. Haacke[1,3], S. C. Liefers[1], G. M. Verstappen[1], J. F. Van Nimwegen[1], E. Brouwer[1], A. J. Stel[1], F. K. L. Spijkervet[2], A. Vissink[2], H. Bootsma[1], B. Van der Vegt[3], F. G. M. Kroese[1]. *[1]University Medical Center Groningen, University of Groningen, Rheumatology and Clinical Immunology, Groningen, Netherlands*; *[2]University Medical Center Groningen, University of Groningen, Oral and Maxilofacial Surgery, Groningen, Netherlands*; *[3]University Medical Center Groningen, University of Groningen, Pathology and Medical Biology, Groningen, Netherlands*

Background: Salivary gland biopsies play an important role in the classification and diagnosis of primary Sjögren's syndrome (pSS). Currently, salivary gland biopsies are considered positive for pSS if the focus score (FS), calculated by the number of characteristic lymphocytic periductal infiltrates per 4 mm2, is ≥1. However, the FS has several limitations, and other histopathological parameters, such as (pre-)lymphoepithelial lesions, IgA/IgG plasma cell shift and germinal centers can also be present in salivary glands of pSS patients. Although the diagnostic value of these histopathological features in pSS was already shown separately, no study explored the added diagnostic value of these histopathological parameters together.

Objectives: To evaluate the diagnostic accuracy of the labial salivary gland biopsy based on multiple histopathological parameters (FS, (pre-)lymphoepithelial lesions, IgA/IgG plasma cell shift and germinal centers) in patients suspected for pSS.

Methods: Consecutive sicca patients who were clinically suspected for pSS and underwent a labial gland biopsy were included. Classification of patients as pSS or non-SS was based on clinical vignettes scored by an expert panel of three experienced rheumatologists. Labial gland biopsies were analyzed for the four histopathological parameters: focus score (FS) and presence of (pre-)lymphoepithelial lesions, IgA/IgG plasma cell shift and germinal centers. Sensitivity and specificity of these histological parameters were calculated, and ROC analysis was used to determine the optimal cut-off value for the number of histopathological parameters needed to diagnose pSS.

Results: Of the 103 included patients, 38 patients were classified as pSS and 65 as non-SS sicca by the expert panel. In pSS patients, the prevalence of FS≥1 was 82%, followed by 68% for presence of (pre-)lymphoepithelial lesions, 63% for plasma cell shift and 24% for germinal centers. FS≥1 showed the highest sensitivity for pSS (82%), but specificity was higher for the other three parameters (98-100%, Table 1). Although the sensitivity of presence of ≥2 (out of 4) histopathological parameters was comparable to the sensitivity to FS alone, the specificity of presence of ≥2 (out of 4) histopathological parameters increased with 12% to 100%. Regarding the biopsy item in the ACR-EULAR criteria, specificity increased from 84% to 95% when FS≥1 was replaced by the presence of ≥2 histopathological parameters.

Conclusion: The diagnostic accuracy of the labial gland biopsy increases when other histopathological parameters besides FS are taken into account. Also, the performance of the ACR-EULAR criteria increases when the biopsy item is replaced by the presence of ≥2 histopathological parameters. This will lead to a lower number of false positive biopsies and a lower number of patients misclassified as pSS.

Table 1. Sensitivity, specificity, positive and negative predictive value of histopathological parameters for the diagnosis of primary Sjögren's syndrome (pSS), within the total diagnostic sicca cohort of patients suspected for pSS.

		Sensitivity	Specificity	PPV	NPV
Focus score≥1	N=103	82% (31/38)	88% (57/65)	80% (31/39)	89% (57/64)
(pre-)lymphoepithelial lesions	N=101	68% (26/38)	98% (62/63)	96% (26/27)	84% (62/74)
IgA/IgG plasma cell shift	N=103	63% (24/38)	100% (65/65)	100% (24/24)	82% (65/79)
Germinal centers	N=102	24% (9/38)	100% (64/64)	100% (9/9)	69% (64/93)
≥2 histological parameters	N=102	79% (30/38)	100% (64/64)	100% (30/30)	89% (64/72)

POS1457 CLINICAL COURSE AND RISK FACTORS FOR DEVELOPMENT AND PROGRESSION OF INTERSTITIAL LUNG DISEASE IN PRIMARY SJÖGREN'S SYNDROME: A SINGLE-CENTERED, RETROSPECTIVE, OBSERVATIONAL STUDY

Keywords: Sjögren syndrome, Imaging, Lungs

K. A. Lee[1], B. D. Nam[2], B. Y. Kim[3], J. H. Hwang[2], H. S. Kim[1]. *[1]Soonchunhyang University Seoul Hospital, Internal Medicine, Seoul, Korea, Rep. of (South Korea)*; *[2]Soonchunhyang University Seoul Hospital, Radiology, Seoul, Korea, Rep. of (South Korea)*; *[3]Gangneung Asan Medical Center, Internal Medicine, Gangneung, Korea, Rep. of (South Korea)*

Background: Interstitial lung disease (ILD) is the most frequent pulmonary manifestation in patients with Primary Sjögren's syndrome (pSS). Data on the clinical and radiographic course based on high resolution computed tomography (HRCT) findings are limited.

Objectives: We aimed to investigate the long-term course and prognostic factors of patients with primary Sjögren syndrome-associated interstitial lung disease (pSS-ILD).

Methods: This single-center, retrospective study included 120 pSS patients who underwent at least two high-resolution computed tomography (HRCT) scans between March 2013 and February 2021. Clinical symptoms, laboratory data, HRCT findings, and pulmonary function test results were collected. Two thoracic radiologists reviewed the HRCT findings.

Results: In patients with pSS without ILD at baseline (n=81), no development of ILD was found on follow-up (median, 2.8 years). In patients with pSS-ILD (n=39), total disease extent, extent of coarse reticulation, and traction bronchiectasis increased on HRCT, whereas the extent of ground glass opacity (GGO) decreased at follow-up (median, 3.2 years) (each $p<0.001$). In progressive group of pSS-ILD (n=19/39, 48.7%), the extent of coarse reticulation and coarseness score of fibrosis were increased at follow-up ($p<0.05$). Multivariate logistic regression analysis showed that LDH (OR, 1.012) and diffusing capacity for carbon monoxide (OR, 0.922) were independent risk factors for pSS-ILD at baseline. Usual interstitial pneumonia pattern on CT (OR, 15.237) and follow-up duration (OR, 1.403) were independent risk factors for disease progression in patients with pSS-ILD. In response to glucocorticoid and/or immunosuppressants, GGO decreased, whereas the extent of fibrosis increased even after treatment.

Conclusion: In pSS patients with no ILD during baseline evaluation, no newly developed ILD was identified during follow-up over two years. Progression occurred in approximately half of the pSS-ILD patients with slow gradual deterioration. The extent of fibrosis increased, even after anti-inflammatory treatment.

POS1458 PREVALENCE OF SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Keywords: Cardiovascular disease, Sjögren syndrome

N. Zehrfeld[1], S. Benz[2], A. Derda[3], S. Beider[1], E. Kramer[1], G. Sogkas[1], T. Seeliger[4], G. Ahrenstorf[1], A. Dopfer-Jablonka[1], T. Skripuletz[4], T. Witte[1], K. Sonnenschein[3], D. Ernst[1]. *[1]Medizinische Hochschule Hannover, Rheumatology & Immunology, Hannover, Germany*; *[2]University of Mannheim, Faculty of social sciences, Mannheim, Germany*; *[3]Medizinische Hochschule Hannover, Cardiology & Angiology, Hannover, Germany*; *[4]Medizinische Hochschule Hannover, Neurology, Hannover, Germany*

Background: It is well established that patients with inflammatory rheumatic diseases have an increased cardiovascular risk [1]. Most data exists for rheumatoid arthritis, but there are also a few studies for primary Sjoegren's syndrome (pSS)[2].

Objectives: Aim of our study was to investigate the extent of subclinical atherosclerosis in a large group of patients with pSS compared to control subjects without pSS. Secondary, correlations with clinical factors, such as organ involvement or antibody positivity, and disease activity were investigated.

Methods: From September 2021 to April 2022, pSS patients from the outpatient clinic of our hospital were consecutively included after informed consent. In addition, age- and sex-matched control subjects were recruited in a 2:1 ratio via multimedia call for participation. All pSS patients fulfilled current EULAR classification criteria for pSS and had a disease duration of at least 5 years. Participants with additional rheumatic or inflammatory diseases, tumor disease in the past 5 years, or end-organ manifestations of atherosclerotic disease were excluded. Data collection was performed by standardized questionnaire and Doppler ultrasonography for evaluation of plaque extent and intima-media thickness measurements (cIMT).

Results: Analysis included data from 199 pSS patients and 100 control subjects. 38 (19.4%) subjects of the pSS cohort were male and the median age was 58.92 years [50.50-65.21]. The median disease duration (since initial manifestation) of pSS patients was 136 months. The cohorts were analyzed for differences regarding to the cardiovascular risk profile: There were no significant differences in age, gender distribution, tobacco consumption, body mass index (BMI), pre-existing arterial hypertension, hypercholesterolemia, or diabetes mellitus. Similarly, there were no differences in LDL cholesterol, HDL cholesterol, or HbA1c in laboratory tests at enrollment. Only a positive family history for cardiovascular disease was significantly more frequent in the pSS cohort (p=0.003). After adjustment via propensity score matching, the pSS cohort was found to have a significantly greater intima-media thickness (p= <0.001). When age was added as a covariate, there was an earlier onset of intima-media thickening recognizable in the pSS patients (p=0.014). Furthermore, there was a significantly more frequent occurrence of plaque in the pSS cohort (p=0.031). pSS-patients had a 1.82times increased odds of having plaque in comparison to the control cohort. Organ involvement in the pSS-cohort was associated with a thicker cIMT (p=0.025) and pSS-patients with organ involvement also showed a 1.74times increased odds of having plaque compared to pSS-patients without organ involvement.

Conclusion: PSS appears to accelerate the development and progression of atherosclerosis as an independent risk factor. It seems to promote not only an increased incidence of atherosclerotic changes, but also an earlier onset of wall thickening in the sense of vascular aging. An increased risk for patients with organ involvement was observed. Further longitudinal studies are required to answer the question if this subgroup of pSS patients in particular or all pSS patients could benefit of screening with Doppler ultrasonography and preventive medication with HMG-CoA reductase inhibitors or acetyl salicylic acid.

POS1459 THE WEIGHT OF ANTI-LA/SSB ANTIBODIES IN RO/SSA-POSITIVE PATIENTS WITH A NEWLY DIAGNOSED SJÖGREN'S SYNDROME: A PHENOTYPE CHARACTERIZED BY A MORE SEVERE MAJOR AND MINOR GLANDULAR INVOLVEMENT AND A HIGHER BIOLOGICAL ACTIVITY

Keywords: Biomarkers, Autoantibodies, Sjögren syndrome

S. Fonzetti[1], G. Fulvio[1], G. La Rocca[1], I. C. Navarro García[1], G. Governato[1], R. Izzetti[2], V. Donati[3], F. Ferro[1], M. Mosca[1], C. Baldini[1]. *[1]University of Pisa, Rheumatology Unit, Pisa, Italy*; *[2]University of Pisa, Unit of Dentistry and Oral Surgery, Pisa, Italy*; *[3]AOUP, Unit of Pathological Anatomy, Pisa, Italy*

Background: Recently, a growing interest has arisen in investigating the association between patients' serological profiles and the different clinical phenotypes in primary Sjögren's syndrome (pSS). The double positivity for anti-Ro52/anti-Ro60 has been associated with B-cell hyperactivity and a more prominent INF-a signature. Whether the positivity of anti-La/SSB antibodies influences the clinical features of triple positive pSS patients at the time of diagnosis remains controversial.

Objectives: 1.To compare the clinical, biological, histological and ultrasonographic distinctive features of pSS patients presenting a triple positivity for anti-La/SSB and anti-Ro52/anti-Ro60 with those of patients with different serological profiles at the time of pSS diagnosis. 2. To specifically describe the presenting features of pSS patients with a triple positivity in comparison with the features of patients with a double positivity for anti- Ro52/anti-Ro60.

Methods: This is a cross-sectional study including newly diagnosed pSS patients (ACR/EULAR 2016 criteria) enrolled prospectively from 2018 to 2022. Patients were stratified in five groups according to the serological profile (i.e seronegative, isolated anti-Ro52, isolated anti-Ro60, double positive and triple positive). Demographic, clinical, biological and histological data were compared among the groups. Ultrasonographic features of major and minor salivary glands were also analyzed. Data were presented as mean±SD or as percentage frequency, as appropriate. Intergroup comparisons were made using the t-test/Mann–Whitney test for continuous variables and Fisher's exact test for categorical variables.

Results: We included 199 pSS patients (M:F= 19:180, mean age 56±13.7 years). 33/199 (16.58%) were seronegative, 50/199 (25.12%) presented isolated anti-Ro52, 49/199 (24.62%) had double positivity, 55/199 (27.64%) had triple

positivity and 12/199 (6.03%) presented isolated Ro60 antibodies. Triple positives were younger than seronegatives. No further differences in demographic features were detected among the groups. Triple positives were found to have a more complex infiltrate in the minor salivary gland biopsies than double positives with a higher mean Focus Score (2.34±2.05 vs 1.32±0.84, p=0.005) and a higher mean number of ectopic lymphoid structures (2.40±2.88 vs 1.21±1.25, p=0.004). Regarding major salivary glands ultrasound (SGUS), double positives and triple positives were found to have a score ≥2, according the OMERACT system, more frequently than the other groups (p = 0.001, Figure 1). Particularly, triple positives presented SGUS abnormalities more frequently than double positives (68.9 vs 43.6%, p=0.03). The same findings were observed for Ultra-high frequency ultrasonography (UHFUS) of minor salivary glands (Figure 1). Indeed, triple positives had the highest UHFUS scores (p= 0.01). Furthermore, triple positives presented a higher mean ESSDAI score than the other groups including the double positives (p= 0.001) due to a higher disease activity in the ESSDAI glandular and biological domains.

Conclusion: Triple-positive patients were characterized by a more severe glandular involvement documented by ultrasound and histology and by a higher disease activity. These results support the amount of data suggesting that the separate detection of anti-Ro52, anti-Ro60 and anti-La/ SSB may significantly contribute to patients' stratification at the time of the diagnosis, thus paving new avenues for tailored approaches in pSS.

MAJOR SALIVARY GLAND ULTRASOUND AND ELASTOGRAPHY FOR ASSESSMENT OF DISEASE ACTIVITY IN PATIENTS OF PRIMARY SJÖGREN'S SYNDROME

Keywords: Sjögren syndrome, Ultrasound

K. Chandwar[1], D. P. Misra[1], K. Kishor[2], P. Dogga[1], D. Ekbote[2], J. Dixit[1], A. Wakhlu[3], V. Agarwal[1], A. Wakhlu[3]. [1]*Sanjay Gandhi Postgraduate Institute of Medical Sciences, Clinical Immunology and Rheumatology, Lucknow, India*; [2]*King George's Medical University, Clinical Immunology and Rheumatology, Lucknow, India*; [3]*Apollomedics Super Speciality Hospitals, Clinical Immunology and Rheumatology, Lucknow, India*

Background:
Objectives: To assess major salivary gland involvement by ultrasonography and elastography in patients with Primary Sjögren's syndrome (pSS), correlate the severity of ultrasonographic and elastographic involvement of major salivary gland with disease activity.
Methods: In 54 pSS patients, disease activity was assessed by the European League Against Rheumatism (EULAR) Sjögren's Syndrome Disease Activity Index (ESSDAI) and the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI). The Salivary gland were assessed using the Hocevar and OMERACT score and Real time Elastography was performed for the salivary glands and were scored semiquantitatively.
Results: 54 patients of primary Sjögren's Syndrome and 55 controls were included in the study. The patients were younger with a mean age of 37.61±11.56 years (Refer to Figure 1 for demographic and clinical data of pSS patients in the study). Mean USG/Elastography scores were significantly higher (p < 0.001) in cases than controls. ESSDAI correlated strongly with Hocevar Score and OMERACT and Moderately with Elastography. ESSPRI correlated well with Hocevar Score and OMERACT score but poorly with Elastography. All the scores differentiated sufficiently between high and activity efficiently (p<0.001), however, for the OMERACT(p-0.13) and Elastography score(p-0.083) the difference between moderate and low disease activity was not statistically significant. A multivariate linear regression analysis found an association with USG Scores with ESSDAI and ESSPRI, Elastography with ESSDAI and Disease duration.
Conclusion: The Hocevar score had a robust correlation with disease activity. The Elastography scores moderately correlated with disease activity and duration of disease. There was a near-complete correlation of USG scores with Unilateral, Parotid, and submandibular scores.

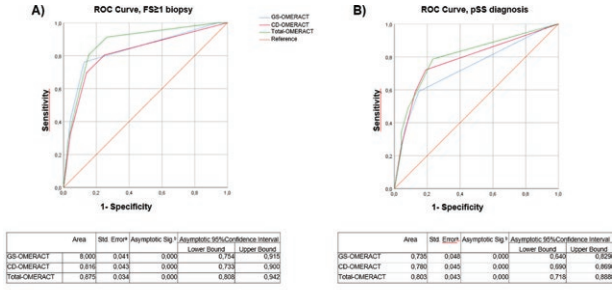
ADVANTAGES OF DOPPLER IN LABIAL SALIVARY GLAND ULTRA-HIGH FREQUENCY ULTRASOUND: CORRELATIONS WITH HISTOLOGICAL INFLAMMATION, PSS DIAGNOSIS, DISEASE ACTIVITY, AND PROGNOSIS



Keywords: Sjögren syndrome, Ultrasound, Prognostic factors

G. Fulvio[1,2], F. Ferro[1], R. Izzetti[3], G. Governato[1], S. Fonzetti[1], G. La Rocca[1], I. C. Navarro García[1], V. Donati[4], M. Mosca[1], C. Baldini[1]. [1]*University of Pisa, Department of Clinical and Experimental Medicine - Rheumatology Unit, Pisa, Italy*; [2]*University of Pisa, Department of Clinical and Translational Science, Pisa, Italy*; [3]*University of Pisa, Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine - Unit of Dentistry and Oral Surgery, Pisa, Italy*; [4]*, Azienda Ospedaliero-Universitaria Pisana, Unit of Pathological Anatomy 2, Pisa, Italy*

Background: Musculoskeletal Doppler US is currently used to estimate the level of inflammation and to differentiate between arthritis and degenerative disease. In addition, Doppler is associated with disease activity and damage, namely prognosis. Recently, a novel colour Doppler Score has been proposed for major salivary glands. However, clinical associations of salivary glands Doppler US are unclear, both in major salivary glands (MSG) and in labial salivary glands (LSG).
Objectives: To investigate potential associations between colour Doppler of LSG Ultra-High Frequency Ultrasound and histology, pSS diagnosis, clinical manifestations and prognosis.
Methods: From January 2021 to October 2022 consecutive patients, undergoing LSG biopsy, were enrolled in our cross-sectional study. LSG Ultra-High Frequency ultrasound (UHFUS) was performed with a 70 MHz probe, evaluating parenchymal inhomogeneity (score 0-3, as MSG four-grade OMERACT grey scale scoring system, GS-OMERACT) and vascularization (score 0-3, as MSG four-grade OMERACT colour Doppler scoring system, CD-OMERACT) and their sum (score 0-6, Total-OMERACT). Patients' histological, biological and clinical features were collected. ACR/EULAR 2016 criteria fulfilment was the gold standard for diagnosis. LSG biopsy with a Focus Score (FS) >1 was considered positive. For statistical analysis, following tests were applied: Student's t test, Mann- Whitney U test, contingency table analysis, Spearman's correlation. Receiver operating characteristic analysis was calculated to assess the accuracy of UHFUS to predict histology inflammation and pSS diagnosis.
Results: 127 patients were enrolled: 61 pSS patients, 47 sicca controls and 20 sicca patients with other connective tissue diseases. GS-OMERACT predicted a positive biopsy with an area under the curve (AUC) =0.835. UHFUS inflammation prediction was increased considering both grey scale and colour Doppler (Total-OMERACT), with a sensitivity=80.4%, a Specificity=84.7% and an AUC raised to 0.875 (Figure 1A). In addition, CD-OMERACT revealed a higher accuracy for pSS diagnosis than GS-OMERACT (AUC 0.780 vs 0.735). Total-OMERACT score was characterised by a sensitivity of 78.7% and a specificity of 76.6% for pSS diagnosis (AUC 0.803, Figure 1B). Both GS-OMERACT and CD-OMERACT, in pSS patients, were correlated with serological activity: autoantibodies (SSA/Ro52, SSA/Ro60, SSB) IgG levels and Rheumatoid Factor. However, CD-OMERACT presented a stronger correlation than GS-OMERACT, and significantly correlated with low C3 and C4 (Table 1). Similarly, both GS and CD also correlated with total ESSDAI and separate lymph nodes, glandular and biological domains. The correlation observed was higher with Doppler signal than inhomogeneity. The latter also exhibited a significant correlation with renal activity. All 5 patients with LSG severe/atypical inflammatory infiltrate had GS-OMERACT score 3 and CD-OMERACT score 3 with a typical pattern: multiple very hypoechoic areas and high perilesional CD signal.
Conclusion: UHFUS Colour Doppler, combined with grey scale, allows a better detection of labial salivary glands inflammation. Compared to grey scale, CD offers a unique opportunity in patient's phenotyping, due to its higher correlation with disease activity and pSS serological hallmarks. Eventually, a high doppler signal could be a key feature to identify more severe/atypical inflammatory infiltrate thus allowing the early recognition of lymphoproliferative complications.

IMMUNOEMATHOLOGIC FEATURES IN A COHORT OF PEDIATRIC PATIENTS WITH SJÖGREN'S SYNDROME: AN OVERLAP WITH AUTOIMMUNE LYMPHOPROLIFERATIVE SYNDROME (ALPS)-LIKE DISORDERS

Keywords: Cytokines and chemokines, Sjögren syndrome

S. Ancona[1], C. Morreale[2], M. DI Filippo[1], G. Simiele[1], C. Lavarello[1,3], C. Malattia[1,3]. [1]*University of Genoa, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetic and Maternal Infantile Sciences (DINOGMI), Genoa, Italy*; [2]*ASP 1 Agrigento, P.O. Barone Lombardo, U.O. Pediatria e Neonatologia, Canicattì, Italy*; [3]*IRCCS Istituto Giannina Gaslini, Clinica Pediatrica e Reumatologia, Genoa, Italy*

Background: Childhood Sjögren's syndrome (cSS) is a chronic autoimmune disease characterized by lymphocytic infiltration of salivary and lacrimal glands leading to their dysfunction [1]. Even though recurrent parotitis and sicca symptoms seems to be the most frequently reported features, cSS could have a wide range of clinical and laboratory manifestations such as autoimmune cytopenia, hypergammaglobulinemia, lymphadenopathy, fever and arthralgia [2]. These manifestations can also be seen in patients with autoimmune lymphoproliferative syndrome (ALPS). ALPS is a rare hematologic disorder characterized by an altered lymphocyte homeostasis due to a defective apoptotic mechanism [3]. In addition, cSS and ALPS are significantly associated with increased risk of lymphoid malignancy, most commonly non-Hodgkin lymphoma.
Objectives: To examine the prevalence of clinical and laboratory characteristics of ALPS in a cohort of pediatric patients with cSS in order to better characterize this autoimmune disorder and discover potential novel therapeutic targets.
Methods: Patients with cSS were recruited from the Paediatric Rheumatology Department at the Gaslini Children's Hospital of Genoa, Italy. All consecutive cSS

patients underwent clinical and ultrasound assessment to evaluate the presence of signs of lymphoproliferation, such as splenomegaly or lymphadenopathy. The following laboratory examination were performed: complete blood count (CBC), total immunoglobulins and immunoglobulins G (IgG) subclasses, vitamin B12 levels, peripheral blood lymphocyte subsets including double negative T cells (DNTs), interleukin 10 (IL-10), interleukin 18 (IL-18) and soluble FAS ligand (sFASL) levels, a lymphocyte apoptosis test and a Next Generation Sequencing (NGS) panel.

Results: Twenty patients were included in the present study. All but one patient were female (95%) with a median age at disease onset of 9,5 years. 4/20 (20%) had persistent lymphadenopathy and 1/20 (5%) had a splenomegaly. Four patients (20%) had persistent cytopenias and 12/20 (60%) had a hypergammaglobulinemia. Three patients (15%) had a deficit of IgG4 and another one (5%) had a deficit of IgG1 and IgG2. Three patients (15%) fulfilled the Oliveira's criteria for ALPS-like disorders [3] and of these, two had mutations in ALPS-like involved genes (PI3KCD and TNFRSF13B). Two other patients (10%) were diagnosed as ALPS-like disorders based on the presence of at least three out of four screening markers in cytofluorimetric panels (DNTs > 1,5%, TCR$\alpha\beta$ B220$^+$ > 60%, CD3$^+$CD25$^+$/CD3$^+$HLA DR$^+$ ratio < 1, CD27$^+$ B cells < 15%) [4]. Overall, 5 out of 20 (25%) cSS patients had an ALPS-like phenotype and started treatment with sirolimus with a good clinical and biochemical response.

Conclusion: This is the first description of an overlapping syndrome between cSS and ALPS. A substantial proportion of cSS patients followed at our Centre fulfilled diagnostic criteria for ALPS-like disorders and were treated successfully with sirolimus, a mammalian target of rapamycin (mTOR) inhibitor. Our results emphasize the need for a broader understanding of the immune dysregulation underlining cSS to identify novel therapeutic targets.

POS1463

FACTORS ASSOCIATED WITH DISEASE DAMAGE AT 20 YEAR FOLLOW-UP IN AN ITALIAN MULTICENTER SJÖGREN'S SYNDROME COHORT

Keywords: Organ damage, Sjögren syndrome

G. Cafaro[1], F. Ferro[2], R. Dal Pozzolo[1], G. Fulvio[2], L. Bruno[1], S. Fonzetti[2], G. La Rocca[2], B. Dei[2], S. Falaschi[2], C. Perricone[1], R. Gerli[1], C. Baldini[2], E. Bartoloni[1].

[1]Rheumatology Unit. University of Perugia., Department of Medicine and Surgery, Perugia, Italy; *[2]Rheumatology Unit. University of Pisa., Department of Clinical and Experimental Medicine., Pisa, Italy*

Background: Sjögren's syndrome (SS) represents a chronic autoimmune disorder characterized by a relatively benign course. However, up to 40% of SS patients develop systemic extra-glandular involvement which, in turn, may lead to long-term damage accrual. Few studies assessed damage accrual in SS with a follow-up ranging from 5 to 10 years. Knowledge of long-term risk of damage and awareness of factors contributing to damage accrual in SS represent important issues to identify patients requiring a closer follow-up and to better stratify therapy.

Objectives: To examine disease damage progression every 5 years until 20 years of follow-up and disease related features associated with higher damage score at 20 years in a multicenter SS cohort.

Methods: A cohort of 252 SS patients fulfilling the 2002 AECG and/or 2016 ACR-EULAR classification criteria was retrospectively analysed. The following variables were collected at diagnosis and every 5-year timepoints until 20 years: demographic, clinical and serologic parameters; disease activity by ESSDAI; Charlson Comorbidity Index (CCI); disease damage by SSDDI and treatments. Patients were grouped according to damage degree at 20 years: "low/no damage", LND (SSDDI ≤ 1) and "moderate/high damage", MHD (SSDDI ≥ 2). Continuous variables were compared by Mann-Whitney U test and categorical variables by Chi-squared test of Fisher's exact test, as appropriate. Significant variables at univariate analysis were include in a multivariable logistic regression analysis model with wild bootstrapping to account for collinearity and heteroscedasticity.

Results: A total of 50 patients (mean age at diagnosis 44±12 years, mean disease duration 24±5 years) had 20 year follow-up. Mean SSDDI increased from 1.2 (±1.5) at 5 to 1.5 (±1.7) at 10 years and from 1.54 (±1.7) at 15 to 2.04 (±2.2) at 20 years. Oral/ocular damage, peripheral nervous (PN) involvement and lymphoproliferative disease mainly contributed to damage accrual. Mean ESSDAI reduced from 6.4 (±3.7) at baseline to 4.9 (±5.4) and mean CCI increased from 1.6 (±0.8) to 3.5 (±1.6) at 20 years. At univariate analysis, MHD patients had significant higher median ESSDAI at all timepoints and CCI at 5 and 20 years, higher frequency of parotid swelling at 5 years (35% vs 7%, p=0.021), low C4 (30% vs 3%, p=0.012) at 15 years and monoclonal component at 20 years (30% vs 7%, p=0.047) and lower of arthritis at 10 years (0% vs 23%, p=0.033) in comparison to LND. Patients with MHD had higher prevalence of glucocorticoid (GC) use at 20 years in comparison to LND (75% vs 27%, p=0.001). Multivariable logistic regression analysis model was able to correctly classify 87.5% of patients. None of the included parameters was independent predictor of outcome variable, likely due to a non-linear relationship among variables and the low subject number included.

Conclusion: This is the first study exploring disease damage at 20 year follow-up in SS patients. Notably, damage occurs early, increases already in the first 5-10 years and is mainly driven by oral and ocular damage, PN involvement and lymphoma. Higher disease activity at baseline and during follow-up and higher GC use, also reflecting a more active disease, represent two important variables contributing to damage. Thus, controlling disease activity since diagnosis and minimizing steroid prescription may reduce long-term damage accrual. Among disease-related features, appearance of parotid swelling in the first 5 years requires awareness. Surely, further studies are needed to identify, at diagnosis, patient phenotype at higher risk of long-term damage.

SLE, Sjön's and APS - clinical aspects (other than treatment)

POS1464

DYSPHAGIA AND RELATED SYMPTOMS ARE FREQUENT, SEVERE AND HEAVILY AFFECT THE QUALITY OF LIFE OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Keywords: Gastrointestinal tract, Sjögren syndrome, Quality of life

A. Alunno[1], F. Carubbi[1], F. M. Mariani[1], J. Cipollone[1], M. Rossi[1], C. Ferri[1].
[1]*Internal Medicine and Nephrology Division, University of L'Aquila, Department of Life, Health and Environmental Sciences, L'Aquila, Italy*

Background: Dysphagia is the most frequent symptom reported by pSS patients with gastrointestinal involvement and may be related to a combination of hyposalivation and oropharyngeal/oesophageal dysmotility.
Objectives: To explore the burden of dysphagia and related symptoms and the access to specialist care in patients with pSS.
Methods: Consecutive patients with pSS fulfilling the 2016 ACR-EULAR classification criteria and referring to our institution were interviewed. Patients reporting swallowing problems filled the Swallowing Quality of Life (SWAL-QOL) questionnaire. The SWAL-QOL includes 10 domains: food selection, burden, mental health, social functioning, fear, eating duration, eating desire, communication, sleep, and fatigue. It also explores presence and frequency of various symptoms such as cough, choke on food or liquids). Patients having sought for specialist care for dysphagia filled the SWAL Quality of Care (SWAL-CARE) questionnaire. The SWAL-CARE includes 2 domains to report on the clinical and general advice received (e.g. on food/drinks to avoid) and on the patient satisfaction. The scores of each domain (Likert scales) are transformed to a 0–100 metric with 100 indicating the most favorable state and 0 the least favorable state. Disease activity (ESSDAI) and patient reported symptoms (VAS scales, ESSPRI, xerostomia inventory (XI) and Oral Health Impact Profile (OHIP)-14) were calculated at the time of enrollment.
Results: An interim analysis on 108 recruited patients as of December 4, 2022 was performed. Twenty-five patients (23%) reported swallowing problems. All SWAL-QOL domain scores and the total SWAL-QOL score were very low while symptom presence and frequency were very high. The most affected domains (mean value <30) were fear, mental health, fatigue and sleep (Table 1). The "mental health" and "social functioning" domains were more affected in people with shorter disease duration regardless of age (p<0.01). Conversely, the "burden" domain, reflecting the capability to cope with dysphagia, was more affected in younger people (p=0.03). A proportion of patients ranging between 48 to 84% reported having symptoms often or almost always and none of the patients responded "never" for any of the symptoms (Figure 1). When exploring how the extent of dryness relates to dysphagia, the VAS scales for xerostomia and xerotrachea did not differ between patients with or without dysphagia. However, patients with dysphagia had significantly higher scores of the XI and the OHIP-14 compared to those without (both p<0.01). No differences in terms of age, disease duration, autoantibody profile and disease activity emerged between pSS patients with or without dysphagia. Focusing on ESSDAI domains, we observed that all patients with dysphagia also had articular manifestations (p<0.01) while haematological manifestations were more frequent in patients without dysphagia (p=0.03). Of the 25 patients with dysphagia only 10 (40%) sought specialist care. Most of the patients judged the advice received poor (mean =10.4) and overall patient satisfaction was very low (mean= 28.5).
Conclusion: Our study demonstrated that dysphagia and related symptoms are frequent and severe in pSS, heavily impact on the patient quality of life and satisfactory specialist care remains an unmet need. Younger people and those with a shorter disease duration seem those whose QoL is more affected. We are currently increasing the patient cohort and planning further investigations in patients with dysphagia (e.g. oesophageal manometry) to better characterise the mechanisms underlying this problem in pSS.

Table 1. Domains and total SWAL-QoL score in pSS patients with dysphagia

SWAL-QoL domains	Mean	SD
Burden	48.3	26.1
Eating desire	31.1	24.4
Eating duration	39.6	28.2
Food selection	42.9	30.0
Communication	38.3	29.6
Fear	28.5	29.5
Mental health	29.2	27.0
Social functioning	35.0	29.5
Fatigue	29.2	25.5
Sleep	25.0	24.1
TOTAL SWAL-QOL	36.4	17.6

ASSOCIATION OF COMPLEMENT ACTIVATION AND TNFA WITH PREGNANCY PROGNOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

Keywords: Systemic lupus erythematosus, Anti-phospholipid syndrome, Biomarkers

A. Isik[1], S. Çınar[2], S. Onder[3], A. Bayram[3], E. Yavuz[3], T. Sarac Sivrikoz[4], I. Kalelioglu[4], C. Cetin[5], Y. Yalçınkaya[5], A. Gul[5], M. Inanc[5], B. Artim-Esen[5].

Background: Complement activation is associated with adverse pregnancy outcomes in in patients with systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS). TNFα is accused in the etiology of impaired placenta development and preeclampsia.
Objectives: We aimed to investigate the association of complement(c) activation and TNFα with poor pregnancy outcomes in patients with SLE/APS.
Methods: Four groups were examined: pregnant SLE/APS (n=37), non-pregnant SLE/APS(n=15), healthy pregnant (n=20) and healthy women (n=14). C3b, C5a and TNFα were tested by ELISA in the serum (s) samples taken at the last trimester of each pregnancy. Collected placental tissues were examined histopathologically and were stained for TNFα and C4d.
Results: sC3b levels and positivity rates were higher in pregnant SLE/APS compared to all other groups (p<0.05 for all). Pregnancy loss (18,9%) and preeclempsia (16,2%) were the most common pregnancy morbidities. Renal (30,5%) followed by hematologic (thrombocytopenia) (19,4%) were the most common flares in pregnant patients with SLE/APS and compared to patients without, they had significantly higher sTNFα levels (p<0,05). The frequency of sTNFα positivity were significantly higher in SLE/APS patients with preeclampsia (p<0.05). Sixty-six % of SLE/APS placentas had C4d deposition whilst none of the healthies were stained (p <0,001). Frequency of strong staning with TNFα in SLE/APS (75,8%) was significantly higher compared to healthy placentas (27,8%) (p<0,001). Decidual vasculopathy, decidual inflammation and villous infarction were significantly more frequent in SLE/APS (Table 1). Significant associations were found between these findings and preeclampsia, intrauterine growth retardation and the need for neonatal intensive care (p<0,001).
Conclusion: Results of our study shows TNFα and complement activation both at tissue level and serum, and supports their association with adverse pregnancy outcome in SLE/APS.Further work is necessary to test whether these biomarkers can be used for follow up and to explore whether TNFα and complement directed therapies may improve maternal/fetal prognosis in patients with SLE/APS.

PREDICTORS OF NEUROPSYCHIATRIC FLARES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM FIVE PHASE III CLINICAL TRIALS OF BELIMUMAB

Keywords: Outcome measures, Systemic lupus erythematosus, Clinical trials

L. Palazzo[1], J. Lindblom[1], N. Çetrez[1], H. Ala[1], I. Parodis[1,2]. *[1]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden*; *[2]Örebro University, Department of Rheumatology, Faculty of Medicine and Health, Örebro, Sweden*

Background: Neuropsychiatric (NP) flares in systemic lupus erythematosus (SLE) constitute a challenging issue for the clinician on many levels as they are rather unpredictable and include severe and potentially life-threatening manifestations [1]. The identification of clinical and serological profiles predictive of NP flares would be instrumental for early detection of NP involvement, thus allowing early treatment, and hopefully resulting in improved outcomes. The B-cell depleting agent belimumab has widely shown ability to reduce rates of flare in SLE (2), but little is known on its potential benefits in the treatment of NPSLE.
Objectives: To evaluate predictors of NP flares in patients with SLE under standard therapy (ST) with or without add-on belimumab, given for active disease yet not ongoing severe NP involvement.
Methods: Data from five clinical trials of belimumab in SLE (BLISS-52 (NCT00424476), BLISS-76 (NCT00410384), BLISS-NEA (NCT01345253), BLISS-SC (NCT01484496), and EMBRACE (NCT01632241)) were used (N=3638). Flares were defined using the British Isles Lupus Assessment Group (BILAG) activity index as development of any new NP BILAG score A in patients with baseline NP BILAG score B, and development of any new NP BILAG score A or B in patients with baseline NP BILAG score C–E during a 52-week follow-up. Predictors of NP flare were investigated using univariable and multivariable Cox regression analysis. A subgroup analysis was performed to determine predictors of *de novo* NP flare in patients with no NP history (baseline NP BILAG E). Organ damage was assessed using the SLICC/ACR Damage Index (SDI). *p* values <0.05 were considered statistically significant.
Results: In total, 105 (2.9%) NP flares were documented. Of these, NP flare occurred in 52 (1.6%) patients with baseline NP BILAG E. In multivariable analysis adjusting for age, sex, ethnicity, and variables that were significant in univariable analysis, male sex (HR: 2.37; 95% CI: 1.31–4.28; *p*=0.004) and NP BILAG score B–D at baseline (HR: 5.91; 95% CI: 3.86–9.06; *p*<0.001) were highly associated with NP flare development in the pooled study population. Belimumab use displayed no clear protection at any dose or administration form. In the subgroup analysis of the baseline NP BILAG E population, male sex (HR: 3.26; 95% CI: 1.51–7.04; *p*=0.003) was the strongest predictor of *de novo* NP flare. In a separate analysis of SDI domains, the NP domain (HR: 3.25; 95% CI: 2.72–3.88; *p*<0.001) was the strongest predictor of NP flare, with cognitive impairment (HR: 14.29; 95% CI: 9.22–22.14; *p*<0.001), transverse myelitis (HR: 21.89; 95% CI: 5.40–88.72; *p*<0.001), and neuropathy (HR: 8.87; 95% CI: 5.59–14.09; *p*<0.001) mainly driving this association.
Conclusion: Current or past NP activity and established organ damage in the NP domain at baseline were the strongest predictors of NP flare in SLE patients treated for active disease yet not ongoing severe NP involvement. Whether belimumab treatment protects against NP events remains unclear and warrants future investigation.

Background: Cardiovascular morbidity, severe infection and renal damage are amongst the most serious complications of SLE.
Objectives: To combine a mendelian randomization (MR) approach and investigation of a clinical SLE cohort to evaluate the contribution of SLE-genetic risk to the development of myocardial infarction (MI), end-stage renal disease (ESRD) and death from bacterial infections (BI).

Methods: 1487 patients with SLE from Norway and Sweden who fulfilled ≥4 ACR-82 (97%), ACR-97 (98%) or SLICC2012 (94%) classification criteria were included in the study. Clinical data was collected from medical charts and causes of death were retrieved from death certificates. Patients were genotyped using the Global Screening Array or the Immunochip (Illumina). Established, independent SLE risk SNPs (p<5e-8, n=67) were selected and summary statistics for coronary artery disease (CAD) and MI were identified for each SNPs using the MRBase catalog. MR was conducted using the inverse variance weighted method as well as three additional MR methods, on the largest available dataset using a strict definition of MI (ncases=11,622, ncontrols=187,840). The same method was used for analysis of the largest available datasets for dialysis (ncases= 648, ncontrols= 212,841) and BI (ncases= 21,132, ncontrols= 197,660). SNP-manifestation associations from the datasets were used to construct weighted MI/CAD, BI and dialysis PRSs for each patient in the clinical cohort.
Results: The MR analysis revealed a significant association between the genetic risk of SLE and MI (p<0.01). The association was robust to outliers and pleiotropy and consistent across the investigated MR methods. No influence by confounding factors such as hypertension, smoking, alcohol consumption or hyperlipidemia was identified. Individually, 14 SLE SNPs displayed association with MI/CAD and were included in the CAD/MI PRS. In addition, we found an association between the SLE genetic risk and dialysis (p<0.05), whereas the association between SLE genetic risk and BI was not statistically significant (p=0.051). SLE SNPs displaying association with dialysis and BI were included in two separate PRSs. In the clinical cohort, 7.7% of patients had experienced at least one MI, with a mean age at the first event of 60 years. Patients with a CAD/MI PRS in the top quartile displayed a three-fold higher risk of MI (OR 3.04 (1.43–6.49), p<0.01) and a higher risk of ischemic heart disease (MI and/or angina pectoris) (OR 2.64 (1.37–5.11), p<0.01) compared with patients with a CAD/MI PRS in the lowest quartile. In total, 35 % of patients fulfilled the ACR-82 nephritis criterion, and 5.8% had developed ESRD. Patients with a high dialysis PRS displayed a higher risk of nephritis (OR 1.72 (1.15-2.58), p=0.0079), however, a significant association with ESRD could not be demonstrated (OR 1.84 (0.67-5.03), p=0.23). Of the 94 patients in our cohort who were deceased at the time of follow-up, 71 had available death certificates, of which 15 (21%) mentioned infection as a contributing factor. In this data we could not find evidence of an association between a high BI PRS and death from infection (p=0.35).
Conclusion: A high genetic risk of SLE displayed a clear association with MI in the general population, and may also be associated with renal morbidity. Our findings show that combining analysis of large biobank datasets and well-characterized clinical cohorts, may be a useful method for understanding the role of individual SLE risk SNPs in the development of severe SLE sub-phenotypes.

LONGITUDINAL CHARACTERIZATION OF DISEASE COMPLEXITY AND FLARES IN SYSTEMIC LUPUS ERYTHEMATOSUS: DEVELOPMENT OF AN ELECTRONIC HEALTH RECORDS ALGORITHM

Keywords: Artificial intelligence, Best practices

S. L. Bosello[1], A. Ortolan[1], C. Masciocchi[2], L. Antenucci[2], L. Lilli[2], L. Petricca[1], M. R. Gigante[1], V. Valentini[2], A. Cesario[2], S. Patarnello[2], M. A. D'agostino[1].
[1]Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario A. Gemelli - IRCCS, UOC di Reumatologia, ROme, Italy; [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Real World Data Facility, Gemelli Generator, ROme, Italy

Background: Systemic Lupus Erythematous(SLE) is a heterogeneous disease, with a relapsing-remitting pattern that contributes to create difficulties for diagnosis and management. Besides, disease activity indices are not always able to capture the complexity of the disease over time and to guide therapy modification. Data mining and machine learning algorithms developed based on Electronic Health Records(EHR) could help in characterizing the disease complexity and electronic trajectory of evolution.
Objectives: to develop a machine-learning methodology to identify SLE phenotypes and flare trajectories in a large longitudinal database.
Methods: an observational retrospective monocenter study was performed using the EHR of our Tertiary Care University Hospital. Adult SLE patients (pts), with at least one hospital contact between January 2012 and December 2020, were included. For each patient, clinical reports including demographics characteristics, symptoms and clinical history retrieved from text notes recorded during the hospitalization and the out-patient visits, laboratory values, medication and laboratory prescriptions as well as therapy, were extracted from EHR (ICD9 710.0 and 695.4 to identify the pts). A predefined combination of Natural Language Processing techniques (NLP) and abnormal laboratory parameters at each visit was used to identify: 1)presence of 8 different SLE clinical phenotypes (hematological, muco-cutaneous, articular, renal, systemic, neurologic, vascular involvement and serositis); 2)disease complexity based on the combination of the presence of single or multiple organ domains involved and therapy escalation (defined as low, medium, high complexity); 3)disease flares in each of the above clinical phenotypes. Data extraction, from unstructured data of EHR, was performed using topic models and rule-based techniques to build a usable data mart. A p-value<0.05 was considered as significant. Typical explorative analyses were also used to identify SLE phenotypes, together with longitudinal analyses, for the observation of evolution of complexity trajectories.
Results: A total of 1000 SLE pts with at least one contact were identified in our EHR; of them 477 presented at least one hospitalization and 255 pts presented at least one year of follow-up with a median of years of observation of 5.0(3.0, 8.0). In the longitudinal cohort of 255 pts, the median number of outpatient clinic contacts was 14(8-20) and of hospitalizations: 1 [0-2]. The median number of clinical phenotypes identified at baseline was 4(2.25-5), with 50.3% of pts having more than 3; and their distribution was: hematological(71.4%), muco-cutaneous(68.2%), articular(64.3%), renal (62.4%), vascular(34.9%), serositis(24.3%), systemic(16.5%), neurological(16.1%). At baseline, SLE complexity was categorized as low, medium and high in 13.7%, 34.5% and 51.8% of cases respectively. During follow up the complexity of pts changed as reported in *Figure 1*, and 93% of pts had a flare. During longitudinal evaluation, 65.9% pts presented hematologic flare, 60% muco-cutaneous, 47.8% renal, 18.8% articular, 12.9% vascular, 7.8% systemic, 5.1% serositis and 3.9% neurological. The median number of flares significantly increased with disease complexity [(3.5(2.0-6.0), 4.0(2.0-8.0), 6(3.0-9.2) in pts with low, medium and high complexity respectively,p<0.05]. Moreover, the severity of flares for each clinical phenotypes also increased according to the patient's complexity(p<0.05). Overall, 279 therapy escalations were made over the follow up time, 62% due to disease flares, and 38% due to other situations (e.g. intolerance, contraindications).
Conclusion: Machine learning algorithms can help to describe SLE heterogeneity and to characterize clinical phenotypes and trajectories of pts. Next step will be the evaluation of the present procedure on external cohorts to develop a tool able to identify situations needing more intensive and personalized care.

POOR LONG-TERM OUTCOMES AND SUBSTANTIAL UNMET NEEDS IN EUROPEAN PATIENTS WITH LUPUS NEPHRITIS

Keywords: Real-world evidence, Comorbidities, Systemic lupus erythematosus

L. Arnaud[1], J. MA[2], K. Pisarczyk[3], E. Park[4], K. Palaniswamy[4], R. Leff[5].
[1]*University Hospitals of Strasbourg, French National Reference Center for Rare Auto-immune Diseases (RESO), Department of Rheumatology, Strasbourg, France*; [2]*Maple Health Group, LLC, New York, United States of America*; [3]*Maple Health Group, LLC, Kraków, Poland*; [4]*Kezar Life Sciences, Medical Affairs, South San Francisco, United States of America*; [5]*Kezar Life Sciences, Clinical Development, South San Francisco, United States of America*

Background: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE), associated with considerable morbidity and an increased risk of end-stage kidney disease (ESKD). Despite various therapies used in clinical practice, a notable proportion of patients may not achieve sustained remission, leading to adverse disease outcomes.
Objectives: To review and summarize evidence on natural history of LN, burden of comorbidities, and real-world (RW) effectiveness of therapy in European patients with LN.
Methods: A targeted literature review was conducted using MEDLINE/Pubmed and Embase to identify studies in patients with LN. Search strategies were developed for the two databases to identify relevant peer-reviewed articles published in English from March 2012 - March 2022, and conference abstracts from 2019. All records were screened according to pre-specified inclusion/exclusion criteria. Studies conducted in a European setting were summarized.
Results: Of 4,216 identified records, 55 studies reported long-term outcomes of disease and RW effectiveness of treatment in European adults with LN. Up to 36% of patients with SLE developed LN, and nearly all LN cases occurred within 5 years of SLE diagnosis. Patients with LN often suffered from serious infection (19-35%), chronic kidney disease (CKD)/ESKD (6-22%), and cardiovascular disease (CVD) (26%), and were more likely to experience cardio- and cerebrovascular events than patients with SLE only (p=0.001). Immunosuppressive therapies contributed to increased infections and patients treated with high-dose steroids (≥0.5mg/kg/day) had 5-times increased risk of infections compared to those on low-dose regimens. Patients with LN had a higher risk of mortality compared to patients with SLE or other lupus manifestations (p<0.001). The main causes of death among patients with LN were infections (8-32%), CVD (22-58%), or malignancies (5-27%). The majority of RW studies evaluated effectiveness of standard of care (SOC) induction and/or maintenance therapy, mostly with mycophenolate mofetil and cyclophosphamide. Treatment response rates varied across the studies likely due to heterogeneity in study design, drug dosing, and patient population; comparative studies did not find significant differences in response rates between the regimens. Overall, 30-86% of patients with LN achieved complete renal response/remission (CRR) within 1 year of starting SOC therapy, and 25-63% achieved CRR within 2 years. Patients who were non-responders after 1 year had a significantly increased risk of mortality and CKD compared to responders (p<0.005), highlighting the need to reach any degree of response. Over a 5-year period, one study reported that only 38% of patients maintained CRR while on SOC, further suggesting inadequate maintenance on existing therapies. Limited studies focused on treatment-experienced/refractory patients, with the majority evaluating rituximab (RTX)-based regimens. After 1 year of treatment, 29-64% of patients with refractory LN treated with RTX achieved CRR and 35% of patients with active LN despite SOC treated with belimumab (BEL) achieved CRR. Despite initial response to current therapies, 20-35% of patients experienced a renal relapse/flare while on maintenance therapy, with one study noting significantly increased risk of proteinuric flares with azathioprine compared to other maintenance therapies (p=0.01). Very limited evidence was identified on the impact of therapy on extra-renal manifestations in patients with refractory LN, with few studies reporting improvements in SLEDAI scores with RTX after 1 year and with BEL over 2 years of treatment.
Conclusion: European patients with LN have substantial burden from comorbidities that contribute to poor long-term outcomes. Treatment with SOC also contributes to increased morbidity and mortality, particularly due to infections. Furthermore, despite initial response to treatment, a notable proportion of patients experience renal relapse, indicating a need for effective therapies that provide sustained remission.

ACCURACY OF DISEASE-SPECIFIC ICD-10 CODE FOR INCIDENT SYSTEMIC LUPUS ERYTHEMATOSUS; RESULTS FROM A POPULATION-BASED COHORT STUDY SET IN NORWAY

Keywords: Systemic lupus erythematosus, Validation, Epidemiology

S. R. Moe[1], H. Haukeland[1,2], C. Brunborg[3], T. Garen[1], A. Botea[4], N. Damjanic[2], G. Wivestad[5], H. Kverneggen Øvreas[6], T. Bøe[7], A. Orre[8], S. Aarrestad Provan[9], Ø. Molberg[1,10], K. Lerang[1]. Background: Accurate estimations of incidence rates are important in all epidemiological studies. Register derived International Classification of Disease (ICD) codes appear near ideal case defining items being seemingly specific and easy to access in large populations, but their applicability in complex clinical syndromes like SLE is still unclear.
Objectives: We aimed to clarify accuracy of ICD-10 coding in incident SLE by directly comparing incidence rates from code-based case-definitions and verified SLE diagnosis by expert clinical assessment in a defined population.
Methods: From administrative data, we identified all individual cases who were registered at least once with the SLE-specific ICD-10 code M32 (i.e M32.1, M32.8 or M32.9) during 1999-2017 in three Southeast Norway counties (including Oslo), with total population 2.1 million. We manually reviewed the chart of every M32 coded case to confirm or reject SLE diagnosis. In cases found not to have SLE, most likely cause of inaccurate ICD-code was recorded. For the analyses of incidence rates by ICD-code, we applied a five-year washout period (1999-2003) and included only cases with first time M32 code from 2004 and onwards. Incidence rates were estimated from five case-definition; (a-c) first occurrence of one or more, two or more and three or more M32 codes from 2004-2017, respectively, (d) SLE diagnosis confirmed by chart review and (e) SLE classified by 1997 American College of Rheumatology classification criteria of SLE. To define accuracy, we applied incidence rate ratios obtained from dividing M32-derived incidence rate to those from SLE diagnosis.
Results: We identified 1975 unique cases registered with a M32 code from 1999-2017. Chart review confirmed SLE diagnosis in 936 of the 1975 cases (45 %), while 1033 (52%) were found to have conditions other than SLE (most frequently another systemic connective tissue disease or cutaneous lupus).
Of the 936 cases with confirmed SLE diagnosis, 323 (34%) were incident in the years 2004-2017 (Table 1). Figure 1a-c shows the incidence curves by different SLE case-definitions. Overall, the incidence rate ratio from two or more M32 code divided by SLE diagnosis was 2.1 (95 % confidence interval 1.8-2.4). Accuracy of ICD-coding was low for incident SLE across all ages, except in those under 25 years were the incidence rate ratio was 1.0 (95 % confidence interval 0.8-1.4) (Figure 1d). When reducing washout period to two instead of five years, the incidence rate ratio from two or more M32 codes divided by SLE diagnosis increased to 4.4 (95% confidence interval 3.8-4.7).
Conclusion: Case definitions based solely on ICD-10 code gave incidence rates of SLE twice as high as when cases were defined by expert clinical assessment, with a maximum discrepancy of seven times more in elderly (70-79 years of age) to a minimum of no discrepancy before 25 years of age.

Table 1. Number of incident cases 2004-2017 in study area by different case definition of SLE

	Total, n	Women, n	Men, n
First occurrence of ICD code 2004-2017[1]			
ICD code of SLE≥ 1 in time period	1035	867	168
ICD code of SLE≥ 2 in time period	670	582	88

POS1473 ASSESSLE- A NEW TOOL TO ASSESS SLE DISEASE ACTIVITY- THE PATIENTS' PERSPECTIVE

Keywords: Systemic lupus erythematosus, Quality of life

D. Paran[1,2], M. Ben-Am[1], L. Mendel[2], A. Polachek[1,2], V. Furer[1,2], O. Elalouf[1,2], J. Wollman[1,2], T. Eviatar[1,2], S. Pel3, S. Kivity[2,4], O. Elkayam[1,2], N. Agmon-Levin[2,5]. *[1]Tel-Aviv Medical Center, Rheumatology, Tel Aviv, Israel*; *[2]Tel-Aviv University, Faculty of Medicine, Ramat Aviv, Israel*; *[1]Tel-Aviv Medical Center, Rheumatology, Tel Aviv, Israel*; *[4]Meir Medical Center, Rheumatology, Kfar Sava, Israel*; *[5]Sheba Medical Center, Clinical Immunology, Angioedema and Allergy Unit. Center for Autoimmune Diseases, Tel-Aviv, Israel*

Background: Systemic lupus erythematosus (SLE) is a heterogeneous, waxing, waning, multisystem autoimmune disease. The complexity and clinical unpredictability of SLE challenge the assessment of disease activity over time, especially in everyday clinical practice. Multiple clinical disease- monitoring instruments have been developed, however, they are limited in ability to detect the change in disease activity over time, too cumbersome to be utilized in daily practice, and do not include patient-reported outcomes (PROs).

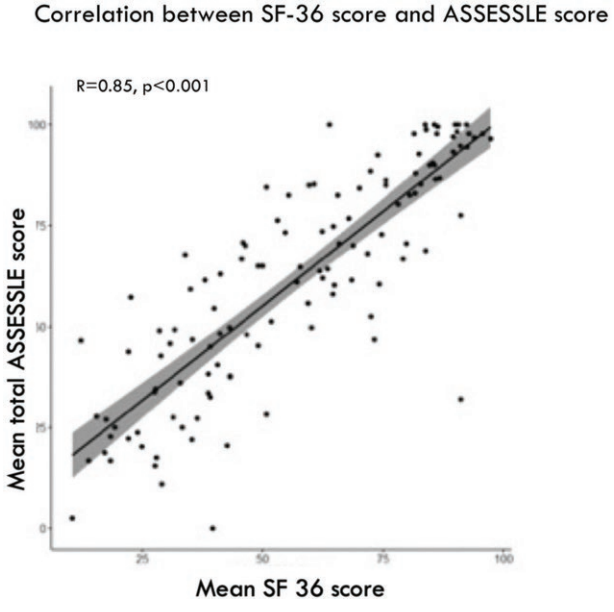

Figure 1.

Objectives: To construct a new disease activity score that will simplify and improve disease activity assessment in daily practice, and include PROs. Here we present the PRO component.

Methods: The new instrument for the assessment of SLE activity is comprised of 7 visual analog scales (VAS), which separately address the physician's global assessment and 6 organ systems. The PRO consists of 5 VAS questions that address general well-being, global disease activity, activities of daily living, medication compliance, and mood. The ASSESSLE PRO is compared to the Short Form Health Survey (SF-36), a 36-item, patient-reported survey of patient health. We applied the ASSESSLE PRO to 46 consecutive patients with SLE attending the rheumatology clinic in 2 tertiary medical centers in Israel.

Results: Psychometric evaluation of the reliability of all 5 PRO questions indicated that question 4, regarding compliance, correlated poorly with the other items and lowered the reliability (Cronbach's α=0.80 95% CI (0.74,0.85). Following the omission of question 4, Cronbach's α was recalculated, leading to increased internal reliability (Cronbach's α = 0.86, 95% CI [0.82, 0.90]). All other remaining items had a satisfactory correlation with the other items ("item-other" correlation between 0.58-0.70). Therefore, the score was computed as the mean of the 4 remaining questions. Aiming to compare the ASSESSLE PRO to the SF-36 survey, the Spearman correlation coefficient between absolute scores was computed and a strong and significant effect was found (R=0.85, p<0.0001). (Figure 1).

Conclusion: The ASSESSLE PRO is a short PRO that allows a reliable, reproducible and simple PRO form showing excellent correlation with the SF-36. Following the omission of question 4, regarding patient compliance, the ASSESSLE PRO consists of only 4 questions, as compared to the SF-36 which requires a response to 36 items. The ASSESSLE PRO seems to have significant advantages due to its intuitive VAS questions and brevity which allows use of this PRO in everyday practice and may increase the validity of disease activity evaluation of SLE when combined with the physician's assessment.

POS1474 TEMPORAL TRENDS IN JOINT SURGERY FOR LUPUS PATIENTS – A POPULATION BASED LONGITUDINAL STUDY

Keywords: Real-world evidence, Registries, Systemic lupus erythematosus

J. Nossent[1,2], H. Keen[2,3], D. Preen[4], C. Inderjeeth[1,2]. *[1]Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*; *[2]The University of Western Australia, Rheumatology Section, Medical School, Crawley, Australia*; *[3]Fiona Stanley Hospital, Rheumatology, Murdoch, Australia*; *[4]The University of Western Australia, School of Population and Global Health, Crawley, Australia*

Background: Joint damage in SLE results from (peri-) articular inflammation and can present as erosive arthropathy (considered to represent the overlap syndrome Rhupus), deforming Jaccoud's arthropathy or osteonecrosis [1,2] in addition to common causes as trauma and degenerative joint disease.

Objectives: We investigated the burden of joint disease requiring orthopaedic procedures (OP) in lupus patients in Western Australia (WA).

Methods: Patients registered in the state-wide Hospital Morbidity Data Collection with a diagnostic code for SLE in the period 1985-2015 (n=2010; 84.7% females, age 42 years (IQR 30-59) were age/gender/index year matched with controls (n=12840, 86% female, age 41 yrs) and procedure codes for arthroplasty, arthrodesis, synovectomy and arthroscopy were extracted. Figures represent median (IQR), frequency (%) and incidence rate (IR) per 100 person years with incidence rate ratios (IRR) to compare IR across groups and over three study decades.

Results: A total of 298 lupus patients (16.1%) underwent 676 OP during 12.3 years follow-up. The IRR for any OP in lupus vs controls was 7.18 (CI 2.5-20.7, p<0.001). In lupus patients, the IR for arthroplasties (1.44, CI 1.26-.56; n=330, 65% hip and knee) and arthrodesis (0.27,CI 0.21-0.34, n= 68) did not change, but IR for synovectomy (n= 58) decreased (0.58 to 0.15) and for arthroscopy (n= 225) increased significantly (0.05 to 1.16). Osteonecrosis affected 32 (1.7%) patients necessitating arthroplasty in 24/32 (75%) while IR for osteonecrosis reduced from 0.19 to 0.11 over time (p=0.12). The proportion of Rhupus patients (with both SLE+RA diagnosis) (11.8%) was stable over time, while OA was a

co-diagnosis in 49.1 % of patients undergoing OP vs 2.6 % in patients not requiring OP. Undergoing an OP (with or without arthroscopy) did not impact on long term survival (logrank p =0.16).

Conclusion: There is a high burden of joint damage in lupus patients as one in six patients required an OP at a rate seven times that of controls. These data illustrate that joint symptoms in lupus patients need careful evaluation, including imaging studies [3] and comprehensive strategies to reduce long term joint damage.

POS1475 EMPLOYMENT TRAJECTORY OF CANADIAN YOUNG ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Work-related issues, Systemic lupus erythematosus, Registries

L. Lim[1,2], M. Konstanidis[3], Z. Touma[4], D. Lacaille[5], U. Oguzoglo[6], C. Peschken[7], N. Anderson[4], R. Kaur[2], E. Pullenayegum[3]. [1]*University of Manitoba, Paediatrics, Winnipeg, Canada*; [2]*University of Manitoba, Children's Hospital Research Institute of Manitoba, Winnipeg, Canada*; [3]*University of Toronto, Dalla Lana School of Public Health, Winnipeg, Canada*; [4]*University of Toronto, Medicine, Winnipeg, Canada*; [5]*University of British Columbia, Medicine, Vancouver, Canada*; [6]*University of Manitoba, Economics, Winnipeg, Canada*; [7]*University of Manitoba, Medicine, Winnipeg, Canada*

Background: Young adulthood, 18-30 years, is a time when many individuals start working. Failing to establish employment during young adulthood could predict lifetime financial hardships. Lack or limited employment could limit access to healthcare benefits, adversely affecting treatment access and health outcomes.

Objectives: To determine the average employment trajectory of childhood- and adult-onset systemic lupus erythematosus patients in young adulthood (YASLE).

Methods: Patients (with ≥ 2 visits) were from two longitudinal cohorts: the Canadian national lupus cohort (via the Canadian Network for Improved Outcomes in SLE, CaNIOS) and the University of Toronto (UT) lupus cohort from Toronto Western Hospital. The CaNIOS cohort (2002-2020) included participants from multiple provinces, the UT cohort only Ontario patients (1983-2020). Participants report employment states annually. The employment states were: employed, unemployed, homemaker, student, work disabled. This was reduced to: employed, unemployed or not in labour force (NLF, student, homemaker, work disabled) for modelling. The Markov multistate model (msm) was used to model employment trajectory. Transition probabilities at 1, 6, 12 years from age 18 years were calculated.

Results: 841 participants (85.4% females): 253 (CaNIOS) and 588 (UT). Mean age (standard deviation, SD) at baseline (cohort entry) was 23.1 (SD 3.7) years. Participants' age: 38.2% (18-20 years), 19.3% (21-23 years), 21.9% (24-26 years), 20.7% (27-30 years). 403 (47.9%) were cSLE. 89.5% completed high school. Median disease duration was 3.3 (0.7-6.6, 25th-75th percentile, P) years. Median follow-up was 2.8 (0.9- 6.5, 25th-75th P) years. At baseline, 16.6% were employed, 5.6% were unemployed and 77.8% were NLF (42 work disabled, 226 homemakers, 386 students). 374/6615 (6%) visits showed state changes. 58% occurred in the NLF group. YASLE patients have the highest probabilities of remaining in the same employment state as baseline (Table 1). With increasing age, there was a reduced rate of staying employed (0.69 to 0.64). Those unemployed showed low probability to become employed (0.28 to 0.38). The NLF group has static rate of transition to employment (0.65), without expected increase with age.

Conclusion: YASLE patients showed minimal or no increase in transitions into employment from non-employed states, and no increase in employment with age as expected in the general young adult population. This could suggest a lowered labour force attachment in YASLE patients, suggesting difficulties in establishing employment during young adulthood. Future work should focus on YASLE patients' perceived barriers and facilitators for employment, to target interventions for supporting patients' employment.

POS1476 AUTOANTIBODY TRAJECTORIES ASSOCIATE WITH CLASSIFICATION AND TREATMENT RESPONSE IN LUPUS NEPHRITIS

Keywords: Biomarkers, Systemic lupus erythematosus, Autoantibodies

A. Fava[1], C. Guthridge[2], J. Kheir[2], C. Wagner[3], M. Petri[1], J. Buyon[4], B. Diamond[5], T. Accelerating Medicines Partnership in Ra/Sle[6], J. Guthridge[3], J. A. James[3]. [1]*Johns Hopkins University, Division of Rheumatology, Baltimore, United States of America*; [2]*Oklahoma Medical Research Foundation, Department of Arthritis and Clinical Immunology, Oklaholma City, United States of America*; [3]*Oklahoma Medical Research Foundation, Department of Arthritis and Clinical Immunology, Oklahoma City, United States of America*; [4]*NYU Grossman School of Medicine, Division of Rheumatology, New York, United States of America*; [5]*Feinstein Institutes for Medical Research, Molecular Medicine and Medicine, Manhasset, United States of America*; [6]*Multiple, Multiple, Multiple, United States of America*

Background: Autoantibodies are a hallmark of lupus nephritis (LN). While there is known heterogeneity in autoantibody expression among LN patients, the association of autoantibodies with LN subtypes and the implications of longitudinal changes in LN are not entirely understood.

Objectives: In this study, we quantified circulating autoantibodies in the Accelerating Medicines Partnership (AMP) LN longitudinal cohort to identify novel serum biomarkers of LN classification and treatment response and to provide insights into the pathogenesis of LN.

Methods: SLE patients meeting ACR or SLICC criteria (n=268) indicated for kidney biopsy by a urine protein/creatinine (UPCR) >0.5 were recruited for this study as part of the AMP. Kidney biopsies were evaluated by a renal pathologist according to ISN/RPS classification, and serum samples were collected at the time of diagnostic kidney biopsy and 3-, 6-, and 12-months post-biopsy. Serum autoantibodies against dsDNA, chromatin, ribosomal-P, Ro, La, Sm, SmRNP, RNP, Jo-1, Scl-70, and centromere-B were measured using the BioPlex 2200 ANA kit (Bio-Rad Technologies, Hercules, CA), while anti-C1q positivity was determined by ELISA (QUANTA Lite, Werfen, Bedford, MA). Clinical response was determined at 12 months using the Abatacept and Cyclophosphamide Combination Efficacy and Safety Study definitions for patients with ISN/RPS class III, IV, V, or a combination thereof and a baseline UPCR ratio >1.0.

Results: Most LN patients exhibited autoantibodies against chromatin (78%) dsDNA (70%), SmRNP (63%), C1q (56%), RNP (54%), and Sm (52%) (Figure 1A). Patients with proliferative LN (class III, IV, III+V, or IV+V) had higher positivity rates of several autoantibodies, including those against dsDNA, chromatin, and C1q, compared to patients with membranous LN (class V) (Figure 1A). Similarly, patients with pure proliferative (class III or IV) and mixed (class III+V or IV+V) LN had significantly higher titers of these autoantibodies compared to those with mesangial (class I or II), membranous, and advanced sclerosis (class VI) LN (Figure 1B-D). Furthermore, increased titers of these autoantibodies were associated with higher odds of having proliferative LN. Proliferative LN patients with a complete treatment response exhibited a significant decline in several autoantibodies including anti-dsDNA, C1q, chromatin, Smith, and ribosomal P (Figure 1F). Autoantibody levels remained relatively stable in partial- and non-responder proliferative LN patients, as well as in patients with membranous LN.

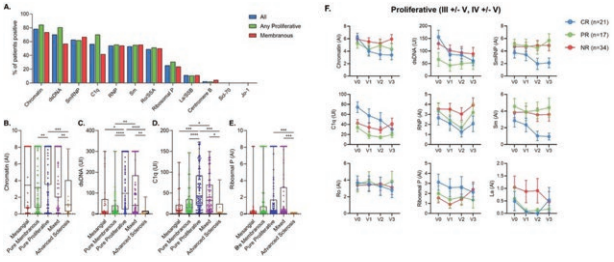

Figure 1.

Conclusion: LN patients exhibit heterogeneous autoantibody profiles associated with ISN/RPS classification. Specifically, levels of autoantibodies against dsDNA, C1q, chromatin, and ribosomal P may serve as noninvasive biomarkers of proliferative LN. In patients with proliferative but not membranous LN, a decline in the titers of several autoantibodies, including many not routinely measured over time, such as anti-Sm, was associated with treatment response, suggesting a possible role in LN pathogenesis. In addition, these autoantibodies may serve as early biomarkers of treatment response.

POS1477 DISEASE FLARES AFTER SARS-COV-2 MRNA VACCINATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ARE ASSOCIATED WITH DISEASE ACTIVITY BEFORE VACCINATION

Keywords: COVID, Vaccination/immunization, Systemic lupus erythematosus

J. Kikuchi[1], Y. Kondo[1], S. Kojima[1], S. Kasai[1], Y. Sakai[1], M. Takeshita[1], K. Hiramoto[1], S. Saito[1], H. Fukui[1], K. Suzuki[1], Y. Kaneko[1]. *[1]Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: While some reports suggest the development and flare of autoimmune inflammatory rheumatic diseases after vaccination, the frequency of disease flare after vaccination in patients with systemic lupus erythematosus (SLE) has been reported to be low. When we assess risk-benefit balance of vaccine administration, it is crucial to understand the effect of vaccines in patients with SLE. However, SARS-CoV-2 mRNA vaccines are new types of vaccines, and little is known about the effectiveness and safety of the vaccines and factors associated with disease flare in patients with SLE after SARS-CoV-2 mRNA vaccination.

Objectives: To elucidate the effect of SARS-CoV-2 mRNA vaccinations including adverse reactions to vaccines, neutralising antibody titres and disease flare rates after their vaccination and the associated factors in patients with SLE.

