**Results:** We included 798 patients, most men (59%) with a mean age of 45 years, 60% with AU HLA-B27 positive, 40% with recurrent AU HLA-B27 negative. A total of 50.2% and 17.5% presented axial and peripheral SpA according to ASAS criteria respectively. Patients with AU and HLA-B27 were more frequently diagnosed of axial (69.8% vs 27.3%, p<0.0001) and peripheral SpA (21.9% vs 11.1%, p<0.0001) than patients with recurrent AU with HLA-B27 negative. In general, we did not detect important differences between groups in the ophthalmologic variables.
**Conclusions:** A high rate of patients with clinically significant AU have an undiagnosed SpA, higher if HLA-B27 was positive.

## Psoriatic arthritis

### FRI0439 EFFECTS OF DIFFERENT ANTI TNF ALPHA TREATMENTS ON LIPID AND CARBOHYDRATE METABOLISM IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS

R. Colia, A. Corrado, N. Maruotti, A. Carriero, F. d'Onofrio, F.P. Cantatore. *Department of Medical and Surgical Sciences, Rheumatology Clinic - University of Foggia, Foggia, Italy*

**Background:** TNFa plays a key role in the pathogenesis of both rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Recent data support the hypothesis that TNFa is involved in the regulation of carbohydrate and lipid metabolism and it is well know that patients with RA and PsA present a high prevalence of metabolic syndrome and insulin resistance.
**Objectives:** The aim of this study is to evaluate the effects of three different anti TNFa drugs on lipid profile, insulin resistance and circulating levels of various adipokines in a cohort of patients with RA and PsA and the possible relationship with activity disease
**Methods:** We evaluated 25 consecutive patients fulfilling the 2010 revised American College of Rheumatology criteria for RA and 66 consecutive patients age and sex matched fulfilling the CASPAR criteria for PsA. At time of recruitment all patients were treated with methotrexate (10 – 15 mg/weekly) and low dose of prednisone (up to 7,5 mg/day). PsA and RA patients were randomly assigned to receive adalimumab (ADA), infliximab (IFX) or etanercept (ETN). For each group we evaluated the effect of treatment on body mass index (BMI), lipid profile, atherogenic index, insulin resistance index (HOMA2-IR), insulin sensitivity index (QUICKI), circulating levels of adipokines (resistin, leptin, adiponectin) and Framingham cardiovascular risk score at baseline (T0) and after 3 (T1) and 6 (T2) months and we correlated these data with disease activity (DAS28).
**Results:** At baseline we found that compared to PsA, RA patients presented a significantly higher disease activity (p<0,01), atherogenic index and insulin resistance (p<0,05 and p<0,01 respectively), whereas serum levels of adiponectin were significantly lower (p<0,05). No differences in BMI, insulin sensitivity index, Framingham cardiovascular risk score, serum lipid profile and circulating levels of resistin and leptin were observed between AR and PsA patients.
Both in RA and in PsA patients the activity disease at baseline positively correlated with atherogenic index and circulating levels of leptin and resistin (r=0,62, p<0,01); conversely, a negative correlation was observed at baseline between disease activity and circulating levels of adiponectin (r=-0,58, p<0,01). Both in RA and PsA patients ADA, IFX and ETN induced a significant reduction of atherogenic index (p<0,05 both at T1 and T2), insulin resistance (p<0,05 both at T1 and T2) and serum levels of leptin and resistin (p<0,01 both at T1 and T2); this reduction positively correlated with the reduction of disease activity. On the other hand, circulating levels of adiponectin and insulin sensitivity index significantly increased after treatment with ADA, IFX and ETN (p<0,05 at T1, p<0,01 at T2) and presented an inverse relationship with the disease activity. No differences were found between different anti TNFa treatments in the two group of patients.
**Conclusions:** These preliminary data confirm the hypothesis that treatment with

anti TNFa biologic drugs can positively affect the lipid metabolism, the atherogenic index and the insulin resistance profile in RA and PsA patients.

## FRI0440 PROGRESSION OF RADIOGRAPHIC AXIAL DAMAGE IN PATIENTS WITH PSORIATIC ARTHRITIS. RELATION WITH CLINICAL AND ANALYTICAL FACTORS

A. Quesada, M.D. Sánchez, L. Pérez, R. Usategui, G. Manzano, C. Hidalgo, O. Martinez, J. del Pino, C. Montilla. *Hospital Universitario de Salamanca, Salamanca, Spain*

**Background:** Axial involvement in psoriatic arthritis (PsA) is a controversial issue. Lack of unanimity in the definition has led to a wide range of levels of prevalence. Moreover, although radiographic progression in patients with spondylitis (AS) is widely known, the different radiographic characteristics of both entities advise against establishing a parallelism between the evolution of the different lesions or the clinical factors which may have an influence on them.
**Objectives:** Measure radiographic progression over four years in patients with PsA and axial involvement. Relate radiographic damage with clinical and analytical factors.
**Methods:** Prospective study with patients diagnosed with PsA according to the CASPAR criteria. Axial involvement was defined as the presence of inflammatory back pain along with sacroiliitis and/or syndesmophytes. Patients with less of five years of evolution from the onset were included. The radiographic damage was measured with the PASRI method. The difference between both measurements was four years. The assessment was carried out by two observers. The clinical factors measured were: age, sex, peripheral involvement, smoking, use of NSAIDs (continuous vs on-demand), biological treatment, measures of activity (BASDAI), function (BASFI) and mobility (BASMI). The analytical variables measured were: VSG, PCR, B-CrossLaps, P1NP and HLA-B27. The presence of a dorsal or lumbar fracture was also assessed according to the semiquantitative Gennant method.
**Results:** 45 patients with PsA and axial involvement were included. The average age was 53.5 years (SD: 12.9). 31 patients were men. The kappa coefficient between both raters was 0.70. Radiographic progression was higher in men (3.13 vs 1.14, p=0.04; in the multivariate analysis: p=0.04, OR: 0.61, 95%CI: 0.39–0.98) and in smokers (active and ex-mokers) (3.81 vs 1.14, p=0.04; in the multivariate analysis: p=0.04, OR: 0.61, 95%CI: 0.48–0.93). The presence of vertebral fracture was associated to patients with a higher radiographic progression (4.85 vs 1.82; p=0.001; in the multivariate analysis: p=0.008, OR: 0.59, 95%CI: 0.39–0.87). No differences were found regarding the presence of peripheral manifestations (2.32 vs 3.57, p=0.3), peripheral joints erosions (2.61 vs 3.1, p=0.4), continuous use of NSAIDs (1.67 vs 2.91, p=0.3), biological prescription (2.04 vs 3.72, p=0.3) or HLA-B27 (2.00 vs 2.79, p=0.5). A correlation was observed between radiographic progression and the initial PASRI score (p=0.001) and between progression and a lower P1NP concentration (p=0.02). Twelve patients did not show radiographic progression. These patients showed lower initial PASRI scores (5.35 vs 12.6, p=0,001; in the multivariate analysis: p=0.03; OR: 0.73, 95%CI: 0.55–0.98) and a lower P1NP concentration (38.7 vs 61.1; p=0.006: in the multivariate analysis: p=0.01; OR: 1.05, 95%CI: 1.008–1.096).
**Conclusions:** As in patients with AS, male gender, smoking and the presence of initial damage were associated to a higher radiographic progression. These patients were associated to a higher rate of vertebral fracture and lower levels of P1NP. Radiographic progression was not associated to inflammatory parameters, peripheral manifestations or to the treatment used. 25% of the patients did not show radiographic progression

## FRI0441 BENEFITS OF DOSE TAPERING STRATEGIES WITHIN THE PSORIATIC ARTHRITIS MULTIDISCIPLINARY UNITS

A. Prada Ojeda[1], M.E. Sánchez-Largo Uceda[2], L. Esteva Jiménez[3], L.G. Sala Icardo[1], S. Ibañes del Agua[2], L. Calzado Villarreal[2] on behalf of Psoriatic Arthiritis Unit Hospital Universitario Torrejon de Ardoz. *[1]Rheumatology; [2]Dermatology; [3]Pharmacy, Hospital Universitario Torrejon de Ardoz, Torrejon de Ardoz (Madrid), Spain*

**Background:** *Psoriatic Arthritis* (PsA), due to the involvement of both the skin and joints, is one of the rheumatic diseases that can most benefit from multidisciplinary work.The collaboration improved the management of difficult-to-diagnose and/or uncontrolled disease in addition to the early diagnosis and treatment of psoriatic arthritis.Biological therapy is a well-established treatment for PsA. Taking into account the proven long-term efficacy and the cost of these treatments, the *Psoriatic Arthritis* Units (PAU) try to consider new strategies of doses as an alternative to the standard dosage in those suitable patients whom achieved clinical remission.
**Objectives:** We present the demographic, economic, and disease activity data of the 88 patients with PsA who were seen in our PAU in the last year.
**Methods:** Distribution: 71,6% Peripheric 11,4% axial; 17% both. The average age was 49.55 years, with 41 males and 47 females. Comorbidities: dyslipidemia 21,6%, Hypertension 18,2%, Diabetes Mellitus 10,2%, Obesity 6,8%, Smoker 22,7%.
**Results:** 63, 6% were treated with at least one systemic treatment (47,7% methotrexate, 8% salazopyrin, 5,7% combined MTX/SSZ and 2,2% others drug). Only 26,1% were treated with Biological therapy (8%adalimumab;8%etanercept;5,7%certolizumab;2,3% ustekinumab and2,3%infliximab). 30,43% of all patients were under lower-dose treatment according to technical data.We reduced the biological dosage after achieving PGA $\leq$1 (clear or almost clear) and DAS28- ERS $<$2, 6 for at least 12 months. Results: 57% with adalimumab 40mg every 21 days; 28% with etanercept (25 mg /week and 25 mg/10 days) and 14% with ustekinumab without induction dose.We calculated the cost savings in euros of the direct expenditure of the pharmaceutical procedures with the modification of the dosage according to each biological treatment. Adalimumab 4295, 25 euros/year/patient (total: 17,181 euros/year) Etanercept (25 mg /week and 25 mg/10 days) 3.937,96 euros /year- 2.503,8 euros/year; Ustekinumab 2.642,96 euros/year. Subsequently, the total savings amount to 26.265,72 euros /year. These savings translate to at least 3 more patients/year to treat with the same budget.
**Conclusions:** The implementation of dose modification strategies with biological therapies is considered to be an innovative tool that maintains treatment goals using the minimum effective dose for those selected patients. The consequences of an adequate treatment strategy directed to keep long-term clinical response in our patients could be both the reduction of the treatment costs and that of the drug exposure. The Psoriatic Arthritis Units permits this new point of view to control the patients and their treatments.

## FRI0442 HISTOPATHOLOGY OF TREATMENT-NAÏVE PSORIATIC SYNOVITIS: A COMPARISON WITH EARLY RHEUMATOID ARTHRITIS

A. Nerviani, W.S. Tan, A. Mahto, M. Di Cicco, I. Lazarou, N. Ng, N. Purkayastha, M. Bellan, F. Humby, S. Kelly, C. Pitzalis. *Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Queen Mary University London, London, United Kingdom*

**Background:** Psoriatic arthritis (PsA) is an inflammatory joint disease associated with psoriasis. With biologics entering the therapeutic scene, treatment outcome has dramatically improved; nonetheless, pathogenesis of the condiiton is still under investigation. Exploring the biological differences between PsA and RA at tissue level may help in understanding their pathological pathways. Little comparative data is available in early and untreated disease. With the use of a minimally-invasive, ultrasound-guided, needle biopsy technique, synovium from patients with early and untreated disease and small joint involvement may be studied.
**Objectives:** To evaluate clinical, sonographic and histological features of early untreated psoriatic arthritis versus rheumatoid arthritis.
**Methods:** Patients were selected from a large prospective cohort of treatment-naïve patients with inflammatory arthritis of under 12 months' duration. All patients underwent a clinical and sonographic assessment of arthritis activity and an ultrasound-guided synovial biopsy prior to treatment. 32 PsA and 23 gender- and age-matched RA patients were included in this cross-sectional analysis. Synovial inflammatory infiltrate were assessed using immunohistochemical staining for CD3, CD68, CD20 and CD138. Tissue was classified as lymphoid (presence of grade 2/3 CD20+ aggregates); fibroid (CD68 sublining score $\leq$2 on a semi-quantitative scale of 0 to 4); or myeloid (CD68 sublining score $>$2, with or without grade 1 aggregates). Gene-expression analysis of 46 pre-selected genes was performed on 16 PsA and 22 RA patients using Fluidigm technology.
**Results:** Demographic and clinical data at the time of biopsy were comparable between PsA and RA; mean symptom duration was 5.5 for PsA and 4.8 months for RA. Mean tender and swollen joint counts were lower in PsA, nonetheless no significant difference could be found in DAS28. US synovial thickness was similar between the two groups, however a significantly higher Power Doppler score was detected in the biopsied joints of RA patients. Histologically, PsA synovitis score was significantly lower compared to RA; accordingly, PsA synovial tissue showed a lower number of B and T lymphocytes, plasma-cells and sub-lining macrophages. Around 50% of RA synovium demonstrated features of the lymphoid pathotype; in contrast, fibroid (40%) and myeloid (37%) pathotypes were prevalent in PsA (chi-square p$<$0.05). Surprisingly, expression of pro-inflammatory cytokines such as TNFa, IL1b, IL6, IL23, IL17A, IL12A at mRNA level was comparable between RA and PsA.
**Conclusions:** Despite similar clinical features, early treatment-naïve PsA and RA are histologically deeply different; inflammatory infiltrate is lower in PsA compared to RA. However, pro-inflammatory cytokines are similarly expressed, suggesting differential pathways of translation from synovitis to clinical phenotype.

**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5321

## FRI0443 DOES THE CYTOKINE PATTERN, INCLUDING THE IL23 - IL17 IMMUNE AXIS, CHANGE IN PREGNANT WOMEN WITH PSORIATIC ARTHRITIS?

A. Pluma Sanjurjo[1], P.M. Villiger[2], F. Förger[2]. [1]*Rheumatology Unit, Hospital Universitari Vall Hebron, Barcelona, Spain;* [2]*Rheumatology Department, Inselspital Bern University Hospital, Bern, Swaziland*

**Background:** During pregnancy, most patients with psoriatic arthritis (PsA) experience a natural improvement of their symptoms. This might be due to the immunological changes that occur in normal pregnancy to allow tolerance to the semiallogeneic fetus. Pregnancy induces a down-regulation of the adaptative immune system and generates a specific cytokine milieu. The balance between T helpers cells (Th), Th1/Th2/Th17, depends on the cytokine milieu and interleukin (IL) 23 promotes the expansion and survival of Th17 cells. The IL23-IL17 axis is up-regulated in PsA.
**Objectives:** The aim of our study is to investigate changes of the cytokines pattern with focus on the IL23-IL17 immune axis during and after pregnancy in PsA patients compared with non-pregnant PsA patients and healthy controls (HC).
**Methods:** Nineteen PsA patients (10 pregnant, 9 non-pregnant) and 19 HC (11 pregnant and 8 non-pregnant) were prospectively studied. Clinical assessment and blood sampling was done in pregnant women before, during and after pregnancy and once in the non-pregnant group. Sera were analyzed for levels of C reactive protein (CRP) and high sensitive CRP (hsCRP) by enzyme linked immunoassay. The following cytokines and regulatory molecules were measured by magnetic bead-based multiplex immunoassay: the activation marker soluble CD40 ligand (sCD40L), the Th1 cytokines tumor necrosis factor α (TNFα) and Interleukin (IL)-1β, the Th2 cytokines IL-4, IL-10, IL-31, IL-33, IL-25 and the Th 23/17 pathway cytokines IL-6, IL-17A, IL-17F, IL-21, IL-22, IL23.
**Results:** In the non-pregnant groups we observed that patients with PsA had higher levels of hsCRP, sCD40L, TNFα, IL-1β, IL-33, Il-6 and IL-22 than HC.
Though pregnant PsA patients had inactive or mild disease activity with normal CRP levels, the hsCRP levels were higher than those of pregnant HC.
In the HC group, pregnant women at the third trimester showed higher levels of IL-10, Il-33 and TNFα than at the postpartum time point. Moreover, healthy women at the third trimester had higher levels of IL-1β, IL-33 and IL-22 than age-matched non-pregnant women.
At the third trimester of pregnancy, patients with PsA displayed higher levels of hsCRP, sCD40L, TNFα and IL-6 than HC. Interestingly, pregnant PsA patients did not show any differences in the cytokine pattern compared to non-pregnant PsA patients.
Most differences appeared when comparing PsA and HC at the postpartum time point. Postpartal patients with PsA showed higher levels of sCD40L, TNFα, IL-1β,IL-10, IL-33, IL-31, IL-6 and IL-22 compared to HC
**Conclusions:** Pregnancy induces no predominance of circulating Th2 cytokines but rather a coexistence of Th1, Th2 and Th17 cytokines. Patients with PsA present a more pronounced inflammatory profile consisting of elevated hsCRP levels, Th1 and Th17 cytokines during pregnancy and postpartum. Thus, inactive disease in pregnant PsA patients was associated with persisting immunological activity including the IL-23 /Th17 immune axis.

## FRI0444 EARLY DETECTION OF PSORIATIC ARTHRITIS: A MULTI-OMIC APPROACH TO DEVELOPING A NEW BLOOD TEST

A.F. Mc Ardle[1], A. Szentpetery[2], S. De Rook[3], A.D.G. De Ganck[4], B. Hernandez[5], O. FitzGerlad[6], S.R. Pennington[7]. [1]*School of Medicine and Medical Sciences, University College Dublin, Dublin;* [2]*Clinical research centre, St. Vincent's Hospital, Dublin 4, Ireland;* [3]*Pediatrische Immunologie, Wilhelmina Kinderziekenhuis, UMC/Utrecht, Netherlands;* [4]*Biogazelle, Biogazelle, Belgium, Belgium;* [5]*School of Maths, UCD;* [6]*Clinical Research Centre, S.t Vincents Universtiy Hospital;* [7]*School of Medicine, UCD, Dublin 4, Ireland*

**Background:** Psoriatic Arthritis (PsA) is a form of seronegative inflammatory arthritis (IA) frequently associated with psoriasis. Similar to other forms of IA, it is a complex heterogeneous disease. While PsA can be characterised by distinct clinical manifestations, at early onset, it often resembles other disease types - especially rheumatoid arthritis (RA). During the treatment and management of the disease important clinical decisions are made and these have a significant impact on patient outcomes. Making an accurate and early diagnosis is particularly important to ensuring that individual patients receive effective and safe medication. Thus, it is widely acknowledged by physicians and patients alike that a new test is needed to facilitate the early and specific diagnosis of PsA [1].
**Objectives:** To (i) identify candidate biomarkers with the potential to segregate patients with PsA from those with RA (ii) explore the value of combining different omic discovery platforms.
**Methods:** Serum samples were obtained from a cohort of 64 patients (32 PsA and 32 RA) defined as early onset (<12 months) and DMARD naïve. Individual baseline samples were analysed using microRNA (miRNA) (n=63), Luminex xMAP (n=62), an aptamer based platform called SOMAscan (n=36) and label free LC-MS/MS (n=64), platforms. Data was imported into Perseus (version 1.5.0.8) for statistical analysis ($p \leq 0.05$). Additionally, data was analysed using a random forest model in R software (version 3.1.0).
**Results:** In this study, by combining 4 different omic technologies it was possible to quantify 376, 48, 1129, 387 analytes by miRNA, Luminex, SOMAscan and LC-MS/MS analysis, respectively. Statistical analysis revealed that a total of 287 analytes were differentially expressed across the two conditions ($p \leq 0.05$). Furthermore, random forest analysis revealed the most discriminatory biomarkers from the miRNA, Luminex and SOMAscan analysis. Figure 1 A-C illustrates the receiver operating characteristic (ROC) curves generated from these analyses. The application of the random forest model to the LC-MS/MS data is part of ongoing work.

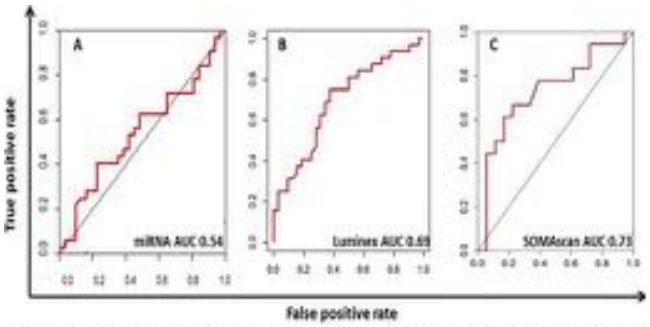

Figure 1. Random forest (RF) Receiver Operating Characteristic (ROC) curves PsA Vs RA. RF analysis of (A) the miRNA data revealed patients could be segregated with an AUC of 0.55. (B) the Luminex data revealed patients could be segregated with an AUC of 0.69 and (C) the SOMAscan data revealed patients could be segregated with an AUC of 0.73

**Conclusions:** By combining the most discriminatory analytes from each type of analysis into a single algorithm, a biomarker signature with increased predictive potency should be identified. Thus, these molecules represent candidates for inclusion into blood based mulit-analyte test that could be used in the diagnosis of PsA.

## FRI0445 TILDRAKIZUMAB TREATMENT IMPROVED MEASURES OF PSORIATIC ARTHRITIS IN ADULTS WITH CHRONIC PLAQUE PSORIASIS

R.G. Langley[1], D. Thaçi[2], K. Reich[3], K. Papp[4], A. Mehta[5], Q. Li[5], C. La Rosa[5]. [1]*Dalhousie University, Halifax, Canada;* [2]*University of Lübeck, Lübeck;* [3]*SCIderm Research Institute and Dermatologikum Hamburg, Hamburg, Germany;* [4]*Probity Medical Research, Waterloo, Canada;* [5]*Merck & Co., Inc., Kenilworth, United States*

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis. Recent evidence with biologic medications that target IL-17 and IL-12/23 (i.e., secukinumab and ustekinumab) have demonstrated efficacy in the treatment of PsA leading to their inclusion in the 2015 EULAR recommendations for the management of psoriatic arthritis [(1)]. Tildrakizumab is an investigational high-affinity, humanized, IgG1/κ, anti-IL-23p19 monoclonal antibody.
**Objectives:** This analysis was done to evaluate the effect of tildrakizumab on PsA endpoints in a small population of patients with PsA participating in a Phase 2 chronic plaque psoriasis study.
**Methods:** A randomized, double-blind study (NCT01225731) was conducted in 355 adults with moderate to severe plaque psoriasis. Patients were randomized to receive tildrakizumab 5 mg, 25 mg, 100 mg, 200 mg or placebo subcutaneously at Weeks 0 and 4, then every 12 weeks for 52 weeks. The primary efficacy endpoint was the proportion of patients achieving a PASI 75 at Week 16. Patients with PsA (defined by subject history) were examined. PsA endpoints included: mean change in Psoriatic Arthritis Screening and Evaluation (PASE), Health Assessment Questionnaire (HAQ), pain assessed with Visual Analog Scale (VAS), and high-sensitivity C-Reactive Protein (hsCRP), measured from baseline through Week 16.
**Results:** 339 patients completed 16 weeks of treatment, PASI 75 responses were 33.3%, 64.4%, 66.3%, 74.4% and 4.4%, in the 5 mg, 25 mg, 100 mg, 200 mg tildrakizumab and placebo groups, respectively ($p \leq 0.001$) [(2)]. Overall, 65 patients (18%) had PsA (5 mg n=8, 25 mg n=15, 100 mg n=17, 200 mg n=17, placebo

n=26). Mean changes from baseline are listed below. Results show numerically greater improvements for all doses of tildrakizumab vs. placebo for PASE, and pain parameters. Additionally, tildrakizumab 25 mg and 200 mg demonstrated numerically greater improvement vs. placebo for HAQ (Table). In the overall study population, mean (SD) changes from baseline at Week 16 in observed hsCRP (mg/L) was -0.8 (5.7), -2.3 (6.1), -2.7 (9.2), -3.0 (13.4), and -1.3 (3.6) for the 5 mg, 25 mg, 100 mg, 200 mg, and placebo groups, respectively; hsCRP results for PsA patients only are shown (Table).

**Table: Mean Changes from Baseline in PsA Parameters***

| | 5 mg (n=6) | 25 mg (n=12) | 100 mg (n=14) | 200 mg (n=13) | Placebo (n=10) |
|---|---|---|---|---|---|
| PASE | 2.2 (-10.3, 14.7) | -7.9 (-17.1, 1.3) | -6.1 (-14.7, 2.5) | -6.1 (-16.1, 4.0) | -0.3 (-10.9, 10.4) |
| HAQ | 0.0 ( -0.3, 0.3) | -0.3 ( -0.5, -0.1) | 0.0 ( -0.2, 0.2) | -0.2 ( -0.4, 0.0) | 0.1 ( -0.1, 0.3) |
| VAS Pain | -13.8 (-38.9, 11.3) | -17.2 (-34.7, 0.3) | -12.3 (-28.7, 4.0) | -16.9 (-33.9, 0.1) | 10.2 ( -8.9, 29.2) |
| hsCRP | -1.9 (2.3) | -3.1 (5.5) | -2.4 (4.3) | -6.0 (21.7) | -1.6 (1.9) |

*Mean changes (95% CI) for PASE, HAQ, and VAS Pain are based on constrained longitudinal data analysis; mean changes (SD) for hsCRP are based on observed data

**Conclusions:** Numerical improvements in measures of PsA were observed with tildrakizumab in a small sample of patients with chronic plaque psoriasis who had concomitant PsA. Tildrakizumab 25 mg, 100 mg, and 200 mg were associated with numerically lower hsCRP levels compared with 5 mg and placebo. Further research is needed to better evaluate tildrakizumab in the treatment of PsA.

## FRI0446 TREATMENT WITH TILDRAKIZUMAB, AN ANTI-IL-23P19 MONOCLONAL ANTIBODY, IMPROVES HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC PLAQUE PSORIASIS

D. Thaçi[1], K. Papp[2], K. Reich[3], R.G. Langley[4], A. Mehta[5], Q. Li[5], C. La Rosa[5]. *[1]University of Lübeck, Lübeck, Germany; [2]Probity Medical Research, Waterloo, Canada; [3]SCIderm Research Institute and Dermatologikum Hamburg, Hamburg, Germany; [4]Dalhousie University, Halifax, Canada; [5]Merck & Co., Inc., Kenilworth, United States*

**Background:** Tildrakizumab is a high-affinity, humanized, IgG1/κ, anti-IL-23p19 monoclonal antibody that has demonstrated efficacy in the treatment of chronic plaque psoriasis, a disorder associated with significant quality-of-life impairment.
**Objectives:** This analysis evaluated Dermatology Life Quality Index (DLQI) questionnaire responses to assess how clinical improvements with tildrakizumab affect specific areas of daily life in psoriasis patients.
**Methods:** This randomized, controlled study (NCT01225731) included 355 patients with moderate-to-severe chronic plaque psoriasis who were randomized to receive placebo, tildrakizumab 5 mg, 25 mg, 100 mg, or 200 mg for 16 weeks in Part 1 of the study. The primary endpoint was the proportion of patients achieving a 75% reduction in the Psoriasis Area and Severity Index (PASI 75). Patients completed the Dermatology Life Quality Index (DLQI) questionnaire to assess the effect of treatment on health-related quality of life. Responses to individual DLQI questions were scored in terms of the level of impairment due to psoriasis: 3 (Very Much) to 0 (Not Relevant or Not at All). Individual questions were grouped and assessed in following categories: Symptoms/Feelings (total score of 6); Daily Activities (total score of 6); Leisure (total score of 6); Work/School (total score of 3); Personal Relationships (total score of 6); Treatment (total score of 3)[(1)]. A change of at least 4 points in the overall score is considered a clinically important change[(2)].
**Results:** There were 339 patients who completed 16 weeks of treatment. PASI 75 responses at Week 16 were 33.3%, 64.4%, 66.3%, 74.4% and 4.4%, in the 5 mg, 25 mg, 100 mg, 200 mg tildrakizumab and placebo groups, respectively ($p \leq 0.001$ vs. placebo); mean changes (95% CI) from baseline in DLQI were associated with PASI 75 responses and are presented in the Table [(3)]. All tildrakizumab doses were associated with a clinically important change (>4 points)[(2)]. Mean changes from baseline to Week 16 in individual DLQI categories are presented (Table). Tildrakizumab 25 mg, 100 mg, and 200 mg doses were associated with the largest improvements in individual categories, particularly in Symptoms/Feelings and Daily Activities.

**Table:** Mean Change from Baseline in DLQI at Week 16

| | 5 mg (N=39) | 25 mg (n=86) | 100 mg (n=88) | 200 mg (n=84) | Placebo (n=41) |
|---|---|---|---|---|---|
| **Mean Change (SD) in Categories*** | | | | | |
| Symptoms/Feelings (total score of 6): | -1.5 (1.5) | -2.9 (1.8) | -2.4 (1.6) | -2.6 (1.9) | 0 (1.7) |
| Daily Activities (total score of 6): | -1.0 (1.4) | -2.0 (1.8) | -1.9 (1.7) | -1.8 (1.8) | 0.6 (1.8) |
| Leisure (total score of 6): | -0.8 (1.4) | -1.4 (2.0) | -1.7 (1.9) | -1.6 (2.0) | 0.1 (1.8) |
| Work/School (total score of 3): | -0.4 (0.8) | -0.9 (1.1) | -0.6 (1.1) | -0.9 (1.0) | -0.2 (1.3) |
| Personal Relationships (total score of 6): | -0.8 (1.7) | -1.3 (1.8) | -1.3 (1.7) | -1.3 (1.6) | -0.8 (1.1) |
| Treatment (total score of 3): | -0.6 (0.9) | -0.9 (1.1) | -0.9 (1.1) | -0.8 (1.1) | 0.3 (1.1) |
| **Overall Mean (95% CI) Changes**[*,**]** | | | | | |
| Overall DLQI | -4.9 (-7.0, -2.8) | -9.2 (-10.6, -7.7) | -8.5 (-9.9, -7.1) | -8.8 (-10.3, -7.4) | 1.0 (-1.1, 3.0) |

*based on observed data
** based on constrained longitudinal data analysis (cLDA)

**Conclusions:** Treatment of chronic plaque psoriasis with tildrakizumab was associated with clinically important changes in DLQI including improvements in symptoms/feelings, daily activities, leisure, work/school, personal relationships, and treatment categories that were correlated with improvements in PASI scores.

## FRI0447 LONG-TERM (156-WEEK) EFFICACY AND SAFETY PROFILE OF APREMILAST, AN ORAL PHOSPHODIESTERASE 4 INHIBITOR, IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM A PHASE III, RANDOMIZED, CONTROLLED TRIAL AND OPEN-LABEL EXTENSION (PALACE 1)

A. Kavanaugh[1], D.D. Gladman[2], J.J. Gomez-Reino[3], S. Hall[4], E. Lespessailles[5], P.J. Mease[6], G. Schett[7], M. McIlraith[8], K. Shah[8], L. Teng[8], J. Wollenhaupt[9]. *[1]University of California, San Diego, School of Medicine, La Jolla, United States; [2]Toronto Western Research Institute, Toronto, Canada; [3]Hospital Clinico Universitario, Santiago, Spain; [4]Monash University, Melbourne, Australia; [5]University of Orléans, Orléans, France; [6]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States; [7]University of Erlangen-Nuremberg, Erlangen, Germany; [8]Celgene Corporation, Summit, United States; [9]Schön Klinik Hamburg Eilbek, Hamburg, Germany*

**Background:** Long-term data on the efficacy and safety of therapies is vital for treatment decision making in chronic diseases such as psoriatic arthritis (PsA). Three-year treatment data from the PALACE 1 (NCT01172938) study of apremilast (APR) in patients with active PsA despite previous conventional disease-modifying antirheumatic drug (DMARD) or biologic therapy has recently become available.
**Objectives:** Using data from 3 years of treatment, examine the longer term efficacy/safety of APR.
**Methods:** Patients were randomized (1:1:1) to placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The PBO-controlled phase continued to Wk 24, with an early escape option at Wk 16. At Wk 24, all remaining PBO patients were re-randomized to APR30 or APR20. Double-blind APR treatment continued to Wk 52; patients could continue APR for up to 4 additional years. Efficacy assessments in years 2 and 3 were conducted at Wks 65, 78, 91, 104, 117, 130, 143, and 156.
**Results:** 504 randomized patients received ≥1 dose of study medication (PBO: n=168; APR30: n=168; APR20: n=168). In an "as observed" analysis, 53.2% (APR30) and 59.6% (APR20) of patients achieved a modified ACR20 response at Wk 52 (Table), regardless of when APR was started (baseline, Wk 16, or Wk 24). Of the patients entering year 2, 65.3% (APR30) and 60.9% (APR20) attained these responses at Wk 104. A total of 92% (260/284) of the patients starting the third year of the trial completed the Wk 156 visit; overall, this is 52% (260/504) of patients randomized at baseline. Patients receiving APR30 at Wk 156 demonstrated sustained improvements, as shown by ACR20 response rates of 65%, swollen/tender joint count mean percent improvements of -81.2% and 73.2%, and HAQ-DI mean change of -0.37, and 41.9% of patients reaching DAS (CRP) <2.6. Similarly, the proportion of patients with HAQ-DI exceeding the minimal clinically important difference (MCID) ≥0.30 threshold, mean change in DAS-28 (CRP), and PASI-75/PASI-50 responses were maintained (Table). No new safety concerns were identified with up to 156 wks of APR treatment. During Wks >104 to ≤156 of APR exposure, the only adverse event (AE) occurring in ≥5%

| | Outcomes at Wk 52 and Wk 156 | | | |
|---|---|---|---|---|
| | Wk 52 | | Wk 156 | |
| | APR30 n=193* | APR20 n=186* | APR30 n=139* | APR20 n=129* |
| ACR20, n/m† (%) | 101/190 (53.2) | 109/183 (59.6) | 69/137 (65.0) | 85/125 (68.0) |
| ACR50, n/m† (%) | 49/191 (25.7) | 45/180 (25.0) | 56/136 (40.6) | 55/125 (44.0) |
| ACR70, n/m† (%) | 27/191 (14.1) | 21/179 (11.7) | 32/135 (23.2) | 22/124 (17.7) |

| HAQ-DI (0-3), mean change | -0.31 | -0.33 | -0.37 | -0.35 |
| HAQ-DI MCID, ≥0.30, n/m† (%) | 85/193 (44.0) | 81/184 (44.0) | 71/139 (51.1) | 60/127 (47.2) |
| DAS-28 (CRP), mean change | -1.26 | -1.42 | -1.90 | -1.92 |
| DAS-28 (CRP) <2.6, n/m† (%) | 41/189 (21.7) | 56/185 (30.3) | 57/136 (41.9) | 64/129 (49.6) |
| PASI -75, n/m† (%)‡ | 31/95 (32.6) | 17/78 (21.8) | 24/67 (35.8) | 15/47 (31.9) |
| PASI -50, n/m† (%)‡ | 52/95 (54.7) | 39/78 (50.0) | 38/67 (56.7) | 25/47 (53.2) |

Data as observed. n/m=number of responders/number of patients with sufficient data for evaluation. †The n reflects the number of patients treated with APR30 and APR20, regardless of when APR was started (baseline, Wk 16, or Wk 24) and who had data available at the specific time point; actual number of patients available for each end point may vary. ‡Denominators vary slightly due to availability of sufficient data for each level of ACR response assessment. §Examined among patients with psoriasis involvement of ≥3% body surface area at baseline and having data at the specific time point

of patients was upper respiratory tract infection; most AEs were mild/moderate in severity. Serious AEs occurred in 6.9% (APR30) and 6.4% (APR20) of patients, similar to rates seen for the earlier study periods, few discontinuations due to AEs (0.7%) occurred over Wks >104 to ≤156.

**Conclusions:** Over 156 wks, among patients remaining in the study, APR demonstrated sustained and clinically meaningful improvements in PsA signs/symptoms, including physical function and associated psoriasis. APR continued to demonstrate an acceptable safety profile and was generally well tolerated.

**Acknowledgement:** We thank Adewale O. Adebajo for his work on the original abstract.

## FRI0448 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE PSORIATIC ARTHRITIS: 2-YEAR EFFICACY AND SAFETY RESULTS FROM THE PHASE 3 RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL, FUTURE 1

A. Kavanaugh[1], P. Mease[2], A. Reimold[3], H. Tahir[4], J. Rech[5], S. Hall[6], P. Geusens[7,8], Z. Wang[9], S. Mpofu[10] on behalf of the FUTURE 1 Study Group.
*[1]UC San Diego School of Medicine, La Jolla; [2]Swedish Medical Centre and University of Washington, Seattle; [3]Dallas VA Medical Center and University of Texas Southwestern Medical Center, Dallas, United States; [4]Barts Health NHS Trust, London, United Kingdom; [5]University of Erlangen-Nuremberg, Erlangen, Germany; [6]Monash University, Melbourne, Australia; [7]University of Hasselt, Hasselt, Belgium; [8]Maastricht University Hospital, Maastricht, Netherlands; [9]Novartis Pharmaceuticals Corporation, East Hannover, United States; [10]Novartis Pharma AG, Basel, Switzerland*

**Background:** Secukinumab, an anti–interleukin-17A monoclonal antibody, provided rapid and significant improvements in multiple clinical domains of psoriatic arthritis (PsA) including, signs and symptoms, joint structural damage, physical function, and quality of life, through 52 weeks (wks) in the Phase 3 FUTURE 1 study (NCT01392326).[1]

**Objectives:** To assess the long-term efficacy and safety of secukinumab in patients (pts) with PsA treated for up to 104 wks in FUTURE 1.

**Methods:** 606 adults with active PsA were randomised to secukinumab or placebo (PBO). Secukinumab pts received a 10 mg/kg i.v. loading dose at baseline (BL), Wks 2 and 4, followed by 150 mg s.c. (IV→150 mg) or 75 mg s.c. (IV→75 mg) every 4 wks from Wk 8. PBO was given on the same dosing schedule. At Wk 16, PBO-treated pts were re-randomised to receive secukinumab 150 or 75 mg s.c. from either Wk 16 or Wk 24, based on clinical response. Clinical assessments at Wk 104 included: ACR 20/50/70, PASI 75/90, DAS28-CRP, SF-36 PCS, HAQ-DI, mTSS, dactylitis, and enthesitis. Efficacy variables are presented from those pts originally randomised to secukinumab. Multiple imputation (binary variables) and a mixed-effect model repeated measures (continuous variables) were used for analyses at Wk 104. mTSS data are as observed.

**Results:** Overall, 476 pts (78.5%) completed 104 wks of study (167 [82.7%] pts in IV→150 mg group; 155 [76.7%] in IV→75 mg group). At Wk 104, ACR 20/50/70 response rates were 66.8/39.0/22.4% with IV→150 mg and 58.6/29.7/17.6% with IV→75 mg, respectively. Sustained clinical improvements with secukinumab through Wk 104 were observed across other clinically important domains of PsA (Table). Responses were sustained through Wk 104 in pts naïve to anti-TNF therapy and in those with an inadequate response or intolerance to these agents (anti-TNF-IR). ACR20 response rates at Wk 104 in anti-TNF-naïve pts were 75.2% and 63.7% with IV→150 mg and IV→75 mg, respectively; corresponding rates in anti-TNF-IR pts were 48.0% and 46.9%. No radiographic disease progression (≤0.5 change in mTSS) was observed between BL and Wk 104 in 84.6% of x-ray completers in the IV→150 mg and 83.9% in the IV→75 mg groups. Over the entire study period (mean exposure to secukinumab of 627.1 days) the type, incidence and severity of AEs were consistent with that reported previously. Infections and infestations were the most common AEs observed with secukinumab (67.9 per 100 pt-years). No cases of TB were reported. Malignant/unspecified tumours and major adverse cardiac events occurred at a rate of 0.6 and 0.7 per 100 pt-years, respectively with secukinumab. No suicides were recorded in secukinumab-treated patients.

Table. Summary of Efficacy Results at Wk 104 (intent-to-treat analysis*)

| Variable | Secukinumab IV → 150 mg N = 202 | Secukinumab IV → 75 mg N = 202 |
|---|---|---|
| ACR 20/50/70 (% responders) | 66.8/39.0/22.4 | 58.6/29.7/17.6 |
| PASI 75/90 (% responders)† | 74.6/61.0 | 63.0/44.6 |
| DAS28-CRP, LS mean change from BL | −1.66 | −1.64 |
| SF-36 PCS, LS mean change from BL | 4.89 | 4.67 |
| HAQ-DI, LS mean change from BL | −0.38 | −0.39 |
| Resolution of dactylitis (%)‡ | 82.6 | 84.6 |
| Resolution of enthesitis (%)‡ | 73.7 | 76.8 |

*Multiple imputation (binary variables) or mixed-effect model repeated measures (continuous variables)
†Data evaluated in pts with psoriasis affecting ≥3% body surface area at BL (n = 108 in treatment arm)
‡Data from pts with these symptoms at BL
ACR, American College of Rheumatology response criteria; BL, baseline; DAS28-CRP, Disease Activity Score 28 using C-reactive protein; HAQ-DI, Health Assessment Questionnaire Disability Index; i.v., intravenous; LS, least squares; N, number of pts randomised; PASI, psoriasis area-and-severity index; SF-36 PCS, Short Form 36 Physical Component Summary

**Conclusions:** Secukinumab provided sustained improvements in signs and symptoms and multiple clinical domains of active PsA in pts who completed 2 years of therapy. Secukinumab was well tolerated with a safety profile consistent with that previously reported.

## FRI0449 INCIDENCE AND PREVALENCE OF PSORIATIC ARTHRITIS IN SOUTH EAST ASIA

V. Ravindran[1], R. Jain[2], M. Thabah[3], A. Nalawade[4], P. Kumar[5], S. Agrawal[6], P. Rath[7], S. Upadhyaya[8], V. Kaushik[9], R. Kiran[10], R. Sekhri[11], V. Sekhri[12], J. Shukla[13], K. Pandey[11], S. Malviya[14], P. Ghosh[11], B.D. Pandey[11]. *[1]Private Practice, Calicut; [2]Private Practice, Jaipur; [3]JIPMER, Pondicherry; [4]Private Practice, Kholapur; [5]Private Practice, Delhi; [6]Artimis, Gurgaon; [7]Max Hospital; [8]Apollo Hospital, Delhi; [9]Apollo Hospital, Chennai; [10]Private Practice, Hyderabad; [11]Fortis Hospital; [12]Private Practice; [13]Fortis, Noida; [14]Medanta, Indore, India*

**Background:** There is under reporting of prevalence of Psoriatic Arthritis among patients with psoriasis in India. The data on prevalence of PsA among patients of the psoriasis varies from 6.25% to 48% in western countries. [1],[2] A relatively low figures are reported from Asian countries.

**Objectives:** To determine the reporting of psoriatic arthritis from dermatology point of view

**Methods:** In this observational study, we identified subjects from hospital recordswho were diagnosed with psoriasisand psoriatic arthritis between 1/07/2010till 31/05/2014and 01/01/2015 till 31/12/2015 inDepartment Dermatologyin a tertiary care Hospital.Age-and sex-specific incidence rates were recorded.In order to sensitize dermatologists about the aspect of psoriatic Arthritis series of close group meetings between dermatologists and Rheumatologists were conducted in order to pick up Arthritis in patients of Psoriasis. Six months post educational intervention, observation of the hospital records regardingdiagnosis of psoriasis and psoriatic Arthritis were recorded.

**Results:** A total of 16842 patients were reviewed during the pre-education intervention period between 01/07/2010 till 31/05/2014. Out of these 771 (4.57%) patients were recorded as psoriasis but none of the patients were recorded as psoriatic arthritis. The mean± SD age of patients with psoriasis was 43.34± 16.72 years, 50.1% were males.A total of 6012 patients were reviewed during the post- education intervention period between 01/01/2015 till 31/12/2015. Out of these 331 (4.92%) patients were recorded as psoriasis and 35 (0.58%) patients were recorded as both psoriasis and psoriatic arthritis. The psoriatic arthritis patients were referred to rheumatologists and all were found to have PsA according to classification of psoriatic arthritis (CASPAR) criteria.The prevalence rate of psoriasis and psoriatic arthritis with age $\leq$10 years, 11–25 years, 26–50 years, 51–70 years, and $>$70 years was found to be 2.06% and 0%, 9.98% and 0.01%,52.9% and 0.9%, 29.8% and 0.8% and 5.2% and 0.6% respectively. The highest prevalence rate of psoriasis and psoriatic arthritis both was between 26–50 years of age

**Conclusions:** Psoriatic Arthritis is underreported from dermatology registries. Rheumatologist and dermatologist should share a platform regarding the concept of Psoriatic Arthritis in patients with psoriasis

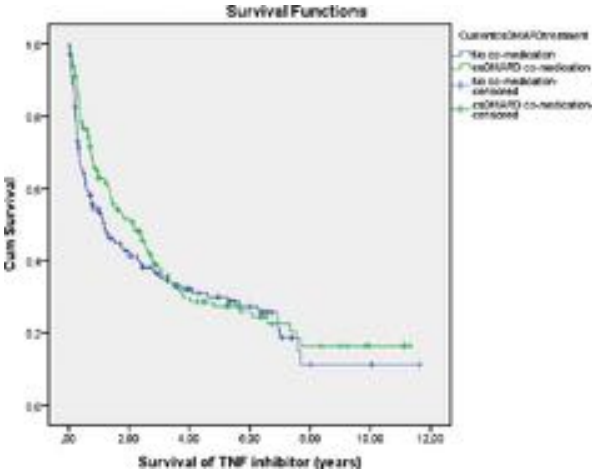
## FRI0450 TUMOR NECROSIS FACTOR INHIBITOR TREATMENT IN PSORIATIC ARTHRITIS: NEED FOR CO-MEDICATION?

B. Michelsen[1], D.M. Soldal[1], A. Kavanaugh[2], D.L. Boyle[2], G. Haugeberg[1,3,4]. *[1]Department of Rheumatology, Hospital of Southern Norway Trust, Kristiansand, Norway; [2]Department of Rheumatology, Allergy and Immunology, University of California San Diego, San Diego, United States; [3]Department of Rheumatology, Martina Hansens Hospital, Bareum; [4]Department of Rheumatology, University of Science and Technology, Trondheim, Norway*



**Background:** Different than for rheumatoid arthritis, the potential benefits of conventional synthetic disease modifying drug (csDMARD) co-medication among psoriatic arthritis (PsA) patients receiving tumor necrosis factor inhibitors (TNFi) remain unclear.[1]

**Objectives:** This study aimed to investigate the role of concomitant csDMARDs on survival of subcutaneous TNFi in Norwegian PsA outpatients between 2000 and 2015.

**Methods:** We included all the PsA patients who initiated first time treatment with adalimumab, etanercept, golimumab and certolizumab in the years 2000–2015 in a Norwegian outpatient clinic. Baseline characteristics and drug survival were compared between patients with and without csDMARD co-medication. The $X^2$ test, independent t-test and Mann-Whitney U test were applied as appropriate for group comparisons. Drug survival was explored by Kaplan-Meier analysis, and patients receiving versus not receiving co-medication were compared using the log rank test. Additional analyses for each of the TNFi were performed. Univariable and multivariable Cox regression analysis were used to identify predictors of discontinuation.

**Results:** Among 371 PsA patients being treated with TNFi, 145 received csDMARD co-medication; 58/118 with etanercept, 48/106 with adalimumab, 21/47 with certolizumab and 18/47 with golimumab, respectively. Mean (SD) age was 54.0 (11.5) years, disease duration 13.1 (9.1) years, years of education 12.9 (3.4), body mass index (BMI) 27.1 (4.3) kg/m$^2$, baseline DAS28 4.1 (1.4), 45.7% were female. Baseline characteristics were similar for patients with and without co-medication, except for a higher percentage of first time TNFi users (67.6%) compared to previous TNFi users (32.4%) in the co-medication group, p=0.001. Drug survival of TNFi was similar for patients receiving versus not receiving concomitant csDMARDs (log rank test p=0,181, figure). In the Cox regression analysis identified predictors for TNFi discontinuation were previous use of TNFi (HR 1.68, 95% CI 1.25–2.26, p$<$0.001) and TNFi type (p$<$0.001). Separate analyses for first time TNFi users did not change the primary outcome. Separate analyses for different TNFi types showed similar drug survival with and without co-medication, except for certolizumab for which a trend toward better drug survival with co-medication was seen.

**Conclusions:** In our population of TNFi treated PsA patients, we found similar drug survival for patients with and without csDMARD co-medication. Identified predictors for TNFi discontinuation were previous use of TNFi and TNFi type.

## FRI0451 SECUKINUMAB PROVIDES RAPID AND SUSTAINED REDUCTIONS IN DACTYLITIS AND ENTHESITIS IN PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSIS OF DATA FROM THE PHASE 3 RANDOMISED, MULTICENTRE, DOUBLE-BLIND, PLACEBO-CONTROLLED FUTURE 2 STUDY

B. Kirkham[1], P. Mease[2], I. McInnes[3], V. Bhosekar[4], S. Mpofu[5], K. Gandhi[6], C. Gaillez[5]. *[1]Guy's and St Thomas' NHS, London, United Kingdom; [2]Swedish Medical Centre and University of Washington, Seattle, United States; [3]University of Glasgow, Glasgow, United Kingdom; [4]Novartis Healthcare Pvt Ltd, Hyderabad, India; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corporation, East Hanover, United States*

**Background:** Dactylitis and enthesitis are common debilitating manifestations of psoriatic arthritis (PsA).[1] Secukinumab has previously been reported to reduce the number of dactylitic digits and enthesitis sites in patients (pts) with PsA, with a greater proportion of pts achieving complete resolution of dactylitis and enthesitis than placebo (PBO) at Week (Wk) 24.[2,3]

**Objectives:** To evaluate the effects of secukinumab on dactylitis and enthesitis through Wk 52 in FUTURE 2 (NCT01752634).

**Methods:** The study design from FUTURE 2 has been reported previously.[2] The proportions of pts with resolution of dactylitis and enthesitis at Wk 24 and Wk 52 were secondary and exploratory endpoints, respectively; additional measures were dactylitic digit and enthesitis counts. Post-hoc analyses included Kaplan Meier (KM) analysis to achieve resolution of enthesitis and dactylitism and proportion of pts with resolution of dactylitis and enthesitis by baseline (BL) severity.

**Results:** Of the 397 pts randomized, 138 (35%) and 253 (64%) had dactylitis and enthesitis, respectively, at BL. KM curves indicate that median time to resolution in dactylitis and enthesitis was Wk 4 for secukinumab 300 and 150 mg. At Wk 24, a greater proportion of secukinumab-treated pts achieved complete resolution of dactylitis and enthesitis than PBO (P$<$0.05); more secukinumab-treated pts had

Table 1. Dactylitis and Enthesitis Data at Wks 24 and 52

| Variable | Secukinumab 300 mg N=100 | Secukinumab 150 mg N=100 | Secukinumab 75 mg N=99 | PBO N=98 |
|---|---|---|---|---|
| Dactylitis at BL, n (%) | 46 (46.0) | 32 (32.0) | 33 (33.3) | 27 (27.6) |
| Dactylitis count at BL, mean | 3.6 | 4.4 | 3.0 | 2.7 |
| Dactylitis count, mean change from BL [95% CI] | | | | |
| Wk 24 | –2.56 [–2.32, 0.89] | –2.53 [–3.16, 0.04] | –1.68 [–2.32, 0.89] | –0.97 |
| Wk 52 | –3.08 [–1.06, 1.11] | –3.11 [–2.31, –0.15] | –1.85 [–2.44, –0.07] | – |
| Enthesitis at BL, n (%) | 56 (56.0) | 64 (64.0) | 68 (68.7) | 65 (66.3) |
| Enthesitis count at BL, mean | 2.82 | 3.19 | 3.16 | 3.06 |
| Enthesitis count, mean change from BL [95% CI] | | | | |
| Wk 24 | –1.68 [–1.27, 0.12] | –1.83 [–1.40, –0.04] | –1.38 [–0.95, 0.40] | –1.11 |
| Wk 52 | –1.68 [–0.38, 0.84] | –1.91 [–0.78, 0.43] | –1.50 [–1.00, 0.19] | – |

Symptoms in those patients with dactylitis/enthesitis at BL; dactylitis count from 20 digits (score of 0–20) and enthesitis count from 6 sites (score of 0–6); mixed-effect model repeated measures (MMRM) data.

complete resolution of symptoms at Wk 52 than Wk 24. Improvements at Wk 24 and 52 were observed regardless of BL severity. A sustained decrease in mean changes from BL to Wk 24 and 52 in dactylitis and enthesitis count were shown in those pts with symptoms at BL (Table), with improvements versus PBO observed by Wk 4 ($P<0.05$).

**Conclusions:** Secukinumab demonstrated a rapid resolution of dactylitis and enthesitis as early as Wk 4 and this was sustained up to Wk 52. A higher proportion of pts achieved complete resolution and reduced mean counts of dactylitis and enthesitis at Wk 52 than Wk 24.

## FRI0452 ARE GM-CSF-PRODUCING TH17 CELLS IMPORTANT IN THE PATHOGENESIS OF PSORIATIC ARTHRITIS?

C. Stober, J. Goodall, H. Gaston. *Medicine, University of Camridge, Cambridge, United Kingdom*

**Background:** Psoriasis [Ps] is a common chronic inflammatory skin condition affecting about 1–2% of the world population; approximately 20–30% of patients have psoriatic arthritis [PsA]. PsA can affect peripheral and axial joints, eyes, ileum, colon and skin. Genetic studies reveal common candidate genes including *IL23R*, *IL12B*, *STAT3*, and *CARD9*, all associated with IL-23 signalling. We demonstrated increased frequencies of $Th_{17}$ cells in patients with Ps and PsA and the clinical importance of IL-23/$Th_{17}$ is revealed by the efficacy of biologics targeting this pathway. Whilst IL-17 was thought to be pathogenic in inflammatory conditions such as experimental autoimmune encephalomyelitis, the redundancy of IL-17 but essential requirement for GM-CSF release by $Th_{17}$ cells was shown. GM-CSF$^+$ T cells were identified in cerebrospinal fluid from patients with multiple sclerosis but a role in the aetio-pathogenesis of PsA has not been established.

**Objectives:** 1) Are GM-CSF$^+$ T cells enriched in peripheral blood and synovial fluid obtained from patients with PsA?
2) Is GM-CSF co-produced with IFN-g?
3) Do CD4$^+$GM-CSF$^+$ T cells express surface markers characteristic of $Th_{17}$?
4) Is GM-CSF release augmented by exogenous IL-23 and/or IL-12?

**Methods:** PBMC or synovial fluid derived from patients with PsA, or healthy donor (HD) PBMC, were stimulated with anti-CD3/anti-CD28 +/– recombinant IL-23 or IL-12. Supernatants were harvested and analysed by ELISA for IL-17, IFN-$\gamma$ or GM-CSF. Alternatively, cells were activated with phorbol myristate acetate (PMA) and ionomycin, and evaluated for the expression of the $Th_{17}$-associated cell surface markers CCR6, CD161 & IL-23R plus IL-17A, IFN-g and GM-CSF by flow cytometry.

**Results:** GM-CSF release from PsA PBMC was higher than that of HD, whereas IFN-g levels were higher in HD. This was most significant on comparing the ratio of IFN-g to GM-CSF. On examining the co-expression of GM-CSF and IFN-g in CD4$^+$ T cells, PsA patients had higher proportions of GM-CSF$^+$ single positive and fewer GM-CSF$^+$IFN-g$^+$ relative to HD. There was also marked enrichment of CD4$^+$GM-CSF$^+$ cells in synovial fluid. On evaluating the expression of the $Th_{17}$-associated markers CCR6, CD161 and IL-23R, we demonstrated that whereas almost all CD4$^+$IL-17$^+$ cells expressed CCR6, approximately 50% of CD4$^+$GM-CSF$^+$ cells expressed this chemokine receptor. Surprisingly, there were fewer PsA patient CD4$^+$GM-CSF$^+$ peripheral blood T cells co-expressing CCR6, CD161 and IL-23R relative to HD. Finally, IL-23 has been shown to render Th17 cells more pathogenic, hence we examined the effect of this cytokine on GM-CSF release. We showed that whilst IL-17 release was enhanced by exogenous IL-23, GM-CSF release was significantly downregulated with little effect on IFN-g. In contrast, IL-12 increased IFN-g and GM-CSF, and reduced IL-17.

**Conclusions:** IL-23 and $Th_{17}$ cells are therapeutic targets in PsA, and mouse models of inflammation suggest that pathogenic $Th_{17}$ cells release GM-CSF. We reveal that GM-CSF release is elevated in patients with PsA, and GM-CSF$^+$ cells are enriched in diseased joints. However, only a proportion of GM-CSF$^+$ cells exhibited features of $Th_{17}$. Furthermore, IL-23 downmodulated GM-CSF whilst enhancing IL-17. Given that GM-CSF was mainly produced by cells *not* co-expressing IFN-g in PsA patients [in contrast to healthy donors], this subset may be pathogenic in PsA and warrants further investigation.

## FRI0453 THE INCREASED PREVALENCE OF NAFLD IS WORRISOME AMONG PATIENTS WITH PSORIATIC ARTHRITIS

C. Gaspari, G. Carvalho, L. Anjos, P. Sampaio-Barros, J. Moraes, C. Gonçalves, C. Saad, C. Goldenstein-Schainberg. *Disciplina de Reumatologia HCFMUSP, São Paulo, Brazil*

**Background:** Non-alcoholic fatty liver disease (NAFLD) affects 20–30% of general population and a wide range of 14–59% patients with cutaneous psoriasis (PsO). Psoriatic arthritis (PsA) has been linked to comorbidities including diabetes, arterial hypertension, dyslipidemia and metabolic syndrome (MetS) though data on NAFLD in PsA is lacking. In fact, in PsA, NAFLD has been evaluatedin only one Italian study affecting 28% patients.

**Objectives:** To evaluate the prevalence of NAFLD in our cohort of patients with PsA.

**Methods:** All patients with PsA regularly followed-up during a 6 month period at our outpatient rheumatology clinic were studied. They were evaluated byabdominal ultrasound (US) and NAFLD was defined in the presence of hepatic steatosis (US = Grades I to III).The occurrence of associated comorbidities, includingarterial hypertension, diabetes and dyslipidemia was recorded and the NCEP-ACT III criteria were applied to identify subjects with metabolic syndrome (MetS). DAS 28, BASDAI and ASDAS were used to assess PsA disease activity, while HAQ was performed to assess functional impairment. Student's t, Chi-square and Fisher's exact tests were performed for statistical analyses and P values $\leq 0.05$ were considered significant.

**Results:** Fifty six PsA patients were initially enrolled, but 3 were excluded due to the presence of alcoholic cirrhosis in 2 and a positive serology for hepatitis C in 1. Among the remaining 53 patients, 26 were males and 27 females, with mean age = 54,8±13 yrs (27–76) and mean disease duration = 14,4±8,1 yrs (04–40). US revealed NAFLD in 33/53 (63%) patients with PsA, confirmed by liver biopsy in 2. Arterial hypertension, diabetes and dyslipidemia affected 81%, 42%, 75% of patients with NAFLD respectively ($P<0.001$). MetS was present in 58,5% (31/53) individuals, significantly more prevalent in patients with compared to those without NAFLD: 26/33 (78.8%) vs. 05/20 (25.0%), $P<0.001$, despite of gender. All disease activity indices (% patients with DAS28$>$2.6), mean BASDAI and mean ASDAS) and HAQ scores were similar among patients with or without NAFLD (55.6% vs 46.7%; 3.1 vs 3.7; 1.9 vs 2.3; 1 vs 0.9 respectively, $P>0.05$).

**Conclusions:** NAFLD is very common in our cohort of PsA patients occurring in over 2/3 regardless of disease activity and associated to MetS in most subjects, suggesting a relationship between these conditions. Moreover, screening for NAFLD inPsA patients is warranted in order to avoid increased overall liver morbidity.

## FRI0454 ENDOTHELIAL DYSFUNCTION IN PSORIATIC ARTHRITIS: EVALUATION BY ENDOTHELIAL-DEPENDENT FLOW-MEDIATED DILATION AND CORONARY FLOW RESERVE

G. Murdaca, G. Bezante, E. Penza, M. Balbi, S. Negrini, F. Puppo. *Dip. Med. Interna IRCCS/Aou San Martino Ist (Ge), Genova, Italy*

**Background:** Patients with psoriatic arthritis (PsA) are at an increased risk for premature cardiovascular disease (CVD) independent of traditional risk factors [1]. Endothelial dysfunction plays a central role in the development of accelerated atherosclerosis.

**Objectives:** To evaluate endothelial dysfunction by assessment of artery endothelial-dependent flow-mediated dilation (FMD) and coronary flow reserve (CFR).

**Methods:** 20 patients (12 males and 8 females – age 57,5 ±10,8 years) affected by PsA according to CASPAR criteria [2] were enrolled. The 10-years cardiovascular Framigham risk score was calculated. Ultrasound assessment of brachial artery FMD was performed according to Corretti et al. [3]. CFR was evaluated by contrast-enhanced Doppler echocardiography and dipyridamole administration as previously described [4].

**Results:** The 10-years cardiovascular Framingham risk score of PsA patients (mean 3.84 ± 3.22) was in the low risk range. The assessment of brachial artery FMD showed a significant reduction of post-ischemic vasodilation in PsA patients (mean -17.70 ± 16%) as compared with normal population (mean +15.00 ± 5%). Coronary flow reserve was under the normal range (CFR $>$2.5) [5] in 15/20 PsA patients.

**Conclusions:** The present results demonstrate that PsA patients with low cardiovascular Framingham risk score have increased arterial stiffness and

decreased coronary arteries flow reserve. These data suggest that endothelial dysfunction may underlie premature atherosclerosis in PsA patients

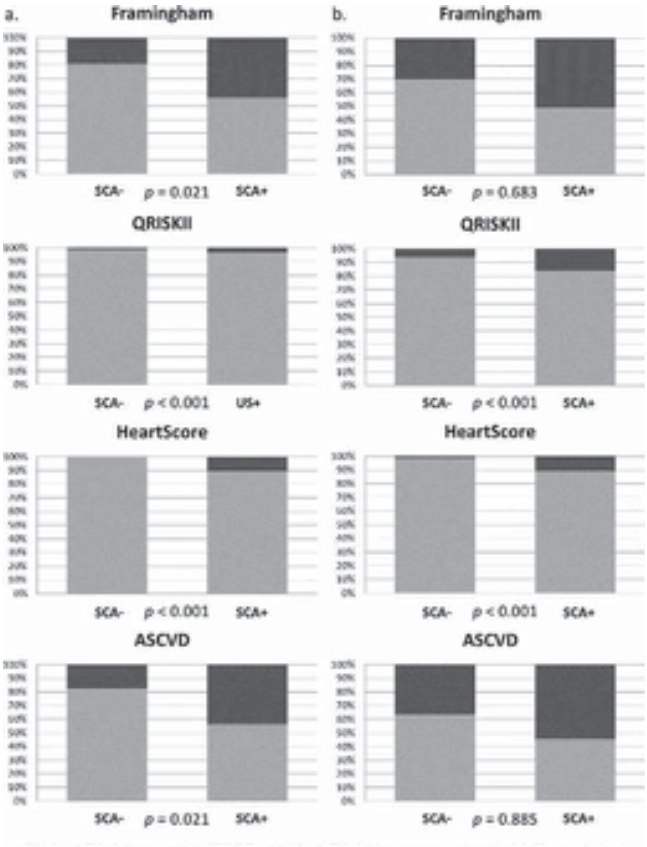
## FRI0455 ALL CARDIOVASCULAR (CV) RISK SCORES SIGNIFICANTLY UNDERESTIMATED CV RISK DEFINED BY CAROTID ULTRASOUND IN PSORIATIC ARTHRITIS- CAN WE IMPROVE THEIR PERFORMANCES?



H.M. Lam, J. Shen, T.H. Cheng, Q. Shang, L.-S. Tam. *Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Sha Tin, Hong Kong*

**Background:** Psoriatic arthritis (PsA) is associated with higher cardiovascular (CV) risk. The performances of established CV risk scores for general population in PsA patients have not been fully evaluated yet. Meanwhile, European League Against Rheumatism (EULAR) recommended to introduce a 1.5 multiplication factor to the CV risk scores for certain patients with rheumatoid arthritis. Whether the multiplication factor could improve the performances of the risk scores in PsA is unknown.

**Objectives:** To evaluate the performances of different CV risk scores and their EULAR modified versions in detecting high CV risk in PsA patients defined as the presence of subclinical atherosclerosis (SCA) determined by carotid ultrasonography.

**Methods:** Four different CV risk scores namely Framingham risk score (FRS), QRISK II, HeartScore and American College of Cardiology and American Heart Association (ACC/AHA) 10-year atherosclerotic cardiovascular disease (ASCVD) and their EULAR recommended modified versions were calculated. Sonographic evaluation measuring carotid intima-media thickness (IMT) and plaque was used to determine SCA. IMT>0.90 mm and/or the presence of plaque were classified as SCA+.

**Results:** 162 patients [49.27±11.9 years, male: 95 (58.6%)] underwent carotid ultrasound were recruited. 142, 137, 128 and 118 patients were eligible to calculate FRS, QRISKII, HeartScore and ASCVD, respectively. 69 (34.3%) patients were considered to have high CV risk based on the presence of SCA. The SCA+ patients were significantly older (55±10 vs 45±12 years; $p<0.001$) and more diabetic [11 (15.9%) vs 12 (12.9%); $p<0.001$]. They also had higher systolic blood pressure (SBP: 138±25 vs 128±17 mmHg; $p=0.003$) and total cholesterol (TC: 5.3±0.9 vs 4.9±0.9 mmol/L, $p=0.005$). All CV risk scores were significantly higher in SCA+ patients (FRS: 17±14 vs 8±8%, $p<0.001$; QRISKII: 13±9 vs 7±7%, $p=0.002$; HeartScore: 3±3 vs 1±2%, $p=0.001$; ASCVD: 14±14 vs 8±8%, $p=0.002$). Areas under the receiver operating characteristic (ROC) curves discriminating SCA+ for FRS, QRISKII, HeartScore and ASCVD were 0.71 (0.63–0.80, $p<0.001$), 0.67 (0.58–0.76, $p=0.001$), 0.67 (0.58–0.77, $p=0.001$), and 0.67 (0.58–0.77, $p=0.001$), respectively. 42 (29.6%), 3 (2.2%), 6 (4.7%) and 35 (29.7%) patients were classified as having high CV risk scores according to FRS>10%, QRISK II>20%, HeartScore>5% and ASCVD>7.5%, respectively. By McNemar's test, all scores significantly underestimated the risk of SCA+ (all $p<0.05$, Figure 1a). By applying the EULAR multiplication factor, 55 (38.7%), 14 (10.2%), 7 (5.5%) and 53 (44.9%) patients were reclassified as having high CV risk, respectively. SCA+ risk was still significantly underestimated by the modified QRISKII and HeartScore, but not by the modified FRS ($p=0.683$) and ASCVD ($p=0.885$) (Figure 1b). EULAR modification increased the sensitivity of FRS and ASCVD in predicting SCA from 44% to 51%, and from 44% to 55%, respectively.

a. Original CV risk scores; b. EULAR modified CV risk scores; p value by McNemar's test. Dark grey: High risk, Light grey: low risk, according to risk scores.

**Conclusions:** All CV risk scores significantly underestimated the risk defined by carotid ultrasonography. EULAR recommended modification improved the sensitivity of FRS and ASCVD to a moderate level.

## FRI0456 ASSOCIATION BETWEEN IMPROVEMENT IN ENTHESOPATHY AND QUALITY OF LIFE: RESULTS FROM ANTI-TNF-NAÏVE PATIENTS WITH PSORIATIC ARTHRITIS IN TWO PHASE 3 USTEKINUMAB TRIALS

I.B. McInnes[1], L. Puig[2], A.B. Gottlieb[3], C. Ritchlin[4], Y. You[5], M. Song[5], S. Kafka[6], K.L. Tang[5], G.J. Morgan[6], P. Rahman[7], A. Kavanaugh[8] on behalf of the PSUMMIT I and II Study Groups. *[1]University of Glasgow, Glasgow, United Kingdom; [2]Universitat Autònoma de Barcelona, Barcelona, Spain; [3]Tufts Medical Center, Boston; [4]University of Rochester, Rochester; [5]Janssen Research & Development, LLC, Spring House; [6]Janssen Scientific Affairs, LLC, Horsham, United States; [7]Memorial Hospital, St. John's, Canada; [8]University of California-San Diego, La Jolla, United States*

**Objectives:** To assess the relationship between changes in enthesopathy and in function/health-related quality of life (HRQoL) in anti-TNF-naïve patients (pts) with psoriatic arthritis (PsA) receiving treatment with ustekinumab (UST).

**Methods:** Adult pts in 2 Phase 3 trials (n=747 anti-TNF naive) with active PsA (≥5 SJC and ≥5 TJC;CRP≥0.3mg/dL) despite DMARD and/or NSAIDs were randomized to UST45mg, 90mg, or PBO at weeks 0, 4, and q12weeks. Stable concomitant MTX was permitted but not mandated. At week16, pts with <5% improvement in TJC & SJC entered blinded early escape (PBO→UST45mg; UST45mg→90mg; 90mg→90mg). Presence or absence of enthesopathy, HAQ-DI, and SF-36 were assessed at baseline and week 24. In this post-hoc analysis, enthesopathy of the Achilles tendon and plantar fascia was assessed as present or absent. Pts were categorized thereafter as follows: improved (enthesopathy present at baseline, but not at week 24), worsened (enthesopathy present at week 24, but not at baseline), and unchanged. Pts with an enthesopathy assessment missing at either time point were included in the unchanged category; those with enthesopathy data missing at both time points were excluded. Early escape pts were also excluded from this analysis. Improvements in HRQoL (assessed by the SF-36 PCS and MCS and physical function (HAQ-DI) were assessed by enthesopathy response category.

**Results:** A total of 591 anti-TNF-naïve pts from both trials were included in the analysis; 45% of pts were female, mean age was 47 years, mean PsA duration was 6.7 years, and 74% had ≥3% body surface area affected at baseline. The proportion of pts with enthesopathy at baseline was similar in the combined UST (46.5%) and placebo (49.4%) groups. At week 24, the proportions of pts with enthesopathy were 22.8% and 35.9% for the combined UST and placebo groups, respectively. Across all pts, those who had an improvement in enthesopathy had

Table 1

| | Enthesopathy Status | | |
|---|---|---|---|
| | Worsened | Unchanged | Improved |
| Overall | | | |
| % improvement in HAQ-DI | n=25 | n=407 | n=136 |
| | 14.0 (34.7) | 23.1 (63.9) | 35.5 (49.5) |
| Change in SF-36 PCS | n=27 | n=395 | n=139 |
| | 2.8 (7.4) | 5.0 (8.7) | 6.6 (8.8) |
| Change in SF-36 MCS | n=27 | n=395 | n=139 |
| | –0.9 (8.1) | 3.4 (10.2) | 6.9 (10.4) |
| ACR 20 responders | | | |
| % improvement in HAQ-DI | n=9 | n=184 | n=88 |
| | 31.3 (31.5) | 52.2 (37.1) | 51.2 (38.7) |
| Change in SF-36 PCS | n=10 | n=189 | n=90 |
| | 7.6 (7.1) | 8.6 (8.9) | 9.2 (8.4) |
| Change in SF-36 MCS | n=10 | n=189 | n=90 |
| | 3.4 (7.0) | 5.1 (10.6) | 7.9 (10.7) |

a greater improvement in functioning and HRQoL, compared with those who did not ($p<0.05$; Table). When the analysis was restricted to those who achieved an ACR 20 response, pts with an improvement in enthesopathy showed a trend of greater improvement in functioning and HRQoL compared to those who had worsened (Table).

**Conclusions:** There is an association between improvement in enthesopathy of the Achilles tendon and plantar fascia and improvement in physical function and quality of life in anti-TNF-naïve pts with PsA in 2 UST trials. Some, but not all, of this improvement may be explained by improvements in peripheral arthritis.

U. de la Princesa, IIS-Princesa, Madrid; [13]Dermatology, Hospital Universitari Parc Taulí, Sabadell; [14]Rheumatology, H. U. de la Princesa, IIS-Princesa, Madrid, Spain*

**Objectives:** To establish recommendations for the management of comorbidities in patients with psoriatic disease (PsD).

**Methods:** A multidisciplinary panel drafted the recommendationsin a nominal group session. Evidence from four systematic reviews was added. Agreement was assessed by two-rounds Delphi technique. Recommendations with an agreement $\geq$7/10 by at least 70% of participants were kept in.

**Results:** A total of 19 recommendations on three key topics were issued: 1) screening of specific comorbidities, 2) specific preventive or therapeutic actions, and 3) general management.

**Conclusions:** Disease control coupled with the management of comorbidities is critical to ensure optimal patient care. These recommendations suggest actions on detection, management and integration of care in PsD.

**Acknowledgement:** GECOAP project was funded by Merck Sharp & Dohme of Spain

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3440

**Abstract FRI0457** – Table 1

| |
|---|
| **Recommendations for the screening of specific comorbidities** |
| CV disease and risk factors should be screened early and periodically; if present, they must be controlled. LE 3, A 9.8 |
| Adequate control of obesity and overweight should be a priority. LE 3, A 9.3 |
| Psycho-affective disorders should be investigated. LE 4, A 8.9 |
| Inquiring about sexual dysfunctions is recommended. LE 5, A 7.7 |
| Pts with ocular symptoms should be referred rapidly to ophthalmology. LE 5, A 8.8 |
| Uric acid and gouty symptoms should be periodically monitored. LE 4, A 8.8 |
| If new skin lesions, skin cancer should be screened, especially if pt. received PUVA, CsA or biological treatment. LE 5, A 8.5 |
| **Therapeutic and preventive actions** |
| Drugs with potential negative effect on comorbidities should be avoided. LE 5, A 9.5 |
| Even in absence of risk factors, it is recommended to inform about CV risk. LE 5, A 8.4 |
| It is advisable to include dietary recommendations, adapted to pt preferences, to prevent overweight and obesity. LE 2, A 8.8 |
| Regular aerobic exercise should be recommended. LE 2, A 9.1 |
| Smoker pts should be encouraged to cease smoking on each visit. LE 3, A 9.8 |
| Pts should be encouraged to cease or reduce alcohol intake. LE 4, A 9.1 |
| It is advised to follow standard guidelines for the prevention of osteoporosis, especially in pts on chronic GC therapy. LE 5, A 8.8 |
| **Recommendations on the management of chronic patients with PD** |
| The management of pts with PsD must be holistic; rheumatologists or dermatologists will play a key role coordinating with other specialists. LE 5, A 9.8 |
| For monitoring and control of comorbidities associated with PsD, it is essential to involve GPs and other specialists, as well as to promote pt empowerment. LE 5, A 9.3 |
| Comorbidities should be assessed at the time of diagnosis, upon Tx changes, and during follow-up*. LE 5, A 8.8 |

**Background:** Psoriatic disease (PsD) is associated with multiple comorbidities. When establishing management protocols, the periodicity for detection and evaluation of such comorbid conditions needs to be specified.

**Objectives:** To establish guidelines for the follow-up of selected comorbidities in patients with PsD.

**Methods:** An expert panel with specialists in Rheumatology, Internal Medicine, Dermatology and General Practitioners defined the comorbidities with higher impact on PsD based on the existing literature and their experience. The periodicity for detection and monitoring of comorbidities in the Rheumatology setting was established by consensus after iterations and systematic review.

**Results:** The expert panel agreed to evaluate comorbidities as part of routine clinical practice at the time of diagnosis, upon changes in systemic treatment and at follow-up visits (evidence level 5, level of agreement 8.8). In any case, monitoring must be customized depending on the risk profile, morbidity, comorbidities and patient preferences. The following table shows the proposed periodicity for detection, assessment, and monitoring of the most important comorbidities in PsD.

**Conclusions:** This proposal for a periodic assessment of comorbidities in patients

## FRI0459 LONGITUDINAL EVOLVEMENT OF PASDAS AND CPDAI AND ITS ASSOCIATIONS WITH PATIENTS CHARACTERISTICS AND TREATMENT IN INCIDENT PSORIATIC ARTHRITIS: RESULTS FROM THE DEPAR STUDY

K. Wervers[1], M. Vis[1], I. Tchetverikov[2], A.H. Gerards[3], M.R. Kok[4], C.W.Y. Appels[5], W.L. van der Graaff[6], J.H.L.M. van Groenendael[7], L.-A. Korswagen[8], J. Veris[7], J.M.W. Hazes[1], J.J. Luime[1] on behalf of DEPAR study group. *[1]Erasmus Medical Centre, Rotterdam; [2]Albert Schweitzer Hospital, Dordrecht; [3]Vlietland Hospital; [4]Maasstad Hospital, Rotterdam; [5]Amphia Hospital, Breda; [6]Beatrix Hospital, Gorinchem; [7]Reumazorg Zuid West Nederland, Roosendaal; [8]Sint Franciscus Gasthuis, Rotterdam, Netherlands*

**Background:** Psoriatic Arthritis (PsA) is a multi-features disease requiring disease activity measures that capture not only joint disease, such as the Composite Psoriatic Disease Activity Index (CPDAI) and the Psoriatic Arthritis Disease Activity Score (PASDAS). Although both are well validated in clinical trials, little data exists on their evolvement in daily clinical care.

**Objectives:** to describe the longitudinal evolvement of CPDAI and PASDAS and its associations with demography, disease, and DMARDs.

**Methods:** Newly diagnosed consecutive PsA patients were recruited in 8 hospitals in the Netherlands from August 2013 to November 2015. Demographic and disease characteristics were registered. Data was analysed in the first 3 months by linear regression and over 12 months using linear mixed model with random intercept for CPDAI (0–15) and PASDAS (0–10)

**Results:** In November 2015 281 patients had had a baseline assessment, of which 234, 198, 157 and 129 had had resp. a 3, 6, 9 and 12 month assessment. The mean age was 50.6 (SD 13.6) and 50.5% were male. In terms of arthritis subtypes, 56 (20%) had monoarthritis, 108 (39%) oligoarthritis, 80 (29%) polyarthritis and 35 (12%) were diagnosed with axial disease, dactylitis or enthesitis only.

PASDAS evolved from a mean of 4.0 points (SD 1.2, n=174) at baseline, to 3.3 (SD 1.1, n=160) at 3 months, and 2.6 (SD 1.1, n=94) at 12 months. CPDAI evolved from 5.5 (SD 2.1, n=229), to 4.4 (SD 2.0, n=213) to 2.97 (SD 1.8, n=113) resp. Associations and their course over time are described in table 1. In summary: MTX had a lowering effect on both the CPDAI and PASDAS in the multivariate analysis, while baseline scores and disease duration had a raising effect. Higher baseline PASDAS and CPDAI values in the multivariate analysis were associated with being female, the presence of oligo- or polyarthritis and tender enthesis, for CPDAI also with the presence of morning stiffness. Similar results were observed in the 3-months linear regression.

Table 1. Univariate and multivariate regression analysis of CPDAI and PASDAS

## FRI0460 SECUKINUMAB SHOWS SIGNIFICANT EFFICACY IN NAIL PSORIASIS: WEEK 32 RESULTS FROM THE TRANSFIGURE STUDY

K. Reich[1], J. Sullivan[2], P. Arenberger[3], U. Mrowietz[4], S. Jazayeri[5], M. Augustin[6], A. Parneix[7], P. Regnault[8], R. You[9], M. Milutinovic[8]. *[1]Dermatologikum, Hamburg, Germany; [2]Holdsworth House Dermatology, Sydney, Australia; [3]Department of Dermatology, Charles University, Prague, Czech Republic; [4]Psoriasis Center at the Department of Dermatology, University Medical Center Schleswig-Holstein, Kiel, Germany; [5]Alliance Dermatology and MOHS Center, Phoenix, United States; [6]Universität Hamburg, Hamburg, Germany; [7]Novartis Pharmaceuticals Corporation, East Hanover, United States; [8]Novartis Pharma AG, Basel, Switzerland; [9]Beijing Novartis Pharma Co. Ltd, Shanghai, China*

**Background:** Nail psoriasis is associated with decreased finger mobility, functional impairment, pain and reduced quality of life [1] and is often resistant to available therapies.[2] It correlates with more severe psoriatic disease and is an important predictor of psoriatic arthritis (PsA).[3] The incidence of nail psoriasis in PsA patients is up to 80%.[4]

**Objectives:** We assessed superiority of secukinumab 300 mg and/or 150 mg vs. placebo (PBO) in treating subjects with moderate to severe psoriasis and significant nail involvement, as assessed by NAil Psoriasis Severity Index (NAPSI) at Week (Wk) 16 and Wk 32 and Psoriasis Area and Severity Index (PASI) at Wk 32. Impact on quality of life was assessed by Nail Assessment in Psoriasis and Psoriatic Arthritis (NAPPA) Patient Benefit Index (-PBI) and Quality of Life (-QOL) at Wk 16.

**Methods:** TRANSFIGURE is a double-blind, randomized, PBO-controlled, parallel-group multicentre phase 3b study. Subjects (N=198) were randomized 1:1:1 to receive either secukinumab 300 mg, secukinumab 150 mg or PBO subcutaneously up to Wk 128. At Wk 16, all subjects receiving PBO were re-randomized 1:1 to receive 300 mg or 150 mg secukinumab.

**Results:** The primary objective of this study was met. Both doses of secukinumab were superior to PBO at Wk 16 with a mean percentage NAPSI improvement from Baseline of -45.3%, -37.9%, and -10.8%, for secukinumab 300 mg, 150 mg and PBO, respectively ($P < 0.0001$). Responses improved further by Wk 32 with a NAPSI change of -63.2% and -52.6%, for secukinumab 300 mg and 150 mg, respectively. At Wk 32, PASI 90 responses were achieved in 72.1% and 61.4% of subjects, and PASI 100 responses in 36.9% and 28.1% for secukinumab 300 mg and 150 mg, respectively. At Wk 16, subjects on secukinumab showed significant improvements in NAPPA-QOL with a median decrease in total score of 60.9%, 49.9% and 15.8% for secukinumab 300 mg, 150 mg and PBO, respectively. The percentage of subjects achieving a weighted NAPPA-PBI global score of 2 and above (i.e. at least moderate benefits) was 75.4%, 61.3% and 8.6% for secukinumab 300 mg, 150 mg and PBO, respectively. The most common adverse events were nasopharyngitis, headache and upper respiratory tract infections, similar to previous studies.

**Conclusions:** In the prospective, placebo-controlled TRANSFIGURE trial, secukinumab demonstrated significant and clinically meaningful efficacy, quality of life improvement and patient-reported benefit in nail psoriasis.

**Background:** Psoriatic arthritis impacts significantly function and quality of life. Although radiographic damage may be more important in rheumatoid arthritis both disability and quality of life are similarly impaired in both groups. Only few data in large cohorts are available to evaluate the impact of the articular and skin involvement in PsA. The BEPAS cohort is a unique opportunity to study cross-sectionally and longitudinally these aspects and their effect on disability and quality of life.