Methods: We enrolled the uninfected patients receiving two doses of vaccine (BNT162b2 or mRNA-1273) between June and October 2021. The neutralizing antibodies in peripheral blood, adverse reactions, and disease flares defined by the SELENA-SLEDAI Flare Index were evaluated four weeks after the second dose of vaccine. The neutralizing antibodies were measured using the STACIA SARS-CoV-2 Neutralization Antibody Test (MBL Corporation, Nagoya, Japan), and the cut-off level of seroconversion was defined as an antibody concentration of more than 1.67 U/mL.

Results: Ninety SLE patients were enrolled. The median age was 46.5 years, and the disease duration was 9.0 years. The median SLEDAI before vaccine administration was 2. Four weeks after the second dose of vaccination, 19 (21.1%) were still negative for neutralising antibodies. Adverse reactions were observed in 88.9%, including fever above 37.5° C in 20.8%. Factors associated with negative neutralising antibodies were older age, anemia (Hb ≤ 11 g/dL), mycophenolate mofetil (MMF) use (p=0.030 [55 years vs 44 years], p=0.014 [36.8 % vs 11.3%], and p=0.029 [42.1% vs 16.9%], respectively). Regarding disease activity, SLEDAI modestly but significantly increased significantly vaccination (p=0.016, median change 0 [IQR: 0–1]). Thirteen (14.4%) and 4 (4.4%) patients experienced flares and severe flares (nephritis in 3 and vasculitis in 1), respectively. High titres of SLEDAI, anti-dsDNA antibodies, rash, and azathioprine use were associated with flares in univariate analysis (p=0.046, p=0.034, p=0.037 and p=0.038, respectively, Table 1). Multivariable logistic regression analysis showed that high levels of SLEDAI and anti-dsDNA antibodies were associated with flares. Types of vaccines, neutralising antibody titres, and frequency of adverse reactions were not relevant for flares.

Conclusion: Older age, anemia, and MMF use are associated with negative seroconversion of neutralising antibodies. Residual disease activity before vaccination is a risk factor for flares.

Table 1. Factors associated with flares after second vaccination.

	Flare, N=14	Non-flare, N=76	Univariable, P-value	Multivariable model 1, P-value	Multivariable model 2, P-value	Multivariable model 3, P-value
Age, years	51 (32.5–61.5)	46 (36–56)	0.622	-	-	-
SLEDAI before first vaccination	2 (0.5–5)	2 (0–2)	0.046	0.031	-	-
Anti-dsDNA antibodies before first vaccination, U/mL	23.1	3.9	0.037	-	0.031	-
Rash before first vaccination, %	7.4 (4.0–54.7)	4.8 (2.7–7.0)	0.033	-	-	0.063
Use of azathioprine before first vaccination, %	38.5	13.0	0.038	0.044	0.122	0.088
Positive neutralizing antibodies, %	76.9	79.2	1.000	0.706	0.357	0.483

Multivariable analysis was performed on three models with separate variables, which are components of SLEDAI.

Framingham risk score (FRS) [1]. However, it is unknown how the QRISK3, the risk score established in the United Kingdom (UK), can estimate the ASCVD risk of Japanese SLE patients in comparison to the risk score validated for the Japanese population.

Objectives: To compare two algorithms for ASCVD risk estimation, QRISK3 and Hisayama study score [2], a general risk calculator used in Japan Atherosclerosis Society (JAS) guideline for Prevention of Atherosclerotic Cardiovascular Diseases 2022, in our cohort of Japanese SLE patients.

Methods: We performed a cross-sectional study in SLE patients attending Kyoto University Hospital by using questionnaires and laboratory tests. In primary prevention subjects without high-risk comorbidities (peripheral artery disease, chronic kidney disease, diabetes) and aged 40 to 79, both the Hisayama study score based on traditional risks (sex, systolic blood pressure, glucose intolerance, serum lipid and smoking) and QRISK3 (ethnicity was selected as "Other Asians") were calculated to estimate the ASCVD risk over the next 10 years.

Results: Among 335 patients enrolled, 105 were eligible for both ASCVD risk calculators. QRISK3 estimated 46 patients as high risk (score >10 %), while the Hisayama study score classified no patients as high risk. The patients classified as high risk by QRISK3 had significantly higher Hisayama study score (4.71 [3.99-5.43] vs 2.28 [1.77-2.80], p<0.0001) and more traditional risks, such as old age (59.8 [57.6-62.1] vs 48.1 [46.8-49.4], p<0.0001), current smoking (9 [19.5%] vs 3 [5%], p=0.02) and hypertension on treatment (22 [47.8%] vs 7 [11.8%], p<0.0001) than the patients with low-moderate risk (Table1). QRISK3 score was positively correlated with the Hisayama study score (r=0.4945, p<0.0001). As a reference for each risk stratification score, the proportions to achieve target values for serum low-density lipoprotein cholesterol (LDL-C) recommended by the JAS guideline were 94.3 % and 69.5 % respectively.

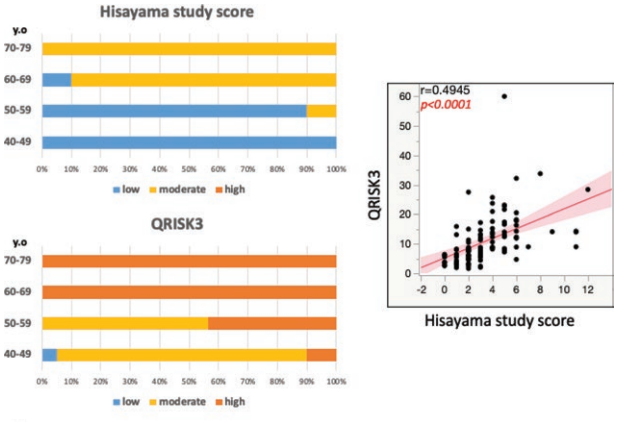

Figure 1.

Conclusion: QRISK3 classified more Japanese SLE patients as high risk of ASCVD when compared to the Hisayama study score. Lipid management might be insufficient according to QRISK3. The validation of QRISK3 by longitudinal studies should be warranted in Japanese SLE patients.

POS1479

MORTALITY OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS: A STUDY OF THE BATH LUPUS COHORT

Keywords: Autoantibodies, Systemic lupus erythematosus, Descriptive studies

J. Ellis[1], E. Korendowych[1], S. Skeoch[1]. [1]*Royal National Hospital for Rheumatic Diseases, Royal United Hospitals Bath NHS Foundation Trust, Rheumatology, Bath, United Kingdom*

Background: The Bath CTD cohort study contains a mixed prevalent and inception cohort of 281 SLE patients recruited between 2001 and 2018 from outpatient Rheumatology clinics at the Royal United Hospital for Rheumatic Diseases, Bath,UK. Work from other lupus cohorts in the UK (1) has demonstrated residual poor mortality outcomes for SLE patients. We set out to describe mortality outcomes for our local cohort of SLE patients, with reference to expected trends and autoantibody profiles.

Objectives:

1) Describe mortality outcomes (proportion of cohort, age of death and cause of death) from a longitudinal cohort of SLE patients.
2) Calculate prematurity of death (years of life lost) for deceased patients with reference to estimated mortality reference figures for the UK population.
3) Compare autoantibody profiles between deceased and non-deceased patients to assess for associations between mortality and patient serology.

Methods: Data was extracted from secure research databases. Copies of death certificates where obtained. Estimated life expectancy (for year of birth and gender) was calculated using Office of National Statistics (ONS) data. Years of life lost (or gained) was calculated. A paired samples t-test was performed to compare the difference between age at death and predicted age at death for the deceased cohort. Autoantibody profiles between deceased and non-deceased patients were compared using Chi squared (Fisher's exact test if n <5) and relative risks, confidence intervals and p values calculated.

Results: The cohort comprised 251 female and 30 male patients. Average age at diagnosis was 37.9 (18 to 62). 97% were ANA positive. 21% (61/281) of the cohort had died. Proportionally more male (13/30) than female (48/251) patients died. Cause of death data was available for 60 patients. The most common causes of death were malignancy (23.3%, 14/60), cardiovascular (21.6%, 13/60) and infection (18.3%,11/60). 8 patients (13.3%) died of SLE. 21 patients died earlier than their predicted life expectancy (-1.5 to – 32.6 years less). Mean of the difference (between actual and predicted life expectancy) for the cohort was + 4.64 (95% CI 0.4281 to 8.854, p value 0.0314). Patients that died early were more likely to die of SLE (20%, 4/20 vs 10%, 4/40), infection (15%,3/20 vs 20%, 8/40) and malignancy (40%,8/20 vs 15%, 6/40) vs than those who died late. Those who died later more likely to die of cardiovascular disease (28%,11/40 vs 10%, 2/20). Numerically those who died early were more likely to be male, older at diagnosis and be dsDNA+ve, but these numbers did not reach statistical significance. No

significant differences in autoantibody profiles were detected between deceased and non-deceased patients.

Conclusion: We observed a bimodal distribution of causes of death, with SLE, malignancy and infection more likely to cause early deaths, and cardiovascular disease more likely to cause later deaths. Across the whole cohort, patients lived longer than was expected. However, a third of patients still died early, suggesting future work should focus on addressing these highest risk patients. Across the cohort proportionally more male than female patients died. This may reflect known differences in life expectancy between genders, but highlights male patients as a group with persisting poorer mortality outcomes. No significant differences in autoantibody profiles were observed between patients that died versus those that survived. This may be because the entire cohort is enriched for positive serology, perhaps making it less likely that differences will be identified.

POS1480 DESCRIBING RENAL FUNCTION TEST USE IN REAL-WORLD DIAGNOSIS AND MONITORING OF LUPUS NEPHRITIS PATIENTS IN EUROPE

Keywords: Systemic lupus erythematosus, Real-world evidence

B. Asin[1], A. Eberhardt[2], A. Fernandes[3], D. Clamp[1], E. Goddard[4]. *[1]Otsuka Pharmaceutical Europe LTD, Wexham, United Kingdom*; *[2]Otsuka Pharma GmbH, Frankfurt, Germany*; *[3]Otsuka Pharmaceutical Development & Commercialization Inc., Rockville, United States of America*; *[4]Adelphi Real World, Bollington, United Kingdom*

Background: Lupus nephritis (LN) is a severe renal manifestation of the autoimmune disease lupus. Tests for renal function, such as estimated glomerular filtration rate (eGFR), should be standard in the diagnosis and monitoring of patients with renal disease as recommended by the Kidney Disease Improving Global Outcomes (KDIGO) Chronic Kidney Disease (CKD) Working Group [1]. These tests are important to identify renal function decline and prompt interventions to prevent further disease progression. It has been found that use of eGFR is low in Italy for CKD patients [2] but data on real-world testing in other countries is limited.

Objectives: To understand renal function test use by nephrologists in the diagnosis and monitoring of LN patients in Europe in a real-world clinical setting.

Methods: Data were sourced from the Adelphi Lupus IV Disease Specific Programme™, a point-in-time survey of nephrologists and their LN patients conducted in France, Germany, Italy, Spain and the United Kingdom in April – October 2021. Nephrologists completed patient record forms covering each patient's management, including tests and assessments used for diagnosis and monitoring. The data was analysed descriptively.

Results: 72 nephrologists provided data for 376 LN patients. Overall, 20% of LN patients in the sample did not have a Glomerular Filtration Rate (GFR) or eGFR test documented to diagnose their condition. The use of these tests at diagnosis was lower in Germany and Italy (≤72%) compared to the other countries where use was over 80%. Of all the patients without GFR/eGFR at diagnosis, only 43% had an alternative renal test completed (e.g. urine protein, creatinine clearance (CrCl), albumin-to-creatinine ratio (ACR) or 'other urinalysis test' (including urine protein creatinine ratio)). Across Europe, the use of GFR/eGFR to monitor patients with LN was 85% or above, apart from Italy where 31% of patients did not have either test. In patients without GFR/eGFR for monitoring, the use of alternative renal tests was higher than at diagnosis (60% vs. 43%). However, 40% of those patients received no other renal test (e.g. urine protein, CrCl or ACR) to monitor their condition.

Conclusion: GFR/eGFR are key markers of renal function as discussed in the KDIGO recommendations [1], but this analysis observed lower-than-expected use of GFR/eGFR among nephrologists. This was especially apparent in Germany and Italy. There may be even less use of these tests among non-nephrology specialities. Lower-than-expected use of these recommended tests indicates a need for improvement in the diagnosis and monitoring of LN patients in Europe. This suboptimal management may be affecting patient outcomes, but further research is needed to assess this. Results are subject to recall bias which was minimised by asking survey respondents to use patient medical records for the completion of forms.

Background: Systemic lupus erythematosus (SLE) has heterogeneous organ manifestations that occur in different combinations at an individual patient level. Current SLE clinical trial eligibility criteria and efficacy endpoints, based on legacy disease activity measures, have multiple weaknesses. Understanding the frequency with which different organ manifestations are represented in contemporary SLE cohorts is required, to allow focus on the most frequent and impactful manifestations of disease in both eligibility criteria and endpoints.

Objectives: To report the prevalence of disease activity in individual organ domains in SLE patients, both overall and in patients meeting the most common disease activity cut-off for clinical trial eligibility (SLEDAI2K ≥6).

Methods: We used data from a multinational SLE cohort, prospectively collected between 2013 and 2020. We analysed data from 4,102 patients with criteria-defined SLE, who contributed 42,345 visits with complete SLEDAI-2K assessments. Disease activity assessed using SLEDAI-2K was categorised according to activity in 9 organ systems: central nervous system (CNS), vasculitis, musculoskeletal, renal, cutaneous, serositis, serological, haematological, and fever. Proportions of organ-specific disease activity in the overall cohort, and stratified by total SLEDAI-2K ≥6 or <6, were calculated.

Results: In the overall cohort, 3,659 patients (89.2%) had SLEDAI-2K >0 on at least one visit (31,290 visits, 73.9%). Serological disease activity was the most prevalent in the cohort overall, affecting 75.5% of patients at least once, followed by renal (41.6%), cutaneous (36.5%), musculoskeletal (20%) and haematological (19%) activity. Infrequent active manifestations affecting <5% of patients were serositis (3.4%), vasculitis (3.4%), CNS (3.0%) and fever (3%). We further examined the prevalence of domain-specific disease activity in patient visits stratified by a SLEDAI-2K cut-off of 6 (Table 1). In patient visits with a SLEDAI-2K >6 (n = 10,031 visits, 24% of total) the most common manifestations were serological (90%) and renal (73%), followed by cutaneous (26%) and musculoskeletal (14%). Conversely, 7.3% of visits with renal, 6.7% with cutaneous, 5.8% with haematological and 1.3% with musculoskeletal activity did not have a SLEDAI-2K ≥6 (Table 1).

Table 1. Frequencies and percentages of patient visits with specific organ system disease activity, stratified by total SLEDAI score cut-off of ≥6 vs <6.

	All visits	SLEDAI<6	SLEDAI≥6	
	n = 42,345	*n = 32,314*	*n =10,031*	*p-value**
Serological	25,745 (60.8%)	16,740 (51.8%)	9,005 (89.8%)	<0.001
Renal	9,684 (22.9%)	2,367 (7.3%)	7,317 (72.9%)	<0.001
Cutaneous	4,806 (11.3%)	2,158 (6.7%)	2,648 (26.4%)	<0.001
Haematological	2,615 (6.2%)	1,862 (5.8%)	753 (7.5%)	<0.001
Musculoskeletal	1,856 (4.4%)	422 (1.3%)	1,434 (14.3%)	<0.001
Serositis	255 (0.6%)	81 (0.3%)	174 (1.7%)	<0.001
Vasculitis	250 (0.6%)	0	250 (2.5%)	<0.001
CNS	200 (0.5%)	0	200 (2.0%)	<0.001
Fever	149 (0.4%)	59 (0.2%)	90 (0.9%)	<0.001

*P-values derived from Pearson's Chi-Squared tests.

Conclusion: Serological, renal, cutaneous, musculoskeletal and haematological manifestations predominate in patients with active SLE in our cohort, with other organs only rarely affected. Measures of improvement in SLE trial endpoints could focus on measuring change in these systems, and omit detailed analysis of rare events. Conversely, a notable proportion of patients with active disease in commonly affected organ domains had SLEDAI-2K <6, meaning they would be excluded from clinical trials. Incorporation of organ-specific activity measures and inclusion criteria for SLE clinical trials may overcome this limitation and improve recruitment to and results of trials.

POS1482 **PREDICTORS AND CLINICAL SIGNIFICANCE OF LUPUS LOW DISEASE ACTIVITY STATE 12 MONTHS AFTER LUPUS NEPHRITIS**

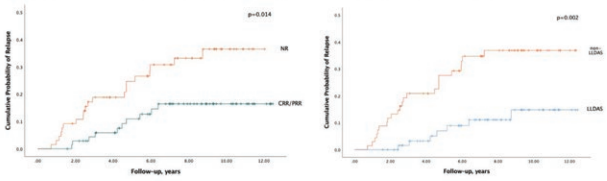
Keywords: Systemic lupus erythematosus, Kidneys, Treat to target

C. K. Cheung[1], S. C. W. Chan[1], C. S. Lau[1]. [1]*University of Hong Kong, Division of Rheumatology and Clinical Immunology, Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong (SAR)*

Background: Lupus nephritis (LN) is a significant comorbidity that affects around 50% of patients with systemic lupus erythematosus (SLE). Complete or partial renal response 12 months after LN is a recommended treatment target. Low disease activity in extra-renal domains by achieving LLDAS may also contribute to one of the critical treatment goals in LN patients [1]. However, the predictors of LLDAS in LN patients and the renal-specific benefits of LLDAS were also not fully understood.

Objectives: To investigate the predictors of LLDAS at 12 months post-LN and the clinical usefulness of achieving this state in LN patients.

Methods: Patients with biopsy-proven LN during 2010-2020 were included. Baseline demographics, blood parameters and urinalysis results were recorded. Patients were then followed up every 4 months to repeat blood tests and urinalysis. Renal response and LLDAS were assessed at 12 months post-LN, and any future relapses were recorded. Complete renal response (CRR) was defined as proteinuria ≤0.5g/day with normal estimate glomerular filtration rate (eGFR); partial renal response (PRR) was defined as a reduction in proteinuria by ≥50% with near normal eGFR. LLDAS was attained by meeting: (1) SLE Disease Activity Index ≤4 with no major organ activity; (2) no new lupus disease; (3) physician global assessment ≤1; (4) prednisolone dose ≤7.5mg; (5) standard maintenance immunosuppressants [1]. Relapse was a biopsy-proven LN after an initial treatment response of proteinuria reduction of ≥50% or to subnephrotic range. We assessed the predictors of LLDAS at 12 months post-LN and performed time-to-relapse survival analysis.



Results: 143 LN patients were included with a median follow-up duration of 10.4 years. At 12 months, 57 (40%), 14 (10%) and 69 (48%) patients achieved CRR, PRR and LLDAS, respectively. Among 136 patients who achieved treatment response, 30 (22%) patients developed LN relapse after a median of 2.98 years. LN at age greater than 30 or the presence anti-smith autoantibodies had significantly lower odds of reaching LLDAS at 12 months after LN, with odds ratio of 0.35 (p = 0.047) and 0.30 (p = 0.043) respectively (Table 1). Patients reaching CRR/PRR and LLDAS both had a significantly lower chance of relapse with p = 0.014 and p = 0.002 respectively (Figure 1).

Table 1. Predictors of LLDAS 12 months post-LN.

	Predictors	Number (row%) in LLDAS 12 months post-LN	Univariate Logistic Regression		Multivariate Logistic Regression

C3=Complement 3; CNI=Calcineurin inhibitors; LLDAS=Lupus low disease activity state; LN=Lupus nephritis; RNP=Ribonucleoprotein; SLE=Systemic lupus erythematosus; Sm=Smith. Significant *p* values are in bold.

Figure 1. Kaplan-Meier Curve of LN relapse risk by CRR/PRR (left) and LLDAS (right)

CRR=Complete renal response; LLDAS=Lupus low disease activity state; NR=No response; PRR=Partial renal response.

Figure 1. Kaplan-Meier Curve of LN relapse risk by CRR/PRR (left) and LLDAS (right)CR-R=Complete renal response; LLDAS=Lupus low disease activity state; NR=No response; PRR=Partial renal response.

Conclusion: Age of LN and anti-smith autoantibodies are predictors of LLDAS 12 months post-LN. We advocate LLDAS as a target for LN patients as LLDAS attainment lowers the risk of future relapse.

POS1483 IS EARLY REMISSION A PREDICTIVE FACTOR FOR STEROID-FREE REMISSION IN SYSTEMIC LUPUS ERITHEMATOSUS? A REAL-LIFE EXPERIENCE FROM A MONOCENTRIC COHORT

Keywords: Remission, Real-world evidence, Systemic lupus erythematosus

D. Zucchi[1,2], C. Tani[1], F. Trentin[1], V. Signorini[1], C. Stagnaro[1], L. Carli[1], F. Ferro[1], E. Elefante[1], C. Cardelli[1,2], D. Schilirò[1], M. Maffi[1], G. Cascarano[1], L. Gualtieri[1], A. Valevich[1], M. Mosca[1]. [1]*University of Pisa, Rheumatology Unit, Department of Clinical and Experimental Medicine, Pisa, Italy*; [2]*University of Siena, Department of Medical Biotechnologies, Siena, Italy*

Background: Glucocorticoid (GC) dose minimization and, if possible, complete withdrawal is one of the main targets in the daily management of Systemic Lupus Erythematosus (SLE).

Objectives: to describe frequency and clinical characteristics of SLE patients in GC-free remission in a real-life setting and to identify predictive factors for achieving GC-free remission.

Methods: this is a retrospective analysis of prospectively collected data from a monocentric SLE cohort. The following variables were retrieved: demographic data, cumulative organ involvement; at last observation: disease activity (SLEDAI-2K score), ongoing therapy, disease state (remission defined according to the 2021 DORIS criteria) and organ damage (SDI score). Disease state at 1 year from disease onset was also recorded.

Results: from our cohort, a total of 390 SLE patients had at least 1 year of follow-up and complete clinical data to be included in the analysis; of these, 142 (36.4%) were in GC-free remission at the last evaluation, and 44 (11.3%) were GC-free for 5 years (Table 1). The mean follow-up duration was 10.5 years (min 1-max 41). No significant differences were found with regard to age at disease onset, disease duration and organ involvement between the GC-free remission group (GC-) and the other SLE patients under GC treatment (GC+). Patients GC- were less frequently taking immunosuppressants (IS) (28.9%, vs 43.5% p<0.01) or biological drugs (6.3% vs 20.2% p<0.01) and were more frequently under HCQ treatment (85.2% vs 75.8%, p=0.03) at last observation. Being GC- at last observation was associated with a significantly lower organ damage with respect to GC+ (mean SDI 0.7 vs 1.5, p<0.01); significant differences regarded cardiovascular (CV) events (4.9% vs 12.1%, p=0.01) and osteoporosis (OP) (12.7% vs 27.0%, p<0.01) were also found. Overall, 212 patients were in remission after 1 year from disease onset (78.2% in GC- and 57.2% in the GC+) and this condition resulted significantly associated with GC-free remission at last evaluation (p<0.01). At multivariate analysis, being in remission at 1 year resulted an independent predictor of GC-free remission (OR=2.06, p=0.02); the multivariate analysis also confirmed that GC- patients were less likely on IS or biological treatment at last evaluation (OR 0.46 p<0,01 and OR 0.20 p<0.01, respectively).

Conclusion: these data suggest that GC-free remission is an achievable goal in SLE patients with today's drugs, and in our cohort GC-free remission is also a IS-free remission in most of patients. Our study also confirms that GC withdrawal has important advantages in term of organ-damage sparing. Of note, the early achievement of remission during the disease history is associated with a good probability of GC withdrawal over time.

POS1484 SELF-ESTEEM AS A DETERMINANT OF SEXUAL FUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

Keywords: Gender/diversity issues, Pregnancy and reproduction, Systemic lupus erythematosus

D. Marengo-Rodríguez[1], M. Ibarra-Velasco Siles[1], A. Barrera-Vargas[1], J. Merayo-Chalico[1,2]. *[1]Salvador Zubirán National Institute of Health Sciences and Nutrition, Immunology and Rheumatology, Ciudad de México, Mexico*; *[2]Reumátika Centro de Vanguardia en Reumatología (Reumatika), Rheumatology, Ciudad de México, Mexico*

Background: Patients with rheumatic diseases, particularly systemic lupus erythematosus (SLE), present with greater sexual dysfunction (SxD) than patients with other chronic diseases. SxD is multifactorial and may be linked to both disease-related and psychological factors, as well as hormonal imbalance and drug treatment. Self-image and self-esteem, which have not been thoroughly studied in SLE patients, may be related to sexual interest and thereby may also affect sexual function.
Objectives: We addressed the association between body self-esteem, global self-worth and sexual functioning in SLE patients.
Methods: We performed a transversal study in a tertiary care center in Mexico City. Patients ≥18 years old who fulfilled EULAR/ACR criteria for SLE were included. Body self-esteem was assessed by the Body Self-esteem Scale (BSES) and global self-esteem by the Rosenberg´s Self-Esteem Scale (RSES). Sexual function was evaluated by the CSFQ-14 questionnaire. Disease activity and damage was assessed by the SLEDAI and SLICC scores, respectively. Relevant demographic, clinical and serological characteristics were recorded. We used univariate and multivariate analysis to determine association between variables. Statistical analysis was performed using SPSS (V.25).
Results: We included a total of 343 patients, in whom self-esteem was analyzed. SxD was assessed in 280 patients, since 62 did not complete the CSFQ-14 questionnaire. Most patients were female (87%), the mean age was 41 years (±12) and mean BMI was 25.65 kg/m^2 (±4.9). The mean SLEDAI and SLICC scores were 2.45 (±2.72) and 0.8 points (±1.04), respectively. The mean score for the RSES was 32.09 (± 5.84) in females and 33.57 (± 4.97) in males. The BSES was 189.5 (±47.3) in females and 207.1 (±36.6) in males. There was no association between these scores and prednisone dosage, BMI, or SLEDAI and SLICC scores. We found that SxD is associated with lower global self-esteem (*p<0.0001*) and lower body self-esteem (*p<0.0001*), according to their respective scores (see Table 1). Also, a correlation between both self-esteem questionnaires (BSES and RSES) and CSFQ-14 scores was found. Interestingly, the correlation was higher in the male population (r=0.45, *p=0.008* and r=0.47 p=*0.006* for BSES and RSES, respectively) than in women (r=0.25, *p=0.0001* and r=0.18 *p=0.004*) in both scores. The multivariate analysis showed that age (*p=0.003*, 0.96 [0.94-0.98 95% CI]) and lower global self-esteem (*p=0.013*, 1.080 [1-1.14 95% CI]) were independent risk factors for SxD. We observed a trend related to lower body self-esteem scores (p=0.055, 1.007 [1-1.15 95% CI]) as a risk factor. Other variables, such as prednisone, major depressive disorder and BMI did not show an association with SxD (see Table 1).
Conclusion: To our knowledge, this is the first study to demonstrate a reliable association between self-esteem and SxD in SLE patients, particularly in male patients. Considering the high impact of both self-esteem and sexual function on quality of life, our findings reinforce the importance of routinely acknowledging the biopsychosocial aspects (and not only the disease-related ones) in the medical care of these patients.

POS1485 SEMIQUANTITATIVE ASSESSMENT OF SYNOVIAL INFLAMMATION ON US-GUIDED SYNOVIAL TISSUE BIOPSIES OF SYSTEMIC LUPUS ERYTHEMATOSUS COMPARED TO OTHER CONNECTIVE TISSUE DISEASES AND RHEUMATOID ARTHRITIS

Keywords: Systemic lupus erythematosus, Synovium

C. DI Mario[1], L. Petricca[2], A. Paglionico[3], V. Varriano[3], M. R. Gigante[2], S. Perniola[3], D. Bruno[3], B. Tolusso[1], S. Alivernini[1,2], E. Gremese[1,3]. *[1]Fondazione Policlinico Universitario A.Gemelli, IRCCS, Immunology Research Core Facility,*

Rome, Italy; [2]*Fondazione Policlinico Universitario A.Gemelli, IRCCS, Division of Rheumatology, Rome, Italy*; [3]*Fondazione Policlinico Universitario A.Gemelli, IRCCS, Division of Clinical Immunology, Rome, Italy*

Background: Systemic Lupus Erythematosus patients might experience the development of arthritis clinically resembling other forms of chronic joint inflammation. However, to date, no systematic analysis of the histological composition of synovitis was performed in SLE patients.
Objectives: To dissect the inflammation degree and the histological composition of synovial tissue of SLE patients compared with other Connective Tissue Disorders (CTD) and naive to treatment Rheumatoid Arthritis (RA).
Methods: Seventy-five patients with connective tissue diseases [n=30 SLE, n=13 Sjogren Syndrome (SS), n=19 Undifferentiated Connective Tissue Disease (UCTD), n=13 other CTD] were included in the study. Thirty-four naive to treatment RA patients were included as comparison. Each patient underwent ultrasound-guided minimally invasive synovial tissue biopsy at the study entry. Each synovial tissue sample was processed for H&E staining for the Krenn Synovitis Score (KSS) assessment by a pathologist blinded to clinical characteristics [1]. This evaluation was implemented with the additional assessment of lymphocytes and plasmacells presence, and with the assessment of the microanatomical organization in terms of inflammatory aggregates presence.
Results: Considering the whole cohort, SLE patients showed comparable synovial inflammation in terms of KSS compared to SS and other CTD (p>0.05 for both). However, synovial tissue of SLE patients showed significantly milder inflammation when compared to naive to treatment RA (p=0.002) and more severe compared to UCTD (p=0.009), mainly in terms of inflammatory infiltrate (p=0.015). Moreover, among SLE cohort, patients with Rhupus showed higher KSS compared to SS (p=0.03), mainly for synovial hyperplasia (p=0.016) and comparable synovial inflammation than naive to treatment RA (p>0.05). Considering the composition of the inflammatory infiltrate, synovial tissue of SLE patients was enriched of lymphocytes compared to synovial tissue of SS (p=0.0028), UCTD (p=0.014) and other CTD (p=0.018), similarly than synovial tissue of naive to treatment RA (p>0.05). Moreover, SLE patients showed, at synovial tissue level, higher rate of plasmacells compared to SS (p=0.038) despite significantly lower than naive to treatment RA (p=0.007). Interestingly, among the whole SLE cohort, synovial tissue of Rhupus patients was enriched of plasmacells compared to synovial tissue of SLE patients (p=0.04). Finally, considering the microanatomical organization of synovial inflammation, SLE patients showed lower rate of synovial aggregates compared to naive to treatment RA (p=0.03), the latter having similar aggregate rate compared to Rhupus patients (p=0.23).
Conclusion: Synovitis in SLE patients, despite milder than in naive to treatment RA, is characterized by more severe features compared to other CTD. In particular, Rhupus patients show a degree of synovial inflammation in terms of KSS and microanatomical organization comparable to naive to treatment RA, supporting the need to dissect pathogenetic pathways driving this clinical phenotype.

POS1486 RELATIONSHIP BETWEEN THE EULAR/ACR CLASSIFICATION CRITERIA AND ORGAN DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Organ damage, Systemic lupus erythematosus

C. C. Mok[1], Y. K. Chung[2], C. Lee[2], L. Y. Ho[1], C. H. To[2]. [1]*Tuen Mun Hospital, Medicine, Hong Kong, Hong Kong (SAR)*; [2]*Pok Oi Hospital, Medicine, Hong Kong, Hong Kong (SAR)*

Background:
Objectives: To study the relationship between the 2019 EULAR/ACR classification criteria and organ damage in patients with systemic lupus erythematosus (SLE)
Methods: Patients involved in a cross-sectional validation study of the EULAR/ACR criteria and judged by a panel of rheumatologists to be clinical SLE were studied. Those who fulfilled the EULAR/ACR criteria at their last clinic visit were stratified into 2 groups based on a cut-off score of 20. The last SLE international collaborating clinic (SLICC) organ damage index (SDI) was compared between these two groups. Relationship among the domains of the EULAR/ACR criteria and SDI in all patients was studied by Spearman's rank correlation.
Results: 562 SLE patients were studied (93.6% women; age 36.5±14.1 years; follow-up duration 11.6±6.6 years). The mean and median EULAR/ACR criteria scores in those who fulfilled the EULAR/ACR criteria (N=542) was 24.6±7.3 and 24 (interquartile range 19-30), respectively. A total of 392 patients had EULAR/ACR scores of ≥20 (group 1) and 150 patients had scores of 10-19 (group 2). Group 1 patients had significantly higher prevalence of fever, alopecia, oral ulcers, acute lupus skin lesions, arthritis, serositis, seizure, hemolytic anemia, leukopenia and renal disease, and so were the anti-dsDNA, anti-Sm, antiphospholipid antibodies and low complement state. Organ damage (SDI score of ≥1) occurred in 232 (42.8%) patients. Patients in group 1 had significantly higher SDI scores in the renal, cardiovascular, dermatological and gonadal domains than group 2. The renal, neuropsychiatric and antiphospholipid antibodies domain scores of the EULAR/ACR criteria correlated positively with the total SDI. The renal domain of the EULAR/ACR criteria had the strongest correlation with renal damage (Rho 0.30; p<0.001). Patients who scored 10 points in the renal domain had significantly higher renal damage score than those scored 8 points or 4 points. Gonadal damage score was also significantly more common in the 10-point than 8-point group.
Conclusion: In addition to disease classification, the EULAR/ACR SLE criteria may have a role in predicting organ damage and disease prognosis.

POS1487 CLINICAL SIGNIFICANCE OF DIFFERENT PROFILES OF ANTI-RO ANTIBODIES IN CONNECTIVE TISSUE DISEASES

Keywords: Autoantibodies, Clinical trials, Organ damage

Y. Chen[1,1,1,1], H. T. Yang[1,1,1,1], D. Liu[1,1,1]. [1]*Shenzhen People's Hospital, Department of Rheumatology and Immunology, Shenzhen, China*

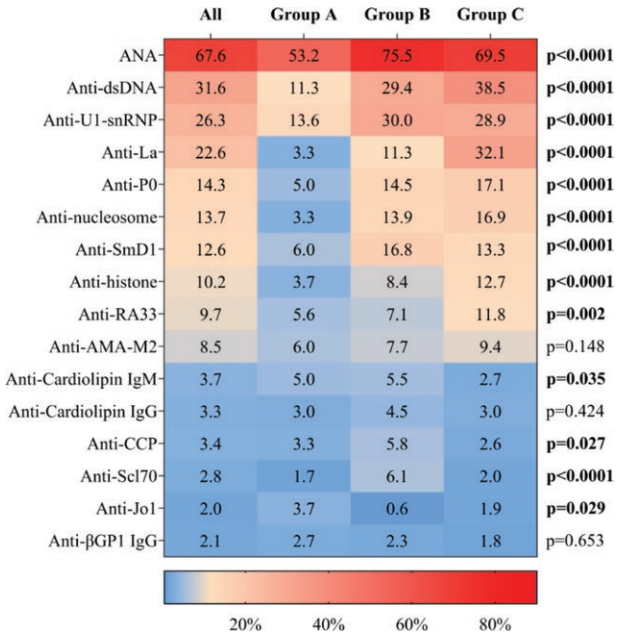

Figure 1 Comparison of autoantibody profiles in patients with positive anti-Ro antibodies

Background: Anti-Ro60 and anti-Ro52 antibodies are associated with different connective tissue diseases (CTDs) [1]. However, the clinical significance of anti-Ro antibodies is not always consistent among different global regions.
Objectives: To investigate the clinical characteristics of patients with anti-Ro antibodies.
Methods: A total of 1596 inpatients with anti-Ro antibodies were included in the study. Demographic, clinical, and serological data were compared between individuals with different profiles of anti-Ro antibodies: patients with anti-Ro52 antibodies alone, patients with anti-Ro60 antibodies alone, and patients with combined anti-Ro52 and anti-Ro60 antibodies.
Results: Of the 1596 patients, 1362 (85.3%) were female, the mean age was 45.5 years, and systemic lupus erythematosus (SLE) (46.0%) and Sjogren's syndrome (SS) (19.0%) were the most common CTD diagnoses. Among the patients with anti-Ro52 antibodies alone, idiopathic inflammatory myopathy (18.8%) and SLE (17.6%) were the most common CTD diagnoses. The coexistent autoantibodies of this group were significantly lower compared with those of the other two groups, while the presence of anti-Jo1 antibodies were significantly higher compared with those of the other two groups (3.7% vs. 0.6% vs. 1.9%, p=0.029) (**Figure 1**). In addition, the patients with isolated anti-Ro52 antibodies were more likely to suffer from interstitial lung disease (35.5% vs.11.3% vs.13.7%, p<0.0001) and pulmonary arterial hypertension (10.1% vs. 5.3% vs. 3.6%, p=0.001) compared with the other two groups of patients (**Table 1**). Compared with patients with isolated anti-Ro52 or anti-Ro60 antibodies, the patients with combined anti-Ro52 and anti-Ro60 antibodies were more likely to suffer from xerophthalmia and xerostomia. Furthermore, hypocomplementemia, hyperglobulinemia, and proteinuria were particularly prevalent in patients with anti-Ro60 antibodies.
Conclusion: Different profiles of anti-Ro antibodies were significantly associated with clinical phenotypic features in CTDs, indicating the potential diagnostic and prognostic value of these antibodies in clinical practice.

POS1488 **LUPUS DAMAGE INDEX REVISION – INITIAL ITEM REDUCTION PHASE**

Keywords: Organ damage, Systemic lupus erythematosus

B. Kundakci[1], M. Barber[2], A. E. Clarke[2], S. Johnson[3], I. N. Bruce[1]. [1]*University of Manchester, Centre for Epidemiology Versus Arthritis, Faculty of Biology, Medicine and Health, Manchester, United Kingdom*; [2]*University of Calgary, Division of Rheumatology, Cumming School of Medicine, Calgary, Canada*; [3]*University of Toronto, Division of Rheumatology, Department of Medicine, Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western and Mount Sinai Hospitals; Institute of Health Policy, Management and Evaluation, Toronto, Canada*

Background: An international initiative is underway to develop a revised systemic lupus erythematosus (SLE) organ damage index (SDI) using a multi-phase process that is supported by the SLE International Collaborating Clinics (SLICC), American College of Rheumatology (ACR) and Lupus Foundation of America (LFA). The first two phases (evaluating the construct of damage and item generation through literature review and an international Delphi exercise) were previously reported [1,2], and 220 candidate items were generated.
Objectives: To report the initial reduction phase results of a five-phase process for developing a revised SDI.
Methods: An international two-part Delphi exercise asked SLE experts and patients to rate 220 items for how appropriate they were for inclusion in a revised SDI on a 9-point Likert scale (where 1 = not at all appropriate and 9 = completely appropriate) considering the new construct of damage in SLE [1]. The definitions of items in plain English were provided for the patient representatives. In the first part of the item reduction Delphi round, participants were asked to suggest any additional items. In the subsequent Delphi round, participants were presented their own rating, median scores and 25th-75th percentiles for each item. They were given the opportunity to revise their rating. Items with ratings less than or equal to 4.0/ 9.0 were considered for removal.
Results: A total of 143 out of 146 participants who completed the first round Delphi for the item generation were invited for the item reduction rounds. Completion rates for the second and third Delphi rounds for the item reduction were 95% and 91.7% respectively. Appropriateness rating scores included the full range of scoring possibilities from 1 to 9. Participants suggested 53 potentially new items, however only 6 were retained, as others were duplicates or invalid.
226 items were presented to re-rate for appropriateness. There was stability in terms of summary median scores and 25th-75th percentiles for each item. Thirty-six items had a median score of less than or equal to 4. Figure 1 shows the number of candidate items identified at different stages of the project. All original SDI items were retained with group median appropriateness scores of 7, 8 and 9; the exceptions were upper gastrointestinal tract surgery (median appropriateness score 5) and osteomyelitis (median appropriateness score 5).

Figure 1. Number of candidate items identified at different stages of Phase II/III during revised SDI development

Conclusion: The item reduction phase using Delphi methods reduced the candidate items for consideration. All original 1996 SDI [3] items were retained in this step. Further steps are now underway to refine and rationalize this candidate list.

Background: Cardiovascular involvement is common in patients with SLE and heart rhythm disorders are frequent in addition to the manifestations included in the classification criteria ACR/EULAR 2019. Previous studies provided evidence that anti-Ro/SSA-positivity is an independent risk factor for marked QTc prolongation; suggesting that subjects who are anti-Ro/SSA-positive may represent a subgroup with an increased predisposition to ventricular arrhythmias, particularly when other QT-prolonging risk factors are concomitantly present [1].

Objectives: The aim of this study is to estimate the prevalence of QTc-prolongation in a monocentric cohort and to evaluate possible correlation with the presence of anti-Ro/SSA-antibodies and other QT-prolonging risk factors.

Methods: An electrocardiographic study (ECG) was proposed to patients affected by SLE consecutively attending our Lupus Clinic from November 2021 to March 2022. All subjects were tested for anti-Ro/SSA-antibodies. Exclusion criteria included: severe valvulopathies, hypertrophic or dilated cardiomyopathy, previous implantation of pacemaker or implantable cardioverter-defibrillator.
QTc measurement was calculated using the Bazett's formula and QTc-prolongation was defined according to American College of Cardiology (ACC)/American Heart Association (AHA) recommendations (QTc>470 ms for males, QTc>480 ms for females) [2]. Data on 24-hour ECG holter were available in 26 patients.
Results: One hundred and forty-one patients with SLE, consecutively attending our clinic, accepted to undergo an ECG, 128 (91%) females, 13 (9%) males; 124 (88%) Caucasians (median age 53.2 [IQR 42.3-58.7], median disease duration 20.0 years [12.0-28.2]). Median QTc was 415ms [IQR 394-436]; only 4/141 (2.8%), all Caucasian and female, had a prolonged QTc (Table 1).

Table 1 Features of patients with prolonged QTc

	age	Anti-Ro/SSA	QTc	Cardiological history	HCQ therapy
1	56	Positive	492 ms	none	yes
2	57	Negative	488 ms	HT, D	no
3	60	Positive	480 ms	HT	yes
4	63	Positive	508 ms	D	no

HT: hypertension, D: dyslipidaemia

Sixty-eight (48%) patients were positive for anti-Ro/SSA-antibodies. No significant differences were observed between anti-Ro/SSA-positive vs. negative patients in term of QTc intervals (416.0 [395-437] ms vs 413.0 [392-432] ms; p=0.545) using Mann-Withney Test. Other electrocardiographic alterations were found: 4 first-degree atrioventricular blocks, 25 bundle branch blocks (BBB), 31 repolarization anomalies, 1 Wolff-Parkinson-White. Patients were grouped according to hydroxychloroquine (HCQ) therapy and antibody profile into 4 groups: HCQ+/Ro/SSA+(56, 39.7%), HCQ+/Ro/SSA-(58, 41.1%), HCQ-/Ro/SSA+ (12, 8.5%) and HCQ-/Ro/SSA- (15,106%); no statistical differences (p=0.178) were observed in QTc length comparing the 4 groups using ANOVA test. Twenty-six (18.4%) underwent a 24-hour ECG holter evaluation. None of these patients had a QTc prolongation, and no major elettrocardiographic anomalies were found. These patients were divided in 4 groups (as previously done for all patients). No statistical differences were found comparing the QTc of groups of patients (p=0.783).
Conclusion: These preliminary data show a lower prevalence of QTc prolongation compared to previous studies, with no differences between anti-Ro/SSA-positive and anti-Ro/SSA-negative patients. Otherwise, considering previous studies which observed a role of anti-Ro/SSA antibodies as an independent risk factor for QTc prolongation, further analysis will be performed in order to identify standardized markers for cardiovascular risk stratification. The evaluation of 24-hour ECG Holter in a larger number of patients and the characterization of anti-Ro/SSA (anti-Ro/SSA-52kD and anti-Ro/SSA-60kD) are ongoing.

Background: The prevalence of depression and associated factors in systemic lupus erythematosus (SLE) are not well known and there are no longitudinal studies addressing this relevant subject in SLE.
Objectives: We aimed to evaluate the prevalence of self-perceived depression in patients with SLE and associated factors in a large, multicenter cohort (RELESSER-PROS).
Methods: Prospective longitudinal study of patients with SLE (1997 ACR criteria) answering positively to the depression question of the Lupus Impact Tracker (LIT) questionary (namely: "I was depressed" question number 7) (LITQ7), over 4 years of follow-up (5 annual visits, V1 to V5). Self-perceived depression was addressed as "depression any time" or "depression most of time", according to the kind of answer to the LITQ7 (answers 1,2,3 or 4 and answers 3 or 4 respectively). Only patients with no missing values in the covariates, making possible run longitudinal models, were included in the multivariable analysis. The following covariates, with potential impact in depression, were considered: SLEDAI, age,

duration of the disease, SLICC/AR DI (SDI), fibromyalgia, Charlson index, smoking, BMI, menopause, sedentary lifestyle, marital status, unemployment and glucocorticoid use. Friedman test was used to test if the change in repeated measures was significative. Generalized estimating equation (GEE) models with binomial response, were built exploring the associations of individual longitudinal determinants with longitudinal assessment of depression. The best model was selected using quasi-likelihood under the independence model information criterion (QIC)

Results: A total of 1463 were included. Mean age: 55 (DS±13.59) years, 90% were female. Mean duration of the disease: 14 (±8.59) years. Fibromyalgia was present in 5.7% (76/1343). Corticosteroids use ranged from 49.4% to 57%, depending on the visit. Median SLEDAI ranged from 0 to 2 and SDI ranged from 1 to 2. Prevalence of "depression any time" was 89.9% (1104/1228) and 34.6% (200/578) were in depression "most of time". Up to 26.5% (153/578) answered to LITQ7 "depression most of time" in the five visits; 89.7% of the patients which perceived themselves as depressed at least in 2 out of 5 visits. Only 6.9% of the patients with previous diagnosis of depression answered "0" to the Q7 of LIT ("none of the time"). Only following covariates showed changes, statistically significative, during the follow up: SLEDAI, SDI, Charlson and glucocorticoids use (Friedman test). Patients with "depression any time" develop more damage at V5 than patients without depression (answer to LITQ7=0) (p = 0.00931, T-test). In the GEE binomial analysis considering all the predefined covariates, that included only patients with no missing values for any of them (namely, 155 patients), fibromyalgia (OR 2.79; 95%CI: 1.28-6.05), unemployment (OR 1.95; 95%CI 1.02 -3.73), and glucocorticoids use (OR 1.88; 95%CI 1.18-2.99) were significant associated with "depression any time". The best model (according QIC) displayed a statistically significant association only with fibromyalgia (OR 2.90; 95%CI: 1.58-5.33) and glucocorticoids use (OR 1.85; 95%CI 1.17-2.93). Neither SDI nor unemployment reached significance here (Table 1). Without entering glucocorticoids, SLEDAI turns significant in the model, suggesting collinearity.

Conclusion: The prevalence of self-perceived depression is high in SLE. Longitudinal data analysis suggests a causal relationship between glucocorticoids use, fibromyalgia and self-perceived depression.

Table 1. best multivariable GEE model

	OR	Lower limit	Upper limit
(Intercept)	0,121	0,028	0,529

POS1493 GLOMERULAR INVOLVEMENT IN ANTIPHOSPHOLIPID SYNDROME

Keywords: Anti-phospholipid syndrome, Vasculitis, Kidneys

S. Monov[1], T. Todorov[2,2], D. Monova[3]. *[1]Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria*; *[2]Medical University - Sofia, Department of General and Clinical Pathology, Sofia, Bulgaria*; *[3]Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria*

Background: Antiphospholipid syndrome (APS) is a complex autoimmune systemic disease, characterized by the presence of circulating antibodies directed against anionic phospholipids and the protein bound to them (aPL), leading to recurrent thrombosis and/or obstetrical complications. Renal manifestation of antiphospholipid syndrome conform a wide spectrum of disease renal syndrome [1, 2]. APS nephropathy (APSN) is considered a renal small-vessels vasculopathy, that can present acutely or chronically.

Objectives: The aim of the study is to identify glomerular lesions in patients with APSN.

Methods: We studied retrospectively 114 patients (51 male, 63 female; age between 19 and 58 years; duration of follow-up was between 2 and 16 years) fulfilling classification criteria for APS. Renal and extra-renal symptoms were analyzed. None of the patients developed SLE in follow up. 18 patients with evidence of renal involvement underwent renal biopsy. All cases had proteinuria and five of them presented nephrotic syndrome.

Results: Of 18 patients with kidney biopsy, 8 (44,44 %) were male and 10 (55,56 %) - female. Four of patients with renal biopsy had membranous glomerulonephritis, two had diffuse proliferative glomerulonephritis, 2 - mesangial C3 nephropathy, 2 - minimal change disease, 1- focal segmental glomerulosclerosis, the other seven had classic pathologic findings consistent with APSN. Chronic lesions with fibrous intimal hyperplasia being the most common. Thrombotic microangiopathy (TMA) in glomeruli was characterized by fibrin thrombi without inflammatory cells or immune complexes. Double contour of the glomerular basement membrane was associated with mesangiolysis and endothelial cell swelling in 5 patients with APSN. Electron microscopy confirmed subendothelial edema. Segmental glomerulosclerosis was observed in 4 patients. Tubulointerstitium was injured with interstitial fibrosis and tubular atrophy. Patients with APS and renal involvement were older (p<0,05), had LA positive test (p<0,005) and low complement levels (p<0,05). Hypertension is present in all cases with APSN, reduced glomerular filtration rate – in 4. All cases had proteinuria and five of them presented with nephrotic syndrome. Microscopic hematuria is observed in 4 patients. The treatment of APSN includes standard anticoagulant treatment for APS, inhibitors of the angiotensin system in patients with hypertension and proteinuria, steroids, intravenous immunoglobulin, cyclophosphamide and azathioprine.

Conclusion: The occurrence of kidney abnormalities including hypertension, proteinuria, or increased serum creatinine levels in patients with APS should lead to a kidney biopsy. Renal pathology revealed that some findings including arterioles obstructed by thrombi and organized components, diffuse collapsed glomeruli and no tubulitis suggested that the extensive tubulointerstitial damage was caused by chronic ischemic changes due to vascular occlusion upstream to the glomeruli. Other findings including mesangiolysis with endothelial cell swelling and arterioles obstructed by non-organized fibrin thrombi indicated that acute TMA was superimposed by chronic TMA.

Background: The pathophysiology of Systemic Lupus Erythematosus (SLE) involves genetic and acquired immune dysregulation, both of which predispose patients to infection. Infections are a leading cause of hospital admission, intensive care unit admission and death.

Objectives: To evaluate the frequency and associated factors of hospitalizations due to infections in patients with SLE.

Methods: Cross-sectional study carried out with the RELESSAR trans registry. Patients with SLE (ACR 1997 criteria) were included. Sociodemographic variables, autoantibodies, manifestations of the disease, comorbidities and activity and chronicity index were analyzed. A serious infection was defined as one that required hospitalization. We evaluated number and localization of the infections, microorganisms and treatments received during the admissions and these variables were compared between patients hospitalized versus not hospitalized.

Results: A total of 1515 patients participated in the registry and 815 patients had been admitted: 41 cases were hospitalized due to infection exclusively and 162 patients of both infection and flare of the disease (total=203). The mean time of admissions was 1.42 (SD 0.99). Graphic 1 shows the number of serious infections per patient. The most frequent localization was the respiratory tract and bacterial were the most frequently microorganism isolated. We compared 203 patients and 646 patients not hospitalized (Table 1). In multivariate analysis, age at SLE diagnosis (OR 0.96 95%CI 0.94-0.98, p< 0.001), level of education (OR 0.89 95%CI 0.83-0.94, p< 0.001), pericarditis (OR 3.25 95%CI 1.89-5.60, p< 0.001), low complement (OR 3.16 95%CI 1.33-8.10, p=0.010), SLICC index (OR 1.95 95%CI 1.61-2.37, p< 0.001) and 10-30 mg/d of prednisone (OR 3.70 95%CI 1.66-9.00, p=0.002), 30-60 mg/day of prednisone (OR 8.40 95%CI 3.58-21.5, p< 0.001), azathioprine (OR 1.67 95%CI 1.02-2.73, p= 0.042), mycophenolate (OR 2.15 95%CI 1.27-3.67, p=0.005) and Igiv (OR 8.25 95%CI 2.33-39.3, p=0.003) were variables independently associated to hospitalization due to infection.

Graphic 1. Number of serious infections per patient.

Conclusion: Almost 25% of patients presented at least one hospitalization due to infection, being the respiratory infections the most frequent. Lower age al diagnosis, lower educational level, higher damage score, low complement, pericarditis, high esteroids doses and immunosuppressant increased the chance of having an admission due to serious infection. As well as the treatment with Igiv, an association that we can only explain by the reason that we only indicate it in severely active and infected patients.

POS1495 LOW INTENSITY OF C1Q DEPOSITION WITH RENAL IMMUNOFLUORESCENCE PREDICTS LONG-TERM POOR RENAL PROGNOSIS IN LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Prognostic factors, Kidneys

K. Hiramoto[1], H. Hanaoka[1], K. Saito[1], H. Fukui[1], J. Kikuchi[1], S. Saito[1], Y. Kaneko[1]. [1]*Keio University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan*

Background: Although the prognosis of lupus nephritis (LN) has been improved due to recent advances in diagnosis and treatment, its long-term renal outcome is still poor. In spite of previous studies that investigated a number of prognostic factors, association of long-term renal outcome with renal histological findings focusing on immunofluorescence has been little elucidated.

Objectives: To clarify renal histological and immunofluorescent findings associated with deterioration of renal function in LN.

Methods: Consecutive patients with biopsy-proven LN class III/IV/V from 2008 to 2017 in our hospital were included in the study. They were classified into two groups: patients with deterioration of renal function and those without. The deterioration of renal function was defined as more than 30% decline in estimated glomerular filtration rate (eGFR) from baseline. Clinical characteristics and renal histological findings with immunofluorescence at the time of LN diagnosis were compared between the two groups.

Results: Sixty-nine patients (class III/IV 34; class III/IV+V 21; class V 14) were included in the analysis. Renal function was deteriorated during 5 years observation in 12 patient (17.4%). There was no significant difference in age (48 vs 42 years, p=0.16), disease duration (11.4 vs 9.8 years, p=0.65), and urinary protein-to-creatinine ratio (2.3 vs 2.2 g/gCr, p=0.56) between the deterioration and non-deterioration groups. The treatment regimens including maximum prednisolone dose (41 vs 47 mg/day, p=0.14), cyclophosphamide use (42 vs 54%, p=0.53) and mycophenolate mofetil use (0 vs 24%, p=0.11) were also not different. Regarding renal histopathological findings, while proportion of III/IV class (83 vs 79%, p=1.00), activity index (1 vs 4, p=0.14), and chronicity index (4 vs 3, p=0.19) were not different between the two groups, intensity of C1q deposition in renal immunofluorescence was significantly weaker in the deterioration group than the non-deterioration group; proportion of C1q deposition in renal immunofluorescence ≤ 1+ was 100% in the deterioration group compared to 47% in the non-deterioration group (p=0.006). When we divided the patients according to the intensity of C1q deposition, the cumulative deterioration rates of renal function were significantly different (p=0.01, Figure 1). The patients with low intensity of C1q deposition (≤ 1) had a lower positivity of serum anti-dsDNA antibody (75 vs 96%, p=0.04) and a higher serum C3 levels (54 vs 40 mg/dl, p=0.03) at LN diagnosis. Anti-SSA antibodies tended to be higher in the deterioration group than the non-deterioration group (80 vs 64%, p=0.43).

Figure

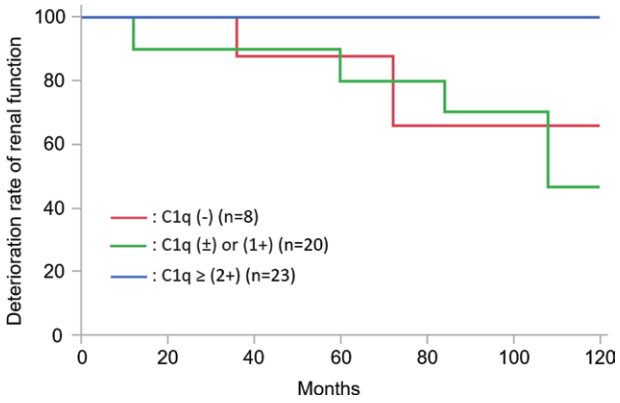

Figure 1.

Conclusion: Low C1q deposition in renal immunofluorescence at LN diagnosis is associated with poor renal prognosis in LN.

THE AUTOANTIBODY FOR BETA-2-GLYCOPROTEIN I COMPLEXED WITH HLA-DR LINKED TO ARTERIAL THROMBOSIS IN FEMALE PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES

Keywords: Autoantibodies, Cardiovascular disease, Anti-phospholipid syndrome

K. Yoneda[1,2], Y. Ueda[1,2], H. Yamada[1,2], K. Nishimura[1,2], S. Sendo[1,2], K. Tanimura[3], H. Arase[4], H. Yamada[3,5], J. Saegusa[1,2]. *[1]Kobe University Hospital, Department of Rheumatology, Kobe, Japan*; *[2]Kobe University Graduate School of Medicine, Rheumatology and Clinical Immunology, Kobe, Japan*; *[3]Kobe University Hospital, Department of Obstetrics and Gynecology, Kobe, Japan*; *[4]Osaka University, Department of Immunochemistry, Research Institute for Microbial Diseases, Suita, Japan*; *[5]Teine Keijinkai Hospital, Center for Recurrent Pregnancy Loss, Sapporo, Japan*

Background: Beta-2-glycoprotein I complexed with HLA-DR molecules (β2GPI/HLA-DR) was found to be a major autoantibody target in APS.

Objectives: We aim to reveal the association between anti-β2GPI/HLA-DR antibodies and vascular thrombosis or obstetric morbidities in females with various systemic rheumatic diseases.

Methods: This was a single-center, retrospective longitudinal study of female patients in our center from 2020 to 2021. Clinical and laboratory data were retrieved from medical records and questionnaires. Anti-β2GPI/HLA-DR antibody was compared with the risk score reported as an adjusted global APS score (aGAPSS). The optimal cutoff value was calculated using receiver operating characteristic (ROC) analysis to detect arterial thrombosis. Finally, we assessed the impact of anti-β2GPI/HLA-DR antibodies on arterial thrombosis in addition to the conventional risk model with multivariable logistic regression analysis.

Results: We evaluated 704 patients, including 66 (obstetric or thrombotic) APS, 13 primary APS, and 78 asymptomatic aPL carriers, that comorbid 260 Systemic Lupus Erythematosus (SLE) or Mixed Connective tissue diseases (MCTD). Seventy-seven patients had one or more histories of arterial thrombosis, and 14 patients of them had a history of both arterial and venous thrombosis. The titers were significantly higher in patients with arterial and venous thrombosis than in those without thrombosis. In cases with aGAPSS>10 or triple positive aPL, the titers tended to be higher. The ROC showed that the sensitivity, specificity, and area under the curve (AUC) for arterial thrombosis were 33.8%, 91.4%, and 0.60 with a cutoff value of 172.359 U/ml. By the multivariable logistic regression analysis with multiple imputation, the odds ratio of anti-β2GPI/HLA-DR antibody ≧172.359 was 5.11(95% confidence interval: 2.84-9.19; P<0.001) (Table 1). When adding the cutoff value to conventional cardiovascular risk factors improved the AUC from 0.677 to 0.730 (p = 0.088). Determined net reclassification improvement and integrated discrimination improvement were statistically significant (Figure 1).

Conclusion: Anti-β2GPI/HLA-DR antibody is associated with arterial thrombosis in females with various systemic rheumatic diseases.

PREVALENCE OF SARCOPENIA IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Sarcopenia, Motor function, Systemic lupus erythematosus

E. Pena[1], R. Cavalheiro Do Espírito Santo[1], L. Dos Santos[1], L. Denardi Dória[1], S. Pilotti[1], D. Nóbrega de Moraes[1], A. L. Mallmann[1], A. A. Gasparin[1], V. Hax[1], T. Muniz Fighra[2], P. M. Spritzer[2], R. Chakr[1], R. Xavier[1], O. Monticielo[1]. *[1]Hospital de Clínicas de Porto Alegre, Division of Rheumatology, Porto Alegre, Brazil*; *[2]Hospital de Clínicas de Porto Alegre, Division of Endocrinology, Porto Alegre, Brazil*

Background: Systemic lupus erythematosus (SLE) is an inflammatory autoimmune disease with multisystem involvement [1]. Organs and systems may be affected, such as the musculoskeletal system [1,2]. This inflammatory condition may lead to a decrease in strength and muscle mass [3]. Sarcopenia is considered a muscle disease that leads to decreased physical functionality, increased risk of falls, fractures, hospitalization and mortality [4,5]. The sarcopenia still needs to be better understood in SLE. Therefore, more studies are necessary to assess the sarcopenia prevalence and the impact on SLE patients.

Objectives: To assess the prevalence of sarcopenia in SLE patients and its associations with clinical parameters.

Methods: In this cross-sectional study, women with SLE (18 to 50 years old) were included. The following data were collected: disease duration, disease chronicity (SLICC/ACR-DI), disease activity (SLEDAI-2k), treatment regimen, quality of life (SLEQoL), physical activity level (IPAQ,min/week), muscle strength by handgrip test (kg) and chair stand tests (seconds), Appendicular skeletal muscle mass (ASM;kg) was evaluated Dual energy X-ray absorptiometry (DXA). Sarcopenia diagnosis (handgrip <16kg or chair stand tests >15s + ASM <15 kg) was based on the values indicated by the European Working Group on Sarcopenia in Older People-2 (EWGSOP2). Severity of sarcopenia was assessed by the Short Physical Performance Battery (SPPB ≤8 points) test. The descriptive analysis, Pearson's or Spearman's correlation coefficients, and Chi-squared test were performed. The significance was considered $p<0.05$.

Results: Forty-nine patients were included [median age: 35.0 (28.0–43.5) years; median disease duration: 8.0 (4.0–14.5)] years. Chronicity and disease activity were low, being 0.0 (0.0-1.0) and 2.0 (0.0-4.0), respectively. The median of physical activity level by IPAQ was 583.60 (0.00–409.50) min/week. The majority of patients (83.7%) showed low physical activity level (IPAQ). The patients presented muscle strength by the handgrip test of 24.71±9.01 kg and 14.32±3.68s using the chair stand test. Eight patients (16.3%) showed low muscle strength by the handgrip test and twenty-four patients (49%) showed low muscle strength by the chair stand test. The mean of ASM was 17.03±2.32 kg. Ten patients (20.4%) had low muscle mass. The prevalence of sarcopenia was 16.3% following the EWGSOP2 criteria. On the other hand, we did not find severe sarcopenia. In addition, we did not find a relationship among sarcopenia and age, disease duration, disease chronicity, disease activity, cumulative corticosteroid dose, quality of life, and physical activity level ($p>0.05$).

Conclusion: The prevalence of sarcopenia was 16.3% in patients with SLE. Almost half of our patients had low muscle strength in the chair stand test (49%) and only 16.3% had low muscle strength by handgrip test. Furthermore, sarcopenia is not associated with clinical parameters. Therefore, further studies should be developed to assess risk factors for sarcopenia in patients with SLE.

POS1498 COMORBIDITIES AND SAFETY EVENTS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Real-world evidence, Systemic lupus erythematosus, Epidemiology

W. Krueger[1], D. Feger[1], A. Friedman[2], T. Doan[2], K. D'silva[2]. *[1]AbbVie, Global Epidemiology, Pharmacovigilance & Patient Safety, North Chicago, United States of America*; *[2]AbbVie, Immunology, North Chicago, United States of America*

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with multiorgan involvement. High disease activity may drive the development of comorbidities and safety events in SLE.

Objectives: To assess the prevalence of comorbidities and history of safety events at the time of Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) assessment and the incidence of newly diagnosed comorbidities and safety events post-SLEDAI assessment among a prevalent cohort of adult SLE patients ≥18 years old.

Methods: This was a retrospective observational cohort study using the OM1 SLE Registry data from January 2013 to February 2022 (OM1, Inc., Boston, MA). The index date was defined as the first observed or estimated SLEDAI score with ≥12 months of prior data occurring after the first observed SLE diagnosis. The baseline period included all observed time prior to and including the index date. The follow-up period for identifying incident comorbidities and safety events included all available data after the index date. Incidence rates were stratified by disease activity.

Results: Among 10,837 patients, mean age was 52 years and 92% were female. The most common existing comorbidities were hypertension (44%), fibromyalgia (32%), anemia (29%), dyslipidemia (29%), thyroid disease (26%), obesity (25%), depression (22%), rheumatoid arthritis (22%), anxiety (19%), and Sjögren's syndrome (18%). History of safety events at baseline most commonly included any infection (11%), abnormal liver function tests, hepatitis, or acute liver injury (ALI) (8%), elevated creatinine or acute kidney injury (AKI) (6%), and any malignancy (5%). Most patients were treated with first-line therapy for SLE (glucocorticoids and/or antimalarials) during follow-up (89%). Use of second-line (methotrexate, azathioprine, leflunomide) and third-line (belimumab, anifrolumab, mycophenolate mofetil, mycophenolic acid, tacrolimus, cyclosporine, voclosporin, rituximab) SLE therapies were less common (29% and 30%, respectively). During follow-up, 36% of patients had no disease activity, 28% had mild activity, 22% had moderate activity, and 14% had severe activity. Greater disease activity was associated with higher rates of incident hypertension, dyslipidemia, anxiety, thyroid disease, end-stage renal disease or dialysis, chronic liver disease/cirrhosis, avascular necrosis, seizures or epilepsy, and Sjögren's syndrome. The most common incident safety events regardless of disease activity were any infection (30.7 per 1000 person-years [PY]), abnormal liver function tests, hepatitis, or ALI (20.3 per 1000 PY), and elevated creatinine or AKI (17.9 per 1000 PY). Correlation between incident safety events and disease activity varied by outcome.

Conclusion: Many common comorbidities occur more frequently among patients with higher SLE disease activity. The association between disease activity and the incidence of safety events was less clear. SLE-related systemic inflammation, comorbidities, and effects of SLE treatment (both positive and negative) likely contribute to patients' risk profiles.

Table 1. Incidence Rates per 1000 person-years Stratified by Index SLEDAI Score

Comorbidity or Safety Event	No Activity N=3,919	Mild N=3,022	Moderate N=2,413	Severe N=1,483
Hypertension	38.0	38.7	42.7	43.3
Dyslipidemia	31.8	32.0	34.3	35.7
Anxiety	26.9	30.9	32.3	38.5
Thyroid disease	23.6	24.3	27.2	29.0
End-stage renal disease or dialysis	3.2	3.6	3.6	5.3
Chronic liver disease	3.6	4.0	5.0	5.2
Avascular necrosis	2.5	2.9	3.4	4.4
Seizures or epilepsy	5.3	6.3	7.1	8.4
Sjögren's syndrome	7.2	7.8	8.2	12.7
Abnormal liver function	16.3	22.4	25.4	19.2
Abnormal kidney function	14.4	20.9	20.3	18.0
Any infection	24.7	23	36.4	30.6
Major adverse cardiovascular events	8.1	9.2	6.3	6.6
Venous thromboembolism	2.3	4.4	4.0	4.6
Any malignancy	7.0	4.6	5.6	5.2

Disease activity cutoffs: No activity (SLEDAI=0), low (SLEDAI=1-5), moderate (SLEDAI=6-10), severe (SLEDAI=11+)

POS1499 FACTORS ASSOCIATED WITH CARDIOVASCULAR EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN A MONOCENTRIC COHORT WITH UP TO 40 YEARS OF FOLLOW-UP

Keywords: Systemic lupus erythematosus, Cardiovascular disease, Antiphospholipid syndrome

N. Farina[1], J. Webster[2], W. Luo[2], D. Garelick[3], S. Moreira Pinto[4], D. Isenberg[2], A. Rahman[2]. *[1]IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*; *[2]University College London, Centre for Rheumatology Research, Division of Medicine, London, United Kingdom*; *[3]The Zabludowicz Center for Autoimmune Diseases, Rheumatology Unit, Tel-Hashomer, Israel*; *[4]Centro Hospitalar Póvoa de Varzim e Vila do Conde, Internal Medicine Service, Povoa de Varzim, Portugal*

Background: Systemic lupus erythematosus (SLE) is associated with an increased cardiovascular risk. Several traditional and disease-specific risk factors have been shown to correlate with the occurrence of cardiovascular events (CVE) in patients with SLE. However, results of previous studies are diverse.

Objectives: The objectives of this study were to report number, type and those factors associated with CVE in patients with SLE in a large, single-centre, ethnically diverse cohort with a long follow-up duration.
Methods: Medical records of patients treated at the Lupus Clinic at University College London Hospital (UCLH) between 1979 and 2020 were retrospectively reviewed. Data about CVE, traditional cardiovascular risk factors, demographic and disease features, and treatment history were collected. Only patients with complete available information were included in the study. Regression analyses were performed to identify factors associated with CVE.
Results: Four hundred and nineteen patients were included in the study. Maximum follow-up length was 40 years. Seventy-one (17%) patients had at least one CVE. Forty (50%) events were VTE, 26 (32.5%) were CVA, and 14 (17.5%) were CAD. Mean age at CVE was 44 (SD 12) years. Median time from diagnosis to CVE was 8 (IQR 4-15) years. Descriptive comparative analysis showed an increased prevalence of hypercholesterolemia (41% vs 28%, p-value=0.035), diabetes (10% vs 4%, p-value=0.027), and antiphospholipid antibodies (aPL) positivity (58% vs 27%, p-value<0.001) among patients with CVE. Furthermore, these patients were treated less frequently with hydroxychloroquine (80% vs 89%, p-value=0.049). However, univariable analysis (**Table 1**) showed that only aPL positivity was significantly associated with CVE. This association was confirmed at multivariable analysis (p<0.001). Survival curve for CVE according to the presence of aPL is shown in **Figure 1**. When analysing different types of CVE, aPL were specifically associated with both venous thromboembolic events (p-value<0.001) and cerebrovascular events (p-value=0.007). Dedicated subanalyses revealed that cumulative glucocorticoid dose (p-value=0.010) and a diagnosis of SLE before 2000 (p-value<0.001) were also significantly associated with CVE.
Conclusion: Cardiovascular disease is highly prevalent among patients with SLE and is associated with aPL, glucocorticoid therapy, and diagnosis before 2000.