**Objectives:** (1) to estimate the severity of disease based on disease activity scores and active inflammation (2) to estimate the impact in terms of health-related quality of life of PsA in Belgium

**Methods:** A cross-sectional analysis at the inclusion visit was performed among all patients included in the BEPAS cohort and subsequently differences between male and female patients were studied. They were evaluated for the demographics, the disease activity at inclusion. Inflammatory parameters were captured at inclusion. HAQ and SF36 patient global assessment and physician global assessment were collected. Gender differences were evaluated by one way ANOVA or Chi –square testing.

**Results:** 461 patients including 263 male patients and 198 female patients with mean age: 52.79 years (±12.29) were recruited in the 17 centers from December 2012 to July 2014.

| Any use of anti-TNF | 142 (54%) | | 86 (43.4%) | | 0025 |

**Conclusions:** The differences in disease activity and consequently the burden of disease between male and female patients with PsA in the BEPAS cohort seem mainly based on the patient global assessment and enthesitis score. Swollen and tender joint counts as well as inflammatory parameters are not responsible for these differences

## FRI0462 GENDER DIFFERENCES IN THE DISEASE EXPRESSION AND ARTICULAR MANIFESTATIONS AMONG PATIENTS WITH PSORIATIC ARTHRITIS. DATA FROM THE BEPAS COHORT

K. De Vlam[1], R. Lories[1], S. Steinfeld[2], F. Van Den Bosch[3], A. Nzeusseu Toukap[4], M. Malaise[5], V. Taelman[1], F. Van Bruwaene[6], M. Van Den Berghe[7], J. Lenaerts[8], R. Joos[9], P. Geusens[10], S. Dall'Armellina[11], I. Peene[12], G. De Brabanter[13], M. Van Den Berghe[14], J. Qu[15], M. Maertens[16], H. Leroi[17] on behalf of BEPAS. *[1]Rheumatology, University Hospitals Leuven, Leuven; [2]Clinique St Jean, Bruxelles; [3]Ugent, Gent; [4]Rheumatology, UCL St Luc, Brussels; [5]Rheumatology, CHU Sart Tilman, Liege; [6]Rheumatology, Heilig Hart Ziekenhuis, Roeselaere; [7]Rheumatology, Algemeen Stedelijk Ziekenhuis, Aalst; [8]Reuma instituut, Hasselt; [9]Rheumatology, ZNA, Antwerpen; [10]ReumaClinic, Genk; [11]Rheumatology, Clinique Notre Dame de Grace, Gosselies; [12]AZ St Jan; [13]Rheumatology, AZ St Lucas, Brugge; [14]Rheumatology, Grand Hopital de Charleroi, Charleroi; [15]Rheumatology, Iris Sud, Brussels; [16]AZ Damiaan, Oostende; [17]Medical Affairs Immunology, MSD Belgium, Brussels, Belgium*

**Background:** Psoriatic arthritis (PsA) is a common form of chronic arthritis strongly associated with the skin disease psoriasis. The gender distribution is considered equal but it is suggested that their might be gender related differences in disease expression, disease activity and outcome. The BEPAS cohort (Belgian Epidemiological Psoriatic Arthritis Study) is a large prospective multicenter real life cohort set up in 17 Belgian large academic and non academic rheumatology practices that offers a unique opportunity to study the disease patterns with their respective articular and skin involvement in this patient group

**Objectives:** (1) To assess gender-related differences in disease patterns and articular manifestations of psoriatic arthritis

**Methods:** A cross-sectional analysis at the inclusion visit was performed among the male and female patients included in the BEPAS cohort. They were evaluated for the demographics, the disease patterns at diagnosis and the presence of clinical articular and extra–articular manifestations at inclusion. Gender differences were evaluated by one way ANOVA or Chi –square testing.

**Results:** 461 patients including 263 male patients and 198 female patients with mean age: 52.79 years (±12.29) were recruited in the 17 centers from December 2012 to July 2014.There was no gender difference in rheumatoid factor, anti–CCP and extra-articular manifestations such as uveitis and inflammatory bowel disease

| | Male (263) | | Female (198) | | P |
|---|---|---|---|---|---|
| | mean | SD | mean | SD | |
| Age of onset PsA | 45.023 | 13.2 | 44.15 | 15 | 0.507 |
| Age of onset PsO | 35.38 | 14.06 | 33.69 | 17.95 | 0.286 |
| PsA disease duration at inclusion | 8.45 | 8.74 | 8.79 | 9.99 | 0.701 |
| HLA B27 (n=112) (%) | 9.8 | | 9.8 | | >0.5 |
| BMI | 27.85 | 4.52 | 26.94 | 5.43 | 0.06 |
| Psoriasis type 1 | 165 (62.7) | | 122 (61.6) | | >0.5 |
| Numbers of DMARDS | 1.62 | 0.95 | 1.59 | 1.017 | 0.735 |
| Actual use of anti TNF | 130 (50.2) | | 74 (37.8) | | 0.008 |
| Oligo at diagnosis (%) | 93 (20.2) | | 61 (13.2) | | 0.305 |
| Poly at diagnosis (%) | 134 (29.1) | | 78 (16.9) | | 0.014 |
| Clinical articular and skin manifestations at inclusion | | | | | |
| IBP (Rudwaleit criteria ≥2/4) | 76 (28.9) | | 81 (40.9) | | 0.007 |
| TJ78 | 3.71 | 6.75 | 4.55 | 7.78 | 0.215 |
| SJ76 | 2.3 | 5.19 | 1.88 | 3.31 | 0.318 |
| Number of enthesitis | 0.73 | 2.13 | 1.63 | 4.08 | 0.004 |
| Number of dactylitis | 0.35 | 1.2 | 0.2 | 0.66 | 0.114 |
| BSA | 4.87 | 11.12 | 3.03 | 6.66 | 0.074 |
| Nail involvement | 85 (32.3) | | 37 (18.9) | | 0001 |

**Conclusions:** The disease patterns and clinical manifestations differ in several aspects between male and female PsA. They have a different clinical articular presentation at diagnosis: male patients have more polyarticular disease while female patients have more entheseal disease. Skin involvement is comparable except for male patients having more nail involvement. These differences might have impact on the disease evolution, severity and treatment decisions.

## FRI0463 SECUKINUMAB IMPROVES MINIMAL DISEASE ACTIVITY RESPONSE RATES IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: DATA FROM THE RANDOMIZED PHASE 3 STUDY, FUTURE 2

L.C. Coates[1], P. Mease[2], B. Kirkham[3], L.D. McLeod[4], S. Mpofu[5], C. Karyekar[6], K. Gandhi[6]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [2]University of Washington, Seattle, United States; [3]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [4]RTI Health Solutions, Research Triangle Park, United States; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corporation, East Hanover, United States*

**Background:** Minimal disease activity (MDA), a validated composite measure in PsA, is gaining acceptance as a target for achieving substantial disease control.
**Objectives:** Secukinumab (SEC), an anti–IL-17A monoclonal antibody, significantly improved the signs and symptoms of PsA over 52 wks in the FUTURE 2 study. This post-hoc exploratory analysis assessed MDA response rates through 52 wks.
**Methods:** 397 patients (pts) with active PsA were randomized to subcutaneous (SC) SEC (300 mg, 150 mg, or 75 mg) or placebo (PBO) at baseline (BL), Wks 1, 2, and 3, and every 4 wks (q4w) from Wk 4. PBO pts were re-randomized to SEC 300 or 150 mg SC q4w from Wk 16 or 24, depending upon clinical response. Pts were considered in MDA when they met at least 5 of the following 7 criteria: 1) tender joint count $\leq$1; 2) swollen joint count $\leq$1; 3) Psoriasis Activity and Severity Index $\leq$1 or psoriasis affecting $<$3% body surface area at BL; 4) pt pain VAS $\leq$15; 5) pt global disease activity VAS $\leq$20; 6) HAQ-DI $\leq$0.5; 7) tender entheseal points $\leq$1. MDA was assessed in the overall population and in pts stratified by prior anti-tumor necrosis factor (anti-TNF) therapy use (anti–TNF-naïve and inadequate response/intolerance to these agents [anti–TNF-IR]) and disease duration ($\leq$2 yrs vs $>$2 yrs since diagnosis). Observed data are shown. 75 mg data are not reported as this was not considered an effective dose (no secondary endpoints were met).
**Results:** In the overall population, 23/100 (23%) and 27/97 (28%) pts achieved MDA at Wk 16 with SEC 150 mg and 300 mg, respectively, vs 9/88 (10%) pts with PBO; these response rates were sustained through Wk 52 (150 mg: 29/88 [33%]; 300 mg: 33/93 [35%]). In the anti–TNF-naïve cohort, a higher proportion of pts achieved MDA at Wk 16 with SEC 150 mg (20/63 [32%]) or 300 mg (22/65 [34%]) vs PBO (8/58 [14%]), with response rates sustained through Wk 52 (150 mg: 23/59 [39%]; 300 mg: 26/63 [41%]). Lower rates were observed in anti–TNF-IR pts (SEC vs PBO at Wk 16: 150 mg, 3/37 [8%]; 300 mg, 5/32 [16%]; PBO, 1/30 [3%]; Wk 52: 150 mg, 6/29 [21%]; 300 mg, 7/30 [23%]). The proportion of pts achieving MDA at Wk 16 and Wk 52 in the overall population was greater for those $\leq$2 yrs since diagnosis vs those $>$2 yrs since diagnosis for both SEC 150 mg and 300 mg. The proportion of pts achieving MDA with SEC at Wk 16 was higher in anti–TNF-naïve pts with low disease duration vs pts with longer disease duration, and higher in the anti–TNF-naïve cohort than the anti–TNF-IR cohort at all times (Figure).

**Conclusions:** SEC pts had higher MDA response rates vs PBO pts at Wk 16, with response rates sustained through Wk 52. Response rates were consistent with those previously reported with anti-TNF therapies in comparable pt populations.[1] This study is the first to report MDA in anti–TNF-IR pts. The finding that greater MDA can be achieved in early anti–TNF-naive PsA pts warrants further research.

## FRI0464 LONG-TERM EFFICACY OF USTEKINUMAB TREATMENT IN PATIENTS AFFECTED BY PSORIATIC ARTHRITIS PREVIOUSLY TREATED WITH TNF INHIBITORS

M.S. Chimenti[1], P. Triggianese[1], A. Ortolan[2], M. Tonelli[1], M. Talamonti[3], L. Costa[4], F. Caso[4], M. Teoli[3], M. Galluzzo[3], R. Ramonda[2], R. Scarpa[4], L. Punzi[2], R. Perricone[1]. *[1]Rheumatology, allergology and clinical immunology, Department of"Medicina dei Sistemi" University of Rome "Tor Vergata", Rome; [2]Rheumatology Unit, Department of Medicine DIMED, University of Padova, Padova; [3]Department of Dermatology, University of Rome "Tor Vergata", Rome; [4]Rheumatology Unit, Department of Clinical Medicine and Surgery, University Federico II, Naples, Italy*

**Background:** IL12 and IL23 are two main cytokines involved in the pathogenesis of immune-mediated diseases. IL-12 is produced by macrophages and B lymphocytes and mediates differentiation of Th1 lymphocytes, while IL-23 is a pro-inflammatory cytokine essential for the differentiation of Th17 cells. Ustekinumab is a human monoclonal antibody directed against the p40 protein subunit shared by IL-12 and IL-23, blocking the signal transmission of both cytokines involved in the pathogenesis of both Psoriasis (PsO) and Psoriatic Arthritis (PsA)
**Objectives:** Evaluate the long-term efficacy of treatment with Ustekinumab in PsA patients previously treated with TNF inhibitors (TNF-i) in real life
**Methods:** We prospectively evaluated patients with PsO and moderate-severe PsA, who were treated with Ustekinumab after the failure of previous TNF-i therapies, in the period January 2013 -December 2015. Clinimetric scores (PASI, DAS44CRP, Pain VAS, Clinicians' VAS, and HAQ) were assessed and biochemical values (ESR, CRP, glucose, cholesterol, uric acid) were measured at baseline (T0) and after 6 (T6), 12 (T12) and 24 (T24) months. Differences between variables were analysed with paired T test ($P<0.05$ as significant)
**Results:** 36 patients (61% men; age (mean±DS): 49.7±11.4) treated with ustekinumab were evaluated (Figure 1A). In 6/36 (16.7%) patients treated with ustekinumab for $<$12 months (mean duration: 7.5 months), a significant reduction of PASI (P=0.02) and Pain VAS (P=0.04) was observed after 6 months of treatment. In patients treated continuously for 12 months, a significant reduction

**A) Table I**

| Demographic and clinical data | Patients (n=36) |
|---|---|
| Male sex (n/%) | 22/61 |
| Age (yrs) | 49.7±11.4 |
| Tobacco smokers (n/%) | 15/41.7 |
| PsO (n/%) | 36/100 |
| Onicopathy (n/%) | 20/55.6 |
| Age at PsO onset | 33.6±12.5 |
| Age at diagnosis | 38.1±10.1 |
| Height (cm) | 170.9±8.4 |
| Weight (kg) | 79.1±17.9 |
| BMI | 27.3±7 |
| Abdominal circumference (cm) | 90.8±14.8 |
| Comorbidities (n/%) | 20/55.6 |
| Cardiovascular (n/%) | 11/30.6 |
| Metabolic (n/%) | 7/19.4 |
| Inflammatory bowel disease | 5/13.9 |
| BPCO (n/%) | 1/2.8 |
| Ustekinumab therapy | |
| 1st line (n/%) | 6/16.7 |
| 2nd line (n/%) | 11/30.6 |
| 3rd line (n/%) | 9/25 |
| 4th line (n/%) | 8/22.2 |
| 5th line (n/%) | 2/5.6 |
| Concomitant DMARDs (n/%) | 30/83.4 |
| PASI | 14.7±11 |
| Pain VAS | 54.0±26.5 |
| Clinician's VAS | 57.1±19 |
| DAS44 | 2.8±1 |
| HAQ | 1.3±1.2 |
| ESR (mm/h) | 29±23.4 |
| CRP (mg/l) | 6.9±6.7 |
| Glucose (mg/dl) | 94.7±14.4 |
| Triglycerides (mg/dl) | 122.6±47.5 |
| Total Cholesterol (mg/dl) | 202.8±35.3 |
| HDL (mg/dl) | 53.4±9 |
| LDL (mg/dl) | 121.1±47 |
| Uric acid (mg/dl) | 2.8±2.7 |

of PASI (P<0.0001), DAS44 (P=0.008), ESR (P=0.03), CRP (P=0.04), and HAQ (P=0.002) was achieved. At T24, a persistent reduction of PASI (P<0.0001), DAS44 (P=0.04), and HAQ (P=0.02) with the rspect to T0 (Figure 1B,C,D) was maintained. Prevalence of patients on DMARDs was higher at T0 (83%) compared to the prevalence after the beginning of the ustekinumab therapy (36%). No significant differences in metabolic parameters were observed during the follow-up while a trend in reduction of uric acid resulted (2.8±2.7 at T0 vs 1±2 at T24).

**Conclusions:** Ustekinumab offers a therapeutic benefit in PsO/PsA patiens who failed TNF-i providing good clinical response both at the skin and joint level.

**Disclosure of Interest:** None declared

## FRI0465 DOES SKIN MATTER IN INCIDENT PSORIATIC ARTHRITIS?

M. Vis[1], I. Tchetverikov[2], K. Wervers[1], A. Gerards[3], C. Appels[4], M. Kok[5], W. van der Graaff[6], J. Veris[7], J. Van Groenendael[8], L. Korswagen[9], J. Hazes[1], J. Luime[1] on behalf of DEPAR. *[1]Rheumatology, Erasmus MC, Rotterdam; [2]Rheumatology, Albert Schweitzer Hospital, Dordrecht; [3]Rheumatology, Vlietland Hospital, Rotterdam; [4]Rheumatology, Amphia Hospital, Breda; [5]Rheumatology, Maasstad Hospital, Rotterdam; [6]Rheumatology, Beatrix Hospital, Gornichem; [7]Rheumatology, RZWN, Goes; [8]Rheumatology, RZWN, Roosendaal; [9]Rheumatology, Sint Franciscus Gasthuis, Rotterdam, Netherlands*

**Background:** Psoriatic arthritis (PsA) is a disease with musculoskeletal and skin inflammation (psoriasis). Attempts are being made to develop comprehensive disease measures to capture global disease activity. However very little is known on how much psoriasis actually affects quality of life (QOL) in patients with PsA.

**Objectives:** In this study we aim to determine to what extent psoriasis affects quality of life in incident Psoriatic Arthritis patients.

**Methods:** Data collected at baseline in the Dutch south west Psoriatic Arthritis Registry (DEPAR) study were used. The DEPAR includes newly diagnosed PsA patients from 8 hospitals in the South-West of the Netherlands. PsA core measurements were collected: Swollen and Tender join count (66/68), enthesitis (LEI and MASES), dactylitis (LDI) and psoriasis (PASI). In addition 3 patient reported measures of quality of life were administered. Short Form-36 (SF-36) is a self-administered 36-item health survey questionnaire. The items are assigned to eight scales grouped in two factors: physical component summary (PCS) and mental component summary (MCS, score 0–100). Skindex-17 is a self-administered 17-item dermatology questionnaire that explores functioning, emotions and symptoms in a Symptoms Subscale (SS; range 0–10) and a Psychosocial Subscale (PS; range 0–24).The DLQI is a self-administered 10-item questionnaire, score 0–30 with higher scores resulting in poorer quality of life. It covers Symptoms and feelings, Daily activities, Leisure, Work and school, Personal relationships and Treatment

**Results:** In total 281 patients were included: mean age was 50.6 (SD 13.6) and 50.5% were male. In terms of arthritis subtypes, 56 (20%) had mono-arthritis, 108 (39%) oligo-arthritis, 80 (29%) poly-arthritis and 35 (12%) were diagnosed with axial disease, dactylitis or enthesitis only. The Median PASI score was 2.3, ranging from 0 to 22.5. Divided in PASI categories (1) this resulted for 12% in no skin disease, 72% mild (>0–7), 11% moderate (7–12) and 5% had severe (>12) psoriasis. Median PASI scores were different for mono, oligo to polyarthritis group: 2.7 (0–12.3), 3.4 (0–22.5) and 4.4 (0–21). Skin related quality of life measured by DLQI showed a median 1 (QR 0–5) and the two subscales of the skindex resulted in a median SS 4 (IQR 2–6) and a PS of 2 (IQR 0–8), and a SF-36 PCS of 40.3 (8.3) and SF-36 MCS of 47.7 (10.4).(table 1) Comparing none and mild psoriasis to moderate and sever psoriasis resulted in median scores for DLQI: 1 vs 5 (p<0.01) and Skindex-17 SS: 4 vs 7 and skindex-17 PS: 2 vs 7 (p<0.01)while significant difference was observed for the bodily pain an emotional role subscales of the SF-36. (P<0.05)

**Conclusions:** Skin involvement in incident Psoriatic Arthritis is in the majority of patients mild with median PASI score of 2.3. About 15% suffered from moderate to severe psoriasis. Skin quality of life measures showed poorer health states for these patients, which was also reflected in the emotional role and bodily pain subscale of more generic QOL questionnaire: SF-36.

## FRI0466 INCREASED RISK OF CANCER IN PATIENTS WITH PSORIASIS: A NATIONWIDE POPULATION STUDY

M.-J. Chiou, Y.-F. Fang, C.-F. Kuo. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

**Background:** Psoriasis is a chronic inflammatory disease that involves hyper-proliferation of keratinocytes in the epidermis. Several studies have reported the relationship between psoriasis and cancer. Population-based estimates for cancer risks in patients with psoriasis is rare

**Objectives:** This study estimated the standardised incidence ratio (SIR) of cancer in patients with psoriasis in Taiwan.

**Methods:** The primary data source was the National Health Insurance database of Taiwan. We identified patients with psoriasis based on a rheumatologist or dermatologist diagnosis. Incident cases who were free or cancers in 2000 were identified. Incidence of cancer was estimated in both incident psoriasis patients and the general population in 2000. To measure the relative risk of cancer in psoriasis patients, we calculated a SIR for all types of cancers and also each cancer type. SIRs were computed as ratios of observed numbers of cancers to the expected number of cancers on the basis of age-specific incidence rates in 5-year age intervals of the entire NHI covered population in 2000.

**Results:** A total of 6,835 incident psoriasis patients (4,472 men, 2,363 women) were identified from 21,226,181 cancer-free beneficiaries of NHI in 2000. Mean age was 46.96 years in men and 41.27 years in women. After a median follow-up of 11 years, cancer was diagnosed in 527 patients with psoriasis and 860,084 in the general population. The most common cancers sites were gastrointestinal tract, oral cavity and pharynx in patients with psoriasis. The overall incidence of cancer was higher in psoriasis patients than the general population (6.92 vs. 3.34 cases per 1,000 patient-years, P<0.001). Psoriasis was associated with an SIR of 1.15 (95% confidence interval [CI], 1.06–1.25) for cancer of all sites. The SIR was 1.95 (95% CI, 1.21–3.14) for skin cancers, 1.59 (95% CI, 1.26–2.02) for oral cavity and pharynx cancers and 1.14 (95% CI=1.00–1.30) for gastrointestinal tract cancers, respectively.

**Conclusions:** Compared with the general population, psoriasis patients have an increased risk for cancer.

**Disclosure of Interest:** None declared

**Background:** Early achievement of minimal disease activity (MDA) is recommended as a valid treat-to-target approach in psoriatic arthritis (PsA).

**Objectives:** The purpose of the current analysis was to evaluate predictors of MDA achievement in PsA patients treated with anti-TNF agents in Canadian routine clinical care.

**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with Infliximab (IFX) or Golimumab (GLM). Eligible people for this analysis included PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 and with available MDA information at baseline, 6 months, and/or 12 months. MDA was defined as the fulfillment of ≥5 of the following criteria: TJC28≤1, SJC28≤1, PASI≤1, Pain (VAS)≤15mm, PtGA (VAS)≤20mm, HAQ ≤0.5, tender entheseal points ≤1. Independent predictors of MDA achievement were assessed with logistic regression.

**Results:** A total of 196 patients (51.4% male and 87.2% bionaive) were included with a mean (SD) age and disease duration of 49.8 (11.1) and 5.4 (6.3) years, respectively. The proportion of patients with MDA was 11.7% at baseline, 43.5% at 6 months, 44.8% at 12 months, and 49.1% at either 6 or 12 months. Among patients with MDA at 6 months, 75.7% had sustained MDA at 12 months. Patients achieving MDA during follow-up had significantly lower disease activity at baseline; mean (SD) disease parameters were: SJC28: 3.24 (3.58) vs. 5.47 (4.31), P<0.001; TJC28: 3.75 (4.00) vs. 8.66 (6.53), P<0.001; pain: 35.39 (25.11) vs. 55.70 (22.93), P<0.001; PtGA: 38.51 (25.00) vs. 56.15 (25.13), P<0.001; HAQ-DI: 0.71 (0.61) vs. 1.33 (0.57), P<0.001; MDGA: 4.25 (2.38) vs. 5.84 (2.07), P<0.001); enthesitis count: 2.62 (1.60) vs. 4.97 (3.48), P=0.008.

Multivariate logistic regression analysis showed that lower baseline HAQ (OR=0.243; P<0.001), lower TJC28 (OR=0.889; P=0.008), and lower enthesitis count (OR=0.817; P=0.817) were significant predictors of MDA achievement over 12 months of treatment.

**Conclusions:** The results of the current analysis have shown that 50% of patients treated with IFX or GLM in routine clinical care achieve MDA within the first year of treatment. Lower baseline HAQ, lower TJC28, and lower enthesitis count were identified as significant predictors of MDA achievement.

## FRI0468 HIGH PREVALENCE OF US DETERMINED SUBCLINICAL SYNOVITIS IN EARLY PSORIATIC ARTHRITIS CORRELATES BETTER WITH THE SJC RATHER THAN TJC: RESULTS FROM THE LEEDS SPARRO COHORT

M. Merashli[1], L. Horton[2], E. Hensor[1], G. De Marco[1], M.A. D'agostino[3], A.L. Tan[1], P. Emery[1], D. Mcgonagle[1], H. Marzo-Ortega[1]. *[1]Rheumatology; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; [3]Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK, Rheumatology Department, APHP, Hôpital Ambroise Paré, and Versailles-Saint-Quentin University, Saint-Quentin en Yvelines, France., Leeds, United Kingdom*

**Background:** Ultrasound (US) is known to be more sensitive than clinical examination in detecting synovitis in psoriatic arthritis (PsA). However, some studies found disparity between the US and clinical findings

**Objectives:** To assess the prevalence of synovial involvement in early PsA using clinical and sonographic assessments.

**Methods:** A total of 49 subjects with early PsA (CASPAR criteria) recruited in the Leeds Spondyloarthropathy Register for Research and Observation (SpARRO) study, a prospective longitudinal observational cohort, was assessed. The mean disease duration is 1.6 ±0.5 years; F:M ratio is 1.3; median SJC76 is 2 (1–2), median TJC78 is 6 (3–17); 90% of subjects had current skin psoriasis. Baseline US scan was performed on 1274 joints including bilateral wrists, MCP2–3, PIP2–3, elbows, knees, ankles & MTP 1–5. Grey Scale (GS) and Power Doppler (PD) were scored on a 0–3 semi-quantitative scale for each joint. Joints were considered clinically active if tender or swollen, and sonographically active if GS≥2 and/or PD≥1. We compared US active (yes/no) against tender (yes/no) and swollen (yes/no). The majority of the patients (88%) were DMARD naive

**Results:** US identified a higher proportion of subclinical synovitis among swollen rather than tender joints in subjects with early PsA. The agreement between clinical examination (tender & swollen) and US findings was high (73 & 87%) respectively. The most common sites for subclinical synovitis were MTP joints. In contrast, wrist tenderness and MTP2 swelling were the highest overestimated joints among the physical examination.

Table 1. Agreement between tender or swollen and US synovitis by joint type

| | Tender | | | | | Swollen | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | PEA % | Sp0 % | Sp1 % | US>CE % | CE>US % | PEA % | Sp0 % | Sp1 % | US>CE % | CE>US % |
| Elbow | 93 | 96 | 22 | 2 | 5 | 97 | 98 | 0 | 3 | 0 |
| Wrist | 60 | 69 | 46 | 2 | 38 | 96 | 98 | 75 | 0 | 4 |
| MCP2 | 83 | 90 | 26 | 2 | 15 | 92 | 96 | 50 | 2 | 6 |
| MCP3 | 82 | 89 | 31 | 1 | 17 | 92 | 96 | 60 | 1 | 7 |
| PIP2 | 77 | 87 | 0 | 1 | 22 | 89 | 95 | 0 | 1 | 9 |
| PIP3 | 72 | 84 | 7 | 2 | 26 | 85 | 92 | 0 | 3 | 12 |
| Knee | 69 | 82 | 12 | 7 | 24 | 85 | 91 | 40 | 3 | 12 |
| Ankle | 82 | 90 | 0 | 2 | 16 | 93 | 96 | 36 | 0 | 7 |
| MTP1 | 52 | 65 | 23 | 28 | 20 | 67 | 0 | 33 | 80 | 11 |
| MTP2 | 64 | 75 | 41 | 22 | 13 | 63 | 4 | 33 | 77 | 14 |
| MTP3 | 76 | 85 | 37 | 13 | 11 | 97 | 98 | 77 | 0 | 3 |
| MTP4 | 65 | 77 | 29 | 14 | 20 | 81 | 86 | 39 | 14 | 5 |
| MTP5 | 78 | 87 | 21 | 5 | 18 | 92 | 96 | 43 | 5 | 3 |
| Total | 73 | 83 | 23 | 8 | 19 | 87 | 73 | 37 | 15 | 7 |

*PEA = percentage exact agreement; CE = clinical examination; Sp0 = agreement specific to a score of 0; Sp1 = agreement specific to a score of 1.

**Conclusions:** The prevalence of subclinical synovitis is high in early PsA. Joint swelling is more likely to correlate with PD or GS in PsA when compared to joint tenderness. As opposed to RA, where clinical tenderness correlates with subclinical synovitis, the tender joint count may not be a reliable clinical measure to assess synovitis in PsA. Possible reasons for the over-estimation of TJC in clinical examination may be the concomitant occurrence of fibromyalgia. Larger studies are needed to confirm our results.

**Disclosure of Interest:** None declared

## FRI0469 MEASURING OUTCOME IN PSORIATIC ARTHRITIS (MOPSA), A NEW WEB-BASED TOOL FOR ASSESSMENT OF PSORIATIC ARTHRITIS SHOWING INITIATION OF TREATMENT CHANGE IN PATIENTS ACHIEVING MINIMAL DISEASE ACTIVITY

M. Elmamoun, A. Szentpetery, P. Gallagher, O. FitzGerald. *Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland*

**Background:** Psoriatic arthritis (PsA) is a heterogeneous disease that includes features of peripheral arthritis, spondylitis, dactylitis, enthesitis, and skin and nail disease. PsA affects about 30% of patients with psoriasis.[1]

Minimal Disease Activity (MDA) is defined as a patient acceptable disease state which is validated and increasingly recognised as a treatment target. MDA is defined when a patient has 5 of the following 7 criteria: tender joint count ≤1, swollen joint count ≤1, tender entheseal point ≤1, PASI ≤1 or body surface area ≤3%, Pain Visual analogue score (VAS) ≤15, patient global ≤20, Health Assessment Questionnaire ≤0.5.[2]

Composite Psoriatic Disease Activity Index (CPDAI) assesses the five domains in PsA. Within each domain a score (range 0–3) is assigned according to predefined cut-offs. The scores for each domain are then added together to give a final score range of 0–15, 0 for no disease and 15 for severe disease.[3]

Recently, Measuring Outcome in Psoriatic Arthritis (MOPsA), a new web-based tool for assessment of PsA was developed and is freely available to use (see https://mopsa.ie). MOPSA will calculate all the scores and determine both MDA and CPDAI. MOPSA provides a graphic representation of CPDAI in the form of a spidergram that can be compared with subsequent visits.

**Objectives:** Our aim was to assess, (1) disease activity using CPDAI and the percentage of patients reaching MDA, in consecutive cohort of established PsA patients attending our unit; and (2) whether treatment change was initiated based on MDA state.

**Methods:** 137 patients with PsA, fulfilling CASPAR criteria, were included in this study. 68 tender joint counts (TJC) and 66 swollen joint counts (SJC) were recorded. Skin scores included Dermatology Quality of Life Index (DLQI), Body Surface Area (BSA) and Psoriasis Area Severity Index (PASI). Patient reported outcome measures (PROMs) included: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Health Assessment Questionnaire (HAQ), Ankylosing Spondylitis Quality of Life (ASQoL). CPDAI was calculated and MDA status was assessed.

**Results:** The mean age was 46.1 (± 11.6) and 72 (52.6%) were females. Clinical outcome measures and PROMs are shown in table 1. The mean CPDAI score was 3.75 (±2.94); 52 (37%) patients reached MDA. Of the 85 patients not in MDA, CPDAI was 5.94±3 in the 37 who had a treatment change and 4.54±2.49 in the 48 who did not. Of those undergoing treatment changes, 7 patients started on biologics, 4 switched to another biologic and 3 had their dose increased. 6 were started on synthetic DMARD, 2 had a second DMARD added to their regimen, and 8 had their dose increased. 6 patients had a short course of systemic steroids while 12 patients had intra-articular steroids injections.

| | |
|---|---|
| Dactylitis, number of patients (%) | 20 (14.6) |
| Dactylitis score | 0.27 (0.71) |
| Enthesitis, number of patients (%) | 38 (27.7) |
| Enthesitis score | 0.49 (0.83) |
| TJC | 4.48 (6.7) |
| SJC | 1.37 (3.2) |
| HAQ | 0.72 (0.77) |
| BASDAI | 1.55 (2.3) |
| ASQoL | 2.47 (4.5) |
| PsAQoL | 4.18 (4.9) |
| DLQI | 3.03 (4.9) |
| PASI | 2.66 (4.0) |
| BSA | 4.02 (7.9) |

Table 1 shows the raw scores for each of the instruments scored. Results are shown as mean (±SD)

**Conclusions:** MOPsA gives a comprehensive assessment of psoriatic disease that can be followed longitudinally. One third of patients in our cohort achieved MDA. CPDAI was higher in those patients not achieving MDA status where treatment was changed.

## FRI0470 LONG-TERM (156-WEEK) SAFETY PROFILE OF APREMILAST, AN ORAL PHOSPHODIESTERASE 4 INHIBITOR, IN PATIENTS WITH PSORIATIC ARTHRITIS: POOLED SAFETY ANALYSIS OF 3 PHASE III, RANDOMIZED, CONTROLLED TRIALS

P.J. Mease[1], D.D. Gladman[2], J.J. Gomez-Reino[3], S. Hall[4], A. Kavanaugh[5], E. Lespessailles[6], G. Schett[7], K. Shah[8], L. Teng[8], J. Wollenhaupt[9]. *[1]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States; [2]Toronto Western Research Institute, Toronto, Canada; [3]Hospital Clinico Universitario, Santiago, Spain; [4]Monash University, Melbourne, Australia; [5]University of California, San Diego, School of Medicine, La Jolla, United States; [6]University of Orléans, Orléans, France; [7]University of Erlangen-Nuremberg, Erlangen, Germany; [8]Celgene Corporation, Summit, United States; [9]Schön Klinik Hamburg Eilbek, Hamburg, Germany*

**Background:** Apremilast (APR), a phosphodiesterase 4 inhibitor, acts to regulate immune activity in psoriatic arthritis (PsA) patients. PALACE 1 (NCT01172938), 2 (NCT01212757), and 3 (NCT01212770) compared the efficacy and safety of APR with placebo (PBO) in patients with active PsA despite prior conventional DMARDs and/or biologics.
**Objectives:** Assess the long-term safety of APR treatment for patients treated for up to 3 years with APR.
**Methods:** Patients were randomized (1:1:1) to PBO, APR 30 mg BID (APR30), or APR 20 mg BID (APR20) stratified by baseline DMARD use (yes/no). The PBO-controlled phase continued to Week 24; PBO patients were re-randomized to APR30 or APR20 at Week 16 (early escape) or Week 24. Double-blind APR treatment continued to Week 52; patients could continue to receive APR during an open-label, long-term treatment phase. Visits in years 2 and 3 were scheduled at 13-week intervals.
**Results:** 1493 patients were randomized and received ≥1 dose of study medication (PBO: n=495; APR30: n=497; APR20: n=501). At the studies' 3-year data cut, a total of 1441 (1209.3 patient-years), 1028 (937.8 patient-years), and 865 (790.4 patient-years) patients received APR in the Weeks 0 to ≤52, Weeks >52 to ≤104, and Weeks >104 to ≤156 periods, respectively, relative to the start of APR. During the Weeks 0 to ≤52 APR-exposure period, adverse events (AEs) occurring in ≥5% of APR-exposed patients were diarrhea, nausea, headache, upper respiratory tract infection, and nasopharyngitis (Table). Most diarrhea and nausea events were reported within the first 2 weeks of treatment and usually resolved in 4 weeks without medical intervention. The frequency of gastrointestinal AEs decreased with longer exposure (i.e., Weeks >52 to ≤104 or >104 to ≤156; Table); occurrence >5% of other common AEs either decreased in frequency or remained stable with prolonged exposure (Table). Most AEs were mild or moderate in severity up to 156 weeks of APR-exposure. Rates of depression remained very low, consistent with earlier findings. The rate of serious AEs (SAEs) was 8.1% during Weeks >104 to ≤156 of APR exposure; most SAEs occurred in 1 patient each. For SAEs of special interest (major cardiac events, malignant neoplasm, opportunistic infection), rates were very low and comparable to those in the first year of treatment. Discontinuation due to AEs was 1.6% during Weeks >104 to ≤156 of APR exposure. Marked laboratory abnormalities were infrequent, and most returned to baseline with continued treatment.

*Includes all patients who received APR during the time interval relative to the start of APR. [a]Autoorgan failure not suspected to be treatment-related. [b]Motor vehicle accident on Study Day 489.

**Conclusions:** APR demonstrated a favorable safety profile and was well tolerated for up to 156 weeks. These data continue to support the lack of accumulation of immunosuppression and a need for specific laboratory monitoring with APR. The incidence of AEs remained stable or decreased with long-term exposure to APR.

## FRI0471 CERTOLIZUMAB PEGOL FOR THE TREATMENT OF PSORIATIC ARTHRITIS: 4-YEAR OUTCOMES FROM THE RAPID-PSA TRIAL

P.J. Mease[1], R. Fleischmann[2], J. Wollenhaupt[3], A. Deodhar[4], D. Gladman[5], B. Hoepken[6], L. Peterson[7], D. van der Heijde[8]. *[1]Swedish Medical Center and University of Washington, Seattle; [2]University of Texas SW Medical Center, Dallas, United States; [3]Schön Klinik, Hamburg, Germany; [4]Oregon Health & Science University, Portland, United States; [5]Toronto Western Research Institute, Toronto, Canada; [6]UCB Pharma, Monheim, Germany; [7]UCB Pharma, Raleigh, United States; [8]Leiden University Medical Centre, Leiden, Netherlands*

**Background:** The RAPID-PsA trial (NCT01087788) has investigated the efficacy and safety of certolizumab pegol (CZP) for the treatment of patients (pts) with psoriatic arthritis (PsA). Previous reports have demonstrated CZP to be safe and efficacious over 96 weeks (wks) of treatment.[1]
**Objectives:** To report 4-year efficacy and safety data from the RAPID-PsA trial of CZP in PsA pts.
**Methods:** RAPID-PsA was double-blind and placebo-controlled to Wk24, dose-blind to Wk48 and open-label (OL) to Wk216. Pts had active PsA and had failed ≥1 DMARD. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks 0, 2, 4) continued on their assigned dose in the OL period. Outcomes assessed included: ACR20/50/70 and PASI75/90 responses, minimal disease activity (MDA), HAQ-DI, pain and patient's global assessment of disease activity (PGADA). Efficacy data are presented for all pts originally randomized to CZP. Data are shown as observed case and with imputation: NRI for categorical and LOCF for continuous measures. The safety set consisted of all pts treated with ≥1 dose of CZP to Wk216.

**Table: A)** Clinical outcomes to Week 216 of the RAPID-PsA trial

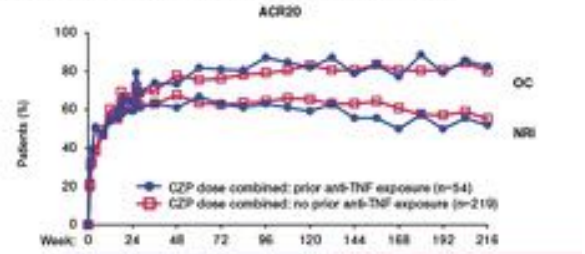
**B)** Patient-reported outcomes to Week 216 of the RAPID-PsA trial

| | CZP 200 mg Q2W (n=138) | | | CZP 400 mg Q4W (n=135) | | | CZP dose-combined (n=273) | | |
|---|---|---|---|---|---|---|---|---|---|
| | BL | Wk24 (LOCF) | Wk216 (LOCF) | BL | Wk24 (LOCF) | Wk216 (LOCF) | BL | Wk24 (LOCF) | Wk216 (LOCF) |
| Outcome, mean | | | | | | | | | |
| HAQ-DI | 1.3 | 0.8 | 0.8 | 1.3 | 0.9 | 0.8 | 1.3 | 0.8 | 0.8 |
| Pain | 59.7 | 31.1 | 29.1 | 61.1 | 32.7 | 27.3 | 60.4 | 31.9 | 28.3 |
| PGADA | 60.2 | 31.1 | 28.3 | 60.2 | 32.5 | 27.0 | 60.2 | 31.7 | 27.7 |

All patients received CZP loading dose of 400mg at Weeks 0, 2 and 4. [a] n=98; [b] n=87; [c] n=185; [d] PASI response rates reported in patients with ≥3% body surface area skin involvement at baseline (CZP 200mg Q2W, n=90; CZP 400 mg Q4W, n=76); [e] n=66; [f] n=42; [g] n=108. BL: baseline; LOCF: last observation carried forward; MDA: minimal disease activity; NRI: non-responder imputation; OC: observed case; PGADA: patient's global assessment of disease activity.



**Results:** 409 pts were randomized, of whom 273 received CZP from Wk0. Of CZP-randomized pts, 91% completed to Wk24, 87% to Wk48 and 67% to Wk216. In the OL period, 17 pts (6.2%) withdrew due to an adverse event (AE) and 5 pts (1.8%) due to loss of efficacy.
ACR responses were sustained in both dose regimens from Wk24 to Wk216 (Table A). In those 166 CZP pts (60.8%) with ≥3% body surface area skin involvement at baseline (BL), PASI75/90/100 responses were maintained to Wk216 (Table A). Improvements in patient-reported outcomes were also maintained through Wk216 (Table B). Pts had further improvements from Wk24 to Wk216 in high-threshold outcomes (ACR70, MDA and PASI100) when either observed case or conservative imputation methods (NRI) were used (Table A).
Pts in the safety set (N=393) had total CZP exposure of 1321 patient-years (PY) with an AE rate (ER) per 100 PY of 258.0. No new safety signals were identified from Wk96 to Wk204, and no additional deaths were reported.
**Conclusions:** CZP efficacy was maintained in PsA pts over 4 years of treatment, with no new safety signals identified. Additional improvements in high-threshold outcomes were seen from Wk24 to Wk216.

## FRI0472 IMPROVEMENTS IN JOINT OUTCOMES OF PSORIATIC ARTHRITIS OVER 4 YEARS OF TREATMENT WITH CERTOLIZUMAB PEGOL IN PATIENTS WITH AND WITHOUT PRIOR ANTI-TNF EXPOSURE

P.J. Mease[1], R. Fleischmann[2], J. Wollenhaupt[3], A. Deodhar[4], D. Gladman[5], B. Hoepken[6], L. Peterson[7], D. van der Heijde[8]. *[1]Swedish Medical Center and University of Washington, Seattle; [2]University of Texas SW Medical Center, Dallas, United States; [3]Schön Klinik, Hamburg, Germany; [4]Oregon Health & Science University, Portland, United States; [5]Toronto Western Research Institute, Toronto, Canada; [6]UCB Pharma, Monheim, Germany; [7]UCB Pharma, Raleigh, United States; [8]Leiden University Medical Centre, Leiden, Netherlands*

**Background:** Previous reports of the RAPID-PsA trial (NCT01087788) have demonstrated the efficacy of certolizumab pegol (CZP) in improving joint outcomes of psoriatic arthritis (PsA) over 96 weeks (wks) of treatment in patients (pts) with and without prior anti-TNF exposure.[1,2]
**Objectives:** To report the efficacy of CZP over 4 years for the treatment of joint outcomes in PsA pts with and without prior anti-TNF exposure.
**Methods:** The RAPID-PsA trial was double-blind and placebo-controlled to Wk24, dose-blind to Wk48 and open-label (OL) to Wk216. Pts had active PsA, had failed ≥1 DMARD, and ≤40% pts could have received 1 prior anti-TNF. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks 0, 2, 4) continued on their assigned dose in the OL period. Joint disease activity was assessed in all pts using tender joint count (TJC), swollen joint count (SJC) and DAS28(CRP), as well as the composite disease activity measures ACR20/50/70. Data are shown as observed case (OC) and with imputation: NRI for categorical and LOCF for continuous measures. Data are presented for all pts originally randomized to CZP with and without prior anti-TNF exposure.
**Results:** 409 pts were randomized and 273 received CZP from Wk0 (54/273 pts had prior anti-TNF exposure). Of pts randomized to CZP at baseline, 91% completed to Wk24, 87% to Wk48 and 67% to Wk216.
CZP treatment was associated with improvements in all measures of joint disease activity to Wk24. Improvements in outcomes including TJC, SJC and DAS28(CRP), as well as the composite measures ACR20/50/70, were sustained through to Wk216 of the trial and were similar in pts with and without prior anti-TNF exposure (Figure). Greater improvements were observed in those pts completing to Wk216, as expected (Figure, OC data). Pts experienced further improvements from Wk24 to Wk216 in the high-threshold outcome ACR70 when either OC or NRI was used (Table).
At Wk216, ACR20 responses were similar regardless of dose regimen in pts with and without prior anti-TNF exposure (pts with anti-TNF exposure [OC]: 200mg Q2W: 81.8%; 400mg Q4W: 83.3%; pts without prior anti-TNF exposure [OC]: 200mg Q2W: 75.0%; 400mg Q4W: 85.3%).

**Figure:** Joint outcomes in patients with or without prior anti-TNF exposure

| | Pts with prior anti-TNF exposure CZP dose combined (n=54) | | | Pts without prior anti-TNF exposure CZP dose combined (n=219) | | |
|---|---|---|---|---|---|---|
| | Wk24 (NRI) | Wk216 (NRI) | Wk216 (OC; n=34) | Wk24 (NRI) | Wk216 (NRI) | Wk216 (OC; n=151) |
| **Outcome, %** | | | | | | |
| ACR20 | 59.3 | 51.9 | 82.4 | 60.3 | 55.3 | 80.1 |
| ACR50 | 44.4 | 40.7 | 64.7 | 41.6 | 43.8 | 63.6 |
| ACR70 | 25.9 | 29.6 | 47.1 | 26.0 | 36.1 | 52.3 |

| | BL | Wk24 (LOCF) | Wk216 (LOCF) | Wk216 (OC) | BL | Wk24 (LOCF) | Wk216 (LOCF) | Wk216 (OC) |
|---|---|---|---|---|---|---|---|---|
| **Outcome, mean** | | | | | | | | |
| TJC | 21.4 | 11.1 | 9.5 | 4.9 (n=34) | 20.3 | 8.4 | 6.4 | 3.7 (n=151) |
| SJC | 12.6 | 3.4 | 2.4 | 1.4 (n=34) | 10.3 | 3.0 | 1.9 | 1.1 (n=151) |
| DAS28(CRP) | 5.2 | 3.1 | 2.9 | 2.4 (n=34) | 4.9 | 3.0 | 2.6 | 2.3 (n=145) |

BL: baseline; LOCF: last observation carried forward; NRI: non-responder imputation; OC: observed case.

**Conclusions:** Improvements in measures of joint disease activity were observed in PsA pts to Wk24 and efficacy was sustained over 4 years. Efficacy remained similar in pts with and without prior anti-TNF exposure in all joint outcomes assessed.

## FRI0473 WHAT PROPORTION OF PATIENTS WITH PSA FAIL TO ACHIEVE MDA BASED ON PATIENT REPORTED OUTCOMES? AN ANALYSIS FROM A PROSPECTIVE, OBSERVATIONAL REGISTRY

P. Rahman[1], A. Avina-Zubieta[2], R. Arendse[3], W. Bensen[4], P. Baer[5], J. Kelsall[6], M. Starr[7], J. Stewart[8], D. Sholter[9], M. Zummer[10], L. Picard[11], E. Rampakakis[12], E. Psaradellis[12], K. Masolova[13], A. Lehman[13], F. Nantel[13], C. Tkaczyk[13], B. Osborne[13]. *[1]Faculty of Medicine, Memorial University, St. Johns; [2]Arthritis Research Canada, Richmond; [3]University of Saskatchewan, Saskatoon; [4]St. Joseph's Healthcare, Hamilton; [5]Ontario Medical Association, Toronto; [6]St. Paul's Hospital, Vancouver; [7]McGill University, Montreal; [8]Penticton Regional Hospital, Penticton; [9]University of Alberta, Edmonton; [10]University of Montreal, Montreal; [11]Rheumatology Practice, Moncton; [12]JSS Research, Montreal; [13]Medical Affairs, Janssen, Toronto, Canada*

**Background:** Recent treat-to-target guidelines in PsA recommend that minimal disease activity (MDA) is achieved as early as possible. Patient reported outcomes (PROs) have been criticized for not accurately assessing PsA disease activity as they may reflect aspects not directly related to PsA such as fibromyalgia, depression or other comorbidities.
**Objectives:** The aim of this analysis was to assess the proportion of patients failing to achieve MDA based on PROs in a real-world, routine clinical care setting in Canada.
**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, ankylosing spondylitis, or PsA with infliximab (IFX) or golimumab (GLM). Eligible participants for this analysis included those with PsA treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 and with available MDA information at baseline, 6 months, and/or 12 months. MDA was defined as the fulfillment of $\geq$5 of the following criteria: TJC28$\leq$1, SJC28$\leq$1, PASI$\leq$1, pain (VAS)$\leq$15 mm, PtGA (VAS)$\leq$20 mm, HAQ$\leq$0.5, tender entheseal points $\leq$1. Near MDA was defined as fulfillment of 4 criteria.
**Results:** A total of 196 PsA patients (51.4% male) were included with a mean (SD) age of 49.8 (11.1) years and disease duration since diagnosis of 5.4 (6.3) years. The majority (62.2%) received concomitant DMARD therapy. The proportion of patients with MDA at baseline, 6 months and 12 months was 11.7%, 43.5%, and 44.8%, respectively. Overall, achievement of each individual MDA criterion was: TJC28: 43.0% of cases; SJC28: 51.3%; PASI 68.7%; pain: 27.7%; PtGA: 34.9%; HAQ: 36.8%; entheseal points: 79.4%. Among the 309 instances of non-MDA, 51 (16.5%) were near MDA cases. The most common reason for non-MDA in near MDA cases was patient-reported pain (82.4%) followed by PtGA (68.6%), and HAQ-DI (60.8%). Assuming that these criteria were met (i.e., not included in the MDA formula), the total number of MDA instances would increase from 29.6% to 36.7% (HAQ), 37.6% (PtGA), and to 39.2% (pain).
**Conclusions:** The results of the current analysis have shown that, similar to prior analyses in RA, the most common limiting factors in achieving MDA in PsA are PROs, including PtGA, pain, and HAQ-DI, accounting for as many as 82.4% of near MDA cases. Further analyses are required to identify the determinants of the differences in PROs and clinical outcomes.

## FRI0474 SERUM LEVEL OF IL-23 AND IL-23R POLYMORPHISMS IN PATIENTS WITH PSORIATIC ARTHRITIS

R. Sokolik[1], K. Gebura[2], L. Korman[1], B. Wysoczanska[2], P. Wiland[1], K. Bogunia-Kubik[2]. *[1]Department of Rheumatology, Medical University; [2]Laboratory of Clinical Immunogenetics and Pharmacogenetics, L. Hirszfeld Institute of Immunology and Experimental Therapy, Wroclaw, Poland*

**Background:** Interleukin (IL) - 23 is one of the of cytokines involved in systemic inflammation. Interaction between this cytokine and its receptor (IL-23R) that plays an important role in pathogenesis of psoriatic arthritis (PsA).
**Objectives:** The present study aimed to assess the associations between polymorphisms within gene coding IL-23R, IL-23 serum levels and disease activity in patients with PsA.
**Methods:** Fifty-two PsA patients (diagnosed by the criteria recommended by CASPAR group) were genotyped for the IL-23R (rs11209026 and rs7530511) polymorphisms. The nuclear factor kappa (NF-kB1 (rs28362491; ins/del)) polymorphism (associated with the promoter activity of this gene and cytokine gene expressions, including IL-23) was also analyzed in PsA patients group. IL-23 serum levels were assessed by ELISA in patients with PsA, and for comparison, 10 healthy individuals. These laboratory data were further related with clinical characteristics of the patients. Disease Activity Score was measured (swollen and tender joints, ESR, CRP) in addition to BASDAI, BASFI, VAS, and PASI scores.
**Results:** Significantly ($p<0.05$) elevated levels of IL-23 cytokine were observed in PsA patients (126.5 pg/ml) when compared to control group (24.9 pg/ml). Moreover, IL-23 serum levels were associated with the IL-23R rs7530511 polymorphism. Patients carrying the IL-23R T allele characterized with higher concentrations of IL-23 in serum (299.1 vs 86.8, $p<0.05$). Interestingly, patients with the IL-23R T allele were also more frequently carrying the ins/ins homozygous NF-kB1 genotype (associated with a better promoter activity and higher expression of cytokines) (7/17 vs 4/34, distribution of the T allele among ins/ins vs del allele positive patients, p=0.03). No association was found between for IL-23 levels or IL-23R polymorphisms and disease activity.
**Conclusions:** Patients with PsA characterize with higher serum levels of IL-23 than healthy individuals. IL-23 concentrations in serum of PsA patients are associated with the polymorphism (rs7530511) of IL-23 receptor encoding gene.
**Disclosure of Interest:** None declared

## FRI0475 FREQUENCY AND PREDICTORS OF CARDIOVASCULAR EVENTS IN A BICENTRIC COHORT OF PSORIATIC ARTHRITIS FROM SPAIN

R. Queiro, P. Tejón, I. Morante, I. Cabezas, A. Brandy, M. Alperi, M.A. Belmonte, J.L. Riestra, L. Arboleya, J. Ballina. *Rheumatology, HUCA, Oviedo, Spain*

**Background:** Cardiovascular (CV) comorbidity is frequent in psoriatic arthritis (PsA). This population shows a higher frequency of traditional CV risk factors (CVRF) when compared to normal population. However, additional traits related to the inflammatory nature of the disease may also suppose an additional risk beyond that attributable to classic CVRF.
**Objectives:** To analyze the prevalence and predictors of CV events in a wide cohort of PsA patients recruited at two rheumatology departments from Spain.
**Methods:** We included (cross-sectional) 340 PsA patients (CASPAR criteria) from two different rheumatology departments in Spain. There were 190 males and 150 females (mean age: 55 ± 13 yrs). Both subpopulations were similar in terms of age, sex distribution and disease duration. Prevalence and predictors of CV events (coronary heart disease, ictus and/or ischemic peripheral vascular disease) were analyzed. Initially, a univariate analysis was performed to examine unadjusted associations of potential risk factors. Significant variables in the univariate analysis were then introduced in a multivariate analysis with a backward stepwise approach. The statistical analysis software package used was SPSS v.19.0. Patients gave their informed consent and an institutional ethics committee approved the final version of the study.
**Results:** Distribution of classic CVRF was as follow: Diabetes 14%, hypertension 36%, dyslipidemia 31%, tobacco 27%, obesity 35% and 24% had overweight. Thirty two out of 340 subjects (9.4%) developed 41 CV events: 15 coronary events, 15 ictus and 11 events of ischemic peripheral vascular disease. Compared to men, women had more diabetes (29.5% vs. 18%, p=0.049) and obesity (44% vs. 29%, p=0–010), even though the frequency of CV events did not differ between sexes. In multivariate analysis, an age of psoriasis onset $\geq$40 yr (OR 4.1, 95%CI: 1.04–16.2, $p<0.001$) and dyslipidemia (OR 5.8, 95%CI: 1.5–22.8, $p<0.001$) were found independently related to the risk of coronary events. Hypertension was an independent predictor of ictus (OR 8.0, 95%CI: 1.7–38.1, $p<0.001$). When analyzing CV events as a whole, an age of psoriasis onset $\geq$40 yr (OR 3.4, p=0.03), a polyarticular pattern during evolution (OR 2.9, p=0.04), hypertension (OR 5.3, p=0.007) and dyslipidemia (OR 2.6, p=0.07), were found independently associated to the risk of CV events in multivariate analysis.
**Conclusions:** In our context, CV comorbidity of PsA may be explained by a conjunction of classic CVRF, late onset of psoriasis, and the inflammatory burden of joint disease. A better management of these factors should be the basis for improvement of CV health of these patients

## FRI0476 COMORBIDITIES IN PSORIATIC ARTHRITIS: PATIENT EDUCATION COUNTS

S.Z. Aydin, O. Bayindir, M.F. Oksuz, A. Dogru, G. Kimyon, E.F. Tarhan, A. Erden, S. Yavuz, M. Can, G.Y. Cetin, L. Kilic, O. Kucuksahin, A. Omma, C. Ozisler, D. Solmaz, A.M. Onat, B. Kisacik, D.E. Ersozlu Bozkirli, M. Aydin, L. Akyol, M. Cinar, S.M. Pehlevan, A. Tufan, F. Yildiz, A. Balkarli, F. Erbasan, R. Mercan, E.K. Gunal, F. Arslan, T. Kasifoglu, S. Senel, S. Kobak, B. Yilmazer, S. Yilmaz, T.M. Duruoz, A. Kucuk, E.O. Gonullu, K. Aksu, Y. Kabasakal, M. Sahin, N. Cakir, S. Erten, M. Sayarlioglu, E. Dalkilic, S. Akar, C. Acikhel, N. Atakan, U. Kalyoncu. *PsART (Psoriatic Arthritis Registry of Turkey), Ankara, Turkey*

**Background:** Comorbidities are frequent in Psoriatic arthritis (PsA) and can have an impact on morbidity and mortality.
**Objectives:** We aimed to investigate the frequency of different comorbidities in

PsA, how comorbidities have an impact on PsA features and which factors were associated with the occurrence of comorbidities in a large number of patients, using PsART (Psoriatic Arthritis Registry of Turkey)registry.
**Methods:** PsART is a national, web-based registry where consecutive patients with PsA are recruited and demographic, clinical and therapeutic information are collected as well as comorbidities. The following comorbidities are questioned: Hypertension (HT), hyperlipidemia, depression, diabetes mellitus (DM), hyperuricemia, coronary arterial disease, liver disease, cerebrovascular accident, cancer, and depression. BMI more than 30 is recorded as obesity. Patients with or without comorbidities were compared for their demographic features and outcome tools.
**Results:** One thousand and sixty-nine patients whom comorbidity data were available were analyzed. Within these 693 (64.8%) were women. Mean (SD) age was 46.9 (12.8), with a median (range) PsA duration 45 (0–545) months. The number of patients with 1, 2 and 3 comorbidities were 642 (60.1%), 345 (32.3%), and was 191 (17.9%), respectively. Frequency of comorbidities was obesity in 327 (30.6%), HT in 256 (23.9%), hyperlipidemia in 199 (18.6%), depression in 188 (17.6%), DM in 161 (15.1%), hyperuricemia in 74 (6.9%), coronary artery disease in 39 (3.6%), liver disease 38 (3.6%), cerebrovascular event in 19 (1.8%), and cancer history 16 (1.5%). Patients with at least one comorbidity were older (51.1 (11.8) vs 40.9 (11.7), $p<0.001$) and had a higher disease activity (according to tender joint count (3.9 (5.2) vs 2.9 (4.2), p=0.001), pain (4.6 (2.6) vs 4.0 (2.6), p=0.006), patient global assessment (4.5 (2.4) vs 4.0 (2.5), p=0.014), fatigue (4.9 (2.5) vs 4.0 (2.6), $p<0.001$)). Education was found to contribute on comorbidities as patients with at least one comorbidity had less education in terms of school years (7.6 (4.4) vs 9.7 (4.4) years, $p<0.001$). This was also found separately for some of the comorbidities: Patients with DM (mean (SD) years of education 6.7 (4.2) vs 8.8 (4.5), $p<0.001$), HT (6.7 (4.3) vs 8.9 (4.5), $p<0.001$), cerebrovascular event (5.5 (2.9) vs 8.4 (4.5), p=0.012) and depression (7.5 (4.1) vs 8.6 (4.6), p=0.004) had less education compared to patients who don't have those comorbidities.
**Conclusions:** Our registry supported that comorbidities are frequent in PsA increasing the complexity of the disease and have an impact on the disease severity. Patients with comorbidities are less educated showing that education and awareness are important to improve patient outcomes in PsA in long term.

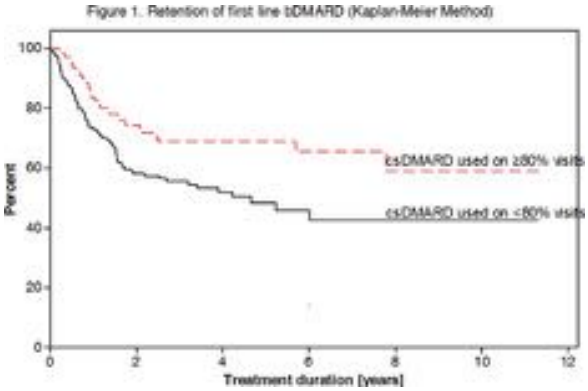
## FRI0477 A MODIFIED VERSION OF THE PSORIATIC ARTHRITIS DISEASE ACTIVITY SCORE (MPASDAS) USING SF-12 AS A MEASURE OF QUALITY OF LIFE MAY BE MORE FEASIBLE IN CLINICAL PRACTICE

V. Chandran[1,2], M. Got[3], S. Li[2], A.V. Perruccio[2,3], D.D. Gladman[2,3].
*[1]Department of Medicine, Laboratory Medicine and Pathobiology, Institute of Medical Science, University of Toronto; [2]Krembil Research Institute; [3]University of Toronto, Toronto, Canada*



**Background:** The Psoriatic Arthritis Disease Activity Score (PASDAS) is a newly developed composite disease activity measure that summarizes psoriatic arthritis (PsA) disease activity with a score ranging from 0–10. PASDAS captures articular and extra-articular manifestations of the disease and the impact of the disease on the patient via the following variables: swollen and tender joints, dactylitis, Leeds enthesitis index, C-reactive protein, Health Assessment Questionnaire, physician and patient global disease activity, and the physical component summary score (PCS) of the medical outcomes survey Short Form 36 (SF-36). A limitation of PASDAS is that the score depends on the patient completing the SF-36, which requires a significant amount of time to complete. A shorter 12-question subset of SF-36, the SF-12, with the same range of values, agrees well with the SF-36 in many patient populations.
**Objectives:** The objective was to measure the agreement between PASDAS calculated using the standard scoring formula and mPASDAS calculated by replacing the SF-36-PCS with SF-12-PCS.
**Methods:** 100 PsA patients attending the University of Toronto PsA clinic for follow-up visits were consecutively recruited in June and July 2015. All variables required to calculate PASDAS were collected and PASDAS was calculated for each patient. The 12 item responses for SF-12 were extracted from the SF-36 questionnaires. A mPASDAS score was subsequently calculated based on the PASDAS scoring formula where SF-36-PCS is replaced by SF-12-PCS. A Bland-Altman plot of the differences in scores calculated via PASDAS and mPASDAS measured agreement between the two sets of scores. The rate of missclassification when categorizing the patient's disease activity state as high, moderate or low using the mPASDAS instead of PASDAS was also examined.
**Results:** The analysis [N=100, 53% male, mean (SD) age 57.3 (11.9) years, mean (SD) disease duration 16.9 (11.7) years] revealed that the mean (SD) PASDAS was 3.29 (1.39) and the mean (SD) mPASDAS was 3.24 (1.27). The Bland-Altman plot showed a mean difference (95%CI) between mPASDAS and PASDAS of -0.05 (-0.07, -0.03). The lower limit and upper limits of the difference was (-0.24 [95%CI -0.21, -0.28]) and 0.14 [0.10, 0.17]), respectively. Five (5%) patients were misclassified (4 to the lower disease activity category) when mPASDAS was used instead of PASDAS.
**Conclusions:** mPASDAS and PASDAS shows strong agreement without clinically significant systematic bias in mPASDAS scores. In clinical settings, the mPASDAS may replace PASDAS in disease activity assessment given the strong agreement and low misscalssification rate along with significantly reduced questionnaire burden.

## FRI0478 DOES CO-MEDICATION WITH CSDMARDS HAVE AN IMPACT ON THE RETENTION OF BDMARDS IN PSORIATIC SPONDYLOARTHRITIS? DATA FROM BIORX.SI

Ž. Rotar, A. Hočevar, S. Praprotnik, M. Tomsic. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** In clinical practice we often extrapolate experience and evidence from patients with RA to patients with PsA. The body of evidence supporting the use of csDMARD co-medication in PsA patients treated with bDMARDs is weak.
**Objectives:** Our aim was to determine whether co-medication with csDMARDs has an impact on the retention of bDMARDs in PsA.
**Methods:** In December 2015 we extracted data of patients with PsA treated with the first bDMARD with at least one follow-up visit from the mandatory national registry BioRx.si. Appropriate descriptive statistics methods were used to describe the cohort. Where applicable appropriate post hoc tests were used to compare the baseline characteristics. We used the unadjusted Kaplan-Meier method with log rank test as the post hoc test to assess the retention of the bDMARDs depending on co-medication with csDMARDs (i.e. methotrexate or leflunomide or sulfasalazine).
**Results:** At the time of extraction 276 (44% female) patients with a median (IQR) age of 49.5 (42.0–56.6) years treated for 733 person years satisfied the inclusion criteria. Median follow-up time was 1.5 years (0.6–3.2) years. 50%/20%/18%/12% were treated with adalimumab/etanercept/golimumab/infliximab, respectively. Methotrexate/leflunomide/sulfasalazine were predominantly used as co-medication in 70%/9%/5% of patients while 16% never received csDMARD co-medication. There was no significant difference in the retention of the initial bDMARD depending on csDMARD use at the initiation of the bDMARD or when the csDMARD was used on <50% of follow-up visits. However, the bDMARD retention was significantly longer when csDMARD was used on more than 80% of follow-up visits (p=0.005; Figure 1).

Figure 1. Retention of first line bDMARD (Kaplan-Meier Method)

**Conclusions:** Regular co-medication with csDMARDs seems to improve the retention of the first line bDMARDs in PsA in daily clinical practice.

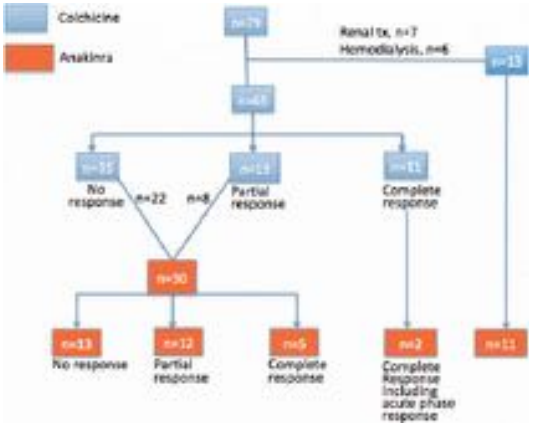
## FRI0479 EFFICACY OF COLCHICINE AND IL-1 INHIBITORS IN AMYLOIDOSIS ASSOCIATED WITH FAMILIAL MEDITERRANEAN FEVER: A RETROSPECTIVE ANALYSIS

B. Toz[1], S. Tacar[2], E. Oguz[1], M. Erdugan[1], B.A. Esen[1], S. Kamali[1], L. Ocal[1], B. Erer[1], A. Gül[1]. *[1]Division of Rheumatology Istanbul School of Medicine, Istanbul University; [2]Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey*



**Background:** Familial Mediterranean fever (FMF), the most common form of hereditary autoinflammatory diseases, is associated with increased risk for secondary (AA) amyloidosis
**Objectives:** We herein aimed to investigate the features of FMF patients with amyloidosis with respect to their responses to current therapies
**Methods:** We enrolled FMF patients with amyloidosis who were regularly followed-up for at least 6 months between 1978 and 2015 into the study. Starting times for colchicine, anakinra or canakinumab and treatment responses were noted. Proteinuria (spot urine protein/creatinine ratio) and C-reactive protein (CRP) levels were measured in every three months of follow-up. Partial response

was defined as ≥50% decrease in baseline proteinuria accompanied by a normal serum creatinine level, whereas complete response was defined as <0.3 gr/d baseline proteinuria and stable serum creatinine. Correlations between treatment responders and continuously elevated or normalized CRP levels were tested by using a chi-square test

**Results:** We identified 79 FMF patients with documented secondary amyloidosis, and all were on colchicine treatment. Their demographic features are shown in Table 1. Mean time to diagnosis after the first symptom was 10 years. Patients were evaluated for partial and complete response after mean follow-up period of 66±85 months. Response to colchicine was observed in 30/65 patients [partial response in 19 (29%), complete response in 11 (17%)]; and 54% was non-responder to colchicine. Anakinra was added to treatment in 22 patients with inadequate response to colchicine, which resulted in partial response in 12, and complete response in 2. Eight patients with partial response to colchicine also received anakinra for better control of attacks and/or elevated acute phase response, and a complete response was achieved in 3 patients. In 3 patients, anakinra was switched to canakinumab because of local injection site reaction (1 patient) and persistence of proteinuria (2 patients). Among those, two patients had partial response, and another underwent hemodialysis due to progressive kidney failure. No significant association was observed between normalized CRP levels and response to treatment with respect to proteinuria and creatinine levels (colchicine; p=0.67, anakinra/canakinumab;p=0.82). No serious infection requiring hospitalization was detected in association with IL-1 blockade.

Table 1. Demographic features of FMF patients with amyloidosis

| | |
|---|---|
| Male/Female | 40/39 |
| Age of onset (mean ± SD, range) | 16±12 (2–68) |
| Age of diagnosis (mean ± SD, range) | 27±13 (7–70) |
| Family history of FMF | 47% |
| Disease follow-up duration (mo) | 66±85 (6–480) |
| Time to diagnosis (mo) | 121±136 (2–576) |
| Family history of amyloidosis (%) | 18% |
| Arthritis at presentation (%) | 60% |
| MEFV variations (n=46) | M694V, 68%<br>V726A, 10%<br>M680I, 15%<br>Others, 7% |
| IL-1 inhibitors n (%) | 43 (54%) |
| Patients on hemodialysis | 7 (9%) |
| Renal Transplantation n (%) | 17 (21%) |
| High CRP levels in attack-free periods n (%) | 31 (39%) |

**Conclusions:** Amyloidosis still remains as an important complication of FMF, and a satisfactory response to colchicine could be observed in an important proportion of patients. Treatment with IL-1 inhibitors seems to be an effective and safe option for those patients with an inadequate response to colchicine

**Disclosure of Interest:** None declared

## FRI0480 THIOL/DISULPHIDE HOMEOSTASIS IN FAMILIAL MEDITERRANEAN FEVER

A. Doğru[1], A. Balkarlı[2], G.Y. Cetin[3], S. Neselioglu[4], O. Erel[4], M. Sahin[1], S.E. Tunc[1]. *[1]Department of Internal Medicine, Division of Rheumatology, Suleyman Demirel University, Faculty of Medicine, Isparta; [2]Department of Internal Medicine, Division of Rheumatology, Antalya Training and Research Hospital, Antalya; [3]Department of Internal Medicine, Division of Rheumatology, Kahramanmaras Sutcu Imam University, Faculty of Medicine, Kahramanmaras; [4]Department of Clinical Biochemistry, Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey*

**Background:** Familial Mediterranean fever (FMF) is an autoinflammatory disease that include recurrent episodes of peritonitis, pleuritis, and arthritis, with accompanying fever. FMF is caused by mutations in MEFV and typically diagnosed during childhood. Thiol/disulphide homeostasis, marker of oxidative stress, is associated with an increased in inflammatory cytokines in many inflammatory diseases.

**Objectives:** We aimed to investigate the dynamic thiol/disulphide homeostasis in patients with FMF during attact free period.

**Methods:** Fifty five patients with FMF during attact free period, 55 patients with Ankylosing Spondylitis (AS) during inactive period and 55 age-and sex matched controls were included in the study. Native thiol, total thiol and disulphide levels were studied by the Erel and Neşelioğlu method.

**Results:** Total thiol and disulphide levels were significantly lower in FMF group compared to healthy controls. Native thiol levels were detected to be significantly increased in FMF groups compare to AS group. However, total thiol levels were similar in FMF and AS group. Ratios obtained using plasma native thiol, total thiol, and disulphide levels differed significantly between the FMF, AS and the control group.

Table 1. Plasma thiol–disulphide levels of FMF, AS and control group

| Parameter | FMF (n=55) | AS (n=55) | Control (n=55) | P* |
|---|---|---|---|---|
| Native thiol, μmol/L | 328.99±56,92 | 308.07±40.49 | 336.52±40.44 | 0.005 |
| Total thiol, μmol/L | 351.51±56.03 | 337.75±44.69 | 371.86±42.22 | 0.001 |
| Disulphide, μmol/L | 11.25±6.4 | 14.83±6.99 | 17.67±6.43 | 0.001 |
| Disulphide/native thiol, % | 3.61±2.56 | 4.85±2.40 | 5.35±2.15 | 0.001 |
| Disulphide/total thiol, % | 3.27±2.09 | 4.34±1.91 | 4.77±1.72 | 0.001 |
| Native thiol/Total thiol, % | 93.45±4.19 | 91. 31±3.82 | 90.45±3.45 | 0.001 |

Values are presented as mean ± standard deviation. *P values are comparing the native thiol, total thiol, disulphide, disulphide/native thiol, disulphide/total thiol, native thiol/total thiol in each group.

**Conclusions:** Thiol levels, an important anti-oxidant, was found to be significantly lower. Subclinical inflamation may be continued in FMF patients during attact free period. Randomised controlled trials with large patient populations might help clarify this issue.

**Disclosure of Interest:** None declared

## FRI0481 NO CHANGE IN SELF-REPORTED PAIN FROM PRE-PREGNANCY TO SIX MONTHS POSTPARTUM IN WOMEN WITH JUVENILE IDIOPATHIC ARTHRITIS

B. Jakobsen[1], H.S. Koksvik[1], K. Ursin[1], M. Wallenius[1,2]. *[1]National Advisory Unit on Pregnancy and Rheumatic Diseases, St. Olavs Hospital, NKSR; [2]Norwegian University of Science and Technology, Faculty of medicine, Departement of Neuroscience, Trondheim, Norway*

**Background:** There are no previous studies on health related quality of life (HRQL) related to pregnancy in women with juvenile idiopathic arthritis (JIA). One study on a small population with rheumatoid arthritis (RA) using the short form 36 (SF-36) to measure HRQL, has shown that RA women reported a worsening in the aspect of bodily pain 12 and 24 weeks postpartum compared to pre-pregnancy (1).

**Objectives:** To study the impact of pregnancy on the aspect of bodily pain aspect in self- reported HRQL using SF-36 from pre-pregnancy to six months postpartum on women with JIA.

**Methods:** 25 women with JIA were followed from pre-pregnancy to six months postpartum. HRQL was measured using the SF-36 form resulting in eight multi-item subscales. In this study the aspect of bodily pain in SF-36 was explored. Registrations were recorded pre-pregnancy (within one year before conception), 1st trimester (1–12 weeks), 2nd trimester (13–27 weeks), 3rd trimester (28–40 weeks), six weeks and six months postpartum. The Wilcoxon test for related samples was performed.

**Results:** Mean age of the JIA women was 29 years (range 20–36) and mean disease duration 21 years (range 4–32). The mean number of DMARDs used before pregnancy was 0.64 (range 0–2). Correspondingly, the mean number of DMARDs were 0.68 (range 0–1) six months postpartum. The pre-pregnancy scores were tested to each of the other time points.

There was a statistically significantly improvement in self-reported pain from pre-pregnancy to six weeks postpartum (p=0.019), but no difference was observed at six months postpartum.

Table 1. SF-36 aspect of bodily pain from pre-pregnancy up to six months postpartum presented with mean scores and 95% confidence interval (CI)

| | Pre-pregnancy | 1st trimester | 2nd trimester | 3rd trimester | 6 weeks postpartum | 6 months postpartum |
|---|---|---|---|---|---|---|
| Mean BP | 55 | 63 | 60 | 57 | 66 | 61 |
| 95% CI | (42–67) | (51–74) | (51–68) | (47–68) | (55–76) | (46–73) |

**Conclusions:** There was a no statistically significant change in self-reported pain from pre-pregnancy to six months postpartum, but a significantly improvement was seen from pre-pregnancy to six weeks postpartum in this study population of JIA women.

## FRI0482 ANTI-TNFα THERAPY AND SWITCHING IN SEVERE UVEITIS OF VOGT-KOYANAGI-HARADA SYNDROME. REPORT OF TWO CASES AND LITERATURE REVIEW

B.J. Flores [1], C. Fernández [2], J. Blanco [3], N. Palmou Fontana [2], R. Blanco [2]. *[1] Rheumatology, Hospital Universitario Puerta de Hiero, Madrid; [2] Rheumatology, Hospital Universitario Marqués de Valdecillla, Santander; [3] Rheumatology, Hospital Universitario de Basurto, Bilbao, Spain*

**Background:** Vogt-Koyanagi-Harada disease is a multisystem autoimmune disorder mediated by T-cells directed against antigens of tissues that contain melanin. Clinically it's characterized by diffuse bilateral granulomatous panuveitis. Although conventional immunosuppresive therapy such as cyclosporine (CsA), azathioprine (AZA) or methotrexate (MTX) the disease can remain active and complicated by blindness.
**Objectives:** Our aim was to review the cases of VKH syndrome uveitis in a reference unit for the past five years especially those patients with anti-TNFα therapy.
**Methods:** We reviewed all the cases of posterior uveitis or panuveitis in a reference unit between January 2010 to December 2015. VKH syndrome was diagnosed by international standard criteria [(1).] The treatment was reviewed particularly those with anti-TNFa therapy refractory to conventional immunosuppresives. In addition we reviewed the literature of anti-TNF α therapy in a VKH uveitis syndrome
**Results:** 104 were assessed. 5 cases (4 wome /1 man) met criteria VKH syndrome, mean age was 45 years. In all cases the initial treatment was high doses of corticosteroids and conventional immunosuppressive therapy CyA (4 cases), AZA (2 Cases) CsA + AZA (2 cases). In two patients with failure to AZA + CsA, infliximab (IFX) was prescribed Weeks 0, 2 and 6 and each 8 weeks. In both cases (intorelancy and ineffectiveness to infliximab), "switch" to adalimumab 40 mg/sc biweekly achieving an adequate clinical response and remission of uveitis. In addition to the two cases in our series in the literature review we found 9 articles related to anti-TNF α therapy in VKH syndrome (Table). We found 9 series with 25 patients (14 with ADA/11 IFX). In most of them remission of intraocular inflammation was observed, 13 patients with ADA (92.8%)/10 IFX (90.9%). There are no published cases of "Switching" between anti-TNF agents in VKH.
**Conclusions:** In VKH syndrome uveitis refractory to conventional immunosuppressive, anti-TNF therapy may be a treatment option. In cases of inadequate response to the first anti-TNFa "switching" to another anti-TNFa is an option, however, these preliminary data should be tested in randomized prospective studies with larger numbers of patients.

## FRI0483 IS THERE A DIFFERENCE IN AUTOIMMUNE MYOPATHIES WITH AND WITHOUT RAYNAUD'S PHENOMENON? A CAPILLAROSCOPY STUDY

C. Pomirleanu [1,2], G. Strugariu [1], C. Belibou [1], R. Maxim [1], L. Petrariu [1], C. Ancuta [1,2]. *[1] Rheumatology 2, Clinical Rehabilitation Hospital; [2] University of Medicine and Pharmacy "Gr.T.Popa", Iasi, Romania*

**Background:** The autoimmune myopathies (IM) comprise a broad spectrum of acquired muscular disorders characterized by autoimmune damage of skeletal muscle and complex visceral involvement, leading to chronic dysfunction and disability.
**Objectives:** The aim of our study was to assess the association between Raynaud's phenomenon (RP) and capillaroscopic findings in patients with polymyositis (PM), dermatomyositis (DM) and anti-synthetasic syndrome (ASS), and to identify possible correlation with clinical and serological pattern.
**Methods:** Nailfold videocapillaroscopy (Optilia 200x) was performed in a cohort of 27 patients diagnosed with IM, 12 with RP and 15 age-, sex-, and disease-duration-matched without RP, and 19 healthy controls. Total number of capillaries, enlarged and giant capillaries, ramified capillaries, haemorrhages, haemosyderin deposits were each scored by a semiquantitative assessment, while the disorganization of the vascular array and avascular area were scored as present/absent.
Data about IM activity (Myositis Disease Activity Assessment Tool), severity (Myositis Damage Index) and physical function (Stanford HAQ) were also collected.
Findings were analysed using linear and logistic regression, adjusted for age and sex (SPSS-19 software).
**Results:** Patients with IM were frequently abnormal, with significant lower capillary density, higher dimensions, enlarged capillaries, haemorrhages and haemosyderin deposits as compared with healthy controls ($p<0.001$).
80% of cases reported RP as the first manifestation of their disease, with frequently nailfold capillary abnormalities as compared to non-RP patients ($p<0.01$). Enlarged capillaries ($p<0.01$), avascular areas ($p<0.05$) and capillary hemorrhages ($p<0.05$) were typically described in DM and most of ASS patients, but not in PM without RP.
In addition, a scleroderma-like capillaroscopy pattern was identified in RP-positive patients, either DM or ASS. On the other hand, either normal or nonspecific capillaroscopy findings were found in RP-negative and PM.
Pulmonary involvement ($p<0.01$) and arthritis/arthralgia ($p<0.01$) were significantly more common in ASS with RP, especially in those who developped RP years before myositis, while digestive (proximal dysphagia) manifestations ($p<0.01$) were more common in DM with RP, particularly in those with late-onset RP.
We found an association between the presence of either active or late scleroderma pattern, elevated serum CK and disease activity: capillary loss was significantly associated high muscle and global disease activity, as well ($p<0.05$).
Anti-Jo-1 and anti-PL12 antibodies were associated with reduced capillary density ($p<0.05$), whereas anti-SRPs associated with reduced capillary density, enlarged capillaries and hemorrhages ($p<0.05$).
**Conclusions:** RP is associated with particular capillaroscopic findings in different IM subsets, suggesting that prognostic relevance of RP in myositis should be evaluated.
Significant changes in the capillary pattern reported in IM, particulary reduced density, size abnormalities, haemorrhages, indicating that nailfold videocapillaroscopy may be useful as an outcome measure of microvascular disease in IM

## FRI0484 IGG4 RELATED HYPERTROPHIC PACHYMENINGITIS: DIAGNOSTIC APPROACH AND THERAPEUTIC OUTCOMES

E. Bozzalla Cassione, M. Lanzillotta, G. Passerini, M. Tresoldi, M.G. Sabbadini, E. Della Torre. *Unit of Medicine and Clinical Immunology, IRCCS San Raffaele Scientific Institute, Milan, Italy*

**Background:** IgG4 Related Disease (IgG4-RD) is a fibro-inflammatory condition characterized by IgG4 positive lymphoplasmacytic infiltrate of affected tissues. Meningeal involvement, typically of the dura mater, represents one of the most challenging manifestations of IgG4-RD in terms of diagnostic and therapeutic approach (1). Case reports have suggested the potential utility of cerebrospinal fluid (CSF) IgG4 measurement in the differential diagnosis of IgG4 Related Hypertrophic Pachymeningitis (IgG4-RHP) (2).
**Objectives:** To assess the usefulness of CSF analysis in the diagnosis of IgG4-RHP. To describe the clinical, serological and radiological response of IgG4-RHP to different therapeutic regimens.
**Methods:** Five pts (3 females and 2 male) with biopsy-proven IgG4-RHP were evaluated through serological, radiological, and microbiological studies before and after immunosuppressive treatment. CSF analysis for intrathecal IgG4 production was performed in all pts before therapy, and in 3 pts after therapy. Serum and CSF IgG subclasses were measured through ELISA assays. Intrathecal IgG

subclasses production was assessed through the IgG Index and the IgG-LOC.
**Results:** Cranial nerve deficit was the common clinical presentation of HP. Magnetic resonance imaging showed thickening of the dura mater in all pts. Serological and CSF results are reported in Table 1. CSF analysis before treatment revealed increased IgG4 values, IgG4 Index, and IgG4-LOC in all pts with an average value of 9.64 mg/dL (normal 0.01–0.33 mg/dL), 4.14 (normal <0.7) and 8.15 (normal <0) respectively. Pt 1 was treated with intravenous (i.v.) methylprednisolone, oral prednisone, i.v. cyclophosphamide, and, rituximab; Pt 2 was treated with oral prednisone and methotrexate; Pt 3 was treated with oral prednisone; Pt 4 was treated with oral prednisone, methotrexate, azathioprine, and oral cyclophosphamide; Pt 5 was treated with i.v. methylprednisolone, cyclophosphamide, and rituximab. Patient 2, 3 and 4 responded to therapy with a marked clinical improvement and an almost complete resolution of the meningeal thickening. Pt 1 had a minimal response to therapy with only a partial reduction of the meningeal thickening. Patient 5 had a poor response to therapy with no improvement of the meningeal thickening. CSF IgG4 (0.07 mg/dL), IgG4 Index (0.23) and IgG4-LOC (0) normalized after treatment in Patient 4, and decreased without normalization in Pts 1 and 5 (CSF IgG4 0.54 and 3.99 mg/dL, IgG4 Index 0.81 and 5.1, and IgG4-LOC 0.09 and 3.46, respectively).