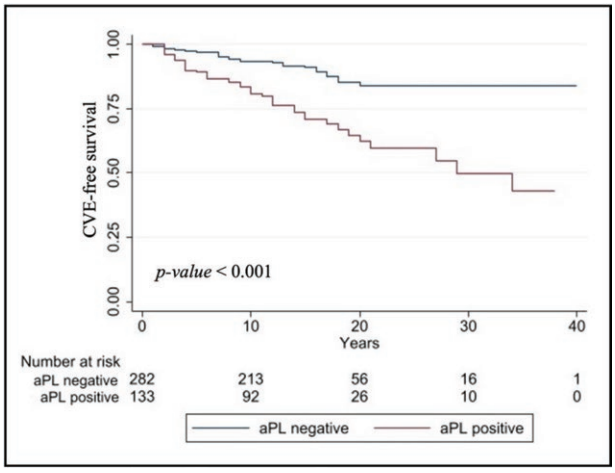

Figure 1. Survival curves for cardiovascular events according to the presence of antiphospholipid antibodies. aPL, antiphospholipid antibodies.

Table 1. Univariable Cox regression analysis to evaluate the association between independent variables and cardiovascular events in the whole study population.

ALL-CAUSE MORTALITY IN A SYSTEMIC LUPUS ERYTHEMATOSUS COHORT

Keywords: Gender/diversity issues, Real-world evidence, Systemic lupus erythematosus

M. A. Petri[1], J. Levy[2], U. Sbarigia[3], D. Goldman[4]. *[1]The Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, United States of America*; *[2]Johns Hopkins Bloomberg School of Public Health, Health Policy and Management, Baltimore, United States of America*; *[3]Janssen Pharmaceutica NV, Global Services, Beerse, Belgium*; *[4]Johns Hopkins University, School of Medicine, Baltimore, United States of America*

Background: Multiple studies have documented that patients with SLE have a higher all-cause mortality. Active disease contributes to early deaths with later deaths more likely due to cardiovascular disease and malignancy.
Objectives: In this study we present the pattern of mortality in a single long-term, prospective cohort using death certificates to document cause of death.
Methods: The cohort consists of 2,238 patients (92% female, 52% Caucasian, 39% African American) with 92% from Maryland and surrounding states (MD 71%, VA 9%, PA 7%, DE 3%, WV 1%, DC 1%). Death records for 1,288 patients lost to follow up prior to 2020 were obtained from the National Death Index (NDI) at the Center for Disease Control (Atlanta, GA). The NDI identified 11,369 death records from 1985 to 2019 as possible matches based on name, gender, race, and date of birth. Primary and secondary causes of death were provided for the best match for each patient. The causes of death were based on CDC classifications of ICD10 and ICD9 codes. Lupus was identified as a cause of death if ICD10 code M32.X or L93.0, or ICD9 code 695.X or 710.0 was listed on the death record. There were 207 death records identified by matching the NDI data elements and the date of death on the certificate to the date of death reported by the family. Analysis of these 207 records provided the following set of criteria that identified additional death records from the remaining 1,079 patients lost to follow up: 1) date of death occurred after the patient was lost to follow up; 2) at least six out of seven data elements sent to NDI matched those on the death record; and 3) EITHER lupus was listed as a cause of death on the death record OR the state of residence matched the state listed on the death record. Using these criteria, an additional 297 death records were found (Table 1).
Results: The leading primary causes of death listed on the death certificate were: lupus (n=116, 23%), cardiovascular (n=114, 23%), cancer (n=74, 15%), infection (n=66, 13%), other (n=55, 11%), respiratory (n=28, 6%), accidental (n=17, 3%), renal (n=9, 2%) and gastrointestinal (n=8, 2%). Lupus deaths and accidental deaths occurred at a significantly younger age (p-values less than 0.05 for paired t-tests; Figure 1). African Americans died at a younger age compared to Caucasians (50 ± 15 years vs 58 ± 16 years, p<0.001). African Americans had a higher proportion of deaths from infections and renal causes compared to Caucasians (p=0.0017 Likelihood ratio test).
Conclusion: SLE patients died at an average of 55 years of age for all causes of death (compared to life expectancies of >80 years for females in the US), with lupus and cardiovascular disease identified as the leading causes of death on death certificates. Cancer and infection were the third and fourth causes of death. African Americans died younger than Caucasians and had more infection and renal causes of death. Only respiratory deaths were significantly more common in Caucasians.

Table 1 – Matching Criteria for Death Records

Date of Death after Lost to Follow Up	NDI Criteria Match	Lupus = Cause of Death	State Match	Family Reported Deaths	Additional Death Records	Total Death Records

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with a broad range of clinical manifestations and a high unmet need. Real-world data on SLE are available and currently scattered across more than 50 registries worldwide. The Lupus Federated Data Network (LupusNet) is an interdisciplinary initiative that aims to standardize data and harmonize methodology to create a large, global SLE database from existing registries.

Objectives: This initiative will allow the analysis of real-world data across lupus registries worldwide.

Methods: The central paradigm of LupusNet is a federated model whereby the data reside with the respective registries/data owners and analyses are executed at the local center. As data from different sources have different infrastructures, the Observational Medical Outcomes Partnership (OMOP) common data model (CDM) will be used to standardize data into a common format. Standardization will reduce the heterogeneity in data structure and semantics, allowing for uniform data analysis, collaborative research, large-scale analytics, and sharing of sophisticated tools and methodologies. LupusNet will include prospective, observational registries designed to capture real-world data on demographics, treatments, and outcomes in patients with SLE. Other data, including data originating from randomized clinical trials, will also be part of this initiative.

Results: Currently, 6 registries representing 4 regions of the globe and ~30,000 lupus patients are engaged at the start of this initiative. Examples of the types of data from each registry that are available for standardization and harmonization in LupusNet are shown in **Figure 1**. Other lupus registries that may be interested in participating in this initiative should contact the authors. Participating registries are not required to collect all types of data to be included in the initiative. Contact the LupusNet team at www.lupusnet.org.

Conclusion: Through the standardization of global registry data, LupusNet hopes to demonstrate the potential of real-world evidence to answer important questions related to SLE with the ultimate goal of improving patient outcomes.

HERPES ZOSTER INCIDENCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE COHORT STUDY

Keywords: Real-world evidence, Systemic lupus erythematosus

N. Stempniewicz[1], A. Steffens[2], K. Kim[1], A. Jorga[3], C. Bell[4], M. Ducharme[2], H. Trenz[2], D. Singer[1]. [1]*GSK, Medical Affairs, Philadelphia, United States of America*; [2]*Optum, HEOR, Eden Prairie, United States of America*; [3]*GSK, Medical Affairs, New York, United States of America*; [4]*GSK, Value Evidence and Outcomes, Durham, United States of America*

Background: Herpes zoster (HZ) results from reactivation of the varicella-zoster virus and is characterized by a painful dermatomal rash. HZ is associated with increased healthcare costs and reduced patient quality of life.

Objectives: To estimate HZ incidence in patients with systemic lupus erythematosus (SLE) and in a general immunocompetent adult population in the United States.

Methods: This retrospective cohort study used administrative claims data (Optum Research Database) to identify adults (≥18 years) between October 2015 and May 2022 who were assigned to one of two cohorts based on ICD-10-CM diagnosis codes: SLE cohort and immunocompetent cohort. Patients with diagnosis codes for other immunocompromising conditions (ICC) were excluded from the immunocompetent cohort and from the main SLE cohort to create a sub-cohort (SLE without other ICC). The immunocompetent cohort represented a random sample of 1 million individuals meeting the cohort criteria. Indexing occurred at the later of 12 months of continuous enrollment (CE) or the first SLE diagnosis for the SLE cohorts, and after 12 months of CE for the immunocompetent cohort. Patients with HZ vaccination prior to index or a HZ diagnosis in the 12-month baseline period were excluded. Patients were followed for a variable period from index until the earlier of an incident HZ diagnosis or censoring event (HZ vaccination, disenrollment, death, or the end of the study period). Overall incidence rates of HZ were estimated in each cohort and stratified by age at index, and by baseline disease severity for the SLE cohorts using a published algorithm [1].

Results: The SLE cohort included 60,430 patients, among which 21,206 comprised the SLE without other ICC cohort. The immunocompetent cohort included 1,000,000 patients. Mean (standard deviation) age and percent female for the SLE (55 [15] years; 89% female) and for the SLE without other ICC (53 [16] years; 89% female) cohorts were higher compared to the immunocompetent (46 [18] years; 50% female) cohort ($p < 0.001$). For the SLE cohort, HZ incidence (95% confidence interval [CI]) per 1,000 person-years was 19.72 (18.93-20.55) overall and 16.27 (15.04-17.58) and 21.50 (20.48-22.56) per 1,000 person-years for patients aged 18-49 and ≥ 50 years, respectively. HZ incidence (95% CI) for the SLE without other ICC cohort was 14.03 (12.83-15.32) per 1,000 person-years

overall (18-49 years: 11.24 [9.61-13.07]; ≥50 years: 16.08 [14.39-17.91]). HZ incidence (95% CI) for the immunocompetent cohort was 5.64 (5.53-5.74) per 1,000 person-years (18-49 years: 3.46 [3.35-3.57]; ≥50 years: 8.57 [8.37-8.77]). HZ incidence rates in the SLE cohorts increased with baseline disease severity (Table 1).
Conclusion: HZ incidence was high among patients with SLE. HZ prevention strategies in this population may be warranted.

POS1503 LONGITUDINAL STUDY OF PREGNANCY OUTCOMES IN INDIGENOUS VERSUS NON-INDIGENOUS LUPUS PATIENTS IN WESTERN AUSTRALIA

Keywords: Systemic lupus erythematosus

J. Nossent[1,2], C. Inderjeeth[1,2], D. Preen[3], H. Keen[1,4]. [1]*The University of Western Australia, Rheumatology Section, Medical School, Crawley, Australia*; [2]*Sir Charles Gairdner Hospital, Rheumatology, Nedlands, Australia*; [3]*The University of Western Australia, School of Population and Global Health, Nedlands, Australia*; [4]*Fiona Stanley Hospital, Rheumatology, Murdoch, Australia*

Background: Ethnicity remains a key determinant of outcome in SLE and Indigenous Australian patients (IA) are disproportionately affected in term of renal failure and mortality [1,2]. Pregnancy in SLE patients associates with maternal and foetal morbidity, but there is no data on pregnancy in IA SLE patients.
Objectives: To compare pregnancy outcomes and complications between IA and non-IA (NI) patients with SLE over three decades between 1985-2015.
Methods: Using state-wide hospital morbidity data, we compared rates for live birth (LB), abortive outcome (AO), preterm birth and gestational complications across pregnancies in IA (n = 31) and non-Indigenous (NI) SLE patients (n = 357) in Western Australia over a thirty-year period. Results presented are medians compared by Kruskal-Wallis test and proportions with odds ratios (ORs) (95% CI) compared by $\chi 2$ testing across groups and study decades.
Results: A total of 702 SLE pregnancies were recorded (62 in IA and 640 in NI). Median age at first pregnancy was significantly lower in IA (27 years, IQR 20-32) than NI patients (30 years, IQR 26-34) (p<0.001), with no difference in median number of pregnancies (2 vs 2, OR 1.1 CI 0.56-2.4). Over the whole study period, LB rate was similar for IA and NI patients (74.2 % vs 72.8, OR p=0.45); however, LB rate increased from 65.5 to 79.6% in NI patients over time (p=0.01) and decreased from 88.9 to 75.9 in IA patients (p=0.34). In NI patients, the proportion of caesarean births was stable over time (35.5 to 37.7%, p= 0.56) but decreased in IA patients (44.4 to 20.7%, p=0.24). Preterm birth occurred in 10.3 % of live births in NI and 9.7 % of IA patients (OR 1.14, CI 0.49-3.10, p = 0.82) with the proportion of preterm deliveries increasing over time in both groups (from 0 to 10.3% in IA and from 4.9 to 7.9% in NA). A single case of congenital heart block occurred (prevalence 0.15%). Gestational diabetes (16.1 vs 2.4 %), infections 12.4 vs 4.1%) and renal disease (22.6 vs 4%) complicated more pregnancies in IA patients (all p<0.001) and showed increasing rates over the three study decades, while these rates remained stable in NI patients except for an increase in diabetes (1.3 to 5.1%).
Conclusion: While LB rates have increased in NI lupus patients over time, they decreased in IA patients in association with an increase in comorbid complications. This suggest that stricter monitoring of pregnancy in IA lupus patients is required to achieve the level of improvement observed in NI lupus patients, that is in line with current literature data [3].

Background: Lupus nephritis (LN) is one of the most frequent serious Lupus manifestations and it is an important risk factor for overall morbidity and mortality in patients with SLE. Despite potent anti-inflammatory and immunosuppressive therapies, it persists with a significant number of patients who progress to chronic renal failure.
Objectives: To evaluate the prevalence of LN and the characteristics of patients with this complication in search of a potential higher risk profile for the development of kidney disease.
Methods: It was a retrospective, observational and analytical study, based on the database of the national registry of SLE of the Argentine Society of Rheumatology (RELESSAR). Adult patients who met the ACR 1997 Classification Criteria were included. Sociodemographic data, time of disease evolution, and delay in diagnosis were collected. The antibody profile, activity indices (SLEDAI), comorbidities (Charlson), treatments and damage (SDI) were determined. Patients with current or past LN were compared with those without LN.
Results: 1502 patients were analyzed, of which 643 (42.8%) had LN. The predominant histological classes were class IV in 253 cases, class III in 81, class II in 78, and class V in 33 patients. In the univariate analysis, patients with LN were characterized by belonging more frequently to the mestizo ethnic group (p=0.017), having a younger age at entry into the registry (p<0.001), less delay in diagnosis in months (p<0.001) and longer disease duration (<0.001). They also presented higher SLEDAI in the last evaluation (p<0.001) as well as low complement levels (p<0.001) and a higher frequency of positive anti-SM antibodies (p<0.007). Within the comorbidities they had significantly more dyslipidemia (p<0.001) and arterial hypertension (p <0.001). They had more episodes of hospitalization (p<0.001), more serious infections (p<0.001) and a higher SLICC damage index (p=0.001). The treatments received any time were Azathioprine (44.3% vs 27.9%, p<0.001), Cyclophosphamide (66.2% vs. 8.72%, p<0.001), mycophenolate mofetil (47.0% vs 7.37%, p< 0.001), mycophenolic Acid (5.59% vs. 0.39%, p<0.001) and Belimumab (3.7% vs. 8.03%, p<0.001). The multivariate analysis is described in Table 1.
Conclusion: In the RELESSAR registry, the prevalence of LN was 42.8%. These patients were characterized by being more frequently of mestizo origin, younger at last evaluation, and of lower socioeconomic level. There was also a correlation with the global activity of the disease as well as with low complement levels and anti-SM antibodies positive. Within the comorbidities there was a strong association with arterial hypertension. We also highlight the negative association with acute cutaneous lupus and with the presence of antiphospholipid antibodies.

Table 1. - Result of the multivariate model.

Characteristics	OR	CI	p
Age at last visit	0.96	0.94-0.97	<0.001
SLE duration	1.01	1.00-1.01	<0.001
SES Media/low/very low	1.65	1.02-2.71	0.044
SLEDAI	1.09	1.06-1.13	<0.001
Acute Cutaneous Lupus	0.57	0.42-0.78	<0.001
Positive Anti SM antibodies	1.43	1.06-1.92	= 0.019
Low Complement (> than 10 days or persist during the last 10 days	4.52	2.78-7.65	<0.001
Negative Anti phospholipid antibodies	1.74	1.27-2.39	<0.001
Arterial Hypertension	3.00	2.10-4.31	<0.001
Gastroduodenal ulcer	0.36	0.17-0.73	0.006

POS1505 THE IMPACT OF HIGH-RISK ANTIPHOSPHOLIPID ANTIBODIES PROFILE ON MAJOR ORGAN DAMAGE PROGRESSION IN SYSTEMIC LUPUS ERYTHEMATOSUS: CSTAR MULTIPLE PROSPECTIVE COHORT STUDY

Keywords: Organ damage, Autoantibodies, Systemic lupus erythematosus

D. Yufang[1], J. Zhao[1], Q. Wang[1], X. Tian[1], M. LI[1], X. Zeng[1]. [1]*Peking Union Medical College Hospital (PUMCH), Rheumatology, Beijing, China*

Background: With the improvement in survival, the prevention of cumulative organ damage has become a major goal in the management of systemic lupus erythematosus (SLE). Patients with autoimmune disease suffered from an increasing risk of cardiovascular disease (23·3 events per 1000 patient-years [1]). Although antiphospholipid (aPLs) antibodies, including anticardiolipin antibodies, anti-β2 glycoprotein I, and lupus anticoagulant, were associated with vascular events in antiphospholipid syndrome, the role of APLs in SLE patients was not yet determined.
Objectives: Based on the Chinese SLE treatment and research (CSTAR) multi-center prospective study, we aimed to identify the predictive value of high-risk aPLs on cumulative organ damage progression in SLE.
Methods: Demographic characteristics, autoantibody profiles, clinical manifestations, disease activity status, and organ damage were collected at baseline. High-risk aPLs profile was defined according to 2019 EULAR recommendations for APS [2] (the presence of lupus anticoagulant, or double or triple aPL positivity, or the presence of persistently high aPLs titers).
Results: A total of 2132 SLE patients with full follow-up data were recruited and 424 (19.9%) showed high-risk aPLs profiles. 453 (21.2%) patients developed new organ damage during a mean follow-up of 4.40±2.64 years, and 143(31.6%) are cardio-cerebral vascular damage. At baseline, patients with high-risk aPLs profile have a higher rate of neurological involvement (12.5% vs 7.6%, p=0.001). As shown in Figure 1, cox regression analysis showed that high-risk aPLs profile can predict new-onset organ damage (HR=1.99, 95% CI, 1.63-2.43, p<0.001) and cardio-cerebral vascular damage (HR=7.83, 95% CI, 5.56-11.03, p<0.001). After adjusted of gender(male), age, smoking history, diabetes mellitus, hypertension, and other SLE related potential confounders, high-risk aPLs profile was still found to be an independent predictor which can predict cardio-cerebral vascular events (HR=7.12, 95% CI, 5.03-10.14, p<0.001) (Figure 1).

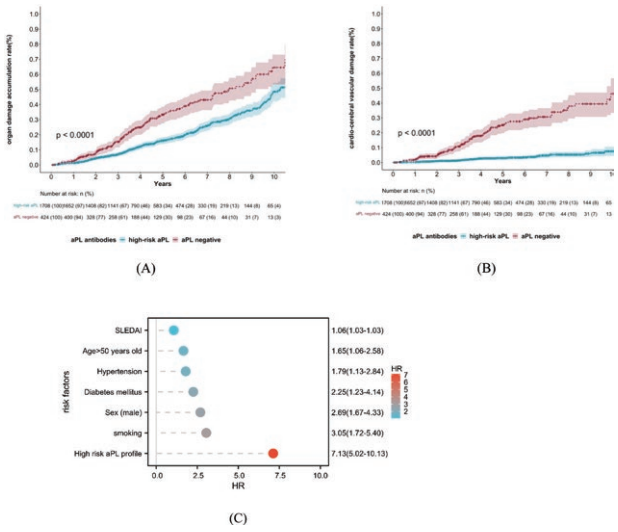

Figure 1. (A). Cumulative probability of new-onset organ damage in patients with or without high-risk aPLs profile. (B). Cumulative probability of cardio-cerebral vascular damage in patients with or without high-risk aPLs profile. (C). Risk factors of cardio-cerebral vascular damage in SLE patients.

Conclusion: SLE patients with high-risk aPLs profile warrant more care and surveillance of cardio-cerebral vascular events during follow-up.

Background: Systemic lupus erythematosus (SLE) can result in impaired daily physical function through various mechanisms including active disease, chronic damage, and mental health symptoms that are common in the disease. However, the key drivers of reduced physical function are poorly understood, and no large-scale global studies investigating this have been conducted to date.

Objectives: To investigate key factors that contribute to impaired physical function in SLE globally.

Methods: SLE patients were identified from the COVAD 2 database, a global register of more than 20,000 respondents. Healthy controls (HC) were included to compare differences in physical function using the Patient Reported Outcome Measurement Information System (PROMIS) questionnaire. Demographics, medication, comorbidities, disease activity, Global Physical Health (GPH) and Global Mental Health (GMH) were collected. Multivariable regression analysis was used to identify contributing factors to favourable or poor physical function (measured by PROMIS Physical Function shortform PF-10a score).

Results: 979 SLE patients and 3358 HCs were included in analysis. Patients with SLE had significantly lower PF-10a score as compared to HCs (median 42, IQR 36-47 vs median 49, IQR 45-50, p<0.0001). Determinants of physical function status in patients with SLE are summarised in Table 1. Briefly, factors associated with poor physical function included increasing age (-0.042, 95% CI -0.069 to -0.015, p=0.002) and methotrexate use (-0.928, 95% CI -1.844 to -0.012, p=0.047). Diabetes (-1.862, 95% CI -3.481 to -0.243, p=0.024) and interstitial lung disease (ILD) (-2.441, 95% CI -4.366 to -0.517, p=0.013), but not asthma or COPD, also contributed to lower PF-10a score. From a mental health perspective, anxiety (-0.970, 95% CI -1.853 to -0.087, p=0.031) but not depression contributed to a lower physical function score. Higher Pain Visual Analogue Scales (VAS) (-2.889, 95% CI -3.107 to -2.671, p<0.001) and Fatigue VAS (-1.459, 95% CI -1.974 to -0.945, p<0.001) also contributed to lower PF-10 scores. Hydroxychloroquine use (0.844, 95% CI 0.190 to 1.498, p=0.012) and higher GPH score (2.287, 95% CI 2.079 to 2.494, p<0.001) were associated with favourable physical function.

Conclusion: Patients with SLE show significantly reduced physical function compared with HCs. Key contributors to poor physical function include intercurrent diabetes and ILD. Screening for, and aggressive early treatment of these conditions may confer improved long-term function. As expected, higher levels of pain and fatigue were associated with poor physical function. Methotrexate use was also identified as a contributing factor to reduced function, which could represent its use in articular manifestations that limit physical function. Importantly, use of hydroxychloroquine was associated with favourable physical function, adding to the well-recognised benefits of this drug in SLE.

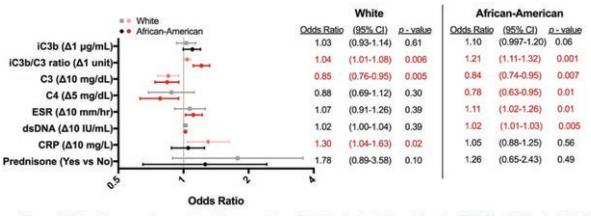
POS1507 IC3B/C3 RATIOS MORE STRONGLY CORRELATE WITH SLE DISEASE ACTIVITY IN AFRICAN-AMERICANS COMPARED WITH WHITES

Keywords: Biomarkers, Systemic lupus erythematosus

D. Sen[1], V. Strand[2], Q. Fu[3], A. Kim[1]. [1]*Washington University School of Medicine, Medicine, St. Louis, United States of America*; [2]*Stanford University School Medicine, Rheumatology/Immunology, Stanford, United States of America*; [3]*Tufts University - School of Arts and Sciences, Community Health, Medford, United States of America*

Background: Complement activation is a hallmark of SLE pathophysiology. We previously found that iC3b/C3 ratios associated with active disease and clinically meaningful changes in SLE disease activity. Since SLE is more severe in non-white populations, we hypothesized that iC3b/C3 ratios would be a more sensitive marker of disease activity in nonwhite populations.

Objectives: We examined the relationship of iC3b/C3 ratios between African-American (AA) and White subjects with classified SLE.



Methods: 159 adult SLE patients treated at the Washington University Lupus Center were enrolled in this observational study. 83 patients with 3-7 study visits were used for this longitudinal analysis. C3 and C4 were measured by nephelometry; iC3b by a lateral flow assay using an investigational medical device. SLE disease activity was measured using the SLEDAI 2K Responder Index-50 instrument. Statistical analyses were performed using SAS v9.4. Multilevel regression models examined associations for SLE disease activity. Ordinal logistic regression models with generalized estimating equation modeling (GEE) examined associations for clinically meaningful changes since the outcome variable is ordinal. Odds ratios and 95% confidence intervals were estimated using Proc GLIMMIX and Proc GENMOD.

Results: iC3b/C3 ratios and C3 associated with active disease in AA and White SLE subjects, with the association of the iC3b/C3 ratio in AA was stronger (Figure 1). In addition, AA with SLE associated C4, ESR, and dsDNA with active disease, while Whites associated with CRP. In multiple regression analysis, iC3b/C3 ratios independently associated with active disease in both groups, although the effect was more pronounced in AA (AA: OR=1.48, 95% CI=1.21-1.82; Whites: OR=1.17, 95% CI=1.02-1.34). Furthermore, in univariate regression analysis, only the iC3b/C3 ratio in AA associated with clinically meaningful changes in disease activity.

Conclusion: iC3/C3 ratios better correlated with active disease in AA compared to Whites. Furthermore, iC3b/C3 ratios correlated with clinically meaningful changes in disease activity only in AA. These data suggest that complement activation in SLE is dependent on race.

Background: Improvement on health-related quality of life (HRQoL) in patients with Systemic Lupus Erythematosus (SLE) remains a challenge. There is limited data on the level of agreement on remission according to physician and patient and remission impact on HRQoL and long-term outcomes.

Objectives: To investigate the prevalence and level of agreement between remission according to physician and patient criteria and to evaluate the impact of remission on HRQoL in patients with SLE.

Methods: Prospective study of patients included in RELESSER-PROS, a multicenter register of SLE patients. Protocol of the register has been previously described [1]. Remission according to physician was defined in agreement with DORIS 2021 criteria: clinical SLEDAI 0, physician global assessment ≤2 on a 0-10 Likert scale (equivalent to ≤0.5 on a 0-3 scale), stable low-dose prednisone (≤5mg) and stable immunosuppressive/ biologic agents if remission on therapy. Remission according to patient was defined as SLAQ (Systemic Lupus Activity Questionnaire) question 1 with no flare in the last 3 months (score 0). Patients were classified in three groups according to remission status by DORIS, SLAQ or both. Level of agreement was assessed using kappa statistics. Acceptable level of agreement was considered if kappa >0.60.

Results: 1102 patients, with a follow-up of at least 2 years (data from 3 visits available) were included in this analysis. Patient characteristics according remission status at baseline are presented in the Table 1. At baseline, remission by DORIS was present in 16.1%, by SLAQ 16.7% and 2.45% by both. Remission by DORIS was more frequent among patients with higher education, on immunosuppressant and biological therapy and patients with history of hospitalization; remission by SLAQ was more frequent among women, obese patients, and those on antimalarials ($p<0.05$). Symptoms reported in patients who considered themselves in remission were mainly cutaneous and articular (53.3%). Mean SLEDAI in patients on remission by SLAQ was 3.28 (3.78). Patients in remission by DORIS had significantly better results in patient reported outcomes (PRO) measured by EQ-5D and LIT ($p<0.05$). Level of agreement in remission according to physician and patient was 78.04% (k=0.061) at baseline, 63.39% (k=0.039), and 62.73% (k=0.099) in year 2 and 5 respectively. Kappa level of agreement was low.

Conclusion: Our results reflect low level of agreement between physician and patients in terms of remission status with increasing disagreement in the follow-up. Patients in remission by DORIS shows better results in EQ-5D and LIT.

Background: There is an increasing need for data exploring the effect of remission on kidney-oriented outcomes and terminal organ damage in patients with lupus nephritis (LN).
Objectives: To investigate the effects of renal-extrarenal clinical remission on chronic kidney disease (CKD) development and organ damage accrual in patients with LN.
Methods: We performed a multicentric retrospective cohort study on biopsy-proven LN patients with at least five years follow-up, in whom we assessed i) the minimum duration of remission able to prevent CKD (serum creatinine >1.0mg/dl with eGFR <60ml/min/1.73 m2 and inactive urinary sediment, confirmed by at least three determinations for at least 3 months); ii) the impact of remission on organ damage increase, evaluated by the SLICC Damage Index (SDI). Renal-extrarenal clinical remission was defined as serum creatinine <1mg/dl, eGFR>60 ml/min/1.73m2, proteinuria <0.5g/24h and cSLEDAI=0, lasting for at least one year. Cox regression was used to test the effect of different durations of remission on CKD and SDI accrual. The minimum duration of remission needed to prevent CKD was estimated through Kaplan-Meier curves. The potential relationship between renal-extrarenal clinical remission and SDI was assessed by Spearman correlation between percentage of follow-up spent in remission and annual increase in SDI.
Results: 303 LN patients were included (females 86.5%, mean follow-up 14.8 (9.8-22.0) years). 84.8% achieved renal-extrarenal clinical remission that persisted for 8.70 (5.40-13.30) years. Overall, 17.6% patients developed CKD after a median of 14.1 (8.9-20.9) years. Patients achieving remission developed CKD significantly less frequently than patients never achieving remission (12.1% vs. 56.6%, p<0.001). Among patients with at least 10-year follow-up (n=224), a remission duration of at least 2 years protected from CKD development (p<0.001), yet the best CKD-free survival was obtained in patients reaching at least 3 years of remission (HR95%CI 2.34 (1.38-3.98) p<0.001) (**Figure 1**). Considering the whole population, the increase in SDI from baseline to the last observation was significantly higher in patients who had never achieved remission (median: 2[1-3] vs. 1[0-1]; p= 0.047). We observed that the higher the percentage of follow-up spent in remission, the lower the yearly SDI accrual (r=-0.324, p<0.001). Among patients achieving remission, the risk of any SDI increase was significantly lower in patients maintaining at least 3 years on remission vs. shorter durations (HR95% CI 0.54 (0.31-0.54), p=0.03).
Conclusion: Renal-extrarenal clinical remission is an achievable treatment target which protects against CKD development and SDI increase in patients with LN. At least 3 years of renal-extrarenal clinical remission confers significant protection against renal function deterioration and chronic damage, hence emerging as a desirable therapeutic target for LN.

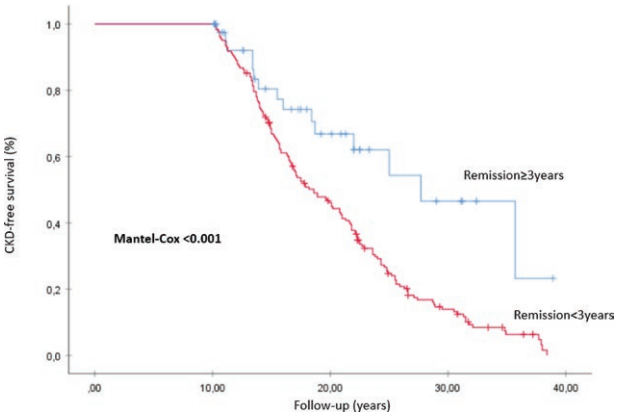

Figure 1. CKD-free survival according to years spent in remission (Kaplan-Meier method; Mantel-Cox for comparison)

POS1511

PERSISTENCE OF RENAL-EXTRARENAL REMISSION AND EFFECT ON RISK OF SLE FLARES AND OF CHRONIC KIDNEY DISEASE IN PATIENTS WITH LUPUS NEPHRITIS

Keywords: Systemic lupus erythematosus, Kidneys, Remission

G. Moroni[1,2], M. Gatto[3], G. Frontini[4], M. Calatroni[1,2], S. Quaglini[5], F. Reggiani[1,2], B. Trezzi[6], L. Iaccarino[3], R. A. Sinico[1], A. Doria[3]. *[1]IRCCS Humanitas Research Hospital, Nephrology and Dialysis Division, Milan, Italy*; *[2]Humanitas University, Department of Biomedical Sciences, Milan, Italy*; *[3]University of Padova, Unit of Rheumatology, Department of Medicine, Padua, Italy*; *[4]San Paolo Hospital, ASST SS Paolo e Carlo, Unit of Nephrology and Dialysis, Milan, Italy*; *[5]University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy*; *[6]Università degli Studi di Milano Bicocca, Department of Medicine and Surgery, Milan, Italy*

Background: How renal and extrarenal remission affects risk of flares and of chronic kidney damage (CKD) development in systemic lupus erythematosus (SLE) patients with active lupus nephritis (LN) was not clearly disentangled.
Objectives: To investigate the effect of maintained or interrupted renal-extrarenal clinical remission on the risk of SLE flares and CKD development in LN.
Methods: We conducted a retrospective cohort study on biopsy-proven LN patients in whom we evaluated i) the probability of achieving and maintaining renal-extrarenal clinical remission; ii) the impact of renal-extrarenal clinical remission on the risk of SLE flares and CKD development (defined as serum creatinine >1.0mg/dl with eGFR <60ml/min/1.73 m2 and inactive urinary sediment, confirmed by at least three determinations for at least 3 months); iii) the predictors of renal-extrarenal clinical remission. Renal-extrarenal clinical remission was defined as serum creatinine <1mg/dl, eGFR>60ml/min/1.73m2, proteinuria <0.5g/24h and cSLEDAI=0 lasting for at least one year. Time to renal-extrarenal clinical remission, the likelihood of its maintenance and the risk of SLE flares were estimated through Cox regression.
Results: 303 patients were included in the study. Over a 14.8-year-follow-up, 46 patients never achieved while 257 achieved remission after a median of 1.44 (0.69-3.58) years from initial therapy for LN. In 142 out of 257 patients, remission ended after a median of 3.6 (2.30-5.90) years due to SLE flares. 115 patients maintained an uninterrupted remission for 9.5 (5.8-14.5) years. At multivariate analysis, age >40 years (OR95%CI: 1.017 (1.005-1.028); p=0.004), hydroxychloroquine use (OR95%CI:1.384 (1.109-1.661); p=0.021) and absence of arterial hypertension (OR95%CI: 0.699 (0.425-0.975); p= 0.011) were independent predictors of renal-extrarenal clinical remission. CKD occurred in 56% of patients who had never reached renal-extrarenal clinical remission, in 21.8% of those who lost remission due to SLE flares and in none of those who maintained remission permanently (p<0.0001). Five, 10 and 15 years after the beginning of

renal-extrarenal clinical remission 63%, 47% and 38% of patients respectively were still in remission. After the 15th year from the start of renal-extrarenal clinical remission, no patient developed SLE flare and remission persisted without interruption until the end of the observational period. The risk of SLE flares decreased to 10%, 5% and dropped to 2% on remission lasting<5, 5-10 and 10-15 years respectively. No achievement or loss of renal-extrarenal clinical remission due to SLE flares were associated with CKD development.

Conclusion: Older age, hydroxychloroquine use, absence of arterial hypertension predict remission among LN patients upon initial therapy. The longer the remission, the higher the chance of it persisting uninterrupted, and the lower the risk of SLE flares and of CKD.

Antovic[7]. *[1]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden*; *[2]Karolinska sjukhuset Solna, Coagulation Unit, Department of Hematology, Stockholm, Sweden*; *[3]Örebro University, School of Medical Sciences, Örebro, Sweden*; *[4]Karolinska Institutet, Division of Biostatistics, Institute of Environmental Medicine, Stockholm, Sweden*; *[5]Karolinska Institutet, CLINTEC, Karolinska Institutet, Stockholm, Sweden*; *[6]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden*; *[7]Karolinska Institutet, Department of Medicine Solna, Division of Rheumatology, Karolinska Institutet, Stockholm, Sweden and Rheumatology, Karolinska University Hospital, Stockholm, Sweden*

Background: Recurrent thrombosis in patients with antiphospholipid syndrome (APS) is a major clinical concern and treatment challenge. Data regarding risk factors and markers of recurrent thrombosis in APS patients, particularly during long-term follow-up, is limited.

Objectives: We aimed to study the effect of cardiovascular (CV) risk factors and antiphospholipid antibody (aPL) profiles on recurrent thrombosis in APS. We continued to explore if the occurrence of thrombocytopenia and decline in kidney function over time could be considered risk factors.

Methods: This retrospective cohort study comprises all patients identified with APS in the electronic medical records at Karolinska University Hospital, Sweden 2014-2020. The patients were followed until death, last medical visit, and thrombotic event. Cox proportional-hazard model was used to estimate hazard ratios (HR) and 95% confidence intervals (95% CI) between groups. A time-varying model was applied when the effect of the occurrence of thrombocytopenia and decline in renal function and time to recurrent thrombosis were assessed. Ethical approval was obtained from the Swedish Ethical Review Authority.

Results: 263 patients were included in the cohort and 52.1% of patients had primary APS. The median age at inclusion was 45 years (35–60) and 66% were women. During follow-up, 47 re-thrombotic events occurred; 29 arterial and 18 venous events, with an incidence of 4.1 per 100 person-years (95% CI: 3 – 5.3). A significant CV risk factor for re-thrombosis was current smoking; hazard ratio 3.62 (95% CI: 1.4 – 9.2). Twenty-two patients (64.7%) with re-thrombosis were triple positive for aPL compared to 99 (43.2 %) without any event at follow-up (p <0.01). There was no difference in the number of patients with re-thrombosis between the primary and secondary APS. The time-varying Cox regression analyses revealed chronic kidney disease (eGFR<60) and thrombocytopenia (platelet count $<100x10^9$) hazard ratios 2.41, (95% CI: 1.2 – 5.0) and 7.60 (95% CI: 1.9 – 30.1), respectively, as the major risk factors for re-thrombosis in this cohort of APS patients. The cumulative mortality incidence was 4.5% (n=12). The most common cause of death was sepsis due to bacterial infection at a median age of 63 (IQR 51-71).

Conclusion: Our results demonstrate that the decline of kidney function and the occurrence of thrombocytopenia in APS patients over time are major risk factors for recurrent thrombosis. Adequate surveillance and treatment options are necessary to improve kidney function and thrombocytopenia and thereby prevent further morbidity in APS patients.

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by thrombosis (arterial, venous or small vessel) or obstetrical events and persistent antiphospholipid antibodies (aPL), according to the Sydney classification criteria. Many studies have performed cluster analyses among patients with primary APS and associated autoimmune disease, but none has focused solely on primary APS.

Objectives: We aimed to perform a cluster analysis among patients with primary APS and asymptomatic aPL carriers without any autoimmune disease, to assess prognostic value.

Methods: In this multicenter French cohort study we included all patients with persistent APS antibodies (Sydney criteria) measured between January 2012 and January 2019. We excluded all patients with systemic lupus erythematosus or other systemic autoimmune diseases. We performed hierarchical cluster analysis on the factor analysis of mixed data coordinates results with baseline patient characteristics to generate clusters.

Results: We identified four clusters: cluster 1, comprising "asymptomatic aPL carriers", with low risk of events during follow-up; cluster 2, the "male thrombotic phenotype", with older patients and more venous thromboembolic events; cluster 3, the "female obstetrical phenotype", with obstetrical and thrombotic events; and cluster 4, "high-risk APS", which included younger patients with more frequent triple positivity, antinuclear antibodies, non-criteria manifestations, and arterial events. Regarding survival analyses, asymptomatic aPL carriers relapsed less frequently than the others, but no other differences in terms of relapse rates or deaths were found between clusters.

Conclusion: We identified four clusters among patients with primary APS, one of which was "high-risk APS". Clustering-based treatment strategies should be explored in future prospective studies.

POS1514 DIFFERENTIALLY EXPRESSED GENES OF PATIENTS WITH LUPUS NEPHRITIS THROUGH INTEGRATIVE BIOINFORMATICS

Keywords: Biomarkers, -Omics, Systemic lupus erythematosus

R. Martinez[1], C. Elizondo Solis[1], A. Montoya Rosales[2], M. Salinas Carmona[1], N. Macias-Segura[1]. [1]*Servicio y Departamento de Inmunología, Service and Department of Immunology, Monterrey, Mexico*; [2]*UANL - CIDICS, Immunomodulators Laboratory, Monterrey, Mexico*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune chronic disease characterized clinically by periods of flares and remission. Although its pathophysiology has not yet been well understood, it is well documented that SLE courses with systemic inflammation, as well as affection to specific organs [1]. Lupus nephritis (LN) is the most common complication and cause of death appearing in SLE patients, often leading to end-stage renal disease [2]. A type I interferon (IFN) signature is present in SLE, however, there is no consensus on which genes are expressed in LN. We performed a metanalysis through integrative bioinformatics to identify differentially expressed genes (DEGs) in patients with LN.
Objectives: We aimed to identify and assess overlapped DEGs of patients with LN through integrative bioinformatics and functional enrichment analysis.
Methods: We designed a search strategy in the Gene Expression Omnibus platform to identify datasets of expression profiling by array of kidney samples of patients with LN. The inclusion criteria were: 1) Presence of healthy controls in the datasets, and 2) Analysis of data with GEO2R. The exclusion criteria were: 1) Incomplete information in the datasets, 2) Failure to identify cases and controls, or 3) Gene expression through RNAseq. DEGs were filtered when $p < 0.05$ and logfold change > 2 or < -2. We assessed the DEGs with David database and performed a prediction analysis with GeneMania. Protein-protein interactions analysis was realized with String through Cytoscape platform, and iRegulon was used to predict a possible regulatory target of the cluster.
Results: 3 datasets fulfilled the inclusion criteria and 9 DEGs were identified. Prediction analysis yielded 23 co-expressed genes. David database recognized the principal biological processes involving those genes (Table 1). PPI analysis recognized the top 10 genes with the strongest interactions, and proposed STAT1 as the regulatory target (Figure 1).

Table 1. ***Top 3 biological processes involving overlapped DEGs among the datasets, in which the IFN signature is present.***

Biological Processes		
Term	**Gene Count**	***p*-value**
Defense Response to Virus	21	1,6E-33
Response to Virus	15	3,4E-25
Negative Regulation of the Viral Genome	11	1,7E-20

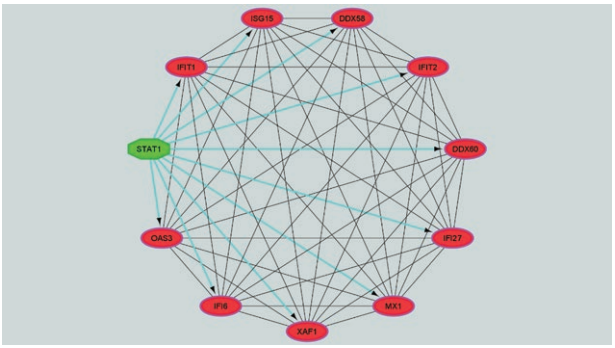

Figure 1. *DEGs with the strongest interactions in patients with LN, in which the IFN signature is present.*

Conclusion: We aimed to identify and assess DEGs of patients with LN and recognize the ones with the strongest interactions. Our results suggest that type I IFN is crucial on the pathophysiology of LN, and STAT1 can serve as a possible therapeutic target for treating LN. We propose further *in vivo* studies to validate these results, given that they can serve as diagnostic biomarkers and even possible therapeutic targets for LN treatment.

POS1515 PREVALENCE AND CLINICAL FEATURES OF LATE AND VERY LATE ONSET SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Outcome measures

I. A. Gennaio[1], M. Zen[1], E. Fuzzi[1], M. Gatto[1], M. Larosa[1], L. Iaccarino[1], A. Doria[1]. [1]*University of Padua, Department of Medicine, DIMED, Padua, Italy*

Background: Whether late-onset (LO) SLE is associated with a different, more benign disease course and better prognosis than early-onset SLE is still contradictory.[1-3]
Objectives: To describe the prevalence and clinical features of LO-SLE and very late onset (VLO) SLE and to compare their outcomes with those of non-LO SLE.
Methods: We performed a retrospective study using prospectively collected data from our cohort involving 516 patients with SLE (ACR criteria) followed between 2008 and 2022. Patients older than 50 or older than 60 years at SLE onset were defined as LO-SLE and VLO-SLE, respectively. Demographic data, and clinical and treatment history were retrieved from clinical charts. SLEDAI-2K, daily prednisone dose, SLICC Damage Index (SDI), and low disease activity (according to LLDAS definition) [1] at last follow-up in 2022 were assessed. Early mortality, within 10 years after diagnosis, was assessed in patients diagnosed in the last 15 years.
Results: Among 516 SLE patients regularly followed, 38 (7.4%) were LO-SLE: mean±SD age at diagnosis 56.5 ±5.7 years (range 50-72), females 78%. Of them, 10 (2% of the overall cohort) were VLO-SLE: mean±SD age at diagnosis 65 ±4.0 years (range 60-72), females 60%. Compared to early-SLE patients, LO-SLE patients had more frequently skin involvement and positive antiSSA/SSB antibodies (Table 1). Compared to non-LO-SLE, no difference in life-threatening manifestations was observed, including renal and neuropsychiatric involvement. The same trend was found in VLO-SLE. Accordingly, the use of immunosuppressants (including types of drugs) and biologics was similar (Table 1). At last follow-up, SLEDAI-2K was lower in LO-SLE patients (1±2 vs. 2±3, p=0.01), whereas the proportion of patients on glucocorticoids (21% vs 37%) and in LLDAS (84% vs 74%) was similar to that observed in non-LO-SLE. Despite that, SDI was higher in LO-SLE (2, range 0-8) than in non-LO-SLE patients (1, range 0-10, p=0.004) but after excluding items possibly related to aging (cataract, osteoporosis, low GFR, malignancy) the difference was not significant anymore. Among 165 patients diagnosed in the last 15 years, mortality was similar in LO and early-onset SLE, although deaths within 10 years after diagnosis (2 cases) all occurred in early-SLE patients.

Conclusion: According to our data, LO- and VLO-SLE are uncommon and seem not to be associated with more benign disease outcomes. Since life-threatening manifestations can occur in LO-SLE, these patients deserve regular follow-up.

POS1516 CHARACTERISATION OF AN ANA-ARTHRITIS BASKET POPULATION FOR CLINICAL TRIALS

Keywords: Undifferentiated connective tissue disease, Systemic lupus erythematosus, Sjögren syndrome

J. Arnold[1,2], L. M. Carter[1,2], M. Y. MD Yusof[1,2], S. U. Hassan[1,2], K. Dutton[1,2], Z. Wigston[1,2], S. Dass[1,2], E. Vital[1,2]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]Leeds Teaching Hospitals NHS Trust, NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom*

Background: Musculoskeletal (MSK) manifestations are common in systemic lupus erythematosus (SLE) and other ANA-associated rheumatic musculoskeletal diseases (ARMDs). Presently clinical trials recruit patients from individual diagnoses; consequently, recruitment is often difficult, effect sizes using multi-organ outcome measures are small and licensed therapies are only available to patients with SLE. Basket trials that pool patients with similar clinical or immunological features from many conventional legacy diagnoses may improve trial outcomes and access to therapy.

OBJECTIVES:

1. To characterise a pooled population of patients with MSK manifestations associated with any of multiple ANA-RMDs
2. To assess the homogeneity of this population in terms of disease activity, patient reported outcomes, quality of life, therapeutics, and immune biomarkers
3. To explore the validity of MSK-BILAG across ANA-RMDs

Methods: Participants were ANA+, met criteria for an ARMD (SLE, pSS, IIM, SSc, MCTD), or had a consultant diagnosis of undifferentiated CTD. Patients with MSK manifestations were identified by MSK items of validated instruments and medical history terms. We collected patient and physician-reported outcomes, SLE gene expression signatures, and flow cytometry for major cell subsets. The pooled ARMD population was compared to healthy controls using t-tests. Variables were compared across ARMDs using ANOVA and χ^2 tests. Physician VAS was compared between MSK-BILAG grades for all diseases.

Results: Of 294 ANA-RMD patients 215 with MSK manifestations were analysed. Key clinical variables are shown in Table 1. We found no difference between ARMDs for IFN, plasmablast, neutrophil, myeloid, inflammation and erythropoiesis scores, nor for naïve, memory B cells, plasmablasts, T cells, monocytes, NK or NKT cells in flow cytometry. Physician VAS was strongly associated with BILAG grade across all ARMDs.

*Or n(%) where indicated

Conclusion: MSK manifestations have similar clinical impact and immune profile across ARMDs. Current therapies used are similar. ANA-arthritis is therefore a homogenous and impactful population for basket trials.

POS1517 MICROANGIOPATHY, INDEPENDENT RISK FACTOR FOR DAMAGE ACCRUAL IN ANTIPHOSPHOLIPID SYNDROME: A RETROSPECTIVE MULTI-CENTER STUDY

Keywords: Organ damage, Anti-phospholipid syndrome

A. Hoxha[1], G. Carli[2], A. Calligaro[3], T. Del Ross[3], M. Favaro[3], M. Tonello[3], A. Tosetto[4], A. Doria[5], P. Simioni[1]. *[1]General Internal Medicine and Thrombotic and Hemorrhagic Unit, University of Padua, Italy, Padua, Italy*; *[2]Hematology Department, San Bortolo Hospital, Vicenza, Italy, Vicenza, Italy*; *[3]Rheumatology Unit, Department of Medicine, University of Padua, Padua, Italy, Padua, Italy*; *[4]Hematology Department, San Bortolo Hospital, Vicenza, Italy, Vicenza, Italy*; *[5]Rheumatology Unit, Department of Medicine, University of Padua, Padua, Italy, Padua, Italy*

Background: Antiphospholipid syndrome is characterized from venous, arterial and small vessels thromboembolic events leading to significant morbidity and mortality despite current treatments. Albeit, the acute diseases manifestations of antiphospholipid syndrome are well known, data on damage accrual are still lacking.

Objectives: To assess the frequency of accrual damage in antiphospholipid syndrome (APS) and to evaluate the association with different laboratory and clinical APS subsets.
Methods: Medical records of 274 patients, 231 (84.3%) female and 43 (15.7%) males with a mean (±SD) age at diagnosis of 37.8 (±11.5) years, followed prospectively from 1990 to 2021, were reviewed.
Results: Ninety-six (35%) presented pregnancy morbidity alone, 140 (51.1%) thrombosis alone and 38 (13.9%) both thrombosis and pregnancy morbidity. A single, double or triple antiphospholipid antibodies (aPL) positivity was registered, respectively in, 82 (29.9%), 78 (28.5%) and 114 (41.6%) of the patients. Following a mean (±SD) follow up of 208.4 (±91.7) months, a total of 58 (21.2%) organ damage accrual was recorded. This included neurological damage in 19 (32.8%) patients, hemiparesis in 9, epilepsy in 7 and cognitive dysfunction/dementia in three cases, cardiac valvopathy in 4 (6.9 %) patients of which 3/4 (75%) require valve replacement with mechanical valve in two cases and bioprosthetic in one. Chronic heart failure was found in 4 (6.9%) patients, chronic renal failure in 15 (25.9%), amputation due to peripheral arterial thrombosis in 5 (8.6%), visual loss in 2 (3.4%), post thrombotic syndrome in 6 (10.3%), adrenal insufficiency in one (1.7%). Some of the patients present more than one organ disfunction. Both thrombotic and thrombotic and pregnancy morbidity subsets were significantly associated with a higher rate of damage accrual compared with pregnancy morbidity alone, respectively p<0.0001 (OD 40.7; 95% CI: 6.9-418.8) and p<0.0001 (OD 61.9; 95% CI 10.5-659.7). Moreover, the presence of microangiopathy as well as the presence of both venous and arterial thrombosis were significantly associated with damage accrual, respectively (p<0.0001, OD 10.99; 95% CI 5.7-21-36) and (p=0.001). Regarding laboratory subsets, triple aPL positivity was significantly associated with a higher rate of damage accrual compared to single and double aPL, respectively, p<0.0001 (OD 9.6; 95% CI: 3.7-23.5) and p<0.0001 (OD 4.8; 95% CI: 2.2-10.81). At the multivariate analysis only microangiopathy was an independent risk factor for damage accrual (p=0.001).
Conclusion: Overall, our data show a higher frequency of damage accrual in APS patients. Microangiopathy was independent risk factor for damage accrual. These findings should be in mind when counselling APS patients and might help guide clinicians in therapeutic decision.

POS1518 PULMONARY INVOLVEMENT IN LUPUS IS ASSOCIATED WITH ENHANCED MORBIDITY: A MULTICENTRE STUDY

Keywords: Lungs, Systemic lupus erythematosus, Autoantibodies

M. Gerosa[1,2], G. A. Ramirez[3], L. M. Argolini[1], I. Scotti[1], C. Artusi[1], L. Moroni[3], E. Bozzolo[3], M. R. Pellico[2], L. Cavallo[3,3], L. Dagna[3], R. Caporali[1,2]. *[1]ASST Gaetano Pini-CTO, Lupus Clinic, Department of Clinical Rheumatology, Milan, Italy*; *[2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy*; *[3]IRCCS Ospedale San Raffaele, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milan, Italy*

Background: Although several studies report a high incidence of pulmonary manifestations in SLE, lung involvement is often underestimated in SLE clinical assessment [1]. This is also mirrored by the absence of pulmonary manifestations other than pleurisy in the old and new classification criteria for SLE [2]. Moreover, limited evidence on the management of SLE-related pulmonary manifestations is available.
Objectives: To assess prevalence and clinical impact of the spectrum of SLE-related pulmonary manifestations and their association with patient autoantibody profiles in a large SLE cohort and to describe the effectiveness of different therapeutic approaches in distinct clinical settings.
Methods: Patients followed at the Lupus Clinics of ASST G. Pini-CTO and San Raffaele Hospital (Milan, Italy) were enrolled. Data regarding demographics, disease characteristics, autoantibody profile, pulmonary manifestations, damage accrual and treatment were collected. The following types of lung involvement were recorded: pleurisy, acute lupus pneumonitis, interstitial lung disease (ILD), alveolar haemorrhage, pulmonary embolism, arterial pulmonary hypertension and shrinking lung syndrome.
Results: Of the 471 SLE patients enrolled, we identified 78 patients (16.5%) displaying at least one pulmonary manifestation. Epidemiological data on each manifestation are reported in Table 1. Pleurisy was the most common pulmonary manifestations and manifested at disease onset in most cases (56%). Patient home environment (urban vs countryside) did not seem to impact the risk of developing lung disease. Damage accrual was relevant, as 2/3 of patients displayed at least 1 point increase in SLICC Damage Index (SDI) after the onset of lung involvement in comparison to baseline. All patients received at least one steroid course. Immunosuppressive treatment choices and efficacy differed among distinct manifestations: only half of the patients with pleurisy received immunosuppression, mainly azathioprine, with 100% of improvement, while 80% of cases of ILD received immunosuppression, predominantly mycophenolate, with a 50% risk of non-response. By comparing demographics and clinical characteristics among cases and controls, we found a significantly lower median age at disease onset (p=0.002) and a higher frequency of male sex (18% vs 9%; p=0.07), joint involvement (p=0.02) and constitutional symptoms (p=0.02) in patients with lung involvement, while no differences were observed in the autoantibody profile, including anti-dsDNA and anti-ENA autoantibodies.
Conclusion: Our study confirms that, in addition to the known epidemiological burden of pleurisy, other types of pulmonary involvement can complicate the disease course and contribute to damage accrual. In particular, ILD can frequently occur and respond to immunosuppressants in only half cases. Consistent with the association of lung involvement with increased morbidity, higher-risk categories for severe disease such as males and subjects with early-onset SLE were more represented among patients with pulmonary manifestations.

Background: Clinically evident kidney disease eventually occurs in up to one-half of SLE patients.

Objectives: To describe sociodemographic, clinical, serological and treatment characteristics of a multicenter and multiethnic Latin American SLE cohort of patients with or without lupus nephritis (LN)

Methods: GLADEL2.0 is an ongoing observational cohort. Patients were categorized according to renal involvement: Group I (LN never); II (prevalent renal involvement currently inactive); III (prevalent renal involvement, currently active) and IV (incident renal involvement). Demographic, clinical manifestations, treatments, disease activity were examined at baseline. A descriptive cross-sectional analysis was performed.

Results: A total of 991 SLE patients were included, 884 (89.2%) female and 656 (68.3%) Mestizos (Amerindian and European ancestry). Median (IQR) age at cohort entry was 35 (28-45) years and disease duration were 67 months (18-139). Patients with incident LN had a higher proportion of males, were younger, had shorter disease duration and were more frequently Mestizos. Pericarditis and anti-dsDNA were less frequent in group I and MMF in groups I and IV (Table 1). A predominance of class IV (49%) was evidenced in 510 patients in which a kidney biopsy was performed.

Conclusion: Baseline characteristics of GLADEL2.0 well characterized lupus patients' cohort with or without LN are described with distinct demographic, clinical and laboratory patterns that will allow both centralized laboratory evaluation of urinary biomarkers and exploratory biomarker analyses including transcriptome and their impact on the outcome of these patients.

Background: The Systemic Lupus Erythematosus Disease Activity Score (SLE-DAS) has been recently developed and validated, providing improved accuracy and sensitivity for changes in SLE disease activity in comparison to SLE Disease Activity Index 2000 (SLEDAI-2K) [1]. New recommendations to standardize the Physician Global Assessment (PGA) scoring may improve its reliability [2].

Objectives: To assess the intra- and interrater reliability of SLE-DAS, SLE-DAI-2K and PGA for measuring SLE disease activity.

Methods: A set of 24 clinical vignettes were abstracted, each from a real clinical visit of patients followed at an academic lupus clinic. These vignettes were selected to include a wide spectrum of SLE manifestations, organ-system involvements, and global severity of disease activity. Abstracted data were presented in a standardized format, including demographic, past medical history, current clinical picture and treatment, laboratory, and other workup assessments. A group of 19 raters were recruited as a random multicenter sample of Rheumatologists. All raters completed a preliminary training session on scoring rules for SLE-DAS, SLEDAI-2K and PGA. Each rater scored each clinical vignette with SLE-DAS, SLEDAI-2K, and PGA through an online survey. The scoring was repeated in a second round 7-14 days after the first one. The clinical vignettes were randomly ordered for each round. Inter and intra-rater reliability of each instrument was estimated using the intraclass correlation coefficient (ICC) with 95% confidence intervals (95%CI), based on single-measurement, absolute agreement, with a two-way random effect or two-way mixed-effects model, respectively.

Results: The 19 raters included 8 rheumatologists and 11 rheumatology trainees from 11 hospitals, with a mean of 12.1±7.1 and 3.6±0.5 years of rheumatology practice, respectively, and 78.9% of the participants assess ≤5 SLE patients per week in their regular clinical practice. The 24 clinical vignettes included 83.3% female patients, with a mean of 36.5±17.9 years of age. Active SLE organ involvement included: skin rashes (20.8%); arthritis (12.5%); nephritis (12.5%); thrombocytopenia (12.5%); cardiac/pulmonary involvement (12.5%); mucocutaneous vasculitis (8.3%); serositis (8.3%); neuropsychiatric lupus (8.3%). Systemic vasculitis, myositis, alopecia, hemolytic anemia, and leukopenia were each present in 4.2% of the vignettes. Hypocomplementemia and/or high anti-dsDNA were present in 75.0%. Twenty-one percent of the cases were in remission. All raters completed the survey, totaling 912 case assessments. Scores attributed by the raters ranged from 0.37 to 49.53 in SLE-DAS, 0 to 24 in SLEDAI-2K, and 0.0 to 3.0 in PGA. The interrater reliability was good for SLE-DAS and SLEDAI-2K, and moderate for PGA. The intra-rater reliability was excellent for SLE-DAS, and good for SLEDAI-2K and PGA (Table 1).

Table 1: Interrater and intra-rater reliability of SLE-DAS, SLEDAI-2K and PGA.

	ICC (95%CI)	
	Interrater reliability	**Intra-rater reliability**
SLE-DAS	0.877 (0.807-0.934)	0.908 (0.891-0.923)
SLEDAI-2K	0.812 (0.717-0.896)	0.892 (0.871-0.909)
PGA	0.704 (0.578-0.828)	0.900 (0.881-0.916)

CI: confidence interval; ICC: intraclass correlation coefficient.

Conclusion: SLE-DAS presents high intra- and interrater reliability for measuring SLE disease activity. The high reliability of SLE-DAS is an important quality both in clinical practice and research, allowing consistent scoring among different clinicians including those who are not SLE experts.

Psoriatic arthritis - treatment

POS1521 CHARACTERISTICS OF DIFFICULT TO TREAT PSORIATIC ARTHRITIS: A COMPARATIVE ANALYSIS

Keywords: Psoriatic arthritis, bDMARD

C. Philippoteaux[1], A. Marty-Ane[1], C. Martin[2], P. Philippe[1], J. Paccou[1], B. Cortet[1], R. M. Flipo[1], J. G. Letarouilly[1]. *[1]Lille University Hospital, Rheumatology, Lille, France*; *[2]Lille University Hospital, Statistics, Economic Evaluation, Data-management Unit, Lille, France*

Background: The concept of difficult-to-treat rheumatoid arthritis (D2T RA) has recently emerged. It is defined by the persistence of disease activity and the failure of at least 2 b/tsDMARDs of 2 different mechanisms of action (MoA) [1]. In this definition, the period of time during which the treatments have failed is not included. The D2T concept has not yet been applied with consensus in psoriatic arthritis (PsA).
Objectives: To study the characteristics of patients with D2T PsA to better identify the potential causes of treatment failure. The 2nd objective was to study a sub-group of D2T PsA patients with a predefined time criteria.
Methods: A monocentric retrospective longitudinal study was performed in a tertiary center. PsA diagnosis was based on CASPAR criteria. Patients were followed up from February 2004 to August 2022. Patients starting a b/tsDMARDs with a minimum of 2-year follow-up were included. D2T PsA patients were defined as patients who received more than 2 b/tsDMARDs with different MoA among b/tsDMARD available. These patients were compared to non-D2T PsA patients (nD2T PsA) using statistical tests. Very D2T PsA patients were defined as patients who received at least 2 b/tsDMARDs in less than 2 years during the time of follow-up.
Results: 150 patients were included, 49 were D2T PsA and 101 nD2T PsA. Baseline characteristics are presented in the Table 1. No statistical difference was found between the 2 groups regarding main comorbidities, including fibromyalgia and depression. In the D2T PsA group, 91.7% and 69.1% of patients received an anti-TNF alpha as the 1st and 2nd lines of treatment; anti-IL17 drugs represented 0% and 12.2% of 1st and 2nd lines; anti-IL12-23 represented 8% and 18.4% of prescriptions in 1st and 2nd lines. After 3 lines, 38.8% of patients had received 3 bDMARDs with different MoA, 30.6 % received 2 bDMARDs with different MoA. 17 patients were categorized as very D2T PsA. When compared to the rest of the D2T PsA group, no significant difference was observed. Proportion of men was 64.7% (p=0.39). Mean age was 55.0 ± 8.3 yo (p=0.67) and mean BMI was 30.4 ± 6.5 kg/m^2 (p=0.65).

Table 1. Baseline characteristics of patients

Parameters	N	D2T PsA n = 49	N	nD2T PsA n = 101	p value
Men	49	29 (59.2)	101	52 (51.5)	0.37
Age (years), mean ± SD	49	54.2 ± 11.9	101	53.7 ± 14.2	0.82
BMI, mean ± SD	46	29.6 ± 7.2	96	27.7 ± 5.7	0.093
PsA duration (years), median (IQR)	49	17.0 (8.0 to 20.0)	99	11.0 (6.0 to 21.0)	0.22
Current smoker status	49	16 (32.7)	101	33 (32.7)	1.00
Clinical PsA characteristics at baseline					
Axial involvement	48	21 (43.8)	100	26 (26.0)	**0.030**
Peripheral involvement	49	49 (100)	101	99 (98)	NA
Monoarthritic	48	3 (6.3)	101	11 (10.9)	-
Oligoarthritic	48	22 (45.8)	101	51 (50.5)	-
Polyarthritic	48	23 (47.9)	101	37 (36.6)	-
Dactylitis	45	10 (22.2)	101	32 (31.7)	0.24
Psoriasis at baseline	49	6 (12.2)	101	12 (11.9)	0.95
Structural damage at baseline (axial and peripheral)	42	32 (76.2)	96	49 (51.0)	**0.006**
IBD	49	0 (0.0)	101	3 (3.0)	NA
Baseline CRP (mg/L), median (IQR)	40	13.6 (6.0 to 31.5)	86	8.1 (3.0 to 20.0)	0.11
BASDAI Baseline, mean ± SD	8	65.1 ± 16.6	22	58.5 ± 11.7	0.23
bDMARD discontinuation due to poor dermatological control	47	19 (40.4)	101	19 (18.8)	**0.005**

Values are expressed as number (%) unless otherwise stated. BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; bDMARD: biological disease modifying antirheumatic drug; BMI: body mass index; CRP: C-reactive protein; (n)D2T: (non) difficult-to-treat; HLA: human leukocyte antigen IBD: inflammatory bowel disease; IQR: interquartile range; N: number of available observations; NA: not applicable; PsA: psoriatic arthritis; SD: standard deviation.

Conclusion: Significant differences were found between the characteristics of patients D2T PsA and nD2T PsA, which were the presence of axial manifestation, structural damage at baseline and discontinuation due to poor dermatological control. Limitations exist about applying the EULAR D2T RA definition to PsA. The inclusion of a time period should also be considered.

Background: The IL-23p19 inhibitor guselkumab (GUS) has shown robust efficacy vs placebo (PBO) in phase 3 DISCOVER-1 and -2 studies of adults with active psoriatic arthritis (PsA) [1,2], with continuous overall clinical improvement observed through 2 years of DISCOVER-2 [3]. GUS has previously been shown to significantly reduce levels of inflammatory biomarkers associated with PsA over 24 weeks [4].
Objectives: To assess whether earlier changes (by Week [W] 24) in serum biomarker levels associate with long-term (W100) clinical response to GUS.
Methods: DISCOVER-2 enrolled biologic-naïve adults with active PsA ≥6 months defined by the CASPAR criteria, swollen and tender joint counts ≥5, and C-reactive protein (CRP) ≥0.6 mg/dL. Patients (pts) were randomized 1:1:1 to GUS 100mg at W0, W4, then every 4 weeks (Q4W); GUS at W0, W4, then Q8W; or PBO [2]. Using Spearman linear regression and General linear model, serum cytokine levels determined in GUS-treated pts (pooled Q4W/Q8W) were assessed for: 1) correlations between reductions in cytokine levels, including selected Th17 cytokines (IL-17A, IL-17F, IL-22), acute phase cytokines (CRP, serum amyloid protein A [SAA], IL-6), and β-defensin 2 (BD-2), from baseline (BL) at W24 and in PsA disease severity from BL at W100, measured by changes in Disease Activity in PSoriatic Arthritis (DAPSA) scores, Psoriatic Arthritis Disease Activity Score (PASDAS), and Psoriasis Area and Severity Index (PASI) scores (significant correlation=r>0.25 and p<0.05); and 2) associations between changes in selected cytokine levels from BL through W24 and achievement of ACR50 response at W100.
Results: BL demographics, disease severity, and medication use of GUS-treated DISCOVER-2 pts with available biomarker data (N=100) were consistent with the overall GUS-treated DISCOVER-2 population (N=493). With GUS treatment, PASI score change from BL at W100 correlated with changes from BL at W24 in serum BD-2, IL-17A, IL-17F, and IL-22 levels (all r>0.25, p<0.05; **Table 1**), though PASDAS and DAPSA score change at W100 did not correlate with changes in these biomarkers at W24. DAPSA score change at W100 correlated with changes at W24 in serum IL-6. W100 ACR50 responders (N=53) to GUS also demonstrated significantly lower serum CRP, SAA, and IL-6 levels at W24 than nonresponders (N=39) (p<0.05; **Figure 1**).
Conclusion: This analysis reported correlations between earlier changes in Th17 cytokine levels and long-term reductions in PASI scores, and associations between earlier changes in acute phase cytokine levels and long-term ACR50 response with GUS. The substantial reductions in these cytokines from BL at W24 may portend durable improvements in skin and joint symptoms of PsA.

POS1523

EFFICACY OF SECUKINUMAB ON INDIVIDUAL DOMAINS OF PSORIATIC ARTHRITIS: EXPERIENCE FROM ROUTINE CLINICAL PRACTICE IN THE CZECH NATIONAL REGISTRY ATTRA

Keywords: Registries, bDMARD, Psoriatic arthritis

K. Pavelka[1], L. Klementová[2], J. Baranová[2], J. Zavada[1], T. Philipp[3], Š. Tichý[1], H. Mann[1]. [1]*Institute of Rheumatology, n/a, Prague, Czech Republic*; [2]*Institute of Biostatistics and Analysis, n/a, Brno, Czech Republic*; [3]*3rd Faculty of Medicine Charles University, Rheumatology, Prague, Czech Republic*

Background: Psoriatic arthritis (PsA) is a heterogeneous disease with a number of skeletal and extraskeletal manifestations. It is desirable that DMARDs affect the maximum number of domains of PsA manifestations. Only limited data regarding the impact of bDMARD treatment on individual domains in routine clinical practice is available.

Objectives: The aim of the study is to assess how the IL-17A inhibitor secukinumab affects the individual domains of PsA in the routine clinical practice using data from the ATTRA national registry in the Czech Republic.

Methods: ATTRA is a prospective registry of patients receiving bDMARD therapy for rheumatic diseases collecting data on efficacy, safety and quality of life of all patients treated in the Czech Republic. Adult patients with psoriatic arthritis treated with secukinumab were included in the analysis. The monitored indicators were survival on therapy, DAS 28 ESR, response to treatment according to EULAR, HAQ, EuroQol, physician-assessed psoriasis, dactylitis, enthesitis, nail involvement, physical function and ability to work. Patients were described at the beginning of secukinumab treatment and after 3, 6, 12, 18, and 24 months through absolute and relative frequencies in categorical variables and means with standard deviations (SD) and medians with 5th and 95th percentiles when describing continuous variables. Survival on therapy was computed through the Kaplan-Meier method. Statistical analyses were conducted using IBM SPSS Statistics (version 25.0).