**Conclusions:** CSF analysis of intrathecal IgG4 production represents a useful tool for orienting the differential diagnosis of idiopathic HP especially when meningeal biopsy is not feasible. The variability in the responses to immunosuppressive therapies might be due to differences in the disease phenotypes and drug penetration in meningeal layers.

Nolla[17], M.A. Gonzalez-Gay[18]. *[1]Servicio de Reumatología, H. General, Valencia; [2]H. Marqués de Valdecilla, Santander; [3]Servicio de Oftalmología, H. General, Valencia; [4]Servicio de Oftalmología, IBOA, Valladolid; [5]H. de León, León; [6]H. Clinic, Barcelona; [7]H. Clinico S.Carlos, Madrid; [8]H. Basurto, Bilbao; [9]H. La Fe, Valencia; [10]H. Donostia, San Sebastián; [11]H. Santiago de Compostela, Coruña; [12]H. Dr. Negrín, Las Palmas; [13]H. Alcorcón, Madrid; [14]Servicio de Oftalmología; [15]H. Miguel Servet, Zaragoza; [16]H. Puerta del Mar, Cadiz; [17]H. Bellvitge, Barcelona; [18]Servicio de Reumatología, H.Marqués de Valdecilla, Santander, Spain*

**Objectives:** Cystic macular edema (CME) is the most serious complication of uveitis and the most common cause of blindness. Our objective was to compare the efficacy and safety of adalimumab (ADA) vs infliximab (IFX) as the first biological drug in uveitic cystoid macular edema (CME) due to Behçet's disease (BD) during 1 year follow-up.
**Methods:** In a multicentre study of 175 patients with BD and uveitis refractory to conventional therapy, 34 patients had CME, defined by (OCT >300μ) at baseline. IFX (3–5 mg/kg 0,2, and 6 weeks and then every 4–8 weeks) was used in 12 cases and ADA (40 mg/2 weeks) in 22 cases. The main objective was the absence of CME. Secondary objectives: improvement in visual acuity (VA) (increased AV >20% in at least one of two eyes), inactive anterior chamber inflammation, vitritis, retinitis and retinal vasculitis. A bivariate analysis was performed to compare the response to biological therapy (ADA and IFX).
**Results:** We studied 34 patients (63 affected eyes). No statistically significant baseline differences were observed between both groups (IFX vs ADA) sex (men/women 4/6 vs 11/11; p=0.35), mean age (37.3±10.1 vs 41.5±8.3; p=0.2) HLAB51 positive (70% vs 80.9%; p=0.5), duration of uveitis before anti TNF alpha treatment [median (IQR]; 36 [10–82] vs 33 months [15.5 to 83]; p=0.8), VA (0.4 ± 0.33 vs 0.46±0.29; p=0.44); retinal vasculitis (75% vs 77%; p=0.87); retinitis (46% vs 30%; p=0.2); macular thickening (140.9±410.13 vs 409.46±138.55; p=0.98); combined treatment (58.33% vs 59.1%; p=0.96). We found differences in the presence of cells in the anterior chamber (Median [IQR]; 1 [0–1.2] vs 1 [0–3]; p=0.02) and vitritis (median [IQR], 1 [0–2] vs. 3 [0.5 -3]; p=0.002). Regarding the main objective, the improvement of CME is higher in patients treated with ADA during first month of treatment maintained at a year, although the difference is not statistically significant (table). With IFX we observed an improvement during the first month of treatment in vitritis, that became inactive, in the disappearance of the anterior chamber cells, and in retinitis and vasculitis that also became inactive. In no case statistically significant differences are reached. When adjusting for duration of illness, age and sex these differences remain. After a year of treatment all patients with retinitis and vasculitis in its baseline improve (ADA and IFX).

## FRI0486 TOCILIZUMAB TREATMENT FOR UVEITIC CYSTOID MACULAR EDEMA REFRACTORY TO OTHER SYNTHETIC AND BIOLOGICAL IMMUNOSUPPRESSIVE DRUGS. MULTICENTRE STUDY OF 23 PATIENTS

E. Beltrán-Catalán[1], C. Fernandez[2], R. Blanco[2], V. Calvo-Río[2], M. Hernandez[3], M. Mesquida[4], A. Adan[5], V. Hernandez[5], D. Diaz[6], G. Diaz[7], I. Calvo[8], A. Atanes[9], L. Linares[10], C. Modesto[11], M.A. Gonzalez-Gay[2]. *[1]Servicio de Reumatología, H.General, Valencia; [2]H.Marques de Valdecilla, Santander; [3]H.General, Valencia; [4]S.Oftalmología; [5]H.Clinic, Barcelona; [6]S.Oftalmología, H.Clinico S.Carlos, Madrid; [7]H. de Málaga, Malaga; [8]S.Pediatría, H. la Fe, Valencia; [9]HUCA, Coruña; [10]H.Arrixaca, Murcia; [11]H.Vall Hebrón, Barcelona, Spain*

**Objectives:** Cystoid macular edema (CME) is the leading cause of blindness in uveitis, which often requires more aggressive treatment based on associating corticosteroids and synthetic and biological systemic immunosuppressive drugs. Our objective was to evaluate the efficacy and safety of Tocilizumab (TCZ) in a series of patients with refractory CME.
**Methods:** A Multicentre study of 23 patients with CME secondary to non-infectious uveitis who had inadequate response or intolerance to traditional treatment with corticosteroids and at least one conventional immunosuppressive drug including in some cases biological therapy. CME was defined by (OCT>300μ). The outcome variables were the degree of inflammation of the anterior chamber and vitreous, visual acuity and macular thickness. The results are expressed as mean ± SD for normally distributed variables, or as median [interquartile range] when are not. Comparison of continuous variables was performed using theWilcoxon test.
**Results:** 23 patients (16 females/7 males) with CME were studied. With a mean age of 33.5±17.7 years. Associated disease were: juvenile idiopathic arthritis (n=9), Behçet's disease (n=6), Birdshot retinochoroidopathy (n=4) and idiopathic

(n=4). Ocular pattern was: panuveitis (n=8), anterior uveitis (n=6), posterior uveitis (n=5) and intermediate uveitis (n=4). Most patients had bilateral involvement (n=22). Prior to TCZ patients received: intraocular corticosteroids (n=20), intravenous methylprednisolone (n=6), methotrexate (MTX) (n=18), cyclosporine A (CsA) (n=16), mycophenolate (n=4), azathioprine (n=2), cyclophosphamide (n=1), sulfasalazine (n=1), daclizumab (n=1), acetazolamide (n=1), thalidomide (n=1), leflunomide (N=1), infliximab (n=8), adalimumab (n=17), etanercept (n=2), golimumab (n=2), rituximab (N=2), abatacept (n=3), anakinra (n=1). TCZ administration schedule was 8 mg/kg/4 weeks iv. in all patients except in one that administration was every 2 weeks. Monotherapy (n=11) and in combination with conventional immunosuppressive: MTX (n=6), CsA (n=5) and leflunomide (n=1). A statistically significant reduction was observed in macular thickness from 418.84±177.14 to 240.00±54.73 m; p=0.00009 during the first year of treatment with TCZ. Most of intraocular inflammation parameters showed also a rapid improvement after initiation of TCZ. (TABLE) Visual acuity improved in a statistically significant way from 0.4±0.32 at baseline to 0.59±0.30 after a year of treatment p=0.0002. Prednisone dose was reduced from 15.69±14 to 2.92±2.46 after a year of treatment. After 13.1±8.55 months minor side effects were observed: nausea (n=1), viral conjunctivitis (n=1) and bullous impetigo (n=1). Remission was achieved in 13 patients.

**Conclusions:** TCZ seems an effective and safe treatment in patients with uveitic CME refractory to other synthetic and biological immunosuppressive drugs.

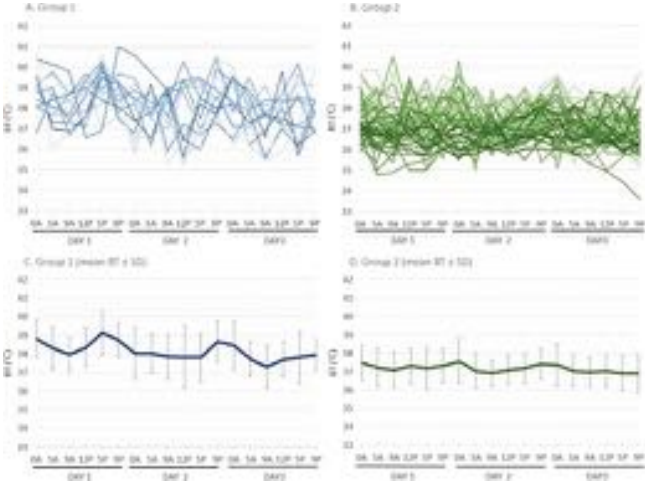
## FRI0487 ASSOCIATION BETWEEN FEVER PATTERN AND CLINICAL MANIFESTATIONS IN ADULT ONSET OF STILL'S DISEASE: UNBIASED ANALYSIS OF FEVER PATTERN USING HIERARCHICAL CLUSTERING

E.Y. Ahn [1], H.M. Kwon [1], W. Hwang [2], E.Y. Lee [1], E.B. Lee [1], Y.W. Song [1], J.K. Park [1]. *[1] Division of Rheumatology, Department of Internal Medicine, Seoul National Univ. Hospital; [2] Data Science for Knowledge Creation Research Center, Seoul National University, Seoul, Korea, Republic Of*



**Background:** Adult onset of Still's disease (AOSD) is a systemic inflammatory disease characterized by fever, arthritis, salmon pink rash and elevated serum inflammatory markers. The classical fever of AOSD is intermittent with a quotidian or double-quotidian pattern. However, a significant subset of AOSD exhibits persistently high fever with little temperature fluctuation. It remains unclear as to whether the certain fever pattern is associated with specific clinical manifestations.

**Objectives:** To investigate the association between fever pattern and clinical characteristics in patients with AOSD.

**Methods:** A total of 70 patients with AOSD who were treated as inpatient at Seoul National University Hospital from 2004 through 2015 were enrolled. Patients were grouped based on the fever curves on days 2, 3 and 4 using hierarchical clustering. The clinical and laboratory characteristics of the groups were compared.

**Results:** 70 patients were divided into 2 groups based on the fever curves. The group 1 with 14 patients had a higher mean temperature (38.1±0.4℃ vs. 37.2±0.5℃, p<0.001) with wider daily variation (2.7±0.9℃ vs. 1.9±0.7℃, p<0.001) as compared to 56 patients in the group 2.

Group 1 tended to be younger (38.4 ± 14.7 years vs. 46.1 ± 17.6 years, p=0.141) (Figure). Fever, arthritis, arthralgia and rash did not differ between them. However, group 1 tended to have more pericardial and lung involvement (42.9% v.s 23.2%, p=0.181). Group 1 had significantly lower platelet count (198,900 ± 68,000/μl vs. 312,900 ± 156,900/μl, p=0.0001), higher LDH (816.6 ± 376.4 IU/L vs. 477.5 ± 327.1 IU/L, p=0.002), higher mean ferritin level (27,004.1 ± 48,891.5 ug/mL vs. 6,852 ± 10,628.2 ug/mL, p=0.072) and d-dimer (9.5 ±7.9 ug/mL vs 3.3 ± 3.4 ug/mL) as compared to group 2, whereas white blood cell count, hemoglobin levels, CRP levels did note differ between the both groups. Group 1 tended to require longer time to a clinical remission (455.5 ± 850 days vs. 9.4 ± 115.7 days, p=0.137).

**Conclusions:** The unbiased analysis of fever reveals the presence of at least 2 distinctive fever patterns in AOSD. Spiking fever with higher daily variation was more often associated with higher inflammatory markers and coagulopathy and required longer treatment. Thus, fever pattern might be a prognostic factor in AOSD and AOSD patients with spiking fever might need more intensified treatment.

## FRI0488 A PHASE III PIVOTAL UMBRELLA TRIAL OF CANAKINUMAB IN PATIENTS WITH AUTOINFLAMMATORY PERIODIC FEVER SYNDROMES (COLCHICINE RESISTANT FMF, HIDS/MKD AND TRAPS)

F. De Benedetti [1], J. Anton [2], M. Gattorno [3], H. Lachmann [4], I. Kone-Paut [5], S. Ozen [6], J. Frenkel [7], A. Simon [8], A. Zeft [9], E. Ben-Chetrit [10], H. Hoffman [11], Y. Joubert [12], K. Lheritier [12], A. Speziale [12], G. Junge [12]. *[1] IRCCS Ospedale Pediatrico Bambino Gesú, Rome, Italy; [2] Hospital Sant Joan de Déu, Barcelona, Spain; [3] Pediatric Rheumatology, G. Gaslini Institute, Genoa, Italy; [4] UK National Amyloidosis Centre, University College London Medical School, London, United Kingdom; [5] Hôpital Kremlin Bicetre, University of Paris SUD, Paris, France; [6] Hacettepe University Children's Hospital, Ankara, Turkey; [7] University Medical Center Utrecht, Utrecht; [8] Radboud University Medical Centre, Nijmegen, Netherlands; [9] Pediatrics Rheumatology, Cleveland Clinic, Cleveland, United States; [10] Rheumatology Unit, Hadassah–Hebrew University Medical Center, Jerusalem, Israel; [11] University of California, La Jolla, United States; [12] Novartis Pharma AG, Basel, Switzerland*

**Background:** Periodic fever syndromes (PFS) are a group of rare autoinflammatory conditions, which includes, among others, cryopyrin-associated periodic syndromes (CAPS), familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD), TNF-receptor associated periodic syndrome (TRAPS). Canakinumab (CAN), a fully human, highly specific anti-IL-1β neutralising monoclonal antibody, is effective in CAPS.[1] IL-1β has been shown to be involved in the pathogenesis of FMF, HIDS/MKD and TRAPS, for whom no approved treatment exists. A series of small open label studies suggested efficacy of CAN in colchicine resistant/intolerant FMF (crFMF), HIDS/MKD and TRAPS.[2,3] We report the efficacy and safety of CAN from the randomised treatment epoch of a phase III trial in patients (pts) with crFMF, HIDS/MKD or TRAPS.

**Objectives:** Primary objective of this phase III pivotal trial was to demonstrate that CAN 150 mg (or 2 mg/kg for pts ≤40 kg) sc q4w is superior to placebo (PBO) in achieving a clinically meaningful response defined as resolution of the index flare at Day 15 and no new disease flares over 16 wks of treatment. Secondary objectives were: % pts who achieved a physician global assessment of disease activity (PGA) <2 (minimal/none); % pts with C-reactive protein (CRP) ≤10 mg/L; serum amyloid A level (SAA) ≤10 mg/L at Wk 16.

**Methods:** The trial (NCT02059291) consists of 3 disease cohorts (crFMF, HIDS/MKD and TRAPS) and 4 study epochs (E1–4): a screening epoch (E1) of up to 12 wks, a randomised treatment epoch (E2) of 16 wks, a randomised

**Table. Primary and secondary endpoint results at Week 16 and summary of safety**

| | Cohort | CAN (150 mg q4w) | Placebo | p-value |
|---|---|---|---|---|
| Proportion of responders, n (%) | crFMF | 19 (61.29) | 2 (6.25) | <0.001* |

| | TRAPS | 2 (27.3) | 2 (66.7) | – |
| Patients with any SAE, n (%) | crFMF | 2 ( 9.5) | 1 ( 20.0) | – |
| | HIDS/MKD | 0 (0.0) | 2 (50.0) | – |
| | TRAPS | 0 (0.0) | 0 (0.0) | – |

n = number of patients who achieved primary or secondary endpoint; AE, adverse event; SAE, serious adverse event. *Indicates statistical significance (one-sided) at the 0.025 level based on Fisher exact test/logistic regression model for the primary endpoint/for the secondary endpoint. #Patients who had no new flare over the 16 weeks of treatment.

withdrawal epoch (E3) of 24 wks and an open-label treatment epoch (E4) of 72 wks. Pts (age ≥2 years) with crFMF, HIDS/MKD or TRAPS with a flare during E1 were randomised (1:1) in E2 to receive CAN or PBO. Safety assessments included adverse events (AEs).

**Results:** Of 181 pts (crFMF, n=63; HIDS/MKD, n=72; TRAPS, n=46) randomised in E2, 6 pts discontinued (5 PBO; 1 CAN). In all 3 disease cohorts, the proportion of pts who were responders for the primary outcome at Wk 16 was significantly higher with CAN vs PBO (Table). At Wk 16, a significantly higher proportion of pts achieved PGA score <2, CRP ≤10 mg/L and SAA ≤10 mg/L in the CAN group vs PBO in all 3 cohorts (Table). No new safety findings were reported in the CAN-treated pts through E2 (Table).

**Conclusions:** These results demonstrated superior efficacy of canakinumab at dose level of 150 mg q4w after a 16 weeks treatment period compared to placebo. The overall safety profile was not distinct from previous controlled studies and expectations in an auto-inflammatory patient population.

Speziale[11], G. Junge[11], J. Gregson[11], F. De Benedetti[12]. *[1]UK National Amyloidosis Centre, University College London Medical School, London, United Kingdom; [2]Radboud University Medical Centre, Nijmegen, Netherlands; [3]Hospital Sant Joan de Déu, Barcelona, Spain; [4]Pediatric Rheumatology, G. Gaslini Institute, Genoa, Italy; [5]Hôpital Kremlin Bicetre, University of Paris SUD, Paris, France; [6]Hacettepe University Children's Hospital, Ankara, Turkey; [7]University Medical Center Utrecht, Utrecht, Netherlands; [8]Rheumatology Unit, Hadassah–Hebrew University Medical Center, Jerusalem, Israel; [9]University of California, La Jolla; [10]Pediatrics Rheumatology, Cleveland Clinic, Cleveland, United States; [11]Novartis Pharma AG, Basel, Switzerland; [12]IRCCS Ospedale Pediatrico Bambino Gesú, Rome, Italy*

**Background:** Periodic Fever Syndromes (PFS) are rare autoinflammatory conditions including Familial Mediterranean Fever (FMF), Hyper-IgD Syndrome/ Mevalonate Kinase Deficiency (HIDS/MKD), and TNF-Receptor Associated Periodic Syndrome (TRAPS).[1] It has been shown that colchicine-resistant FMF (crFMF), HIDS/MKD and TRAPS considerably impact physical and emotional aspects of patients' lives.[2–4] Open label studies suggested that canakinumab (CAN), a fully human and highly specific anti-IL-1β monoclonal antibody, is efficacious in crFMF, HIDS/MKD and TRAPS.[5–7] To date, there is no data showing the effect of CAN on Health-Related Quality of Life (HRQoL) in PFS patients.

**Objectives:** To evaluate the effect of CAN on HRQoL using Child Health Questionnaire – Parent Form 50 (CHQ-PF50) and SF-12 Health Survey (SF-12) in PFS patients.

**Methods:** In a Phase 3 randomised placebo controlled study of CAN in PFS (NCT02059291), SF-12 Physical Component Summary (PCS) and Mental Component Summary (MCS) were assessed in adults. For children (>5–<18 years), CHQ-PF50 Physical (PhS) and Psychosocial (PsS) Summary scores were assessed.

**Results:** 181 patients were randomised to CAN or placebo in 3 cohorts (63 crFMF, 72 MKD/HIDS, 46 TRAPS). 71 adults ≥18 years and 110 children (age range ≥2–<18 years). Patients reported early clinically meaningful improvement in SF-12 PCS scores reported at Week (Wk) 5 which were sustained and increased to a large effect size by Wk 16 for all indications (Table). Similarly, clinically meaningful improvements in SF-12 MCS, CHQ-PF50 PhS and PsS was observed in all indications, with the exception of PsS in HIDS/MKD and TRAPS patients (Table).

Table 1. Patient reported outcomes

| | Mean change from baseline (n/N) | | | | | |
|---|---|---|---|---|---|---|
| | crFMF | | HIDS/MKD | | TRAPS | |
| | Week 5 | Week 16 | Week 5 | Week 16 | Week 5 | Week 16 |
| SF-12 PCS | 7.9 (29/30) | 9.55 (30/31) | 13.81 (15/15) | 13.81 (14/14) | 9.63 (16/17) | 11.64 (13/14) |
| SF-12 MCS | 4.83 (29/30) | 4.27 (30/31) | 6.41 (15/15) | 8.14 (14/14) | 5.65 (16/17) | 5.51 (13/14) |
| CHQ-PF50 PhS | 13.2 (21/24) | 20.1 (18/21) | 5.5 (32/34) | 9.9 (27/29) | 7.4 (16/18) | 14.9 (13/14) |
| CHQ-PF50 PsS | 4.1 (21/24) | 7.2 (18/21) | 1.8* (32/34) | 5.2 (27/29) | 0.9* (16/18) | 1.2* (13/14) |

N = total number of patients; n = patients who received at least one dose of canakinumab. *Minimal important difference[8,9] from baseline was *not* achieved.

**Conclusions:** Canakinumab showed rapid improvement by Week 5 in patient reported outcomes in adults and children with PFS, which was sustained through Week 16.

## FRI0490 INFERTILITY AND PREGNANCY IN RHEUMATIC DISEASES: THE UTILITY OF A MULTIDISCIPLINARY PROTOCOL FOR THE MANAGEMENT OF THESE PATIENTS

I.C. Chalmeta[1], J. Ivorra[1], B. Marcos[2], C. Diaz[3], E. Beltran[4], R. Negueroles[1], J.L. Valero[1], C. Feced[1], F. Ortiz[1], L. Gonazlez[1], I. Martinez[1], E. Labrador[1], K. Arevalo[1], E. Grau[1], C. Alcañiz[1], J. Fragio[5], J. Roman[1,6]. *[1]Rheumatology; [2]Gynecologist&Obstretics; [3]Fertility Unit, Hospital la Fe; [4]Hospital General; [5]Hospital la Fe; [6]Rheumatology, Universidad Católica Valencia, Valencia, Spain*

**Background:** Pregnancy in rheumatic diseases is a process that requires careful handling, beginning with proper planning. Infertility and chronic use of teratogenic drugs are some common situations in these patients, giving them a high-risk obstetrics.

**Objectives:** To established a protocol for planning and monitoring pregnancies in patients with rheumatic diseases

**Methods:** Retrospective review of a follow-up protocol for patients with rheumatic diseases and pregnancy wishes. This protocol includes: preconception consultation to asses fertility of the couple, as well as pregnancy couselling and establishment of a appropriate pharmacological treatment; after pregnancy period start, monthly consultations by a multidisciplinary team; and finally, a postpartum consultation after delivery

**Results:** A total of 51 patient with different rheumatic diseases were included: Sistemic Lupus Erythematosus (8 patients), Sjogren'S Syndrom (10 patients), Rheumatoid arthritis (13 patients), Psoriatic arthritis (5 patients), Behcet's disease (3 patients), Spondiloarthritis (2 patients), Familial Mediterranean Fever (2 patients), Conective mixed Tissues Disease (1 patient), Primary Antiphospholipi Syndrom (2 patient) an Hyper IgD Syndrome (1 patient). The results were: Infertility was detected in 8 couples and assisted reproductive techniques was requieres in 7 (6 IVF and 1 insemination). Safe Pharmacological treatments were used: sulfasalazine (4), hydroxychloroquine (13), azathioprine (2). Biological DMARDs in 3 patients (1 infliximab and Certlizumab in 2). Other treatments were: steroids (12) and intravenosus immunoglobulins for fetal heart block (2). All patients with thrombophilia have been treated with LMWH alone or plus aspirin. The course of pregnancy was:delivery at term (28), delivery pre-term (3)**, miscariages (3)*, pregnancy on course (7), neonatal death (1) and 8 patients are plannig the pregnancy. The abortions have occurred in 2 patients with lupus erythematosus and in 1 patient with rheumatoid arthritis. Postpartum care of newborns with mothers with positivity anti-Ro has objectified a neonatal transfer of Acs in 100% of cases;only 8 of them developed neonatal SLE.

**Conclusions:** A satisfactory evolution of pregnancy was observed in 87% of our patients, a fact that supports our impression that this process should be approached in a multidisciplinary team. Infertility is a situation that should be considered and treated at an early stage in this patients, preferably before preconceptional period.

## FRI0491 ETIOLOGY AND CLINICAL FEATURES OF UVEITIS IN A TERTIARY CENTER IN TURKEY

D. Arslan Tas[1], I. Turk[1], N. Cuzdan Coskun[1], O. Kudas[1], S.O. Badak[1], E. Esen[2], S. Sızmaz[2], N. Demircan[2]. *[1]Division of Rheumatology; [2]Department of Ophthalmology, Çukurova University Medical Faculty, Adana, Turkey*

**Background:** Uveitis is inflammation of uvea (iris, ciliary body, choroid). Uveitis is classified as anatomically (anterior, intermediate, posterior, panuveitis) and etiologically (infectious, non-infectious and masquerade) (1).
**Objectives:** The aim of this study was to investigate etiology and clinical properties of uveitis in a tertiary center in Turkey.
**Methods:** Uveitis patients who admitted to our hospital from 2013 to 2015 were evaluated. Age, gender, type of uveitis, course of the attacks and etiology were noted.
**Results:** One hundred patients with uveitis (54% men, 46% women; age 40.01±14.1 years) were included in the study. The course of the disease was mostly acute (42%) followed by recurrent (36%) and chronic form (22%). Specific diagnosis was established in 68% of patients; whereas 32% of patients were evaluated as idiopathic. Etiology was spondiloartropathy (SpA) in 30%, Behçet's disease in 16%, infectious in 13%, connective tissue disease associated in 6%, sarcoidosis in 2% and malignancy associated uveitis in 1% of the patients. 67% of the patients had unilateral and 33% of patients had bilateral uveitis.
The characteristic properties of patients with SpA were as 56% men and 43% women; aged 43.57 ± 16.45 years. 60% of the patients with SpA had anterior, 40% had panuveitis. 46% of SpA patients had recurrent, 43% had acute and 10% had chronic uveitis. HLA B27 was positive in 50% of SpA patients. Sacroiliitis on MRI was detected in 76% of patients.
There were 32 idiopathic uveitis patients (53.1% women). Panuveitis was the most common type (37.5%) among idiopathic uveitis patients, followed by posterior uveitis (34.4%), anterior uveitis (21.9%) and intermediate uveitis (6.2%), respectively.
There were 16 patients with Behçet's disease, 62.5% of them were men. 62.5% of patients with Behçet's disease had panuveitis, 18.8% had anterior and 18.8% had posterior uveitis.
**Conclusions:** According to the literature posterior segment involvement is a rare presentation of SpA associated uveitis (2).The results of this study are noteworthy that higher incidence of panuveitis can be seen in SpA patients.

## FRI0492 LONG-TERM SAFETY AND EFFICACY OF CANAKINUMAB IN PATIENTS WITH CAPS: FINAL RESULTS FROM THE BETA-CONFIDENT REGISTRY

J.B. Kuemmerle-Deschner[1], H. Hoffman[2], P.N. Hawkins[3], T. van der Poll[4], U.A. Walker[5], A. Speziale[6], H.H. Tilson[7], Y. Joubert[6]. *[1]University Hospital Tuebingen, Tuebingen, Germany; [2]University of California, La Jolla, CA, United States; [3]University College London Medical School, London, United Kingdom; [4]Academic Medical Center, University of Amsterdam, Amsterdam, Germany; [5]University Hospital; [6]Novartis Pharma AG, Basel, Switzerland; [7]University of North Carolina, Chapel Hill, United States*

**Background:** Cryopyrin-associated periodic syndrome (CAPS), is a rare autoinflammatory disease encompassing a spectrum of 3 phenotypes with an estimated population frequency ranging from 1–3 per million.[1,2] The β -confident Registry (NCT01213641) is a multicenter, long-term, prospective, observational study with an enrollment period of 5 years (yrs) to monitor the long-term safety and efficacy of canakinumab (CAN) for CAPS. Here we report the overall final results.
**Objectives:** The primary objective of the Registry was to monitor the safety of CAN, focusing on SAEs including serious infections, vertigo, malignancies and hypersensitivity reactions.
**Methods:** Cumulative safety data were reported as incidence rate per 100 patient-yr (IR/100 pyr) from the enrollment of the first patient (November 2009) until end of study (December 2015). The registry protocol did not mandate any visits or procedures; however, all observed and reported AEs and SAEs or AEs potentially related to CAN were recorded. Efficacy was measured using physician global assessments (PGA).
**Results:** Overall, 288 patients were enrolled at 39 sites across 13 countries with mean patient exposure duration of 3.6 yrs. Of these, 22 (8%) discontinued CAN: 5 due to AEs, 10 due to poor efficacy and patient preference; and 7 due to unknown reasons. The IR/100 pyr for overall AEs was 100.0. Among the phenotypes of CAPS, patients with familial cold autoinflammatory syndrome (FCAS) had the lowest IR/100 pyr (78.0) compared to patients with Muckle–Wells syndrome (MWS) (IR/100 pyr 113.4) and neonatal onset multisystem inflammatory disease (NOMID) (IR/100 pyr 119.0). The most common AEs were infections and infestations (IR/100 pyr, 39.1). Overall, 161 SAEs were reported by 86 patients (IR/100 pyr, 16.3), most commonly, infections (IR/100 pyr, 5.0). One death (metastatic rectal adenocarcinoma in 76-yr-old MWS patient) was reported. Of 23 patients that received pneumococcal vaccination (PPV), 15 (65%) reported local post-PPV injection site reactions, of which 5 were considered as serious. Based on PGA, 50% of patients had no disease activity, whereas most of the others experienced mild/moderate disease activity up to Month 48. Similarly, disease activity was absent or mild/moderate in patients with *NLRP3* mutation negative CAPS (n=13) treated with CAN.
**Conclusions:** The β-confident Registry is the largest CAPS cohort documented in a registry. This registry demonstrated that safety profile of canakinumab was consistent with previous findings and efficacy was sustained for more than 5 years. Canakinumab therapy was also effective in patients with *NLRP3* mutation negative CAPS.

## FRI0493 CLINICAL FEATURES OF THE VOGT-KOYANAGI-HARADA SYNDROME

J. Losanto, N. Colman, M. Duarte. *Reumatologia, Hospital de Clínicas, San Lorenzo, Paraguay*

**Background:** Vogt-Koyanagi-Harada's disease (VKHD) is a bilateral, diffuse and chronic granulomatous panuveitis characterized by serous retinal detachment. This disease is often associated with neurological, auditory and dermatological disorders. The incidence of appearance is low, affecting mainly young women between 30 years approximately.
**Objectives:** The objective of the present study was to describe and to analyze the characteristics of patients with VKHD, followed in a third level hospital.
**Methods:** Retrospective and descriptive study of patients with EVKH. A large number of clinical, epidemiological variables and treatment were recorded. Statistical analysis was performed with SPSS19.0 program. The qualitative variables were expressed as frequencies and percentages, quantitative variables in mean.
**Results:** In the last 5 years, 3727 clinical records were reviewed and 8 patients were included. Of these, 5 (62.5%) were women with a mean age at diagnosis of 43 years old. All patients referred decreased visual acuity, 100% with bilateral panuveitis and 75% were associated with serous retinal detachment. Dermatological disorders was found in 25% (i.e. vitiligo, poliosis and alopecia), neurosensorial hearing loss in 25% and 12.5% of patients presented asthenia and fever. Neurological symptoms (ie epilepsy, meningismus, confusion, impaired balance) were found in 37.5%. About treatment, all patients received high doses of systemic glucocorticoids and 25% also received non-steroidal anti-inflammatory drugs (NSAIDs). 37.5% of patients received cyclophosphamide, 62.5% azathioprine and 12.5% methotrexate. Visual acuity improved in 75% of cases. Ocular complications were seen in 50% of patients, 12.5% with cataracts, 25% synechiae and glaucoma and band keratopathy in 12.5%. No patients required vitrectomy, nor developed ocular hypertension. Currently only 1 patient has active disease.
**Conclusions:** In our series of VKHD patients, we found that all required immunosuppressive therapy due to the severity of the disease and with this aggressive treatment, the prognosis of this disease was favorable.
**Acknowledgement:** Dra Gabriela Avila.
**Disclosure of Interest:** None declared

## FRI0494 ARTHRITIS POST CHIKUNGUNYA FEVER: CLINICAL PROFILE OF A POPULATION OF PATIENTS IN A SECONDARY CARE HOSPITAL

J. Losanto[1], A. Ojeda[1,2], F. Giménez[2]. *[1]Reumatologia, Hospital de Clínicas; [2]Consultorio de Reumatología, Hospital de Villa Elisa, San Lorenzo, Paraguay*

**Background:** Chikungunya fever is a viral disease caused by an alphavirus that belongs to the Togaviridae family, it is transmitted by mosquitoes of the gender Aedes. Acute symthomps manifests with high fever, skin rash and arthritis. A high percentage of patients can develop severe and disabling poliarthritis. In 2015 there was an outbreak of this desease in outskirts of the capital city, presenting several cases of arthritis of chikungunya fever
**Methods:** Retrospective, descriptive and cross-sectional study of patients who consulted in a secondary care hospital from Villa Elisa city, for persistent joint pain after chikungunya's fever in the period from March to June of 2015. It was conducted describing the characteristics of clinical state, demographic, treatment and patient outcomes. Statistical analysis was performed with SPSS19.0 program. The qualitative variables were expressed as frequencies and percentages, quantitative variables in mean.

**Results:** 26 patients from the capital city and outskirts were included, 92% of females with the average age of 47.2 years old. The average duration of acute fever was 2.86 days. The predominant symptoms were headache (76.9%), joint pain (92.3%). 92.3% had skin rash in the acute stage, with an average duration of 4.5 days. The joint symptoms began after an average of 14 days after the fever started. The metacarpal phalangeal and interphalangeal joints were affected in 73% of patients, the radiocarpal joints and knees in 76.9%, shoulders in the 50% and feet in 92.3%.
All patients were treated with NSAIDs and 20/26 patients (76.9%) was added prednisone at a dose of 40 mg/day with fast and gradual tapering treatment in two weeks, with 92.3% with partial or total relief of symptoms. In 2 patients (7.6%) was decided to add methotrexate for recurrence of the arthritis, whit the decrease of corticosteroids doses.
**Conclusions:** Chikungunya's fever is a major public health problem with increasing cases reports in urban areas, especially for its ability to generate medium and long-term rheumatological complications. It is important to mention the high frequency of hand and feet involvement, leading to several degrees of disability as well impairments, even laboral absenteeism because of the intensity of the pain.
Even though the follow-up period is short, it is highlighted the excellent response to this treatment with short time of corticosteroids, although it is needed a longer follow up to define the appropriate treatment according to the evolution and outcome of cases, and with this develop protocols for such cases.
**Disclosure of Interest:** None declared

## FRI0495 THE COMBINED PREVALENCE OF RARE DISEASES IN RHEUMATOLOGY DEMONSTRATES A SUM MORE THAN DOUBLE TO THAT OF ANKYLOSING SPONDYLITIS

J. Leyens[1], C. Stieber[1,2], T.T.A. Bender[1], M. Mücke[1,3], M.F. Seidel[1,4]. *[1]Center for Rare Diseases Bonn (ZSEB), University Hospital of Bonn; [2]Institute of Human Genetics, University Hospital of Bonn; [3]Department of Palliative Medicine, University Hospital Bonn; [4]Department of Oncology, Hematology and Rheumatology, Medizinische Klinik III, University Hospital Bonn, Bonn, Germany*

**Background:** Rare diseases (RD) in rheumatology are heterogeneous and thus lack a systemic classification. By definition, prevalences of RD range up to 5/10 000 in Europe. Clinical courses comprise a vast variety of musculoskeletal symptoms such as arthritis, myositis, vasculitis, autoimmune organ involvement and bone diseases. The impact of RD for health care systems is widely unknown and individual patients are prone to unsatisfactory diagnoses and/or treatments.
**Objectives:** The objective of this study was to identify and classify RD in rheumatology and estimate their combined prevalence. The data may give a better understanding for this area of rheumatology, may aid specified centers for RD, and perhaps sharpen the overall perception of health care systems.
**Methods:** Databases (pubmed.org, abstract archives of the European League Against Rheumatism and the American College of Rheumatology, and Orpha.net) were searched for the following terms: rare in combination with arthritis, arteritis, connective tissue disease, rheumatic and vasculitis. Furthermore, terms were used in various combinations including arthralgia, autoimmune, fever, inflammation, joint pain, muscle pain, myalgia and swollen joint. Identified syndromes were then classified according to the following terms and data: differential diagnosis, etiology, genetics, prevalence, principal symptom, prognosis, and therapy. The overall total point prevalence for all RD in rheumatology was estimated by adding up all single point prevalences available.
**Results:** A total of 82 syndromes and diseases were identified. Classification was as follows: arthritis (n=17) and vasculitis (n=18), fever syndromes (n=13), collagen diseases (n=10), myositis (n=9), and overlaps/others (n=15). Fifty-two diseases showed a chronic progressive course. The mortality was variable in many diseases and thus could not be determined precisely. Point prevalence data were available for 49 syndromes and diseases, and added up to a total point prevalence of 49/ 10 000. Forty-nine of these in part pathophysiologically quite distinct RD are treated with corticosteroids.
**Conclusions:** Rare diseases in rheumatology are most often chronic or progressive. Symptoms are variable, they include arthritis, organ and skin involvement. The estimated combined prevalence of all RD in rheumatology is significant with 49/10 000: it is double or more than that of ankylosing spondylitis with 18/10 000 [(1)]. Treatment options are often restricted to corticosteroids presumably because of the scarcity of randomized controlled trials. Health care systems should assign RD the same importance as any other common disease in rheumatology.

## FRI0496 LONG TERM SAFETY AND EFFICACY OF ANAKINRA IN ADULT PATIENTS WITH REFRACTORY RECURRENT IDIOPATHIC PERICARDITIS

K. Antonatou[1], P. Vasileiou[2], C. Koutsianas[1], G. Lazaros[2], D. Vassilopoulos[1]. *[1]Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory; [2]1st Department of Cardiology, National University of Athens Medical School, Athens, Greece*

**Background:** Our previous open label study has shown that IL-1 inhibition with anakinra was an efficacious, safe and steroid-sparing agent for the short term treatment of refractory recurrent idiopathic pericarditis in adults. However long term data are not available in such patients.
**Objectives:** The aim of this study, which is a follow-up of the initial cohort of patients, was to assess the long term safety and efficacy of Anakinra in adult patients with refractory recurrent idiopathic pericarditis.
**Methods:** Eleven patients with treatment-resistant idiopathic recurrent pericarditis were included (a new patient was added to the initial cohort of 10 patients). All patients were resistant and/or intolerant to previous treatment with aspirin and/or NSAIDs, colchicine and corticosteroids (CS) while two (18%) had failed azathioprine therapy. Initially all were treated with daily subcutaneous injections of Anakinra (100 mg) with gradual tapering of the administered dose (daily for 6 months, followed by every other day for 6 months). Recurrences as well as adverse events were recorded in all patients.
**Results:** Among the 11 patient included there were 6 males with a mean age of 42 ± 16.8 years and a median disease duration of 37 months. Patients had a median of 8 recurrences prior to Anakinra initiation and were CS-resistant (mean daily prednisolone dose at baseline: 14.7 ± 7.6 mg). Patients were followed for a period of approximately 3 years (median follow-up time: 35 months). All patients responded initially to Anakinra and all were able to discontinue CS rapidly (median time to discontinuation: 6 weeks). During the long term, follow-up, 3 patients discontinued anakinra (27.5%) and remain free of recurrences without any treatment ever since. Five patients (45%) remain on a reduced dose of Anakinra (once a week n=1, twice a week n=1, three days a week n=1, four days a week n=2). Most recurrences occurred while the dose of Anakinra was reduced from three to two injections per week (mean number of recurrences: 2.2 ± 1.4). Three patients continue on full dose Anakinra (one had started therapy 3 months ago). None of these patients had restarted CS. No significant side effects were seen during the long term follow up of these patients and no patient discontinued therapy due to side effects.
**Conclusions:** During long term follow-up, Anakinra remains a highly efficacious and safe medication for the treatment of refractory recurrent idiopathic pericarditis in adults. All patients remain CS-free and more than a quarter (27.5%) of them were able to discontinue all therapies. Approximately half remain on a reduced dose Anakinra with excellent disease control.