Results: A total of 426 patients were included in the study, of which 237 were women and 189 were men. The average age at the start of treatment was 51 ± 12 years, duration of the disease 10 ± 8 years. About 40% of patients were bDMARD naïve, 60% had failed 1 or more bDMARDs. At the start of secukinumab treatment, 66.4% were on concomitant csDMARD therapy, with 47% receiving methotrexate (MTX) in monotherapy or in combination with other csDMARDs. Survival on therapy was 79.1% (95% CI: 75.0; 83.3) at 1 year, 69.6% (95% CI: 64.6; 74.6) at 2 years, and 53.6% (95% CI: 44.8; 62.5) at 5 years of treatment. The reason for treatment discontinuation was primary non-response (30.6%), secondary non-response (47.6%) and adverse effects (6.5%). Mean DAS 28 had decreased from initial 5.0 ± 1.3 to 2.5 ± 1.1 after 2 years of treatment. Remission (DAS 28 < 2.6) was achieved by 54.1% and low disease activity (DAS 28 ≤ 3.2) was achieved by 74.8% of patients still on secukinumab (Figure 1). There was also a significant improvement in the assessment of physical function and quality of life (HAQ, SF 36, EuroQol). The prevalence of heel enthesitis decreased from 12.2% to 1.5%, prevalence of dactylitis from 22% to 4.7%, and prevalence of moderate to severe nail involvement from 33.2% to 3.8% during the first 2 years of treatment. 43.8% (95% CI: 32.2; 55.4) were able to resume work and 13.9% (95% CI: 8.7; 19.0) of PsA patients lost their jobs during the first two years of treatment. The overall safety of the treatment was good with no unexpected serious side effects.

Figure: Achieving remission and a state of low disease activity with secukinumab in the treatment of PsA in the Czech national registry ATTRA

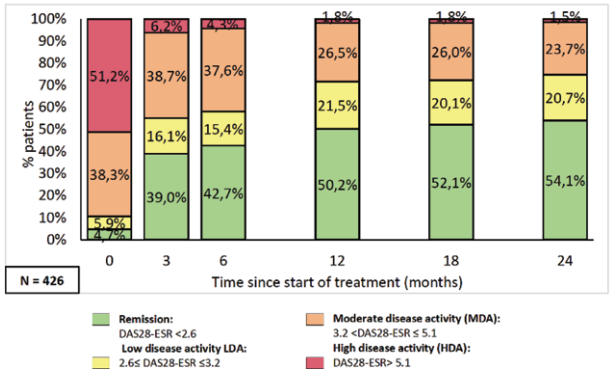

Figure 1. Achieving remission and a state of low disease activity with secukinumab in the treatment of PsA in the Czech national registry ATTRA

Conclusion: This analysis of patients in a national registry demonstrated a robust and long-term effect of secukinumab in the treatment of individual PsA domains: arthritis, dactylitis, enthesitis, nail involvement, psoriasis, quality of life and in increasing work capacity in patients with PsA.

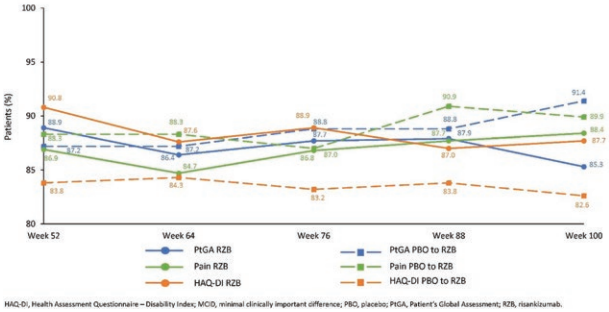
Ostor[4]. *[1]Copenhagen University Hospital,The Parker Institute, Copenhagen, Denmark*; *[2]AbbVie Inc, n/a, North Chicago, United States of America*; *[3]Probity Medical Research, Alliance Clinical Research, Waterloo, Canada*; *[4]Cabrini Hospital, Monash University and Emeritus Research, Canberra, Australia*

Background: Risankizumab (RZB) demonstrated efficacy and safety in the treatment of psoriatic arthritis (PsA) in phase 3 trials KEEPsAKE-1 (NCT03675308), patients with an inadequate response to disease-modifying antirheumatic drugs (DMARD-IR), and KEEPsAKE-2 (NCT03671148), DMARD-IR and inadequate responders to biologics.



Objectives: This analysis aims to assess the durability of the RZB treatment response on health-related quality of life (HRQoL) and patient-reported outcomes (PROs) in patients with PsA at Week 100.

Methods: In the KEEPsAKE 1 and 2 trials, patients were randomised 1:1 to receive RZB 150 mg or PBO in the 24-week double-blind period. During the open-label maintenance period, all patients received RZB 150 mg. This analysis evaluated observed cases of RZB-treated patients who achieved minimal clinically important differences (MCIDs) in PROs at Week 24. Results are presented as the percentage of patients, of those who achieved MCIDs at Week 24, who maintained MCIDs in PROs from Week 52 to Week 100. MCIDs included a ≥10-point decrease in Patient's Global Assessment (PtGA), ≥10-point decrease in Pain, ≥0.35-point decrease in Health Assessment Questionnaire – Disability Index (HAQ-DI), ≥4-point decrease in Functional Assessment of Chronic Illness Therapy (FACIT) – Fatigue, ≥2.5-point increase in 36-Item Short Form Survey (SF-36) physical component summary (PCS), ≥1.1-point decrease in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), ≥1-point decrease in morning stiffness, and ≥20% reduction in Work Productivity and Activity Impairment Questionnaire (WPAI) Presenteeism, ≥15% in Work Productivity Loss, and ≥20% in Activity Impairment.

Results: In KEEPsAKE 1, 54–68% and 31–52% of RZB-treated patients and PBO to RZB patients achieved MCIDs across PROs at Week 24, respectively. In KEEPsAKE 2, 44–67% and 33–47% of RZB-treated patients and PBO to RZB patients achieved MCIDs across PROs at Week 24, respectively. Among the patients who achieved MCIDs at Week 24 in KEEPsAKE 1, a high percentage of RZB and PBO to RZB-treated patients maintained MCIDs from Week 52 to 100 in PtGA (RZB: 85.3–88.9%; PBO to RZB: 87.2–91.4%), Pain (RZB: 84.7–88.4%; PBO to RZB: 87.0–90.9%), and HAQ-DI (RZB: 87.0–90.8%; PBO to RZB: 82.6–84.3%) (**Figure 1**). In KEEPsAKE 2, similarly high percentages of RZB and PBO to RZB-treated patients maintained MCIDs in PtGA (RZB: 77.0–80.5%; PBO to RZB: 78.4–84.0%), Pain (RZB: 77.2–85.6%; PBO to RZB: 84.3–94.2%), and HAQ-DI (RZB: 74.0–83.8%; PBO to RZB: 89.6–95.8%). At Week 100, 77.6–88.9% and 73.5–95.5% of RZB and PBO to RZB-treated patients, respectively, in KEEPsAKE 1 maintained MCIDs in FACIT-Fatigue, SF-36 PCS, BASDAI, morning stiffness, and WPAI; similar results were demonstrated in KEEPsAKE 2 (RZB: 73.1–96.4%; PBO to RZB: 76.2–100.0%) (**Table 1**).

Conclusion: In KEEPsAKE 1 and 2 trials, the majority of RZB-treated patients with PsA who achieved MCID in PROs at Week 24 maintained responses through Week 100. Achieving MCIDs at Week 24 is associated with sustained and clinically meaningful changes in HRQoL.

Figure 1. Percentage of patients who maintained MCIDs through Week 100 in patients who achieved MCIDs at Week 24 in PtGA, Pain, and HAQ-DI in KEEPsAKE 1

HAQ-DI, Health Assessment Questionnaire – Disability Index; MCID, minimal clinically important difference; PBO, placebo; PtGA, Patient's Global Assessment; RZB, risankizumab.

BIOLOGICS THERAPIES FOR PSORIASIS AND PSORIASIS ARTHRITIS AFFECT ON FUTURE RISK FOR DEVELOPING MAJOR ADVERSE CARDIOVASCULAR EVENTS

Keywords: Cardiovascular disease, bDMARD, Psoriatic arthritis

A. Dotan[1], N. Ben-Shabat[1], D. Mcgonagle[2], A. Watad[1], H. Amital[1]. *[1]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center,Tel-Hashomer, Israel, Sackler Faculty of Medicine,Tel-Aviv University,Tel-Aviv, Israel, Department of Medicine 'B', Ramat-Gan, Israel*; *[2]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Major adverse cardiovascular events (MACE) are some of the numerous comorbidities associated with psoriasis (PsO) and psoriasis arthritis (PsA). Previous studies addressed the contribution of sufficient anti-inflammatory therapy for PsO and PsA in decreasing MACE incidence [1,2].
Objectives: Assessing the risk of developing MACE in patients with pre-existing PsO treated with different treatment regimens; topical treatment, conventional disease-modifying anti-rheumatic drugs (cDMARDs), and biologic disease-modifying anti-rheumatic drugs (bDMARDs) which had not previously studies sufficiently on real-world data.
Methods: We conducted a retrospective exploratory study with real-world data using the databases of the third largest Israeli health maintenance organization, 'Meuhedet' which covers approximately 1,300,000 subjects. All patients of 'Muehedat' diagnosed with PsO from January 2000 until January 2020 were included in the analysis. Overall, 61,003 patients with PsO were detected. In addition, each PsO patient was paired with four control subjects by gender, age, and ethnicity (general, Arabic, or Orthodox). We defined PsO and PsA according to physicians' diagnoses. MACE included patients with either cerebral vascular accident (CVA), ischemic heart disease (IHD), or peripheral artery disease (PVD). The date of the MACE incident was defined by the first occurrence of one of the diagnoses. We classified the patients diagnosed with PsA into a separate group; thus, patients were categorized according to their diagnosis (control, PsO or PsA). Furthermore, we analyzed the patients by the most advanced treatment prescribed to the patient; sub-grouped 1- topical therapy, sub-grouped 2 - cDMARDs (methotrexate or sulfasalazine), sub-grouped 3 - bDMARDs (anti-TNF, anti-IL17, or anti-IL12/23 agents) (**Table 1**). The Incident cases of MACE were analyzed according to the different lines of therapy mentioned above. In addition, Time-dependent Cox proportional hazard models were used to evaluate the adjusted risk of developing MACE by treatment group.
Results: 287,392 patients were included after exclusion by the defined criteria, contributing a total of 2,997,001 patient-years. Adjusted Cox proportional hazards regression analysis showed that the risk of developing MACE in PsO patients treated with topical treatment and those treated with cDMARDs was significantly higher in comparison to controls (Topical, HR: 1.1, CI: 1.02 - 1.1, p-value: <0.001; cDMARDs, HR: 1.2, CI: 1.0 - 1.5, p-value: 0.05). Yet, the risk of developing MACE in PsO patients treated with bDMARDs was not significantly different compared to controls (HR: 1.1, CI: 0.82 - 1.5, p-value: 0.55). On the contrary, the risk of developing MACE in all treatment groups of PsA patients was found to be significantly higher in comparison to controls (Topical, HR: 1.6, CI: 1.45 - 1.7, p-value: <0.001; cDMARDs, HR: 1.4, CI: 1.2 - 1.6, p-value: <0.001, bDMARDs, HR: 1.6, CI: 1.35 - 1.8, p-value: <0.001) (**Figure 1**). This analysis was adjusted to gender, body mass index (BMI), age of PsO diagnosis, lifetime diagnosis of diabetes mellitus type 2 (DM2), dyslipidemia, hypertension (HTN), and chronic heart failure (CHF); notably, male gender, higher BMI, older age, DM2, dyslipidemia, HTN, and CHF were all associated with a greater risk of developing MACE.
Conclusion: Despite that the psoriasis and arthritis severity is higher in patients treated with bDMARDs treatment compared to those treated with cDMARDs and topical treatment alone, bDMARDs have a protective effect on the risk of developing PsA.

Background: The prevalence of nail disease in patients with psoriatic arthritis (PsA) ranges between 41% and 93% [1]. Psoriatic nail disease is intimately linked to adjacent distal interphalangeal joint (DIP) disease, and it is important to ascertain whether DIP-nail complex behaves differently under different biological therapies.
Objectives: The aim of this analysis was to comparatively assess the effect of ixekizumab (IXE) and adalimumab (ADA) at the individual digit level in improving nail and joint disease, in patients with PsA and concomitant nail involvement.
Methods: This post hoc analysis included patients from SPIRIT-H2H (NCT03151551) treated with either IXE or ADA who had baseline nail disease (NAPSI total score >0) and DIP involvement in at least one simultaneous digit, with either tenderness, swelling or both, at the individual digit level for each hand. Proportions of patients having a NAPSI total score >0 and proportions of patients having DIP involvement (tenderness or swelling) were evaluated at baseline and Week 24; post-baseline assessments were compared between treatment arms using Fisher's exact test.
Results: Of the intent-to-treat population of SPIRIT-H2H (N=566), 354 patients had a NAPSI total score >0 and DIP involvement (swelling or tenderness) in at least 1 digit simultaneously at baseline (IXE, N=186 and ADA, N=168). Of these patients, significantly fewer IXE- vs. ADA-treated patients had a NAPSI total score of > 0 at Week 24 (p<0.05 for 9/10 digits; Table 1) and numerically fewer IXE- vs. ADA treated patients had DIP involvement at Week 24 across all 10 digits (p<0.05 for 4/10 digits; Table 1). Numerically fewer IXE- vs. ADA-treated patients had joint tenderness at Week 24. A similar pattern of improvement was seen out to Week 52 (Table 1).
Conclusion: In this analysis, in patients from SPIRIT-H2H with psoriatic arthritis who had nail involvement and DIP involvement at baseline, patients treated with IXE had less nail involvement, less DIP involvement and less tenderness compared to those treated with ADA at Week 24.

EFFECTS OF APREMILAST ON CHANGES IN CARDIOMETABOLIC PARAMETERS BY DIABETES AND OBESITY STATUS IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Cardiovascular disease, Comorbidities, Psoriatic arthritis

P. J. Mease[1], D. D. Gladman[2], I. B. Mcinnes[3], S. Cheng[4], S. Colgan[4], Y. Klyachkin[4], L. Teng[5], N. N. Mehta[6]. Background: The prevalence of cardiometabolic diseases including obesity and diabetes are higher in patients with psoriatic arthritis (PsA) than those without PsA. Apremilast (APR) is associated with weight loss and a reduction in HbA1c.
Objectives: To evaluate the effects of APR on cardiometabolic parameters over 52 weeks in patients with active PsA from 5 pooled phase 3 trials.
Methods: Data from 5 randomized, placebo-controlled, phase 3 studies (PALACE 1–4 and ACTIVE) in patients with active PsA receiving APR 30 mg BID were pooled. Included in this analysis were patients who were treated with APR for 52 weeks. Changes from baseline to Week 52 in low and high density lipoprotein (LDL, HDL), body mass index (BMI), and HbA1c were assessed and stratified by baseline level of these parameters and Week 52 disease activity (Clinical Disease Activity Index for Psoriatic Arthritis [cDAPSA] remission/low disease activity [REM/LDA] vs moderate/high disease activity [ModDA/HDA]).
Results: Data from 781 patients with PsA who received APR were pooled (mean age: 50 years, 55% female). Mean LDL was 119.6 mg/dL in the overall population at baseline and decreased by 2.0 mg/dL on average at Week 52 (**Figure 1**). The greatest decreases in LDL were seen in patients with the highest LDL levels at baseline (**Figure 1**). Similar favorable changes in HDL were observed. A total of 34/65 (52.3%) moved from the high LDL category (≥160 mg/dL) at baseline to borderline (>129 – <160 mg/dL) or normal (≤129 mg/dL) at Week 52 and 49/128 (38.3%) changed from borderline high to normal LDL levels (**Table 1**). Mean BMI was 30.3 kg/m^2 in the overall population at baseline and decreased by 0.5 kg/m^2 at Week 52 (**Figure 1**). A trend was again seen where patients with higher BMI at baseline saw greater decreases in BMI at Week 52 (**Figure 1**). Additionally, 24/267 (9.0%) patients changed from the obese category (≥30 kg/m^2) to the overweight category (25 – <30 kg/m^2) and 25/204 (12.3%) patients changed from the overweight category to the normal category (<25 kg/m^2) (**Table 1**). Mean HbA1c was 5.6% in the overall population at baseline and decreased by 0.1% at Week 52 (**Figure 1**). Greater changes in HbA1c were seen in patients who were pre-diabetic (HbA1c 5.7% – <6.5%) and diabetic (HbA1c ≥6.5%) at baseline vs those who had normal HbA1c (HbA1c <5.7%) (**Figure 1**). Furthermore, 60/119 (50.4%) patients who had prediabetes changed to normal HbA1c levels and 10/25 (40.0%) moved from diabetes to pre-diabetes (**Table 1**). Results were consistent across Week 52 cDAPSA psoriatic disease activity subgroups; greater changes in cardiometabolic parameters were seen in patients with higher baseline LDL, BMI, or HbA1c regardless of whether REM/LDA was achieved at Week 52.
Conclusion: APR treatment was associated with improvement in cardiometabolic parameters observed across psoriatic disease activity groups. The most favorable changes were seen in patients with high LDL, low HDL, obesity, or diabetes at baseline. These findings suggest that those with a high burden of comorbid cardiometabolic diseases and active PsA treatment may gain benefit beyond joint disease with APR. However, these findings require larger, prospective studies.

Figure. Changes in Cardiometabolic Parameters from Baseline to Week 52 by Baseline Subgroup

Includes patients who were treated with APR for 52 weeks and had both baseline and Week 52 values.

Table. LDL, BMI, and HbA1c Shift from Baseline to Week 52

	Week 52 LDL (mg/dL), n/N (%)		
Baseline LDL (mg/dL)	Normal (≤129)	Borderline (>129 – <160)	High (≥160)
Normal (≤129)	274/322 (85.1)	41/322 (12.7)	7/322 (2.2)
Borderline (>129 – <160)	49/128 (38.3)	63/128 (49.2)	16/128 (12.5)
High (≥160)	13/65 (20.0)	21/65 (32.3)	31/65 (47.7)
	Week 52 BMI (kg/m²), n/N (%)		
Baseline BMI (kg/m²)	Normal (<25)	Overweight (25 – <30)	Obese (≥30)
Normal (<25)	111/124 (89.5)	13/124 (10.5)	0/124 (0.0)
Overweight (25 – <30)	25/204 (12.3)	163/204 (79.9)	16/204 (7.8)
Obese (≥30)	0/267 (0.0)	24/267 (9.0)	243/267 (91.0)
	Week 52 HbA1c (%), n/N (%)		
Baseline HbA1c (%)	Normal (<5.7)	Pre-diabetes (5.7 – <6.5)	Diabetes (≥6.5)
Normal (<5.7)	224/231 (97.0)	6/231 (2.6)	1/231 (0.4)
Pre-diabetes (5.7 – <6.5)	60/119 (50.4)	53/119 (44.5)	6/119 (5.0)
Diabetes (≥6.5)	1/25 (4.0)	10/25 (40.0)	14/25 (56.0)

Includes patients who were treated with APR for 52 weeks.

PREDICTION OF LOW DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH SECUKINUMAB IN REAL WORLD – DATA FROM THE GERMAN AQUILA STUDY

Keywords: Artificial Intelligence, Real-world evidence, Psoriatic arthritis

A. Vodencarevic[1], J. Brandt-Juergens[2], D. Peterlik[1], B. Gmeiner[1], U. Kiltz[3]. *[1]Novartis, Novartis Pharma GmbH, Nürnberg, Germany*; *[2]Rheumatologie, Schwerpunktpraxis, Berlin, Germany*; *[3]Rheumazentrum Ruhrgebiet, Herne und Ruhr-Universität Bochum, Herne, Germany*

Background: Secukinumab (SEC) proved to be an effective treatment for patients with psoriatic arthritis (PsA) in previous randomized clinical trials [1]. There is only limited knowledge on prediction of low disease activity (LDA) and treatment strategy in PsA patients under SEC treatment in routine clinical care.
Objectives: Using real-world data from the German non-interventional study AQUILA [2], the main objectives were (1) to predict LDA in individual PsA patients treated with SEC through machine learning methods and (2) to identify the most important predictors and their influence on the prediction using explainable artificial intelligence (XAI).
Methods: Data of 1041 PsA patients from the AQUILA study were used. Thirty-three demographic, clinical and treatment parameters at baseline (BL) served as input data to develop prediction models. LDA was defined as physician global assessment (PhGA) ≤ 2 at week (w) 16 (+/- 6 w). Samples were divided into training (70%) and validation (30%) cohorts. Ten different prediction models were applied and compared. Model performance was measured using area under the receiver operating characteristic curve (AUROC) which represents the probability that a randomly selected patient with LDA will have higher prediction to achieve LDA than a patient with moderate/high disease activity. Additionally, sensitivity and specificity of the prediction model were computed and express the proportion of correctly identified patients who reach or don't reach LDA at w16, respectively. Shapley XAI estimated importance and impact of each predictor based on how it affected the change in individual prediction [3].
Results: The most influencing predictor was patient global assessment (PGA) at BL, followed by PhGA, number of pretreatments with biologics, tender joint count and age (Figure 1 A). AUROC of the best prediction model was 0.68 in validation cohort. Sensitivity and specificity were 0.62 and 0.64, respectively. Applied XAI approach showed that lower BL values of all main predictors have higher probability of reaching LDA at w16. The highest probability was evident in biologic-naive patients (Figure 1 A). The approach also provided visual explanations of patient-individual predictions: Variables with values shown in green color increased probability of reaching LDA at w16, whereas red ones showed the opposite effect (Figure 1 B).
Conclusion: A promising prediction model accuracy of LDA in PsA patients treated with SEC could be reached and validated. Identified main predictors at BL, such as PGA and number of pretreatments with biologics, and their direction of influence on the prediction mostly match the existing clinical knowledge [4]. The analysis showed that XAI can provide useful clinical insights in patient-individual predictions, potentially guiding PsA treatment decisions in future.

Background: Sustained minimal disease activity (MDA) is achieved by a minority of patients (pts) receiving biologics for psoriatic arthritis (PsA) [1]. Pt-reported MDA domains are less frequently achieved than physician-reported domains [2,3]. Here, we assessed MDA achievement in pts with PsA and inadequate response to 1–2 tumour necrosis factor inhibitors (TNFi-IR).
Objectives: Identify PsA disease domains and factors contributing to the lack of MDA achievement at Week (W)48 for TNFi-IR PsA pts treated with guselkumab (GUS) using data from the Phase 3b COSMOS trial.
Methods: In COSMOS, adults with active PsA (swollen/tender joint counts [SJC/TJC] each ≥3) and TNFi-IR were randomized 2:1 to subcutaneous GUS 100 mg or placebo (PBO) at W0, W4, then every 8 weeks. PBO pts crossed over to GUS at W16 (early escape) or W24 (planned). MDA was defined as fulfilment of ≥5/7 domains: tender entheses (Leeds Enthesitis Index [LEI]; 0–6) ≤1; Health Assessment Questionnaire – Disability Index (HAQ-DI; 0–3) ≤0.5; pt pain (0–100) ≤15; Psoriasis Area and Severity Index. (PASI; 0–72) ≤1; Pt Global Assessment (PtGA; 0–100) ≤20; SJC (0–66) ≤1; and. TJC (0–68) ≤1. Fibromyalgia (pFM) was defined at baseline (BL) using TJC minus SJC ≥7 as a proxy [3]. A longitudinal trajectory of achieving each MDA domain through W48 was derived (non-responder imputation). Time to achieving each domain was assessed with. Kaplan–Meier analyses; to account for differences in scales and domain strictness, scores were also normalized to SJC (0–66) scale. Response predictors (for pts not meeting each MDA domain criteria at BL) were identified using multivariate regression for time to achievement (Cox proportional hazards) and W48 achievement (logistic) of MDA.
Results: GUS pts (n=189) showed improvement from BL in all MDA domains, with overall W24/48 response rates (%) of: LEI (74.5/79.8), HAQ-DI (26.1/37.0), pt pain (14.7/30.6), PASI (66.8/81.5), PtGA (24.5/39.9), SJC (46.2/63.0) and TJC (14.7/28.3) respectively. Times to achievement of minimal scores for LEI, SJC and PASI were faster than for PtGA, HAQ-DI, pt pain and TJC for native-scale scores; when normalized, PtGA, HAQ-DI and pt pain showed a slower response (**Figure 1**). Higher BL HAQ-DI and worse fatigue (lower functional assessment of chronic illness therapy [FACIT]-fatigue score) were significantly associated with longer time to HAQ-DI ≤0.5; these factors plus older age predicted W48 non-achievement of HAQ-DI ≤0.5 (**Table 1**). Worse BL pt pain and fatigue were significant predictors of longer time to pt pain ≤15; these factors plus pFM predicted W48 non-achievement of pt pain ≤15. Worse BL fatigue was also significantly associated with longer time to PtGA ≤20 and W48 non-achievement of PtGA ≤20. Higher TJC, methotrexate (MTX) use and no pFM at BL were significantly associated with longer time to TJC ≤1; higher BL TJC, MTX and older age predicted W48 non-achievement of. TJC ≤1.
Conclusion: GUS provided sustainable improvement in all MDA domains through W48. Physician-reported domains (LEI, PASI and SJC) were achieved faster than pt-driven domains (PtGA, HAQ-DI, pt pain and TJC). BL domain scores, worse fatigue and MTX use (for TJC only) were inversely correlated with MDA in the refractory domains.

Background: While data on real-life retention of SEC in patients (pts) with PsA is accumulating, there are few data on predictive factors of this retention.
Objectives: To assess if objective signs of inflammation (OSI) were predictive of SEC retention at 1 year.
Methods: French retrospective study collecting between Oct 2019 and May 2022 data from PsA pts a) having initiated and received at least one dose of SEC between Aug 2016 and Aug 2018 (cohort 1) and Sept 2018 and Nov 2020 (cohort 2) (b) with at least a 1 year follow-up period. Retention rate of SEC at 1 year was estimated by the Kaplan Meier (KM) method. OSI were defined by at least one of the following within the 3 months before initiation of SEC: CRP> N, confirmed

clinical dactylitis, confirmed clinical synovitis or ultrasonography power-Doppler positive synovitis. The following a priori baseline preselected factors of SEC retention at 1 year (cohort, ≥1 OSI, age, sex, BMI, smoking, axial feature, history of arthritis or synovitis/ psoriasis/ uveitis/ IBD, diagnostic delay, disease duration, SEC line (L) of biologic/targeted synthetic (b/ts)DMARD, SEC dose, csDMARD/ corticosteroids at initiation, history of fibromyalgia/ depression) were analyzed by cox model regression. Only variables with <20% missing data were included in the model after multiple imputation and stepwise selection (significance level for entering variables = 20%; for removing variables = 10%). OSI and cohort variables were forced into the model whatever their significance level or rate of missing data.

Results: 842 pts (male: 38.6%, mean age: 52.5 ± 12.3 years, mean disease duration: 8.7 ± 8.5 years) from 50 centers were included in the analysis. At initiation of SEC, 63.0% of pts had ≥ 1 OSI and respectively 15.8%, 24.2% and 60.0% were in 1st, 2nd and ≥ 3rd (L) of b/ts DMARD. The 1 year retention rate for SEC was 64% [95%CI: 61%-68%] and was numerically greater in 1st L vs 2nd and ≥3rd L (77% [69%-84%], 65% [59-72%], 61% [57%-66%] respectively). The 1 year retention rates of SEC were 65% [61%-69%] and 69% [62%-75%] respectively for OSI+ and OSI- at SEC initiation. In multivariate analysis after adjustment, OSI was not identified as predictive of SEC discontinuation at 1 year (HR=1.19 l0.93;1.52], p=0.169). The others predictive factors identified are listed in Table 1.

Table 1. Predictive factors of SEC discontinuation at 1 year identified by multivariate cox regression analysis

Predictive factors (* reference)		SEC retention at 1 Year$	HR*adjusted*# [95% CI]	p vs ref	p type III
Secukinumab treatment line	1st L (N=129)*	77%			0.011
	2nd L (N=199)	65%	1.61 [1.05; 2.48]	0.030	
	≥ 3rd L (N=499)	61%	1.82 [1.23; 2.69]	0.003	
Age	<= 40 (N=132) (ref)	60%			0.085
	]40;60] (N=474)	66%	0.71 [0.52; 0.98]	0.040	
	> 60 (N=221)	66%	0.69 [0.48; 0.99]	0.045	
csDMARD at SEC initiation	No (N=501)*	63%			0.034
	Yes (N=326)	69%	0.77 [0.60; 0.98]	0.034	
Corticosteroids at SEC initiation	No (N=708)*	68%			<.001
	Yes (N=119)	54%	1.71 [1.26; 2.31]	<.001	
History or suspicion of fibromyalgia	No (N=753)*	66%			0.016
	Yes (N=74)	56%	1.57 [1.09; 2.26]	0.016	

Interpretation for predictor: HR> 1: the hazard of discontinuation at 1 year is X times higher in category vs reference.$ without imputation for missing data# adjusted on cohort and OSI

Conclusion: In this large cohort of PsA patients, the overall retention rate of SEC was 64% at 1 year in daily practice. Previous exposure to b/tsDMARD, concomitant corticosteroids at initiation of SEC and history of fibromyalgia were associated with an increased risk of SEC discontinuation at 1 year while concomitant csDMARD at initiation of SEC and age > 40 year with a decreased risk.

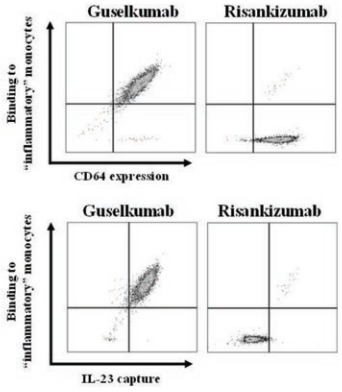
Background: Monoclonal antibodies targeting the interleukin (IL)-23p19 subunit are effective in the treatment of psoriatic disease but have different molecular attributes that may translate to differences in clinical efficacy. Within this class, guselkumab (GUS) is a fully human IgG1 monoclonal antibody with a native Fc region, while risankizumab (RIS) is a humanised IgG1 antibody with a mutated Fc region. Binding of these therapeutic antibodies to Fcγ receptor (FcγR) I, also known as CD64, is of interest, as $CD64^+$ IL-23-producing myeloid cells are increased within inflamed tissue of patients with psoriatic disease [1]. Furthermore, the incidence and prevalence of psoriatic arthritis increases with the severity of psoriasis [2], and joint disease activity is positively correlated with frequency of peripheral $CD64^+$ monocytes [3].



Objectives: Functional characteristics of the antigen-binding and Fc regions of GUS and RIS were compared.

Methods: IL-23 binding affinity was evaluated *in vitro* using a kinetic exclusion assay (KinExA) and surface plasmon resonance. *In vitro* cellular potency was measured by impact on IL-23-induced signal transducer and activator of transcription 3 (STAT3) phosphorylation in human peripheral blood mononuclear cells. Binding of GUS and RIS to FcγRs was assessed in cells transfected with individual FcγRs. Primary human "inflammatory" monocytes differentiated with granulocyte-macrophage colony-stimulating factor and interferon-γ (IFN-γ) were induced to produce IL-23 via toll-like receptor stimulation and used to assess binding of GUS and RIS to CD64 and potential capture of endogenously secreted IL-23 by flow cytometry. The potential for GUS binding to CD64 on IFN-γ primed monocytes to trigger activation was assessed using a 41-plex cytokine bead assay.

Results: GUS and RIS displayed comparable picomolar binding affinity for IL-23 and equivalent high potency for inhibiting IL-23-induced STAT3 phosphorylation. GUS showed strongest binding to CD64 compared with other FcγRs, whereas RIS had negligible binding to any FcγR. GUS, but not RIS, showed dose-dependent Fc-mediated binding to CD64 on primary human "inflammatory" monocytes. Moreover, CD64-bound GUS was able to simultaneously capture IL-23 endogenously secreted from the same cells (**Figure 1**). GUS binding to CD64 on monocytes did not induce cytokine production.

Conclusion: GUS, but not RIS, simultaneously binds $CD64^+$ myeloid cells via its Fc region and neutralises IL-23 with high affinity and potency. Our *in vitro* data suggest a mechanistic benefit through enrichment of GUS within inflamed tissue of patients with psoriatic disease, where $CD64^+$ IL-23-producing myeloid cells are increased, such that GUS potently neutralises IL-23 at its source of production. These findings may contribute to differences in clinical-therapeutic profiles between antibodies.

Figure. Guselkumab binds to the surface of CD64⁺ "inflammatory" monocytes and captures IL-23 at its source of production. Representative flow cytometry dot plots showing that guselkumab, but not risankizumab, binds to the surface of "inflammatory" monocytes, correlating with CD64 expression (*top panels*), and simultaneously captures IL-23 endogenously secreted from the same cells (*bottom panels*).

POS1532 WHAT IS THE REAL IMPACT OF DEPRESSION ON CLINICAL RESPONSE TO THERAPY IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS?

Keywords: Psoriatic arthritis, bDMARD

A. Martins[1,2], D. Santos Oliveira[1,2,3], R. Nicolau[2,4], T. Martins-Rocha[1,2], A. Bernardo[1], S. Pimenta[1,2], M. Bernardes[1,2], L. Costa[1]. *[1]São João Universitary Hospital Center, Rheumatology, Porto, Portugal*; *[2]Faculdade de Medicina da Universidade do Porto - FMUP, Medicine, Porto, Portugal*; *[3]Faculdade de Medicina da Universidade do Porto - FMUP, CINTESIS, Porto, Portugal*; *[4]Centro Hospitalar Tondela - Viseu, Epe, Rheumatology, Viseu, Portugal*

Background: The estimated prevalence of depression in patients with psoriatic arthritis (PsA) ranges from 20 to 30% and is higher than in the general population. The relationship between depression, systemic inflammation, disease activity and response to therapy in PsA patients remains unclear and under investigation. Patients with depression seems to have overexpression of pro-inflammatory cytokines involved in the pathogenesis of PsA, such as interleukin (IL)-6, IL-17 and tumor necrosis factor-alpha (TNF-α). On the other hand, depression leads to pain sensitization and plays a pivotal role in the shaping of pain responses and patient reported outcome measures (PROMs).

Objectives: To compare the response to therapy in PsA patients with or without depression, treated with biologic disease-modifying antirheumatic drug (bDMARD) for the first time.

Methods: An observational monocentric retrospective cohort study of patients with PsA (according to CASPAR criteria) registered in the national database (Reuma.pt), who started their first bDMARD between June 2010 and December 2021, was conducted. Demographic data, disease activity data, functional parameters and response to therapy 12 months after the start of bDMARD were collected. Depression was defined according to Hospital Anxiety and Depression scale (HADS). In patients who didn't fill out the questionnaire, depression was identified by consulting medical records. For patients with peripheral involvement, DAS28 (4V), CDAI and SDAI were collected at baseline. For patients with axial involvement, Ankylosing Spondylitis Disease Activity Score (ASDAS)-C-reactive protein (CRP) was also collected. American College of Rheumatology (ACR) response criteria, change in Ankylosing Spondylitis Disease Activity Score (ΔASDAS), BASDAI50 response, change in HAQ (ΔHAQ) and EULAR response (good, moderate or no response) were calculated at month 12. Chi-square test and t-test were conducted (for categorical and normally distributed continuous variables, respectively). A p-value <0.05 was considered statistically significant.

Results: 129 PsA patients were included (66 females, 51.2%). The mean age was 52.2±10.9 years and the disease duration was 13.9±7.2 years. All patients were treated with bDMARD, 122 (94.6%) with anti-TNFα agents and 7 (5.4%) with anti-IL-17 agents. Thirty-two (24.8%) patients had depression and the mean value of HADS was 10.0±3.8. The majority of these patients were treated with antidepressants (n=25, 78.1%). Patients with and without depression had similar sociodemographic characteristics, except for gender, since there were significantly more females in the depression group (p<0.001). These 2 groups had similar disease activity scores at baseline. Patients with depression and peripheral involvement had a significantly lower ACR20/50/70 responses (p=0.001, p=0.002 and p=0.001 respectively) after 12 months of therapy. Also, these patients had a significantly poorer EULAR response (p=0.002). Furthermore, patients with depression and axial involvement had a lower Δ-ASDAS (p=0.03) and a lower BASDAI50 response (p=0.06), after 12 months of therapy. Switch due to ineffectiveness in the first 12 months was higher in patients with depression (p=0.002).

Conclusion: In our study, depression was associated with poorer response to therapy and higher bDMARD discontinuation rates. Depression might be associated with a pro-inflammatory state but also has a close relationship with chronic widespread pain which can influence some composite disease activity measures. Clinical judgement of the degree of disease activity, using objective measures of disease activity, is important in patients with depression, in order to avoid inappropriate escalation of therapy. Furthermore, recognition and treatment of depression in patients with PsA are crucial, as this might improve their quality of life and also their ability to manage their rheumatic disease.

BIMEKIZUMAB TREATMENT RESULTED IN CLINICALLY MEANINGFUL IMPROVEMENTS IN THE PSORIATIC ARTHRITIS IMPACT OF DISEASE-12 (PSAID-12) SCORES USING POOLED RESULTS FROM TWO PHASE 3 TRIALS IN PATIENTS WITH PSORIATIC ARTHRITIS

Keywords: Psoriatic arthritis, Patient reported outcomes, Clinical trials

Background: The Psoriatic Arthritis (PsA) Impact of Disease-12 (PsAID-12) questionnaire assesses PsA impact from the patient (pt) perspective [1]. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17A and IL-17F, has shown superior efficacy vs placebo (PBO) and tolerability to 16 weeks (wks) in pts with PsA [2,3].
Objectives: To assess the efficacy of BKZ from the pt perspective, over 16 wks of treatment, using data from two phase 3 trials.
Methods: Analysis of pts with PsA randomised to subcutaneous BKZ 160 mg every 4 wks vs PBO in BE OPTIMAL (NCT03895203, N=712, biologic DMARD-naïve pts) and BE COMPLETE (NCT03896581, N=400, tumour necrosis factor alpha inhibitor-inadequate responders). PsAID-12 total and single-item domain scores range from 0 to 10; higher scores indicate worse status. Change from baseline (CfB) data and clinically meaningful within pt improvement response (threshold: decrease of ≥3 from baseline [BL] when respective PsAID-12 score ≥3 at BL) for total and single-item domain scores were calculated. Missing data imputed using multiple imputation (continuous) and non-responder imputation (binary).
Results: Of 1,112 pts randomised to BKZ or PBO, 96.5% completed Wk 16. BL characteristics were generally similar between treatment groups within trials; mean age: 49.3 years, BMI: 29.5 kg/m^2, years since diagnosis: 7.2; 46.6% male. At BL, mean (SD) PsAID-12 total score: 4.1 (2.0) BKZ, 4.2 (2.0) PBO. Mean (SE) Wk 16 PsAID-12 total CfB: –2.0 (0.1) BKZ, –0.5 (0.1) PBO (**Table 1**). Clinically meaningful response rate for Wk 16 PsAID-12 total score: 41.9% BKZ, 8.4% PBO with results similar in both pt populations (**Figure 1**). Similar differences between BKZ and PBO results were found for single-item domain responders, for example Wk 16 PsAID-12 pain score response rate: 46.5% BKZ, 18.7% PBO; skin problem score response rate: 68.5% BKZ, 21.4% PBO (**Table 1**).
Conclusion: By Wk 16, over half of BKZ-treated pts reported clinically meaningful improvements in most PsAID-12 single-item domain scores assessing PsA-specific symptoms and impact. Results may support shared treatment decisions.

Background: Given the chronic, long-term nature of psoriatic arthritis (PsA), sustaining high levels of disease control with treatment is important. Assessing the maintenance of response in patients (pts) that achieve treatment targets is of interest, particularly as pts can experience loss of response with long-term therapy [1]. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F in addition to IL-17A, has demonstrated rapid, statistically significant and clinically meaningful joint and skin efficacy responses at Week (Wk) 16 versus placebo (PBO), in pts with PsA [2,3]. Responses were sustained to Wk 52 [4].

Objectives: To report the maintenance of response in joint and skin efficacy outcomes to 52 wks in BKZ-treated pts with PsA who were responders at Wk 16.

Methods: BE OPTIMAL (NCT03895203) included a 16-wk double-blind, PBO-controlled period, and a 36-wk active treatment-blind period. Biologic disease-modifying antirheumatic drug (bDMARD)-naïve pts were eligible if they had adult-onset, active PsA with ≥3 tender and ≥3 swollen joints, and ≥1 active psoriatic lesion and/or history of psoriasis. Pts were randomised 3:2:1 to subcutaneous BKZ 160 mg every 4 wks (Q4W), PBO or reference arm (adalimumab 40 mg every 2 wks). At Wk 16, PBO pts switched to subcutaneous BKZ 160 mg Q4W (PBO/BKZ). Maintenance of response is reported as the percentage of BKZ-treated pts who achieved a response at Wk 16, who maintained that response at Wk 52. Data are reported for pts randomised to subcutaneous BKZ 160 mg Q4W at baseline. Endpoints include American College of Rheumatology (ACR)20/50/70, Psoriasis Area and Severity Index (PASI)75/90/100, minimal and very low disease activity (MDA, VLDA), and Disease Activity Index for PSoriatic Arthritis (DAPSA) remission or low disease activity (REM+LDA; ≤14) and remission (REM; ≤4) responses. Wk 16 responders are reported using non-responder imputation (NRI); maintenance of response to Wk 52 is reported using NRI and observed case (OC) data. The number of treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ, including pts who switched from PBO to BKZ at Wk 16.

Results: At baseline, 431 pts were randomised to BKZ 160 mg Q4W; 217/431 (50.3%) had psoriasis affecting ≥3% body surface area (BSA). 414/431 (96.1%) pts completed Wk 16 and 383 (88.9%) completed Wk 52. The majority of pts who achieved responses at Wk 16 maintained their response at Wk 52, across a range of joint and skin outcomes (**Figure 1**). At Wk 16, 268 (62.2%), 189 (43.9%) and 105 (24.4%) pts achieved ACR20/50/70, respectively. Of those responders, ACR20/50/70 responses were maintained at Wk 52 by over 80% of pts: 88.4%, 86.8%, 82.9% (NRI); 92.9%, 91.1% and 87.9% (OC). Of 217 pts with psoriasis affecting ≥3% BSA at baseline, 133 (61.3%) and 103 (47.5%) achieved PASI90/100 at Wk 16. The majority of pts maintained the response at Wk 52: 82.7%, 79.6% (NRI); 94.0%, 89.1% (OC). The same pattern was observed for the composite measures of efficacy. 194 (45.0%) pts achieved MDA at Wk 16; of those, 85.6% (NRI) and 90.7% (OC) maintained their response at Wk 52. A high proportion of Wk 16 responders also maintained their response at Wk 52 for VLDA, DAPSA REM+LDA and DAPSA REM (**Figure 1**). To Wk 52, 555/702 (79.1%) pts reported ≥1 TEAE whilst receiving BKZ; 46 (6.6%) reported serious TEAEs.

Conclusion: With BKZ treatment, a high proportion of Wk 16 responders maintained robust efficacy responses to Wk 52, including across joint, skin and composite efficacy outcomes. The safety profile of BKZ was consistent with previous reports [2,3].

Figure 1: Maintenance efficacy responses to Week 52, in Week 16 responders (NRI)

Randomised set. Wk 16 responders reported as NRI; maintenance of response to Wk 52 reported as NRI. ªIn pts with psoriasis affecting ≥3% BSA at baseline. Pts are considered to achieve MDA and VLDA when they meet 5/7 and 7/7 of the following criteria, respectively: TJC ≤1, SJC ≤1, PASI ≤1 or BSA ≤3%, pt pain (VAS ≤15 mm), pt global assessment (VAS ≤20), HAQ-DI ≤0.5 and tender entheseal points (LEI) ≤1. DAPSA score is the sum of SJC, TJC, pt pain (VAS 0–10), pt global assessment (VAS 0–10) and C-reactive protein (mg/L). DAPSA REM+LDA is defined as DAPSA total score ≤14; DAPSA REM is defined as DAPSA total score ≤4.

Abbreviations: ACR20/50/70: ≥20/50/70% improvement in American College of Rheumatology criteria; BSA: body surface area; DAPSA: Disease Activity Index for PSoriatic Arthritis; HAQ-DI: Health Assessment Questionnaire–Disease Index; LDA: low disease activity; LEI: Leeds Enthesitis Index; MDA: minimal disease activity; NRI: non-responder imputation; PASI: Psoriasis Area and Severity Index; PASI75/90/100: ≥75/90/100% improvement in PASI; Pt: patient; REM: remission; SJC: swollen joint count; TJC: tender joint count; VAS: visual analogue scale; VLDA: very low disease activity; Wk: week.

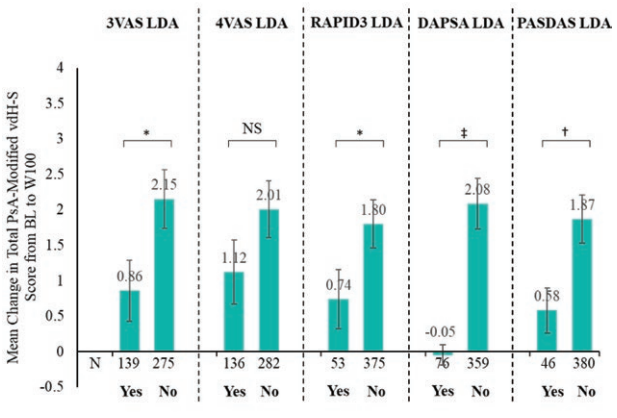
Background: Guselkumab (GUS), a fully human IL-23p19 subunit inhibitor, was shown to reduce mean changes in radiographic progression vs placebo (PBO) by week (W)24 [1] and to be associated with low rates of radiographic progression through W100 among GUS-treated patients (pts) with PsA, irrespective of dosing regimen (every [Q] 4W or Q8W) [2] Furthermore, earlier clinical response predicted improved long-term radiographic outcome in GUS-treated pts with active PsA [3]. The recently developed 3 Visual Analogue Scale (VAS) and 4 VAS scores are the first short multidimensional composite measures specifically for use in PsA routine clinical care [4].

Objectives: Determine whether early improvement in 3VAS/4VAS predicts radiographic change through W100.

Methods: DISCOVER-2 included biologic-naïve pts with active PsA (≥5 swollen and ≥5 tender joint counts [SJC/TJC]; CRP ≥0.6 mg/dL) randomized (1:1:1) to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W at W24. In the current analysis, only pts randomized to GUS were included (N=493), pooling Q4W and Q8W. Response at W8 was defined as achievement of low disease activity (LDA) in 3VAS (≤3.4), 4VAS (≤3.5), RAPID3 (≤6), DAPSA (≤14), and PASDAS (≤3.2). Association of W8 response with change from baseline (BL) to W100 in total PsA-modified van der Heijde-Sharp [vdH-S] score was assessed with the independent samples t-test and generalized linear models adjusting for known BL determinants of radiographic progression (vdH-S score, age, gender, and CRP). Pairwise correlations and agreement in LDA classification between the endpoints assessed were assessed with Pearson's correlation coefficient and the kappa statistic, respectively.



Results: Among GUS-treated pts not meeting the respective endpoints at BL, 32.9%, 31.6%, 12.4%, 17.8%, and 10.8% achieved LDA in 3VAS, 4VAS, RAPID3, DAPSA, and PASDAS, respectively, at W8. LDA achievement in 3VAS (0.86 vs. 2.15, p=0.03), RAPID3 LDA (0.74 vs. 1.80, p=0.049), DAPSA LDA (-0.05 vs. 2.08, p<0.001), and PASDAS LDA (0.58 vs. 1.87, p=0.006) at W8 were associated with significantly less radiographic progression through W100 **(Figure 1)**. For 4VAS, achievement of remission (≤2.1; 0.71 vs. 1.84, p=0.045), but not LDA (1.12 vs. 2.01, p=0.142), was also associated with improved radiographic outcome. In multivariate analyses, improved response to GUS treatment at W8 in all endpoints assessed was associated with numerically less radiographic progression through W100. 3VAS and 4VAS at W8 showed strong correlations with RAPID3 (r_{3VAS}=0.787; r_{4VAS}=0.877) and PASDAS (r_{3VAS}=0.795; r_{4VAS}=0.790) and moderate correlations with DAPSA (r_{3VAS}=0.466; r_{4VAS}=0.524), whereas fair to moderate agreement (kappa range: 0.325-0.545) in LDA classification was noted.

Conclusion: Approximately one-third of GUS-treated patients achieved early response (W8 LDA) in 3VAS/4VAS, which was associated with reduced rates of radiographic change, as was early response in the other outcomes assessed. These results suggest that, in addition to their usefulness in assessing disease activity in routine clinical care, 3VAS and 4VAS, the former being more sensitive, may predict long-term radiographic changes.

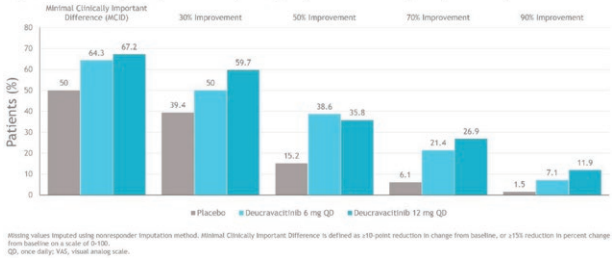
Background: Pain is commonly cited by patients with psoriatic arthritis (PsA) as affecting their daily activities and quality of life. Pain signaling involves a variety of cytokines, such as interleukin (IL)-17, interferon (IFN)-γ, and IL-6. TYK2 mediates signaling of key cytokines, such as IL-23, which is upstream of IL-17, involved in PsA pathogenesis. Deucravacitinib (DEUC) is a first-in-class, oral, selective, allosteric inhibitor of TYK2, approved in multiple countries for the treatment of adults with plaque psoriasis [1,2]. DEUC was efficacious vs placebo (PBO) in a phase 2 trial in patients with active PsA, and cytokine levels were reduced with DEUC treatment vs PBO, including IL-17A and other cytokines reflecting

downstream anti-inflammatory effects of TYK2 inhibition, including IL-6 and tumor necrosis factor alpha [3,4].

Objectives: To characterize the effect of DEUC on pain across different instruments, and alignment across pain instruments, in patients in the phase 2 PsA trial.

Methods: Patients with PsA (N=203) were randomized 1:1:1 to PBO, DEUC 6 mg once daily (QD), or DEUC 12 mg QD. Three instruments were used to assess pain up to week 16: (1) Patient Global Assessment of Pain visual analog scale (Pain VAS), scored from 0-100; (2) Psoriatic Arthritis Impact of Disease (PsAID) Pain instrument, scored from 0-10; and (3) 36-Item Short-Form Health Survey (SF-36) Bodily Pain question, which asks patients to rate their pain on scale of 1-6 ranging from "none" to "very severe." Mean change from baseline (BL) in pain scale scores, the proportion of patients who reported meaningful improvements in pain, and Pearson's correlation between pain scales (Pain VAS and PsAID Pain) and disease efficacy measures were evaluated.



Results: BL mean Pain VAS score was 64.1 and BL mean PsAID Pain score was 6.4, and scores were generally similar across treatment groups. Percentages of patients who reported improvements in Pain VAS (**Figure 1**) and PsAID Pain were consistently greater with DEUC treatment compared with PBO, with improvements in pain being similar between males and females across instruments. The pain assessments correlated with one another both at baseline (**Table 1**) and over time through week 16, with some divergent responses to pain questions also being observed. At baseline, both assessments of pain strongly correlated with Psoriatic Arthritis Disease Activity Score (PASDAS) and with Patient Global Assessment of Disease Activity (PtGA) (**Table 1**).

Conclusion: A higher proportion of patients with PsA treated with DEUC reported clinically meaningful improvements in pain compared with PBO. Patient-reported pain was overall well-correlated across instruments; however, some divergence was also observed.

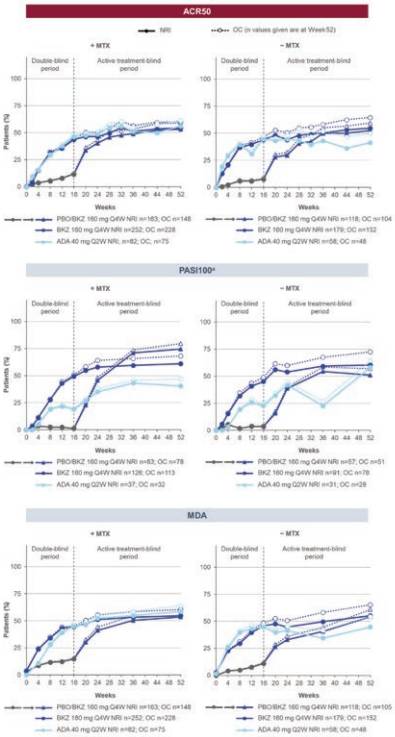
Background: Given the chronic nature of psoriatic arthritis (PsA), understanding long-term efficacy and safety of biologic monotherapy or therapy in combination with ongoing methotrexate (MTX) is of interest. Studies have shown reduced efficacy of tumour necrosis factor inhibitors without MTX than with MTX [1]. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has shown efficacy and tolerability to 52 weeks (wks) in patients (pts) with PsA [2].

Objectives: To report BKZ efficacy and safety to Wk 52 from the phase 3 study BE OPTIMAL in bDMARD-naïve pts with PsA, with or without ongoing concomitant MTX.

Methods: BE OPTIMAL (NCT03895203) comprised a 16-wk double-blind placebo (PBO)-controlled period and a 36-wk active treatment-blind period. Pts were randomised 3:2:1 subcutaneous BKZ 160 mg every 4 wks (Q4W):PBO:reference arm (adalimumab [ADA] 40 mg Q2W). From Wk 16, PBO pts received BKZ 160 mg Q4W. Pts could not adjust their background medication during the 16-wk PBO-controlled period. Efficacy and safety were evaluated by concomitant MTX use at baseline (BL). Missing data were imputed using non-responder (discrete) or multiple (continuous) imputation.

Results: 761/852 (89.3%) pts completed Wk 52 (+ MTX: 454/497 [91.3%], – MTX: 307/355 [86.5%]). BL characteristics were generally similar +/– MTX: mean age 48.1 vs 49.4 years, BMI 29.1 vs 29.4 kg/m^2, 5.7 vs 6.2 years since diagnosis, 47.3% vs 46.2% male, 49.5% vs 50.4% with psoriasis affecting ≥3% body surface area. To Wk 52, the proportion of BKZ-randomised pts who achieved American College of Rheumatology (ACR)50, complete skin clearance (Psoriasis Area and Severity Index [PASI]100) and minimal disease activity (MDA) were similar regardless of BL MTX use. Fewer pts receiving ADA – MTX achieved ACR50 or MDA at Wk 52 compared to ADA + MTX (**Figure 1**). Other Wk 52 efficacy

responses on BKZ were generally of a similar magnitude +/– MTX (**Table 1**). To Wk 52, pts with ≥1 treatment-emergent adverse event +/– MTX: PBO/BKZ 124/158 (78.5%) vs 89/113 (78.8%), BKZ 214/252 (84.9%) vs 150/179 (83.8%), ADA 63/82 (76.8%) vs 50/58 (86.2%).



Conclusion: BKZ treatment demonstrated consistent sustained clinical efficacy across disease manifestations to Wk 52 in bDMARD-naïve pts with PsA, irrespective of concomitant MTX. BKZ was well tolerated in pts with PsA with or without MTX.

Background: A higher prevalence of comorbidities, such as obesity, prior treatments, and certain demographics (e.g., age and sex) in patients (pts) with psoriatic disease (PsD) may lead to an increased risk of adverse events (AEs), sometimes serious [1]. Guselkumab (GUS), a fully human, selective IL-23p19-subunit inhibitor approved to treat (tx) adults with active psoriatic arthritis (PsA) and moderate to severe plaque psoriasis (PsO), has shown a favorable safety profile consistent between PsA and PsO pts through up to 2 and 5 years (yrs) of follow-up in the pooled PsA and PsO trials, respectively [2].

Objectives: An integrated post hoc analysis evaluated GUS safety in subgroups of pts with PsD, stratified by baseline (BL) characteristics of interest, using pooled safety data from 11 Phase 2/3 trials of GUS, including four in PsA (Phase 2, DISCOVER-1, DISCOVER-2, COSMOS) and seven in PsO (X-PLORE, VOYAGE-1, VOYAGE-2, NAVIGATE, ORION, ECLIPSE, Japanese registration).

Methods: GUS 100 mg subcutaneous (SC) was administered at Week (W) 0, W4, then every 4 W (Q4W) or Q8W in PsA trials and at W0, W4, then Q8W in PsO trials (additional doses were investigated in X-PLORE). Pts randomized to placebo (PBO) crossed over to GUS Q4W or Q8W at W24 in PsA trials and to GUS Q8W at W16 in 5 of the PsO trials. Pooled safety data were summarized for the PBO-controlled period (PsA: W0-24; PsO: W0-16) and through the end of the reporting period (PsA: up to 2 yrs; PsO: up to 5 yrs). Incidence rates of key safety events were adjusted for duration of follow-up and reported per 100 pt-yrs (PY), along with 95% CI. BL characteristics of interest in pts randomized to GUS or PBO (N=3318), were prior biologic use (26% yes; 74% no), age (94% <65; 6% ≥65 yrs), sex (62% male; 38% female), and BMI (26% under/normal weight; 34% overweight; 40% obese).

Results: During the PBO-controlled periods, 1061 pts received PBO (395 PY) and 2257 received GUS (856 PY). Through the end of the reporting periods, 4399 GUS-tx pts (PsA: 1508; PsO: 2891) contributed 10,787 PY of follow-up (PsA: 2125 PY; PsO: 8662 PY). BL characteristics were similar across 4 PsA trials and generally similar across 7 PsO trials. The PsO trials included more males and pts with extensive skin disease than the PsA trials. Distribution of PsD pts across BL subgroups generally provided sufficient sample size, although pts ≥65 yrs accounted for only 6% of all PsD pts. Throughout the PBO-controlled period, pooled incidence rates of overall AEs were generally similar between GUS- and PBO-tx pts and rates of serious AEs (SAEs), AEs leading to study agent discontinuation, infections, and serious infections were low and comparable between GUS- and PBO-tx pts, regardless of the BL characteristics assessed. The rates of safety events evaluated were stable or reduced through the end of the reporting period for GUS-tx pts within each BL subgroup (Figure 1).

Figure. Rates of AEs, SAEs, and AEs Leading to Discontinuation Stratified by BL Characteristics (events/100 PY [95% CI])[a]

[a] Confidence intervals based on an exact method assuming that the observed number of events follows a Poisson distribution. Events are counted only once if events were started from same date with same derived term.
[b] Includes pts who discontinued study treatment early with the last study treatment (PBO or GUS) administered prior to W16/24 and who did not receive any study agent (PBO or GUS) at or after W16/24; all data including the final safety follow-up visit collected through up to 2 years were included in this period.
[c] Only includes data prior to administration of GUS in PBO pts who switched from PBO to GUS.
[d] Only includes data after administration of GUS in PBO pts who switched from PBO to GUS.
BMI=body mass index, under/normal weight: <18.5-24.9; overweight: 25.0-29.9; obese: 30.0-34.9; d/c=discontinuation.

Conclusion: This comprehensive integrated analysis of GUS safety demonstrated a favorable safety profile across a broad population of pts irrespective of the BL characteristics assessed. Overall, safety event rates in GUS-tx pts were comparable to or lower than PBO during short-term follow-up. Rates of SAEs and serious infections remained low and stable through long-term follow-up.

SAFETY AND EFFICACY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS AND INADEQUATE RESPONSE TO BIOLOGICS: 3-YEAR RESULTS FROM THE PHASE 3 SELECT-PSA 2 STUDY

Keywords: Psoriatic arthritis, Targeted synthetic drugs, Safety

P. J. Mease[1], A. Setty[2], K. Papp[3], F. Van den Bosch[4], S. Tsuji[5], M. Keiserman[6], K. Carter[2], R. Mccaskill[2], E. Mcdearmon-Blondell[2], P. Wung[2], W. Tillett[7].

Background: The efficacy and safety of upadacitinib (UPA) in patients (pts) with psoriatic arthritis (PsA) and inadequate response to ≥1 biologic disease-modifying antirheumatic drug (bDMARD-IR) have been demonstrated up to 56 and 104 weeks of treatment [1,2].
Objectives: To assess the long-term safety and efficacy of UPA in bDMARD-IR pts with PsA through 152 weeks of treatment in the SELECT-PsA 2 study.
Methods: Pts were randomized to receive UPA 15 or 30 mg once daily (QD), or placebo (PBO) for 24 weeks, followed by blinded switch to UPA 15 or 30 mg QD for pts initially randomized to PBO. After 56 weeks, pts continued their assigned dose up to 152 weeks in an open-label extension (OLE). Following approval of the 15 mg QD dose, the protocol was amended and all pts on UPA 30 mg QD were switched to the approved dose (earliest switch at week 116). Endpoints assessed at 152 weeks included: % of pts achieving 20/50/70% improvement in American College of Rheumatology (ACR) criteria, minimal disease activity (MDA), and 75/90/100% improvement in Psoriasis Area and Severity Index, as well as patient-reported outcomes. Efficacy data were evaluated using non-responder imputation (NRI) and as-observed (AO) data (binary endpoints), and mixed effect model for repeated measures (continuous endpoints). Treatment-emergent adverse events (TEAEs) through 3 years (cut-off date, 05 May 2022) are also reported.
Results: Of the 641 pts randomized to receive UPA 15 or 30 mg QD, or PBO followed by UPA 15 or 30 mg QD (n=211, 218, 106, and 106, respectively), 478 entered the OLE. Improvements in efficacy outcomes with UPA observed at 56[1] and 104[2] weeks were maintained through the OLE, with ACR20 achieved by 43–51% (NRI) and 79–87% (AO) of pts across treatment arms at week 152. The highest % of MDA responders at week 152 (31% [NRI] and 44% [AO]) were in the continuous UPA 15 mg arm (**Table 1**). UPA was well tolerated through 152 weeks, with no new safety signals identified. The overall exposure-adjusted event rates for any TEAE were higher for UPA 30 vs 15 mg (295 vs 226 events/100 PY, respectively [**Figure**]).
Conclusion: Observed improvements in the signs and symptoms of PsA with UPA were maintained through 3 years of treatment in bDMARD-IR pts. The long-term safety profile of UPA in this treatment-refractory population was consistent with its known safety profile across indications.

Table 1. Efficacy endpoints at week 152

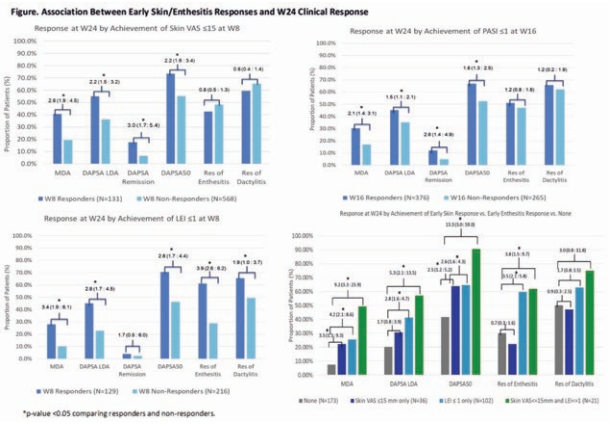
EARLY SKIN AND EARLY ENTHESITIS RESPONSES IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH GUSELKUMAB ASSOCIATE WITH LONG-TERM RESPONSE: POST HOC ANALYSIS THROUGH 2 YEARS OF A PHASE 3 STUDY



Keywords: Enthesitis, Psoriatic arthritis, Skin

L. Coates[1], J. Ramírez[2], D. Mcgonagle[3], S. Aydin[4], M. Zimmermann[5], F. Nantel[6], M. Shawi[7], E. Rampakakis[8,9], P. Nash[10], P. J. Mease[11]. Background: Guselkumab (GUS), an IL-23p19 inhibitor, has demonstrated efficacy in psoriatic arthritis (PsA) across key Group for Research and Assessment of Psoriasis (PsO) and Psoriatic Arthritis (GRAPPA)-recommended domains [1,2]. Skin disease and enthesitis have been identified as disease manifestations with earlier response times than others [3].
Objectives: In this analysis we: (a) Determined whether early skin and/or entheseal response predicts future response in other PsA domains; (b) Evaluated the trajectory for achieving skin/entheseal responses by 52 weeks (W) in patients (pts) without early responses.
Methods: Pts in the DISCOVER-1 and DISCOVER-2 (D1/2) studies were adults with active PsA despite standard therapies. D1 pts had ≥3 swollen and ≥3 tender joints (SJC/TJC) and C-reactive protein (CRP) ≥0.3 mg/dL; D2 pts had SJC ≥5, TJC ≥5, and CRP ≥0.6 mg/dL. 31% of D1 pts received 1-2 prior TNF inhibitors; D2 pts were biologic-naïve. Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then every 8 weeks (Q8W); or placebo. These post hoc analyses included only pooled GUS Q4W and Q8W pts (N=748). Early skin response was defined as PsO Area and Severity Index (PASI) score ≤1 at W16 or skin visual analogue scale (VAS) ≤15mm at W8 among pts with a baseline (BL) PASI score >1 and skin VAS >15mm (first assessment time for both); early entheseal response was defined as Leeds Enthesitis Index (LEI) score ≤1 at W8; and categories of early response were defined as skin VAS ≤15mm only vs LEI score ≤1 only vs combined skin VAS ≤15mm & LEI score ≤1 vs none at W8. Potential responses at W24 & W52 included achievement of minimal disease activity (MDA), Disease Activity in PsA (DAPSA) low disease activity (LDA) or remission, DAPSA50, and enthesitis/dactylitis resolution. Associations between early skin/entheseal response and W24/W52 response were assessed with crosstabulations and logistic regression.
Results: Early skin response associated with greater odds of achieving W24 MDA, DAPSA LDA, DAPSA remission, and DAPSA50, but not enthesitis or dactylitis resolution (Figure 1). Early entheseal response associated with greater odds of achieving all W24 outcomes, including resolution of enthesitis or dactylitis, with the exception of DAPSA remission; DAPSA remission was achieved by a greater proportion of early responders, though the association was significant only at W52. In pts with both BL PsO and enthesitis, early responders in both domains were even more likely to subsequently demonstrate MDA, DAPSA LDA, DAPSA50, DAPSA remission only at W52, and dactylitis resolution than pts with individual responses. Among pts who did not achieve early responses, approximately half did so by W52.
Conclusion: Early skin and entheseal responses predicted long-term clinical response, including disease remission. A synergistic effect was observed, in which pts with BL PsO and enthesitis exhibiting early response in both domains were more likely to achieve later clinical response. These results highlight the importance of early response in these two domains on the trajectory of long-term pt outcome.

LONG-TERM EFFICACY AND SAFETY OF UPADACITINIB IN PATIENTS WITH PSORIATIC ARTHRITIS: 3-YEAR RESULTS FROM THE PHASE 3 SELECT-PSA 1 STUDY

Keywords: Psoriatic arthritis, Safety

I. Mcinnes[1], K. Kato[2], M. Magrey[3], J. F. Merola[4], M. Kishimoto[5], D. Haaland[6,7], Y. Li[2], Y. Liu[2], J. Liu[2], R. Lippe[8], P. Wung[2]. [1]*University of Glasgow, College of Medical, Veterinary, and Life Sciences, Glasgow, United Kingdom*; [2]*AbbVie, Inc, Immunology, North Chicago, United States of America*; [3]*Case Western Reserve University School of Medicine, Rheumatology, Cleveland, United States of America*; [4]*Harvard Medical School, Brigham and Women's Hospital and Harvard Medical School, Boston, United States of America*; [5]*Kyorin University School of Medicine, Department of Nephrology and Rheumatology, Mitaka, Japan*; [6]*McMaster University, Hamilton, ON, Canada*; [7]*The Waterside Clinic, Barrie, ON, Canada*; [8]*AbbVie Deutschland GmbH & Co. KG, Immunology, Wiesbaden, Germany*

Background: Upadacitinib (UPA) improved symptoms in patients (pts) with psoriatic arthritis (PsA) with prior inadequate response or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug (nbDMARD-IR) through week (wk) 104 or 2 years of treatment in SELECT-PsA 1 [1].
Objectives: To evaluate efficacy and safety of UPA vs adalimumab (ADA) through wk 152 or 3 years from the ongoing long-term open-label extension of SELECT-PsA 1.
Methods: Pts were randomized to receive UPA 15 mg (UPA15) or UPA 30 mg (UPA30) once daily, ADA 40 mg (ADA) every other wk, or placebo (PBO). At wk 24, PBO pts switched to UPA15 or UPA30. Following approval of UPA15, the

protocol was amended so pts on UPA30 switched to UPA15 (earliest at wk 104). Efficacy was assessed through wk 152, and safety through June 13, 2022.

Results: Of 1704 pts randomized, 911 completed 152 wks of treatment. The proportions of pts achieving. ≥20%/50%/70% improvement in American College of Rheumatology criteria (ACR20/50/70), minimal disease activity (MDA), and ≥75%/90%/100% improvement in Psoriasis Area and Severity Index at wk 152 were generally consistent with those at wk 104[1]. UPA had greater ACR20/50/70 and MDA responses vs ADA, and a greater mean change from baseline (BL) in Health Assessment Questionnaire-Disability Index, pt's assessment of pain, and Bath Ankylosing Spondylitis Disease Activity Index vs ADA. Change from BL in modified total Sharp/van der Heijde score were similar between UPA30 and ADA, and numerically higher with UPA15 **(Table 1)**. The overall UPA safety profile remained unchanged (**Figure 1**) [1,2]. UPA had numerically higher rates of serious infection (SI), herpes zoster (HZ), anemia, lymphopenia, creatine phosphokinase (CPK) elevation, and non-melanoma skin cancer (NMSC) vs ADA. Increases for SI, HZ, anemia, and CPK elevation with UPA were dose dependent. Rates of major adverse cardiovascular events, venous thromboembolism, and malignancy excluding NMSC were low and generally similar across groups. The most common cause of death was COVID-19.

Conclusion: Efficacy of UPA in nbDMARD-IR pts with PsA was maintained through 3 years of treatment. No new safety signals were identified.

Background: The Psoriatic Arthritis Impact of Disease (PsAID) is a patient-reported questionnaire assessing multiple domains in patients with psoriatic arthritis (PsA), developed under the aegis of EULAR, and recommended by OMERACT and GRAPPA. To be usable in different contexts, translations and cross-cultural validations are necessary. Arabic is the sixth most-spoken language in the world; however, many patient-reported outcomes are not available in Arabic.

Objectives: To translate, culturally adapt and validate the PsAID-12 questionnaire in Arabic, to study its psychometric properties, and to evaluate its association with the demographic and disease characteristics of PsA patients.

Methods: This multicentric multinational study was conducted by the Arab League of Associations of Rheumatology (ArLAR) research group (ARCH). Validated methodologies were applied. (A) Phase 1: Translation of PsAID-12 into Arabic, including a double translation, synthesis by a steering committee, back-translation, and cognitive debriefing with feasibility and timing assessment with a sample of patients with PsA in four countries. (B) Validation phase: Cross-sectional study, with a longitudinal part for reliability testing, conducted in thirteen Arab countries. Patients were consecutive adult patients, diagnosed with PsA (rheumatologist opinion + CASPAR criteria), literate, and agreeing to participate. Data collected: (1) From the patient: PsAID-12 in Arabic, demographic and disease information, Health Assessment Questionnaire (HAQ), Patient Global Assessment for pain and disease activity (PGA), Fibromyalgia Rapid Screening Tool (FiRST) and Patient Health Questionnaire (PHQ4). (2) From the rheumatologist: Disease Activity in Psoriatic Arthritis (DAPSA) score. Psychometric properties of the PsAID-12 were investigated: internal consistency (Cronbach α), construct validity (Spearman correlation with DAPSA, HAQ, PGA, FiRST, PHQ4), and test-retest reliability (intraclass correlation coefficients (ICCs) and Cohen kappa at one week). (C) Factors associated with high PsAID-12 total score (defined as >= 4) were explored using multivariable binary logistic regression.

REFERENCES:

[1] Translation phase: a culturally adapted questionnaire was obtained, with minor rephrasing and addition of examples for better clarity. Feasibility was scored at 2/10 (SD 1.7) (10 being the most difficult) and the time needed to complete the questionnaire was 4.16 minutes.

[2] Validation phase: in 554 patients from 13 countries, mean age was 45 years [SD 13], 57% were females. The mean PsAID score was 3.86 (SD 2.33). Internal consistency was excellent (Cronbach $\alpha = 0.95$). The correlation coefficients with other measures were moderate to strong (range, 0.63 to 0.78 (Figure 1). Test-retest reliability (N=138 patients) was excellent (ICC 0.95 (95%CI 0.86;0.93) and agreement between the first and second measurements was substantial (Cohen kappa 0.797).

[3] In the multivariable analysis, factors associated with a higher PsAID were DAPSA, FiRST, and PHQ4 (after adjustment for axial involvement, education, gender, and CRP).

Conclusion: The Arabic PsAID is a consistent, reliable, and feasible measure in patients with PsA. The correlation with other PsA-related measures appears similar to the correlation noted in other cultures and languages. The PsAID appears to be a stable measure of impact across cultures. These results comfort the recommendation to use the PsAID for clinical practice and research purposes.

POS1543 EFFICACY OF RISANKIZUMAB IN THE TREATMENT OF PSA PATIENTS WITH LIMITED AND EXTENSIVE JOINT INVOLVEMENT

Keywords: Psoriatic arthritis, Enthesitis, Remission

A. Ogdie[1], C. T. Ritchlin[2], D. D. Gladman[3], P. M R Nakasato[4], R. Liu[4], C. Kaufmann[4], B. Padilla[4], L. Gossec[5]. *[1]University of Pennsylvania Perelman School of Medicine, Division of Rheumatology, Philadelphia, United States of America*; *[2]University of Rochester Medical Center, Department of Medicine, Rochester, United States of America*; *[3]Toronto Western Hospital, University of Toronto, Schroeder Arthritis Institute, Krembil, Research Institute, Toronto, Canada*; *[4]AbbVie, Department of Immunology, North Chicago, United States of America*; *[5]Pitie Salpetriere Hospital, Rheumatology Department, Paris, France*

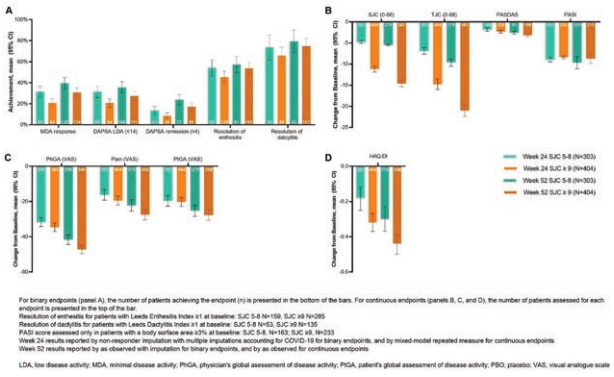
Background: PsA is a systemic disease involving multiple domains. Peripheral joints are frequently affected, and patients often initially present with asymmetrical oligoarthritis (2-4 swollen joints). KEEPsAKE 1 and KEEPsAKE 2 are double-blind, phase 3 clinical trials that evaluated the efficacy of risankizumab (RZB) versus placebo (PBO) for the treatment of adults with active PsA and at least 5 tender and swollen joints. RZB is a humanized monoclonal antibody that binds specifically to the p19 subunit of interleukin 23 and is approved to treat PsA.

Objectives: Here we assess response rates in PsA patients with limited (5 to ≤ 8) and extensive (≥ 9) swollen joint count (SJC) after treatment with RZB to examine whether its efficacy differed according to the extent of joint involvement.

Methods: In KEEPsAKE 1 and KEEPsAKE 2, patients were originally randomized 1:1 to receive RZB 150 mg or PBO at weeks 0, 4, 16 and every 12 weeks thereafter with an open label extension beginning for all patients at week 24 and is currently ongoing. Integrated efficacy results are reported for continuous endpoints by mixed-effect model repeated measure for week 24 and by as observed for week 52. Categorical endpoints are reported by non-responder imputation.

Results: Of the 707 patients initially randomized to RZB across both trials, 303 had a limited (5 to ≤ 8) SJC and 404 had extensive SJC (≥ 9) at baseline. Baseline characteristics for each group are presented in **Table 1**. At baseline, both groups of patients had high disease activity with a mean Disease Activity in PsA (DAPSA) score of 31.47 in the limited joint involvement population and 57.31 in the extensive joint involvement population (**Table 1**). In both groups, patients achieved minimal disease activity (MDA), Disease Activity in PsA (DAPSA) remission or low disease activity and resolution of enthesitis and dactylitis at weeks 24 and 52 (**Figure 1**). A higher proportion of patients in the limited joint involvement population achieved these stringent end points than did patients with extensive joint involvement (**Figure 1**). Both patient groups also had a decreased total number of swollen or tender joints at weeks 24 and 52 compared to baseline and showed improved scores for PsA disease activity (PASDAS), Psoriasis Area and Severity Index (PASI), Physician and Patient's Global Assessment of Disease Activity, pain, and HAQ-Disability Index (**Figure 1**). As expected, a greater reduction in swollen and tender joints was seen in patients in the extensive joint involvement population, due to a higher baseline joint involvement. Efficacy

results were maintained or further improved from week 24 to 52 for both limited and extensive SJC patients (**Figure 1**)



Conclusion: RZB is efficacious in reducing signs and symptoms of PsA in patients, regardless of patterns of joint involvement. More patients in the limited joint involvement group achieved stringent treatment targets such as MDA and DAPSA remission at both weeks 24 and 52.

Background: Patients (pts) with psoriatic arthritis (PsA) exposed to tumour necrosis factor inhibitors (TNFi) may have attenuated response or higher adverse event (AE) risk with subsequent treatment. Tofacitinib efficacy/safety in PsA pts was shown in 3 Phase (P)3 trials and 1 long-term extension (LTE) trial.

Objectives: Assess long-term safety/efficacy of tofacitinib in TNFi-inadequate responder (IR) and biologic disease-modifying antirheumatic drug (bDMARD)-naïve PsA pts.

Methods: Pooled data from P3 trials (NCT01877668/NCT01882439/NCT03486457) of PsA pts receiving ≥1 tofacitinib dose and 1 LTE trial (NCT01976364) of PsA pts receiving tofacitinib 5 mg BID (dose switching allowed after 1 month) were stratified by TNFi-IR or bDMARD-naïve status at P3 trial baseline (BL). Safety assessed in P3/LTE trials. Efficacy assessed in LTE trial only to Month (M)36 (longitudinal models, data as observed): MDA and HAQ-DI (≥0.35 improvement) response rates and change from BL (Δ) in PASDAS. Data reported as all tofacitinib (pts receiving ≥1 tofacitinib dose) or constant tofacitinib 5 mg BID (pts assigned to tofacitinib 5 mg BID in P3/LTE trials or placebo→tofacitinib 5 mg BID in P3 trials and maintained this dose).

Results: 408 TNFi-IR (incl. 29 TNFi-exposed with unknown IR status) and 562 bDMARD-naïve pts from P3/LTE trials were assessed. Differences in P3 trial BL characteristics in TNFi-IR vs bDMARD-naïve pts included longer disease duration (all tofacitinib, mean: 8.9 vs 5.6 years), higher HAQ-DI scores (mean: 1.2 vs 0.9) and a higher proportion (%) of pts aged ≥65 years (9.6 vs 7.7) and from North America (27.5 vs 8.0). Treatment-emergent AE (TEAE) incidence rates were higher in TNFi-IR vs bDMARD-naïve pts; serious AE (SAE), serious infection (SI) and herpes zoster (HZ; all tofacitinib) incidence rates were numerically higher in TNFi-IR vs bDMARD-naïve pts (confidence intervals [CIs] overlapped; Table 1). Deaths, malignancies excl. non-melanoma skin cancer (NMSC), NMSC, major adverse cardiovascular events (MACE) and venous thromboembolism (VTE) events were observed (Table 1). Tofacitinib response/improvements were sustained to M36 in pts remaining in LTE trial, regardless of prior treatment. At all time points, TNFi-IR vs bDMARD-naïve pts had lower MDA response rates and slightly lower HAQ-DI response rates (Figure 1) and ΔPASDAS (all tofacitinib/constant tofacitinib 5 mg BID: M1 -2.3/-2.5 vs -2.9/-3.0; M6 -2.5/-2.8 vs -3.0/-3.1; M12 -2.7/-2.9 vs -3.0/-3.2; M24 -2.9/-3.1 vs -3.2/-3.4; M36 -3.0/-3.2 vs -3.1/-3.4).

[a]Concomitant csDMARD required at start of P3 trials; allowed but not required in LTE trialMedian exposure (range), days: [b]988 (1, 1544); [c]744 (1, 1715)[d]Adjudicatedn, number of pts with events; PY, pt-years

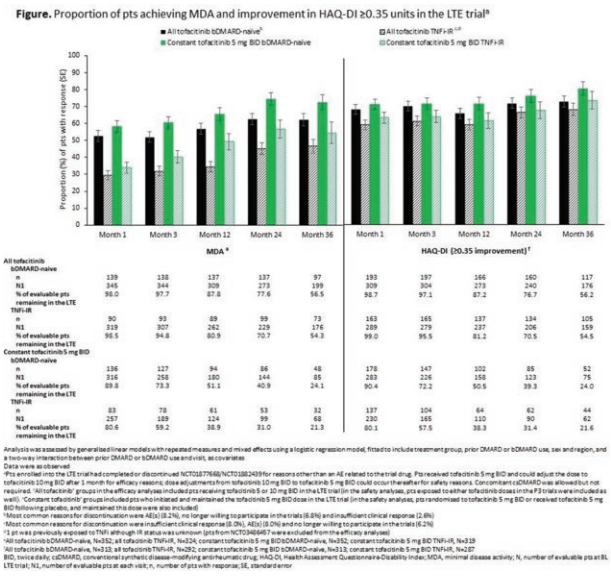

Figure. Proportion of pts achieving MDA and improvement in HAQ-DI ≥0.35 units in the LTE trial[a]

Conclusion: For pts remaining in LTE trial, tofacitinib efficacy was greater in bDMARD-naïve vs TNFi-IR pts; response was maintained over time in both groups. Incidence rates were higher for TEAEs and numerically higher for SAE, SI and HZ (all tofacitinib) in TNFi-IR vs bDMARD-naïve pts. Results consistent with other advanced PsA treatments. Limitations included small event numbers, as observed data and BL characteristic differences.

MODULATION OF SERUM BIOMARKERS IN PATIENTS WITH PSA TREATED WITH RISANKIZUMAB IN THE PHASE 3 KEEPSAKE 2 STUDY

Keywords: Psoriatic arthritis, Biomarkers, Clinical trials

B. Ravishankar[1], P. Lal[1], T. Sornasse[1], B. Wang[2], Y. Bi[3], M. Saltarelli[1], Y. Fang[1], B. Padilla[4], J. F. Merola[5], O. Fitzgerald[6]. *[1]AbbVie Inc, Precision Medicine Immunology, South San Francisco, United States of America*; *[2]AbbVie Inc, Data Science and Statistics, North Chicago, United States of America*; *[3]AbbVie, Data Science and Statistics, Worcester, United States of America*; *[4]AbbVie Inc, Immunology Clinical Development, North Chicago, United States of America*; *[5]Harvard Medical School, Brigham and Women's Hospital, Boston, United States of America*; *[6]University College Dublin, Conway Institute for Biomolecular Research, Dublin, Ireland*

Background: Risankizumab (RZB) is a selective interleukin (IL) 23 p19 subunit monoclonal antibody that inhibits IL-23. RZB 150 mg has shown greater improvements in key clinical domains such as skin, joints, enthesitis, and dactylitis compared with placebo (PBO) in patients with active psoriatic arthritis (PsA) in the global phase 3 trials KEEPsAKE 1 (NCT03675308) and KEEPsAKE 2 (NCT03671148) [1,2].

Objectives: To elucidate the mode of action of RZB in patients with PsA by assessing the dynamics of circulating protein biomarkers in the KEEPsAKE 2 study.

Methods: Serum samples from patients who participated in the optional biomarker exploratory analysis in the KEEPsAKE 2 study (PBO, n=189; RZB 150 mg, n=183) were used for this analysis. A commercially available multiplexed Proximity Extension Assay platform was used to assess the levels of 92 inflammation-related protein biomarkers (BMs) and a validated immunoassay was used to evaluate beta-defensin 2 (BD-2) in serum samples collected at baseline, week 4, and week 24. Changes from baseline in protein levels were expressed as log2 fold change. A repeated measure mixed linear model was used to determine BMs modulated by RZB. Correlations between relative BM levels and disease activity measures were derived using Pearson's correlation; Psoriasis Area and Severity Index (PASI) was transformed as log10 (x+1) before the analysis.

Results: Key demographics and baseline characteristics for the subset of patients included in the biomarker evaluation were comparable between PBO and RZB and were consistent with those reported in the total population for the clinical study. At baseline, the relative levels of 10 BMs (chemokine ligand 20 [CCL20], IL-17A, IL-17C, IL-24, IL-6, S100 calcium-binding protein A12 [S100A12], oncostatin M [OSM], vascular endothelial growth factor A [VEGF-A], C-X-C motif chemokine ligand 1 [CXCL1] and colony stimulating factor 1 [CSF-1]) positively correlated with at least 1 baseline disease activity measure. IL-6 was significantly and positively correlated with the inflammation marker high sensitivity C-reactive protein [hsCRP]) and musculoskeletal endpoint (Psoriatic Arthritis Disease Activity Score [PASDAS]). CCL20, IL-17A, IL-17C, and BD-2 (BMs known to contribute to psoriasis) were correlated with baseline PASI. RZB treatment significantly decreased IL-17A, IL-17C, IL-6, and BD-2 compared with PBO treatment at week 4 (the earliest time-point when samples were available), with further decreases continuing through week 24 (**Figure 1**). In patients with PsA treated with RZB the decrease in IL-6 correlated with PASDAS improvement, while the decrease in BD-2 correlated with PASI improvement.

Conclusion: IL-23, a cytokine that is important in the generation, maintenance, and proliferation of Th17 cells, serves as a major contributor to the pathophysiology of PsA [3]. Treatment with the IL-23 inhibitor RZB downregulated biomarkers associated with musculoskeletal and skin-related disease activity, and resulted in a favorable clinical response for patients with active PsA. Further investigation is needed to assess the possible relationship between changes in IL-23–related biomarkers at week 4 and long-term clinical response.

POS1546 PATIENTS WITH PSORIATIC ARTHRITIS AT BIOLOGIC THERAPY SWITCH: THE COREVITAS PSORIASIS REGISTRY

Keywords: Registries, Psoriatic arthritis

P. J. Mease[1], E. Jones[2], A. Sima[3], S. Beaty[4], R. Low[4], B. Gomez[4], M. Gurrola[3], M. Lebwohl[5]. *[1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rhuematology, Seattle, United States of America*; *[2]CorEvitas, LLC, Epidemiology, Waltham, United States of America*; *[3]CorEvitas, LLC, Biostatistics, Waltham, United States of America*; *[4]UCB Pharma, Immunology, Smyrna, United States of America*; *[5]Icahn School of Medicine at Mt. Sinai, Dermatology, New York City, United States of America*

Background: Up to 40% of patients with psoriasis (PsO) develop psoriatic arthritis (PsA), which can have a significant impact on health-related quality of life (HRQoL) [1]. Among patients with both PsO and PsA (PsO/PsA) who are treated with a biologic agent, individual symptom profiles and response to treatment can vary, with many patients switching biologic agents over their disease course. Whether patient-centred factors, beyond skin clearance, influence biologic switching remains a critical gap in the medical literature.

Objectives: To evaluate the association of psoriatic disease burden with biologic agent switch among patients with PsO/PsA in a real-world setting.

Methods: This study included data from the CorEvitas PsO Registry, a prospective, multicentre, non-interventional registry that collects data at ~6-month intervals. Biologic therapy initiations by patients with plaque PsO and dermatologist-diagnosed PsA or history of ≥3 PsO Epidemiology Screening Test (PEST) score who initiated a biologic agent at a registry visit and had ≥1 visit in the subsequent 30 months between April 2015 and August 2021 were included in this study. Disease burden at each follow-up visit after biologic initiation was defined by combinations of Psoriasis Area and Severity Index (PASI) level (≤10 vs >10) with Dermatology Life Quality Index (DLQI) level (≤5 vs >5) or patient-reported joint pain (VAS-100) level (<40 vs ≥40) [2]. The outcome of biologic switch, defined as a start of a different biologic agent within 45 days of discontinuing the initial biologic, was assessed at each follow-up visit. Proportional hazards regression was used to calculate hazard ratios (HR) and 95% confidence intervals (CIs) to evaluate associations between disease burden categories and biologic switch, adjusted for age, sex, race, ethnicity, duration of PsO, baseline disease burden category, body mass index (BMI), employment status, number of comorbidities, and treatment history.

Results: There were 2,580 patient-initiations included in this study. The mean age at patient-initiation was 52 years (Standard Deviation=13) and 52% occurred in females. Over 56% of patient-initiations were obese (BMI≥30), and 27% had at least one comorbidity. Twenty percent of patient-initiations switched biologic agents over 30 months of follow-up after a median (Interquartile Range) of 6.5 (4.6, 12.4) months of treatment. Patients with combined highest skin involvement and impact on HRQoL (PASI>10 & DLQI>5) were 14 times more likely to switch biologic (HR=14.2; 95% CI: 10.7, 18.9) than those with the lowest combined skin involvement and impact on HRQoL (PASI≤10 & DLQI≤5). Patients with DLQI>5 were over five times more likely to switch biologic vs the DLQI≤5 group among patients with PASI≤10 (HR=5.25; 95% CI: 4.23, 6.51) and nearly twice as likely to switch biologic among those with PASI>10 (HR=1.70; 95% CI: 1.06, 2.71). Similarly, patients with joint pain ≥40 had nearly a four times higher likelihood of switching vs the pain <40 group among those with PASI≤10 (HR=3.78; 95% CI: 2.91, 4.92) and tended to be more likely to switch biologic in patients with PASI>10 (HR=1.35; 95% CI: 0.79, 2.33).

Conclusion: Patients with PsO/PsA treated in a real-world clinical setting with more significant disease burden due to impaired HRQoL (DLQI and joint pain) after initiation were more likely to switch biologic agents, regardless of PASI level. These findings suggest that patient-centred factors, as well as skin clearance, have an important impact on the occurrence of biologic agent switch and the management of patients with PsO/PsA.

Background: BDMARD treatments in patients with psoriatic arthritis (PsA) are initiated after insufficient response to csDMARD either in monotherapy or by in parallel continuing csDMARDs. Here, the value of MTX in combination with bDMARDs in PsA is still unclear. We designed an investigator-initiated, randomized, placebo-controlled trial (IIT) in active PsA to examine the potential impact of MTX-continuation or -initiation parallel to newly started UST on different outcomes beyond clinical examination (MSUS; PsASon22 score [1]).

Objectives: To compare sensitive imaging efficacy outcomes measured by MSUS changes [PsASon22] from week 4 and 24 to baseline in UST+PBO vs UST+MTX (stratified to ongoing or new onset of MTX treatment).

Methods: A total of 186 patients with active PsA (defined as TJC≥4, SJC≥4 [68/66 joint count] and DAS28≥3.2) were screened for eligibility. 173 patients were randomized to UST+MTX (new or ongoing) or UST+PBO. 84 patients were included in the subgroup analysis with MSUS scoring of PsASon22 at BL, weeks 4 and 24. Results were compared between the groups with prior MTX treatment (UST+ ongoing MTX or UST+PBO) and with new initiation of MTX to UST (UST+ new MTX or UST+PBO) according to the study design.

Results: BL data were well-balanced between treatment groups (UST+MTX, n=44; UST+PBO, n=40) and subgroups with exception of slightly higher age (mean age 53.3 years) and more (45%) female patients in the UST with ongoing MTX group. All baseline data are shown in Table 1. After UST initiation, improvement of inflammatory activity measured by MSUS using PsASon22 score was seen early at week 4 in all treatment groups. The improvement was delayed in patients with previous MTX failure ("prior MTX") and, in overall less pronounced compared to the patients without previous MTX treatment (Figure 1). At week 24,

clinical meaningful changes in PsASon22 score were seen in all treatment groups but with most prominent differences in both treatment groups with UST+PBO.
Conclusion: IL12/23 inhibition with UST is an effective treatment for active PsA independent of MTX use. Data from this IIT indicate that additional MTX has no positive impact on UST efficacy for musculoskeletal manifestations such as arthritis and enthesitis measured sensitively by PsASon22 ultrasound score validated for PsA monitoring. Moreover, by monitoring in MSUS, patients on UST monotherapy seem to benefit best from the treatment.

Background: Enthesitis in patients with psoriatic arthritis (PsA) can be a therapeutic challenge.
Objectives: To explore the impact of tumor necrosis factor inhibitors (TNFi) on enthesitis in patients with PsA in the EuroSpA collaboration network [1].
Methods: Prospectively collected data from biologic-naïve PsA patients ≥18 years at diagnosis, who initiated a TNFi between 2010-2020 and had available baseline data on enthesitis (defined as tenderness at any enthesis included in the Maastricht Ankylosing Spondylitis Enthesitis Score (MASES, mainly axial entheses) and/or Spondyloarthritis Research Consortium of Canada score (SPARCC, peripheral entheses) were pooled from European countries in the EuroSpA collaboration. Changes from baseline to follow-up (6-24 months) in enthesitis scores were calculated both for the first (TNFi-1) and second TNFi (TNFi-2), as were the percentage of sites with complete resolution of enthesitis.
Results: Demographics and clinical variables of the 723 patients who had a baseline evaluation by MASES (N=549) and/or SPARCC (N=358) are detailed in Table 1. Of these, 192 (35%) and 239 (66.8%) had enthesitis by MASES (3.1±2.4, mean±standard deviation) and SPARCC (3.9±3.4) scores, respectively. The patterns of involvement are shown in Figure 1. MASES/SPARCC baseline and follow-up scores for TNFi-1 were available for 93/85 patients, respectively. Corresponding values were 27/38 patients for TNFi-2. Following TNFi-1, 58 (62.4%) patients (MASES) and 43 (50.9%) patients (SPARCC) achieved complete resolution of enthesitis. These proportions were lower following TNFi-2. SPARCC sites observed an overall lower site-specific enthesitis resolution as compared to MASES sites (61.1% vs 76.2% for TNFi-1).
Conclusion: Real-life registry data on enthesitis from several European countries are presented. Enthesitis resolution was observed in a substantial proportion of patients with PsA following TNFi-1.

BETTER DRUG SURVIVAL ON MONOCLONAL ANTIBODIES COMPARED TO ETANERCEPT IN FIRST LINE ANTI-TNF THERAPY IN PATIENTS WITH PSORIATIC ARTHRITIS MAY BE DUE TO DIFFERENTIAL THERAPEUTIC RESPONSE IN SKIN INVOLVEMENT: A PROPENSITY SCORE-MATCHED ANALYSIS FROM THE NATIONWIDE CZECH ATTRA REGISTRY

Keywords: Psoriatic arthritis, Skin, bDMARD

Š. Tichý[1], L. Nekvindová[2], J. Baranová[2], K. Pavelka3, P. Horak[4], J. Vencovský5, J. Zavada3. [1]*Institute of Rheumatology, Department of Rheumatology of the 1st Faculty of Medicine and Rheumatology Institute, Prague, Czech Republic*; [2]*Institute of Biostatistics and Analyses, Ltd, Institute of biostatistics and analyses, Brno, Czech Republic*; [1]*Institute of Rheumatology, Department of Rheumatology of the 1st Faculty of Medicine and Rheumatology Institute, Prague, Czech Republic*; [4]*University Hospital Olomouc, Third Department of Internal Medicine - Nephrology, Rheumatology and Endocrinology, Olomouc, Czech Republic*; [1]*Institute of Rheumatology, Department of Rheumatology of the 1st Faculty of Medicine and Rheumatology Institute, Prague, Czech Republic*

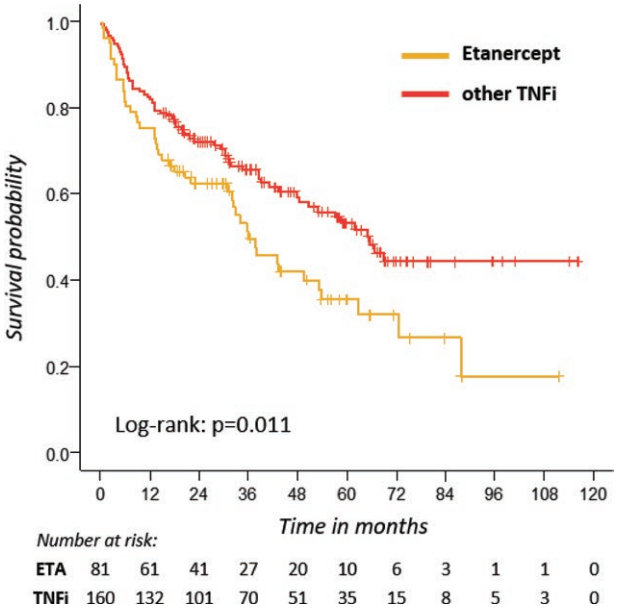

Figure 1. Drug survival of etanercept vs. other TNF inhibitors in patients with PsA.

Background: Etanercept is an agent of specific molecular structure and its efficacy in extraarticular disease differs from monoclonal antibodies. This could affect drug survival in some rheumatic diseases with a larger presence of extraarticular involvement.
Objectives: To compare the drug survival of etanercept to monoclonal anti-TNF antibodies in psoriatic arthritis and describe the response of skin disease to treatment in the two groups.
Methods: Patients with PsA starting first-line biological treatment from 01/01/2012 to 30/06/2020 were enrolled from the Czech ATTRA registry and split into two groups as either being treated with etanercept (ETA) or any other anti-TNF. Propensity scores were calculated using covariates based on statistically significant differences in the baseline characteristics and clinical relevance (Table 1). PS was then used to match 81 etanercept to 160 other TNFi patients. We performed a Kaplan-Meier survival analysis and checked for statistical significance using the log-rank test. We calculated survival rates at set time points, median survival time in each group and the hazard ratio of etanercept for drug discontinuation. The Physician global assessment of psoriasis variable (measured on a numerical rating scale 0-5) was sorted in categories of mild (0-1), intermediate (2-3) and severe (4-5) and respective percentages were calculated in the propensity-matched groups at 3, 6, 12 and 24 months. Pearson's chi-squared test or Fisher's exact test were used to check the differences for statistical significance.
Results: We found significantly worse drug survival on ETA compared to other TNFi at each time point (Figure 1). The median survival time on ETA was 35.8 (95% CI 25.1 – 46.6) months compared to 65.7 (95% CI 51.9 – 79.6) months on other TNFi. The HR of ETA for treatment termination was 1.61 (95% CI 1.11 - 2.34), p=0.011. At baseline, there were no differences in skin disease severity. The percentages of mild, intermediate and severe skin disease were 22.2%, 59.3% and 18.5% on etanercept and 25.0%, 55.6% and 19.4% on other TNFi, p=0.853. At 3 months, skin disease was significantly more severe in ETA with 50.0%, 44.8% and 5.2% compared to 76.2%, 23.8% and 0% on other TNFi, p<0.001. At 12 months, the respective percentages were 66.6%, 31.9% and 2.1% on ETA and 84.7%, 15.3% and 0% on other TNFi, p=0.015; at 24 months 62.9%, 37.1% and 0% compared to 84.9%, 15.1% and 0%, p=0.010.
Conclusion: Etanercept had worse drug retention than monoclonal antibodies in PsA. Patients treated with ETA had more severe skin disease during follow-up compared to those treated with other TNFi, which could lead to earlier switching to another drug.

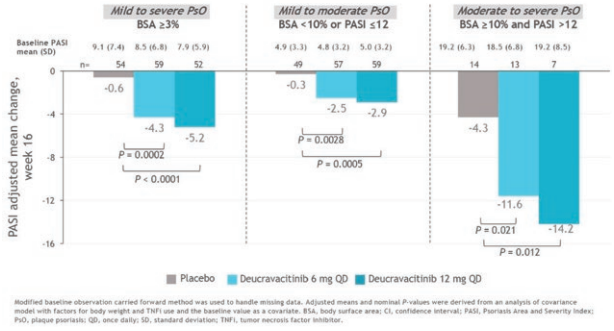
IMPACT OF ORAL, SELECTIVE, ALLOSTERIC TYROSINE KINASE 2 (TYK2) INHIBITOR, DEUCRAVACITINIB, ON PSORIASIS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM A PHASE 2 TRIAL

Keywords: Skin, Targeted synthetic drugs, Psoriatic arthritis

A. B. Gottlieb[1], A. Armstrong[2], J. F. Merola[3], A. Napoli[4], M. Nowak[5], S. Banerjee[6], T. Lehman[7], P. J. Mease[8]. *[1]Icahn School of Medicine at Mount Sinai, Dermatology, New York, United States of America*; *[2]University of Southern California, Dermatology, Los Angeles, United States of America*; *[3]Brigham and Women's Hospital, Brigham Dermatology Associates, and Harvard Medical School, Dermatology and Rheumatology, Boston, United States of America*; *[4]Bristol Myers Squibb, WW Medical I&F, Princeton, United States of America*; *[5]Bristol Myers Squibb, Clinical R&D, Princeton, United States of America*; *[6]Bristol Myers Squibb, Clinical Development, Princeton, United States of America*; *[7]Bristol Myers Squibb, WW Medical Immunology, Princeton, United States of America*; *[8]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Rheumatology, Seattle, United States of America*



Background: TYK2 mediates signaling of key cytokines (eg, IL-23) involved in plaque psoriasis (PsO) and psoriatic arthritis (PsA) pathogenesis. Deucravacitinib (DEUC) is a first-in-class, oral, selective, allosteric TYK2 inhibitor approved in multiple countries for the treatment of adults with PsO. This was based on superiority of DEUC to apremilast and placebo (PBO) in a variety of PsO disease activity measures in 2 phase 3 trials in patients with moderate to severe PsO [1,2]. In addition, DEUC was efficacious on multiple measures of arthritis severity compared with PBO in a phase 2 trial in patients with active PsA who had ≥1 PsO lesion (≥2 cm) [3]. In patients with body surface area (BSA) ≥3% at baseline (mild to severe; 80% of patients in this trial), a greater proportion of patients achieved a ≥75% reduction in Psoriasis Area and Severity Index (PASI 75) with DEUC treatment (6 mg QD: 42.4%, *P*=0.01; 12 mg QD: 59.6%, *P*<0.0001) vs PBO (20.4%) at week (wk) 16.
Objectives: This analysis further evaluated the impact of DEUC on PsO in patients with PsA in the phase 2 trial.
Methods: The phase 2 double-blind PsA trial randomized patients (N=203) 1:1:1 to PBO, DEUC 6 mg once daily (QD), or 12 mg QD. After wk 16 (Part A), patients could enroll in an optional, double-blind period until wk 52 (Part B). In Part B, patients receiving DEUC who achieved minimal disease activity (MDA) at wk 16 continued DEUC treatment to wk 52. Measurements of PsO disease activity, including mean BSA, mean PASI score, and achievement of PASI and BSA thresholds, were assessed.
Results: At baseline (BL), PsO characteristics were generally comparable across treatment groups, with most patients (≥74%) having mild to moderate PsO (BSA <10% and PASI ≤12; **Table 1**). At wk 16, significant decreases from BL in mean PASI score were observed with DEUC treatment vs PBO both in patients with mild to moderate PsO as well as in those with moderate to severe PsO (BSA ≥10%; PASI >12) (**Figure 1**). These significant changes in PASI were observed in the mild to moderate PsO population even with very low BL PASI scores. Significant decreases in PASI from BL were observed with DEUC treatment vs PBO in both patients with background csDMARD use (DEUC 6 mg, -4.0 and 12 mg, -4.9 vs PBO, -2.3; *P*<0.05 for both) and those without csDMARD use (-3.7 and -4.0 vs -2.5, respectively; *P*<0.001, for both). At wk 16, a greater proportion of patients treated with DEUC vs PBO achieved PASI ≤1 in patients with mild to severe PsO (DEUC 6 mg, 32.2% and 12 mg, 44.2% vs PBO, 18.5%) and in patients with moderate to severe PsO (23.1% and 28.6% vs 0.0%, respectively). In mild to severe PsO, decreases in mean PASI score at wk 16 were maintained through wk 52 in patients who continued treatment with DEUC 6 mg (absolute PASI score, wk 16: 2.39, wk 52: 1.22) and 12 mg (wk 16: 0.64, wk 52: 0.24).
Conclusion: Treatment with DEUC significantly improved PsO in patients with PsA, regardless of BL PsO severity and background csDMARD use. Of note, improvement in the subgroup of patients with moderate to severe PsO in this trial was comparable to that observed in the phase 3 POETYK PSO-1 trial in patients with moderate to severe PsO [1].

POS1551 DRUG SWITCHING DUE TO INEFFICACY IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH BIOLOGICAL AGENTS. DAILY CLINICAL EXPERIENCE

Keywords: Psoriatic arthritis, bDMARD, Epidemiology

M. Rodríguez Laguna[1], D. Freites Nuñez[1], M. P. Álvarez[1], J. P. Otazu Moudelle[1], C. Martinez Prada[1], L. León[2,3], B. Fernandez[1], L. Abasolo[2]. *[1]Hospital Clínico San Carlos, Rheumatology, Madrid, Spain*; *[2]Instituto de Investigación Sanitaria San Carlos (IdISSC), Rheumatology, Madrid, Spain*; *[3]Universidad Camilo José Cela, Health Sciences, Madrid, Spain*

Background: Psoriatic arthritis (PsA) is a chronic and heterogeneous inflammatory disorder that requires targeted treatment. Biological agents are often one of the first therapy regiment; however, PsA patients can experience a first line biological drug lack of efficacy. Although there are currently a variety of therapies, there is a gap of knowledge to identify the correct treatment algorithms that can be followed when PsA patients need to switch their therapy due to inefficacy.
Objectives: To evaluate the switching therapy regimens due to inefficacy in PsA patients on treatment with biological agents.
Methods: Retrospective longitudinal observational study. Subjects: Cohort of patients who assisted the outpatient rheumatology clinic from January 2006 to December 2021, and followed up to June 2022, diagnosed with PsA according to ICD-10 code and on treatment with biological agents. Main outcome: Switching of a first line of biological treatment due to inefficacy. Covariables: Sociodemographic, clinics and treatment. Statistical analysis: To estimate biological agent switching inefficacy rates, survival techniques were used, expressing the incidence rate (IR) per 100 patients*year with their respective CI at 95% [CI 95%].
Results: 141 patients with a diagnosis of PsA and on treatment with biological agents were included, with an 893.09 Patients*year follow-up. 52.48% were female, the mean age was 48.06 ± 13.22 years and 94 (80.34%) were actively working. 105 patients (74.47%) presented peripheral arthritis and 22 (15.60%) inflammatory low back pain as principal clinical domain. 108 (76.60%) patients had a history of psoriasis at baseline. 262 courses of treatment were recorded. Throughout the follow-up, Tumor necrosis factor inhibitor (TNFi) was the most used biological agent with 192 courses (73.28%) flowed by interleukin-17 inhibitors with 43 (16.41%) courses of treatment. 243 courses were on combination therapy, 185 (76.13) with methotrexate. Describing the switching due to inefficacy, 109 were recorded with a 12.20 IR [10.11-14.72], similar IR occurred according to age range, 79 occurred in female sex (IR 18.28 [14.66-22.79]), 27 (IR 18.12 [12.43-26.42]) presented inflammatory low back pain, 7 (IR 49.54 [23.61-103.91]) had dactylitis and 16 (IR 30.80 [18.87-50.28]) enthesitis. 67 (IR 11.04 [8.67-14.02]) switching had previous history of psoriasis and 65 (IR 10.73 [8.41-13.68]) were on combination therapy with methotrexate. Table 1, shows the therapy regimens switching inefficacy rates for each type of drug.
Conclusion: The biological drug switching rate due to inefficacy in our study was 12.20 per 100 patients*year. In this description study, we have identified some clinical disease manifestations and therapy regimen factors that might affect the drug switching due to inefficacy on PsA. TNFi seems to be the drug with the lowest rate of switching due to inefficacy in our study.

Table 1. Incidence rates of drug switching due to inefficacy per 100 *patient year in PsA patients treated with biological agents.

	Patients*year	Events (n)	IR	95% CI
Total, discontinuation	893.09	109	12.20	10.11 – 14.72
Abatacept	5.90	2	33.88	8.47 – 135.50
Interleukin-17 inhibitors	70.84	18	25.40	16.01 - 40.33
Ustekinumab y Guselkumab	10.29	5	48.59	20.23 - 116.75
JAK inhibitors	14.06	5	35.56	14.80 - 85.45
Tumor necrosis factor inhibitors	792.00	79	9.97	8.00 – 12.43

POS1604 IL-13 INHIBITION USED FOR ATOPIC DISEASES IS ASSOCIATED WITH RISK OF PSORIATIC ARTHRITIS

Keywords: Spondyloarthritis, Psoriatic arthritis, Genetics/epigenetics

S. S. Zhao[1], K. Hyrich[1,2], Z. Yiu[3], A. Barton[2,4], J. Bowes[4]. *[1]University of Manchester, Centre for Epidemiology Versus Arthritis, Manchester, United Kingdom*; *[2]Manchester University NHS Foundation Trust, NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom*; *[3]NIHR Manchester Biomedical Research Centre, Centre for Dermatology Research, Manchester, United Kingdom*; *[4]University of Manchester, Centre for Genetics and Genomics Versus Arthritis, Manchester, United Kingdom*

Background: Inhibitors of the IL-13 pathway, such as dupilumab and tralokinumab, are licensed to treat atopic diseases such as eczema and asthma. Musculoskeletal adverse events that resemble enthesitis and psoriatic arthritis (PsA) after dupilumab initiation have been reported, but evidence is limited to case reports and spontaneous pharmacovigilance with uncertain causal inference. Naturally occurring genetic variation in drug targets can provide insight into their potential adverse effects.
Objectives: To investigate whether genetically proxied IL-13 inhibition (IL-13i) increases risk of PsA and other spondyloarthritis-related diseases.
Methods: Dupilumab is recognised to reduce eosinophil count in clinical studies; we therefore used it as the biomarker of IL-13i. We instrumented IL-13i using missense (protein coding) variants within the *IL13* gene that are associated with circulating eosinophil count at genome-wide significance ($p<5x10^{-8}$) in a study of 563,946 individuals. Outcome genetic associations were taken from studies of PsA, psoriasis, Crohn's disease, ulcerative colitis, ankylosing spondylitis and iritis. To examine instrument validity, we used atopic eczema and asthma as positive control outcomes, and rheumatoid arthritis as a negative control. We used the ratio method, with estimates scaled to per standard deviation (SD ~$0.14x10^9$/L) reduction in eosinophil count.
Results: One missense variant, rs20541, was selected to proxy IL-13i. Genetically proxied IL-13i was associated with increased risk of PsA (OR 37.39; 95%CI 11.52, 121.34), psoriasis (OR 20.08; 4.38, 92.01), Crohn's disease (OR 3.49; 1.38, 8.81), but not ulcerative colitis, ankylosing spondylitis or iritis. IL-13i was associated with reduced risk of positive control outcomes, but not with the negative control (Table 1).
Conclusion: Genetically proxied IL-13 inhibition is associated with increased risk of PsA, psoriasis and Crohn's disease, which may be a class effect relevant to

other IL-13i that are not yet reported to have Th17-type adverse events. These findings are compatible with the hypothesis that Th2 cytokines IL-4/-13 may act as a restraint toward Th17-type disease activation in some organs. Clinicians assessing adverse events after dupilumab initiation should be aware of incident PsA and related features. This study demonstrates the value of genetic instrumental variable analyses in evaluating rare adverse events in the study of drug safety.

Table 1. Effect of genetically proxied interleukin-13 inhibition on psoriatic arthritis and related diseases.

Outcome	Number of cases/ controls	Odds ratio	95% confidence interval	p
Psoriatic arthritis	3,609/ 9,192	37.39	11.52, 121.34	$1.64x10^{-9}$
Psoriasis	10,588/22,806	20.08	4.38, 92.01	$1.12x10^{-4}$
Crohn's disease	5,956/14,927	3.49	1.38, 8.81	0.01
Ulcerative colitis	6,968/20,464	0.92	0.40, 2.13	0.85
Ankylosing spondylitis	9,069/13,578	0.94	0.80, 1.10	0.45
Acute and subacute iritis	3,126/209,287	1.12	0.47, 2.64	0.80
Atopic eczema (positive control)	10,788/30,047	0.12	0.06, 0.23	$8.49x10^{-11}$
Asthma (positive control)	56,167/352,255	0.21	0.16, 0.28	$9.25x10^{-30}$
Rheumatoid arthritis (negative control)	14,361/43,923	0.85	0.37, 1.98	0.71

POS1605 A PROOF-OF-CONCEPT STUDY EVALUATING THE USE OF FUNCTIONAL BRAIN MAGNETIC RESONANCE IMAGING IN ASSESSING TREATMENT RESPONSE IN PSORIATIC ARTHRITIS PATIENTS

Keywords: Psoriatic arthritis, Pain, Imaging

E. Espartal[1], X. Michelena[1], S. Marsal[1], A. Rovira[2], D. Pareto[2], A. Erra[1]. [1]*Vall Hebron University Hospital, Rheumatology Department, Barcelona, Spain*; [2]*Vall Hebron University Hospital, Section of Neuroradiology (Department of Radiology, IDI), Barcelona, Spain*

Background: Inflammatory cytokines can alter the way the central nervous system processes pain as shown in patients with rheumatoid arthritis [Rech et al., 2013]. However, the relationship between TNFα inhibition and pain processing in individuals with psoriatic arthritis (PsA) has not been investigated.

Objectives: To assess the feasibility of functional magnetic resonance imaging (fMRI) paradigm to estimate the respone to pain and the effect of treatment in PsA patients (pts).

Methods: 6 pts with active PsA eligible to start a TNFi were included: 3 were naïve to biological disease modifying anti-rheumatic drugs and 3 were experienced. Four healthy subjects (HS) were also included. Subjects were scanned in a 3.0T scanner at baseline (BL) and week 1 (W1) after starting treatment. Each acquisition included 2 fMRI runs. The physician selected a swollen and tender joint (affected joint) and a control joint in the contralateral hand (non-affected joint). First, the brain pain response was investigated pressing the non-affected joint followed by the affected joint. The fMRI effect of pressure was represented for each subject individually, for each time point ($p<0.0001$ uncorrected level, minimum extension 10 voxels). We provided a descriptive analysis of the differences in PsA pts brain response between BL and W1 and the clinical response evaluated by the percentage of improvement of Disease Activity in Psoriatic Arthritis (DAPSA) score and visual analogue scale pain (VASp) change.

Results: All subject's demographic characteristic and PsA patients' clinical response are shown in Table 1. Brain response to pressure in HS produced activation in the sensory motor cortex, with more or less involvement of additional areas in the prefrontal, parietal and temporal cortex. In PsA pts with a higher treatment response (PsA 1, 2, 5), the brain response to pressure did not show any activation at BL whilst sensory motor cortex activation was seen at W1, with amygdala and insula activation in pts PsA 2 and 5 and prefrontal and frontal activity in pts PsA 1 and 2. In those with less response (PsA 3, 4, 6), the sensory motor cortex was activated at BL with little changes when evaluated at W1 (Figure 1). No evident differences in brain response activation were observed between naïve and TNFi experienced patients.

Conclusion: The proposed fMRI paradigm seems to be a promising candidate to predict response to treatment with TNF inhibitors in PsA patients. Studies with more patients are needed to confirm our preliminary results.

Table 1. All subject's demographic characteristic and PsA patients' clinical response

Variables	HS1	HS2	HS3	HS4	PsA1	PsA2	PsA3	PsA4	PsA5	PsA6
Age (year)	48	30	26	59	61	52	47	66	23	63
Sex (F/M)	F	F	F	F	M	F	F	M	F	F
BMI	20	17	20	22	34	24	29	30	19	19
TJC BL					6	15	13	22	7	8
SJC BL					5	12	3	11	6	5
CRP BL (mg/dL)					0.27	0.35	0.80	0.60	0.33	0.45
CRP W1 (mg/dL)					0.04	0.05	0.44	0.16	0.14	0.20
TNFi naive					Yes	Yes	Yes	No	No	No
DAPSA improvement (%)					57	46.4	22.6	12.8	70.4	16.6
VASp change (Δmm)					-14	-21	-5	0	-51	-7

HS: healthy subject; PsA: psoriatic arthritis patient; BMI: body mass index; TJC: tender joint count; SJC: swollen joint count; CRP: C-reactive protein; TNFi: TNF inhibitor; VASp: visual analogue scale pain; BL: baseline; W1: week 1.

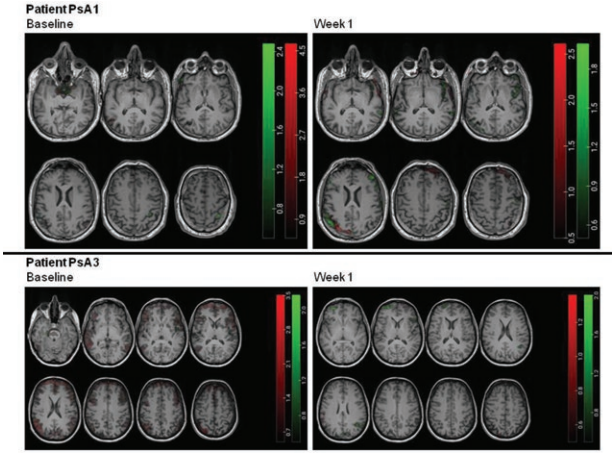

Figure 1 : Brain fMRI response to pressure of the non-affected joint (green) and the affected joint (red) overlaid on top of the structural image. Upper panel corresponds to a patient with clinical improvement (PsA1) and lower panel to a patient that did not respond (PsA3) at baseline (left column) and week 1 (right column). Differences are observed in the sensorimotor cortex activation between patients: there is an increase in the activation after week 1 in PsA1 while PsA3 showed activation at baseline but not in week 1.

POS1606 DIFFERENTIAL AND COMBINATORIAL MECHANISM OF ACTION OF GOLIMUMAB AND GUSELKUMAB IN ULCERATIVE COLITIS INDUCTION THERAPY: IL-23 BLOCKADE DRIVES RESTORATION OF NORMAL EPITHELIUM AND MUCOSAL HEALING

Keywords: Clinical trials, Organ damage, Remission

P. Desai[1], P. Branigan[1], D. Richards[1], D. Mcgonagle[2], M. Vetter[1], D. Cua[1], T. Freeman[1]. [1]*Janssen Research & Development, LLC, Immunology, Spring House, PA, United States of America*; [2]*Leeds Biomedical Research Centre, University of Leeds, Leeds, United Kingdom*

Background: The combination treatment of golimumab (GOL), a tumor necrosis factor-alpha (TNFα) antagonist, and guselkumab (GUS), an interleukin (IL)-23 inhibitor was shown to induce higher rates of clinical remission, endoscopic improvement, and histologic remission than each monotherapy in a randomized phase 2 induction study in TNFα-naïve patients with moderate-to-severely active ulcerative colitis (UC) (VEGA; NCT03662542).
Objectives: To investigate the underlying mechanism of action of GOL, GUS, and the combination (GUS+GOL).
Methods: Colon biopsies were obtained at screening and at Week 12 in patients who received GOL (n=48), GUS (n=52), or GUS+GOL (n=50). Tissue transcriptional profiles were determined with RNA-seq. Differentially expressed genes were analyzed in the context of cell-type specific transcriptional modules by first defining a gene correlation network and unsupervised network clustering. We then developed a method to create a single-cell-derived co-expression network using published UC single-cell data to provide high-resolution gene modules associated with specific cell types and pathways. Gene set variation analysis (GSVA) was used to quantitatively assess changes in specific biologic modules in the context of responder and non-responder analyses.
Results: By Week 12, combination therapy induced a greater magnitude of transcriptional changes in the colon compared with each monotherapy (Table 1). These genes were associated with IL-23/Th17/myeloid-related processes, inflammation, and epithelial homeostasis. Significant changes were observed in Th17 cells and inflammatory epithelial cell modules in patients that achieved endoscopic improvement (subscore 0 or 1) at Week 12 compared with non-responders (Table 1). The magnitude of change relative to baseline was greater in the GUS monotherapy and GUS+GOL arms compared with GOL alone. These changes were consistent with a decrease in crypt destruction in responders at Week 12, as observed by histologic changes in the Geboes score. Genes modulated by GUS+GOL were indicative of greater suppression of inflammation, particularly myeloid cell activation and inflammatory fibroblast development. In contrast, genes modulated by either GUS or GUS+GOL were associated with increased epithelial normalization and decreased Th17 activity compared to GOL alone.
Conclusion: Combination induction with GOL+GUS for 12 weeks drove a greater reduction in inflammation and improvement in epithelial homeostasis compared to each monotherapy, demonstrating the differential and complementary mechanisms of action of TNFα and IL-23 blockade. Combination therapy drives a significant increase in the overall magnitude of response with marked improvement in the restoration of normal epithelium.

Table 1. Differentially expressed genes at Week 12 compared with baseline pre-treatment

	Golimumab	Guselkumab	Combination
Number of genes up at Week 12	633	495	4,776
Number of genes down at Week 12	709	613	4,867
Th17 module: Responder vs Non-Responder Week 12 (p-value)	<0.001	<0.001	<0.001
Th17 module: Responder Week 12 vs Baseline (p-value)	<0.05	<0.001	<0.001
Th17 module: Non-Responder Week 12 vs Baseline (p-value)	NS	0.01	<0.001
Epithelial module: Responder vs Non-Responder Week 12 (p-value)	<0.01	<0.001	<0.001
Epithelial module: Responder Week 12 vs Baseline (p-value)	<0.05	<0.001	<0.001
Epithelial module: Non-Responder Week 12 vs Baseline (p-value)	NS	<0.01	<0.001

P-values associated with GSVA enrichment of biologic modules associated with endoscopic response and at Week 12.

POS1607 BIOLOGICS THERAPIES FOR PSORIASIS DECREASE FUTURE RISK FOR DEVELOPING PSORIATIC ARTHRITIS

Keywords: bDMARD, Disease-modifying drugs (DMARDs), Psoriatic arthritis

A. Dotan[1], N. Ben-Shabat[1], D. Mcgonagle[2], H. Amital[1], A. Watad[1].
[1]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel-Hashomer, Israel, Sackler Faculty of Medicine, Tel-Aviv University, Department of Medicine 'B', Ramat-Gan, Israel; *[2]The Leeds Teaching Hospitals NHS Trust & Leeds Institute of, University of Leeds, Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Psoriasis (PsO) is an inflammatory skin disorder with an estimated worldwide prevalence of 2–4% [1]. Psoriatic arthritis (PsA) is highly associated with higher severity of PsO, present in up to 30% of patients and 0.3–1.0% of the global population and PsA typically develops after PsO [1,2]. There are some contradictory studies in relationship to the impact of biological therapies for PsO in relationship to the prevention of PsA.
Objectives: To ascertain whether biological therapies for pre-existing psoriasis (PsO) may reduce the incidence of psoriatic arthritis (PsA) according to different treatment regimens for PsO ranging from topical therapy to biological therapy.
Methods: We conducted a retrospective exploratory study with real-world data from the third largest Israeli health maintenance organization, 'Meuhedet' which covers approximately 1,300,000 subjects. All patients of 'Muehedat' diagnosed with PsO from January 2000 until January 2020 were included in the analysis. Overall, 61,003 patients with PsO were detected. In addition, each PsO patient was paired with four control subjects by gender, age, and ethnicity. Patients diagnosed with PsA before the diagnosis of PsO or less than six months after were excluded from the analysis. We defined PsO according to physicians' diagnoses. PsA included patients with either peripheral or axial arthritis. Patients were classified according to their treatment; Group 1-topical therapy, phototherapy or no therapy, Group 2 - conventional DMARDs (cDMARDs; methotrexate or sulfasalazine), Group 3 -biologics DMARDs (bDMARD) The incident cases of PsA were analyzed according to the aforementioned different lines of therapy. Patients in the bDMARDs group were further sub-grouped according to the first-line prescribed treatment. Time-dependent Cox proportional hazard models were used to evaluate the adjusted risk of developing PsA by treatment group. Data analysis was conducted with Python Software Foundation, Python Language Reference, version 3.9.12, R version 4.2.0, RStudio (RStudio Team, 2020), and the 'Survival' package (v3.2; Therneau, 2020).
Results: 58,671 patients were included contributing a total of 628,228 patient-years. This analysis was adjusted to gender, body mass index (BMI), age of PsO diagnosis, time from psoriasis diagnosis to the group treatment, and number of biological treatments lines. Adjusted Cox proportional hazards regression analysis showed that the risk of developing PsA in PsO patients treated with cDMARDs was significantly higher in comparison to those treated with topical therapy (HR: 2.76, CI: 2.19 – 3.48, p-value: <0.001). On the contrary, the analysis also showed that the risk of developing PsA in PsO patients was significantly decreased in those treated with biological agents in comparison to topical therapy (HR: 0.62, CI: 0.42 – 0.90, p-value: <0.014).
Conclusion: PsO patients treated with cDMARDs are at higher risk of developing PsA in comparison to those treated with topical therapy alone which may reflect the severity of extent of psoriasis in the c DMARD group been linked to PsA. Biological therapy decreased risk of developing PsA in comparison to topical therapy.

POS1608 **MIRNA BIOMARKERS FOR ARTICULAR AND CUTANEOUS RESPONSE TO METHOTREXATE IN PSORIATIC ARTHRITIS**

Keywords: Genetics/epigenetics, Disease-modifying drugs (DMARDs), Psoriatic arthritis

O. Cruz Correa[1], D. Ganatra[1], A. Garrido[1], R. Machhar[1], S. Lively[2], M. Kapoor[2,3], D. D. Gladman[1,4]. *[1]Schroeder Arthritis Institute, Krembil Research Institute, Psoriatic Arthritis Research Program, Toronto, Canada*; *[2]Schroeder Arthritis Institute, Krembil Research Institute, Osteoarthritis Research Program, Toronto, Canada*; *[3]University of Toronto, Department of Surgery and Department of Laboratory Medicine and Pathobiology, Toronto, Canada*; *[4]University of Toronto, Division of Rheumatology, Faculty of Medicine, Toronto, Canada*

Background: Psoriatic arthritis (PsA) is a chronic, progressive disease associated with psoriasis that can lead to joint damage, disability, and increased mortality. Early diagnosis and management of inflammation is essential for improving clinical outcomes. Methotrexate (MTX) is the recommended first-line treatment for early PsA patients with polyarthritis and relevant skin involvement, however many patients are unresponsive to therapy. MicroRNA (miRNA) modulate gene expression at a post-transcriptional level and constitute a promising source of biomarkers that could enable the future personalization of treatment plans.
Objectives: To identify a set of miRNAs that serve as biomarkers for MTX treatment response by comparing miRNA expression between responders and non-responders before initiation of therapy.
Methods: From our prospective PsA database we identified biologic-naive PsA patients satisfying the CASPAR criteria before the initiation and 6 months after MTX treatment. Articular response to MTX was defined as achieving a treatment target of low disease activity (4 ≤ DAPSA < 14) or remission (DAPSA < 4). Cutaneous response to MTX was defined as a reduction of at least 50% in PASI score. miRNA expression was evaluated in biobanked serum samples through next-generation sequencing. Differential expression was assessed by linear modelling with empirical Bayes moderation (using the Limma R package). Linear models were corrected for sequencing batch, age, sex, ethnicity, BMI, smoking, use of NSAIDs, MTX treatment duration and dose. Enrichment of biologic pathways corresponding to gene targets of the identified miRNAs was examined using the integrative tool pathDIP by restricting the analysis to literature curated pathways and experimentally detected protein-protein interactions with a prediction confidence of 0.99.
Results: 70 biologic-naive, PsA patients were included in the study. Articular and cutaneous response to MTX was observed in 28.57% and 34.28% of patients, respectively. Pretreatment expression of miR-127-3p was significantly lower in patients showing an articular response to MTX ($p<0.001$). Of note, miRNA 127 expression has been associated with a protective effect in inflammatory lung fibrosis and osteoarthritis[1]. A set of 7 miRNAs (miR-155-5p, miR-140-3p, miR-432-5p, miR-382-5p, miR-532-5p, miR-139-3p, and miR-379-5p) were significantly associated ($p<0.01$) with cutaneous response to MTX. The most commonly enriched signaling pathway targeted by these miRNAs is the PI3K/AKT/mTOR which is a key regulator of keratinocyte proliferation[2].

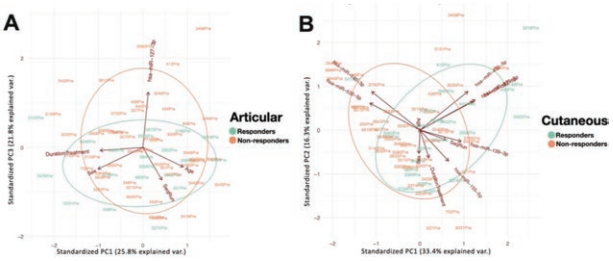

Figure 1. Principal component analysis of samples before methotrexate (MTX) treatment. A. Patients showing articular response to MTX (reaching treatment target of low disease activity or remission: DAPSA score below 14) present lower expression of miR-127-3p. B. Patients showing cutaneous response to MTX treatment (reaching a reduction of 50% in PASI) present lower expression of miR-140-3p and miR-532-5p and higher expression of miR-155-5p, miR-432-5p, miR-382-5p, miR-139-3p and miR-379-5p.

Conclusion: We identified miR-127-3p as a biomarker of articular response, and 7 other miRNAs as biomarkers of cutaneous response to MTX treatment in PsA patients.

NO BURN-OUT IN PEDIATRIC-ONSET BEHÇET'S DISEASE PATIENTS DURING ADULTHOOD FOLLOW-UP

Keywords: Behcet's disease

T. Bozkurt[1], M. Karabacak[2], H. Karataş[1], S. Kutluğ Ağaçkıran[2], T. Ergun[3], H. Direskeneli[2], F. Alibaz-Oner[2]. *[1]Marmara University School of Medicine, Department of Internal Medicine, Istanbul, Turkey*; *[2]Marmara University School of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[3]Marmara University School of Medicine, Department of Dermatology, Istanbul, Turkey*

Background: Although onset of Behçet's Disease (BD) is common in the second or third decade, initial symptoms occur under the age of 16 years in 4–26% of the patients [1].
Objectives: In this study we aimed to assess the clinical course of pediatric onset BD in adulthood period.
Methods: The files of 1114 BD patients were reviewed retrospectively. 51 (4.6%) (F/M:21/30) pediatric-onset BD patients were included in the analysis. Demographic and clinical characteristics, follow-up and treatment data of the patients were recorded from files.
Results: The median age at diagnosis was 16 (14-17) years, and the median follow-up duration was 51 (26-96) months. Of all patients, 33.3% (n=17) had ocular involvement, 27.5% (n=14) had vascular involvement, 17.6% (n=9) had central nervous system involvement, and 3.9% (n=2) had gastrointestinal system involvement. Erythema nodosum was more common in females (p=0.008) and vascular involvement was more common in males (p=0.025). At the end of follow-up, 32 (62.8%) patients had major organ involvement, half of them had at the time of diagnosis. Forty-seven (M:27/F:20) patients had a follow-up with median of 50 (20-82) months in adulthood period. Thirty-one (65.6%) patients had major organ involvement. While 20 (64.5%) patients had major organ involvement in the pediatric period, 11 (35.5%) patients developed major organ involvement in adulthood. Overall, 19 (40.4%) patients had active disease manifestations (relapse and/or new major organ involvement) in adulthood follow-up. Of these patients, 11 (57.9%) had new major organ involvement, 7 (36.8%) had a relapse of the same organ, and one (5.3%) had both new major organ involvement and a relapse. The disease course of patients is seen in Table 1.
Conclusion: Our results show that, about half of the pediatric-onset BD patients still have active disease manifestations (mainly new major organ involvement) in adulthood period.

Table 1. Disease course of patients followed in adulthood period.

Patients followed in adulthood	**n=47 (%)**
Major organ involvement in childhood	20 (42.6%)
Relapse or/and new major organ involvement	*8 (17%)*
No relapse or major organ involvement	*12 (25.5%)*
Mucocutaneous disease in childhood	27 (57.4%)
New major organ involvement	*11 (23.4%)*
No major organ involvement	*16 (34%)*

POS1553

THE SIGNIFICANT ASSOCIATION OF HLA-A26 WITH UVEITIS AND GASTROINTESTINAL INVOLVEMENT IN PATIENTS WITH BEHÇET'S DISEASE IN A MULTICENTER STUDY

Keywords: Behcet's disease

T. Nakajima[1], H. Tsuji[1], R. Inaba[2], R. Saito[1], K. Nishimura[2,3], A. Morinobu[1]. *[1]Kyoto University, Rheumatology and Clinical Immunology, Kyoto, Japan*; *[2]Kurashiki Central Hospital, Endocrinology and Rheumatology, Kurashiki, Japan*; *[3]Kobe University, Rheumatology and Clinical Immunology, Kobe, Japan*

Background: Specific haplotypes of human leukocyte antigen (HLA) are associated with susceptibility and disease activity of Behçet's disease (BD). However, the clinical importance of HLA-A26 in BD is not well recognized compared to that of HLA-B51.
Objectives: This study aimed to examine the association between HLA-A26, HLA-B51, clinical manifestations, and disease severity in BD, especially focusing on HLA-A26 possession.
Methods: This study was a multicenter cross-sectional observational study and patients with BD were enrolled from 2006 to 2021. All patients met the International Criteria for BD [1] or the diagnostic criteria of the Behçet's Disease Research Committee of Japan [2]. Disease severity was evaluated using Krause score reflecting the entire spectrum of disease manifestations [3]. Both serotypes and genotypes were accepted for HLA typing.
Results: In total, 200 patients were enrolled in this study. Uveitis was observed in 95/196 patients (48.5%) and gastrointestinal involvement in 57/167 patients (34.1%). HLA haplotypes were identified for HLA-B51 (n = 52/106, 49.1%), HLA-A26 (n = 25/88, 28.4%), and both HLA-B51 and HLA-A26 (n = 6/88, 6.8%). While HLA-A26 showed no significant association with clinical manifestations without adjustment for HLA-B51, HLA-A26 possession showed a higher frequency of uveitis (HLA-A26 positive vs. negative: n = 6/6, 100% vs. n = 16/32, 50.0%, respectively, p = 0.03) and higher Krause scores (median: 7 vs. 5, respectively, p = 0.02) under conditions with HLA-B51. Furthermore, the association between uveitis and gastrointestinal involvement was influenced by HLA-A26: HLA-A26 possession was associated with a higher frequency of uveitis in patients with gastrointestinal involvement (HLA-A26 positive vs. negative: n = 5/9, 55.6% vs. n = 0/21, 0%, respectively, p = 0.001), as well as for gastrointestinal involvement in patients with uveitis (HLA-A26 positive vs. negative: n = 5/11, 45.5% vs. n = 0/24, 0%, respectively, p = 0.001). All 5 patients with both uveitis and gastrointestinal involvement had HLA-A26 (HLA-A26 positive vs. negative: n = 5/21, 23.8% vs. n = 0/58, 0%, respectively, p = 0.001).
Conclusion: HLA-A26 was associated with severity of BD and uveitis in patients with HLA-B51, and was associated with coexistence of uveitis and gastrointestinal involvement. This study suggested the importance of confirming HLA-A haplotype in patients with BD.

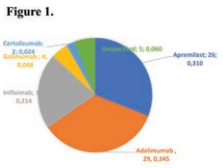
Background: Recurrent oral and genital ulcers are the most nagging clinical manifestations of Behcet's disease (BD) and colchicine should be used first for the treatment and prevention of ulcers relapse. In contrast, TNF-α inhibitors (TNFi) are helpful in resistant cases, leading to a rapid improvement of mucosal lesions [1]. More recently, the phosphodiesterase-4 inhibitor apremilast was evaluated in two RCTs showing a significant improvement of oral ulcers compared to placebo [2, 3]. Moreover, several observational studies also investigated the effectiveness of apremilast in BD patients with mucosal ulcers [4].

Objectives: To date, there are no comparative data about the effectiveness between TNFi and apremilast in mucocutaneous involvement of BD. The present study aims to compare the effectiveness between TNFi and apremilast on oral ulcers of BD.



Methods: Data on patients classified as BD (according to International Criteria for BD and International Study Group criteria) who underwent apremilast or TNFi for refractory oral ulcers from March 2017 to January 2022 in 7 tertiary rheumatology centers (6 Italian and 1 Spanish) were retrospectively analyzed. Retrieved data including demographics and clinical characteristics were collected. We also recorded the presence of active oral aphtosis at either baseline, 3-month and 6-month follow-up as well as the occurrence of oral ulcers during the intervals between visits. Patients on TNFi were considered controls for nearest-neighbour propensity score (PS-)-matching (neighbours for replacement matching, minimum 1, maximum 4). PS is an epidemiological tool used for the adjustment of non-randomized longitudinal studies. It is a conditional probability of being exposed to a disease given an asset of covariates. In brief, this was carried out using the patients' age, disease duration and gender, with a selected calliper of 0.2. Chi-square test was used to test difference between proportions of patients with active aphtosis in both groups at different follow-up times.

Results: Among 159 patients with BD on TNFi or apremilast, the matching algorithm retrieved 84 patients. More in detail, 26 patients in the apremilast group and 58 patients in TNFi group. All had active aphtosis at treatment start. Clinical ad demographic characteristics of patients at baseline are reported in Table 1 and Figure 1 and 2. Concerning proportion of patients with active oral aphtosis, no difference was observed either at 3-month (p=0.60) and 6-month (p=0.66) follow-up visits (Figure 2). Consistently, the rate of flares in the time intervals between visits was not different between groups (46.15% vs 37.93% from month 0 to 3, p=0.47; 34.62% vs 34.48% from month 3 to 6, p=0.99).

Conclusion: The main limitations of our study are the small sample size and the short-term follow-up. Nevertheless, we provide evidence that apremilast and TNFi show similar effectiveness, inducing a meaningful and early benefit in BD patients with refractory oral ulcers.

POS1555

MEASUREMENT OF COMMON FEMORAL VEIN WALL THICKNESS IS A USEFUL DIAGNOSTIC TOOL TO DIFFERENTIATE OCULAR BEHÇET'S DISEASE FROM OTHER INFLAMMATORY UVEITIS

Keywords: Ultrasound, Behcet's disease

S. Kutluğ Ağaçkıran[1], E. Kardes[2], A. Ağaçkıran[3], H. Direskeneli[1], F. Alibaz-Oner[1]. *[1]Marmara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*; *[2]University of Health Sciences, Umraniye Training and Research Hospital, Department of Opthalmology, Istanbul, Turkey*; *[3]University of Health Sciences, Umraniye Training and Research Hospital, Department of Radiology, Istanbul, Turkey*

Background: Diagnosis of Behçet's Disease (BD) can be challenging, especially in patients presenting with single major organ involvement. Our group showed that common femoral vein (CFV) wall thickness measured by Doppler ultrasonography (US) can be a non-invasive diagnostic method [1] and can also be used to diagnose incomplete BD [2]. Since ocular involvement of BD may result in irreversible vision loss if untreated, it is important to diagnose without delay and initiate immunosuppressive therapy promptly.

Objectives: In this study, we aimed to assess the discriminative role of CFV wall thickness measurement in uveitis associated with BD compared to other inflammatory uveitis.

Methods: Patients with BD uveitis (n=41) and age-gender matched 58 non-BD uveitis patients were included in the study. Demographics, clinical characteristics, and treatment data were recorded during routine visits. CFV wall thickness was measured by an experienced and blinded radiologist on the same day.

Results: Twenty-four (58.5%) of BD patients and 23 (39.7%) of non-BD patients were male. All BD patients had panuveitis. 3 (3.0%), 8 (8.1%), 8 (8.1%) of non-BD patients have anterior uveitis due to sarcoidosis, HLA-B27 positivity, ankylosing spondylitis, respectively, and 7 (7.1%) had idiopathic anterior uveitis. 12 non-BD patients had panuveitis caused by sarcoidosis. The most common complaint was decreased visual acuity in both groups. Right CFV (0.73 mm± 0.08) and left CFV (0.73 mm± 0.07) wall thickness of BD patients was significantly higher than right and left CFV (0.57 mm± 0.1 for both) wall thickness of non-BD patients (p < 001).

Conclusion: Diagnosis of ocular BD can be challenging, especially when there is no other clinical finding or organ involvement specific to BD. Our results suggest that measurement of CFV wall thickness by Doppler US can be helpful for the differentiation of ocular BD from other causes of inflammatory uveitis in daily practice.