## FRI0497 THE INTERLEUKIN-1 INHIBITOR CANAKINUMAB FOR FAMILIAL MEDITERRANEAN FEVER: LONG-TERM BENEFICIAL EFFECT IN A COHORT OF 14 PATIENTS

K. Laskari[1], P. Boura[2], G.N. Dalekos[3], A. Garyfallos[4], D. Karokis[5], D. Pikazis[6], L. Settas[7], G. Skarantavos[8], E. Tsitsami[9], P.P. Sfikakis[1]. *[1]Rheumatology Unit, 1st Dept. of Propaedeutic Internal Medicine, Athens University Medical School, Athens; [2]Clinical Immunology Unit, 2nd Dept. of Internal Medicine, Aristotle University Medical School, Thessaloniki; [3]Department of Medicine, Thessaly University Medical School, Larissa; [4]4th Department of Internal Medicine, Aristotle University Medical School, Thessaloniki; [5]Private rheumatologist, Patras; [6]Department of Pathophysiology, Athens University Medical School, Athens; [7]First Dept. of Internal Medicine, Rheumatology Section, Aristotle University Medical School, Thessaloniki; [8]Bone Metabolic Unit, 1st Dept. of Orthopedics; [9]First Department of Pediatrics, Athens University Medical School, Athens, Greece*

**Background:** Interleukin-1 (IL-1) is a major mediator of the inflammatory cascade in Familial Mediterranean Fever (FMF) and an established therapeutic target (1).
**Objectives:** To assess the efficacy and safety of the IL-1 inhibitor Canakinumab in adult and adolescent patients with refractory FMF.
**Methods:** Fourteen patients (7 men) with genetically confirmed FMF, fulfilling the Tel Hashomer criteria, aged 38.5 years (median, range 13–70), with median disease duration of 14 years and active disease despite colchicine (n=9) or both colchicine and anakinra (n=5), received Canakinumab 150mg subcutaneously (sc) every 4 (n=7) or 6 (n=2) or 8 weeks (n=5) for a median of 18 months (range 7–53). Canakinumab was given as monotherapy in 8; 6 patients received concomitant treatment with colchicine and/or corticosteroids.
**Results:** Eleven out of 14 patients (79%) achieved complete clinical remission (median time 2 months), while normalization of all laboratory parameters associated with inflammation occurred in 92% of patients (median time 3 months). The remaining patients achieved partial responses. Response was maintained until the last visit in all but 4 patients. Reducing the Canakimumab administration

interval led to suppression of disease activity in three cases, whereas in another two patients drug administration intervals could be increased without disease exacerbation. The corticosteroid dose was significantly reduced during follow up. The FMF50 score (2) was achieved by 50% and 86% of patients at 1 and 12 months, respectively. Canakinumab was well tolerated; one patient experienced an urinary tract infection and another one a viral gastroenteritis.

**Conclusions:** The rapid and sustained response to Canakinumab in the majority of our patients, together with the favorable safety profile, encourages its further use in FMF.

## FRI0498 CLINICAL CHARACTERISTICS OF IGG4-RELATED DISEASE: A RETROSPECTIVE ANALYSIS OF 166 CHINESE PATIENTS

K.-H. Yu. *Rheumatology, Chang Gung Memorial Hospital, Kuei-Shan, Taiwan, Province of China*

**Background:** Since the initial recognition of autoimmune pancreatitis (AIP), elevated serum IgG4 levels and increased numbers of IgG4-positive plasma cells in tissues have been regarded as diagnostic hallmarks of the disorder. However, the role of the IgG4 level in other non-AIP IgG4-RD is unclear.

**Objectives:** To investigate the clinical features and factors associated with IgG4 test positivity over an 8-year period in 166 patients with IgG4-related diseases (IgG4-RD).

**Methods:** The medical records of 2,968 adult subjects who underwent serum IgG4 level tests conducted between December 2007 and August 2014 were reviewed.

**Results:** Among 2,968 patients, 166 (5.6%) were diagnosed with IgG4-RD and 2,802 (94.4%) were determined to have other diseases (non-IgG4-RD group). The mean IgG4 level in subjects with IgG4-RD was 1087.5 mg/dL (median: 597.0, range: 15–6790 mg/dL), which was significantly higher than that of subjects with non-IgG4-RD (mean: 104.1, median: 75.0, range: 1–4400 mg/dL; $p<0.0001$). Among the 166 IgG4-RD patients, the mean age was 58.5 ± 15.9 years (range: 21–87). Of 166 patients with IgG4-RD, 87 (52.4%) had an IgG4-RD other than autoimmune pancreatitis (non-AIP IgG4-RD). Twenty-seven out of 166 IgG4-RD (16.3%) patients had other organ involvement (OOI) outside of the pancreatobiliary system. IgG4 levels were elevated (>135 mg/dL) in 143 (86.1%) of 166 patients with IgG4-RD and in 652 (23.3%) of 2,802 patients with non-IgG4-RD ($p<0.001$). The present study showed that the best IgG4 cutoff was 222 mg/dL for the diagnosis of IgG4-RD.

**Conclusions:** In the present study, we demonstrated that more than half of the diseases associated with IgG4-RD were non-AIP IgG4-RD. Among the 166 IgG4-RD patients, the manifestations covered the full range of organ system involvement. Moreover, the best IgG4 cutoff (measured with nephelometry using a Siemens BN ProSpec instrument and Siemens reagent) was 222 mg/dL for IgG4-RD.

**Disclosure of Interest:** None declared

## FRI0499 LONG TERM SURVIVAL OF IMMUNOSUPPRESSIVE THERAPIES IN UVEITIS PATIENTS

A. Gómez-Gómez [1], Z. Rosales-Rosado [1], L. Arietti-López [1], P. Arriola-Villalobos [2], C. Lopez-Abad [2], E. Pato-Cour [1], L. Rodriguez-Rodriguez [1]. *[1] Rheumatology; [2] Ophthalmology, Hospital Clinico San Carlos, Madrid, Spain*

**Background:** Uveitis encompasses a diverse group of inflammatory diseases associated with a significant risk of substantial and sometimes permanent visual loss. Although corticosteroids are the initial treatment, immunosuppressive therapy (IST) may be needed in case of inadequate response and/or side-effects. Most of the data regarding efficacy, tolerability and discontinuation rates of ISD in uveitis patients comes from clinical trials, as data from observational studies in uveitis are scarce. However, it is important to take into account that the trial settings are different from day-to-day clinical practice, which limits the validity of the extrapolated data to patients in daily practice.

**Objectives:** To assess the long-term survival of ISTs in uveitis patients in real-life clinical practice. Factors associated with discontinuation were also analyzed.

**Methods:** An observational retrospective longitudinal study of uveitis patients taking ISTs from 1989 to 2014 was conducted. The primary endpoint was IST discontinuation due to: clinical improvement, inefficacy, adverse drug reaction (ADRs), and other causes. Incidence rates of discontinuation (IR) per 100 patient-years were estimated. Variables associated with specific causes of discontinuation were analyzed using Cox bivariate and multivariate models.

**Results:** We included 225 courses of IST in 95 patients (565.3 patient-years of observation). Cyclosporine [62 patients (65.3%)], methotrexate [44 (46.3%)], azathioprine [28 (29.5%)], and anti-TNFs [30 (31.6%)] were the most frequently used. Treatment was suspended in 116 cases (IR 20.5 with 95% confidence interval [17.1 to 24.6]). In the first year of therapy 75% continued on IST, and after ten years, the retention rate was 16%. The IRs due to clinical improvement, inefficacy and ADRs were 8.0 [5.9 to 10.7], 5.1 [3.6 to 7.4], and 4.4 [3.0 to 6.5], respectively. The IRs of all cause discontinuation for cyclosporine, methotrexate, azathioprine, and anti-TNFs were 21.7 [16.3 to 28.8], 10.9 [7.3 to 16.3], 18.7 [12.4 to 28.2], and 24.1 [16.0 to 36.2] per 100 patients-year, respectively.

In the multivariate analysis, combined therapy was associated with a higher rate of discontinuation, regardless the cause. Presence of vasculitis was associated with a higher rate of discontinuation due to clinical improvement, and presence of macular edema was associated with higher risk of discontinuation due to inefficacy.

**Conclusions:** The major causes of IST discontinuation in cohorts of uveitis patients were clinical improvement and inefficacy. Methotrexate showed the lowest rate of discontinuation, while anti-TNFs showed the highest rate.

Combine therapy with IST was associated with higher discontinuation rate regardless the cause. Presence of vasculitis and macular edema were associated with a higher risk of discontinuation due to clinical improvement and inefficacy, respectively.

## FRI0500 IDIOPATHIC GRANULOMATOUS MASTITIS: A SINGLE CENTER EXPERIENCE

M. Cinar [1], S. Yilmaz [1], M. Cakar [1], S. Pay [2]. *[1] Division of Rheumatology, Gulhane Military Medical Academy, School of Medicine; [2] Division of Rheumatology, Yüksek Ihtisas University, Special Koru Hospital, Ankara, Turkey*

**Background:** Idiopathic granulomatous mastitis (IGM) is a rare benign inflammatory disease of the breast. Difficulties can be experienced in the treatment of IGM due to the lack of a common consensus in the literature. Treatment options include corticosteroids, surgical treatment, immunosuppressive drugs and conservative treatment with antibiotics.

**Objectives:** To present our experience about patients with IGM on immunosuppressive therapy.

**Methods:** The data of patients with a diagnosis of IGM under immunosuppressive therapy followed in the rheumatology outpatient clinic of a tertiary center enrolled between September 2010 and August 2015 were evaluated retrospectively. 16 histopathologically diagnosed patients receiving immunosuppressive therapy were evaluated for their treatments and treatment responses.

**Results:** The mean age of the patients, the average duration of immunosuppressive therapy and the average follow-up period were 35.9±6.5 years, 19.6±14.1 months and 28.3±17.8 months, respectively. Initially, 15 patients received (93.8%) steroids and methotrexate, and 1 patient (6.2%) was treated only with steroids. All patients responded well to initial therapy. Eight (53.3%) patients achieved remission with steroid + methotrexate. 2 of the other 7 patients relapsed after discontinuation of steroids and 1 after discontinuation of steroid + methotrexate. A positive response was obtained after the restart of treatment with steroids and methotrexate in these patients. Of these 7 patients, no recurrence was observed in 3 (42.9%) patients with only methotrexate and in 4 (57.1%) patients in the maintenance treatment with steroids and methotrexate. Lowered dose of steroid was associated with recurrence during follow-up of the patient taking only steroids as the initial treatment. 5 patients (33.3%) taking methotrexate had drug side effects, not necessitate stopping the treatment.

**Conclusions:** Systemic immunosuppressive therapy is safe and effective in IGM. Azathioprine and methotrexate have been the most frequently used immunosuppressive drugs in the literature. Our experience with methotrexate-based regimen allows the rapid reduction of the steroid dose and leads to remission.

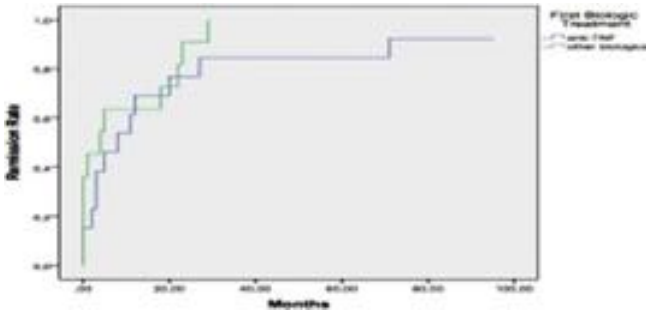
## FRI0501 INVESTIGATION OF JOINT HYPERMOBILITY IN INDIVIDUALS WITH INDIRECT HYPERBILIRUBINEMIA AND ACROCYANOSIS

M. Cinar [1], M. Cakar [1], K. Ozturk [2], S. Yilmaz [1], A. Dinc [3]. *[1] Division of Rheumatology; [2] Department of Gastroenterology, Gulhane Military Medical Academy, School of Medicine; [3] Rheumatology Center, Patio Clinic, Ankara, Turkey*

**Background:** Hypermobility represents the excessive mobility of the joints. Joint hypermobility syndrome (JHS) is defined as the musculoskeletal symptoms in individuals with hypermobility in the absence of any systemic rheumatic disease, and the incidence in the general population is about 0.5%. A biochemical or structural disorder affecting collagen synthesis is assumed as an underlying mechanism in hypermobility syndrome. In animal studies, bilirubin has been shown to reduce fibrosis induced by bleomycin. In these studies, it is suggested that bilirubin leads to hypermobility by affecting the structure or function of

collagen. In addition, our observation in clinical practice is that hypermobility and acrocyanosis is more common in patients with indirect hyperbilirubinemia.
**Objectives:** This study aimed to evaluate the frequency of hypermobility and acrocyanosis in patients with indirect hyperbilirubinemia.
**Methods:** The study recruited 120 consecutive patients with indirect hyperbilirubinemia examined in gastroenterology outpatient clinics of a university hospital and 107 healthy individuals as a control group with normal bilirubin levels. Patients were examined for the presence of hypermobility and acrocyanosis. Hypermobility was determined by using Beighton scoring (Score, 0–9). To conclude whether the JHS was present, Brighton criteria were used. Acrocyanosis was identified by history and compatible physical examination.
**Results:** The mean age of the patients and the control group enrolled in the study were 33.4 ± 12.9 and 36.2 ± 11.2 years, respectively (p=0.09). 100 of the patients (83%) and 78 (73%) of the control group of were males (p=0.075). The average indirect bilirubin levels of the study and control groups were 1.44 ± 0.66 mg/dL and 0.37 ± 0.18 mg/dl, respectively. By Beighton scoring, 23 patients (19.2%) in the study group and 3 (2.8%) individuals in the control group had joint hypermobility. The difference between groups was statistically significant ($p<0.001$). 4 patients in the study group and 1 individual in the control group had JHS, and the difference was not statistically significant (p=0.220). In 35 (29.2%) of study patients and 12 (11.2%) individuals in the control group had acrocyanosis. The difference between groups was statistically significant (p=0.001). Joint hypermobility did not have any significant relationship with the presence of acrocyanosis (p=0.441).

Image 1. Beighton scoring system. Each of these movements can be made is regarded as one point.



**Conclusions:** According to the results of our study, joint hypermobility and acrocyanosis is more frequent in patients with indirect hyperbilirubinemia compared to controls. This finding suggests that bilirubin has a role in both diseased. It should be determined whether they share a common or difference pathogenic pathway.

## FRI0502 BIOLOGIC AGENTS IN REFRACTORY ADULT STILL'S DISEASE: BETTER RESPONSE RATES AND ACCEPTABLE SAFETY WITH ANAKINRA AND TOCILIZUMAB

B. Toz[1], M. İnanç[1], N. Senturk[2], B. Erer[1], B. Artım Esen[1], S. Kamali[1], L. Ocal[1], A. Gül[1]. *[1]Division of Rheumatology Istanbul School of Medicine, Istanbul University; [2]Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey*

**Background:** There is no randomized controlled trial data to guide us for the management of Adult Still's Disease (AOSD) patients refractory to conventional treatments.
**Objectives:** We herein aimed to analyze retrospectively the treatment results of a series of refractory AOSD patients, who received different biologics.
**Methods:** We screened our database for patients diagnosed with AOSD between 1987–2015, and reviewed charts of those patients refractory to corticosteroid and DMARD combination and received biologics including TNF, IL-1 and IL-6 inhibitors. Patients were grouped according to their first biologics as TNF-inhibitors (TNF-i) or others [anakinra (ANK) or tocilizumab (TCZ)]. We also analyzed the patient responses according to their disease course characteristics as polycyclic or chronic patients. Time to remission were analysed by Kaplan-Meier method, and the association of response with first biological treatment was analysed by regression analysis
**Results:** Twenty-four patients with refractory AOSD (chronic=9 and polycyclic=15),who received biologic treatments with a mean duration of 41±27 months. The first biological treatment was TNF-i in 14 and other agents in 10 (ANK in 7 and TCZ in 3).Of the patients,50% were switched from TNF-i to ANK or TCZ. Comparison of the patients according to their first biologic therapy is given in Table 1. The patients who received other biologics were associated with a better response as the first treatment and tended to achieve remission earlier compared with those who received TNF-i as their first biological treatment (median time to remission 4 vs, 8 months, log-rank p=0.44). Joint involvement was more common and skin involvement tended to be more common in the chronic course group (100% vs 50%,78% vs 36%, respectively). While the duration of biologic treatment tended to be longer in the chronic course group (51 mo vs 28 mo,p=0.04), duration of remission was similar between the groups (26 mo vs 20 mo, p=0.4). The remission rate tended to be higher in the polycyclic group, whereas CRP and ESH tended to be lower in the chronic group. Complete remission rates under biologics course were as follows: 63% with TCZ 8mg/kg (7/11), 61% with ANK 100–200mg (11/18), 27% with etanercept (3/11), and 9% with infliximab (1/11) treatments. Regression analysis showed that selection of TCZ or ANK biologics as the first biologic was associated with a better response independent of the disease course type (estimate 2.5, 95% CI 0.3–4.7, p=0.026).No serious infection was observed in patients treated with biologics. In two patients severe skin reactions occurred with ANK and infliximab and, in one patient an immune thrombocytopenia developed under TCZ treatment.

| | TNF inhibitors (n=14) | Anakinra ( n=7) or Tocilizumab (n=3) |
|---|---|---|
| Current age (years) | 37±13 | 35±10 |
| Age at diagnosis (years) | 26 (20–59) | 26 (5–46) |
| Follow up (months) | 72 (18–252) | 54 (26–288) |
| Gender (% males) | 31 | 46 |
| Sore throat (%) | 54 | 73 |
| Skin involvement (%) | 54 | 46 |
| Joint involvement (%) | 85 | 55 |
| Hepatotoxicity (%) | 31 | 46 |
| CRP (mg/L) | 115±88 | 131±78 |
| ESR (mm/h) | 101±30 | 102±32 |
| Ferritin (ng/ml) | 1000 (281–29979) | 1280 (424–5181) |

**Conclusions:** This case series of AOSD patients suggest that ANK and TCZ seem to be better treatment choices in terms of remission rate and time to remission in patients refractory to conventional treatments
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4994

## FRI0503 EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH CRYOPYRIN ASSOCIATED PERIODIC SYNDROMES: AN OPEN-LABEL, PHASE-III, EXTENSION STUDY

P.A. Brogan[1], M. Hofer[2], J.B. Kuemmerle-Deschner[3], B. Lauwerys[4], A. Speziale[5], K. Leon[6], X. Wei[7], R. Laxer[8]. *[1]Department of Infection Inflammation and Rheumatology, UCL Institute of Child Health, and Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom; [2]Unité Romande de Rhumatologie Pédiatrique, Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [3]University Hospital Tuebingen, Tuebingen, Germany; [4]Cliniques Universitaires Saint Luc and Université Catholique de Louvain, Brussels, Belgium; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corporation, New Jersey, United States; [7]Novartis Pharma, Beijing, China; [8]University of Toronto, The Hospital for Sick Children, Toronto, Ontario, Canada*

**Background:** Cryopyrin-Associated Periodic Syndrome (CAPS), a rare hereditary auto inflammatory disorder, constitutes 3 phenotypes: familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and chronic infantile neurologic cutaneous and articular syndrome/neonatal onset multisystem inflammatory disease (CINCA/NOMID).[1] Canakinumab (CAN), a fully human monoclonal anti-human interleukin-1β (IL-1β) antibody is indicated for the treatment of CAPS patients (either ≥2 years or ≥4 years with body weight ≥7.5 kg.[2] Here, we present longer-term efficacy and safety of CAN in patients with CAPS aged >24 months.
**Objectives:** To assess long-term efficacy of CAN with respect to relapse in CAPS patients who completed the core (CACZ885D2307) study
**Methods:** CAPS pts (aged ≥1 years), who completed the core study, received a starting dose of 2 mg/kg s.c. of CAN every 8 weeks, in continuation with the core study. Patients who received a dose adjustment in the core study were allowed to continue same dose in the extension trial. Efficacy was evaluated by physician's global assessment (PGA), C-reactive protein (CRP) and serum amyloid A (SAA) levels. Safety was assessed in terms of adverse events (AEs).
**Results:** Of 17 pts enrolled, 12 (70.6%), 4 (23.5%) and 1 (5.9) were of MWS, NOMID and FCAS phenotypes, respectively. All 17 pts were complete responders; 16 (94.1%) had no relapse and 1 (5.9%) NOMID patient had a relapse at the end of study (EOS). PGA improved over the extension study with decline in severity

till EOS. The number of pts with absent autoinflammatory disease improved from 23.5% (4 pts) to 64.7% (11 pts). This improvement was also observed in the assessment of skin rash; proportion of patients with absent skin disease increased from 29.4% (5 pts) to 94.1% (16 pts). The mean decrease in CRP and SAA levels from baseline were -10.4mg/L and -54.36/L respectively. Overall, 10 (58.8%) pts had AEs suspected to be related to study drug; the most common were diarrhoea, pneumonia, rhinitis and cough (3 pts each). Eight (47.1%) pts experienced at least 1 Serious AE (4 MWS and 4 NOMID pts); with pneumonia being the most common 2 (11.8%). No deaths were reported during the study.

**Conclusions:** CAN effectively maintained clinical and serological efficacy in CAPS pts. No new safety findings were observed and the safety profile of CAN was consistent with previous studies, which corroborates the long-term use of CAN in the treatment of CAPS patients.

## FRI0504 PROGNOSTIC FACTORS OF ADULT ONSET STILL'S DISEASE: ANALYSIS OF 100 CASES IN 3 TERTIARY REFERRAL CENTERS

P. Ruscitti[1], P. Cipriani[1], F. Ciccia[2], F. Masedu[3], D. Iacono[4], V. Liakouli[1], G. Guggino[2], F. Carubbi[1], O. Berardicurti[1], P. Di Benedetto[1], M. Valenti[3], G. Triolo[2], G. Valentini[4], R. Giacomelli[1]. *[1]Division of Rheumatology, University of L'Aquila, L'Aquila; [2]Division of Rheumatology, University of Palermo, Palermo; [3]Division of Medical Statistic Unit, University of L'Aquila, L'Aquila; [4]Division of Rheumatology, Second University of Naples, Naples, Italy*

**Background:** Adult onset Still's disease (AOSD) is rare inflammatory disease [1]. Three different patterns of AOSD have been identified: i. monocyclic pattern, characterized by a systemic single episode; ii. polycyclic pattern, associated with multiple flares, separated by remissions; iii. chronic pattern, related to a persistently active disease with associated polyarthritis [2]. Until now, the treatment of AOSD remains largely empirical, lacking controlled clinical trials [1].

**Objectives:** We aimed to investigate clinical data of AOSD patients and any possible correlation among these features and the outcome of patients.

**Methods:** Clinical data of 100 AOSD patients were recorded. All patients fulfilled the Yamaguchi AOSD diagnostic [3]. Gender, age, clinical features, disease activity Pouchot's score [4], complications, serum ferritin, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP), treatments, comorbidities, patterns and AOSD-associated death, were reported. Furthermore, we evaluated any possible correlation among these clinical features and the outcome of patients, by using linear regression analysis.

**Results:** One hundred consecutive AOSD patients (66 men, 34 women), whose age at diagnosis was 45.35±16.23 (mean±SD), were enrolled. All patients experienced fever, 86 patients showed joints involvement, 79 patients showed splenomegaly, skin rash was present in 78 patients, 62 patients showed hepatic involvement, 57 patients showed enlargement of lymph nodes. The Pouchot's score, 6.11±2.02 (mean±SD), confirmed the activity of the disease. Sixteen patients experienced different complications, mainly the macrophage activation syndrome. A strong increase of inflammatory markers (mean±SD) was observed: serum ferritin was 2560.07±3726.64 ng/mL, ESR was 67.28±26.65 mm/hr, CRP was 78.35±72.76. All the patients received steroids at different dosages, and 55 patients were treated with steroids and immunosuppressive drugs, mainly methotrexate and ciclosporin. Thirty-two patients were treated with biologic agents: 5 with anakinra, 8 with tocilizumab, and 19 with TNF inhibitors. Twenty-nine patients showed the monocyclic pattern, 22 patients showed the polycyclic pattern, 33 patients showed the chronic pattern. AOSD-associated death occurred in 16 patients. Regression analysis showed that Pouchot's score ($p=0.011$), the presence of any complication ($p<0.0001$) and associated comorbidities ($p<0.0001$) correlated with the unfavorable outcome.

**Conclusions:** This study provides information on the clinical, laboratory, therapeutic, and prognostic features in a large cohort of AOSD patients. The Pouchot's score, the presence of complications and comorbidities were significantly associated with the AOSD-associated death.

## FRI0505 UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE: A 121 PATIENTS AUDIT FOCUSING ON INITIAL DIAGNOSIS AND CHANGES OVER TIME

R. Ionescu[1,2], M. Leandro[1,3]. *[1]Rheumatology, University College London Hospitals, London, United Kingdom; [2]Rheumatology and Internal Medicine, Sfanta Maria Hospital, Bucharest, Romania; [3]Rheumatology, University College London, London, United Kingdom*

**Background:** The diagnosis of Undifferentiated Connective Tissue Disease (UCTD) has raised controversy over the years regarding making the diagnosis, evolution and prognosis. Le Roy et al[1] in 1980 and most recently Mosca et al[2] in 2014 proposed classification criteria for UCTD, but confusion still exists regarding making the diagnosis of UCTD, evolution and prognosis of the syndrome and how the patient should be followed up over time.

**Objectives:** Evaluate disease evolution, treatment and follow up plan in patients with UCTD diagnosis. Assess whether there are any factors that may predict disease evolution and should require regular follow up.

**Methods:** This was a retrospective study of patients followed up in a specialist clinic in a tertiary referral centre (University College London Hospitals) with a diagnosis of UCTD, focusing on clinical and serological features, treatment, follow up and disease evolution over time.

**Results:** A total of 121 patients were included in the study: 93% were females; the mean age at disease onset was 39 years (range 20 to 80); and the patients were followed up for at least 1 year (mean 12 years, range 1 to 40). 78% of these patients had a stable diagnosis of UCTD, while in 22% diagnosis changed over time: 9% evolved into a specific connective tissue disease (CTD) - 4 Systemic Lupus Erythematosus, 3 Sjogren's Syndrome, 1 Rheumatoid Arthritis, 1 Systemic sclerosis and 1 Anti-synthetase Syndrome -, 7% had a change of diagnosis from a specific CTD to UCTD, 4% evolved into an overlap syndrome and 2% of the patients were no longer diagnosed as having any CTD at the end of the study. The most prevalent manifestations were joint pain (arthralgia/arthritis) in 89% of the patients, fatigue 80%, Raynaud's phenomenon 63%, skin rashes 49% and sicca symptoms 45%. Lung involvement was observed in 11% of the patients within which 8% had a nonspecific interstitial pneumonia (NSIP) and 3% had a usual interstitial pneumonia (UIP) pattern. 36% of the patients were noted to have associated gastro-oesophageal reflux disease. Serological features included positive ANA in 98%, anti-RNP 33%, anti-Ro 32%, Rheumatoid Factor 20% and hypocomplementemia was observed in 19% of the patients. 7% of the patients did not require any treatment for their UCTD, but the majority of patients were treated with Hydroxychloroquine only (75%), and the rest with other immunosupressants/immunomodulators.

**Conclusions:** In our study the majority of patients initially diagnosed with UCTD kept this diagnosis over time but 13% of patients evolved to a defined CTD or an overlap syndrome and in 2% of patients, symptoms and serological features eventually resolved. Although, UCTD is often mild, significant major organ involvement such as interstitial lung disease can occur[3], as well as evolution to a defined CTD or overlap syndrome. This should guide follow up of these patients in clinic.

## FRI0506 PREGNANCY IN PATIENTS WITH UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE: CLINICAL OUTCOMES IN 78 CASES

R. Vagelli[1], C. Tani[1], L. Carli[1,2], D. Totti[1], M. Tristano[1], F. Strigini[1], M. Mosca[1]. *[1]Clinical and Experimental Medicine, University of Pisa, Pisa; [2]GenOMeC PhD, University of Siena, Siena, Italy*

**Background:** Pregnancy is considered to be an important factor that may affect the course of autoimmune diseases; few data are currently available in the literature on pregnant patients with diagnosis of undifferentiated connective tissue disease (UCTD).

**Objectives:** To assess the outcome of pregnancy and evaluate the percentage of disease flare in a cohort of patients with UCTD.

**Methods:** We conducted a prospective study on 78 pregnancies in 64 UCTD patients, regularly monitored from the positive pregnancy test until the postpartum period by a multidisciplinary team including rheumatologists and obstetricians at our unit from 2000 to 2015.

**Results:** The mean age of patients at pregnancy was 34.1 (range 21–43) and the mean disease duration was 7.26 years. Only 3 patients presented hematologic disease activity at the beginning of pregnancy and none of the patients had experienced previous renal involvement. 20.8% of UCTD patients presented antiphospholipid (aPL)-antibodies positivity (only 2 cases of triple positivity of LAC, anti-β2GPI and ACLA) and the same percentage had anti-Ro positivity.

At the beginning of pregnancy 38.5% of patients was taking treatment: 20 hydroxychloroquine, 13 low doses of steroids and 11 aspirin. On average, the duration of pregnancy was 39 weeks (range 34–42), the mean birth weight was 3118.3 g (range 2122–4500 g). Eight pregnancies (10.5%) ended in miscarriage in the first trimester; the following obstetric complications occurred in 34.7% of the remaining successful deliveries: preterm delivery, small or large for gestational age (SGA/LGA), preeclampsia, premature membrane ruptures (PROM), increased transaminases. Six patients experienced a disease flare, 3 during pregnancy and 3 in puerperium: of these patients, 3 had a major flare progressing to SLE with the occurrence of lupus nephritis. No correlations were found between the incidence of obstetric complications and the positivity of aPL-antibodies, the use of steroids, the alterations of uterine artery Doppler velocimetry. The only variable correlated with the incidence of flare was the positivity of anti ds-DNA at the beginning of the pregnancy ($p<0.001$).

**Conclusions:** Our data suggest that UCTD as other connective tissue diseases should be carefully monitored during pregnancy as these patients present with obstetric complications. As in non pregnant UCTD patients anti-dsDNA are predictors of possible evolution to SLE, therefore these patients need careful monitoring during pregnancy.

## FRI0507 ANAKINRA TREATMENT IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: A SINGLE-CENTER EXPERIENCE

S. Ugurlu, H. Ozdogan, B. Ergezen. *Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey*

**Background:** Approximately 5 to 10% of FMF patients do not respond to colchicine treatment and/or intolerant to colchicine because of side effects. Several case reports and case series have pointed out the efficacy of IL-1 blockade in colchicine resistant FMF subgroup.

**Objectives:** To review the patients followed in our center with FMF who received Anakinra, an anti IL-1 receptor antagonist, in terms of outcome and side effects.

**Methods:** 36 FMF patients who were treated with Anakinra were retrospectively reviewed with regard to indication, effect on disease activity and acute phase response, adverse events. Patient global assessment was recorded before and after Anakinra treatment. Nine patients were pregnant at the time of the treatment and reported previously (1).

**Results:** There were 27 FMF patients with FMF who were treated with Anakinra for various indications (colchicine resistant recurrent febrile attacks in 21, colchicine related side effects in 6). The mean age of the 27 patients was 33.16±10.29 years. The mean duration of the disease was 19.29±10.94 years. There were various co-existing pathologies among this study group like Ankylosing Spondylitis (1), SLE (1), Behçet's disease (1) and Gout (1). The mean colchicine dose was 2.03±2.031 mg/d. The mean duration of anakinra treatment was 14,18± 18.39 months. Nine teen patients reported no attacks after anakinra treatment whereas 5 patients reported at least 50% decrease in the attack frequency and 3 patients reported less than 50% decrease in attack frequency. Mean patient global assessment decreased from 8,57±2,23 to 2,61±2,82 under Anakinra treatment ($p<0.001$)

As for the adverse events, four patients had allergic reactions under Anakinra treatment (severe disseminated rash in 1 patient and severe injection site reaction in 2 patients and tolerable injection side reaction in 1) therefore the treatment was terminated for 3 patients with severe allergic reactions. One patient had genital warts and urinary tract infection after the injections and Anakinra was stopped. One of our patients reported that her psoriatic lesions got worse on Anakinra. Twenty one patients reported no adverse events during the course of treatment.

Anakinra treatment was terminated in overall 11 patients for various reasons: Inadequate response in 3, allergic reactions in 3, flare in psoriatic plaques in 1, infection and genital warts in 1, full recovery in 2 and patient's preference in 1. Sixteen patients are still on Anakinra treatment.

**Conclusions:** Colchicine resistance or intolerance in FMF, although not very common, is an issue in daily rheumatology practice. During our experience with Anakinra, we reported remarkable decrease in the frequency of attacks in many patients with relatively tolerable side effects. Among patients whom Anakinra treatment was terminated, the most common reason was injection site reaction. We state that Anakinra is an effective alternative in patients with inadequate response or intolerance

## FRI0508 EXPERIENCE WITH INTERLEUKIN-1 INHIBITOR CANAKINUMAB IN AUTO-INFLAMMATORY DISEASES AND SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN CLINICAL PRACTICE

S.O. Salugina, M. Kaleda, E. Fedorov, I. Nikishina. *Children, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Interleukin-1 inhibitor Canakinumab (a humanized anti- Il-1β monoclonal antibody) is gaining wider use in Russian clinical practice recently for treatment of auto-inflammatory diseases (AIDs). Experience with Canakinumab for systemic juvenile idiopathic arthritis (SoJIA), considered as AIDs, is being accumulated as first and second line *biologic agents* therapy. In Russia Canakinumab was initially marketed in 2011 for cryopyrin-associated periodic syndromes (CAPS), in 2013 – for SoJIA.

**Objectives:** To assess efficacy and tolerability of Canakinumab in AIDs and SoJIA patients in clinical practice.

**Methods:** Use Canakinumab at our Institute was commenced in 2012 y. The study included 19 pts, among them 12 had AIDs (including CAPS – in 8 pts: MWS – in 6, and CINCA/NOMID- in 2 pts; TRAPS - in 3 pts; Schnitzler syndrome – in 1), 7 pts had SoJIA. Among AIDs pts there were 7 females and 5 males, 9 pediatric and 3 adult pts, 2 pts from pediatric population getting adult by the time of analysis. Mean AIDs pts age at inclusion was 18,6 y (3–44), infantile disease onset was recorded in 9 pts, in 6 out of them – it was a neonatal onset from the moment of birth. Two familial MWS cases were included. Disease duration ranged from 3 to 44 years. Genetic mutations were established in 9 pts, including: gene NLRP3- 6 (Thr436Ile, Thr438Ile, Thr350Met – in 4 pts (two familial cases)), gene TNFRSF1A - 3 (His51Tyr, Cys59Arg, Cys99Arg). All AIDs pts presented with rash, fever, conjunctivitis or uveitis (8), neurosensory deafness (4), arthritis symptoms (9), lymphadenopathy (7), CNS involvement in 2, abdominal pain (5), stomatitis (4), physical retardation in CINCA/NOMID pts, intellectual retardation and cognitive impairment in 1 patient. SoJIA pts were aged 3,5 -17,5 y.o. predominantly males (5), with disease duration 1 - 16 y. All pts presented with systemic manifestations, 4 pts had severe polyarthritis. Increased levels of acute phase markers were documented in all pts. Canakinumab efficacy was estimated based on changes in ESR, CRP and WBC count vs baseline.

**Results:** Canakinumab was administered s/c at 2–4mg/kg (max 150 mg) once every 8 weeks in AIDs pts, and at 4–6mg/kg (max 300mg) once in every 4 weeks in SoJIA pts. Canakinumab therapy duration in AIDs pts varied from 3mo to 2,5y, in SoJIA pts – from 9mo to 4y. Rapid clinical improvement was documented in all pts, with resolution of systemic manifestations and normalizing levels of acute phase markers. Prolonged ESR and CRP normalization was observed in one CINCA/NOMID patient. In 4 SoJIA pts arthritis manifestations were not sufficiently controlled. Canakinumab tolerability was satisfactory in all AIDs and SoJIA pts. No serious adverse reactions were documented. Canakinumab discontinuation in one SJIA patient was associated with secondary drug failure and onset of macrophages activation syndrome (MAS).

**Conclusions:** The single Federal Center experience with Canakinumab in clinical practice in AIDs and SoJIA pts demonstrated high efficacy and good tolerability of this medication. No serious adverse events were noted. In SoJIA pts Canakinumab use should be viewed as possible option at early stages of the disease with systemic and initial joint involvement, whilst efficacy in pts with advanced arthritis turned out to be insufficient.

## FRI0509 PREVALENCE OF SARCOIDOSIS AND AUTOINMUNE DISEASE IN NOT NECROTIZING GRANULOMATOSIS

V. Alende [1], B. Sopeña [1], J. Cameselle Teijeiro [2], A. Gonzalez Quintela [1]. *[1] Internal Medicine; [2] Pathology, Complexo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela, Spain*

**Background:** The diagnosis of not necrotizing granulomatosis (NNG) is very frequent in clinical practice. Physicians often focused their attention on sarcoidosis. However, there are many conditions that can cause this histological diagnosis, including infectous diseases, neoplasms or inflamatory diseases. There ara a few studies into the spectrum of pathologies that cause NNG; consequently, except for sarcoidosis, little information is available (1,2).

**Objectives:** This study has been designed to determine the prevalence of sarcoidosis and autoinmune diseases in not necrotizing granulomatosis.

**Methods:** We recolected all the tissue samples described as not necrotizing inflammation from 1 January 2010 to 31 december 2014 in the University Hospital of Santiago de Compostela. We recolected socio-demographic, analytical and tissue characteristics. We followed these patients and we described the final diagnosis.

**Results:** During the study period, a total of 290 samples of 207 patients were involved. The 50.7% were women, their mean age was 51,23 years. Concerning the sample origin, the distribution was as follows: skin 68 (32,9%), lymphadenopathy 55 (26,6%), Transbronchial biopsy 30 (14,5%), lung 12 (5,8%) and others 42 (20,2%). Concerning to final diagnosis, we found sarcoidosis 124 (59,9%); infectous diseases 16 (7,7%), including tuberculosis infection 8 (4,0%) and nontuberculous mycobacterial infection 3 (1,4%); Foreign body granulomatosis 13 (6,3%); neoplasms 12 (5,9%); autoinmune disease 6 (3,1%),

2 of them Wegener granulomatous (0,9%), 1 chronic polyarticular arthritis (0,5%), 1 Autoimmune hepatitis (0,4%), 1 systemic lupus erythematosus (0,5%) and 1 alopecia (0,5%); rosacea 3 (1,4%); Crohn disease 2 (0,9%); cheilitis 2 (0,9%) and amyloidosis 1 (0,5%). The diagnosis was not determinated in 12 patients (5,9%).
**Conclusions:** The prevalence of sarcoidosis in NNG is almost 50%. However, the autoinmune disease is considerably lower (2,5%), being Wegener granulomatous the most frequently reported autoinmue disease as it has been described in the literature. The alternative diagnosis most frequent was infectous diseases, including tuberculosis. In 90% of cases, final diagnosis was realized.

## FRI0510 LONG-TERM POST PARTUM FOLLOW-UP OF UNDIFFERENTIATED CONNECTIVE TISSUE DISEASES NEWLY DIAGNOSED DURING PREGNANCY

V. Ramoni[1], M. Romano[1], C. Rocchetti[1], B. Vitolo[1], F. Beneventi[2], C. Cavagnoli[2], E. Locatelli[2], M. Simonetta[2], C. Klersy[3], R. Caporali[1], C. Montecucco[1]. *[1]Rheumatology, IRCCS Policlinico S. Matteo; [2]Gynecology, IRCCS Policlinico S. Matteo; [3]Statistics, IRCCS Policlinico S. Matteo, Pavia, Italy*

**Background:** Undifferentiated connective tissue disease (UCTD) is a group of systemic autoimmune conditions not fulfilling the classification criteria for a definite connective tissue disease (CTD). While an average of 20–40% of UCTD patients develop a defined CTD during follow-up, the remaining patients maintain an undefined diseases.
**Objectives:** The objective was to assess flare or differentiation into well-defined CTD of UCTD newly diagnosed during pregnancy and to evaluate the prevalence of obstetric complications in the context of the new diagnosis.
**Methods:** We examined 54 patients with UCTD newly diagnosed during pregnancy, followed during pregnancy and after delivery at our rheumatologic unit. Diagnosis of UCTD was made at the time of pregnancy. Women in their first trimester ($T_0$) were screened using a two-step approach using a self-administered 10-item questionnaire, a subsequent testing for rheumatic autoantibodies (ANA, anti-dsDNA, ENA, anticardiolipin antibodies, anti-β2-glycoprotein I antibodies and lupus anticoagulant) and evaluation by a rheumatologist, who made the final diagnosis. The same questionnaire was re-administered at least one year after delivery ($T_1$) and the same rheumatic autoantibodies were tested at the same time.
**Results:** Fourty-two patients (77.77%) showed persistence or worsening of symptoms and 45 (83.33%) had at least one positivity for autoantibodies at $T_1$. The diagnosis of UCTD was confirmed in 29 patients (53.70%). Sixteen (16/54) women (29.62%) received a final diagnosis of another rheumatic disease: 12 patients with systemic lupus erythematosus (22.22%), 2 (3.70%) antiphospholipid syndrome, 1 (1.85%) spondyloarthritis and 1 (1.85%) Behçet disease. Amelioration of symptoms with a resulting unconfirmed diagnosis was seen among 9/54 (16.67%) of them. We then focused on the pregnancy that was ongoing at $T_0$. We observed some obstetrical complications: 3 miscarriages, 3 fetal loss, 6 hypertensive disorders, 4 intrauterine growth restriction, 6 preterm deliveries and 8 small for gestational age babies. These major obstetrical complications were not significantly different in the three different groups of new diagnoses. Also in the univariate analysis performed through Fisher's test for each single obstetric complication there was no significant difference between groups.
**Conclusions:** The questionnaire is an optimal screening method to detect undiagnosed rheumatic diseases in pregnancy, in particular UCTDs. Furthermore, in spite of their evolution or remission, UCTDs are always associated with negative effects on the outcome of pregnancy.