POS1556 EFFICACY OF APREMILAST TREATMENT FOR ARTHRITIS IN BEHÇET'S DISEASE

Keywords: Behcet's disease, Disease-modifying drugs (DMARDs)

R. Wakiya[1], Y. Ushio[1], H. Shimada[1], S. Nakashima[1], T. Miyagi[1], K. Sugihara[1], R. Mino[1], M. Mizusaki[1], K. Chujo[1], T. Kameda[1], H. Dobashi[1]. [1]Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa, Japan

Background: The arthritis that occurs in Behcet's disease (BD) is considered to be an oligoarthritis but one of the intractable symptoms related to quality of life [1]. Apremilast is effective for oral ulcers in BD, but its efficacy against arthritis has not been well established.
Objectives: This study aims to determine the effect of apremilast treatment on arthritis in BD.
Methods: Patients diagnosed with BD disease between January 2011 and June 2022 who had a history of arthritis within the past five years were included in this study. Patients with Behçet's disease treated with apremilast were compared with those not treated (control group). Frequency of oral and genital ulcers, skin lesions, arthritis, and other typical domains of Behcet's disease, evaluated every 3 months for 12 months. The number of tender and swollen joints and DAS28 as indicators of arthritis activity and Behçet's disease activity form (BDCAF) as an indicator of disease activity were investigated retrospectively.
Results: There were 55 patients with Behçet's disease available for analysis in this study, 16 of whom were treated with apremilast. There was no clear difference between the two groups for pre-existing BD disease domains. Active lesions at the beginning of the analysis included significantly more oral ulcers and skin pustules in the apremilast group than in the control group, but there was no significant difference in the incidence of arthritis (Table 1). Similarly, there were no significant differences in the number of swollen joints, tender joints, or serum CRP levels between the two groups. The frequency of having arthritis was present in 56.3% of the apremilast group at baseline and decreased in the apremilast group at 3 and 6 months, but remained unchanged in the control group (Figure 1). In the apremilast group, not only did oral ulcers, genital ulcers, and skin pustular lesions improve after 3 and 6 months, but DAS28 and BDCAF also significantly decreased after 3 months (DAS28: p = 0.0010, BDCAF: p = 0.0019).
Conclusion: Apremilast is effective against arthritis as well as skin mucosal lesions in BD and could be one of the treatment strategies for arthritis in BD.

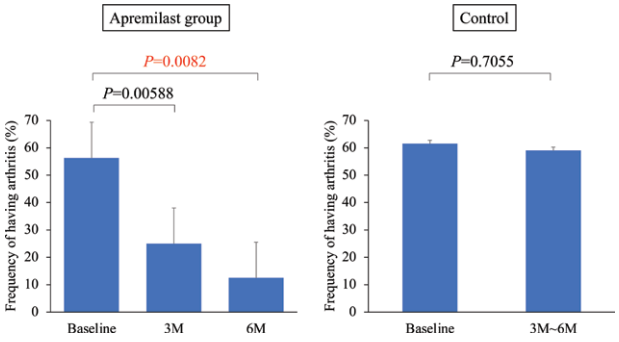

Figure 1. Effect of apremilast treatment on the rate of specific organ lesionsThe graph summarizes changes in the rate of oral ulcers, genital ulcers, skin lesions, and arthritis in the control group and at baseline (0M), 3 (3M), and 6 (6M) after apremilast treatment. P-values were determined using McNemar test. M, months.

POS1557 MUSCULOSKELETAL ULTRASOUND IN PATIENTS WITH HEREDITARY ANGIOEDEMA DUE TO C1-INHIBITOR DEFICIENCY: PROBING DISEASE ACTIVITY AND DAMAGE

Keywords: Descriptive studies, Rare/orphan diseases, Ultrasound

P. Triggianese[1], G. Raffone[1], A. D'antonio[1], E. Greco[1], S. Modica[1], A. Bergamini[1], M. S. Chimenti[1]. [1]*University of Rome Tor Vergata, Rheumatology Allergology and Clinical Immunology, Rome, Italy*

Background: Hereditary angioedema (HAE) due to C1 esterase inhibitor protein (C1INH) deficiency is a rare disorder (1:50000) that is characterized by widely variable and potentially fatal attacks of subcutaneous and submucosal swelling which are generally self-limiting. The defect of C1INH allows for a dysregulated kallikrein–kinin pathway, and thus for the overproduction of bradykinin with, in turn, the consequent activation of the bradykinin B2 receptors. The resulting increased vascular permeability induces painful angioedema attacks most often involving the hands. Musculoskeletal ultrasound (MSUS) enables evaluation of the soft tissues, providing additional and more accurate assessment of inflammation and visualization of structural damage.
Objectives: To explore the potential damage at the site of angioedema attack, we performed an US-study of hands and wrists in consecutive C1INH-HAE patients referring to the HAE Reference Centre at "Tor Vergata" University Hospital in Rome (Italy).
Methods: Consecutive C1INH-HAE patients underwent biochemical analyses and, in the same day, MSUS evaluation that has been performed by an expert rheumatologist at wrists and hands. The US (Esaote MyLab™X75, 4-15 MHz) semi-quantitatively graded subcutaneous tissue edema, synovitis/tenosynovitis-like lesions, erosions, osteophytes, and bone edema according to the 2021 Outcome Measures in Rheumatology (OMERACT). HAE Quality of Life Questionnaire (HAE-QoL) and HAE Activity Score (HAE-AS) were registered.
Results: 94 C1INH-HAE patients from 50 independent families (aged 43.2 ± 17 yrs) has been included, with 60% females and 20.6% smokers. All patients experienced recurrent acute attacks at the hands: a third of the cohort (31.3%) was on long-term-prophylaxis at the time of the study and 20% of subjects had the last acute attack more than 12 months before. In 75% of the cohort, the HAE-QoL described a mild-moderate QoL and HAE-AS showed a mild disease activity. Smokers were prevalent among patients in high disease activity than in patients in low disease activity (P<0.05). High level of C-reactive protein (≥5 mg/dl) has been documented in 13.8% of patients while rheumatoid factor and anti-cyclic-citrullinated-peptide-antibody (ACPA) resulted in rare cases (2.1% for both). A vitamin D deficiency (< 7 ng/dl) has been registered in 3.6% of patients although insufficient vitamin D (7-30 ng/dl) resulted in 50% and hyperuricemia (>7 mg/dl) in 4% of cases. ANA titer≥1:160 occurred in 25.5%. The joint pain at the hands/wrists have been reported by 70% of patients: patients with joint pain showed a lower mean C1INH antigen level and a higher number of attacks in the last 3 months than patients without (P<0.05). Patients with at least 1 US lesion (62.8%) were significantly older and affected by a greater number of angioedema attacks than patients without lesions (37.2%, P<0.05 for both). US lesions were mainly represented by osteophytes (63.5%) and cartilage damage (35.3%). Synovitis/tenosynovitis involving at least 1 joint has been documented in 44.7% of the cohort but a positive Power Doppler signal was revealed in rare cases (2.1%). The subcutaneous tissue edema resulted in a third of the cohort (29.8%). Cartilage damage and subcutaneous edema was similarly distributed among hands and wrists. The distal radioulnar joints were the most affected (25.5%) while metacarpophalangeal were affected in 17.6% of cases. Synovitis/tenosynovitis was mild-moderate in 98% of cases. In patients showing subcutaneous tissue edema, it was documented in 78.7% of cases at the hands and in 21.3% at the wrists.

Conclusion: C1-INH-HAE patients reported pain at joint level in an elevated frequency. Our findings support the role of MSUS in C1-INH-HAE patients by highlighting that US lesions at the specific sites of attacks, although mild, occur in more than a half of patients and appear to be linked with the age and/or disease duration and the number of attacks.

Background: Autoinflammatory periodic diseases (AID) can be treated with the interleukin-1β inhibitor canakinumab (CAN). CAN has been shown to be safe and effective in controlled trials and routine clinical practice.

Objectives: In this study general safety parameters in patients with canakinumab in cryopyrin-associated periodic syndromes (CAPS), familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and tumor necrosis factor receptor-associated periodic syndrome (TRAPS) on CAN therapy were investigated in routine clinical practice.

Methods: RELIANCE is a prospective, non-interventional, observational study in Germany enrolling pediatric (age ≥2 years) and adult patients with a clinically confirmed diagnosis of AID who routinely receive CAN. Efficacy and safety parameters are recorded at baseline and assessed at 6-month intervals.

Results: Data from N=232 patients (N=229 with baseline visit yet documented) diagnosed with autoinflammatory diseases enrolled in the RELIANCE registry between October 2017 and December 2022 were included in the present interim analysis. Median age of the total study cohort was 20.0 years (2–80 years), 52% were female and median duration of CAN treatment before study entry was 2 years (0–15 years). During the study, 898 adverse events (AE) occurred in N=164 patients (71%). Among the most common AE classified as suspected adverse drug reactions (ADR) were decreased neutrophil count (8 events, IR 1.46), increased inflammatory markers (12 events, IR 2.19), nasopharyngitis (14 events, IR 2.55), and pyrexia (17 events, IR 3.10). In N=35 patients (15%), a total of 98 serious adverse events (SAE) were reported. Of these events, 31 SAE were classified as suspected adverse drug reactions (SADR; Table 1). During the last 3 years of observation within the study, incidence rates (IR) decreased from 76.21 to 51.44 (ADR) and 7.44 to 5.66 (SADR). Patients receiving greater than standard dose CAN experienced higher levels of ADR/SADR compared to patients under less than standard and standard dosing. How much high dosage or severeness of disease contribute to this phenomenon remains unclear. AE related dose reductions have not been reported. **Conclusion:** The 48-month interim data of the RELIANCE study confirm sustained safety of long-term treatment with CAN in the entire study population.

Table 1. Overview of adverse events in the RELIANCE study across all study indications (N=232 patients).

AE	Number of events		IR‡ per 100 patient-years	
All types of AE	898		163.82	
ADR	282		51.44	
SAE	**Number of events**		**Incidence rate‡ per 100 patient-years**	
All types of SAE	98		17.88	
SADR	31#		5.66	
Patients with adverse drug reactions by dose category, n (%)	**Less than standard dose (N=58)**	**Standard dose (N=60)**	**Greater than standard dose (N=85)**	**Dose missing (N=29)**
ADR	13 (22.4)	15 (25.0)	37 (43.5)	10 (34.5)
SADR	2 (3.4)	2 (3.3)	7 (8.2)	1 (3.4)

#Abdominal pain, Alport's syndrome, appendicitis, arthralgia, blister, cardiovascular disorder, chest pain, circulatory collapse, dehydration, diplopia, dyspnoea, erythema, febrile convulsion, gastroenteritis, glomerulonephritis, Haemophilus test positive, myalgia, oedema, pneumonia, premature delivery, skin discoloration, tachycardia, tonsillitis bacterial, tonsillitis streptococcal, vision blurred (1 event each, IR 0.18‡), tonsillectomy (2 events, IR 0.36‡), pyrexia (3 events, IR 0.55‡), not yet coded (1 event, IR 0.18‡)‡ IR = number of events * 36525/ sum of observation days (=200218)ADR, suspected adverse drug reaction; AE, adverse event; SADR, suspected serious adverse drug reaction; SAE, serious adverse event

POS1559

THE CHARACTERISTICS OF THE PATIENTS UNDER NINTEDANIB TREATMENT DUE TO INTERSTITIAL LUNG DISEASES ASSOCIATED WITH CONNECTIVE TISSUE DISEASES

Keywords: Sjögren syndrome, Lungs, Systemic sclerosis

E. Tekgoz[1], S. Colak[1], E. Cimen Gunes[1], N. Ocal[2], D. Dogan[2], C. Tasci[2], M. Çınar[1], S. Yilmaz[1]. [1]*University of Health Sciences, Gulhane Faculty of Medicine, Rheumatology, Ankara, Turkey*; [2]*University of Health Sciences, Gulhane Faculty of Medicine, Pulmonology, Ankara, Turkey*

Background: Nintedanib provides a decline in the reduction of forced vital capacity (FVC) in patients with progressing lung fibrosis.
Objectives: To assess demographical, clinical, and radiological characteristics of the patients with connective tissue diseases (CTDs) associated interstitial lung disease (ILD), who were under nintedanib treatment.
Methods: This retrospective observational study was conducted with the patients who received nintedanib for progressing lung fibrosis associated with CTDs. The patients who had followed up between January 2020 and December 2022 included in the study. The demographical, clinical, and radiological data were obtained from patients' files.
Results: Twenty-two (14.8%) patients (11 male/11 female) with CTD related ILD who had a mean age of 65.9 ±7.6 had received nintedanib. The median disease duration was 49.5 (35.8-101.8) months for CTD and 43 (26.3-95) months for ILD. Eighteen (81.8%) patients had a CTD diagnosis prior to an ILD diagnosis. The median duration for nintedanib treatment was 10.5 (7-14.8) months. Eight (36.4%) patients had Sjogren's syndrome, 7 (31.8%) patients had systemic sclerosis, 5 (22.7%) patients had rheumatoid arthritis, and 2 (9.1%) patients had undifferentiated CTD. Ten (45.5%) patients had a history of smoking. Only one patient was using nintedanib 150 mg/day due to gastrointestinal intolerance. Hypertension was the most frequent comorbidity in 5 (22.2%) patients, and the second most frequent one was pulmonary hypertension in 3 (13.6%) patients. During 6 minutes walking test, 12 (55.5%) patients had desaturation. According to high-resolution computed tomography (HRCT) findings, 18 (81.8%) patients had usual interstitial pneumonia (UIP) pattern, and 4 (18.2%) patients had nonspecific interstitial pneumonia (NSIP) pattern. The most frequent parenchymal pattern was UIP (p<0.005). There was no mortality in the study group. Twelve (55.5%) patients had received at least one immunosuppressive treatment. Nintedanib was initiated due to the progression of fibrosis in HRCT in half of the patients or declined pulmonary function test results in the other half. All patients had worsening pulmonary symptoms. The mean FVC value of the patients at the beginning was 87±12.2 ml, and it was 89.3±14.8 ml at the 6th-month follow-up visit with no statistically significant difference (p=0.51). Four (66.7%) patients had stable findings, 2 (33.3%) patients had progression on HRCT, of whom had control HRCT under nintedanib treatment. Combined with nintedanib, cyclophosphamide (1 patient), rituximab (1 patient), azathioprine (3 patients), and mycophenolate mofetil (4 patients) were used. The most common side effect of nintedanib was diarrhea.

Table 1. Demografic and clinical characteristics of the study group

		Nintedanib (n = 22)
Gender, n (%)	Female	11 (50)
	Male	11 (50)
Age, [a] year		65.9±7.6
Disease duration for CTD, [b] month		49.5 (35.8-101.8)
Disease duration for ILD, [b] month		43 (26.3-95)
Duration of nintedanib treatment, [b] month		10.5 (7-14.8)
Sjogren's syndrome, n (%)		8 (36.4)
Systemic sclerosis, n (%)		7 (31.8)
Rheumatoid arthritis, n (%)		5 (22.7)
Undifferentiated CTD, n (%)		2 (9.1)
Desaturation with 6 minutes walking test		12 (55.5)
Interstitial lung disease, n (%)	UIP	18 (81.8)
	NSIP	4 (18.2)
FVC ml, [a] initiation		87±12.2
FVC ml, [a] 6th month		89.3±14.8
CT findings, 6th month*	Stabil, n (%)	4 (66.7)
	Progression, n (%)	2 (33.3)

CTD= Connective tissue disease, ILD= Interstitial lung disease. NSIP= Nonspecific interstitial pneumonia, UIP= Usual interstitial pneumonia, FVC= Forced vital capacity, CT= Computerize tomography[a]Mean (SD). [b]median (Q1-Q3).

Conclusion: Nintedanib is a promising agent for progressive lung fibrosis in patients with CTD-related ILD. Since physicians can safely combine it with immunosuppressive agents, more patients will benefit in the course of time. Prospective studies with longer follow-up, and larger samples are necessary to examine the role of nintedanib on lung fibrosis.

USING SURVIVAL CLASSIFICATION AND REGRESSION TREES AND SURVIVAL RANDOM FOREST TO INVESTIGATE ASSOCIATIONS AMONG FACTORS FOR CANCER PROGRESSION AND ARTHRITIS CONTROL IN A MULTI-CENTER RETROSPECTIVE COHORT OF PATIENTS WITH IMMUNE CHECKPOINT INHIBITOR ASSOCIATED INFLAMMATORY ARTHRITIS

Keywords: Prognostic factors, Inflammatory arthritides, Malignancy

D. Jannat-Khah[1], L. Cappelli[2], P. Reid[3], J. Sparks[4], N. Abdel-Wahab[5], C. Calabrese[6], C. Aude[7], N. Ghosh[7], K. K. Chan[7], A. Bass[7]. [1]*Hospital for Special Surgery, Rheumatology, New, United States of America*; [2]*Johns Hopkins University School of Medicine, Rheumatology, Baltimore, United States of America*; [3]*University of Chicago Medical School, Rheumatology, Chicago, United States of America*; [4]*Harvard Medical School, Rheumatology, Boston, United States of America*; [5]*MD Anderson, Rheumatology, Houston, United States of America*; [6]*Cleveland Clinic, Rheumatology, Cleveland, United States of America*; [7]*Hospital for Special Surgery, Rheumatology, New York, United States of America*

Background: It is unknown whether particular presentations of immune checkpoint inhibitor-associated inflammatory arthritis (ICI-IA) are associated with better cancer responses or faster time to arthritis control. Machine learning methods have the ability to determine important factors in datasets where there are often many variables.
Objectives: To identify variables associated with arthritis control and cancer progression among persons with ICI-IA.
Methods: This study is ancillary to a retrospective observational study of 147 DMARD-treated (TNFi, IL-6Ri, or methotrexate) patients with ICI-IA seen at 6 U.S sites. Variables from the medical record included demographics, patterns of swollen joints, medications, lab values, and concomitant irAEs. Arthritis control and cancer progression were the two outcomes analyzed. survival Classification and Regression trees (sCART) were created using the rpart and partykit R packages [1]. Random Survival Forest (RSF) was performed using the R package randomForestSRC [2]. Variable importance (VI) for sCART and Relative Importance Score (RIS) were computed to assess influential variables..
Results: We analyzed 147 people with ICI-IA. 69% received PD-1/PD-L1 monotherapy, and 43% had melanoma. ICI-A treatment was a TNFi in 17%, IL6Ri in 26%, methotrexate in 33%, and 24% received >1 DMARD. Median time to cancer progression was 333 (IQR 110, 811) days for the 26% that progressed. Median time to arthritis control was 109 days (IQR 32, 287) for the 93% that achieved control. For cancer progression the following were identified by both sCART and

Table 1. Demographics, Variable Importance (VIMP) from survival Classification and Regression Trees (sCART) and Relative Importance Score (RIS) from Random Survival Forest (RSF).

		Arthritis Control		Cancer Progression	
Characteristic	(%) Or median(IQR)	sCART VIMP [1]	RSF RIS [2]	sCART VIMP [1]	RSF RIS [2]
Steroid duration, days	318 (181, 658)	12	1.0	23	1
Cancer type		6	0.49	14	
First DMARD class		3	0.37	2	
>1 DMARD	36 (24.5)	11	0.33	4	0.37
ICI type*		1	0.05	5	0.22
Study site		19	0.02	8	0.36
Age (years)	62.3 (52.2, 69.0)	7	0.42	10	0.04
Maximum prednisone dose (mg)	40 (20,60)	4		6	0.10
Arthritis affected Joints					
Knee	106 (72.1)	1	0.75		
Shoulder	54 (36.7)	11		2	0.49
Wrist	82 (55.8)		0.46		0.41
Hand	111 (75.5)		0.23		0.35
Elbow	44 (29.9)	10	0.25	1	
Ankle	64 (43.5)	4	0.10		
Total Joint Count	3 (2, 4)	5	0.23	15	0.26
Characteristics ≤3 for sCART VIMP and ≤0.3 RIS from RSF		Sex, cancer stage, number of IRAEs, Sicca, thyroiditis, colitis, RF+, RF+ or CCP+, arthritis affecting hip, feet			

[1]sCART VIMP the higher the number the more influential the variable[2]sRF RIS A value of 1 indicates an influential variable; values that are negative or close to 0 are "noise" variables.*ICI combination vs monotherapy

RSF as important: steroid duration, total joint count (TJC), study site, maximum steroid dose, ICI type, shoulder arthritis, >1 DMARD and number of IRAEs. For classifying arthritis control, the following variables were found to be important in both sCART and RSF: steroid duration, >1 DMARD, elbow arthritis, age, cancer type, TJC and first DMARD (Table 1). The Figure 1 shows the sCART for arthritis control.

Conclusion: Both methods, SCART and RSF, demonstrated the important influence of steroid duration on arthritis control and cancer progression. Machine learning methods demonstrated the potential prognostic importance of specific joint involvement for each outcome- knee for time to arthritis control and shoulder and wrist for cancer progression.

MIXED CONNECTIVE TISSUE DISEASE AND COURSE OF PREGNANCY - RESULTS FROM THE NATIONWIDE PREGNANCY REGISTER REVNATUS

Keywords: Registries, Pregnancy and reproduction, Mixed connective tissue disease

H. S. Koksvik[1], B. Jakobsen[1], H. Bjørngaard[1], T. T. Pedersen[1,2], M. Wallenius[1,3]. *[1]St. Olavs hospital, Trondheim University Hospital, Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Trondheim, Norway*; *[2]Norwegian University of Science and Technology (NTNU), Department of Clinical and Molecular Medicine, Trondheim, Norway*; *[3]Norwegian University of Science and Technology (NTNU), Institute of Neuromedicine and Movement Science, Trondheim, Norway*

Background: Mixed connective tissue disease (MCTD) is a complex and multisystemic disorder of unknown etiology. MCTD is classified by the presence of antibodies to U1-RNP and associated with clinical symptoms like "puffy hands", Raynaud's phenomenon, arthritis, synovitis, sclerodactyly/acrosclerosis and/or myositis. It is commonly diagnosed in women of reproductive age. Pregnancy outcomes are reported in previous studies with discrepancies in the rate of pregnancy-related complications [1].

Objectives: To describe the course of pregnancy in patients with MCTD.

Methods: We prospectively collected data on pregnancy outcome in women with MCTD through the nationwide Norwegian quality registry on pregnancy and rheumatic diseases (RevNatus) from 2016-2022. All women were diagnosed with ICD-10 code M35.1. 48 pregnancies in 38 women were recorded. One woman had twin birth.

Results: Mean maternal age at first trimester was 31 years, (SD= 4,3). Mean disease duration was seven years (SD= 4,2). One patient had BMI > 30 at first trimester, and one patient had diabetes. Median gestational age at delivery was 37 weeks (range 25-41). No stillbirths were recorded. Two pregnancies were not planned. 69% of the women were in clinical remission at inclusion.

	At enrollment (N=48)	1. trimester (N=37)	2.trimester (N=35)	3.trimester (N=39)	delivery (N=48)	6 weeks post partum (N=48)
CRP in mg/l mean (SD)	5 (8)	4 (10)	7 (9)	3 (2)		3 (4)
CRP >5mg/l n (%)	8 (17)	4 (11)	12 (35)	3 (8)		2 (5)
patient global (VAS 0-100) mean (SD)	30 (28)	32 (32)	29 (27)	40 (28)		22 (22)
patient pain (VAS 0-100) mean (SD)	21 (21)	19 (22)	22 (23)	25 (22)		19 (22)
patient fatigue (VAS 0-100) mean (SD)	46 (28)	53 (31)	49 (31)	45 (27)		34 (24)
Use of Hydroxykloroquin n (%)	32 (67)	30 (79)	26 (74)	30 (77)		31 (65)
Miscarriages < week 12 N					4	
Birth weight (gram) of singleton mean					2995	
Birth weight (gram) of singleton born at term mean					3265	
Preeclampsia n (%)					8 (17)	
HELLP n (%)					4 (8)	
Vaginal delivery n (%)					22 (46)	
Caesarean section planned n (%)					8 (17)	
Caesarean section acute n (%)					12 (26)	

Conclusion: Most patients with MCTD in this cohort had a favourable course and outcome of pregnancy and most pregnancies were planned. Four patients were diagnosed with HELLP syndrome and we observed an increased rate of preeclampsia compared to the frequency reported in the Norwegian birth registry (NFR) (17% vs 4%) and we found lower mean birth weight in gram compared to NFR (2995 vs 3480). Hydroxykloroquin was used by a majority (>70%), of the women throughout pregnancy and might have contributed to the favorable course and outcome. Analysis on the association to specific risk factors predicting adverse pregnancy outcomes should be done in the future.

POS1562

FACTORS ASSOCIATED WITH HANDGRIP STRENGTH IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Keywords: Rare/orphan diseases, Inflammatory arthritides, Sarcopenia

M. Kulyk[1], M. Dzhus[1,2], R. Lories[3,4], K. De Vlam[3,4]. *[1]Bogomolets National Medical University, Kyiv, Ukraine, Internal Medicine Department No 2, Kyiv, Ukraine*; *[2]"Olexander Clinical Hospital of Kyiv," Ukraine, Rheumatology department, Kyiv, Ukraine*; *[3]UZ Leuven, Department of Rheumatology UZ Leuven and Skeletal Biology and Engineering Research Center, Leuven, Belgium*; *[4]KU Leuven, Department Development and Regeneration, Leuven, Belgium*

Background: Decreased handgrip strength is associated with many adverse outcomes, including increased all-cause mortality, and is considered a key criterion for sarcopenia [1, 2].
Objectives: The study aims to determine handgrip strength in young adults with juvenile idiopathic arthritis (JIA) and to detect factors associated with low handgrip strength.
Methods: The single-center, cross-sectional study included 46 young adults with JIA. Anthropometric and clinical characteristics were collected, including assessment of disease activity by DAS28 and JADAS27 indices and calculation of articular and extra-articular damage by JADI-A and JADI-E indices. To determine hand grip strength, dynamometry with Jamar hand dynamometer, three times for both hands with the time of rest and fixed the highest value, was used. Thresholds for reduced muscle strength were as follows: <27 kg for males; <16 kg for females. To determine the bone mineral density (BMD) and bone mineral content (BMC) dual photon X-ray absorptiometry (DXA) was done. Calculation of skeletal mass index (SMI=appendicular lean mass divided by height^2) was counted. Logistic regression analyses estimated the associations of the following independent variables: age, sex, BMI, disease activity, articular and extra articular damage, BMD, BMC, on the dependent variable handgrip strength. Statistical significance was defined as a p-value <0.05.
Results: The study involved 26 female and 20 male patients. The average age of the patients was 24.4±5 years; the average age at the onset of the disease was 10.1±4.4 years. Thirty-two patients had reduced muscle strength (70%). Factors associated with handgrip strength are presented in Table 1.

Table 1. Univariate logistic regression analyses: factors associated with reduced handgrip strength in young patients with JIA

Lean mass total, g		-0.00025 ± 0.00008	0.001	0.9997 (0.9996-0.9999)	0.94 (0.82 – 0.99)
Skeletal mass index, kg/m^2		-2.29 ± 0.73	0.002	0.10 (0.02 – 0.42)	0.97 (0.86 – 0.99)

Conclusion: The results of our study demonstrate a high prevalence of low handgrip strength, up to 70 % among young patients with JIA. In these participants, lower BMI, lower total BMD and arms, legs, total lean mass and SMI, longer disease duration, higher disease activity by JADAS27 and articular index damage JADI-A, and higher percentage fat were linked to reduced handgrip strength.

ARTHRITIS PHENOTYPE FOLLOWING CHECK POINT INHIBITION IS UNSPECIFIC AND SERONEGATIVE IN MOST PATIENTS – RESULTS FROM THE PROSPECTIVE OBSERVATIONAL RIMRA STUDY

Keywords: Inflammatory arthritides, Disease-modifying drugs (DMARDs), Malignancy

M. Heiberg[1], S. W. Syversen[1], K. Irgens[2], H. Bitter[3], G. Bakland[4], M. Nyakas[5], H. Ødegård[2], H. Vestaby[3], I. L. Knutsen[4], K. Bergsmark[1], E. A. Haavardsholm[1], M. D. Mjaavatten[1]. *[1]Diakonhjemmet Hospital, Center for treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Oslo, Norway*; *[2]Ålesund Hospital, Department of Rheumatology, Ålesund, Norway*; *[3]Sorlandet Hospital, Division of Rheumatology, Department of Medicine, Kristiansand, Norway*; *[4]University Hospital of North Norway, Department of Rheumatology, Tromsø, Norway*; *[5]Oslo University Hospital, Department of Oncology, Oslo, Norway*

Background: Patients with rheumatic immune related adverse events (irAEs) after cancer therapy with immune check point inhibitors represent a new challenge for rheumatologists. The incidence of irAEs is expected to increase and more knowledge about pathogenesis, disease course and treatment response is needed. The ongoing RIMRA (Rheumatic Immune Related Adverse events in patients treated with check point inhibitors) study aims to describe clinical presentation, disease course and outcome of rheumatic irAEs in patients treated with immune check point inhibitors.
Objectives: To describe baseline characteristics and treatment of arthritis patients included in the RIMRA cohort.
Methods: RIMRA is an ongoing prospective, observational study including adult patients with de novo symptoms of rheumatic disease or flare of established rheumatic disease after > 1 dose of treatment with immune check point inhibitor. Eligible patients who are referred to Rheumatology departments at Diakonhjemmet Hospital, (DH), Oslo University Hospital Rikshospitalet (RH), University Hospital of North Norway (UNN), Ålesund Hospital (ÅH) and Hospital of Southern Norway (HSN) are asked to participate in the study. Clinical and biochemical data

Values are mean (SD), if not otherwise indicated.

as well as blood samples for biobanking, are collected at study visits at baseline and after 3,6 and 12 months. Patients are treated at the discretion of the treating rheumatologist in collaboration with the oncologist.

Results: Between August 2018 and January 2023 56 patients have been included at 4 centers (DH, UNN, ÅH, HSN). 49 patients had de novo disease and 7 patients had flare of preexisting rheumatic disease (RA n=5, PsA n=2). Polyarthritis was the dominant phenotype in 45% of the patients followed by oligoarthritis and monoarthritis (Figure 1). Joint distribution was heterogenic. 7 patients were positive for RF/anti-CCP, of whom 5 had preexisting RA. Disease characteristics at baseline are presented in Table 1. The mean Clinical Disease Activity Index (CDAI) score was 18, corresponding to a level of moderate disease activity. Throughout the study period anti-rheumatic treatment has been given to the following proportions of patients: i.a steroid injection:45%, prednisolone: 71%, methotrexate: 30%, anti-TNF: 21%, tocilizumab: 1,7%, sekukinumab: 1,7 %, ustekinumab: 1,7%, leflunomide: 1,7%, apremilast: 1,7%. Death has been registered in 13 (23%) patients, of whom 10 patients had received prednisolone, 3 patients had received methotrexate and 1 patient had received anti-TNF treatment.

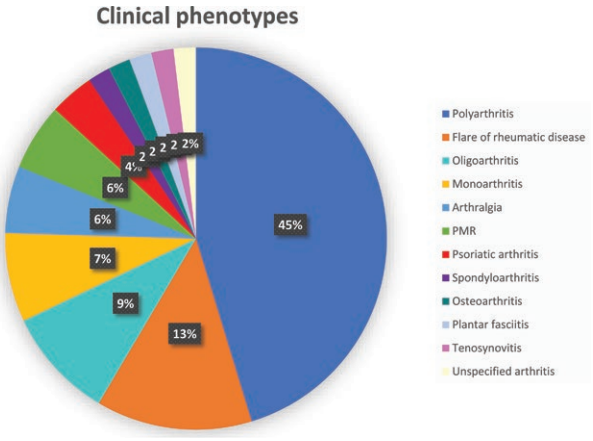

Figure 1.

Conclusion: Most patients with rheumatic immune related adverse events in the RIMRA study have seronegative inflammatory arthritis with no specific arthritis pattern/phenotype. The disease activity varies, but is on average moderately high upon referral to rheumatologist, as reflected in both CDAI and CTCAE grading at baseline. Most patients need anti-rheumatic treatment.

POS1564 AUTOIMMUNE INNER EAR DISEASE WITH A RHEUMATOLOGIC APPROACH

Keywords: Descriptive studies, Tapering, Best practices

M. Diaz Menindez[1], A. M. Chindris[2], R. Butendieck[1], Y. Li[1], C. Razvan[3], K. Britt[2], F. Berianu[1]. [1]*Mayo Clinic, Rheumatology, Jacksonville, United States of America*; [2]*Mayo Clinic, Endocrinology, Jacksonville, United States of America*; [3]*Mayo Clinic, Internal Medicine, Jacksonville, United States of America*

Background: Autoimmune inner ear disease (AIED) is a rare entity that presents with sensorineural hearing loss. In the US, the incidence rate is less than 5 per 100,000 people [1]. The pathophysiology behind the disease is thought to be a humoral and cell-mediated process that damages the cochlea [2]. Clinical presentation is characterized by fluctuating, asymmetric hearing loss that tends to progress over time. Half of patients with AIED present with vestibular (eg, dizziness, vertigo, imbalance) and other ear symptoms (eg, tinnitus, ear pressure and aural fullness) [2,3]. Diagnosis of AIED remains challenging as no diagnostic test has demonstrated high sensitivity or specificity [1]. Diagnosis remains clinical and based on response to corticosteroids, which suggests the disease's autoimmune nature. Corticosteroid-sparing agents have been used with various degrees of success [1-4].

Objectives: The aim of our study was to describe our experience treating patients with AIED with immunosuppressive therapy.

Methods: We performed a retrospective chart review of patients diagnosed with AIED at all Mayo Clinic locations for the past 10 years. AIED was diagnosed based on 3 main characteristics: progressive fluctuating hearing loss, response to high-dose corticosteroids, and audiometric evidence supporting sensorineural hearing loss. We recorded audiography results at the time of diagnosis and 1 and 3 months after treatment. We divided treatment efficacy into 2 categories: subjective (patient-reported) and objective (audiometric) improvement.

Results: Thirty-one patients met the inclusion criteria; the mean age was 48.5 years and 17 were women. Patients were initially evaluated by the Department of Otorhinolaryngology and 29 patients were subsequently referred to the Department of Rheumatology with a mean of 12.2 weeks after the first evaluation. While initial hearing loss was more commonly unilateral (21 [67.7%]), it remained unilateral in only 8 (25.8%) patients. Tinnitus, aural fulness, and ear pressure were the 3 most common ear symptoms, followed by imbalance, vertigo, dizziness, and discharge. Treatment with corticosteroids showed improvement of hearing and vestibular symptoms during the first month, but no further improvement by the end of the third month. Other immunosuppressive medications were used with various degrees of response (Table 1). Methotrexate was the second most used therapy with 11 of 17 patients reporting an improvement in symptoms.

Conclusion: Prompt treatment of these patients is vital to prevent irreversible hearing loss. Corticosteroids remain the criterion standard initial treatment; however, our study supports potential use of corticosteroid-sparing agents such as methotrexate for long-term therapy. Our study has some limitations including small patient population and a retrospective design.

POS1565 ACUTE PERICARDITIS WITH PLEUROPULMONARY INVOLVEMENT, FEVER AND ELEVATED C-REACTIVE PROTEIN: A SYSTEMIC AUTOINFLAMMATORY DISEASE? A COHORT STUDY

Keywords: Innate immunity, Lungs, Cardiovascular disease

A. M. Pisacreta[1], R. Mascolo[1], M. Nivuori[1], C. Caccia[1], G. DI Marco[1], C. Carollo[1], A. Pedroli[1], F. Casarin[1], E. Tombetti[1,2], A. Brucato[1,2]. [1]*ASST Fatebenefratelli-Sacco, Department of Internal Medicine, Milan, Italy*; [2]*Fatebenefratelli Hospital, University of Milan, Department of Biomedical and Clinical Sciences, Milan, Italy*

Background: Pericardial diseases may involve only the pericardium, or may be part of a systemic condition, with an inflammatory phenotype sharing similarities with autoinflammatory diseases.

Objectives: This cohort study aims to describe the prevalence and features of systemic phenotype of pericarditis characterized by pleuropulmonary involvement, fever, and elevation of C-reactive protein (CRP), comparing this phenotype with other forms of pericarditis.
Methods: All patients in our center were enrolled in a prospectively maintained registry from 2019 to 2022. 412 patients with idiopathic recurrent pericarditis were analyzed. "Systemic" subset was defined as the presence of all of the following criteria: fever > 38 C°, CRP higher than 2 times normal values, pleural effusion detected with any imaging techniques. The absence of any of the 3 criteria was defined as "isolated" subset.
Results: We found that 211 (51.2%) of 412 patients presented the systemic subset and the variables significantly associated with this subset in univariate analysis (p<0.001) were: higher mean age of onset 45.5 (±SD 17.2) vs 39.9 (±SD 16.4) years, higher mean CRP values 128.8 (95% CI 117.8-139.8) vs 49.9 (95% CI 41.5-58.3) mg/L, higher proportion of pericardiocentesis 40 (19%) vs 3 (1.5%), higher mean leukocyte count 13143.3 (95% CI 12790.4-13496.2) vs 9910.3 (95% CI 9556.2-10264.4)/mm^3, higher mean neutrophils number 10402.5 (95% CI 10082.1-10723) vs 6779.8 (95% CI 6505.2-7054.4)/mm^3 and lower mean lymphocyte count 1693.9 (95% CI 1621.9-1765.8) vs 2079.3 (95% CI 1979-2179.6)/mm^3. As results the neutrophil-to-lymphocyte ratio was higher in systemic phenotype: 6.6 (95% CI 6.2-6.9) vs 3.4 (95% CI 3.3-3.6). Anti-IL1 therapy was started more frequently in the systemic subgroup (55/211, 26%) than in the isolated subset (15/201, 7.5%) (p < 0.001). On multivariate analysis neutrophil count and lymphopenia, were statistically associated with the systemic subset (p < 0.001).
Conclusion: These results demonstrate the clinical relevance of the systemic phenotype in a referral center and confirm its analogy with the autoinflammatory diseases, suggesting a pivotal role of IL1 in the genesis of this subset.

SOLVING SARCOIDOSIS: A TRANSCRIPTOME-BASED META-ANALYSIS OF CLINICAL SARCOIDOSIS STUDIES ILLUSTRATES SHARED PATHOPHYSIOLOGY, EXAMINES MEDIATORS OF FIBROSIS, IDENTIFIES CANDIDATE BIOMARKERS AND SUGGESTS A THERAPEUTIC MECHANISM OF JAK INHIBITION

Keywords: -Omics, Biomarkers, Rare/orphan diseases

I. Lindquist[1], J. Rosenbaum[2], M. Friedman[1]. *[1]Oregon Health and Science University, Arthritis & Rheumatic Diseases Division, Portland, United States of America*; *[2]Legacy Devers Eye Institute, Ophthalmology, Portland, United States of America*

Background: Sarcoidosis is a systemic, non-caseating granulomatous disease driven by a dysregulated immune response to environmental antigens. Disease manifestations are driven by both active inflammation and resultant fibrosis in a wide variety of tissues, but the dynamics and mediators of these two states are not well understood. Diagnosis relies on imaging and biopsy and treatment typically includes steroids. JAK inhibitors have been utilized as steroid-sparing therapies for cutaneous and pulmonary sarcoidosis, however the mechanism is unclear.
Objectives: We performed a meta-analysis of 20 transcriptome studies on clinical sarcoidosis to explore perturbed pathways, examine mediators of fibrosis, prioritize candidate biomarkers, and study the JAK/STAT pathway.
Methods: We searched publicly available data repositories for clinical sarcoid datasets with healthy controls and at least 3 biological replicates evaluated with transcriptome analysis and found 20 studies (14 microarray and 6 RNAseq), comprising 316 sarcoid patients and 383 healthy controls. The majority of samples came from peripheral blood; tissue-based samples included lung, skin, anterior orbit, lacrimal gland and lymph nodes. We performed differential gene expression on each of the 20 studies independently with Limma (microarray) and DESeq2 (RNAseq). Results were merged for the 17,705 genes that were evaluated by at least 9 of the studies. For microarray studies, data from the probe with lowest adjusted p-value and largest absolute fold change (FC) was selected. Genes were selected for pathway enrichment analysis if at least 10 studies identified them as differentially expressed. Candidate biomarkers were genes that were consistently differentially expressed in both tissue and peripheral samples with a fold change magnitude of at least 1.5x. Pathway enrichment analysis was performed with Reactome. We mined our dataset with 232 fibrosis related genes identified by the FibROAD project and the 11 central genes of the JAK/STAT pathway.
Results: We prioritized 2,349 genes that were differentially expressed in the majority of the datasets. Unsupervised clustering of these studies showed a distinct difference between peripheral and tissue sample types. Of the 15 biomarker candidates, some have been associated with sarcoidosis (ie STAT1, ITGA6, LEF1) and others have been reported in tuberculosis (ie GBP5, ANKRD22), however the majority have not been associated with either (ie RHOH, SPTBN1, UBASH3A). Pathway enrichment identified significant perturbation of interferon signaling and antigen presentation which supports two established mechanisms of sarcoid pathophysiology: an abnormal TH1 response and existence of MHC risk alleles. Qualitative exploration of the JAK/STAT pathway (Figure 1) shows a predominant upregulation of the pathway, most strongly in STAT1 and JAK2. We prioritized 25 fibrosis related genes that were significantly differentially expressed in at least 10 of our studies and included STAT1, HBEGF, FOXP1 and JAK2.
Conclusion: This meta-analysis summarizes the current transcriptional landscape of sarcoidosis, including pathophysiology, mediators of fibrosis, biomarkers and therapeutics targeting the JAK/STAT pathway. We hypothesize that JAK2 may be an important therapeutic target for sarcoid by disrupting the JAK/STAT component of an abnormal TH1 response as well as a possible JAK2/STAT1 associated fibrosis mechanism.
Reference: Cited inline.

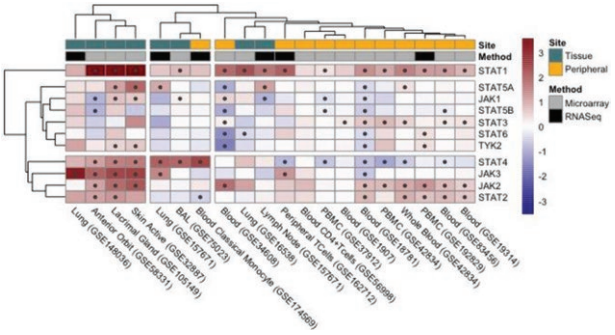

Figure 1. Meta-analysis of 11 JAK/STAT pathway genes show significant differential expression(•) which is most notable in STAT1, JAK2 and STAT2. Red indicates higher expression (log2fold change) in sarcoid compared to control.

OUTCOMES AND PREDICTORS OF CHRONIC IMMUNE CHECKPOINT INHIBITOR INDUCED INFLAMMATORY ARTHRITIS: DATA FROM THE CANADIAN RESEARCH GROUP OF RHEUMATOLOGY IN IMMUNO-ONCOLOGY (CANRIO) RETROSPECTIVE COHORT

Keywords: Inflammatory arthritides, Malignancy, Prognostic factors

A. Ladouceur[1], L. Gonzalez Arreola[2], S. Jamal[2], M. Hudson[1], J. Pope[3], S. Hoa[4], J. Roberts[5], D. Moon[6], A. Karmali[2], T. Nevskaya[3], E. Schmidt[1], N. Toban[4], L. Cho[5], T. Barnetche[7], C. Ye[6]. *[1]McGill University, Medicine, Montreal, Canada*; *[2]University of British Columbia, Medicine, Vancouver, Canada*; *[3]University of Western Ontario, Medicine, London, Canada*; *[4]Université de Montréal, Medicine, Montréal, Canada*; *[5]Dalhousie University, Medicine, Halifax, Canada*; *[6]University of Alberta, Medicine, Alberta, Canada*; *[7]CHU de Bordeaux, Médecine, Bordeaux, France*

Background: Immune checkpoint inhibitors (ICI) improve overall survival and progression-free survival in many types of malignancies and are the new pillar of cancer treatment [1]. ICIs harness a patient's own immune system to fight their cancer. However, this activation of the immune system can result in off-target immune-related adverse events (irAEs). One of the most disabling irAE is inflammatory arthritis (ir-IA) [2] affecting up to 7.5% of those treated with ICI [3]. Unlike most irAE which usually resolve within a few months, ir-IA can become chronic and persist even after ICI cessation, requiring long term immunosuppression [4]. The factors associated with chronic ir-IA and its significance regarding tumor outcomes remain largely unknown. With the increasing use of ICI in the adjuvant therapy, it is important to understand predictors and outcomes of chronic ir-IA in order to best counsel patients.

Objectives: To determine predictors and outcomes of chronic ir-IA in cancer patients exposed to ICI.

Methods: The CanRIO group, established since 2018, includes 9 academic sites in Canada and aims to describe the clinical presentation, management and outcomes of patients who developed rheumatic irAE (Rh-irAE) or those with pre-existing autoimmune diseases exposed to ICI using standardized data collection. The sites pooled data to develop a retrospective cohort of patients identified as having a Rh-irAE. We identified patients who developed ir-IA defined by new onset joint tenderness or synovitis in the absence of pre-existing rheumatic disease and who had at least 3 months of follow-up following ICI cessation. Chronic ir-IA was defined as having either persistent symptoms of ir-IA or the continued use of prednisone or DMARDs 3 months after ICI cessation.

Results: The CanRIO Retrospective Cohort included 193 ir-IA individuals of which 54 met our inclusion criteria. Forty-five of 54 (83%) had chronic ir-IA. Fifteen (33%) were female. Nineteen (42%) patients with chronic ir-IA had melanoma, 14 (31%) lung cancer and 8 (18%) genito-urinary cancer. Thirty-three (73%) were treated with anti PD-1/PD-L1, 14 (31%) with combination and none with anti-CTLA-4 only. Thirty-five (78%) were treated with conventional DMARDs and 1 (2%) with biologic DMARDs. Univariable logistic regression showed that ir-IA was more likely to become chronic in those with peripheral synovitis compared with those who did not have peripheral synovitis at presentation, (Table 1). Patients with chronic ir-IA had greater overall survival and progression-free survival compared to those with acute ir-IA (log rank tests, p<0.01), (Figure 1).

Conclusion: A large proportion of ir-IA becomes chronic. The presence of synovitis at presentation is associated with arthritis persistence. Ir-IA is associated with improved overall survival and progression-free survival.

ANAKINRA TREATMENT IN COLCHICINE RESISTANT PERICARDITIS: A SINGLE CENTER EXPERIENCE

Keywords: Rare/orphan diseases, Heart, bDMARD

Z. Toker Dincer[1], E. Yilmaz[1], M. B. Ates[1], O. Corbali[1], S. Ugurlu[1]. [1]*Istanbul University - Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Recurrent pericarditis (RP) may be encountered in autoinflammatory diseases, such as familial Mediterranean fever (FMF), however, the etiology stands principally unknown [1]. Alternative treatments have been suggested for the treatment of colchicine-resistant cases whether idiopathic or related to FMF [2].

Objectives: This study describes our experience of anakinra treatment for colchicine-resistant pericarditis cases.

Methods: All patients with pericarditis followed in our center who received anakinra since 2014 were evaluated retrospectively. Relevant data were retrieved from archives and verified with telephone interviews. Therapeutic efficacy, as well as the side effect profile, of anakinra was assessed.

Results: Our series consists of 15 patients (10 males, 5 females) with colchicine-resistant pericarditis whose demographic, clinical, and treatment features are given in Table 1. The mean age was 38.9±15.9. 6 cases were secondary to FMF and the remaining were idiopathic other than one perimyocarditis and one multisystem inflammatory syndrome in adults. Two of all patients whose autoinflammatory genetic panels were screened were detected to carry FMF mutations K695R het. and E148Q. The median follow-up duration was 53 months (range 10-174); the median number of recurrences before anakinra was 4 (range: 1-14). Ten patients (66.7 %) experienced no episode of pericarditis (mean episode count: 0.86) during anakinra treatment. Corticosteroids were discontinued in all patients except one transplant recipient. The anakinra dose of those who progressed attack-free was tapered without relapse in 5 cases, whereas 7 cases relapsed after tapering. Currently, 11 patients carry on anakinra treatment, while 3 patients stopped anakinra since remission was achieved. No side effect of anakinra was observed, with the exception of skin reaction in two patients.

Table 1. Demographic features of patients and response to anakinra therapy

Patient #	Age/ Sex	Diagnosis/ Etiology	Duration of pericarditis before anakinra treatment (mo)	Prior medication(s)	Number of recurrences before anakinra	Anakinra treatment duration (mo)	Time to corticosteroid discontinuation (mo)	Recurrences during regular anakinra treatment	Current treatment dose
1	56/F	FMF	88	CLC, CS	2	13	NA	0	100 mg/day
2	14/F	FMF	24	CLC, CS, NSAIDs	5	2	1	3	Switched to canakinumab
3	21/M	RPM	36	CLC, CS, NSAIDs	2	3	4	2	100 mg/day
4	77/M	IRP	11	CLC, CS	3	42	0	0	100 mg/3-days-in-a-week
5	49/M	MIS-A	3	CLC, NSAIDs	4	3	NA	0	Withdrawn-Remission
6	55/M	IRP	120	CLC, CS	6	29	0	1	100 mg/day
7	18/M	IRP	1	CLC, CS, NSAIDs	1	18	1	0	Remission

14	27/M	FMF	15	CLC, CS	5	49	1	0	100 mg/3days
15	23/M	FMF	8	CLC, CS	5	29	1	0	*On demand full dose

F: Female, M: Male, IRP: Idiopathic recurrent pericarditis, FMF: Familial Mediterranean fever, RPM: Recurrent Perimyocarditis, MIS-A: Multisystem Inflammatory Syndrome in Adults, CLC: colchicine, NSAIDs: Nonsteroidal anti-inflammatory drugs, CS: Corticosteroid, NA: Not applicable*Patient -under colchicine treatment- uses anakinra only in the event of a FMF attack because of injection site skin reactions.

Conclusion: Anakinra was found to be a safe and effective agent against colchicine-resistant pericarditis, notably recurrent pericarditis. Long-term treatment should be anticipated when initiating treatment and dose tapering should be kept in mind for patients in remission. Relapses should be watched for attentively in tapering and anakinra should be resumed promptly in case of a recurrence. Furthermore, anakinra is important in sparing cortisol treatment.

POS1569 CONTRIBUTION OF GENETIC ANALYSIS TO THE DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER

Keywords: Genetics/epigenetics

H. Akar[1], D. Gün Bilgiç[2], Ö. Soysal Gündüz[3]. [1]*Manisa Celal Bayar University, Internal Medicine, Manisa, Turkey*; [2]*Manisa Celal Bayar University, Medical Genetics, Manisa, Turkey*; [3]*Manisa Celal Bayar University, Rheumatology, Manisa, Turkey*

Background: Familial Mediterranean fever (FMF) affecting mainly Mediterranean and Middle Eastern populations.is an autosomal recessive inherited inflammatory disease caused by mutations in the Mediterranean fever (MEFV) gene. It is characterized by periodic attacks of fever and inflammation affecting serosal membranes. The most common symptoms of the disease are fever, abdominal pain, arthritis, erysipelas-like erythema, pleuritis, and pericarditis. Patients are usually treated by life-long colchicine, which has been shown to be effective in preventing the attacks of FMF as well as the development of amyloidosis. FMF diagnosis remains often difficult due to the lack of pathognomonic laboratory findings. The definitive clinical classification of FMF is made by Tel Hashomer criteria [1]. Genetic analyzes may support the clinical diagnosis of patients for mutation complications.

Objectives: This study aimed to not only investigate the contribution of MEFV mutations to FMF diagnosis but also to show whether there is a phenotype–genotype correlation in the same patient population.

Methods: We evaluated 12 MEFV gene mutations screened with a commercial kit based on real-time polymerase chain reaction technique in 1064 adults between January 2016 and November 2021. We were able to interview 208 of 484 people with AAA mutations by telephone. We investigated whether they were diagnosed with FMF according to Tel Hashomer criteria or clinician opinion, and compared their clinical and genetic characteristics. In addition, it was investigated whether there was a colchicine or interleukin-1 inhibitor drugs use report issued for drug fee exemption from the medical records of everyone who underwent genetic analysis, since it assumed the diagnosis of FMF in our country.

Results: According to the results of 1064 genetic analysis (484 with MEFV mutation), 228 patients (21.4%) were either still using colchicine with the diagnosis of FMF or had previously used colchicine before IL-1 inhibitor treatment. The rate of giving colchicine with the diagnosis of FMF in patients with MEFV mutation (39.7%) was found to be significantly higher than those without mutation (p<0.001). Of the 208 patients with genetic mutations which we interviewed by telephone, 89 (42.8%) met the Tel Hashomer criteria. The most detected mutations in patients meeting Tel Hashomer criteria were M694V (46,1%), M680I (24,7%), V726A (8,9%), and E148Q (8,9%) respectively. The positive significant associations were found between M694V and M680I homozygous mutations and definite/probable diagnosis according to Tel Hashomer criteria (p=0,001, p=0,021, respectively). A negative correlation was found between E148 heterozygous mutation and diagnosis (p=0,002). When the relation between genetic mutations and clinical findings was examined, it was shown that there was a positive correlation between fever and M694V, and between abdominal pain and M680I (p=0,000, p=0,007, respectively). Patients with the E148Q mutation had significantly less fever and abdominal pain (p=0,028, p=0,017, respectively).

Conclusion: Considering that approximately one-fifth of those undergoing genetic analysis are diagnosed with FMF, it can be concluded that unnecessary genetic testing is performed in our hospital. In clinical practice, the precence of MEFV gene mutations M694V and M680I is helpful for FMF diagnosis. E148Q mutation were not been found to be associated with both the diagnosis and the clinical findings. Genetics plays a critical role in confirming the diagnosis, but it should never take the place of a clinical diagnosis. The clinicians should be aware of the indications and limitations of genetic testing and know how to interpret the results.

Background: Familial Mediterranean Fever (FMF) is characterized by recurrent attacks of fever, serositis, and elevated laboratory parameters (CRP, SAA). According to EULAR recommendations, treatment goals are the control of acute attacks and subclinical inflammation as well as the improvement of patient´s quality of life. In a phase 3 pivotal study (CLUSTER study), FMF patients have been successfully treated with the interleukin-1β inhibitor canakinumab (CAN).
Objectives: The RELIANCE registry explores the long-term efficacy and safety of CAN under routine clinical practice conditions in pediatric (age ≥2 years) and adult patients with FMF and other recurrent hereditary fever conditions.
Methods: RELIANCE is a prospective, non-interventional, observational study that enrolls patients with clinically confirmed diagnoses of FMF routinely receiving CAN. Clinical data, physician assessments and patient-reported outcomes are assessed at baseline and 6-monthly intervals.
Results: This interim analysis includes baseline as well as 18- and 36-month data from N=96 FMF patients (CAN-pretreated: N=71, CAN-naïve: N=20) enrolled by December 2022. Median age in this cohort was 21.5 years (2–61 years) and the proportion of female patients was 46%. At baseline, median duration of prior CAN treatment was 1.0 years (0–6 years). The MEFV genotype has been documented in 67 patients. Among 53 (79%) carriers of pathologic MEFV variants, 17 were homozygous, 6 heterozygous plus a second pathologic variant, 8 heterozygous plus a non-pathologic variant, and 22 heterozygous plus wild type. At month 36, disease activity was mild (3 and 2 out of 10) according to patients rating and lab parameters. Physician assessment indicated disease remission in 60% of the patients (53% at baseline) and 57%/14% of the patients having no/mild-moderate disease activity. The majority of patients reported no impairment of social life (100%, 75%) nor negative impact on mood (88%, 100%) due to the disease. Disease activity parameters decreased in the observation period, particularly in patients without prior CAN therapy (Table 1). In total, 22 serious adverse events (SAE) were reported, of which 3 were classified as drug related.
Conclusion: Interim data from the RELIANCE study, the longest running real-life CAN registry confirm efficacy and safety of long-term CAN treatment in FMF patients.

POS1571

CARDIOVASCULAR DISEASES IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER OVER 50 YEARS OF AGE

Keywords: Cardiovascular disease, Rare/orphan diseases, Epidemiology

S. Karup[1], B. Ayci[1], S. N. Baspinar[2], F. N. Azman[1], S. Ugurlu[2]. [1]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, Turkey*; [2]*Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey*

Background: Familial Mediterranean Fever (FMF) is one of the most common monogenic autoinflammatory diseases inherited in an autosomal recessive manner. FMF attacks are characterized by episodes of fever and serositis lasting up to 3 days. The most important long-term complication is renal amyloidosis (Alghamdi, 2017). Furthermore, FMF can lead to cardiovascular complications (Malik et al., 2021; Vampertzi et al., 2020; Erken & Erken, 2018).
Objectives: Cardiovascular diseases (CVD) in patients with FMF are not elucidated. CVD includes hypertension, coronary artery disease, heart failure, heart valve diseases, arrhythmias, and hyperlipidemia.
Methods: This study surveyed patients with FMF over 50 years of age.
Results: 343 patients with FMF over 50 years of age were enrolled. Our results demonstrated that 173 of 343 (50.3%; male n=126, female n=47) patients have CVD whereas 170 patients (49.7%; male n=98, female=72) do not have CVD. The means of age were 59.1±7.37 in patients with CVD and 56.1±5.07 in patients without CVD. The means of symptom onset ages were 24.1±15.4 in patients with CVD and 23.9±13.3 in patients without CVD. The median diagnostic delay was 17.9±15.6 in patients with CVD and 18.6±16.3 in patients without CVD. Illness duration was 17.1±9.95 in patients with CVD and 16.4±9.63 in patients without CVD. Among CVD, hypertension (n=148, 43.14%) is the most frequent concomitant comorbidity, followed by coronary artery disease (n=44, 12.82%), hyperlipidemia (n=32, 9.32%) heart valve insufficiency (n=11, 3.20%), heart failure (n=5, 1.45%), and arrhythmias (n=5, 1.45%) (Figure 1). A statistically significant increase in colchicine resistance is observed in patients with CVD (n=30, p<0.031) compared to patients without CVD. Patients with CVD are significantly more adherent to colchicine treatment (n=117, p<0.025). Patients with CVD use significantly more antidepressant drugs (n=27, p<0.002) and bisphosphonates (n=7, p<0.008). Multiple drug usage is significantly more encountered in patients with CVD (n=21, p<0.001). A statistically significant rise in active biologic agent receipt is present in patients with CVD (n=17, p<0.009).
Conclusion: In patients with FMF over 50 years of age, the presence of CVD might be an independent risk factor for the development of colchicine resistance, reflecting the requirement of active biological agents. Patients with CVD could have an increased risk for major depressive disorder and osteoporosis.

POS1572

AN OVERVIEW TO THE INTERSTITIAL LUNG DISEASES RELATED TO CONNECTIVE TISSUE DISEASES: A RETROSPECTIVE ANALYSIS

Keywords: Descriptive studies, Lungs

S. Colak[1], E. Tekgoz[1], E. Cimen Gunes[1], N. Ocal[2], D. Dogan[2], C. Tasci[2], M. Çınar[1], S. Yilmaz[1]. [1]*University of Health Sciences, Gulhane Faculty of Medicine, Rheumatology, Ankara, Turkey*; [2]*University of Health Sciences, Gulhane Faculty of Medicine, Pulmonology, Ankara, Turkey*

Background: Interstitial lung disease (ILD) is a critical manifestation of connective tissue diseases (CTDs) that may cause morbidity and mortality.
Objectives: This study aimed to evaluate the clinical and demographic characteristics and treatment of the patients who had CTD-related ILD.
Methods: This retrospective observational study includes patients who followed up with CTD-related ILD in a tertiary rheumatology outpatient clinic between January 2020 and December 2022. Patients' files were assessed retrospectively for demographic, clinical, and radiologic data.
Results: There were 149 patients (96 Female/53 Male) with a mean age of 62.6±11.8. The CTD types of the patients were Sjogren's syndrome (SS) in 49 (32.7%) patients, rheumatoid arthritis (RA) in 47 (31.3%) patients, systemic sclerosis (SSc) in 40 (26.7%) patients, undifferentiated CTD in 9 (6%) patients, inflammatory myositis in 3 (2%) patients, and systemic lupus erythematosus (SLE) in one (0.7%) patient. The median disease duration was 58 (24-134.5) months for CTDs. According to computed tomography findings, 86 (57.7%) patients had nonspecific interstitial pneumonia (NSIP), 48 (32.2%) patients had usual interstitial pneumonia (UIP), 9 (6%) patients had lymphocytic interstitial pneumonia (LIP), 6 (4%) patients had organizing pneumonia (OP). The median disease duration was 35.5 (12-65.8) months for ILD. Patients with NSIP were more frequent in the SSc and SS groups, with 29 (33.7%) patients for each. Both UIP and OP were most frequent in the RA group (45.8% and 66.6%, respectively). LIP was common in the SS group (77.8%). Seventy-five (50%) patients were diagnosed with CTD prior to ILD, 20 (13.3%) patients were diagnosed with ILD prior to CTD, and 54 (36%) patients had CTD and ILD diagnoses concurrently. NSIP was more frequent among female patients (p=0.001), but no significant difference was found in terms of gender among patients with UIP. Immunosuppressive (IS) treatment for ILD was more frequently initiated for patients with NSIP than for UIP. The mainly preferred drug for initiation ILD therapy was rituximab for RA patients, mycophenolate mofetil for myositis, and azathioprine for other disease groups. In addition to IS treatment, usually, 7.5-30 mg/day prednisolone was administered for both NSIP and UIP. Prednisolone up to 100mg/day was used for OP treatment. Only two patients with OP used azathioprine as IS treatment added to prednisolone. RA patients with LIP did not receive an IS treatment for pulmonary involvement. Besides, mycophenolate mofetil and azathioprine were given to two patients with LIP associated with SS. Six patients (4 NSIP/2UIP) died that of whom were using IS agents.

Table 1. Demografic and clinical characteristics of the study group

Characteristics of the patients				Interstitial lung disease (n = 149)
Gender, n (%)	Female			96 (64.4)
	Male			53 (35.6)
Age, [a] year				62.6±11.8
Disease duration for CTD, [b]month				58 (24-134.5)
Disease duration for ILD, [b]month				35.5 (12-65.8)
	NSIP (n=86)	UIP (n=48)	OP (n=6)	LIP (n=9)
Sjogren's syndrome, n (%)	29 (33.7)	12 (25)	1 (16.7)	7 (77.8)
Rheumatoid arthritis, n (%)	19 (22.1)	22 (45.8)	4 (66.6)	2 (22.2)
Systemic sclerosis, n (%)	29 (33.7)	11 (22.9)	0 (0)	0 (0)
Undifferentiated CTD, n (%)	6 (7)	2 (4.2)	1 (16.7)	0 (0)
Inflammatory myositis, n (%)	2 (2.3)	1 (2.1)	0 (0)	0 (0)
Systemic lupus erythematosus, n (%)	1 (1.2)	0 (0)	0 (0)	0 (0)

CTD= Connective tissue disease, ILD= Interstitial lung disease, NSIP= Nonspecific interstitial pneumonia, UIP= Usual interstitial pneumonia, OP= Organizing pneumonia, LIP= Lymphocytic interstitial pneumonia[a]mean±standard deviation), [b]median (Q1-Q3)

Conclusion: ILD is a critical manifestation of CTDs. IS biologic treatment options may be required during the management of CTD-related ILD.

Background: Autoinflammatory periodic fever syndromes are characterized by severe systemic and organ inflammation as well as high burden for the patients and their families. Successful treatment was achieved in clinical trials and in real life with the interleukin-1β inhibitor canakinumab (CAN) leading to rapid remission of symptoms and normalization of laboratory parameters in most patients.
Objectives: The present study explores the long-term efficacy and safety of CAN under routine clinical practice conditions in pediatric (age ≥2 years) and adult patients with autoinflammatory periodic fever syndromes including TRAPS (tumor necrosis factor receptor-associated periodic syndrome).

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany. Patients with clinically confirmed diagnoses of TRAPS who routinely receive CAN are enrolled to evaluate efficacy and safety of CAN under standard clinical practice conditions. Disease remission by physicians´ assessment, disease activity and fatigue by patients' assessment, days absent from school/work due to study indication, and inflammatory markers were assessed at baseline and at 6-monthly intervals.
Results: The interim analysis of TRAPS patients enrolled by December 2022 includes data from baseline (N=21), 18- (N=12) and 30-month visits (N=10). At baseline, median age was 15 years (3–43 years) and median duration of prior CAN treatment was 1 year (0–4 years). The proportion of female patients was 67%. At month 30, 3 patients received standard dose CAN, 4 patients greater than standard dose CAN and 2 patients lower than standard dose CAN. Preliminary results indicate stable remission by physicians´ assessment (in 62.5 % of patients), low disease activity by patient´s assessment (1.5 out of 10) and inflammatory markers within normal limits (**Table 1**). However, a fatigue score of 4 out of 10 might contribute to the impairment of social life reported by patients. One patient was affected by N=9 serious adverse events, none of which was classified as drug related.
Conclusion: The present interim data from TRAPS patients indicate that long-term CAN treatment is safe and effective. Patient reported fatigue and impairment of social life leave room for further improvement. Further RELIANCE interim and end-of-study data will be analyzed to assess efficacy and safety of long-term CAN treatment in patients with TRAPS.

Table 1. Baseline characteristics and interim analysis data of patients with TRAPS.

	Baseline	18 months	30 months
Number of patients, N	21	12	10
Number (%*) of patients in disease remission (physician assessment)	11 (58)	7 (78)	5 (62.5)
Patient´s assessment of current disease activity; 0–10, median (min; max)	1.5 (0; 8)	0.0 (0; 5)	1.5 (0; 6)
Patient´s assessment of current fatigue; 0–10, median (min; max)	1.5 (0; 8)	4.0 (0; 7)	4.0 (0; 8)
Number (%*) of patients without impairment of social life by the disease	64 (60)	3 (43)	3 (50)
Number (%*) of patients with days absent from work/ school during last 6 months	8 (40)	3 (25)	3 (33)
Current influence of the disease on mood; % of patients* with negative I positive I no influence	20 I 40 I 40	20 I 20 I 60	0 I 25 I 75

Background: The SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, and osteitis) is a rare disease (<1/10,000) with multiple cutaneous and musculoskeletal manifestations [1]. The most common dermatological manifestations are palmoplantar pustulosis (PPP) and severe acne (SA). Musculoskeletal manifestations are diverse, including the thoracic wall, spine, temporomandibular joint, and peripheral joints [2]. It is considered as part of spondyloarthropathies, however, no significant relationship with HLA-B27 has been found [3]. For treatment, non-steroidal anti-inflammatory drugs (NSAIDs), disease-modifying drugs (DMARDs) and bisphosphonates have been traditionally used. More recently, new therapies such as apremilast and biological DMARDs (4) are being used more frequently.
Objectives: To examine the characteristics of individuals diagnosed with SAPHO syndrome during follow-up at multiple Rheumatology Services in Spain.
Methods: This is a descriptive, cross-sectional, multi-center study, carried out in the Rheumatology Services of several hospitals in Spain. A convenience sampling was carried out, including all patients with SAPHO under active follow-up.
Results: 50 patients were included (76% women), with a mean age of 48.56 (±12,28) years. The mean BMI was 24.84 (±4.31). Regarding cardiovascular risk factors, 36.2% and 23.4% were smokers and ex-smokers, respectively. 18% had hypertension, 28% had dyslipidaemia and 8% were diabetic. Regarding of the musculoskeletal involvement, the most affected region was the anterior chest wall (74%), followed by peripheral arthritis (56%) and the spine (34%). 24% presented enthesitis and only 6% dactylitis. The most frecuent skin involvement was palmpplantar pustulosis in 54% (27), the distribution of dermatological manifestations is shown in Figure 1.

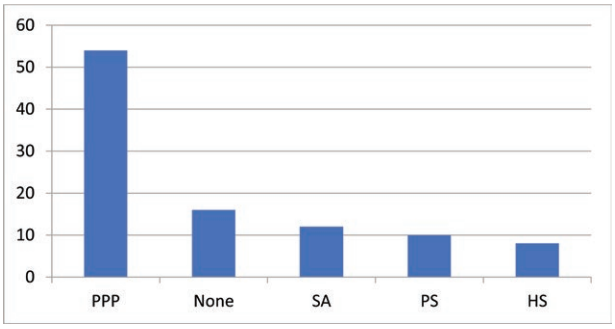

Figure 1. Skin manifestations in SAPHO syndrome.

In laboratory tests at diagnosis, acute phase reactants were slightly elevated, with a mean of CRP of 11.13 (±17.34) and ESR of 21.21 (±24.56). HLA-B27 and CW6 were positive in 12% (6) and 6% (3) of patients, respectively. The most commonly used imaging tests in the diagnosis and follow-up were plain x-rays (90%), MRI (76%), bone scintigraphy (72%), and CT scan (52%). The least used test was ultrasound, used in 17 patients (34%). The treatment was mostly based in NSAIDs, 94% of patients received it at some point. 60% used DMARDsc (mostly methotrexate). 50% of patients received bDMARDs, and 9 patients received more than two bDMARDs throughout the follow-up. The distribution of the first bDMARD used is shown in Table 1.

Table 1. First bDMARD used in the treatment of SAPHO syndrome in our cohort.

bDMARD	N	% patients (25/50)	% FAMEb/other molec's (25/25)
Adalimumab	12	24	48
Infliximab	4	8	16
Etanercept	3	6	12
Ustekinumab	2	4	8
Secukinumab	1	2	4
Anakinra	1	2	4
Apremilast	1	2	4
Cartolizumab-pegol	1	2	4
Total	25	50	100

The course of the disease was mostly recurrent (54%) with asymptomatic periods between flare-ups. About half of the patients (44%) in follow-up currently have active disease.

Conclusion: Our cohort presented axial involvement like other series and significant peripheral involvement. The most frequent skin condition was PPP. Half of the patients in our cohort required bDMARD, with ADL being the most widely used.

Clinical cases

POS1575 ASSOCIATION OF IGG4-RELATED DISEASE AND SYSTEMIC RHEUMATIC DISORDERS

Keywords: Rare/orphan diseases

V. Batani[1], M. Lanzillotta[1], J. Mahajne[1], F. Pedica[2], D. Palumbo[3], E. Venturini[3], L. Dagna[1], E. Della Torre[1]. [1]*San Raffaele University Hospital, Unit of Immunology, Rheumatology, Allergy and Rare Diseases, Milano, Italy*; [2]*San Raffaele University Hospital, Pathology Unit, IRCCS San Raffaele Scientific Institute, Milano, Italy*; [3]*IRCCS San Raffaele Scientific Institute, Unit of Clinical and Experimental Radiology, Experimental Imaging Center, Milano, Italy*

Background: Autoimmune disorders can occur together especially in genetically predisposed individuals.