## FRI0511 THE EFFECT OF ATTACK FREQUENCY ON QUALITY OF LIFE (QOL) AND MENTAL HEALTH IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER (FMF)

M.E. Enecik[1], A. Omma[1], Y. Karaaslan[2]. *[1]Rheumatology, Ankara Numune Education and Research Hospital; [2]Rheumatology, Hitit University Medical Faculty, Ankara Numune Education and Research Hospital, Ankara, Turkey*

**Background:** FMF is an inherited autoinflammatory disease characterized by recurrent episodes of fever, acute serosal inflammation and pain. The QoL and mental health of FMF patients may be affected due to life-long disease, attack frequency, resistance of the disease, and severe complications such as amyloidosis.
**Objectives:** In this study, we investigated the effect of attack frequency on QoL and mental health (MH) in FMF patients.
**Methods:** A total of 149 patients (79 F, 70 M) diagnosed with FMF in Ankara Numune Education and Research Hospital Rheumatology Clinic, and 100 healthy controls (HC) (54 F, 46 M) were included in the study. Patients diagnosed with FMF according to Tel-Hashomer criteria. Mean±SD age of FMF patients is 36±10 year, and mean±SD age of HC is 35±8 year, NS. Mean±SD at onset of FMF patients is 17±4 year, and mean±SD age of disease duration is 107±71 months. FMF patients were classified as the ones that had >2, 1–2, and no attacks in the previous 3 months. The QoL was determined with SF-36, and MH was analyzed with Hospital Anxiety and Depression Scale (HADS). Student t test was used to compare FMF and HC groups for HADS-Anxiety (HADS-A) and HADS-Depression (HADS-D) scores, and physical component summary scores (PCSS), mental component summary scores (MCSS), and subscale scores of SF-36. One Way Anova was used to analyze FMF patients for HADS-A and HADS-D, and PCSS and MCSS of SF-36 in relation with attack frequency. The associations of age, gender, SF-36 and HADS scores in both groups, and comparisons of SF-36 and HADS scores in relation with age at diagnosis and duration of disease in FMF patients were analyzed with Pearson's correlation. $p<0.05$ was regarded as significant.
**Results:** The summary scores of SF-36, and HADS-A and HADS-D of FMF patients and HC are presented in Tables 1. SF-36 summary scores, and HADS scores of FMF patients in relation with attack frequency, and SF-36 subscale scores of FMF patients and HC are presented in Table 2 and Figure 1. There were no significant correlations among age and gender, and QoL and mental health scores in either group. PCSS and MCSS of SF-36 were significantly lower, and HADS-A and HADS-D scores were significantly higher in FMF patients compared to HC ($p<0.001$). In addition, attack frequency showed negative correlations with PCSS and MCSS, and positive correlations with HADS-A and HADS-D in FMF patients ($p<0.001$). PCSS and MCSS showed negative correlations with HADS-A and HADS-D in FMF patients ($p<0.001$). Age at diagnosis and duration of disease were not correlated with QoL or MH scores.

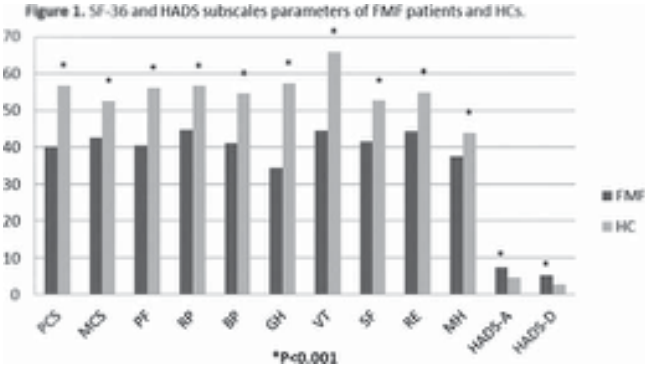

Table 1. Comparison of PCS, MCS, HADS-A and HADS-D in FMF patients and HC

| | FMF patients (n=149) | HC (n=100) | P values |
|---|---|---|---|
| PCS | 40±7* | 56±3* | <0.001 |
| MCS | 43±8* | 52±2* | <0.001 |
| HADS-A | 7.4±1.6* | 4.5±1.5* | <0.001 |
| HADS-D | 5.3±2.1* | 2.8±1.5* | <0.001 |

Table 2. PCS, MCS, HADS-A and HADS-D scores of FMF patients according to frequency of attacks in the last 3 months

| | >2 attack (n=32) | 1–2 attack (n=41) | No attack (n=76) |
|---|---|---|---|
| PCS | 28±5* | 34±7* | 42±6* |
| MCS | 32±5* | 33±5* | 46±6* |
| HADS-A | 8.5±1.5* | 8.2±1.0* | 7.2±1.7* |
| HADS-D | 8.8±0.7* | 7.6±0.8* | 4.5±1.8* |

*Mean ± SD. SD: Standart deviation, NS: Not significant.

**Conclusions:** In this study, we found lower QoL scores, and higher anxiety and depression scores in FMF patients compared to HC. Attack frequency determined this effect independent of age and gender.

FRI0512 **IGG4-RELATED DISEASE IS ASSOCIATED WITH A HISTORY OF MALIGNANCY**

Z. Wallace[1], C. Wallace[2], L. Lu[1], H. Choi[2], J. Stone[2]. *[1]Rheumatology Unit; [2]Rheumatology, Massachusetts General Hospital, Boston, United States*

**Background:** IgG4-related disease (IgG4-RD) is a fibroinflammatory disease of unclear etiology[1]. Some studies suggest that IgG4-RD predisposes patients to malignancy or is a *forme fruste* of cancer[2], but we have frequently observed IgG4-RD patients with a history of malignancy preceding the clinical onset of IgG4-RD.
**Objectives:** We sought to determine whether a history of malignancy was more common among patients at the onset of IgG4-RD compared to controls.
**Methods:** We identified IgG4-RD patients with a history of invasive malignancy from a well-defined cohort of 125 patients and compared their malignancy history to those of two reference groups. First, we calculated a standardized prevalence ratio against general US population estimates from the Surveillance, Epidemiology, and End Results (SEER) database. Second, we identified up to five age- and gender-matched controls for each case and calculated the odds of malignancy among those with IgG4-RD compared to controls using conditional logistic regression.
**Results:** The mean age at IgG4-RD onset was 50.3±14.9 years and 61% of the patients were male. Twenty (16%) had been diagnosed with 21 malignancies before the diagnosis of IgG4-RD. The observed prevalence of malignancy in this cohort was 2.5 times higher (95% CI:1.1–3.6) than expected compared to the SEER database. Compared with matched controls, a history of malignancy was more than three-fold higher in IgG4-RD (OR 3.1;95% CI:1.6–6.2).
**Conclusions:** Our findings suggest that malignancy is associated with the subsequent development of IgG4-RD in a subset of patients with IgG4-RD. Potential explanations include shared risk factors for both IgG4-RD and cancer, the triggering by cancer of autoantigen expression leading to IgG4-RD, and an increased risk of IgG4-RD resulting from cancer treatment.

## Diagnostics and imaging procedures

FRI0513 **VALIDATING MRI-DETECTED INFLAMMATION THRESHOLDS PREDICTIVE OF STRUCTURAL DAMAGE PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A RANDOMIZED PLACEBO-CONTROLLED TRIAL**

H.A. Ahmad[1], J.F. Baker[2], M. Østergaard[3], J. Ye[1], P. Emery[4], P.G. Conaghan[4]. *[1]Bristol-Myers Squibb, Princeton; [2]University of Pennsylvania, Philadelphia, United States; [3]University of Copenhagen, Copenhagen, Denmark; [4]University of Leeds, Leeds, United Kingdom*

**Background:** In rheumatoid arthritis (RA), the concept that subclinical inflammation causes damage progression is now well established, but there is little work on how much inflammation is safe.[1] A previous study established RA MRI Scoring (RAMRIS) synovitis and osteitis thresholds (≤3 each and ≤9 [≤3 plus 2*≤3] as a total inflammation score) that correlated with a low risk of structural damage progression.[2] Further validation of these thresholds may guide physicians in clinical practice more reliably to identify individuals with a low likelihood of structural damage progression.
**Objectives:** To validate the performance of RAMRIS synovitis, osteitis and combined total inflammation thresholds in the prediction of structural damage progression.[1]
**Methods:** AVERT (Assessing Very Early Rheumatoid arthritis Treatment) was a Phase IIIb, randomized, active-controlled, 24-month trial, with a 12-month, double-blind treatment period. Patients with early RA received abatacept + MTX, abatacept monotherapy or MTX. Contrast-enhanced MRIs of the dominant hand and wrist were performed. MRI data were pooled from all three treatment arms (intent-to-treat population) for this *post hoc* analysis. Inflammation (synovitis, osteitis and combined) and erosion were scored by two central readers at baseline, Month 6 and Month 12. Structural damage progression was defined as erosion change >0.5. Patients were stratified into "low" and "not low" risk groups for MRI structural progression based on their inflammation scores at the start of the observation period: low: ≤3 for synovitis, ≤3 for osteitis and ≤9 when combined (with osteitis double-weighted due to its strong correlation with progression), as suggested by Baker et al.[2] Log odds ratio of probability of progression were compared between subgroups.
**Results:** 351 patients were randomized and treated, with MRIs at baseline; 276 (78.6%) and 235 (67.0%) also had MRI data available at Month 6 and Month 12, respectively. The percentage of patients with structural damage progression at follow-up was significantly higher in the "not low" versus "low" risk subgroup for all comparisons (Table). The probability of progression from Month 6 to Month 12 was significantly lower among patients with synovitis score ≤3, osteitis score ≤3, and total inflammation score ≤9 at Month 6.

| MRI progression from 0 to 12 months by MRI scores at baseline | | | | | | |
|---|---|---|---|---|---|---|
| | Synovitis | | Osteitis | | Synovitis + (2*Osteitis) | |

**Conclusions:** The applied inflammation thresholds distinguished between patients with RA at lower or higher risk of structural damage progression, validating the previously proposed thresholds. This provides further support for the clinical value of measuring inflammation via MRI, as well as its role in predicting structural damage progression.

FRI0514 **ADDING MRI OF THE SPINE TO THE ASAS CLASSIFICATION CRITERIA FOR AXIAL SPONDYLOARTHRITIS, REDUNDANT OR BENEFICIAL? DATA FROM THE SPONDYLOARTHRITIS CAUGHT EARLY (SPACE)-COHORT**

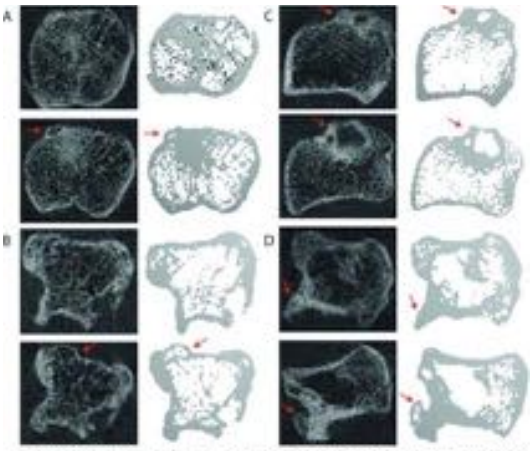
Z. Ez-Zaitouni[1], P. Bakker[1], M. de Hooge[1], R. van den Berg[1], M. van Lunteren[1], M. Reijnierse[2], K. Fagerli[3], R. Landewé[4], M. van Oosterhout[5], R. Ramonda[6], F. van Gaalen[1], D. van der Heijde[1]. *[1]Rheumatology; [2]Radiology, LUMC, Leiden, Netherlands; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Rheumatology, AMC, Amsterdam; [5]Rheumatology, GHZ, Gouda, Netherlands; [6]Rheumatology, University of Padova, Padova, Italy*

**Background:** The ASAS definition of a positive MRI is solely based on inflammation in the sacroiliac joints (SIJ), although spinal inflammatory lesions on MRI suggestive of axial Spondyloarthritis (axSpA) may also occur. It is not well known how often inflammation in the spine occurs in absence of inflammation in the SIJ and consequently what the utility is of including inflammation in the spine in the definition of a positive MRI.
**Objectives:** To analyze the prevalence of spinal inflammation on MRI in patients with chronic back pain (CBP) at baseline and one-year follow-up, and to evaluate the yield of adding MRI-spine as imaging criterion to the ASAS classification criteria for axial SpA.
**Methods:** The SPACE-cohort includes patients with CBP (≥3 months, ≤2 years, onset <45 years) from five participating centres in Europe. All available baseline (BL) and one-year follow-up (FU) MRI of SIJ and spine were scored by 2 well-calibrated readers. MRI-SI were scored according to the ASAS definition. Bone marrow oedema suggestive of axSpA was assessed in the entire spine and only counted if visible on ≥2 consecutive slices. To define a positive MRI-spine, two cut-off values were used: ≥3 inflammatory lesions (ASAS consensus definition) and ≥5 inflammatory lesions (defined as the best cut-off in earlier analyses). Adjudication for the ASAS definition by an experienced reader was performed in case of disagreement and all modalities were considered positive if 2/3 readers agreed.
**Results:** All patients with both MRI-spine and MRI-SIJ available at BL (n=329) and FU (n=168) were included in the analyses. At BL 43/329 (13.1%) of patients

had a positive MRI-SIJ, of which 7/43 (16.3%) patients had a positive MRI-spine (ASAS consensus definition, ≥3 inflammatory lesions) and 2/43 (4.7%) if defined by ≥5 inflammatory lesions. Positive MRI-SIJ at FU was seen in 28/168 (16.7%) patients, 14 of which were also positive at BL; MRI-spine positivity was identified in 2/28 (7.1%) and 1/28 (3.6%) patients for the ASAS definition defined by ≥3 and ≥5 inflammatory lesions, respectively. In total, 4 patients had a positive MRI-spine and a negative MRI-SIJ: at BL 2 patients according to the ASAS definition of whom 1 also fulfilled the alternative definition. At FU this was 2 (different patients than at baseline) and 0 patients, respectively. Addition of MRI-spine to the classification criteria by the ASAS definition of ≥3 inflammatory lesions would lead to classification of 3 additional patients via imaging arm, with 1 patient already fulfilling the clinical arm.

**Figure 1.** Prevalence of positive MRI-SI according to ASAS definition and positive MRI-Spine at baseline and one-year follow-up using two different cut-off values; ≥3 inflammatory lesions (ASAS consensus definition) and ≥5 inflammatory lesions, respectively.

| BASELINE | | MRI of the SI joints | | |
|---|---|---|---|---|
| | | Positive | Negative | |
| MRI of the Spine, cut-off ≥3 inflammatory lesions | Positive | 7 | 2 | 9 |
| | Negative | 36 | 284 | 320 |
| | Total | 43 | 286 | 329 |
| | | MRI of the SI joints | | |
| | | Positive | Negative | |
| MRI of the Spine, cut-off ≥5 inflammatory lesions | Positive | 2 | 1 | 3 |
| | Negative | 41 | 285 | 326 |
| | Total | 43 | 286 | 329 |



| FOLLOW-UP | | MRI of the SI joints | | |
|---|---|---|---|---|
| | | Positive | Negative | |
| MRI of the Spine, cut-off ≥3 inflammatory lesions | Positive | 2 | 2 | 4 |
| | Negative | 26 | 138 | 164 |
| | Total | 28 | 140 | 168 |
| | | MRI of the SI joints | | |
| | | Positive | Negative | |
| MRI of the Spine, cut-off ≥5 inflammatory lesions | Positive | 1 | 0 | 1 |
| | Negative | 27 | 140 | 167 |
| | Total | 28 | 140 | 168 |

**Conclusions:** In this cohort, a positive MRI-spine in the absence of sacroiliitis on MRI was rarely seen Addition of MRI-spine as an imaging criterion to the ASAS criteria had a low yield in number of classifications. Therefore, performing MRI of the spine at either baseline or one-year follow-up is of little value in patients with short duration of CBP and suspicion of axial SpA.

## FRI0515 QUANTIFICATION AND IMPACT OF SECONDARY OSTEOARTHRITIS IN PATIENTS WITH ANTI-CITRULLINATED PROTEIN ANTIBODIES POSITIVE RHEUMATOID ARTHRITIS

C.P. Figueiredo[1,2], D. Simon[2], M. Englbrecht[2], J. Haschka[2,3], A. Kleyer[2], S. Bayat[2], A.J. Hueber[2], R.M. Pereira[1], J. Rech[2], G. Schett[2]. *[1]Bone Metabolism Laboratory, Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; [2]Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [3]Medical Department II, The VINFORCE Study Group, St. Vincent Hospital, Vienna, Austria*

**Background:** Erosions have been described as the hallmark of bone damage in RA, resembling catabolic changes [1]. Usually bone erosions in RA are not accompanied by proliferative bone changes, which are typically found in psoriatic arthritis and spondyloarthritis [2]. Although such changes are much less pronounced in RA than in other diseases, RA patients may not be completely spared from bony proliferations, which likely resemble the development of secondary osteoarthritis.
**Objectives:** To search for evidence of secondary osteoarthritis in patients with rheumatoid arthritis (RA) in a cross-sectional and longitudinal setting and to relate osteophyte formation to functional outcome.
**Methods:** Anti-citrullinated protein antibody positive (ACPA+) RA patients underwent high-resolution peripheral quantitative computed tomography (HR-pQCT) of the hand. Cross-sectional and longitudinal measurements were performed. Number and size of osteophytes as well as bone erosions were documented. Relation of osteophytes to bone erosions and to demographic and disease specific data was evaluated by multiple logistic regression models.
**Results:** 202 ACPA+ RA patients were enrolled in the cross-sectional and 77 subjects in the longitudinal analysis (interval: 1.5 years). The mean number and size of osteophytes was 1.3±2.3 and 9.4±23.9 $mm^3$ respectively. Osteophyte number was significantly ($p<0.001$) correlated to erosion number and osteophyte size to erosion size ($p<0.001$). Moreover, presence and size of osteophytes were related to age ($p<0.001$), disease duration ($p<0.001$) and health assessment questionnaire (HAQ) ($p=0.013$). Multivariate regression analyses showed an independent association between osteophytes and erosions. In the longitudinal analysis the mean number ($p=0.033$) and size ($p<0.001$) of osteophytes significantly increased in RA patients during their disease course (Figure 1).

Transversal sections of metacarpal heads at baseline (upper image in A-D) and follow-up measurement (lower image in A-D). Red arrows indicate osteophytes.

**Conclusions:** Age, disease duration and bone erosions are associated with osteophytes indicating development of secondary osteoarthritis in patients with RA.

## FRI0516 ULTRASONOGRAPHIC ASSESSMENT OF NEWLY DEVELOPED ELDERLY-ONSET RHEUMATOID ARTHRITIS: A COMPARISON WITH YOUNGER-ONSET RHEUMATOID ARTHRITIS

A. Suzuki[1], T. Okai[2]. *[1]Department of Rheumatology, Mitsui Memorial Hospital; [2]Center for Rheumatology and Joint Surgery, Kawakita General Hospital, Tokyo, Japan*

**Background:** Elderly-onset RA (EORA) is defined as the onset of RA at 65 years of age or older and Patients with EORA frequently present with acute onset of the disease dominated by stiffness and pain in the shoulder and their daily activities are generally impaired. However, specific knowledge on sonographic findings in patients with newly-developed EORA remains limited.
**Objectives:** The aim of the present study was to clarify specific sonographic features in patients with new-onset EORA.
**Methods:** We included consecutive patients who were diagnosed with RA according to the 2010 ACR/EULAR classification criteria. EORA was defined as a RA onset at ≥65 years of age and YORA as an onset at <65 years. Prior to the initiation of therapy, we evaluated positivity for anti-CCP antibodies as well as DAS28-ESR and HAQ score. Musculoskeletal ultrasonography was performed at the initial visit and the investigation sites included the dominant side of the shoulder (long head biceps tendon, subacromial-subdeltoid bursa, and glenohumeral joint), wrist, metacarpophalangeal (MP) joints, and knee joint. Gray scale (GS) and power Doppler (PD) signals were subjectively graded for each site using a semi-quantitative scoring method, which consisted of a scale of 0–3, and the sum of the GS scores of a single joint was calculated as the total GS score for each joint and the sum of PD scores as the total PD score. We investigated sonographic differences between EORA and YORA and the relationships between disease activity variables and ultrasonographic findings were analyzed in patients with EORA using Spearman's correlation coefficient. Proportions were calculated by Fisher's exact test.
**Results:** EORA was diagnosed in 47 patients (mean age 79.4 ± 7.3 years) and YORA in 35 patients (age 48.1 ± 12.5 years). The positive ratios of GS and PD signals were 91.3% and 83.1%, respectively, at the shoulder joint in EORA patients, and both proportions were significantly higher than those in YORA patients (61.2% for GS [$p<0.01$] and 50.0% for PD [$p<0.01$]). The remainder of the examined joints including the wrist, MP and knee joints showed no significant differences in the GS or PD positive ratios between the two groups. We subsequently stratified EORA patients according to anti-CCP antibody positivity.

The t-GS score of the shoulder joint was significantly higher in the anti-CCP negative group than in the positive group (4.6 ± 2.0 and 2.8 ± 2.5, respectively, $p<0.05$). However, the remainder of the examined joints showed no significant differences. Furthermore, no significant differences were observed between the two groups in terms of the t-PD scores of all joints. In EORA patients, the t-GS and t-PD scores of the shoulder joint strongly correlated with the HAQ score ($r=0.72$, $p<0.0001$, $r=0.68$, $p<0.0001$, respectively) and, among the shoulder joint components, long head biceps tendon showed the strongest correlation both in the t-GS and t-PDS scores ($r=0.64$, $p<0.0001$, $r=0.55$, $p<0.001$). The t-PD scores of the shoulder, wrist, and MP joints correlated with DAS 28-ESR ($r=0.62$, $p<0.0001$, $r=0.43$, $p<0.05$, $r=0.38$, $p<0.05$).

**Conclusions:** Shoulder joint involvement was a specific feature in patients with EORA and contributed to functional disability and increased disease activity.

## FRI0517 THE OMERACT ULTRASONOGRAPHIC CRITERIA FOR ELEMENTARY LESIONS IN CALCIUM PYROPHOSPHATE DEPOSITION DISEASE: RESULTS OF A DELPHI PROCESS BY ULTRASOUND WORKING GROUP

A. Adinolfi[1], G. Filippou[1], C.A. Scirè[2], N. Damjanov[3], G. Carrara[2], V. Picerno[1], C. Toscano[1], G. Bruyn[4], M.A. D'Agostino[5], A. Delle Sedie[6], E. Filippucci[7], M. Gutierrez[8], M. Micu[9], I. Moller[10], E. Naredo[11], Z. Pascal[12], C. Pineda[8], F. Porta[13], W. Schmidt[14], L. Terslev[15], V. Vlad[16], P. Zufferey[17], B. Frediani[1], A. Iagnocco[18] on behalf of OMERACT group "US in CPPD". *[1]University of Siena, Siena; [2]SIR Epidemiology Unit, Milan, Italy; [3]University of Belgrade, Belgrade, Serbia; [4]Department of Rheumatology, MC Groep, Lelystad, Netherlands; [5]Université Versailles Saint-Quentin en Yvelines, Paris, France; [6]University of Pisa, Pisa; [7]Università Politecnica delle Marche, Jesi, Italy; [8]Instituto Nacional de Rehabilitación, Mexico City, Mexico; [9]Rehabilitation Clinical Hospital, Cluj-Napoca, Romania; [10]Instituto Poal, Barcelona; [11]Hospital GU Gregorio Marañón, Madrid, Spain; [12]Lausanne University Hospital, Lausanne, Switzerland; [13]University of Florence, Florence, Italy; [14]Immanuel Krankenhaus Berlin, Berlin, Germany; [15]Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen, Denmark; [16]Sf. Maria Hospital, Bucharest, Romania; [17]Lausanne University Hospital, Lausanne, Switzerland; [18]Università la Sapienza, Rome, Italy*

**Background:** In the last years, the role of Ultrasound (US) for the diagnosis of calcium pyrophosphate deposition disease (CPPD) has been extensively growing. However, some issues have still to be resolved, being one of the most important the heterogeneity of the criteria used for the identification of calcium pyrophosphate crystals (CPP) deposits.

**Objectives:** The aim of this study was to define the US elementary lesions in CPPD

**Methods:** The panel of experts was compound by 18 members of the Omeract US group, especially interested in microcrystalline arthritides.

The first step was a systematic literature review aimed to select the studies regarding US and CPPD in order to collect all the definitions about US elementary findings in CPPD. The definitions retrieved by the literature were used for drawing up a first group of propositions. The experts evaluated these definitions, adding any further preposition according to their experience that could improve the initial set. According to the systematic review, the propositions about US elementary lesions were divided by anatomical structure: fibrocartilage, hyaline cartilage, tendons and synovial fluid. For each structure were defined: shape, echogenicity, localization and behaviour at dynamic scanning.

In the next rounds, the experts voted their level of agreement for each proposition according to the Likert scale (1 strongly disagree 5:strongly agree) with the possibility to add comments. After each round, a facilitator modified the prepositions according to the comments received. The consensus for each preposition was considered achieved if the agreement was equal or more than 75%

| Structure | Shape | Echogenicity | Localization | Behavior at Dynamic scanning |
|---|---|---|---|---|
| Fibrocartilage | deposits of variable shape | hyperechoic (similar to the bone cortex) | localized within the fibrocartilage structure | remain fixed and move together with the fibrocartilage during dynamic assessment (i.e. joint movement and probe compression) |
| Hyaline cartilage | deposits varying in size and shape | hyperechoic (similar to the bone cortex echogenicity) that do not create posterior shadowing | Localized within the hyaline cartilage | the deposits remain fixed and move together with the hyaline cartilage (i.e. joint movement and probe compression) |
| Tendon | multiple, linear (parallel to the tendon fibrillar structure and not in continuity with the bone profile) deposits | Hyperechoic (in relation to the tendon echogenicity), that generally not create posterior shadowing. The deposits maintain their high degree of echogenicity even at very low levels of gain and are not affected by anisotropy as the surrounding tendon. | Localized within the tendon | remain fixed and move together with the tendon during movement and probe compression. |
| Synovial fluid | deposits of variable size (from punctuate to large) | hyperechoic (similar to the bone cortex echogenicity), that generally not create posterior shadowing. | Localized within the synovial fluid | are mobile according to joint movement and probe pressure. |

**Results:** Three Delphi rounds were necessary in order to reach agreement. After the first round, 20 of the 93 definitions retrieved by the literature reached the consensus. During the second one, 23 propositions achieved the agreement while, after the last Delphi round, the number of propositions increased to 27. All the members responded to all the phases of the survey.

Final definitions for US identification of CPPD are illustrated in Table 1

**Conclusions:** To our knowledge this is the first set of definitions for US identification of CPPD created according to a consensus procedure between experts. These definitions should help sonographers to classify correctly patients with suspected CPPD thus giving the possibility to organise multicentre studies. However, the reliability and the diagnostic accuracy of this set has to be assessed before they become integral part of the daily clinical practice

Warrington[14], W.A. Schmidt[21]. *[1]Medical University Innsbruck, Innsbruck; [2]Medical University Graz, Graz, Austria; [3]Center for Rheumatology and Spine Diseases and COPECARE, Glostrup, Denmark; [4]MC Groep Hospitals, Lelystad, Netherlands; [5]Esbjerg Hospital, Esbjerg, Denmark; [6]Université Versailles St-Quentin, Boulogne-Billancourt, France; [7]Southend University Hospital, Southend, United Kingdom; [8]University Hospital La Paz, Madrid, Spain; [9]Hospital for Rheumatic Diseases, Haugesund, Norway; [10]Charles University, Prague, Czech Republic; [11]Asklepios Medical Center Bad Abbach, Bad Abbach, Germany; [12]Sapienza Università di Roma, Rome, Italy; [13]University of California, Los Angeles; [14]Mayo Clinic, Rochester, United States; [15]Arcispedale Santa Maria Nuova, Reggio Emilia, Italy; [16]Pomeranian Medical University, Szczecin, Poland; [17]Norfolk and Norwich University Hospital, Norwich, United Kingdom; [18]Hospital General Universitario Gregorio Marañón, Madrid, Spain; [19]Lisbon Academic Medical Centre, Lisbon, Portugal; [20]St. Elizabeth's Medical Center, Boston, United States; [21]Immanuel Krankenhaus Berlin-Buch, Berlin, Germany*

**Background:** In a systematic literature review (SLR), we identified halo sign, stenosis, occlusion, compression sign and a decreased vessel wall pulsation as elementary ultrasound (US) lesions in giant cell arteritis (GCA).

**Objectives:** To establish consensus-based definitions for the key elementary US lesions in GCA.

**Methods:** We invited 25 rheumatologists from 13 countries experienced in musculoskeletal and vascular US to participate in a Delphi exercise. Based on the results from the SLR and international expert consensus a questionnaire was developed including 12 statements on the definitions of normal temporal and extra-cranial large arteries, arteriosclerosis, halo sign, stenosis, occlusion, compression sign, and vessel wall pulsation. The experts were asked to express their level of agreement or disagreement with the proposed statements. A consensus was defined as agreement of $\geq$75% of participants.

**Results:** The response rate was 24/25 (96%) in round 1 and 24/24 (100%) in round 2. A consensus was achieved for 9/9 Delphi statements [normal temporal and extra-cranial large arteries, arteriosclerosis, halo sign, stenosis of temporal and extra-cranial large arteries, occlusion, compression sign (temporal arteries), US assessment of compression sign (temporal arteries) in round 1. In round 2, 3/3 Delphi statements (arteriosclerosis, halo sign, stenosis of temporal arteries) were redefined. The statements on vessel wall pulsation (definition and assessment) and measurement of vessel wall thickness did not reach the threshold for consensus. The halo and compression signs were deemed to be the most important US signs for GCA with 100% and 83.3% expert agreement, respectively.

**Conclusions:** This is the first international consensus on definitions for elementary US lesions in GCA. The next steps of the OMERACT project will be web- and patients based exercises testing the reliability of the new definitions.

**Disclosure of Interest:** None declared

**Objectives:** To produce ultrasound (US) consensus-based definitions of cartilage change in rheumatoid arthritis (RA) and assess its intraobserver and interobserver reliability in a web-based exercise.
**Methods:** We conducted a Delphi study on US defined cartilage change and a proposed semiquantitative (SQ) US scoring system for cartilage change in RA. A written Delphi questionnaire was developed based on a systematic literature review and expert international consensus and was distributed via consecutive written questionnaires by email to a group 35 rheumatologists from 17 countries with experience in musculoskeletal US. Taskforce members performed US B mode examination of the metacarpal cartilage in metacarpophalangeal joints 2–5 in RA patients and the images were collected in an electronic database. A reference image atlas of cartilage changes was developed for scoring 123 anonymized images including 25 duplicate images. These were sent to the participants who independently scored the images. Intraobserver reliability was assessed by Cohen's kappa and interobserver reliability by Fleiss' kappa.
**Results:** Group agreement (76–100%) was reached for 6 statements concerning: i) MSUS definition and assessment of normal hyaline cartilage, ii) elementary cartilage lesions in MSUS and iii) grading of elementary cartilage lesions in patients with RA in a two-round Delphi consensus process. A three-grade SQ (0–2) scoring system (grade 0, normal cartilage; grade 1, minimal change: blurring of outer and/or subchondral margin, focal thinning or incomplete loss of homogeneity of echostructure; grade 2, severe: diffuse thinning or complete loss of homogeneity of echostructure) was agreed for scoring cartilage damage in RA. Both intra- and inter-observer reliability were good (κ value of 0.87 and 0.64 respectively).
**Conclusions:** This study demonstrates that US is a reliable tool for evaluating cartilage in RA and strongly supports the use of a new reliable semiquantitative MSUS scoring system for cartilage change.
**Disclosure of Interest:** None declared

## FRI0520 COMPARISON OF 18F-FLUORO-DEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY AND COMPUTED TOMOGRAPHY ANGIOGRAPHY FOR THE DIAGNOSIS OF GIANT CELL ARTERITIS: A PROSPECTIVE, CASE-CONTROL STUDY

D. Lariviere, K. Benali, B. Coustet, N. Pasi, J.-F. Alexandra, P. Dieude, T. Papo, K. Sacre. *Paris-7 UNIVERSITY, APHP, Bichat Hospital, Paris, France*

**Background:** Diagnosis of giant cell arteritis (GCA) is still a challenge. 18F-fluoro-deoxyglucose positron emission tomography scan (FDG-PET) and computed tomography angiography (CTA) are promising imaging techniques for the detection of GCA
**Objectives:** To compare the diagnostic performance of FDG-PET and CTA in patients with giant cell arteritis (GCA).
**Methods:** FDG-PET and CTA were acquired in 24 consecutive patients in whom temporal artery biopsy (TAB) was performed for suspected GCA. Results of FDG-PET and CTA were compared with the final clinical diagnosis based on a) the American College of Rheumatology GCA criteria set, b) clinical judgment including outcome under corticosteroids, and c) the absence of an alternative diagnosis after a 6 months follow-up. Sensitivity, specificity, and positive and negative predictive values (PPV, NPV) were calculated for each method.
**Results:** Fifteen of the 24 patients (62.5%) were ultimately diagnosed as having GCA. Strong FDG uptake in large vessels was found in 10 patients who all had GCA. Mean maximal standard uptake values (SUVmax) per patient measured at all the arterial territories were of 3.7 [range: 2.8–4.7]. FDG uptake was negative in 14 patients including 9 and 5 patients without and with GCA, respectively. Mural thickening suggestive of aortitis or branch vessel arteritis was observed on CTA in 11 patients with and 2 patients without GCA. No mural thickening was observed in 11 patients including 7 patients without and 4 patients with GCA. Overall, sensitivity of FDG-PET and CTA was 66.7% and 73,3%, respectively; specificity was 100% and 84.6%, NPV was 64.3% and 64.6%, and PPV was 100% and 84.6%, respectively.
**Conclusions:** Both FDG-PET and CTA have a strong diagnostic yield for the diagnosis of GCA. FDG-PET appeared to have a higher PPV as compared to CTA and may be the preferred noninvasive technique to evaluate patients with suspected GCA.
**Disclosure of Interest:** None declared

## FRI0521 RELIABILITY OF AN OMERACT RHEUMATOID ARTHRITIS TENOSYNOVITIS SCORING SYSTEM FOR WRIST AND HAND

D. Glinatsi[1], P. Bird[2], F. Gandjbakhch[3], E.A. Haavardsholm[4], P.G. Conaghan[5], M. Østergaard[1] on behalf of the OMERACT MRI in Arthritis Working Group. *[1]Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]University of NSW, Sydney, Australia; [3]Hôpital Pitié-Salpétrière, APHP, université Paris VI, Paris, France; [4]Diakonhjemmet Hospital, Oslo, Norway; [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

**Background:** Tenosynovitis in the hand occurs frequently and early in rheumatoid arthritis (RA) and sensitive outcome measures are important to assess and monitor the inflammatory activity. Magnetic resonance imaging (MRI) can visualize tenosynovitis and a semiquantitative scoring system for tenosynovitis in the hand has previously been suggested[1]. However, it did not include the metacarpophalangeal (MCP) flexor tendons. Furthermore, each increment of the scale covered a broad interval of tenosynovitis severity, potentially improving reliability but with a risk of reducing sensitivity to change over time.
**Objectives:** To assess the intra- and inter-reader agreement of a proposed OMERACT tenosynovitis scoring system in the wrist and MCP flexor tendons in the hands of RA patients.
**Methods:** Axial T1-weighted pre- and post-contrast fat-suppressed MR image sets (0.8mm slice thickness) of the hand of 43 patients receiving rituximab were obtained at baseline and after 3 (n=5), 6 (n=8), 9 (n=15) or 12 (n=15) months. The images were read and scored twice on separate days with intermediate re-randomization and re-anonymization by 4 readers blinded to patient data but not to chronology. The tendons of 6 extensor and 3 flexor tendon compartments of the wrist and 4 flexor tendon compartments of the 2nd to 5th MCP joints were assessed. Tenosynovitis was defined as peritendinous effusion (PE) or post-contrast enhanced tenosynovial proliferation (ETP) on 3 consecutive slices.

**Table 1** Intra- and inter-reader agreement for the wrist, metacarpophalangeal (MCP) flexor tendons and total score

| | PEA | 80.62 | 83.37 | 76.94 | 81.98 | 79.07 | 70.35 | 81.03 | 82.04 | 74.91 |
| | PCA | 98.45 | 98.67 | 96.46 | 100 | 100 | 98.26 | 98.93 | 99.08 | 97.01 |
| | SDC | | | 2.34 | | | 1.13 | | | 2.86 |
| INTER-READER | AvmICC | 0.94 | 0.90 | 0.91 | 0.96 | 0.97 | 0.94 | 0.96 | 0.96 | 0.94 |
| | PEA | 42.51 | 48.06 | 50.26 | 40.99 | 48.71 | 42.44 | 42.04 | 48.57 | 47.85 |
| | PCA | 81.14 | 82.17 | 83.98 | 86.92 | 89.83 | 87.21 | 82.92 | 84.53 | 84.97 |
| | SDC | | | 1.65 | | | 0.87 | | | 1.82 |

Single measure intra-class correlation coefficients (SimICC) and average measure intra-class correlation coefficients (AvmICC) were calculated for intra-reader and inter-reader agreement respectively. An ICC ≥0.50 was considered good and an ICC ≥0.80 was considered very good. Percentage of exact agreement (PEA) was defined as the percentage of tendons given the same score within and between the readers (expressed as the average percentage for wrist, MCP tendons and total scores). Percentage of close agreement (PCA) was defined as the percentage of tendons given scores that differed ≤1 within and between the readers (expressed as the average percentage for wrist, MCP tendons and total scores). Smallest detectable change (SDC) was calculated for change scores and expresses the minimal amount of change that can be discriminated from the measurement error of the scoring system.

Pathologies were measured perpendicularly to the tendon at the thickest point of the effused or enhanced tenosynovium. Tenosynovitis was scored as follows: 0: no PE or ETP, 1: >0 but <1.5mm PE or ETP, 2: ≥1.5 but <3mm PE or ETP, 3: ≥3mm PE or ETP. Change in tenosynovitis over time was assessed using descriptive statistics and the Wilcoxon signed-rank test. Intra- and inter-reader agreement was calculated using single measure and average measure intra-class correlation coefficients (ICC), percentage of exact and close agreement (PEA and PCA) and the smallest detectable change (SDC).

**Results:** The mean (SD) change in tenosynovitis score between baseline and follow-up was -1.38 (2.84) for wrist, -0.94 (1.85) for MCP flexor tendons and -2.31 (4.63) for total score (all $p<0.01$). Intra- and inter-reader ICC for status scores were very good in all readers for all parameters (except baseline scores in the MCP region in 1 reader). Intra-reader ICC for change scores were good to very good in all readers for all parameters, and inter-reader ICC for status and change scores were very good in all readers for all parameters. Intra-reader PEA for status and change scores was above 57% and PCA was above 95% for all parameters. Inter-reader PEA was above 40% and PCA was above 81% for all parameters. Intra-reader SDC was below 3.0 for all parameters, except for total score in 1 reader (3.04). Inter-reader SDC was below 2.0 for all parameters (table 1).

**Conclusions:** The proposed OMERACT tenosynovitis scoring system showed high intra- and inter-reader agreement for wrist and MCP tendons and is a reliable tool for MRI-assessment of tenosynovitis in the RA hand, underpinning its likely responsiveness in subsequent randomized controlled trials.

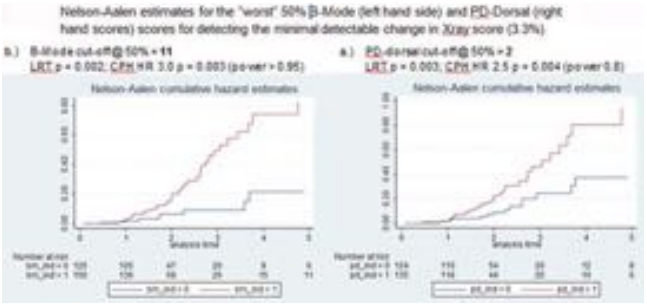
## FRI0522 ULTRASOUND-DETECTED SYNOVITIS MAY PREDICT RADIOGRAPHIC DAMAGE PROGRESSION IN RHEUMATOID ARTHRITIS OVER THE NEXT FIVE YEARS – A PROSPECTIVE COHORT STUDY NESTED IN THE SWISS QUALITY MANAGEMENT PROGRAM (SCQM)

B. Möller[1], P. Zufferey[2], L. Brulhart[3], G. Tamborrini[4], A.M. Nydegger[5], D. Dan[1], V. Grobety[6], M.J. Nissen[7], A. Staerkle[8], A. Finckh[7], B. Aubry-Rozier[2], H.-R. Ziswiler[9], M. Andor[8], A. Atkinson[10], A. Scherer[11] on behalf of SONAR Group for Musculoskeletal Ultrasound in Rheumatology. *[1]Rheumatology, Immunology & Allergology, Inselspital - Bern University Hospital, Bern; [2]Rheumatology, Lausanne University Hospital, Lausanne; [3]Hôpital neuchâtelois la Chaux-de-Fonds, la Chaux-de-Fonds; [4]Bethesda-Spital, Basel; [5]Rheumatology, Klinik Schloss Mammern, Mammern; [6]Hôpital Cantonal, Fribourg; [7]Rheumatology, University Hospitals of Geneva, Geneva; [8]Prodorso, Zurich; [9]Osteorheuma; [10]Rheumatology, Inselspital - Bern University Hospital, Bern; [11]SCQM, Zurich, Switzerland*



**Background:** Ultrasound and MRI are novel diagnostic imaging tools for evaluating rheumatoid arthritis (RA) disease activity in clinical research settings, but their use in daily practice is still limited. Since 2010, standardized grey scale ultrasound (GSUS) and Power Doppler ultrasound (PDUS) assessments, which are reimbursed by the Swiss health insurances, were included as an optional tool in the regular SCQM program work-up for RA patients.

**Objectives:** To study the predictive value of GSUS and PDUS for radiographic damage progression in RA patients in an observational real life setting.