Objectives: We here aimed to assess the occurrence of IgG4-related disease (IgG4-RD) in association with other systemic immune-mediated conditions.

Methods: We retrospectively analyzed the clinical records of our routinely followed patients with IgG4-RD for pre-existing or concomitant immune-mediated disorders. IgG4-RD was diagnosed based on histological findings and on the 2011 Comprehensive Diagnostic criteria. Associated immune-mediated disorders were diagnosed based on available classification and/or diagnostic criteria.

Results: Two-hundred and thirty-four patients with a definitive diagnosis of IgG4-RD were included in this study. A pre-existing immune-mediated connective tissue disease was reported in 6/234 patients (3%): one case each of sarcoidosis, Takayasu arteritis (TA), eosinophilic granulomatosis with polyangitis (EGPA), and rheumatoid arthritis; and two cases of granulomatosis with polyangitis (GPA). Organs involved by IgG4-RD included the lungs, the pancreas, the peritoneum, lacrimal glands, meninges and orbits. Sarcoidosis, EGPA, and TA preceded the onset of IgG4-RD. GPA preceded IgG4-RD onset in one case and occurred simultaneously in the other case. Rheumatoid arthritis occurred together with IgG4-RD in one case.

Conclusion: IgG4-RD can present in the context of pre-existing systemic immune-mediated disorders. Our observation suggests that "secondary" IgG4-RD may preferentially complicate chronic granulomatous conditions including large- and small-vessels vasculitis as well as sarcoidosis.

Background: VEXAS (Vacuoles, E1 enzyme, X-linked, Autoinflammatory, Somatic) syndrome is an adult-onset multisystem autoinflammatory disease caused by a somatic mutation in the ubiquitin-activating enzyme (UBA1) gene in myeloid or erythroid precursor cells, causing a variety of symptoms including fever, cytopenia, vacuoles in myeloid and erythroid progenitors, dysplastic bone marrow, neutrophilic dermatosis, pulmonary infiltrates, chondritis and/or vasculitis.

Objectives: This report describes an atypical initial presentation of peri-orbital inflammation and neurological manifestations associated with this newly recognized syndrome.
Methods: This is a case report.
Results: An 82-year-old male with insulin-treated diabetes mellitus type II, prostate hyperplasia and chronic atrial fibrillation, presented with persistent unilateral peri-orbital swelling and pain for 6 months. An initial evaluation in the ophthalmology department with biopsy showed no evidence of malignancy, myositis, vasculitis or IgG4-related disease. Due to significantly elevated inflammatory markers (CRP 250-300 mg/L, ESR around 100 mm/h), the patient received high-dose glucocorticoids (60mg Prednisolone) with a good clinical response. During the tapering of Prednisolone, the patient developed a maculopapular skin rash in the lower extremities. Skin biopsy showed signs of urticaria-like dermatitis, while immunofluorescence examination was negative. In the following months, he was hospitalized three times due to recurrent fever, generalized weakness, fatigue and general asthenia. Extensive evaluation regarding infectious and neoplastic causes was negative. An extensive autoimmune panel (including ANA and ANCA) was tested and came out negative. CT scan of the thorax and abdomen was unremarkable. During the last hospitalization, he developed expressive aphasia and fascial paresis. MRI of the brain showed signs of leptomeningeal enhancement. Examination of the cerebral fluid showed pleocytosis (leucocyte count 124, with monocytosis), while all cultures were negative. He came to the rheumatology department in November 2022 for further evaluation. He had generalized myalgias and arthralgias but no arthritis. The skin rash had disappeared. The inflammatory markers were still highly elevated and he had a mild anemia, normocytic and normochromic, but no thrombocytopenia or leukopenia. PET-CT scan showed hyperactive bone marrow, while subsequent biopsy showed normal hematopoiesis without signs of dysplasia and no vacuoles. Endoscopic evaluations revealed no pathological findings. Prednisolone was re-introduced after PET-CT with good regress of the symptoms. Repeated MRI of the brain showed regression of the area with enhancement while all neurological symptoms had subsided. A few weeks later, we received the result of the genetic testing showing a mutation of the UBA1 gene, confirming the diagnosis of VEXAS. Our patient had already started methotrexate as a cortisone-sparing agent and started tapering off Prednisolone, so far with reasonable clinical response.
Conclusion: VEXAS syndrome should be suspected in elderly patients (especially males) with systemic inflammation when other common conditions are excluded. Orbital/peri-orbital inflammation and neurological manifestations can occur and should raise the suspicion of VEXAS.

POS1577 VENOUS INFLAMMATION MIGHT BE ONE OF THE FEATURES OF VEXAS SYNDROME AND ASSOCIATED THROMBOSIS

Keywords: Rare/orphan diseases, Imaging

H. Karadeniz[1], M. Cerit[2], A. Tufan[1,3], Y. Kanthi[4]. [1]*Gazi University Faculty of Medicine, Rheumatology, Ankara, Turkey*; [2]*Gazi University Faculty of Medicine, Department of Radiology, Ankara, Turkey*; [3]*National Human Genome Research Institute/NIH, Inflammatory Disease, Maryland, United States of America*; [4]*National Heart, Lung, and Blood Institute, Division of Intramural Research, Maryland, United States of America*

Background: VEXAS syndrome is an often fatal, X-linked disease characterized by hematological dysplasia overlapping with severe autoinflammatory manifestations. Thrombosis, predominantly as unprovoked venous thrombosis, has been reported in up to 56% of VEXAS patients. Although chronic inflammation, vasculitis, endothelial dysfunction, disrupted anticoagulant mechanisms, or prothrombotic antibodies are suggested mechanisms, the exact pathogenesis of thrombosis is yet to be elucidated. VEXAS has clinical similarities with Behçet's syndrome (BS), a systemic vasculitis involving arterial and venous vessels of all sizes. Recently, venous wall thickening (VWT) on Doppler ultrasound has been shown to be a highly sensitive and specific (>80%) finding for the diagnosis of BS. Given the clinical and pathogenetic similarities with BS, we thought venulitis might be the underlying cause of thrombosis in VEXAS syndrome.
Objectives: Herein, we report venulitis in two consecutive VEXAS patients with the demonstration of severe thickening of the walls of large veins.
Methods: Bilateral lower extremity common femoral veins (CFV) were examined with Doppler ultrasound in craniocaudal direction for the presence of thrombi, occlusion, venous insufficiency, and arterial occlusive disease. VWT was measured using the methodology described by Alibaz-Oner F et al. **[1].** All measurements were performed thrice, and the arithmetic mean of them was given as the result. We also assessed the internal jugular vein (IJV) in one patient but not in the other due to the jugular venous catheter. VEXAS patients had thickened walls on ultrasound in all examined large veins.
Results: Demographic and clinical features of our VEXAS patients are presented in Table 1. VWT in BS seemed significantly greater than non-inflammatory DVT (0.34±0.1 mm) but not significant with the anti-phospholipid syndrome (APS, 0.49 ±0.1 mm) **[2].** Our VEXAS patients had VWT greater than BS and APS suggesting remarkable vein inflammation. Patients with extensive thrombosis (Case#1) had the most severe VWT of CFV on the affected side, while the latter case (Case#2) had equivalent VWT in both CFVs.
Conclusion: Consequently, our findings suggest that venulitis might be one of the features of VEXAS syndrome and the underlying mechanism for thrombosis. Further studies are needed to clarify the role of inflammation in venous thrombotic diseases.

POS1578 JAK INHIBITORS AND VEXAS SYNDROME: A SUCCESSFULLY CASE TREATED WITH FILGOTINIB

Keywords: Targeted synthetic drugs, Treat to target, Rare/orphan diseases

S. Bindoli[1], E. Bertoldo[2], A. Doria[1], C. Baggio[1], P. Sfriso[1]. [1]*University of Padova, Rheumatology Unit-Department of Medicine, Padova, Italy*; [2]*University of Verona, Rheumatology Unit-Department of Medicine, Verona, Italy*

Background: VEXAS syndrome is a novel described autoinflammatory entity for which the diagnosis is defined by somatic mutations in the *UBA1* X-linked gene in hematopoietic progenitor cells. The clinical manifestations are heterogeneous, ranging from autoinflammatory symptoms to the presence of underlying hematologic disorders. Response to treatment in VEXAS is very poor and to date the therapeutical strategies adopted are only partially effective. However, recently described cohorts of VEXAS patients treated with Janus-Kinases Inhibitors (JAK-I) demonstrated that these drugs can be effective for the treatment of several manifestations related to the disease.
Objectives: To describe the case of a 65-year-old man affected by VEXAS who was successfully treated with the selective JAK-1 inhibitor filgotinib.
Methods: We present the case of a 65-year-old man, diagnosed with a myelodysplastic syndrome (MDS grade 3, sec WHO, 2016) one year earlier, presenting with a recent history of leukocytoclastic vasculitis, deep vein thrombosis, tenosynovitis, and ear chondritis. He was admitted to the hospital for hyperpyrexia (39° TC), increased inflammatory markers, macrocytic anemia with Hb 7,7 g/l and MCV 104 fL and requiring multiple blood transfusions, and shortness of breath caused by a pleural effusion; after excluding neoplastic conditions, infections, and other potential mimickers (such as vasculitis), a genetic analysis was performed, revealing the somatic mutation Met41Leu (c.121A>C) in the *UBA1* gene. Methylprednisolone was started from 16 mg/day (not reducible for recurrent flares). A peripheral blood smear was stained with May Grunwald-Giemsa staining to perform a cytogenic evaluation of leucocytes. Oil immersion microscopy with 1000× magnification was applied for the analysis.
Results: Following the diagnosis of VEXAS, the patient started filgotinib 200 mg/day, with a subsequent clinical and biological improvement that allowed for a slow reduction of glucocorticoids. After 1.5 month his laboratory exams showed: Hb 9,4 g/L, MCV 106 fL, C-reactive protein (CRP) 2,24 mg/dL. At peripheral blood smear, the patient had granulocytes with morphological changes, including cytoplasmic vacuoles (2%), immature neutrophils (29.8%) such as band neutrophils, hyposegmented neutrophils, and pseudo Pelger Huët-like morphology. Vacuolated/activated monocytes (4.5%) and nuclear abnormality (binucleated cells, buds) were also observed.
Conclusion: VEXAS syndrome is a new genetically-determined rare disease that requires a prompt treatment to avoid a rapid worsening. Glucocorticoids often represent the first line therapy and blood transfusion support is usually required; however, given the promising results derived from recently published cohorts, JAK-inhibitors, in particular selective JAK-1 (filgotinib, upadacitinib), or JAK1/2 blockers (ruxolitinib), may represent a suitable therapeutic approach.

POS1579 VEXAS SYNDROME IN A PATIENT WITH BIOPSY POSITIVE GCA AND IMAGING PROVEN LARGE VESSEL VASCULITIS TREATED WITH TOCILIZUMAB

Keywords: Comorbidities, Vasculitis, Rare/orphan diseases

A. Ugwoke[1], J. Keay[1], A. Zarif[1], E. E. P. Htut[1]. [1]*Cambridge University Hospitals, Rheumatology, Cambridgeshire, United Kingdom*

Background: VEXAS syndrome (Vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) was first reported in late 2020 in 25 men, mostly in their fifth decade of life or after, with adult-onset concomitant autoinflammatory disease and myeloid dysplasia (Beck et al., 2020). It is the first for a proposed new subset of 'haemato-inflammatory diseases and its underlying pathophysiology is thought to be governed by monogenic, somatic missense mutations affecting Met-41 of in the myeloid-restricted UBA1 gene. This results in deranged cellular ubiquitination and a broad range of clinical manifestations (Beck et al., 2020).
Objectives: We describe the case of a patient with the ultimate unifying diagnosis of VEXAS syndrome with an initial presentation of cranial GCA and PET-CT proven large vessel vasculitis. Immunosuppressive regime was challenging due to patient co-morbidities including brittle diabetes and myelodysplastic syndrome.
Methods: Case report.
Results: A 73-year-old gentleman with a history of type 2 diabetes mellitus was admitted with persistent fever, recurrent orbital swelling, thrombophlebitis and severe weight loss of 30kg over 24 months. A wide infectious screen revealed no source with ongoing symptoms despite antibiotic therapy.

Table 1. Blood Results.

Components	Result
HB 125-172g/L	70
MCV 80-101.0 FL	96.2
WBC 3.6-10.5 10*9	19.4
NEUT 1.50-7.70 10*9	18.68
LYMP 1.10-4.00 10*9	0.33
PLAT 160-370 10*9	109
UREA 2.5-7.8mmol/L	9.3
CREAT 62-115umol/L	86
Na 133-146mmol/L	125
CRP 0-9mg/L	292
Procalcitonin 0.00-0.50	0.78
Albumin 35-50g/L	16
Adj Ca 2.20-2.60mmol/L	2.40

Prior review at the bone marrow failure clinics had revealed a macrocytic anaemia with a Heamoglobin of 96g/L, MCV of 105.1FL and thrombocytopenia of 117 X10*9. Bone marrow biopsy revealed hypercellularity with trilineage dysplasia however genetic screening did not detect the UBA1 missense mutation. CT scan revealed perivascular stranding and thickening around the origin of the right carotid and subclavian artery. PET CT scan showed high tracer uptake in the wall of the ascending aorta, subclavian, carotid arteries and bone marrow. New onset headache, jaw pain,scalp tenderness and shoulder stiffness prompted a temporal artery biopsy which revealed lymphohistiocytic inflammatory infiltrates in the intima with focal loss of internal elastic lamina. 60mg of prednisolone led to dramatic resolution of symptoms and inflammatoryb markers. A diagnosis of VEXAS was revisited due to the unique combination of inflammatory and haematological features.Repeat bone marrow biopsy using a newer version of haem oncology gene panel was positive for UBA1 missense variant in exon 3 (c. 122T>C, p.Met41Thr.). Vacuoles were found to be present on erythroid precursor cells. He developed fatigue, rashes and CRP>100 on tapering down prednisolone to 20mg OD. SC Tocilizumab was introduced rather than Methotrexate and Leflunomide due to bone marrow failure. SC Tocilizumab was switched to Intravenous form to optimise bioavailability. He is clinically stable on IV tocilizumab with slower wean of steroid. He suffers with heavy burden of steroid toxicity, including weight gain, erratic blood sugars, steroid induced acne, hypertension and recurrent infection.
Conclusion: VEXAS, should be explored as a potential unifying diagnosis in conditions of overlap between autoinflammatory and haematological condition. Treatment paradigm is still evolving with no current standardised regime hence fraught with uncertainty between high risk of morbidity/mortality from uncontrolled and poorly treated inflammation versus iatrogenic complications from steroid therapy. There is a research gap pertaining to patient cohorts with specific patterns of systemic disease.

POS1580 A CASE SERIES OF VEXAS SYNDROME IDENTIFIED IN THE WEST MIDLANDS, UNITED KINGDOM

Keywords: Rare/orphan diseases

M. Ford[1], T. Khan[2]. [1]*Warwick Hospital, Rheumatology, Warwick, United Kingdom*; [2]*Birmingham City Hospital, Rheumatology, Birmingham, United Kingdom*

Background: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome was first described in 2020 when a mutation in ubiquitin activating enzyme 1 (UBA1) was identified in three patients [1]. This adult-onset autoinflammatory and haematological disease primarily affects males over the age of 50 years. The clinical features are diverse but commonly include skin lesions, non-infectious fever, weight loss, lung involvement, arthralgia/arthritis, relapsing chondritis, ocular symptoms, venous thrombosis, and lymphadenopathy [2]. Whilst corticosteroids are effective, high doses are often required to control the disease and the ideal standard of care, including the choice and efficacy of steroid-sparing agents, is yet to be defined.

Objectives: After identifying three cases of VEXAS in our region within a 6-month period, our objective was to present each case alongside the current knowledge of the condition in order to increase the awareness amongst clinicians.
Methods: We examined each case, comparing the clinical features, investigations, management, and events leading to the diagnosis.
Results: The cases are presented in the table below.

Table 1.

	Case 1	Case 2	Case 3
Demographics	Male, White-British, 59 years old	Male, White-British, 73 years old	Male, White-British, 76 years old
Clinical Features	Fatigue, Fever, Weight loss, Arthralgia, Diarrhoea, Subcutaneous nodules, Lymphadenopathy, Salivary gland swelling, Epididymo-orchitis	Fatigue, Fever, Weight loss, Erythematous papules, Cough, Lymphadenopathy, Ocular involvement, Nasal crusting and discharge	Fatigue, Fever, Weight loss, Arthritis, Diarrhoea, Lymphadenopathy, Headache, Sinusitis, Uveitis, Lung involvement
Investigations (present in all patients)	Macrocytic anaemia, significantly raised inflammatory markers, diffuse marrow activity on PET Scan, reactive features on bone marrow and lymph node biopsy, multiple negative microbiology and immunology investigations, UBA1 mutation		
Management, including outcome	Excellent response to corticosteroid (normalisation of CRP). Clinical deterioration at 15mg daily prednisolone. Azathioprine (minimal benefit).	Multiple blood transfusions. Excellent response to corticosteroid (normalisation of CRP). Methotrexate (awaiting response)	Moderate response to corticosteroid (CRP improvement). Clinical deterioration at 15mg daily prednisolone.
Working diagnosis prior to VEXAS diagnosis	Polyarteritis Nodosa/ vasculitis	Unspecified vasculitis	Giant cell arteritis
Time from presentation to diagnosis	13 months	12 months	41 months
Specialties involved	Rheumatology, Acute Medicine, Haematology, Dermatology, Infectious diseases, Ophthalmology, Respiratory, Immunology, Gastroenterology, Urology	Rheumatology, Acute Medicine, Haematology, Dermatology, Infectious Diseases, Ear Nose and Throat.	Rheumatology, Acute Medicine, Haematology, Infectious diseases, Ear Nose and Throat, Orthopaedics, Respiratory, Ophthalmology, Geriatric Medicine, Immunology, Gastroenterology

Conclusion: The true prevalence of VEXAS is unknown however after we diagnosed three cases of the condition in a short period of time, it is perhaps more prevalent than initially thought. Clinicians should remain vigilant and consider genetic testing in patients presenting with the common inflammatory and haematological manifestations.

Background: VEXAS syndrome (vacuoles, E1enzyme, X-linked, autoinflammatory, somatic) is a X-linked autoinflammatory condition. The 3 most frequent somatic missense mutations affect methionine 41 of exon 3 (p.Met41Thr, p.Met41Val, p.Met41Leu) of ubiquitin-activating protein (UBA)1 gene, which encodes the E1 protein. Patients are usually men in their fifth-to-seventh decade of life and present with inflammatory symptoms, as well as hematologic manifestations with progressive bone marrow failure.
Objectives: We describe 2 patients with some key features that allow us to diagnose this syndrome.
Results: Case 1. AM, 78-year-old man, with chronic kidney disease. In August 2021 onset of left orbital inflammation, treated with antibiotics. A month later admission to our hospital for normocytic anemia, inflammation, oligoarthritis, moderate thrombocytopenia, superficial vein thrombosis and severe respiratory failure due to cryptogenic organizing pneumonia, which required ICU admission: no response to antibiotic therapy but to high dose iv steroid. He was discharged with oral prednisone (PDN), discontinued in three months. New hospitalization for headache, periorbital inflammation, diplopia, and right lateral gaze. No CNS involvement at brain CT-scan. Lab: Hb 9 g/dL, MCV 104 fl CRP 28 mg/dL, ESR 126 mm/h, ferritin 2710 ng/mL, fibrinogen 1142 mg/dL, creatinine 1.5 mg/dL. Normal levels of vitamin B12, folate, haptoglobin, LDH. Autoimmunity and microbiological work-up negative. MRI: bilateral orbital cellulitis, submandibular and parotid gland inflammation. PET-CT with ^{18}F-FDG: diffuse uptake in skeleton, spleen and in pulmonary left superior lobe. Bone marrow aspirate: no signs of myelodysplastic syndrome (MDS): vacuoles in the myeloid and erythroid series. UBA1 gene point mutation p.Met41* Val on bone marrow blood. PDN (0.75 mg/kg/day) was started with benefit on symptoms, anemia and inflammation. Mycophenolate mofetil was introduced as steroid sparing agent and PDN was tapered to 10 mg/day. Macrocytosis has not improved although Hb levels increased with normal reticulocyte count. CRP and ESR are normal and serum ferritin decreased. Case 2. SR, 70 years old man, in October 2021 he had superficial venous thrombosis of right leg, treated with LMWH. Two months later left leg deep venous thrombosis (DVT) and pulmonary thromboembolism, fever, arthritis, weight loss, elevation of CRP (23 mg/dL), Hb 13.3 g/dL with normal MCV. Apixaban and antibiotic were started. After the discharge, onset of periorbital edema with maxillary and ethmoid sinusitis and right arm DVT were diagnosed, and apixaban was changed into warfarin. Genetic and acquired thrombophilia were excluded. At ^{18}F-FDG PET scan diffuse increased uptake in bone marrow. Again periorbital edema and dysphagia. MRI: edema and solid tissue with contrast enhancement of left pyriform sinus without evidence of lymphadenopathy. ER admission for urticarial rash, fever, and severe chest pain due to pericarditis: elevated CRP, and macrocytic anemia (Hb 9.5 g/dl, MCV 107 fl) with normal folic acid and B12 vitamin. Infections and CTD were ruled out. Bone marrow biopsy findings were coherent with MDS. Though vacuoles absence, UBA1 pMet41Val missense mutation was found. PDN 1 mg/kg/day with subsequent tapering was started with clinical improvement, normalization of acute phase reactants and Hb concentration (13.8 g/dl), but persistent macrocytosis. The subsequent needed dose of PDN was > 25 mg/day and the patient is a candidate for 5-Azacytidine therapy.
Conclusion: The VEXAS syndrome increased the awareness of complex associations between MDS and adult-onset inflammatory conditions. In our experience recurrent periorbital edema could be a clinical clue for this syndrome. Macrocytic anemia appeared with persisting inflammation after some months and supports the link between inflammation and MDS development; nevertheless macrocytosis remain stable irrespective of clinical and acute phase reactants improvement. Finally,the lack of vacuolization on bone marrow biopsy should not preclude a search of UBA1 gene mutation.

HPR Patients' perspectives, functioning and health (descriptive: qualitative or quantitative)

POS1583-HPR **THE EFFECT OF VITAMIN D DEFICIENCY ON EXERCISE CAPACITY, RESPIRATORY MUSCLE STRENGTH, AND PERIPHERAL MUSCLE STRENGTH IN PATIENTS WITH CONNECTIVE TISSUE DISEASES**

Keywords: Vitamin D, Systemic sclerosis, Systemic lupus erythematosus

F. Sarı[1], D. Saraç[2], S. Bayram[3], S. Baglan Yentur[4], N. G. Tore[3], D. Oskay[3], A. Tufan[5]. *[1]Bingöl University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Bingöl, Turkey; [2]Izmir Katip Çelebi University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, İzmir, Turkey; [3]Gazi University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Ankara, Turkey; [4]Firat University, Department of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Elazığ, Turkey; [5]National Human Genome Research Institute, Inflamatuar Disease Section, Rockville Pike, United States of America*

Background: Vitamin D is one of the fat-soluble vitamins and is also a group of sterols that are hormone and hormone precursors. Vitamin D deficiency and/or insufficiency have been found to be associated with many chronic diseases, including cancers, metabolic syndrome, and autoimmune diseases. Vitamin D is involved in modulation of immune responses in autoimmune disorders including multiple sclerosis, asthma, diabetes mellitus, connective tissue disorders such as rheumatoid arthritis (RA) or systemic lupus erythematosus (SLE). In addition; Previous studies conducted in other patient populations indicate that higher vitamin D levels are related to higher exercise capacity, muscle strength, and better lung function.
Objectives: The purpose was to investigate the effects of vitamin D deficiency on exercise capacity, respiratory muscle strength, and peripheral muscle strength in patients with connective tissue disease (CTD).
Methods: This cross-sectional observational study included CDT (SLE and systemic sclerosis (SSc)) patients and healthy participants. Serum 25(OH)D, calcium, and phosphorus levels were measured and Vitamin D levels 10.0-20.0 ng/mL defined insufficiency and levels <10.0 ng/mL defined deficiency. The exercise capacity, respiratory muscle strength, and peripheral muscle strengths were set as the primary outcomes of the study. Secondary outcomes included evaluation of physical activity, dyspnea, pain, emotional status, fatigue, and quality of life.
Results: There were 23 SLE (36.82±10.06), 21 SSc (44.38±14.63), and 24 healthy controls (37.62±11.74). Compared to healthy controls, CTD groups with vitamin D deficiency had significantly lower respiratory muscle strength ($p<0.001$), peripheral muscle strength (knee extension and shoulder flexion) ($p<0.05$), exercise capacity ($p<0.05$), physical activity ($p<0.05$), and quality of life ($p<0.05$) while having significantly more dyspnea ($p<0.001$), pain ($p<0.001$), fatigue ($p<0.001$), anxiety, and depression ($p<0.05$).
Conclusion: The results of our study indicate that vitamin D deficiency is associated with reduced muscle strenghts and related symptoms and complaints in CTD patients, hence, in order to increase the efficacy of rehabilitation and treatment programs, attention should be paid to vitamin D levels and should be corrected appropriately.

POS1584-HPR **IMPACT OF TELEMEDICINE ON DISEASE ACTIVITY ASSESSMENT: A CASE-CROSS OVER NESTED WITHIN A COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS**

Keywords: Systemic lupus erythematosus, Outcome measures, COVID

I. Almaghlouth[1], H. Almalag[2], H. Alzuhair[1], A. Bedaiwi[1], L. Hassen[1], S. Alzomia[1], B. Alanazi[1], S. Alahmari[1], K. N. Asfina[1], N. Khalil[1], M. A. Omair[1], M. Bedaiwi[1]. *[1]King Saud University, Rheumatology Unit, Department of Medicine, Riyadh, Saudi Arabia; [2]King Saud University, Clinical pharmacy, Riyadh, Saudi Arabia*

Background: The utilization of telemedicine has been rapidly growing among patients with rheumatic disease especially following COVID-19 pandemic. The ease and convenience seems to dominate the reasons of such growth. Yet the effect of this approach on patients with systemic lupus erythematosus (SLE) is yet to be revealed.
Objectives: In this study, we aimed to examine the effect of telemedicine in SLE patients on the outcome of disease activity.
Methods: This is a case-cross over study nested within the national prospective cohort of SLE, Saudi Arabia. SLE patients who fulfils the SLICC classification criteria within the period between March 2020 to March 2021 and have been assessed at three-time point with three months' time difference between assessments according to standardized protocol were included. Telemedicine was conducted at first point while in person assessment were used for second and third points. Primary outcome was difference in SLEDAI-2K score. Primary analysis was conducted using GEE model and adjusted for potential confounders including demographics, medications and changes in steroid doses. Several sensitivity analyses were conducted to mitigate selection and time varying confounders.
Results: A total of 92 participants were included. Majority of them were females (88%), with a mean (±SD) age of 36 (±13). mean (±SD) disease activity scores at baseline as follows: SLEDI 5 (±5); SRI 3.8 (±3.5); SDI 1 (±1). Mean difference of SLEDI score of -1.641 (95% CI -2.773 — -0.510), p=0.005* between telemedicine and follow up visits. Adjusted value and mean with mean diffrence in Figure 1. Results were consistent in all sensitivity analyses.
Conclusion: We found that the Telemedicine assessment was associated with much higher disease activity score compared to in person in subsequent assessments which may suggest potentially overestimation of disease activity and later assessment accuracy. Cautious adoption is suggested in SLE patients with active disease.

POS1585-HPR **"SO, MEN WILL BE ABLE TO RECEIVE #METHOTREXATE FOR LUPUS AND RHEUMATOID ARTHRITIS BUT NOT WOMEN" THE OVERTURN OF ROE V. WADE BEYOND ABORTION**

Keywords: Qualitative research methods, Pregnancy and reproduction, Quality of life

J. B. Negrón[1], M. Rodríguez-Malavé[1]. *[1]Instituto de Investigación Social y Sanitaria, Departamento de Investigación, Guayanilla, Puerto Rico*

Background: On June 24, 2022; the Supreme Court of the United States (US) overturned the right established in Roe v. Wade to terminate a pregnancy. Roe v. Wade, 410 U.S. 113 (1973), was a landmark decision of the US Supreme Court in which the Court ruled that the Constitution conferred the right to have an abortion. This decision returns to the states the power to set abortion laws. Pregnant people considering abortion already had been dealing with a near complete ban in Oklahoma and a prohibition after six weeks in Texas. Other states immediately passed abortion ban laws prohibiting the use of abortive methods, which include the medication used for this procedure such as prostaglandins, mifepristone, and methotrexate (MTX). In the case of MTX, despite its use as an abortive agent, it has been a cornerstone drug in the treatment of rheumatic and musculoskeletal diseases (RMDs). Consequently, the medication ban laws has triggered a deep fear among people with RMDs and the health professionals who treat them which have voiced concerns about potential restrictions. Some of these concerns were expressed in social media (SoMe) platforms specially on Twitter.
Objectives: To explore and analyze SoMe data on Twitter to better comprehend the short-term implications of the overturn of Roe v. Wade for those treating RMDs as well as for those living with RMDs.
Methods: This study is a secondary source convergent parallel mixed methods study using SoMe public data. All the tweets publicly posted using "#Methotrexate or Methotrexate" were tracked with Keyhole (http://www.keyhole.co). The tweets were monitored from June 24 to July 1. A combination of SoMe performance data with a qualitative analysis of tweets was conducted. In addition, usage metrics and location were collected. Regarding the qualitative analysis we performed a hashtag co-occurrence analysis and a content analysis.
Results: A total of 5,180 posts using #Methotrexate or Methotrexate were generated. Retweets were more frequent than original posts and replies. In addition, female users posted more than 50% of all publications. Users from 88 countries tweeted using the tracked hashtag or keyword. However more than half of all publications came from the US (73%). Focusing the analysis at the national level, users from the 50 states tweeted using the tracked hashtag or keyword. However, five states made up 38% of all publications: California (10%), New York (10%), Texas (9%), Florida (5%), and Pennsylvania (4%). From the hashtag co-ocurrence analysis the three pairs of hashtags with higher co-ocurrence with #Methotrexate were: #roevswade, #abortionishealthcare, and #rheumatoidarthritis. These relations provided context to the MTX restrictions and revealed more details about the complexities of the judicial decision. Finally, from the content analysis three main themes were generated: (i) Violence against women, (ii) Health policy without public health intelligence, and (iii) Call for strategic alliances in favor of public health.
Conclusion: Biological sex differences will condition the usage of MTX. Men will be able to continue their treatment without hesitation. However, women treated with MTX could lose the continuity of their treatment and may be switched to another medication. Moreover, women in childbearing age with a recent RA diagnosis could be denied MTX as the standard of care for the initial management of the disease. Inequity in access to treatment is a political decision, just as it is to reproduce inequities and vulnerabilities through the actions taken. Not having access to MTX for RMDs is a critical issue. Limiting the access to MTX endangers the physical and mental health of people with RMDs. MTX is an affordable drug and the options to replace it are very expensive for poor people with minimal or no health insurance. Our study is a snapshot of the immediate effects of the overturn of Roe v. Wade in the treatment and management of RMDs. Future research should focus on the mid-term and long-term effects of this decision in the states level and its impact in health outcomes in people with RMDs.

POS1586-HPR DOES DEVELOPING SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) MAKE A DIFFERENCE IN PATIENTS WITH UNDERLYING IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP)?

Keywords: Geographical differences, Systemic lupus erythematosus

S. F. Skh Ali[1], F. Yahya[1], N. A. Mohd Zin[1], A. E. S. Mohamed Ridza[1], P. C. Bee[2].
[1]*Universiti Malaya Medical Centre, Rheumatology, Kuala Lumpur, Malaysia*; [2]*Universiti Malaya Medical Centre, Hematology, Kuala Lumpur, Malaysia*

Background: An estimate of 30–40% of patients with thrombocytopenia have idiopathic thrombocytopenic purpura (ITP) and thrombocytopenia is a common manifestation of systemic lupus erythematosus (SLE). Previous studies have shown the incidence of SLE in patients with ITP to be between 7% and 30% [1,2]. However, there are limited data on this especially in an Asian population.
Objectives: This study aims to investigate the incidence of SLE among Asian patients with underlying ITP and assess the differences between ITP patients who develop SLE and ITP patients who do not.
Methods: A retrospective review of electronic medical records of ITP patients from University of Malaya Medical Centre in Kuala Lumpur was conducted from January 2000 to June 2022. All adult patients with a diagnosis of ITP, verified by treating physicians, who fulfilled inclusion criteria within the time period were included into the study. Patients who subsequently developed SLE were identified. Patients with known SLE who developed secondary ITP after SLE diagnosis were excluded from the study. Data collected included age, sex, race/ethnicity, basic demographics, initial symptom presentation, comorbidities, and blood tests including hemoglobin and platelet levels upon initial presentation of ITP.
Results: Total of 181 ITP patients who fulfilled the inclusion criteria were recruited; 25 (13.8%) were males, 84 (46.4%) patients were of Chinese race and 30 (17.6%) were of Indian race. Eleven (6%) patients developed SLE with a mean age of ITP presentation at 35 years. There were no Indian race ITP patients who developed SLE in comparison to other races (p=0.01). Patients who developed SLE had lower haemoglobin at ITP diagnosis (8.0 [4.08] vs 11.8 [2.83] g/dL, p=0.005) and also lower levels of platelets upon diagnosis of ITP (3.0 [2.00-10.75] vs 24.0 [6.00-53.25] x109/L, p=0.025) in comparison to ITP patients who do not develop SLE. There were no differences in initial symptom presentation or comorbidities between the 2 groups.
Conclusion: Our study found that there are racial differences and differences in hematological presentation upon diagnosis of ITP in patients with ITP who subsequently develop SLE. However, further larger studies are required to further explore the differences, especially in the Asian population.

POS1587-HPR DISABILITY IN AN ITALIAN COHORT OF RHEUMATIC DISEASES: A MIXED METHOD STUDY FOR THE ANALYSIS OF THE PHENOMENON AND PROPOSALS FOR NURSING APPROACH

Keywords: Descriptive studies, Nursing, Quality of life

M. R. Melis[1], K. El Aoufy[1], T. Bacci[2], E. Corsi[1], E. Coli[1], C. Fantauzzo[1], G. Gambardella[1], O. Marrani[1], T. Pucci[1], M. Zolferino[1], M. Matucci-Cerinic[1], S. Guiducci[1]. [1]*Careggi Hospital, Rheumatology, Florence, Italy*; [2]*University of Florence, Science in Nursing, Florence, Italy*

Background: Rheumatic diseases are heterogeneous clinical conditions that often lead to functional disability with consequent impairment of Quality of Life (QoL). Assessing the risk factors of disability is required to find improvement strategies geared toward patient empowerment and implementation of current health services.
Objectives: The aim of the present observational-descriptive study was to analyse the impact of disability in an Italian cohort of rheumatic patients and suggest nursing intervention hypotheses to approach disability-related problems and improve QoL in rheumatology patients.
Methods: Data collection was carried out through in-person or remote interviews with rheumatic patients of a Rheumatology Unit in Florence, Italy. The interviews aimed at observing the phenomenon of disability and the following questionnaires were administered: Short Form-12 (SF-12) for QoL, Health Assessment Questionnaire (HAQ-DI) for disability, Visual Analogue Scale (VAS) for pain, Work Productivity and Activity Impairment Questionnaire: General Health (WPAI:GH) for workability. Afterwards, the nursing group met to discuss the results and, based on recent literature, propose strategies for approaching the patient with disabilities in daily clinical practice.
Results: 21 rheumatic patients were interviewed. For mental and physical health SF-12 showed scores of 47.6 and 46.1, respectively. Pain level averaged 2.2 score, while disability index as assessed with HAQ-DI was 0.3 score. As for the workability, 50% of the sample interviewed work on average for 33.6 hours with a mean of 2.6 hours of absence from work due to the disease. Lastly, 6.25% report work suspension with disability pension due to illness. Nursing intervention hypotheses to curb disability-related problems and improve QoL in rheumatology patients are summarized as follows in Figure 1.

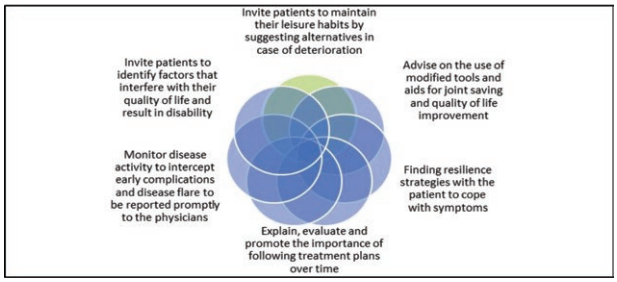

Figure 1. Proposals for nursing approach in disability

Conclusion: Psychological well-being falls within the determinants of QoL, jointly with other factors such as occupational and relational well-being and control of disease progression, in line with the reviewed studies. Understanding and investigating the determinants of QoL for each patient is the starting point for holistic care geared toward his or her well-being: this attitude cannot be separated from a multidisciplinary approach by healthcare professionals.

POS1589-HPR HIGH DISEASE ACTIVITY HAS A NEGATIVE EFFECT ON PAIN CATASTROPHIZING, FEAR AVOIDANCE AND BODY AWARENESS LEVELS IN PATIENTS WITH ANKYLOSING SPONDYLITIS- A PRELIMINARY STUDY

Keywords: Pain, Spondyloarthritis, Patient reported outcomes

N. B. Karaca[1], G. I. Kinikli[2], S. Sezer[3], B. Keleşoğlu[4], G. Kınıklı[5]. [1]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Physiotherapy and Rehabilitation, Ankara, Turkey*; [2]*Hacettepe University, Faculty of Physical Therapy and Rehabilitation, Department of Musculoskeletal Rehabilitation, Ankara, Turkey*; [3]*Ankara Training and Research Hospital, Department of Rheumatology, Ankara, Turkey*; [4]*Dışkapı Yıldırım Beyazıt Training and Research Hospital, Department of Rheumatology, Ankara, Turkey*; [5]*Ankara University, Faculty of Medicine, Department of Rheumatology, Ankara, Turkey*

Background: Ankylosing spondylitis (AS) is a rheumatic disease that affects patients in a biopsychosocial framework due to its chronic inflammatory nature. It is known that patients with AS experience negative body judgment and insecurity and anxiety about their bodies [1], high levels of fear of movement, depression [2], low level of physical activity [3].

Objectives: The aim of this study was to investigate the effects of disease activity (DA) on depression, physical activity, pain catastrophizing, fear avoidance, and body awareness in patients with ankylosing spondylitis.

Methods: Thirty AS patients were included in the study. Socio-demographic informations of patients were collected. The mean age of the patients was 40.27 ± 10.38 years. Beck Depression Inventory (BDI), International Physical Activity Questionnaire-Short Form (IPAQ-SF), Pain Catastrophizing Scale (PCS), Tampa Scale for Kinesiophobia (TSK), and Body Awareness Questionnaire (BAQ) were used for depression, physical activity, pain catastrophizing, kinesiophobia and body awareness levels of the patients, respectively. DA was measured with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and a score of four and higher than four was considered active.

Results: Patients characteristics were similar between the groups (p>0.05). A statistically significant difference was observed in PCS (p= 0.004), TSK (p=0.007), and BAQ scores (p=0.015) when the groups were compared (Table 1). The patients in the low DA group had mild depression, and the group with high DA had moderate depression. Catastrophizing pain and fear of movement were higher in the group with higher DA; body awareness level was lower (p<0.05). A high kinesiophobia level was detected in both groups.

Conclusion: It was observed that high disease activity negatively affected catastrophic thoughts, body awareness, and kinesiophobia in patients with AS. These parameters should be considered in the management of disease activity in AS patients for optimum results.

POS1590-HPR ASSOCIATION OF SELF-PERCEIVED ORAL HEALTH STATUS WITH ESSPRI REPORTED BY PATIENTS WITH SJÖGREN'S SYNDROME

Keywords: Descriptive Studies, Patient reported outcomes, Sjögren syndrome

O. E. Alvarez-González[1], E. Quintana-Aguilar[1], H. Guerra[1], J. A. Cardenas-de la Garza[1], J. C. Riega-Torres[1], L. R. Aguilar Rivera[1], C. M. Skinner Taylor[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario "Dr. José Eleuterio González", Rheumatology, Monterrey, Mexico*

Background: Salivary gland hypofunction, manifested as xerostomia in Sjögren's syndrome (SS), causes dental, language, and nutritional problems, leading to a detriment in oral health [1]. The Geriatric/General Oral Health Assessment Index Spanish Version (GOHAI-SP) is a useful tool that has been used to assess the self-perception of oral status in SS patients [2].

Objectives: To describe oral health status using the GOHAI-SP in patients with primary (pSS) and secondary (sSS) Sjögren's syndrome and correlate it with EULAR SS Patient Reported Index (ESSPRI), Schirmer's test for both eyes and unstimulated salivary flow (USF).

Methods: A cross-sectional and observational study was conducted from October to December 2022 in the rheumatology service of the Hospital Universitario "Dr. José Eleuterio González", Mexico. Patients meeting ACR/EULAR criteria for pSS and sSS were included and assessed with ESSPRI and GOHAI-SP during their follow-up appointment or contacted by telephone. The latter index consists of 12 questions on a 1 to 5 Likert-type scale. The lowest obtainable score is 12 and the maximum 60. Scores ≤ 44 were classified as poor oral health, moderate from 45 to 50, and good ≥ 51. Questions 1-4 assesses oral functionality, 6, 7, 9-11 psychosocial status; 8 and 12 for pain. Objective data such as Schirmer's test and USF/15 minutes were obtained from patients' charts.

Results: A total of 41 patients were included: 31 (75.6%) with pSS and 10 (24.4%) with sSS most of whom were woman (n=40, 97.6%) with a mean age of 53.41 (SD: 12.58). The median score of GOHAI-SP was 50 [IQR 43.5-52], medians for dryness, fatigue, and pain reported in ESSPRI domains were: 3 [0-7], 2 [0-6.5] and 1 [0-5]; for Schirmer test 5 [1-16] and 10 [3-17.5] in right and left eyes respectively and USF 1.5 [0.5-2.25]. The self-perceived health status was classified as good in 19 (46.3%), moderate and poor both in 11 (26.8%). We found that the worse the self-perceived oral condition, the higher ESSPRI medians for dryness (p <0.001), fatigue (p 0.003) and pain (p 0.002) were reported. No significant differences were found when compared to Schirmer and USF tests. Results for Spearman's correlation model are shown in Table 1. No significant differences were found between pSS and sSS groups.

Conclusion: The greater the severity of dryness, fatigue and muscular or joint pain, the greater the functional impairment of mouth and oral pain; as well as the worse the psychosocial aspect manifested as concern, nervousness, discomfort and limitation of interaction with people due to the dental appearance.

POS1591-HPR BREASTFEEDING IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

Keywords: Pregnancy and reproduction

A. Carrazco Chapa[1], D. C. Rubio Torres[1], D. Ramos[1], S. M. Delgado Ayala[1], G. Sandoval[1], C. M. Skinner Taylor[1], L. Pérez Barbosa[1], J. A. Cardenas-de la Garza[1], D. Á. Galarza-Delgado[1]. [1]*Hospital Universitario Dr. José Eleuterio González, Rheumatology, Monterrey, Mexico*

Background: The World Health Organization recommends exclusive breastfeeding for the first 6 months of life and then starting complementary feeding while continuing breastfeeding until 2 years of age or older [1]. However, women with autoimmune rheumatic diseases (ARDs) face barriers of ignorance regarding medications that are compatible with breastfeeding and the control of their disease activity. It has been reported that some women did not follow through with their desire to breastfeed due to concerns about their ARDs medications, the baby's health, and low milk supply. Nowadays, international guidelines agree that most drugs used in rheumatology are compatible with breastfeeding [2].

Objectives: To describe the frequency of breastfeeding in women with ARDs.

Methods: An observational, cross-sectional and descriptive study. A survey on breastfeeding was carried out on patients with ARDs who had ever been pregnant, belonging to the Pregnancy and Reproductive Health Clinic for Rheumatic Diseases (CEER) of the University Hospital "Dr. José Eleuterio González", in Mexico.

Results: A total of 63 patients were included, with a mean age of 38.84 (±7.49). The diagnosis most frequently reported was rheumatoid arthritis with 35 (55.6%), followed by systemic lupus erythematosus with 9 (14.3%). Other diagnoses were antiphospholipid syndrome, juvenile idiopathic arthritis and undifferentiated connective tissue disease each one with 1 (1.6%) respectively, primary Sjögren's syndrome, scleroderma and spondylarthritis each one with 2 (3.2%) respectively and others with 10 (15.9%). The urban area was the most common place of residence with 61 (96.8%), while only 2 (3.2%) patients habited in the rural area. College education was the most predominant education level with 33 (52.4%). The sociodemographic and breastfeeding characteristics are found in **Table 1.** 49 (77.8%) of the patients referred that they had breastfed their last child. Regarding the duration, 3 (6.1%) reported having continued to breastfeed for less than 1 month and 24 (49%) for less than 6 months, being the cessation of milk production being the main cause of abandonment with 10 (37.1%) in those who breastfed for less than 6 months. Of the 14 (22.2%) patients who did not offer to breastfeed, the most frequent reason they reported was low milk production with 4 (28.6%), followed by their illness with 3 (21.4%). The other reasons can be observed in **Figure 1**.

Conclusion: Most of the surveyed patients with ARDs provided breastfeeding, however, more than half of them discontinued it before 6 months, with cessation of milk production being the most frequent reason.

POS1592-HPR UTILISING THE PERSPECTIVES OF PATIENTS WITH FIBROMYALGIA ON PHYSICAL ACTIVITY PROMOTION: A QUALITATIVE STUDY

Keywords: Fibromyalgia, Physical therapy/physiotherapy, Qualitative research methods

N. Sermenli Aydın[1], F. Saritas[2], E. Tonga[3]. *[1]Marmara University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, İstanbul, Turkey*; *[2]Haydarpaşa Numune Training and Research Hospital, Department of Rheumatology, İstanbul, Turkey*; *[3]University of Leicester, Leicester Lifestyle and Health Research Group, Leicester, United Kingdom*

Background: Physical activity (PA) promotion remains a significant clinical challenge in patients with fibromyalgia (FM) despite its evidenced beneficial impact on health outcomes [1]. Integrating behavior change theory into PA interventions ensures efficient interventions through the understanding of PA behaviors [2].
Objectives: The aim of this study was to determine the behaviours, needs and beliefs of patients with FM regarding PA interventions with the use of Social Cognitive Theory (SCT) constructs.
Methods: A Qualitative study was designed using semi-structured interviews according to 5 SCT constructs (ie, Behavioral Capability, Outcome Expectations, Self-efficacy, Self-regulation, Social Support). Female patients with FM, aged between 18-65 years (n=10) were interviewed for 30-60 minutes. Data were audio recorded, transcribed verbatim and analyzed using the content analysis technique. Besides two researchers independently conducted the thematic analysis.
Results: Totally nine main themes were determined. Key themes comprising the behavioural capability were [1]lack of knowledge on PA and [2]person-centered approach. Outcome expectations are associated with [1]health benefits. It emerged that self-efficiency is affected by four themes as follows; [1]past negative experiences, [2]environmental barriers, [3]personal barriers and [4]follow up. Besides, [1]incorporating the PA into daily life were categorized as self-regulation and [1]constructive social dialogs categorized as social support parameters of the theory. The themes, subthemes and supporting quotations related to the SCT structures are summarized in Table 1.
Conclusion: This study revealed the factors, needs, and beliefs related to PA behaviour in FM patients based on SCT and provided suggestions for how SCT constructs could be used to develop the optimal PA intervention. Future research should design PA interventions for FM patients based on behaviour change theories and evaluate the efficacy of these interventions.

Table 1.

SCT Construct	Key Themes	Subthemes	Supporting Quotations
Behavioral Capability	Lack of knowledge	-FITT (frequency, intensity, time, type of exercise) recommendations	"…every day 1 hour.." "… 3 times a week …" "… 5000 steps…"
		-Definition and differences of the terms PA and exercise	"I guess both are the same things."
	Person-centered approach	-Desire to take tailored advice	"I would like to know how much exercise I should do, how I should do it"
Outcome Expectations	Health benefits	-Lose weight -Reduce the symptoms	"Of course, exercise is beneficial for health, but my priority is to lose weight."
Self-efficacy	Past negative experiences	-Inappropriate exercise programs -Unrealistic expectations	"I started Pilates class. But I quitted because it was too much. I had incredible pain."
	Environmental barriers	-Location/accessibility -Safety issues	"Dogs scare me when I go for a walk, and it scares me when it's dark"
	Personal barriers	-Lack of money -Lack of time -Lack of motivation	"Without motivation, you don't feel as though you have the ability to take action."
	Follow-up	-Feeling responsible to someone (HCP) -Self monitoring	"I need a driving force. If you give homework it can be helpful for me."
Self-regulation	Incorporate PA into daily life	-Set a spesfic time -Break up into short session	"Sometimes I can get some exercise before dinner or at lunch break"
Social Support	Constructive social dialogs	-Positive mindset -Peer support -Family support	"I want to be with patients who are open to communication and healing."

GASTROINTESTINAL INVOLVEMENT IS ALREADY REPORTED IN AN ITALIAN VEDOSS COHORT: RESULTS FROM A RHEUMATOLOGICAL NURSE ASSESSMENT

Keywords: Systemic sclerosis, Gastrointestinal tract, Nursing

K. El Aoufy[1], M. R. Melis[1], G. Bandini[1], G. Ghezzi[1], E. Russo[1], B. S. Fioretto[1], E. Romano[1], A. Amedei[1], I. Rosa[1], M. Manetti[1], S. Guiducci[1], A. Moggi Pignone[1], M. Matucci-Cerinic[1,2], L. Rasero[3], Y. Longobucco[3], S. Bellando-Randone[1]. *[1]University of Florence, Experimental and Clinical Medicine, Florence, Italy*; *[2]IRCCS San Raffaele Hospital, Unit of Immunology, Rheumatology, Allergy and Rare diseases, Milan, Italy*; *[3]University of Florence, health science, Florence, Italy*

Background: Gastrointestinal tract (GIT) is often involved in Systemic Sclerosis (SSc), even in the very early diagnosis of SSc (VEDOSS). In SSc, the oesophagus is mainly involved, followed by the anorectum: therefore, the GIT is the second most affected organ system in SSc patients. Patient education performed by rheumatology nurses on GIT symptoms prevention and management can be of help in the disease management, starting from a meticulous data collection.
Objectives: The aim of our study was to investigate the differences, in VEDOSS and SSc patients of GIT involvement assessed by the UCLA GIT questionnaire administered by rheumatology nurses.
Methods: 50 patients (22 VEDOSS and 28 SSc) from the Scleroderma Unit of Careggi University Hospital were enrolled. Demographic data, Raynaud's phenomenon, autoantibodies, videocapillaroscopy patterns, puffy fingers and digital ulcers were recorded for VEDOSS and SSc patients. GIT symptoms, disability and quality of life were respectively assessed by the administration UCLA GIT 2.0, HAQ and SF36 questionnaires guided by the rheumatology nurse.
Results: Demographic data, Raynaud's phenomenon, autoantibodies, videocapillaroscopy patterns, puffy fingers and digital ulcers manifestations are reported in Table 1 for both groups of patients. Disability and quality of life, respectively assessed by HAQ and SF36 are shown to be more significantly modified in the SSc group than in the VEDOSS ($p < 0.05$), especially the impact of the disease on physical health ($p<0.005$) (table2). Moreover, VEDOSS patients presented GIT symptoms and pain, assessed by UCLA GIT 2.0 and VAS pain, not different from the SSc group ($p > 0.05$) (Table 2). GIT symptoms and complications such as gastroesophageal reflux disease (GERD), malnutrition, diarrhea, constipation, and small intestinal bacterial overgrowth, occurred in both SSc and VEDOSS groups impairing significantly patients' quality of life.
Conclusion: our data suggest that it is important to consider GIT involvement also in VEDOSS patients. Therefore, a specific assessment of GIT involvement should be always performed in clinical practice. This work also shows that the role of Rheumatology nurses is important as their help in patients' assessment of patients reported outcomes and symptoms becomes pivotal to prepare the patient for the physician's analysis. Thus, recognising the early GIT involvement with a standard screening may lead to shape an early treatment to improve patients' quality of life.

HPR Service developments, innovation and economics in healthcare

POS1594-HPR A REGIONAL MULTICENTRE REVIEW OF THE DELAY TO DIAGNOSIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITS- HOW WELL ARE WE DOING? RESULTS FROM THE SCAN GROUP (UK)

Keywords: Health services research, Spondyloarthritis, Best practices

G. Dulay[1], C. Boys[2], A. Chan[3], A. Coy[4], M. Devin[5], L. Goh[1], A. Mcdougall[3], K. Rigler[3], J. Tomkins[6], D. Wallis[6], E. Williams[7]. [1]*Portsmouth Hospitals University NHS Trust, Rheumatology, Portsmouth, United Kingdom*; [2]*Basingstoke and North Hampshire Hospital, Rheumatology, Basingstoke, United Kingdom*; [3]*Royal Berkshire Hospital, Rheumatology, Reading, United Kingdom*; [4]*Salisbury NHS Foundation Trust, Rheumatology, Salisbury, United Kingdom*; [5]*Dorset County Hospital, Rheumatology, Dorchester, United Kingdom*; [6]*University Hospital Southampton, Rheumatology, Southampton, United Kingdom*; [7]*Royal Hampshire County Hospital, Rheumatology, Winchester, United Kingdom*

Background: Due to the insidious onset and non-specific nature of axial spondyloarthritis (AxSpA), there is often a significant delay to diagnosis. The average delay to diagnosis in the UK is 8.5 years [1]. This is associated with several adverse sequalae including poor disease-related quality of life and worse overall health outomes [2,3]. In addition, there are substantial health-economic costs associated with this. Recent modelling data in the UK, commissioned by the National Axial Spondylarthritis Society (NASS), demonstrated the average financial cost of this delay to be £196,000 (221,000 Euros) per person affected [1]. There is a focus on reducing diagnostic delay for patients with AxSpA. The SCAN (South Central Axial Spondylarthritis Network) is a network of NHS (National Health Service) Rheumatology departments in hospitals across south-central UK. The group comprises of; doctors, nurses and physiotherapists. SCAN has a working interest in service development.
Objectives: The SCAN group carried out a service evaluation to establish the average delay to diagnosis for patients with AxSpA across our region. Data was gathered from a total of 7 hospitals within the SCAN region. We also aimed to assess the degree of variability across the 7 different hospitals. The baseline data will be used to support potential implementation of service development initiatives, which in turn, will aim to ultimately reduce the delay to diagnosis for patients with AxSpA across the SCAN region.
Methods: Retrospective patient data was collected from 7 different hospitals within the SCAN network area. Data was gathered on 5-10 sequential cases of newly diagnosed AxSpA at each hospital. A total of 65 cases were included in our dataset. Data was collected on; date of symptom onset, date of diagnosis, age and gender.
Results: Chart 1 summarises our main findings across the 7 different hospitals.

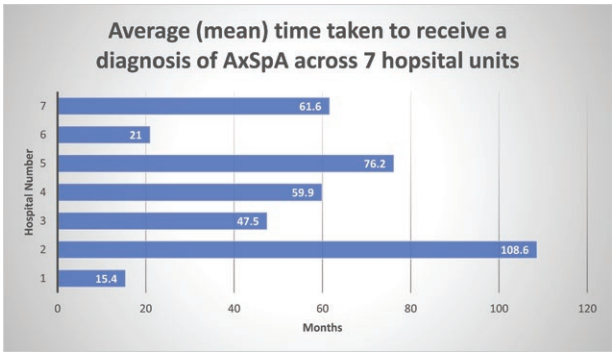

Chart 1.

Based on our representative sample from our region, the overall average (mean) delay to diagnosis in the SCAN area hospitals is 4.6 years. This is new data. The average age of the patients was 37 years old and 70% of the patients were male. The range for delay to diagnosis across the 65 cases was from 1 month to 30 years. The observed variability between the hospitals may be related to sample size, differences within local referral systems or reflective of areas where primary care education has been undertaken. Whilst acknowledging the relatively modest size of the sample, this regional multicentre dataset has allowed us to importantly establish what our average delay to diagnosis is for patients within the SCAN region. This valuable information will provide support for planning and implementation of further regional service improvements.
Conclusion: Our data suggests the delay to diagnosis within our region is significantly shorter than the national average (4.6 years versus national average 8.5 years). However, this delay remains unacceptably long and is likely to be associated with worse disease-related quality of life and a wider detrimental socio-economic impact. The SCAN group will consider introducing changes to the referral processes (*e.g.,* an agreed single referral proforma with local education). We may also aim to replicate any successful local arrangements in place at those hospitals with the shortest delay to diagnosis. We aim to re-evaluate the delay to diagnosis across the SCAN region in 12-36 months where we are optimistic of demonstrating further progress with reducing diagnostic delay for our patients with AxSpA.

POS1595-HPR INTEGRATION OF TELEMEDICINE AND MEDICAL STUDENTS INTO A NEW DIAGNOSTIC PATHWAY FOR PATIENTS WITH SUSPECTED AXSPA: A QUALITATIVE EXPLORATION OF THE PATIENTS' EXPERIENCE

Keywords: Health services research, Qualitative research methods, Patient reported outcomes

K. Boy[1], S. May[1], H. Labinsky[2,3,4], S. Von Rohr[2,3], G. Schett[2,3], A. Ramming[2,3], J. Knitza[2,3], F. Muehlensiepen[1]. Background: Increasing demand and shortage of specialists lead to long waiting times for initial appointments in rheumatology care [1]. These result in diagnostic delays in several rheumatic diseases, with the longest total delay reported for patients with axial spondyloarthritis (axSpA) [1]. Telemedicine, including symptom checkers (SC), capillary self-sampling, and electronic patient-reported outcomes (ePRO) could enable patients to prepare a standardized pre-visit assessment at home. Additionally, fast-track appointments supported by medical students could complement this standardized assessment to enable fast diagnostic assessments and ultimately accelerate start of therapy.
Objectives: This qualitative study was embedded in a clinical trial that investigated a new diagnostic pathway for patients with suspected axSpA, including telehealth tools and fast-track visits supported by medical students. The aim of this qualitative study was to explore patient experiences with this new care model.
Methods: Patients, purposively selected to reflect a heterogeneous sample in terms of age, gender, education and occupation, participated in an explorative, qualitative study using semi-structured phone interviews. Interview data was analyzed using structured qualitative content analysis.
Results: Qualitative interviews were conducted with twenty patients with suspected axSpA (Table 1). Patients perceived the initial consultation supported by students to be equivalent to standard rheumatology care. Patients considered the student consultation to be a valuable option to relieve workforce shortage in rheumatology care. The overall experience with the students was described as holistic and thorough by patients. Some participants pointed out that rheumatic patients often have long medical histories and, thus, may find it difficult to engage with initial care provided lead by students. Patients reported that using SC and performing capillary blood collection helped to better assess their disease status and promote mindfulness in this regard. Some patients described that the SC-questions were unspecific, which led to difficulties answering them. Furthermore, several patients requested a free-text note section to specify their standardized ePRO data. Patients considered the capillary blood collection to be helpful, especially in regard of travel and time savings. Reported disadvantages of self-administered blood collection were uncertainties about the amount of material and the unsustainable packaging material.

Table 1. Patient characteristics

Patient characteristics	Unit	Value (n=20)
Median Age (IQR)	Years	45.6 (18.2)
Mean Age (SD)	Years	43.3 (12.4)
Sex	patient number male/female	12/8
Final diagnosis	patient number axSpA/no axSpA	12/8

Conclusion: Patients perceived the new diagnostic pathway as an efficient and high-quality alternative to standard axSpA-care. Particularly, savings in time and travel were considered favourable by the interviewed patients. Personal comments or chat options could provide an even more individual patient experience.

POS1596-HPR

IMPACT OF THE HEALTH STATUS ON THE WILL TO USE TELEMEDICINE AMONG RHEUMATIC PATIENTS: SECONDARY ANALYSIS OF DATA FROM A GERMAN NATIONWIDE SURVEY

Keywords: Health services research, Telemedicine

F. Muehlensiepen[1,2], P. Petit[2], J. Knitza[2,3], M. Welcker[4], N. Vuillerme[2,5,6].
[1]Brandenburg Medical School Theodor Fontane, Center for Health Services Research, Rüdersdorf, Germany; [2]Université Grenoble Alpes, AGEIS, Grenoble, France; [3]Friedrich-Alexander-University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Department of Internal Medicine 3, Erlangen, Germany; [4]MVZ for RHEUMATOLOGY Dr. Martin Welcker GmbH, -, Planegg, Germany; [5]Institut Universitaire de France, -, Paris, France; [6]Orange Labs & Univ. Grenoble Alpes, LabCom Telecom4Health, CNRS, Inria, Grenoble, France

Background: Telemedicine (TM) is an effective tool to supplement rheumatology care and address staff shortages [1]. A previous study revealed that patients' willingness to try TM is closely connected to their perceived health status [2]. Yet, it is still unclear which factors are associated with patients' motivation to use TM according to the perceived health status.
Objectives: The study aimed to identify factors that determine patients' willingness to try TM (TM-try) and their wish that their rheumatologists offer TM services (TM-wish) according to their perceived health status.
Methods: We conducted a secondary analysis of data from a German nationwide cross-sectional survey among patients with rheumatic and musculoskeletal diseases (RMDs) [3]. Bayesian univariate logistic regression analysis was applied to the data in order to determine which factors were associated with TM-try and TM-wish, respectively. Predictor variables (covariates) studied individually included sociodemographic factors (e.g., age, sex) and health characteristics (e.g., health status). All the variables positively and negatively associated with TM-try and TM-wish in the univariate analyses were then considered for Bayesian model averaging analysis (BMA) after a selection based on the variance inflation factor (≤ 2.5) to identify determinants of TM-try and TM-wish, respectively.
Results: Regarding TM-try, a total of 26 (30.6%) and 45 (27.1%) variables/factors (answers to the 25 questions), out of 85, were found to be positively or negatively associated (ROPE% ≤ 5%) with a perceived okay and bad/very bad health statuses, respectively. Regarding TM-wish, a total of 14 (16.5%) variables/factors (answers to the 25 questions), out of 85, were found to be positively or negatively associated for both a perceived okay and bad/very bad health statuses, respectively. A total of 19 and 13 determinant factors (Figure 1) were identified for TM-try and TM-wish, respectively. Patients with a perceived bad/very bad health status that did not want to try TM were more frequently 60-69 years old, living 10-15 km from the GP's office, being diagnosed with rheumatoid arthritis and had more often less TM knowledge than patients wanting to try TM. Patients with a perceived bad/very bad health status that did wish that TM services were offered by rheumatologist were more frequently older, not documenting their health status and more being diagnosed with osteoporosis than patients wishing that TM services were offered by RM.
Conclusion: Our results indicate that RMD knowledge, age, RMD type, health status documentation and access to technical equipment and infrastructure influence RMD patients' motivation to use telehealth.

POS1597-HPR **ASSESSING THE USE OF VOICE COMMANDS IN THE CLINICAL SETTING**

Keywords: Artificial intelligence, Health services research

J. Martinho[1,2], R. Andev[3], R. Luqmani[3]. *[1]Centro Hospitalar e Universitário de Lisboa Norte, Centro Académico de Medicina de Lisboa, Rheumatology Department, Lisbon, Portugal*; *[2]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina, Unidade de Investigação em Reumatologia, Lisbon, Portugal*; *[3]University of Oxford, Oxford, UK, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom*

Background: Artificial intelligence (AI) could reduce the administrative workload of clinicians, thus allowing them to focus more on clinical work. AI-powered voice-recognition programs can record appointments and request additional diagnostic tests through automatic flows generated by specific voice commands, reducing the administrative burden. Although some clinicians consider these programs helpful in the clinical setting, others consider them challenging to learn and not to save time.

Objectives: To investigate the impact of voice commands in clinical practice: i) on time spent on different tasks (clinical and administrative) during the appointment, ii) on the accuracy of records, iii) on patients' and clinicians' satisfaction.

Methods: We undertook a single-centre prospective quality improvement project between 26/10/22 and 20/12/22 in the rheumatology department of Nuffield Orthopaedic Centre - Oxford University Hospitals. We included patients attending general rheumatology (GR), complex musculoskeletal (CMSK) and vasculitis clinics, performed by clinicians using voice commands (group 1, N=1) and clinicians not using voice commands (group 2, N=4). The voice command program used was Dragon Medical One. We defined "using voice commands" when this tool was used to insert a pre-prepared text template or order diagnostic exams. One investigator attended the clinics and timed the tasks performed during the appointment. Clinicians and patients answered questionnaires attributing satisfaction scores from 0 (very unsatisfied) to 10 (very satisfied). Univariate analysis was performed, as appropriate, using SPSSV25.

Results: Data regarding 80 appointments were collected: 40 from group 1 and 40 from group 2. The proportion of the clinic types in groups 1 and 2 was: GR 52.5% vs. 0%; CMSK 0% vs. 40%; and vasculitis 47.5% vs. 60%, respectively. There were no differences between the groups regarding new and follow-up patients or face-to-face and phone clinics. Group 1 finished recording the consult in a shorter time than group 2 (mean±SD: 5.6±1.8min vs. 8.9±3.7min, p<0.001). The time spent with the patient (mean±SD: 16.9±7.0 vs. 17.7±7.6, p=0.637) and ordering diagnostic tests (mean±SD: 2.9±1.7 vs. 2.7±1.2, p=0.803), did not differ between the groups. To compare the groups performing the same type of clinic, we conducted a subanalysis including only the vasculitis clinics (group 1 N=19 and group 2 N=24). In this setting, group 1 also finished recording the vasculitis consultations in a shorter time than group 2 (mean±SD: 5.2±1.6min vs. 8.9±4.5min, p<0.001). Moreover, group 1 had more final records with spelling mistakes than group 2 (26 vs. 13, p=0.004) but no more clinically significant errors (8 vs. 3, p=0.105). The latter consisted of one drug dose error, seven nonsense sentences from group 1, and 3 nonsense sentences from group 2. Regarding the clinicians' satisfaction levels, 5 out of 7 items evaluated showed significant differences between both groups. Group 1 had higher median scores of satisfaction regarding how the consultation went (9 [1] vs. 8 [1], p<0.001); the time they had to address the patient's concerns (9 [1] vs. 8 [2], p<0.001); and the way the dictation worked (8 [1] vs. 6 [1.75], p<0.001), compared to group 2. Moreover, group 1 felt that they spent more time listening and talking to the patient as opposed to doing administrative work (8 [1] vs. 7 [3], p<0.001), and also considered they had to do less writing (2 [1] vs. 5 [2], p<0.001), than group 2. There was no difference between the groups concerning patient satisfaction levels.

Conclusion: We report that voice commands: (i) were useful in reducing the time spent recording the consultation but did not influence the time spent with the patient or the time spent ordering diagnostic tests; (ii) resulted in a higher number of spelling mistakes but not clinically significant errors; and (iii) improved the clinicians' satisfaction at most levels and did not influence patients' satisfaction. Medical staff should be trained to adopt this technology, and developers should focus on improving accuracy and misspelling minimization.

HPR Professional education, training and competencies

POS1598-HPR **TEACHING AND CLINICAL OUTCOMES OF A NOVEL FELLOWS' INJECTION CLINIC**

Keywords: Education, Patient reported outcomes

W. Martin[1], S. Albano-Aluquin[1], S. Banks[1], N. Olsen[1]. *[1]Penn State Health Milton S. Hershey Medical Center, Medicine - Division of Rheumatology, Hershey, United States of America*

Background: The skills of performing joint/periarticular injections by rheumatology fellows are learned during training but achieving the necessary level of expertise can be challenging if the rotations lack dedicated skills teaching. There is also a paucity of literature reporting how injection proficiency evolves and how the type and number of procedures can affect performance.

Objectives: To combat these issues and enhance fellow training and patient outcomes, we started an exclusive fellows' monthly injection clinic and assessed the learners' progress by analyzing their proficiency scores (PS) over time, and asking if these differ between size of joints and number of procedures done. We selected 10 or more procedures as the number needed to achieve higher expertise and determined the patient response (efficacy) and side effects as secondary outcomes.

Methods: The clinic is led by a single attending rheumatologist who demonstrates the proper technique prior to the encounter, supervises the procedure and provides feedback. Outcome measures include the procedure type classified as small/medium or large joint/periarticular structures. The PS was measured by the same teacher throughout and used a numerical scale of 1-3 defined as 1 – early, 2 – progressing, or 3 - advanced. Factors affecting proficiency score included preparation, technique, and cleanup. Efficacy was measured by successful aspiration and for steroid injections, by patient report of >50% improvement in joint pain at the next follow-up visit. Patients were advised to call the clinic to report any adverse events.

Results: Thirteen clinics took place between December 2020-August 2022. Fellows performed an average of 4 procedures per clinic for a total of 52 procedures. PS were compared at initial (n=15) and last clinic encounter (n=17), and between large (n= 32) and small/medium joints/periarticular procedures (n=20). PS steadily increased over time with higher proficiency achieved by the 3rd or 4th clinic compared to the initial clinic [2(1-3) vs 1(1-2), p=0.018]. Fellows tended to achieve higher PS for large joint/periarticular procedures (hip and knee) compared to the more technically difficult small/medium joint/periarticular procedures (shoulder, feet and hands) [2[1-3) vs 1(1-2), p < 0.0001]. We arbitrarily selected 10 or more procedures as the number needed to achieve higher expertise but found no difference in PS between performing <10 versus > 10 injections [2(1-3) vs 2(1-3), p= 0.35]. The procedures were highly effective and safe with favorable responses seen in 94.0% (49/52 procedures) with no reported side effects.

Conclusion: The longitudinal injection clinic demonstrated a steady improvement in proficiency among fellows while minimum number of procedures needed to attain expertise needs further studies. Our data can provide a useful template for designing a skills-based curriculum for rheumatology training programs.

HPR Interdisciplinary research

POS1599-HPR ANTI-CCP+ AT-RISK INDIVIDUALS HAVE A MILD PHENOTYPE OF PERIODONTAL DISEASE, WHICH IS TREATABLE WITH A COURSE OF NON-SURGICAL PERIODONTAL THERAPY

Keywords: Autoantibodies, Biomarkers

Z. Mustufvi[1], R. Letton[1], K. Harnden[2], R. Chowdhury[2], A. Tugnait[1], P. Emery[2], S. Pavitt[1], K. Mankia[2]. [1]*University of Leeds, School of Dentistry, Leeds, United Kingdom*; [2]*Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Musculoskeletal Medicine, Leeds, United Kingdom*

Background: Rheumatoid autoimmunity may be initiated at mucosal sites such as the periodontium. Patients with RA and anti-CCP+ at-risk individuals have an increased prevalence of periodontal disease (PD) [1]. PD is often asymptomatic and diagnosed by clinical examination. We hypothesised that comprehensive periodontal assessment of CCP+ at-risk individuals would identify PD, which would be amenable to treatment with a single course of non-surgical periodontal therapy (NSPT).

Objectives: To determine the periodontal disease phenotype in anti-CCP+ at-risk individuals and to investigate the feasibility/efficacy of a course of NSPT.

Methods: Anti-CCP+ at-risk individuals with musculoskeletal symptoms but no clinical synovitis ('CCP+ at risk') were recruited from the Leeds CCP cohort. All participants had a high anti-CCP level (>3 X ULN) and had periodontal screening by a dentist, including radiographs. Clinically significant PD was defined as clinical attachment loss ≥4mm on at least two non-adjacent teeth, ≥40mm of cumulative probing pocket depth (minimum 4mm per site). Those with PD were offered NSPT. Periodontal indices were recorded before and after NSPT. Treatment completion occurred when PD had stabilised, as determined by clinically significant reduction in bleeding/probing indices.

Results: Seventy-two CCP+ at-risk were offered screening; 51 (71.8%) accepted. The main reason cited for declining was time pressures. 31/51 (59%) subjects had clinically significant PD and were offered NSPT. Of these, 15 have completed treatment over a median of three treatment sessions (median timeframe 17 weeks). The remaining participants are receiving ongoing treatment. The mean age for patients with PD was 51.22 and 64.5% were female. Seven (22.6%) patients were current smokers, 16 (51.6%) ex-smokers and 8 (25.8%) never smokers. Mean baseline scores were; 49.41% plaque free, 15.14% bleeding, 21.46% mild pocketing, and 4.42% deep pocketing. Radiographic assessment revealed a predominantly mild (stage I/II) disease phenotype; 8 (25.8%) stage I, 11 (35.4%) stage II, 9 (29%) stage III, and 3 (9.7%) stage IV PD. Plaque free scores improved by 27.89% (p<0.05), demonstrating high patient motivation. Bleeding indices, (indicating gingival inflammation) reduced to 8.49%, within the accepted level for PD stabilisation [2]. There was significant probing depth reduction at both mild (10.02%) and deep (3.1%) sites (Table 1).

Table 1. Demographic and clinical data of anti-CCP positive at-risk individuals who underwent periodontal assessment and treatment.

	Variable			
Participants with PD (n=31)	Age (mean/SE)		51.22 (11.09)	
	Females (n/%)		20 (64.5%)	
	Baseline anti-CCP level (n/%)			
	>300u/ml		11 (35.5%)	
	100-300		9 (29%)	
	10-99		11 (35.5%)	
	Baseline radiographic data (n/%)			
	Stage I		8 (25.8%)	
	Stage II		11 (35.4%)	
	Stage III		9 (29%)	
	Stage IV		3 (9.7%)	
Treated patients (n=15)		**Before treatment**	**After treatment**	**P value**
	Mean plaque free scores (%)*	51.23% (SE 21.88)	79.12% (SE 25.23)	<0.05
	Mean bleeding on probing (%)*	16.32% (SE 9.91)	8.49% (SE 4.13)	<0.05
	Mean mild (4-6mm) pocketing* (%)	17.22% (SE 11.1)	7.2% (SE 4.33)	<0.05
	Mean deep (>6mm) pocketing* (%)	3.7% (SE 1.1%)	0.69% (SE 1.7%)	<0.05

Conclusion: Routine periodontal assessment of anti-CCP+ at risk individuals identifies a mild and treatable phenotype of periodontal disease. Periodontal screening and treatment with a course of NSPT is acceptable to at-risk individuals and results in effective treatment of periodontal disease. This approach may form part of future personalised strategies for RA prevention.

Background: healthy lifestyle is known to prevent the progression of rheumatic and musculoskeletal diseases (RMDs). Despite contemporary improvements in RMD clinical care, the management of lifestyle factors has received less attention. Underlying causes may be the lack of awareness and insufficient evidence, but patient and physician education may also play a role.

Objectives: to collect and review currently available materials for health promotion on lifestyle factors for people with RMDs across Europe and to assess their implementation needs.

Methods: materials on lifestyle factors (diet, weight control, physical activity, work participation, alcohol consumption and smoking) were collected from health professionals in rheumatology and patient associations through EULAR and EMEUNET channels.

Results: 38 materials from 11 countries were retrieved (Table 1), including North, South, and Central European regions. Documents (22) or leaflets (12) were the most frequent materials. The most reported factor was diet (23) followed by physical activity (17), whereas information on work participation was scarce [2]. The materials were more commonly focused on rheumatoid arthritis (8), although documents for people with RMDs in general were also frequent (12). Only eight materials included scientific references. Although 23 materials contained some kinds of recommendations, only two were evidence-based, whereas the rest contained general statements. Materials were mostly available in the official national language, and 16 were accessible on the internet, whereas no information on accessibility or

reach was obtained for the remainder. Significant limitations across implementation domains (process model, determinant frameworks, and evaluation) were observed, mostly due to flawed knowledge generation, poor identification of barriers and facilitators, and lack of evaluation frameworks. **Conclusion:** although materials on lifestyle factors were common, they were not always available at the national level across Europe. Current materials are hallmarked by a lack of consistency in formats, layouts, content, focus, lack of scientific evidence and patient involvement. Major impediments for implementation were found. These findings will inform the implementation of EULAR-endorsed recommendations on lifestyle factors for people with RMDs.

Acknowledgements: We thank HPR, PARE associations and EMEUNET for their collaboration in collecting informative materials on lifestyle factors accross European countries.

ADVERSE EVENTS AND ADVERSE REACTIONS WITH THE USE OF ANTITNF'S DETECTED BY THE PHARMACOVIGILANCE PROGRAM OF A SPECIALIZED RHEUMATOLOGY CENTER

Keywords: Disease-modifying drugs (DMARDs), bDMARD

W. Rivero[1], P. Rodríguez-Linares[2], F. Rodriguez[3], G. S. Rodríguez-Vargas[2], A. Rojas-Villarraga[4], P. Santos-Moreno[2]. [1]*BIOMAB - Center for Rheumatoid Arthritis, Pharmaceutical Chemist, Bogotá, Colombia*; [2]*BIOMAB - Center for Rheumatoid Arthritis, Scientific Direction, Bogotá, Colombia*; [3]*BIOMAB - Center for Rheumatoid Arthrtis, Patients Education, Bogotá, Colombia*; [4]*Fundación Universitaria de Ciencias de la Salud FUCS, Research Institute, Bogotá, Colombia*

Background: Pharmacovigilance is the science that is responsible for the detection, notification, and monitoring of possible drug adverse events (DAE) that occur with the administration of medications. In the pharmaceutical service process, the information generated through its programs constitutes evidence that provides a solution to the management of drug-related problems, especially those obtained by biotechnology.

Objectives: The aim of this study is to show the main DAEs and drug adverse reactions (DARs) with the use of anti-TNF (Anti-Tumor Necrosis Factor) drugs detected by the Pharmacovigilance program of an IPS specialized in rheumatology during the period 2018-2022.

Methods: The current method carried out in the institution is the so-called S*pontaneous Notification*. A retrospective review of the DAE and DAR detected by an institutional Pharmacovigilance program with the use of Anti-TNF drugs, in patients with autoimmune diseases, during the period 2018-2022, was carried out. Indicators were established through descriptive statistics to measure the frequency of DAE and DAR.

Results: 408,914 medical records were reviewed, the Table 1 shows the comparative percentages of DAE and DAR detected by the program between conventional disease-modifying antirheumatic drugs (csDMARDs) and biologics during the follow-up period. The Pharmacovigilance program had growth in the detection of DARs with the use of anti-TNF drugs, strengthening knowledge in the information for these. The causality with the anti-TNF was established, being the DAE classified as probable and the DAR as possible. Of the total subgroup of patients treated at the institution for medication application (46,832), notifications were received as follows: (Infliximab 17, Etanercept 17, Adalimumab 22, Golimumab 15, Certolizumab 51). Additionally, dermatological reactions are the most recurrent types of reactions. Herpes is found as the main DAR with Certolizumab

in the last year. According to the results obtained, Certolizumab is the drug that has presented the most adverse reactions during the follow-up period (Figure 1).
Conclusion: Dermatological reactions are the most frequent with anti-TNF drugs. Infliximab and Certolizumab stand out for this type of commitment. Studies are needed in populations from the same country to compare these results and generate more knowledge.

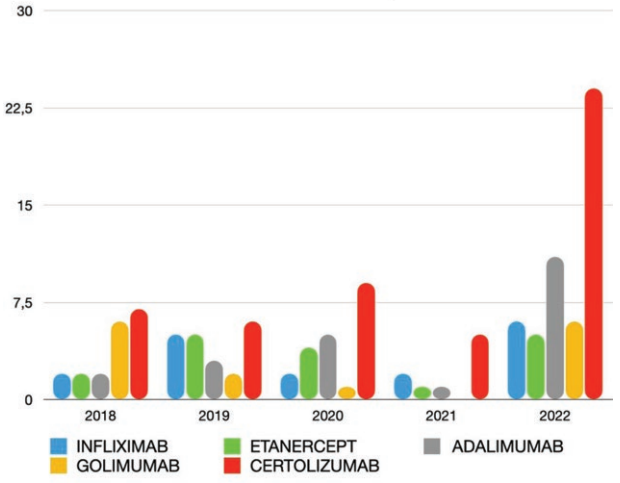
PAIN AND CATASTROPHIZING IN RHEUMATIC DISEASES: IMPACT ON PSYCHOLOGICAL DATA AND QUALITY OF LIFE

Keywords: Pain, Quality of life



C. Chiraz[1], R. Fakhfakh[2], N. El Amri[2], D. Khalifa[2], E. Bouajina[2]. [1]*Sahloul Hospital, Physical Medicine and Rehabilitation, Sousse, Tunisia*; [2]*Farhat Hached Hospital, Rheumatology, Sousse, Tunisia*

Background: Catastrophizing is a common behavior in patients with chronic pain.It is a negative cognitive-affective response to pain. It is thought to be associated with the persistence and exacerbation of chronic pain.
Objectives: To determine the prevalence and the associated factors of catastrophizing in rheumatic diseases(RD).
Methods: A cross-sectional study on patients with RD followed in the rheumatology department of hached hospital. Biological and clinical data were collected from medical records. Depression and anxiety were evaluated by the HAD scale (Hospital Anxiety and Depression scale). Quality of life was assessed by the SF-12, which is a self-assessment scale of quality of life that is a shortened version of the SF-36. Catastrophizing was assessed by the Pain catastrophizing scale (PCS). A PCS score of 30 or more represents a high level of catastrophizing.
Results: Our study included 60 patients with RD: 44 patients with rheumatoid arthritis(RA),12 patients with ankylosing spondylitis(SpA) and 4 patients with psoriatic arthritis (PsA). The mean age was 48.83 years (73.33% female). The mean PCS score was 31± 10.34. The prevalence of high catastrophizing(PCS ≥ 30) was 73.3% in all patients: 72.7% of patients with RA,66.7% with SpA and 100% with PsA. A high catastrophizing score was found in 91.7% of anxious patients and 95% of depressed patients.No statistically significant association of catastrophizing with age nor gender was noted. Catastrophism was significantly associated with depression, anxiety ($p < 10^{-4}$) and pain VAS (p=0.001). The decrease in quality of life assessed by the physical (PCS12) and mental (MCS12) components of the SF12 was significantly associated with catastrophizing ($p < 0.01$).
Conclusion: In our study more than two-thirds of the population had high PCS scores with a significant correlation with pain VAS, anxiety and depression and a low quality of life score.

Table 1. COMPARISON OF ADVERSE REACTIONS BETWEEN CONVENTIONAL AND BIOLOGICAL DMARDs

AÑO	DAR	DAE	csDMARD	BIOLOGICO
2018	52,5%	46%	62,9%	28,7%
2019	39,3%	52,3%	26,1%	61,4%
2020	40,2%	40%	31,3%	65,5%
2021	25,0%	51%	45,8%	52,1%
2022	35,5%	36%	32,0%	68,9%

AB0001 GUT MICROBIOTA IMBALANCE IN INFLAMMATORY ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keywords: Inflammatory arthritides

X. Y. Yin[1,2], D. Qiao[1,2], G. X. Wang[1,2], X. Song[1,2], Q. Y. Su[1,2,3], H. Zhou[1,2], Q. Yu[4], P. F. He[4], X. Li[1,2,3], S. X. Zhang[1,2,3]. *[1]Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; *[2]Shanxi Medical University, Academy of Microbial Ecology, Taiyuan, China*; *[3]The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; *[4]Shanxi Medical University, Shanxi Key Laboratory of Big Data for Clinical Decision Research, Taiyuan, China*

Background: Inflammatory arthritis (IA) is a group of autoimmune arthritis characterized by a pro-inflammatory/anti-inflammatory disbalance of local mediators[1] [2]. Research on the influence of gut microbiota(GM) on systemic IA has exploded in the past decade. GM changes may be a crucial regulatory component in systemic IA[3]. However, the link between them has yet to be fully elucidated.
Objectives: This study aims to study the GM composition of IA to provide evidence for its potential role in the pathogenesis, progress, and treatment of IA.
Methods: We systematically searched the trials for PubMed, EMBASE, Web of Science, Medline, Wanfang database, VIP, CNKI, and CBM database from the establishment of the database to January 1, 2023. Standardized mean difference (SMD) and 95% confidence interval (CI) were calculated to assess alterations in α-diversity and the abundance of certain microbiota families in IA. Literature quality was evaluated according to the requirements of systematic review, and meta-analysis was performed using STATA v.12.0.
Results: A total of 70 studies, including 3,322 patients and 4,412 healthy controls, were identified. Compared with HCs, the GM of patients with IA has a lower Simpson index(SMD=-0.307, 95%CI -0.509, -0.106) and Shannon index(SMD=-0.184, 95%CI -0.344, -0.024). When specific IA was examined, significant decreases were observed in rheumatoid arthritis(Simpson index: SMD=-0.558, 95%CI -0.891, -0.225; Shannon index: SMD=-0.608, 95%CI -0.935, -0.281; ACE: SMD=-0.414, 95%CI -0.697, -0.132; Chao1: SMD= -1.373, 95%CI -1.980, -0.766; eveness index: SMD=-1.863, 95%CI -3.181, -0.544), psoriatic arthritis(Simpson index: SMD=-0.733, 95%CI -1.367, -0.099), osteoarthritis(Chao1: SMD=-0.793, 95%CI -1.096, -0.491) and gout(Simpson index: SMD=-1.037, 95%CI -1.959, -0.115). In other diseases, we found that the α-diversity index was higher than that of the HCs group[reactive arthritis(Shannon index: SMD=0.697, 95%CI 0.265, 1.130; ACE: SMD=1.878, 95%CI 1.375, 2.380; Chao1:SMD=0.835, 95%CI 0.398, 1.273; InvSimpson: SMD=0.823, 95%CI 0.386, 1.260; Observed species: SMD= 2.004, 95%CI 1.491, 2.517); osteoporosis(eveness index: SMD=0.488, 95%CI 0.047, 0.928); ankylosing spondylitis(InvSimpson: SMD=0.525, 95%CI 0.272, 0.777); Juvenile idiopathic arthritis(Observed species: SMD=1.672, 95%CI 1.100, 2.243)]. Furthermore, to exclude sequencing methods' influence on species abundance detection, we conducted a subgroup analysis of Observed species. The results showed that the observed species abundance through high-throughput sequencing was higher(SMD=1.376, 95%CI 0.394, 2.358) and 16S rRNA gene sequencing was lower(SMD=-0.842, 95%CI -1.575, -0.108) than that of HC. At the phylum level, there was a significant reduction in *Firmicutes*(SMD=-0.455, 95%CI -0.796, -0.114) and *Fusobacteria*(SMD=-0.422, 95%CI -0.692, -0.152). At the genus level, the abundance of *Bacteroides*(SMD=0.898, 95%CI 0.003, 0.003) was higher and *Faecalibacterium*(SMD=-0.380, 95%CI -0.713, -0.047) was lower. The two groups had no significant differences in *Bifidobacterium* and *Butyricicoccus*(P >0.05).
Conclusion: Our research showed a definite relationship between IA and GM. Further diet and drug therapy research are needed to explore the relationship between human GM and IA.

AB0002 THE GENETIC BACKGROUND OF ANKYLOSING SPONDYLITIS INDICATES A STRONG CORRELATION WITH OTHER AUTOIMMUNE DISEASES

Keywords: Inflammatory arthritides, Genetics/Epigenetics, Spondyloarthritis

L. Papageorgiou[1,2], M. Zervou[3], T. Zormpa[1], R. Golfinopoulou[1], D. Vlachakis[1], G. Bertsias[3], G. Goulielmos[3], E. Eliopoulos[1]. *[1]Agricultural University of Athens, Department of Biotechnology, Athens, Greece*; *[2]University of West Attica, School of Health and Care Sciences, Athens, Greece*; *[3]University of Crete, Medical School, Heraklion, Greece*

Background: Ankylosing Spondylitis (AS) is considered to be a rare autoimmune disease that has been studied in genetic level the last decades [1]. The cases reported suggest that there might be an improvement in disease diagnosis with an overlap by other autoimmune diseases [2]. Patients can be diagnosed and the clinical symptoms are in alignment with a diagnosis of the disease. Meanwhile, novel studies propose various genetic factors that may be related to the disease has emerged. Most of the patients carrying various subtypes of the *HLA-B27* gene, such as B*2702, B*2703 and B*2710, are at an increased risk of developing AS [3]. Importantly, the relationship between the genetic factors and the development of the disease is still remains unclear.
Objectives: To create the disease genomic grammar (DGG) with the most credible genetic and epigenetic variants as well as and single nucleotide polymorphisms (SNPs) causing the basis for the development of AS and identify the correlation with other candidate autoimmune diseases [4].
Methods: AS related publications have been analyzed with the use of data mining and semantic techniques for the extraction of information regarding SNPs associated with the disease and the estimation of a candidate DGG. The extracted SNPs have been filtered, evaluated, annotated, and classified in the DGG, using several layers of information from well-known biological databases including dbSNP, LitVar, ClinVar, OMIM and KEGG. Moreover, the AS DGG has been further analyzed towards identifying the hidden connections with other autoimmune diseases.
Results: A holistic genetic map of the AS DGG with 658 related SNPs has been estimated and the specific sub-clusters with crucial SNPs have been correlated with several other autoimmune disease including RA, PS, CD and SEL (Figure 1). This indicates that AS has a common genetic background as many other autoimmune diseases [5]. The candidate DGG of the AS has been estimated using the SNPs annotated information and 3 major clusters of SNPs have been estimated. The DGG of the AS, 85% responds to non-coding regions and 15%

responds to coding regions of which 684 related with promoter and coding gene regions as well as pseudogenes, 74 with LNC, miR and LOC regions and 54 with uncharacterized regions (Figure 1). Moreover, they have been identified the most highly correlated genes with AS using the DGG and the frequency-corresponding SNPs (Table 1).

Conclusion: Despite the several studies performed in AS, is still difficult to identify and categorize the representative variants that may contribute to its. Therefore, crucial genes and specific epigenetic locations must be recognized towards understanding the biological mechanisms of the disease [6, 7]. In the framework of the present study, the DGG of AS was created, using novel bioinformatic techniques. The identification of the DGG in AS may assist in the deeper understanding of this rare disease and the hidden connections with other autoimmune diseases, and will also provide beneficial knowledge regarding common biological pathways leading to autoimmunity regardless of the clinical phenotype of each disease.

AB0003 INTERLEUKIN 17A RS2275913 GENE POLYMORPHISM IS RELATED TO SEVERITY AND DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS AND INCREASED SERUM IL17A LEVELS IN EGYPTIAN PATIENTS.

Keywords: Cytokines and chemokines, Rheumatoid arthritis, Genetics/ Epigenetics

M. E. Ibrahim[1], S. A. Fattah[2], M. Abdelfattah[1], E. Mehanna[2]. [1]*Suez Canal University, Rheumatology, Ismailia, Egypt*; [2]*Suez Canal University, Biochemistry, Ismailia, Egypt*

Background: Interleukin 17A (IL17A), one of the IL-17 family, performs a critical role in the inflamed synovial tissue of Rheumatoid Arthritis (RA) patients. Several studies have been performed to investigate the role of IL 17A rs2275913 polymorphism in RA pathogenesis, however, data about its role in RA severity and activity is inconsistent.
Objectives: We aimed to investigate the influence of IL17A rs2275913 polymorphism on IL17A serum levels in Egyptian RA patients and disease severity and activity.
Methods: The study included 100 healthy subjects and 100 RA patients. Gene polymorphism rs2275913 was measured by Taqman genotyping assay in both patients and healthy control groups. IL17A serum levels and clinical and laboratory parameters were measured using the enzyme-linked immune sorbent assay (ELISA) technique.
Results: RA patients showed higher IL 17A serum levels than the control group (121.9 ± 24.3 ng/dl vs 20.4 ± 2.6 ng/dl, P < 0.001). RA patients showed a higher frequency of rs2275913 G allele than healthy subjects (P = 0.01). Patients carrying GG genotype showed higher values of all disease severity parameters including Rheumatoid Factor (52.79 ± 16.65 IU/ml, P<0.001) and Anti-Cyclic Citrullinated Peptide Antibody (36.6 ± 14.86 U/ml, P < 0.001). The high-risk GG genotype carriers had higher IL17A serum levels than the GA and AA genotypes carriers (129.74 ± 23.03 ng/dl vs 107.49 ± 19.85 ng/dl, P <0.001).
Conclusion: The major allele of IL17A rs2275913 polymorphism was associated with higher IL17A serum levels, and greater RA severity. It is thus very likely that the rs2275913 polymorphism of IL17A gene is associated with an increased risk of RA, as well as with higher severity in Egyptian RA patients.

AB0004 THE DISEASE GENOMIC GRAMMAR OF MYASTHENIA GRAVIS INDICATES A COMMON GENETIC BACKGROUND WITH RHEUMATOID ARTHRITIS

Keywords: Genetics/Epigenetics, Rheumatoid arthritis, Inflammatory arthritides

L. Papageorgiou[1,2], M. Zervou[3], R. Golfinopoulou[1], G. Bertsias[3], G. Goulielmos[3], E. Eliopoulos[1], D. Vlachakis[1]. [1]*Agricultural Uniersity of Athens, Department of Biotechnology, Athens, Greece*; [2]*University of West Attica, School of Health and Care Sciences, Athens, Greece*; [3]*University of Crete, Medical School, Heraklion, Greece*

Background: Myasthenia Gravis (MG) is a rare, multifactorial autoimmune disease. It is caused by the presence of autoantibodies to the postsynaptic membrane of the neuromuscular junction causing impairment to neuromuscular transmission [1]. Various SNPs have been associated with MG with a number of genes possibly contributing to the disease pathogenesis [2]. Through the Disease's Genomic Grammar (DGG), as formulated by Bioinformatics tools, common genetic associated components have been established with RA, thus suggesting a genetic overlap in the manifestation of both diseases and possible concurrency in patients [3].
Objectives: To create an ensemble of the genetic factors contributing to MG, to evaluate the most credible SNPs associated with disease manifestation, to establish a relationship with RA and to potentially assist in prognosis, prevention and personalized treatment of both diseases.
Methods: PubMed publications containing the term "myasthenia gravis" were analyzed with data mining and semantic techniques. Data Annotation enhanced the data collected, including SNPs obtained through GWAS, with information including variation type, alleles, relevance with phenotypes and additional clinical, genomic and functional information from databases including dbSNP, LitVar, ClinVar and Genes. Strong-Associated SNPs were further analyzed and validated. Genes related with both MG and RA were used to estimate a gene network with the use of the GeneMANIA tool and genetic and protein interactions, pathways and co-expression was studied.
Results: A candidate DGG was established containing a total 77 SNPs associated with MG and further categorized into three major classes. Within this database, different types of SNPs were identified with 27 SNPs representing Intron Variants (32.5%), 17 were 2KB Upstream/500B Downstream Variants (20.5%), 12 concerned Missense Variants (14.5%) and 7 SNPs were identified as 3' or 5' UTR Variants (8.4%). Class A included 40 Strong-Associated SNPs, related with 24 genes. MG and RA share 10 common Strong-Associated (Class A) SNPs (25%) related with 10 genes, based on the retrieved data. In a second level of analysis, these common genes create a functional network of a total of 29 genes and 855 total links, with 90.1% co-expression as generated by the GeneMANIA tool (Figure 1).
Conclusion: A higher frequency of concurrent autoimmune diseases is observed than the background prevalence and it has been demonstrated that MG coexists with other ADs in population studies [4,5]. Patients with concomitant MG and RA encounter more challenges in the therapeutic aspects of their health, considering that known disease-associated polymorphisms can be utilized in early diagnosis, prognosis and specialized treatment. Identifying the optimal genomic grammar in MG with the use of

novel Bioinformatic tools may assist in the better understanding of this polygenic disease, while its association with RA and other ADs is a helpful step towards comprehending the shared biological pathways leading to autoimmunity. The data resulting from our study can be utilized towards the development of an application designed to assist clinical diagnosis by using the patients' genomic data, like the integrated bioinformatics tools Demetra for endometriosis [6] and Epione for SLE [7].

CHANGES OF SALIVARY MICROBIAL COMMUNITY IN PATIENTS WITH PERIODONTITIS

Keywords: Prognostic factors, Adaptive immunity, Biomarkers

C. Wang[1,2], J. Qiao[2,3], Y. Li[1], M. J. Chang[1,2], R. X. Qi[1], S. X. Zhang[2,3], Q. Yu[1], P. F. He[4]. [1]*Shanxi Medical University, School of Management, Taiyuan, China*; [2]*The Second Hospital of Shanxi Medical University, Department of Rheumatology, Taiyuan, China*; [3]*Ministry of Education, Key Laboratory of Cellular Physiology at Shanxi Medical University, Taiyuan, China*; [4]*Shanxi Medical University, Medical Data Sciences, Taiyuan, China*

Background: Periodontitis (PD) is a chronic, progressive polymicrobial disease[1]. In the context of the microbiome in the pathogenesis of rheumatic disease, microorganisms located in the periodontal tissues play an important role as potential initiators of immune-mediated inflammatory conditions at distant sites[2]. Studies have shown that the microbiota associated with PD is different from that in health, and the chronic inflammatory response induced by salivary microbiota plays an important role in the development of PD.
Objectives: Study to evaluate and quantify the differences in the composition of salivary microbiota in patients with PD, and investigate the correlation between salivary microbiota in patients with PD and clinical variables.
Methods: In the same race, 34 salivary samples of patients with PD and 28 salivary samples of periodontal health controls(HC) were collected for 16S rRNA gene sequencing. Compare salivary microbiota alpha-diversity,beta-diversity and microbial composition (at the phylum and genus levels) were used to determine differences in salivary microbiota characteristics between periodontitis patients and periodontal health controls. LefSe analysis was carried out to identify differentially abundant genera.The correlation between different taxa and clinical variables was calculated by the Spearman rank test.
Results: Consistent with the observed diversity trend, compared with periodontal health, the richness of patients with periodontitis is relatively high ($P<0.05$, Figure 1a), which indicates that the diversity of salivary microbiome in patients with periodontitis is significantly higher. The Beta diversity based on Bray Curtis distance at the species level demonstrated a significant differences in microbial communities between periodontitis patients and periodontal health (analysis of variance, r2=0.094, p=0.001,Figure 1b). At different phylogenetic levels, the 10 selected taxonomic biomarkers showed strong discrimination ability, with log10 LDA score >4.0 (Figure 1e-g). Specifically, at the phylum level, the Firmicutes phylum frequency of periodontitis patients is lower, while the Spirochaetota frequency is higher. Patients with periodontitis have more genus Treponema at the genus level (Figure 1c-d). PICRUSt analysis found that in the KEGG pathway, the function of microbial genes related to amino acid metabolism in the salivary microbiota of periodontitis patients was higher (Figure. 1h). Treponema was positively correlated with periodontal probing depth (PPD). Total, plaque index (PI) and periodontitis extent Calc. Spirochaetota was positively correlated with PPD Total, PI ($p<0.05$, Figure 1i).
Conclusion: Specific salivary microbiota played an important role in the pathogenesis of periodontitis, which may help to diagnose or determine individual susceptibility to periodontitis by detecting salivary microbiota.

CLINICAL, BIOLOGICAL AND GENETIC BIOMARKERS ASSOCIATED WITH DIFFERENT PHENOTYPES OF SYSTEMIC LUPUS ERYTHREMATOSUS IN PARAGUAYAN PATIENTS

Keywords: Systemic lupus erythematosus, Biomarkers, Genetics/Epigenetics

I. Acosta Colmán[1], Z. Morel[1], A. Ayala-Lugo[2], V. Jolly[2], I. De Guillén[2], P. Langjahr[3], M. Vázquez[1], C. Holt[1], A. Paats[1], M. Martínez[4], M. E. Acosta[2]. *[1]Universidad Nacional de Asunción, Facultad de Ciencias Médicas, Departamento de Reumatología, San Lorenzo, Paraguay*; *[2]Universidad Nacional de Asunción, Instituto de Investigación en Ciencias de la Salud, Laboratorio de Genética Molecular, San Lorenzo, Paraguay*; *[3]Universidad Nacional de Asunción, Facultad de Ciencias Químicas, San Lorenzo, Paraguay*; *[4]Laboratorio Curie,., San Lorenzo, Paraguay*

Background: Systemic Lupus Erythematosus (SLE) is a complex autoimmune disease characterized by a very heterogeneous clinical picture that makes diagnosis and follow-up of these patients difficult.
Objectives: Identify correlations between clinical, immunological and genetic biomarkers with clinical manifestations in SLE in Paraguayan patients.
Methods: Retrospective study of data from medical records and immunological and genetic studies of patients with SLE from Paraguay. A descriptive analysis was performed based on the type of variable. HLA allele frequency (DPA1, DPB1, DQA1, DQB1, and DRB1) was calculated and univariate logistic regression analysis was performed between each of the explanatory variables and the presence/absence of each of the phenotypes. The odds ratio. (OR), the 95% confidence interval (95%CI), and the p-value were recorded. Associations with a p-value less than 0.05 were considered statistically significant associations.
Results: 104 patients with SLE were included, 86% female with a mean age value of 32.80 ±10.36 years. An association was identified between anti-dsDNA and the presence of the renal phenotype and anti-dsDNA with the absence of the joint and hematological phenotype. The IgM isotype RF was associated with the absence of the renal phenotype. HLA DQB1* 02:02 and HLA DRB1* 07:01 associated with cutaneous phenotype were identified. An association was identified between the age of onset of the disease and the presence of the joint phenotype. No other associations were identified with the other variables studied.
Conclusion: Possible clinical, immunological and genetic biomarkers of phenotypes have been identified in patients with SLE of Paraguayan origin.

Background: We have previously described the presence of pathogenic-like lymphocyte (CPLs; $CD4^+HLA\text{-}DR^+$) subset within the circulation, that is phenotypically similar to their synovial counterparts. CPLs are inflammatory T effectors that correlate with disease activity and possess a TCR repertoire with strong synovial overlap. We also discovered a similar inflammation-associated T-regulatory (iaTreg; $CD4^+HLA\text{-}DR^+$) circulatory subset, that is activated, suppressive, poised to migrate to inflamed site and sharing TCR between the peripheral and synovial compartments. iaTreg and CPL were found to be phenotypcally quite similar. Their striking similarity, inspired the hypotheses of a common ontogeny driven by the synovial micro-environment, and whether their functionally discordant roles, pointed to an undetermined dynamic interplay.
Objectives: In this study, we seek to establish if a common disease ontogeny exists between synovial CPLs/iaTregs in human arthritis and why CPLs continue to perpetuate synovial inflammation.
Methods: We performed mass cytometry analysis of PBMCs from RA patients and healthy adults. CD4 subsets from active JIA PBMCs, paired JIA SFMCs and healthy paediatric controls were sorted for bulk RNA sequencing. CpG profiling of FoxP3 TSDR site was performed for synovial iaTregs. Treg suppression assays were performed in iaTregs for healthy paediatric controls, paired JIA PBMCs and SFMCs.
Results: Mass cytometry analysis of RA patients revealed memory induction of CPLs and iaTreg as compared with healthy adults. Importantly, CPLs/iaTregs from RA patients demonstrated reactivity to the dnaJP1 peptide, which is a pro-inflammatory epitope in RA patients, thus underscoring disease relevance. Circulatory JIA CPLs/iaTreg subsets displayed transcriptomic convergence, exhibiting (a) common pathway dysregulations, (b) restriction in TCR repertoire and (c) common transcription factor drivers, suggesting a common pathogenic

ontogeny. This phenomenon is further reinforced across the spatial/disease continuum, with synovium CPLs/iaTregs presenting common dysregulated pathways including IFNg signalling. In particular, TCR clonatype sharing in CPLs/iaTregs is higher in the synovium, suggesting a common antigenic origin. To understand the dynamic interplay between CPLs and iaTregs, we assess the regulatory capacity of iaTregs. Epigenetic profiling of CpG sites on the FoxP3 TSDR promoter, revealed typical Treg demethylation status within iaTregs, indicating a stable lineage. Suppression assays reveal that iaTreg rather than non-iaTregs were poised to suppress disease T effectors from JIA PBMC/SFMC, with higher rates of suppression. This is in contrast with healthy controls, where iaTregs were inferior in suppression, mirroring their disease ontogeny. Despite superior suppression from iaTreg in SFMC T effectors, synovial CPLs were resistant to suppression from iaTreg as compared with synovial Non-CPLs. Destabilisation assays in iaTregs, reveal a drop in FoxP3 levels in the presence of IFNg, suggesting a role for IFNg in CPL evasion of suppression.

Conclusion: Our study highlights the disease relevance of CPLs/iaTregs in human arthritis, whilst revealing evidence of a common pathological ontogeny for CPLs/iaTregs, that is antigenically driven by the inflammatory synovium environment. The dynamic interplay between CPLs/iaTregs, could be titled towards suppression evasion through IFNg, allowing for continual synovium inflammation.

AB0008 ROLE OF IL-23/TH17 AXIS CYTOKINES IN RHEUMATOID ARTHRITIS

Keywords: Cytokines and chemokines, Rheumatoid arthritis

J. Meher[1], S. Patel[2], M. S. Siddiqui[1], R. Nanda[2]. [1]*AIIMS, Raipur, General Medicine, Raipur, India*; [2]*AIIMS, Raipur, Biochemistry, Raipur, India*

Background: Rheumatoid arthritis (RA) is an autoimmune inflammatory arthritis driven by an inflammatory cascade of different cytokine families. IL-23/Th17 axis cytokine (IL-23, IL-17) has been studied as a key pathway for disease development and its association with disease severity, joint erosion and functional outcome [1], but the data supplementing to support the hypothesis is lacking and conflicting. Also, there is a paucity of data on the role of IL-23/Th17/IL-17 axis cytokines in an Indian subset of patients.

Objectives: The objective was to find the correlation between serum cytokines (IL-17, IL-23) and clinical parameters of Rheumatoid arthritis patients, e.g., disease activity (DAS28) and functional status.

Methods: This cross-sectional observational study was conducted in General Medicine OPD from 2021 to 2022. ACR/EULAR 2010 classification criteria was used to diagnose RA. Eighty-four consecutive RA patients were recruited after taking consent. Serum IL-17 and IL-23 levels were measured by the ELISA method. Clinical and laboratory parameters, DAS28-ESR, and HAQII were recorded. Data were analyzed to find the correlation between cytokine and disease parameters, and compare cytokine levels in different subgroups.

Results: The study showed a higher proportion of females than males (n=76,90.5% vs n=8,9.5%). 14.28%(n=12) cases were elderly RA. 90.5% were taking cDMARDs, whereas 48.8% (n=41) were steroid users. Majority of cases, 57.14% (n=48) had high disease activity, whereas 25% (n=21) had moderate disease activity. Cases achieved remission was 5.95%. The median value of serum IL-17 and IL-23 were 103.72 pg/ml (IQR=39.91-524.13) and 981.87 pg/ml (IQR=793.25-1205.0), respectively. Swollen joint count, but not tender joint count, correlated positively with both IL-17 and IL-23 levels (r_s=0.229, p=0.036; r_s=0.098, p=0.016, respectively). Among the inflammatory marker, only CRP correlated positively with IL-23 (r_s=0.269, p=0.014). Both IL-17 and IL-23 levels showed an insignificant, weak positive correlation with the disease activity DAS28 (r_s=0.183, p=0.097 & r_s=0.125, p=0.259), respectively. There was no difference in IL-17 and IL-23 levels among the disease severity group (p=0.130 & p=0.215). It was also noted that IL-17 was positively correlated with IL-23 (r_s=0.221, p=0.044). Among the cytokines, only IL-23 had shown a statistically positive correlation with functional status (HAQII) (r_s=0.284, p=0.009). IL-23 level differed significantly between males and females (p=0.013). Also, advanced RA had higher IL-17 level than early RA (p=0.028). Neither IL-17 nor IL-23 level showed any difference between the subgroup e.g., age (younger RA vs elderly RA), obesity (obese vs nonobese), DMARDs or steroid (user vs naïve), serology status (RF+ vs RF- & CCP+ vs CCP-).

Conclusion: Serum IL-17 levels were high in advanced RA as compared to early RA. Both IL-17 and IL-23 correlated positively with the swollen joint count. Only IL-23 was directly correlating with CRP and functional status. Both IL-17 and IL-23 had a weak, insignificant positive correlation with disease activity, and there was no difference in cytokines level among severity classes. Even cDMARD/steroid use did not affect the cytokines level. IL-17 receptor activation triggers transformations of acute synovitis to chronic persistent arthritis [2]. IL-23/IL-17 may be a factor for advanced/erosive disease develoment, which need further research. Hence, blocking IL-23 and IL-17 at an early stage may diminish IL-17 activity, retard the progression to chronic inflammatory arthritis and advanced disease.

Background: Disturbances in B cell immune responses have been implicated in rheumatoid arthritis (RA) pathogenesis since the first weeks of RA development. However, the mechanisms responsible for these immune alterations remain unclear. Follicular helper T (Tfh) cells are crucial for B cell maturation, activation and class-switching as well as for germinal center (GC) formation, whereas follicular regulatory T (Tfr) cells can modulate the GC reaction by suppressing Tfh and B cells.

Objectives: The main goal of this study was to analyze the frequency and phenotype of B, Tfh and Tfr cells in peripheral blood of untreated early RA patients when compared to patients with early non-RA polyarthritis, established RA and healthy controls.

Methods: Blood samples were collected from 35 untreated early polyarthritis patients (<1 year of disease duration), who later evolved into RA (early RA, ERA) (n=23) or other diagnoses (early non-RA, ENRA) (n=12); established seropositive RA patients (n=62) treated with methotrexate and a group of age- and sex-matched healthy controls (n=20). Peripheral blood mononuclear cells were isolated and the frequency and phenotype of B, Tfh and Tfr cells were evaluated by flow cytometry.

Results: ERA patients had similar frequencies of B, Tfh and Tfr cells in circulation when compared to ENRA, established RA and controls. Nevertheless, ERA patients had significantly lower frequencies of pre-switch memory B cells (IgD+CD27+) and higher levels of double negative B cells (IgD-CD27-), CD21low-CD38low B cells and plasmablasts (IgD-CD38++) in peripheral blood when compared to controls. Furthermore, the frequencies of PD-1+ICOS+ Tfh cells and Th2-like Tfh cells were significantly increased in ERA patients when compared to controls. Changes in B, Tfh and Tfr cells phenotype were also observed in ERA patients when compared to controls, particularly an increase of the expression levels of activation markers (CD28, CD69, CD86 and HLA-DR).

Conclusion: ERA patients have alterations in B and Tfh cell subpopulations, but not in Tfr cells, in circulation when compared to healthy controls. Our results suggest a pre-activation state of B and Tfh cells since early RA development, which supports a role of these cells in disease physiopathology.

AB0010 FERROPTOSIS PROMOTES DYSFUNCTION OF NTREG BUT NOT ITREG IN RHEUMATOID ARTHRITIS

Keywords: Adaptive immunity, Cell biology, Rheumatoid arthritis

J. Chen[1], J. Zhao[2], X. Shi[1], Y. Liu[1], Y. Jiang[1], Y. Pan[1], S. Zheng[3]. [1]*The Third Affiliated Hospital of Sun Yat-sen University, Department of Internal Medicine, Division of Rheumatology, Guangzhou, China*; [2]*The Third Affiliated Hospital of Sun Yat-sen University, Department of Internal Medicine, Division of Rheumatology*; *Department of Clinical Immunology, Guangzhou, China*;

[3]The Third Affiliated Hospital of Sun Yat-sen University, Department of Clinical Immunology, Guangzhou, China

Background: Magnetic resonance imaging and histological studies have shown that iron levels are dysregulated in rheumatoid arthritis (RA) patients, with iron accumulation in gray matter and a considerable loss in healthy white matter. Iron accumulation in RA environment is closely related to immune disorders. Deferoxamine (DFO) is an iron complexing agent that has been shown to attenuate RA development. It has previously been reported that the suppression funtction of natural regulatory T cells (nTreg) is impaired in RA patients. It is still unclear how iron disrupts immune cells dysfunction in the RA milieu, and whether regulating iron is beneficial for Treg cell expansion and function maintenance.
Objectives: The purpose of this work is to identiy the underlying gene expression profile of ferroptotic-induced dysregulatory RA-Treg, and to investigate the possible application of TGF-induced Treg (iTreg) in the treatment of RA.
Methods: We established a collagen-induced arthritis (CIA) mouse model, a typical animal model of autoimmune arthritis, and performed single cell RNA-sequencing (scRNA-seq) to discover different Treg populations in the joints of CIA mouse models. We also analyzed RNA-seq data from imidazole ketone erastin (IKE), a ferroptosis inducer treated nTreg and iTreg.
Results: Data from single-cell RNA sequencing further identify two groups of Treg cells that have distinct susceptibility to RA challenges, with the ferroptosis-susceptibility Treg associated with an increased insulin-like growth factor 1 (IGF1)-related transcriptome. Mechanistically, IGF1 receptor (IGF1R) activates the AKT-mTOR pathway, increases aerobic glycolysis, promotes Treg conversion toward Th17 differentiation, and increases pro-inflammatory cytokines production. Moreover, RNA-sequencing analysis indicated that imidazole ketone erastin (IKE), a ferroptosis inducer, increases the expression of ferroptosis-associated genes in nTreg but not iTreg, and iTreg attenuated arthritis progression in the IKE-aggravated CIA model.
Conclusion: Our findings suggest that increasing IGF1 and glycolysis account for Treg dysfunction and inflammation in RA, and the novel iTreg may serve as a potential candidate for RA therapy.

AB0011 **CYTOMETRIC ANALYSIS OF ACTIVATED ENTHESEAL TISSUE RESIDENT T-CELLS REVEALS IL-17F AS THE DOMINANT IL-17 ISOFORM EXPRESSED BY INNATE AND ADAPTIVE LYMPHOCYTES**

Keywords: Spondyloarthritis, Adaptive immunity, Enthesitis

N. Mcdermott[1], T. Macleod[2], A. S. Rao[3], V. Borse[3], P. Loughenbury[3], R. Dunsmuir[3], A. Khan[3], A. Maroof[4], D. Mcgonagle[2,5]. *[1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom*; *[2]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal, Leeds, United Kingdom*; *[3]Leeds Teaching Hospitals NHS Trust, Department of Spine Surgery, Leeds, United Kingdom*; *[4]Exscientia, Immunology Research and Translational Immunology, Oxford, United Kingdom*; *[5]Leeds Teaching Hospital, National Institute for Health Research, Leeds, United Kingdom*

Background: The IL-17/IL-23 pathway has been implicated in many inflammatory diseases such as ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease and psoriasis, and has led to the development of several IL-17 inhibitors. The enthesis is connective tissue where the tendon or ligament attaches to the bone. Enthesitis is the cardinal pathological process in spondyloarthritis (SpA) related diseases and T-cell derived cytokines including IL-17A, IL-17F and TNFα and are thought to be central to SpA immunopathology [1-3]. Clinical advances from the inhibition of both IL-17A and IL-17F has shown great success in treating psoriasis. However, our understanding of IL-17F biology at the human enthesis is rudimentary.
Objectives: Investigate the expression of IL-17A and IL-17F at the enthesis and identify innate and adaptive subsets capable of IL-23-independent production of IL-17.
Methods: Peripheral blood and spinal enthesis samples collected from patients undergoing spinal decompression or surgery for scoliosis correction. Immune cell populations were isolated, for peripheral blood, the lymphocyte population was isolated using red cell lysis and mechanical isolation was used for the enthesis samples. T-cells were stimulated with anti-CD3 (100ng/ml) and soluble CD28 (100ng/ml) for 72hrs in RPMI media. 3-4hrs before the end of the stimulation GolgiPlug was added and the cells harvested for analysis of intracellular IL-17A & IL-17F via flow cytometry or were fixed and frozen for further CyTOF analysis. The same setup was used for IL-23 stimulations with IL-23 (50ng/ml) with or without anti-IL-23p19 (20ng/ml) added to the cells and downstream inflammatory cytokine production was assessed using a multiplex bead immunoassay.
Results: IL-17F was preferentially expressed over IL-17A by CD4+ T-cells in peripheral blood and enthesis after 72hrs of inflammatory activation. Only a small percentage of cells were found to express IL-17A or co-express IL-17A and IL-17F. IL-17 expression by CD8+ T-cells was lower than their CD4+ counterpart, with IL-17F again being the predominant isoform expressed by this cell type. Analysis of IL-17 expression by cell types within the peri-entheseal bone revealed a similar trend to PBMC, albeit, lower expression of IL-17 was observed. CyTOF analysis revealed IL-17A and IL-17F expression from rare $\gamma\delta$ T-cells in the enthesis. The additional IL-23 stimulation enhanced IL-17F production from CD4 T-cells; yet IL-23 alone could not induce IL-17F production. Addition of an IL-23p19 neutralising antibody reduced IL-17F levels equivalent to those seen with TCR activation showing that IL-17 production was not solely dependent on the presence of IL-23.
Conclusion: This is the first study looking at IL-17A and IL17F induction from normal entheses where biological differences between these IL-17A and IL-17F family members has emerged.

AB0012 ANALYSIS OF THE EXPRESSION OF T-BET IN B LYMPHOCYTES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Keywords: Systemic lupus erythematosus, Biomarkers, Cell biology

E. Marasco[1], G. M. Moneta[1], C. Bracaglia[1], I. Caiello[1], C. Farroni[2], R. Carsetti[2], F. De Benedetti[1]. [1]*Bambino Gesu' Children Hospital, Unit of Rheumatology, Rome, Italy*; [2]*Bambino Gesu' Children Hospital, B Cell Physiopathology Unit, Rome, Italy*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease causing significant morbidity and mortality. B cells play a central role in SLE pathogenesis. T-bet, is a transcription factor promoting T helper-1 development. B cells expressing T-bet are expanded in aging, chronically infected individuals, and murine models of autoimmunity [1, 2].
Objectives: The aim of our work is to analyze the expression and regulatory mechanisms of the transcription factor T-bet in B cells of patients with systemic lupus erythematosus (SLE).
Methods: The intracellular expression of T-bet was evaluated by flow cytometry in the different subsets of B lymphocytes of SLE patients and controls (HD). Peripheral blood mononuclear cells (PBMCs) were stimulated in vitro with IFNγ and IFNα and the expression of T-bet was evaluated by flow cytometry. The clinical characteristics of patients were analyzed by Multiple Factor Analysis (MFA). The analysis was carried out with the software R.
Results: We performed B cell staining and assessed the expression of T-bet in B cell subsets in patients with SLE and HD. We observed a significant expansion of naïve B cells and double negative (DN) B cells expressing T-bet in patients with SLE compared to HD (Figure 1A-B). An expansion of T-bet+ naïve B cells above the 99th percentile of HD (>1% of total naïve B cells) was evident in 68% of patients; 47% of patients showed an expansion of T-bet+ DN B cells above the 99th percentile of HD (>22% of total DN B cells). We assessed if patients with expanded T-bet+ naïve or DN B cells showed significant clinical differences from patients without the expanded subpopulations. To this end we collected clinical and laboratory parameters (SLEDAI, organ involvement as classified in the BILAG, damage with SDI, autoantibody profile, treatment and disease duration) and performed a multiple factor analysis (MFA). The aim of this analysis was to reduce the dimensionality of the complex data to few variables without losing information. The first 4 dimensions of MFA explained 58% of the total variance. The first dimension accounted for 23.6% of variance, and it was mostly driven by therapy and BILAG scores; the second dimension accounted for 17.7% of the variance and it was mostly driven by SLEDAI, SDI and serology. Patients with expanded T-bet+ naïve B cells, distributed differently from patients with no expansion of T-bet+ naïve B cells (Figure 1C). The first dimension was the most informative in separating the two groups of patients: significantly higher values were reported for patients with expanded T-bet+ naïve B cells. No differences were observed for patients with and without expanded T-bet+ DN B cells (Figure 1C). We investigated in vitro if the expression of T-bet in B cells was driven by interferons. We stimulated PBMCs of HD with IFNγ or IFNα and assessed the frequency of T-bet+ B cells: both interferons induced the expression of T-bet in naïve (CD19+CD27-) and memory (CD19+CD27+) B cells (Figure 1D). Interestingly, when cells were stimulated with IFNα in the presence of IFNγ-blocking antibodies the expression of T-bet was not induced.
Conclusion: Altogether, T-bet+ naïve B cells are expanded in patients with SLE and define a group of patients with clinically different disease from patients without expanded T-bet+ Naïve B cells. The expression of T-bet is induced specifically by IFNγ and not by IFNα.

AB0013 LONGITUDINAL CHANGES IN VARICELLA ZOSTER VIRUS (VZV)-SPECIFIC T CELL IMMUNITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH DIFFERENT JAK INHIBITORS

Keywords: Adaptive immunity, Rheumatoid arthritis, Targeted synthetic drugs

S. Moustafa[1], C. G. Gialouri[1], K. Thomas[2], C. Koutsianas[1], C. Tsalapaki[1], A. Panagiotopoulos[1], E. Mavrea[1], K. Antonatou[1], E. Hadziyannis[1], D. Vassilopoulos[1]. [1]*Joint Academic Rheumatology Program, National and Kapodistrian University of Athens, School of Medicine, General Hospital of Athens "Hippokration", 2nd Department of Medicine and Laboratory, Clinical Immunology-Rheumatology Unit, Athens, Greece*; [2]*National and Kapodistrian University of Athens, School of Medicine, Attikon University General Hospital, Chaidari, Greece., 4th Department of Internal Medicine, Athens, Greece*

Background: Targeted synthetic agents such as the JAK inhibitors (JAKi) used for the treatment of various inflammatory diseases, including rheumatoid arthritis (RA), have been associated with increased risk for VZV reactivation and herpes zoster (HZ). Although this has been attributed to decreased T cell surveillance of latent VZV, detailed data on the effect of the different JAKi on VZV-specific T cell immunity are limited.
Objectives: To study longitudinally the kinetics of VZV-specific T cells in RA patients treated with different JAKi (baricitinib-BARI, tofacitinib-TOFA, upadacitinib-UPA) or methotrexate (MTX, control group).
Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from RA patients before and after 4 and 12 weeks of treatment with JAKi or MTX. PBMCs were stimulated *in vitro* for 18 hours either specifically with VZV antigen (VZV lysate) or non-specifically with a polyclonal stimulus (Staphylococcus aureus enterotoxin B, SEB) and anti-CD28/49d. The percentage of $CD4^+CD69^+$ effector T cells as well as of VZV specific $CD4^+CD69^+$ T cells expressing IFNγ were measured by flow cytometry.
Results: 22 patients with active RA were included; 16 were treated with JAKi (BARI n=7, TOFA n=4, UPA n=5) and 6 with MTX. For the JAKi group, 88% were females with median age and disease duration of 62 and 8 years, respectively, and mean baseline DAS28-ESR of 5.6, while in the MTX group, 100% were females with median age and disease duration of 57 and 0.5 years and mean DAS28-ESR of 5, respectively. Treatment with JAKi for 12 weeks did not change significantly the % of the overall population of $CD4^+CD69^+$ T cells stimulated *in vitro* with VZV or SEB (p=0.3). Similarly, there was no significant change in the % of SEB-stimulated $CD4^+CD69^+IFN\gamma^+$ T cells between pre-treatment and after 12 weeks of JAKi treatment (median, from 0.1% to 0.075%, p=0.370, Figure 1a). In contrast, there was a significant decrease in VZV-specific $CD4^+CD69^+IFN\gamma^+$ T cells between these 2 time points (median, from 0.049% to 0.01%, p<0.001, Figure 1b). The decrease in VZV-specific T cells was similar between the 3 different JAKi (Figure 1c). Patients treated with MTX (n=6) had a slight decrease in VZV specific T cells, but this did not reach the statistical significance (p=0.5).
Conclusion: Treatment of RA patients for 12 weeks with JAKi significantly reduced VZV-specific T cells without affecting the overall effector T cell population. The effect on VZV specific T cell immunity was similar with the 3 different JAKi. These preliminary findings provide novel information regarding the effect of JAKi on VZV-specific T cell immunity.

AB0014 IMMUNE RESPONSES TO VACCINATION AGAINST HERPES ZOSTER (HZ) IN PATIENTS WITH RHEUMATIC DISEASES UNDER TREATMENT WITH JAK-INHIBITORS: OUR PRELIMINARY RESULTS

Keywords: Adaptive immunity, Vaccination/Immunization, Real-world evidence

C. Sieiro Santos[1,2], A. López Robles[1], C. Álvarez Castro[1], S. Calleja Antolín[3], C. Moriano[1], E. Diez Alvarez[3], J. M. Garcia Ruiz de Morales[2,3]. [1]*Complejo Asistencial Universitario de León, Rheumatology, León, Spain*; [2]*Universidad de León, Universidad de León, León, Spain*; [3]*Complejo Asistencial Universitario de León, Immunology, León, Spain*

Background: Shingrix is a recombinant inactive vaccine available for prevention of herpes zoster (HZ) infection, recently approved for patients with rheumatic diseases under treatment with JAK-inhibitors. Because of its novelty, scant information is available on Shingrix vaccine responses in patients with immune mediated rheumatic diseases (IMRD).

Objectives: To investigate the antibody responses to the HZ vaccine in selected rheumatic diseases treated with JAK-inhibitors (JAKi) pre- and post-Shingrix vaccination (weeks 4–6) and to identify factors associated with reduced immunogenicity.

Methods: Patients with selected rheumatic diseases under treatment with JAKi underwent two series of IM Shingrix vaccine (0.5mL each) administered 2 months apart. Bloodwork was performed 4-8 weeks following 2nd dose of vaccine to assess post- vaccination antibody response. Pre and post vaccination response was then compared using Anti Varicella Zoster Virus IgG Multiplex Flow Immunoassay (MFI). Blood lymphocyte distributions (CD3+, CD4+, CD8+, CD19+) and NK cells, total serum IgG and IgM levels, and VZV-IgG and IgM, were investigated pre- and post-Shingrix vaccination (weeks 4–6).

Results: 38 patients were included, 79% were female with a median age at inclusion of 57±10.5 years. 21% of patients had rheumatoid arthritis, 8% had systemic lupus erythematosus, 16% had psoriatic arthritis, 16% had ankylosing spondylitis and 5% had dermatomyositis. VHZ IgG antibody levels and distributions of lymphocyte subpopulations in peripheral blood pre- and post-immunization are represented in Table 1. Positive humoral responses were observed in 86% of patients. Mean changes VHZ-IgG antibody between post- and pre-vaccination sera were 4.6±0.33 and 1.8±1.98 (p<0.0001), respectively. After immunization, the number of T cells (CD3+, CD4+, CD8+) and NK cells remained relatively unchanged however, the number of B cells (CD19+) increased significantly from 147.4±156 to 780.62±475.5 significantly (p<0.0001). There was a 2.5-fold increase in antibody titers after immunization in RA patients, a 2.4-fold increase in SLE patients, a 2-fold increase in AP patients, a 2.5-fold increase in AS patients and a 3.5-fold increase in DM, with no significant difference between the different patients' subgroups. Results from multivariate regression analysis adjusted by age, gender, disease duration, treatments and glucocorticoid and MTX cumulative dose, showed a negative correlation between VHZ-IgG and age >65 years (β=-0.34, p 0.03), disease duration (β=-0.58, p 0.04) and glucocorticoid cumulative dose (β=-0.42, p 0.02).

Conclusion: Our preliminary results show preserved seroconversion rates and VHZ-IgG antibodies and concurrently increase the number of CD19+ B-cells and total serum IgG in patients with rheumatic diseases on treatment with JAKi. Age>65 years, disease duration and glucocorticoid cumulative dose are negatively correlated with humoral response.

Table 1. Varicella zoster virus IgG Ab levels and distributions of lymphocyte subpopulations in peripheral blood pre- and post-immunization

	Pre-vaccination	Post-vaccination	P value
Total serum IgG (mg/dL)	958±300	1328.5±308	**0.04**
Total serum IgM (mg/dL)	126±98	118.5±156	0.84
VZV IgG Ab (Ab Index)	1.8±1.98	4.6±0.33	**0.0001**
VZV IgM Ab (Ab Index)	0.32±2.1	1.3±3.4	0.72
CD3 (cells/mm3)	1065.5±716.5	1128±721	0.63
CD19 (cells/mm3)	147.4±156	780.62±475.5	**0.0001**
CD4 (cells/mm3)	653±584	783±475.5	0.34
CD8 (cells/mm3)	386.2±260	392.7±297.5	0.42

AB0015 ANTINUCLEAR ANTIBODIES PATTERN CLASSIFIER WITH CONVOLUTIONAL NEURAL NETWORKS

Keywords: Diagnostic tests, Biomarkers, Artificial intelligence

V. Alfaro[1], A. Carpio[1], Y. Stekman[2]. [1]*Simón Bolívar University, Electronic Engineering Department, Caracas, Venezuela (Bolivarian Republic)*; [2]*Inmuno21 Laboratory, Bioanalysis Department, Caracas, Venezuela (Bolivarian Republic)*

Background: To detect antinuclear antibodies (ANA) on the blood's patients is a mostly used technique to diagnose immunologic diseases. The Indirect Immunofluorescence method (IIF) generates images with ANA patterns on them and is commonly used by immunology laboratories around the world. Those patterns are documented in the International Consensus of ANA Patterns (ICAP) and there are 29 of them at present, split into three main groups: Nuclear, Cytoplasmic and Mitotic. Classifying these patterns is a subjective task that has a strong dependence on the physician's experience and training, thus the professionals need a second reader to reach a successful classification of images with these patterns. To support the professionals, we developed a Machine Learning model (ML), based on Convolutional Neural Networks (CNN) able to classify ANA patterns between positive and negative and then classifying only positive samples between the three main groups mentione.

Objectives: Developing a machine learning model to help physicians reach a successful ANA pattern classification without a second reader and to train entry-level professionals to classify different ANA images by themselves.

Methods: Using a public database with 2079 samples of ANA pattern images we defined the limitations of our model; we preprocessed the dataset and made a data augmentation process to avoid overfitting issues. To reach our objectives we define a model with two parts, the first one was a CNN classifying each sample between positive and negative, the second one was another CNN classifying the positive samples from the last step into the main three groups before mentioned. Following this idea, we proved 17 pre-trained CNN and compared their results based on commonly used metrics in machine learning: accuracy, precision, recall and F1. To prove our final model we train it with the mentioned augmented public dataset and test it with a private dataset with 445 samples from Inmuno21 Laboratory in Caracas, Venezuela.

Results: Finally, our model reached acc: 93%, pre: 93%, recall: 93% and F1: 93% classifying between positives and negatives, improving the state of the art models presented before as a solution for this problem1. On the other hand, our model shows an acc: 75%, pre: 85%, recall: 92% and F1: 87% for the second stage, classifying positives samples in Nuclear, Mitotic and Cytoplasmic, becoming the first model documented that be able to classify ANA patterns images in this three groups with multilabel capability and positives-negatives previous discrimination.

Conclusion: It's necessary to make efforts to create a bigger datasets of ANA patterns images, better documented and with more samples for each label, since the major problem we found when we've developed the project was there was poor data and there was only one public dataset that had not samples for each label, the other public datasets were not available, had lower samples amount than the ones used or had no samples in the three main groups. Thus it was necessary to augment data to front the overfitting issues. Despite this, we made

a model that shows high performance compared with state of the art works, and it can be used as a second reader or training partner for new professionals.

AB0016 HEPATITIS B SEROPREVALENCE AND REACTIVATION FREQUENCY IN PATIENTS USING BIOLOGICAL DRUGS OTHER THAN RITUXIMAB; SINGLE CENTER RESULTS

Keywords: bDMARD, Safety

O. Ozdemir Isik[1], E. Basaran[1], D. Temiz Karadağ[1], A. Yazici[1], A. Cefle[1]. [1]*Kocaeli University, Faculty of Medicine, Rheumatology, Kocaeli, Turkey*

Background: Biological drugs target immune or genetic mediators and are important treatment alternatives in rheumatology, especially in patients with inadequate response to the conventional treatment. Hepatitis B reactivation may emerge during the use of these agents. There is a higher risk of reactivation with rituximab (RTX) therapy. The frequency of hepatitis B reactivation with non-RTX biologics is unclear.

Objectives: Hepatitis B seroprevalence and reactivation frequency were evaluated in patients followed in Kocaeli University Faculty of Medicine rheumatology outpatient clinic and treated with non-RTX biological drugs.

Methods: The HBsAg, anti-HBs, and anti-HBcIgG data of 170 patients who received non-RTX biological drug therapy for different indications between 2010 and 2022 were analyzed retrospectively. HBV DNA PCR, liver enzyme elevation and HBeAg reversion were evaluated for reactivation, especially in HBsAg and anti-HBcIgG positive patients. The patients were divided into 5 groups as HBsAg (+) patients (Group 1), HBsAg (-), anti-HBs (+) and anti-HBcIgG (+) patients (Group 2), anti-HBc IgG (+) patients (Group 3), whole serology negative patients (Group 4) and vaccine-immunized anti-HBs (+) patients (Group 5).

Results: The mean age of the study population was 47.4±10.6 years. 57.6% of the patients were ankylosing spondylitis (AS), 24.1% were rheumatoid arthritis, and 8.8% were psoriatic arthritis. Behçet's disease and Takayasu arteritis were observed in 3.5% and 2.4% of patients, respectively. 3.5% of patients were consisting of a various of rheumatological diseases including Familial Mediterranean fever, giant cell arteritis, adult Still's disease. In these patients, anti-tumor necrosis factor (TNF) and non-TNF biological drug (tocilizumab, abatacept, secukinumab) treatment use were 80% and 20%, respectively. Most of patients were in group 4 (n=114, 67.1%). The distribution of patients based on serology is shown in Table 1. The patients in group 1 were receiving antiviral treatment. Other groups did not receive any antiviral therapy. In group 3, reactivation was observed in a patient who was followed up with the diagnosis of AS and on infliximab treatment. After reactivation, this patient started to take the antiviral treatment. In a patient of which was classified in group 1, a non-significant increase in viral load (<1 log10 IU/mL) revealed. However, we did not consider this patient had reactivation due to the normal level of liver enzymes and the absence of HBeAg reversion.

Conclusion: Patients using non-RTX biological treatments have a medium risk in terms of HBV reactivation. However, the usage of antiviral prophylaxis is quite low. In our study, HBV reactivation was observed less. On the other hand, patients should be carefully screened in terms of hepatitis serology in order to prevent the reactivation.

Background: Following treatment of autoimmune disease with anti-CD20 monoclonal antibody, Rituximab, insufficient B cell depletion relates to poor clinical response, in particular an expansion of memory B cells [1].

Objectives: We investigated whether the relative expression of the target antigen CD20 on B cell subpopulations underlies drug resistance.

Methods: Peripheral blood samples from 6 rituximab naïve (RTX-N) patients with autoimmune rheumatic diseases (active systemic lupus erythematosus) and rheumatoid arthritis), 6 patients previously treated with rituximab (RTX-T); and 6 healthy controls (HC) were obtained. B cell subpopulations were defined using the relative expression of IgD and CD27 using flow cytometry.

Results: Patients in the RTX-N group had significantly higher frequency of CD19+CD20-B cells (median=25.9% of total B cell, compared to 1.26% in HC), p =0.0022. CD19+CD20-B cells were predominantly swMBC and DN cells. All patients in the RTX-T group (median 22 months post rituximab) had detectable CD19+CD20-B cells (median=52.25 % of total B cells), of which the majority were swMBC (median=4.54%, range 0.23-74%) and DN B cells (median=53.5%, range 11.6-98.1%). Collectively, we noted that the median frequency of CD19+CD20-B cells in peripheral circulation was higher in RTX-T > RTX-N > HC.

Conclusion: Our preliminary results have identified greater frequency of CD19+CD20- population of B cells in peripheral blood of patients with autoimmune disease, particularly after treatment with rituximab suggesting that they evade rituximab. These are predominantly of the switched MBC and DN B cell subpopulations. Given, the potential of these cells to contribute to disease activity in autoimmune disease, is it now time to seek alternative strategies targeting CD19 in order to overcome rituximab resistance?

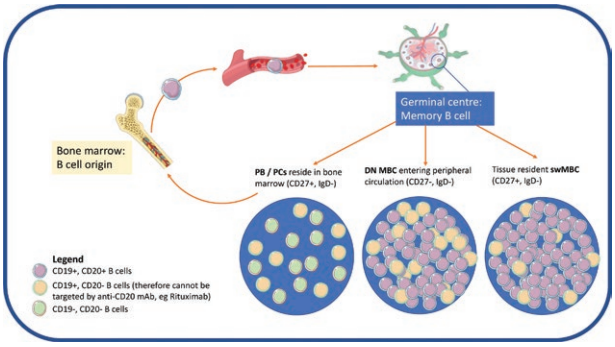

Figure 1.

Figure above demonstrates the cycle of B lineage cells which originate in the bone marrow and migrate into the peripheral circulation and into lymphoid tissues such as lymph nodes and the spleen. In germinal centres the naïve B cells mature into memory B cells which then differentiate into tissue resident switched memory B cells (CD27+, IgD-), or double negative memory B cells entering the peripheral circulation (CD27-, IgD-) or plasma blasts and plasma cells of which the long-lived ones reside in the bone marrow. Proportions of CD19+CD20+ v CD19+CD20- B cells are demonstrated pictorially within each subpopulation. The CD19+CD20- B cells cannot be targeted by anti-CD20 monoclonal antibodies such as rituximab, and therefore alternative strategies to target CD19 may help to overcome rituximab resistance in autoimmunity.

Manzo[1,2]. *[1]University of Pavia, Department of Internal Medicine and Therapeutics, Pavia, Italy*; *[2]Fondazione IRCCS Policlinico San Matteo, Division of Rheumatology, Pavia, Italy*

Background: C-X-C motif chemokine ligand 13 (CXCL13) is a chemokine involved in the recruitment of B cells in secondary lymphoid organs and ectopic inflamed sites. Recent studies in animals models and in healthy individuals have shown that serum levels of CXCL13 correlate with GC activity after immunization, pointing at their role as an early biomarker of the adaptive immune response. In rheumatoid arthritis (RA) CXCL13 systemic expression has been shown to be upregulated. However, the factors involved in CXCL13 systemic upregulation and its significance as putative biomarker in patients with autoimmune diseases are currently unclear.
Objectives: To analyze the dynamics of CXCL13 systemic expression over time in RA after controlled induction of an adaptive immune response.
Methods: Fifty-five autoantibody-positive RA patients with established disease under stable treatment with b/tsDMARDs and with no evidence of previous SARS-CoV-2 infection were included in the study. All patients received two doses of the BNT162b2 vaccine at a three weeks interval. Serum samples were collected at the time of the first BNT162b2 dose (baseline - BL), after three weeks at the time of the second dose (post dose 1 – PD1) and after two further weeks (post dose 2 – PD2). At each time point CXCL13 (pg/mL) and SARS-CoV-2 anti-spike protein antibody titres were measured.
Results: The majority of patients were female (n=42, 76%) and both ACPA and RF positive (n=42, 76%). All patients were receiving stable b/tsDMARD treatment (anti-CTLA4: 23 patients [41.8%], JAKi: 16 [29%], anti-IL6: 8 [14.5%] and anti-TNF alpha: 8 [14.5%]). At baseline the median (IQR) CXCL13 values were 81.1 (58.6-125) and all patients were negative for SARS-CoV-2 anti-spike protein antibody. Effective immunization was confirmed in all patients, in particular in 22/55 (40%) after the first dose and in 55/55 (100%) after the second dose, with a significant increase in SARS-CoV-2 anti-spike protein IgG antibody titer at PD2 (median [IQR], 142 [95.4-224]). Despite the effective induction of an adaptive immune response, no significant changes in the median (IQR) values of CXCL13 were observed at PD1 (three weeks after induction: 92.2 [61.8-141]) and PD2 (two weeks after booster: 74.2 [56-126]) with respect to each other and compared to baseline (Friedman p-value=0,947). Sub-analyses based on patients' stratification according to the b/tsDMARD treatment, confirmed a non-significant variation in CXCL13 titers between baseline, PD1 and PD2 in all groups (Friedman p-value= 0,911). Further sub-analyses limited to patients with baseline-PD1 value of CXCL13<100 pg/ml (to exclude potential biases derived from high starting value of CXCL13 titers on the delta of response) confirmed the absence of significant changes (Friedman p-value= 0.237).
Conclusion: At the time-point analysed, the induction of an adaptive immune response *per se* does not appear sufficient to impact on of the expression dynamics of serum CXCL13 in established autoantibody-positive RA.