**Methods:** For this study, all patients in the SCQM registry with at least one X-ray before and one X-ray after their first ultrasound assessment, with at least 20 of the recommended 22 joints evaluated in the SONAR score [] were included. Ultrasound-skilled rheumatologists which have attended a half-day ultrasound standardization workshop performed optional protocol-guided ultrasound examinations at their own discretion. GSUS and PDUS were scored in accordance with OMERACT standards in a semi-quantitative manner from 0 to 3 for all but the shoulder and thumb joints for a 28 joint status). Radiographic damage of hands and feet were centrally assessed by an assessor blinded to clinical and sonographic data. The present analyses were restricted to hand data. Radiographic damage progression was defined as an increase in the Ratingen Score (range 0–190) beyond the smallest detectable change of 3.3 score points. Univariate and multivariate cox-proportional hazard ratios were calculated for different arbitrary cut-off points in GSUS and PDUS.

**Results:** In total 377 patients were included for separate analyses of PDUS or GSUS scores, Median (mean±SD) disease duration at inclusion was 6.4 (9.5±9.8) years, median Ratingen score was 9.0 and median DAS-28(ESR) at inclusion was 3.4. Thus, the majority of patients had longstanding erosive disease and at least moderate inflammatory disease activity, despite synthetic DMARDs being used in 66%, biological DMARDs in 49% and corticosteroids in 33% of patients. Using cut-off levels for definition of the "worst" 20% (GSUS=18/66, PDUS=6/66), 30% (GSUS=16/66, PDUS=4 /66) or 50% (GSUS=11/66, PDUS=2/66) in GSUS or PDUS scores, a significantly higher proportion of patients ($p<0.05$) with GSUS or PDUS scores higher than each of these GSUS and PDUS thresholds had radiographic damage progression in univariate analyses (power 0.7–0.9).

**Conclusions:** Using PDUS as well as GSUS in routine care may provide valuable information to indicate increased risk for radiographic damage progression on a

long-term basis in established RA. Potential effects of US examinations on later treatment decisions remained in this study unaddressed.

## FRI0523 RELATIONSHIP BETWEEN ULTRASOUND-DETECTED SYNOVITIS, QUALITY OF LIFE AND WORK PRODUCTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS OF WORKING AGE

A. Kosevoi Tichie[1,2], I. Janta[2], J.C. Nieto[2], L. Valor[2], C. Saenz[2], B. Serrano[2], C. Gonzalez[2], J. Lopez[2], I. Monteagudo[2], L. Carreno[2], E. Naredo[2]. *[1]Rheumatology and Internal Medicine, "Sfanta Maria" Clinical Hospital, Bucharest, Romania; [2]Rheumatology, Hospital General Universitario "Gregorio Maranon", Madrid, Spain*

**Background:** Rheumatoid arthritis (RA) is a debilitating disease and can affect both quality of life (QOL) and work productivity (WP) [1]. Ultrasound (US) is an important imaging technique increasingly used as a reliable tool in evaluating and monitoring RA patients [2]. US-detected subclinical synovitis (SS) has been detected in patients in clinical remission [3].

**Objectives:** To investigate the relation between US-detected synovitis, clinically detected synovitis and US-detected SS and QOL and WP.

**Methods:** RA patients, aged between 18 and 59 years, with stable paid employment, were recruited. Clinical aseessment included 42 tender joint count (TJC) and 40 swollen joint count (SJC), Disease Activity Score (DAS) 28 and Health Assessment Questionnaire (HAQ). US assessment included 42 joints. At the joint level subclinical B mode synovitis (SSB) was defined as: absence of tenderness and swelling and presence of B mode score for synovitis ≥1 with or without power Doppler (PD) signal. Subclinical PD synovitis (PSS) was defined as absence of tenderness and swelling and presence of a PD score for synovitis ≥0. Global BM and PD scores for synovitis were assessed using the following scores: TS_B = total score of B-mode synovitis, TS_D = total score of PD synovitis, JS_B = count of joints with B-mode synovitis, JS_D =count of joints with PD synovitis, TSS_B = total score of SSB, TSS_D = total score of PSS, JSS_B = count of joints with SSB, JSS_D = count of joints with PSS. QOL [3] was described using 2 main domains: PCS (physical health) and MCS (mental health). WP was assessd using WPAI (work productivity and activity impairment) questionnaire [4].

**Results:** 104 patients, with a mean age of 49±8 years and a mean disease duration of 141±103 months were included. At the assessment point, most of the patients had long-standing, low activity disease and a low functional impairment, as assessed by the DAS28-ESR and the HAQ, respectively. With the exception of TSS_B, most of the parameters that significantly correlated with QOL and WP were clinical variables. However, these correlations were weak (r ≤0,39), being the highest with TJC.

**Conclusions:** Neither clinical and US detected synovitis nor US detected SS showed a consistent relation with QOL and WP in our population of RA patients. TJC seems to be the clinical parameter that better correlates with QOL and WP.

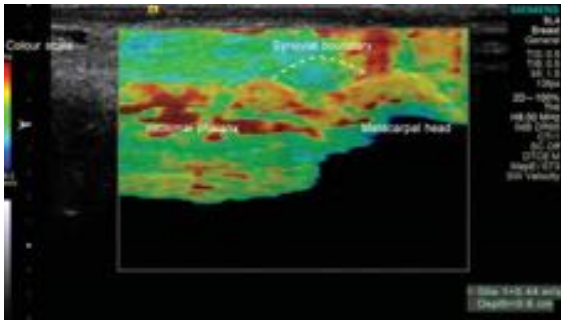
## FRI0524 ULTRASOUND POWER DOPPLER SYNOVITIS IS ASSOCIATED WITH PLASMA IL-6 IN ESTABLISHED RHEUMATOID ARTHRITIS

A.D. Do Prado[1,2], T.S. Baptista[3], L. Petersen[3], M.E. Bauer[3], M.C. Bisi[1], M. Bredemeier[2], D.M. Piovesan[1], I.G. da Silveira[1], J.A. Mendonça[4], H.L. Staub[1]. *[1]Rheumatology Unit, Hospital Sao Lucas da Pontifícia Universidade Católica do Rio Grande do Sul (PUCRS); [2]Rheumatology Unit, Grupo Hospital Conceição (GHC); [3]Laboratory of Immunosenescence, Institute of Biomedical Research, Pontificia Universidade Católica do Rio Grande do Sul (PUCRS), Porto Alegre; [4]Rheumatology Unit, Hospital da Pontifícia Universidade Católica (PUC) de Campinas, Campinas, Brazil*

**Background:** Cytokines have an important role in the pathogenesis of rheumatoid arthritis (RA). Muskuloscketalultrassound (MSUS) is a very useful tool in RA clinical management (1). In the last decades, it has been increasingly used in clinical rheumatology practice worldwide as it has demonstrated consistent and reproducible results among trained rheumatologists (2). Although plasma levels of IL-6 have been related to muskuloscketalultrassound (MSUS) synovitis in early DMARD-naïve RA (3), there are no similar studies in established disease.
**Objectives:** To investigate a possible association of MSUS synovitis and plasma citokines in patients with established RA.
**Methods:** 64 RA patients treated with non-biological DMARDs and 30 healthy controls were included in this prospective cross-sectional study. A blood sample was taken before evaluation of disease activity (DAS28) and ultrasonography (all tests performed in a blinded fashion). MSUS was performed by one of two ultrassound-trained rheumatologists on 10 joints of both hands (wrists, 2nd and 3rd metacarpophalangeal and 2nd and 3rd proximal interphalangeal joints) using high resolution equipment (My Lab 60, Esaote and 18mHZ linear tranducer). Gray scale (GS) and pD (power Doppler) synovitis were evaluated using a semi-quantitative scale (0–3) in individual joints, and their sum (score 10) was calculated. Plasma cytokines (IL-2, IL-4, IL-6, IL-10, IL-17, TNF, IFN-γ, and VEGF) were quantified by flow cytometry (Cytometric Bead Array kit - CBA; BD Biosciences).
**Results:** Levels of all cytokines, excepting VEGF, were significantly higher in RA patients than in controls ($P \leq 0.05$). In RA patients, IL-6, but not other cytokines, correlated positively with DAS28 and swollen joint count ($P \leq 0.01$), as well as with 10-joint pD score (figure 1), and GS and pD of both wrists ($P < 0.01$ for all tests). In multiple linear regression, the association of IL-6 with 10-joint pD score was mantained even after adjustment for DAS28. On the other hand, there was no correlation of IL-6 with tender joint count, 10-joint GS score, or presence of erosions.

Figure 1. Correlation of the 10-joint pD score with IL-6 levels ($r_S$= 0.33, 95%CI[ 0.06 to 0.56, P=0.008). $r_S$= Spearman correlation coefficient.



**Conclusions:** To the best of our knowledge, we report here, for the first time, an association of power Doppler sinovitis and plasma IL-6 independently of DAS28 in patients with established rheumatoid arthritis.

## FRI0525 ELASTOGRAPHIC ULTRASOUND OF METACARPOPHALANGEAL (MCP) SYNOVIUM IN RHEUMATOID ARTHRITIS (RA)

A.M. Sammel[1,2], M.C. Spies[1,2], R. DeCarle[3], M. Rayment[3], F. Joshua[1,2,4,5]. *[1]Prince of Wales Clinical School, University of New South Wales; [2]Rheumatology, Prince of Wales Hospital, Randwick; [3]St George Private Radiology; [4]Combined Rheumatology Practice, Kogarah; [5]Macquarie University, North Ryde, Australia*

**Background:** Shear wave elastographic ultrasound (SW-EUS) assesses the stiffness of human tissues. It is used in liver, thyroid and breast imaging but has never before been studied in synovium. Soft tissues have a slower shear wave velocity (SWV) than stiff tissues. We hypothesised that rheumatoid arthritis (RA) patients would have softer synovium and thus slower SWV than controls.
**Objectives:** The aim of the project was to establish a reproducible scoring system for synovial SW-EUS and use it to compare RA patients with controls. We also set out to assess if SWV varied with disease activity.
**Methods:** A cross sectional study was conducted including nine RA patients and five age and sex matched controls. RA patients were recruited consecutively from a single rheumatology practice. Participants underwent a questionnaire, clinical examination, blood sampling, grey scale ultrasound (GSUS), power doppler ultrasound and SW-EUS ultrasound examination of MCP joints 2 - 5 on the dominant hand. Ultrasound was performed and scored by two blinded musculoskeletal trained sonographers.
**Results:** The average age of participants was 60. The mean RA disease activity score (DAS28-ESR) was in the low to moderate range of 3.65 (range 2.4–7.4). Patients with RA had significantly lower maximum SWV than controls (6.38 m/s vs 6.99 m/s p=0.042). Negative Pearson's correlation coefficients (PCC) were observed between maximum SWV and a range of disease activity markers including GSUS graded synovial thickness (PCC = -0.57, p=0.03) and ESR (PCC = -0.46, p=0.095). SW-EUS had good intra- and inter-observer reliability with intraclass correlation coefficients of 0.66 and 0.58 for maximum SWV and >0.80 for colour scale rated average and minimum SWV.

**Conclusions:** This is the first reported study of SW-EUS in synovial tissue. Maximum SWV was significantly lower in the synovium of RA patients compared with controls. There was a negative correlation between maximum SWV and GSUS graded synovial thickening suggesting that SWV may be lower in more active patients. SW-EUS may have a role in the diagnosis and assessment of disease activity in RA.

## FRI0526 QUALITY OF ULTRASOUND-GUIDED SYNOVIAL BIOPSIES PERFORMED IN CLINICAL PRACTICE

A. Najm[1], G. Bart[1], M.-F. Heymann[2], Y. Maugars[1], B. Le Goff[1]. *[1]Rheumatology; [2]Pathology, Nantes University Hospital, Nantes, France*

**Background:** Synovial tissue is the principal target and end organ involved in the pathogenesis of multiple articular disease processes. Histological and bacteriological analyses of synovial tissue (ST) are useful in clinical practice for the diagnosis of undifferentiated arthritis. Ultrasound (US) allows an evaluation of the synovial thickness and inflammation. It also helps to perform real-time synovial biopsy and detect nearby structures such as tendons, nerves and vessels.
**Objectives:** The aim of this study was to assess quantity and quality of synovial tissue obtained by ultrasound guided synovial biopsies, in clinical practice.
**Methods:** We retrospectively analysed all synovial biopsies performed between January 2007 and December 2014 in the Rheumatology Department of Nantes University Hospital. Synovial biopsies were performed under real-time US guidance (Philips HD11 XE) using a core biopsy needle with a 14 or 16G calibre semi-automatic Tru-cut needle. This technique allows to collect multiple synovial samples during a single procedure. Hematoxylin and eosin stained slides were analysed by one operator (AN), blindly from clinical data. Size, area, presence/absence of synovial tissue, presence/absence of lining layer, other types of tissues were assessed and compared to pathologist's analysis (gold standard).
**Results:** 75 biopsy procedures were analysed (73 patients). 125 samples were

available for analysis corresponding to a median number of samples taken per patient of 1 (IQR 1–3). Mean length and width of the biopsy samples were 6.34 millimetres (mm) (±3.60) and 1.70 mm (±0.77) respectively. The mean total area of the samples was 8.77 $mm^2$.
Biopsies showed synovial tissue at the histological examination in 102 samples (80.1%). The average area of synovial tissue in these samples was 6.36 $mm^2$ corresponding to 72.5% of the total area of biopsied tissue. The other types of tissue present on these biopsies were connective tissue in 101 cases (80.8%), adipose tissue in 42 cases (33.6%), tendon in 14 cases (11.2%) and fibrin in 24 cases (19.2%). The 23 sample retrieving no synovial tissue were composed of fibrin in 15 cases (12%), conjunctive and adipose tissue in 17 cases (13.6%), tendon in 3 cases (3.15%), cartilage in 3 cases (3.15%) and muscle in one case (0.8%).
Synovial lining layer was found in 92.6% of the successful biopsies.
Interobserver reliability for presence/absence of synovial tissue between AN and the pathologist was high with a kappa coefficient of 0.90 (95%CI =0.763 to 1).
**Conclusions:** Our study is the first to assess quality and quantity of synovial tissue obtained by ultrasound guided biopsy, in the clinical setting. In 80% of the biopsy procedures, quantity and quality of the synovial tissue were high enough to allow a proper histological examination. Given the fact that conjunctive and adipose tissues as well as fibrin were frequently seen on histological examination, retrieving a minimal number of 2 samples per patient appears to be required for appropriate pathology assessment in the clinical setting.

## FRI0527 IMPACT OF ULTRASOUND IN TREATMENT DECISION OF RHEUMATOID ARTHRITIS ASSESSED IN ROUTINE CLINICAL PRACTICE

C. Sifuentes-Cantú [1], L. Saldarriaga-Rivera [2], I. Contreras-Yáñez [1], M. Gutiérrez [2], V. Pascual-Ramos [1]. *[1] Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán; [2] Division of musculoskeletal and rheumatic diseases, Instituto Nacional de Rehabilitación, México City, Mexico*

**Background:** Remission or low disease activity is the therapeutic target of rheumatoid arthritis (RA). There is a consistent body of evidence supporting the value of ultrasound (US) findings in the diagnosis, disease activity and treatment monitoring of RA patients. In spite of these pieces of information, the real impact of US in treatment decisions in patients has not yet sufficiently studied.
**Objectives:** To explore the impact of US findings, in terms of proportion of patients in whom treatment recommendation differed after the US examination, in RA outpatients. We also tested the variations of US impact according to the level of patient's disease activity or the physician's experience.
**Methods:** Thirty-five consecutive outpatients were included. In the 1st step a senior rheumatologist (SR) and a trainee in rheumatology (TR), blinded to each other evaluations performed a clinical evaluation including DAS28, then, they independently proposed a treatment recommendation. In the 2nd step, all patients underwent an US examination using the 7-joint US score (2) by an experienced rheumatologist blinded to clinical evaluation, in order to established the sonographic disease activity. In the final step, all the patients returned to both, the SR and the TR, who integrated the US findings to their previous evaluation and reviewed their prescription. Potential changes of treatment (pre- and post-US) between both physician's (SR and TR) were recorded on standardized formats. Patients received final recommendation only from the SR. US usefulness was separately evaluated by the SR and the TR according to a Likert scale (0= not useful at all, 10= very useful).
**Results:** Patients were mainly female (91.4%), with (mean±SD) 44.8±10.1 years of age and (median, Q25-Q75) disease duration of 6.5 years (2.9–11.2). Fifty-one (73%) patients were in DAS28-remission and 29 (27%) showed some disease activity. In 17 clinical evaluations (25%), data from US evaluation modified treatment and it was most frequently increased (64.7%). Interestingly, DAS28 was higher in clinical evaluations where US impacted treatment than in those where US did not: (median [Q25-Q75] DAS28: 2.6 (1.6–3.2) vs. 1.6 (1.1–2.2), p=0.009. Also, there was a higher proportion of active patients among the first group: 47% vs. 20.7%, p=0.06. Twelve of the 17 clinical evaluations where US modified treatment recommendation, were performed by TR vs. 5 performed by the SR: 71% vs. 29%, p=0.09; nonetheless, US usefulness was equally scored by both physicians: 3 (2–7) vs. 3 (2–5), p=0.5.
**Conclusions:** US was an important technique for the treatment decision in routine clinical practice of patients with RA; the impact of US was more frequent in patients with active disease and in TR.

## FRI0528 EPIDEMIOLOGICAL AND CLINICAL RELATIONSHIP OF ULTRASONOGRAPHIC FEATURES OF ACUTE ANSERINE SYNDROME

C.A. Guillen Astete [1], G. Silvestre-Egea [2], A. Boteanu [1]. *[1] Rheumatology Department; [2] Ramon y Cajal University Hospital, Madrid, Spain*

**Background:** Anserine syndrome (AS) includes two pathological presentarions: The anserine bursitis and the anserine enthensytis. Most diagnostics of anserine syndrome are made considering topographic semiotics. It is logical to assume that treatment of different physiopathological features are associated with different clinical history but not necessary with differences in the clinical exam.
**Objectives:** To find relationships between ultrasonographic (US) findings and epidemiological data in patients with anserine syndrome
**Methods:** All the images of ultrasonographic studies of patients from 2013 to 2014 who were clinically assessed due to AS were reviewed. For that purpose we use the electronic database of the A&E department. Gender, age, and time from onset of symptoms were used to find correlation with US findings. US assessments were performed by two trained rheumatologist using standard Eular definitions as part of common clinical practice during the period selected. Findings considered positive were: bursitis and enthesitis.
**Results:** 113 registries which fulfilled the clinical diagnostic criteria were analyzed with their corresponding ultrasonographic images. 38 cases were unrelated to any particular ultrasonogrpahic finding, 20 were compatible with bursitis and 56 with enthesitis. Average age in the three groups were 69 SD 8, 46 SD 7 and 55 SD 9 years old ($P<0.0001$). Patients with bursitis where significantly younger than patients with enthesitis ($P=0.0001$). Also, patients without findings were significantly older than both other groups ($P<0.0001$ for both comparisons). Proportion of female gender was 58.9%, 65,0% and 53.6%, in enthesitis, bursitis and no-findings group, respectively ($P=0.647$). According to time since onset of symptoms, patients with less than a week presented bursitis and enthesitis in 55.17% and 34.48%, respectively. Patients with symptoms within 7 to 14 days presented bursitis and enthesitis in a proportion of 6.67% and 46.67%, respectively. Finally patients with symptoms within 15 days and less than a month presented bursitis in 2.56% and enthesitis in 64.10%. Bursitis was significantly higher in patients with acute symptomps compared to the other two groups ($P<0.001$). In the other hand, most patients with enthesitis were classified into the groups with a longer time since onset of symptoms ($P<0.05$)
**Conclusions:** Our results point as Follows: (1) The probability of identify no US findings is higher in older patients than younger. It is possible that mechanical issues related with the collateral ligament could cause a pain that suggest an anserine syndrome. (2) As earlier the symptoms are, is more factible the finding of bursitis. It could suggest that bursitis is a sign of acuteness. This finding could have relevance in terms of infiltration indication.

## FRI0529 INITIAL VALIDATION OF THE SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS (SPARRA) QUESTIONNAIRE

M.V. Beers-Tas [1], L.V. Tuyl [1], B. Maat [1], W. Hoogland [1], R. Stack [2], K. Raza [2], D.V. Schaardenburg [1]. *[1] Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands; [2] Institute of Inflammation and Ageing, University of Birmingham, United Kingdom*

**Background:** A range of clinical symptoms can be present in people at risk of rheumatoid arthritis (RA). However, information on location, timing, severity and predictive value of symptoms is still largely lacking. The Symptoms in Persons At Risk of Rheumatoid Arthritis (SPARRA) questionnaire has been developed with support of EULAR to provide more insight into these symptoms[1,2].
**Objectives:** To validate the SPARRA questionnaire in an international group of arthralgia patients at risk of RA.
**Methods:** Questions on presence, severity, impact and location of 13 symptoms were derived from a qualitative study in seropositive arthralgia patients[1]. The items are: joint pain or swelling, joint stiffness, burning and tingling sensations, numbness, change in skin colour, muscle cramps, weakness, fatigue, emotional distress, concentration difficulties and sleep problems. Answers are given on an ordinal scale. The number of days with a symptom per month (0, 1–5, 6–15, 16–30 days), severity (none, mild, moderate and severe) and influence on daily activities (no, small, moderate or high impact) were recorded. Finally, patients were asked to describe the pattern of symptom development over time. For this initial analysis of validity, patients were selected from the Dutch arthralgia cohort. We first administered the questionnaire to 30 patients to ask for ambiguities. Thereafter, 46 patients did a test-retest within one week to assess intra-rater agreement using the % agreement and the kappa score.
**Results:** Feedback on the questionnaire was received from 5/30 patients. There were only minor comments that did not lead to adaptations, such as difficulty distinguishing pain from stiffness (n=1) and difficulty describing muscle cramps (n=1). 46 arthralgia patients were assessed at 2 time points. The rater agreement was moderate to good for most items with kappa's of 0.42 to 0.93. We also found acceptable percentages of agreement of 65 to 91 (Table 1). Only tingling sensations and numbness scored low in agreement, with kappa's of 0.37 and 0.15, respectively. The kappa's were good across the presence, severity and impact

Table 1. Test-retest analysis of the SPARRA questionnaire (N=46)

| Items | % agreement[1] | Prevalence of the complaint[2] |
|---|---|---|
| Joint pain | 78% | 83% |
| Joint swelling | 91% | 37% |
| Joint stiffness | 76% | 74% |
| Burning sensations | 78% | 33% |
| Tingling sensations | 65% | 43% |
| Numbness | 74% | 30% |
| Change in skin colour | 87% | 20% |
| Muscle cramps | 78% | 28% |
| Weakness or loss of strength | 83% | 54% |
| Fatigue | 87% | 72% |
| Emotional distress | 83% | 37% |
| Concentration difficulties | 83% | 33% |
| Sleep problems | 83% | 57% |

[1]Retest analysis per item of duration of the complaint during the past month (0, 1–5, 6–15 or 16–30 days). [2]Percentage of patients that had the complaint at least 1 day in the past month in the first questionnaire.

of the item categories. Data on clinical variables and follow-up questionnaires to assess the construct and criterion validity will be presented at the congress.
**Conclusions:** The SPARRA questionnaire seems to be a reliable scale for evaluating symptoms in persons at risk for RA. More follow-up and data from collaborating centers within Europe is necessary for assessment of the construct, criterion and external validity.

## FRI0530 INTRA-AND INTER-OBSERVER RELIABILITY OF NAILFOLD VIDEOCAPILLAROSCOPY – A POSSIBLE OUTCOME MEASURE FOR SYSTEMIC SCLEROSIS-RELATED MICROANGIOPATHY?

G. Dinsdale[1], T. Moore[1], N. O'Leary[1], J. Manning[2], A. Murray[1], M. Berks[1], P. Tresadern[1], J. Allen[3], M. Anderson[4], M. Cutolo[5], R. Hesselstrand[6], K. Howell[7], C. Pizzorni[5], P. Pyrkotsch[4], V. Smith[8], A. Sulli[5], M. Wildt[6], C. Taylor[1], C. Roberts[1], A. Herrick[1]. [1]*University of Manchester, Manchester;* [2]*Salford Royal Hospital, Salford;* [3]*Freeman Hospital, Newcastle upon Tyne;* [4]*University of Liverpool, Liverpool, United Kingdom;* [5]*University of Genova, Genova, Italy;* [6]*Lund University, Lund, Sweden;* [7]*University College London, London, United Kingdom;* [8]*Ghent University, Ghent, Belgium*

**Background:** Nailfold videocapillaroscopy (NVC) has been proposed as an outcome measure for systemic sclerosis [SSc] related microvascular disease.
**Objectives:** To assess the reliability of both measure availability and measured value of 4 parameters extracted from NVC images: capillary density, capillary (apex) width, overall image grade (normal, early, active, late), and the presence of giant capillaries.
**Methods:** 173 subjects were recruited in the study (101 with SSc, 22 with primary Raynaud's phenomenon and 50 controls). Panoramic NVC imaging was performed on all 10 digits using a 300x magnification microscope with green LED illumination for best capillary contrast.
Ten capillaroscopy experts ("raters") from 7 centres assessed images using custom software. Raters were asked to: (1) assess overall image grade ("Normal", "Early", "Active", "Late", "Non-specific", or "Ungradeable"), (2) mark the location of capillary apices (capillary density calculated from distal vessel locations), (3) categorically grade the distal vessels in terms of size and shape, and (4) measure the apical width of distal vessels using a click-and-drag tool.
**Results:** The 10 raters analysed a median (range) of 129 (98–1641) images, returning 3401 evaluations of 1650 images, including a sub-sample analysed twice by the same rater to measure intra-rater reliability. Of these, 2731 evaluations (80%) satisfied the criteria to allow vessel density to be measured (at least 2 distal vessels identified).
The reliability (intra- and inter-rater) of both measure availability and measured value for the 4 parameters are shown in the table. Overall image grade was available in only around 45% of observations due to the exclusion of "non-specific" gradings from the analysis.

Table 1

| | Intra-rater reliability (95% CI) | Inter-rater reliability (95% CI) |
|---|---|---|
| Measure availability | | |
| Distal vessel density | 0.71 (0.62, 0.79) | 0.14 (0.09, 0.21) |
| Mean distal apical width | 0.73 (0.65, 0.79) | 0.26 (0.19, 0.34) |
| Overall image grade | 0.56 (0.48, 0.64) | 0.22 (0.17, 0.27) |
| Presence of giant capillary | 0.69 (0.59, 0.78) | 0.13 (0.08, 0.20) |
| Measure (conditional on availability) | | |
| Distal vessel density | 0.90 (0.88, 0.92) | 0.64 (0.55, 0.71) |
| Mean distal apical width | 0.91 (0.89, 0.92) | 0.85 (0.81, 0.88) |
| Overall image grade | 0.93 (0.92, 0.95) | 0.78 (0.72, 0.82) |
| Presence of giant capillary | 0.71 (0.66, 0.76) | 0.41 (0.33, 0.48) |

**Conclusions:** Capillary density and (especially) apical width, parameters likely to be helpful in quantifying temporal change, were reliable measures in evaluable nailbeds. The reliability of measured values is generally high, but is conditional on measure availability. This must be accounted for when considering the applicability of outcome measures to clinical trial situations. With standardised training (and potentially increased automation of analysis), high magnification NVC has strong potential as an outcome measure of SSc-related microangiopathy.

## FRI0531 DIFFERENCES IN ULTRASONOGRAPHIC DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS WHO ARE IN CLINICAL REMISSION ACCORDING TO DIFFERENT REMISSION CRITERIA

G. Ozen, A.U. Unal, A. Topcu, P. Atagunduz, H. Direskeneli, N. Inanc.
*Rheumatology, Marmara University School of Medicine, Istanbul, Turkey*

**Background:** At the present time remission is the target for treatment of rheumatoid arthritis (RA). Various composite indices are available that can be used to define remission. Although the new ACR/EULAR Boolean criteria is more stringent than others, it is difficult to achieve and even more difficult to sustain this Boolean remission.
**Objectives:** In this study we aimed to determine the differences of the ultrasonographically (US) assessed actual disease activities of the patients in remission according to different remission criteria.
**Methods:** RA patients in clinical remission (DAS28-ESR<2.6) for at least 3 months were included to this cross-sectional study. All patients' remission status according to DAS28-ESR-3, DAS28-CRP, SDAI, CDAI and Boolean based definitions were assessed. A standard gray scale (GS) and power Doppler (PD) US examination of 28 joints (included in DAS28) for the presence of synovitis was performed by an experienced sonographer (NI) blinded to clinical data. US synovitis GS and PD signals were semiquantitatively graded from 0 to 3. Total PD and GS synovitis scores of all sites are recorded as sum scores of PD and GS, respectively.
**Results:** A total of 88 out of 389 RA patients (22.6%) in DAS28 remission were enrolled (F/M=55/33, mean age 53.4±12.0, disease duration 10.5±6.3 years, bDMARDs 44.3%, RF/Anti-CCP positivity 72%). Of the 88 patients, 82 (93.2%), 72 (81.8%), 49 (55.7%), 40 (45.5%) and 33 (37.5%) fulfilled the DAS28-CRP, DAS28-ESR-3, SDAI, CDAI and Boolean remission criteria, respectively. PD synovitis scores which have shown to be associated with erosion development and worse functional outcome were lowest in CDAI, Boolean and SDAI remission. However despite that, those differences in US disease activity parameters (both PD and GS synovitis sum scores and percentages of patients without PD and GS signals [with both omitting and including grade 1 signals]) in remission patients according to different criteria were not statistically significant (*Table 1*). In comparison of US disease activity parameters of remission vs nonremission groups, only patients with Boolean and CDAI remission had significantly lower PD scores compared to their counterpart nonremission group (for both, 1 [0–4] vs 3 [1–7], *P*=0.015).

Table 1. Ultrasonographic disease activities of patients according to different remission criteria*

| | DAS28-ESR REM (n=88) | DAS28-CRP REM (n=82) | DAS28-ESR-3 REM (n=72) | SDAI REM (n=49) | CDAI REM (n=40) | Boolean REM (n=33) |
|---|---|---|---|---|---|---|
| PD sum score (0-84) | 2 (0-5) | 2 (0-5) | 2 (0-5) | 1 (0-4.2) | 1 (0-4) | 1 (0-4) |
| GS sum score (0-84) | 4 (2-8) | 3 (1-8) | 3 (2-8) | 4 (2-8) | 2.5 (0-7) | 2 (0-6.2) |
| PDGS sum score (0-168) | 6.5 (2-13) | 5 (2-13) | 5 (2-13) | 5 (2.5-11) | 4 (0.25-11) | 3 (0-8.2) |
| US joint count with PD signal (0-28) | 2 (0-3) | 1.5 (0-3) | 2 (0-3) | 1 (0-3) | 1 (0-2) | 1 (0-2.2) |
| US joint count with GS signal (0-28) | 2.5 (1-4) | 2 (1-4) | 2 (1-4) | 2 (1-4) | 2 (0-4) | 2 (0-4) |

| PD≥1† | 42 (47.7) | 42 (51.2) | 38 (52.8) | 28 (57.1) | 24 (60) | 21 (63.6) |
| GS=0† | 15 (17) | 15 (18.3) | 11 (15.3) | 10 (20.4) | 11 (27.5) | 10 (30.3) |
| GS≥1† | 36 (40.9) | 36 (43.9) | 31 (43.1) | 22 (44.9) | 20 (50) | 16 (48.5) |
| PD=0 and GS=0† | 14 (15.9) | 14 (17.1) | 11 (15.3) | 9 (18.4) | 10 (25) | 9 (27.3) |
| PD≥1 and GS≥1† | 32 (36.4) | 32 (39) | 27 (37.5) | 20 (40.8) | 19 (47.5) | 16 (48.5) |
| US/C with PD=0† | 34 (42.2) | 34 (28.6) | 19 (26.4) | 14 (28.6) | 14 (35) | 13 (39.4) |
| US/C with PD≥1† | 42 (46.8) | 42 (50) | 38 (48.6) | 28 (57.1) | 24 (60) | 21 (63.6) |
| US/C with GS=0† | 15 (17) | 15 (18.3) | 11 (15.3) | 10 (20.4) | 11 (27.5) | 10 (30.3) |
| US/C with GS≥1† | 36 (40.9) | 36 (43.9) | 31 (43.1) | 22 (44.9) | 20 (50) | 16 (48.5) |

*The values were presented as median (IQR) unless indicated otherwise. †The values were presented as n (%). All P values >0.05

**Conclusions:** US verified joint inflammation is the lowest in RA patients who are in remission according to Boolean and CDAI criteria. However, the clinical significance of this statistically nonsignificant inflammatory activity compared to other clinical remission criteria should be assessed in prospective studies. Till then, in clinical practice if Boolean remission could not be achieved, CDAI or SDAI could also be preferred as the remission target.
**Disclosure of Interest:** None declared

## FRI0532 ASSOCIATION BETWEEN THE 7-JOINT ULTRASOUND SCORE (US7S) AND PHYSICAL FUNCTION IN RHEUMATOID ARTHRITIS

J. Zavada[1], P. Hanova[1], J. Hurnakova[1], M. Uher[2], L. Puczokova[2], S. Forejtova[1], M. Klein[1], H. Mann[1], M. Olejarova[1], O. Sleglova[1], K. Pavelka[1]. *[1]Institute of Rheumatology, Prague; [2]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic*

**Objectives:** To investigate the longitudinal relationship between physical disability and US7S in a prospective cohort of patients with RA.
**Methods:** A cohort of 205 RA pts (49 incident/156 prevalent) (mean±SD age 55±14 years, 47% RF+, 63% ACPA+, DAS28-CRP 3.7±1.5, mHAQ 0.43±0.52, disease duration in incident vs. prevalent pts. 0.9±0.7 vs. 8.1± 8.3 resp.) was followed up longitudinally for 29±9 months. Assessments at baseline and at month 3 and 6, and then every 6 months comprised DAS28-CRP, functional evaluations using the modified Health Assessment Questionnaire (mHAQ) and an ultrasound assessment of the clinically dominant hand and foot by US7S[1]. US7S consists of 5 subscores for synovitis (syn) and tenosynovitis (ten) assessed by grey-scale (GS) and Power-Doppler (PD), and an erosions score (ES). A linear mixed model was used to assess the longitudinal relationship between US7 subscores and mHAQ. Univariate analyses with an interaction term for incident vs. prevalent disease, and a multivariate analysis (with age, sex, BMI, RF and ACPA status, and DAS28-CRP entered as covariates) were performed.
**Results:** In univariate analyses (table) mHAQ was longitudinally associated with GSsyn, PDsyn, PDten and GSten US7 subscores (with resp. β coefficients significantly higher in incident patients), while erosions score was a significant predictor of mHAQ only in prevalent pts. In a multivariate model the US7 subscores were individually no longer significant predictors of mHAQ, although the $R^2$ of the model was improved by addition of US7 items from 43.6 to 46.9 ($p<0.001$ for improvement of $R^2$).

Table 1. Univariate analyses and interaction with incident (i)/prevalent (p) RA (predicted variable – mHAQ)

| Predictor | RA | β (95% CI) | p-value* | p-value** | % variability explained – $R^2$ |

| | p | 0.013 (0.001; 0.026) | **0.047** | | |

*p-value of significance of given β. **p-value of significance of difference between incident and prevalent RA.

**Conclusions:** This study provides evidence that RA related activity and damage reflected by US7S contribute to impaired physical function in RA, and their impact differs in early and established disease. When combined with conventional clinical parameters, the additional explanatory value of US7 for mHAQ was only minor.

## FRI0533 THE DIAGNOSTIC PERFORMANCE OF POST-CONTRAST 3-D ULTRASHORT ECHO TIME SEQUENCE OF SACROILIITIS IN PATIENTS WITH AXIAL SPONDYLOARTHROPATHY COMPARING WITH CONVENTIONAL POST-CONTRAST FAT SUPPRESSED T1 WEIGHTED SEQUENCE

K.H. Jung[1], Y.J. Kim[2], W. Park[1], M.J. Lim[1], M. Carl[3], D.E. Kim[4], M. Hwang[4], J.G. Cha[5], S. Kwon[1]. *[1]Division of Rheumatology, Department of Internal Medicine; [2]Department of radiology, Inha University, Incheon, Korea, Republic Of; [3]GE Healthcare, San diego, United States; [4]GE Healthcare, Seoul; [5]Department of radiology, Soonchunhyang University Hospital, Bucheon, Korea, Republic Of*

**Background:** Axial spondyloarthropathies (axSpA) are chronic inflammatory diseases affecting the sacroiliac joint, spine, peripheral joint, and entheses. Entheses are emphasized as one of the primary targets of axSpA, but they show little signal on conventional clinical magnetic resonance (MR). Recently, the ultrashort echo time (UTE) sequence has been reported to be useful in detecting a signal from the tissues with short T2 such as the ligaments, periosteum, and cortical bone. Contrast enhancement study of UTE sequence showed increased enhancement as a consequence of angiogenesis in a diseased tendon and fibrocartilage. To our knowledge, no prior study has compared the diagnostic performances of post-contrast 3D UTE and conventional post-contrast fat suppressed T1 weighted sequence (FST1WI) for sacroiliitis in patients with axSpA.
**Objectives:** To compare the diagnostic performance of post-contrast 3D UTE and conventional FS1WI for sacroiliitis.
**Methods:** Total 16 patients with axSpA (asSpA group: 10 men, 6 women, mean age: 35.56 years [range: 24–52 years], human leukocyte antigen B 27 positivity 81.25%,) and 10 patients with mechanical back pain (control group: 2 men, 8 women, mean age: 58.6 years [range 34–74 years]) were enrolled in this prospective study. All patients underwent oblique coronal short tau inversion recovery sequence (STIR), pre/post contrast fat suppressed (FS) 3D UTE, and post contrast FST1WI. Active inflammation of the sacroiliac joint was quantitatively analyzed and scored on post-contrast FS 3D UTE and post contrast FST1WI for inflammatory findings, such as osteitis, synovitis, capsulitis, and enthesitis, by two musculoskeletal radiologists with a consensus. The score per active inflammatory finding of 3D UTE and post contrast FST1WI was compared between axSpA group and control group using Wilcoxon rank test.
**Results:** The axSpA group showed higher scores for osteitis and synovitis on both post-contrast FS 3D UTE ($P$ =0.018, 0.025, respectively) and post-contrast FST1WI ($P$ =0.003, 0.005, respectively) and for enthesitis on post-contrast FS 3D UTE with a statistical significance ($P$ =0.004). Post-contrast FS 3D UTE showed statistically significant lower scores for all inflammatory findings than enhanced FS T1 WI sequences did ($P$ <0.05).

Figure 1. Oblique coronal image of the SI joint of a 23-year-old man with ankylosing spondylitis. Bone marrow edema (black arrow) is better visualized on FST1WI (A). However, the erosions (white arrow) and synovial enhancement (white dashed arrow) are more clearly visualized on FS 3D UTE with and without enhancement (B,C).

**Conclusions:** Post contrast 3D UTE can differentiate axSpA and mechanical back pain, especially when considering enthesitis. Although it showed slightly lower diagnostic performance for the active inflammatory finding than post contrast FST1WI did, post contrast 3D UTE might play a supplementary diagnostic role for early diagnosis of axSpA.

## FRI0534 STUDYING BONE MINERAL DENSITY LOSS IN CLINICALLY SUSPECT ARTHRALGIA, ASSOCIATIONS WITH SUBCLINICAL INFLAMMATION AND PROGRESSION TO CLINICAL ARTHRITIS

L. Mangnus[1], H.W. van Steenbergen[1], M. Reijnierse[2], J. Kälvesten[3], A.H.M. van der Helm-van Mil[1]. *[1]Department of rheumatology; [2]Department of radiology, LUMC, Leiden, Netherlands; [3]Radiology, Department of Medicine and Health Sciences, Faculty of Health Sciences, Linköping, Sweden*

**Background:** Peripheral bone mineral density (BMD) can be decreased in early rheumatoid arthritis but it is unknown if BMD loss emerges already before arthritis is clinically apparent.
**Objectives:** We aimed to study if BMD loss occurs in patients with clinically suspect arthralgia (CSA), if it is associated with progression to clinical arthritis and if it is associated with MRI-detected subclinical inflammation.
**Methods:** Patients with CSA had arthralgia for <1 year and were suspect to progress to RA according to their rheumatologists. At baseline a 1.5T MRI was performed of unilateral MCP, wrist and MTP-joints and scored on synovitis, bone marrow edema and tenosynovitis;. summing these features yielded the MRI-inflammation score. Digital X-ray radiogrammetry (DXR) was used to measure BMD on two sequential conventional hand radiographs (mean interval between radiographs 4.4 months). The change in BMD was studied; BMD loss was defined as decrease of ≥2.5 mg/cm$^2$/month. Patients were followed on arthritis development for median 18.4 months.
**Results:** In CSA-patients (n=108) change in BMD was negatively associated with age (β=-0.03, p=0.007). Within CSA-patients BMD loss was associated with arthritis development (adjusted for age HR=6.1, 95%CI=1.7;21.4) and was most frequently measured in the months before clinical arthritis development. The MRI-inflammation scores were associated with the change in BMD (adjusted for age β=-0.05, p=0.047). The MRI-inflammation score and BMD loss were both independently associated with arthritis development (HR=1.1 95%CI=1.1;1.2 and HR=4.6 95%CI=1.2;17.2 respectively).

**Conclusions:** In CSA-patients BMD loss is associated with MRI-detectable subclinical inflammation and with progression to clinical arthritis.

## FRI0535 HAND BONE LOSS IN EARLY RHEUMATOID ARTHRITIS IS INDEPENDENT OF ADALIMUMAB TREATMENT. A SUBSTUDY OF THE OPTIMIZED TREATMENT ALGORITHM IN EARLY RA (OPERA) TRIAL

L.M. Ørnbjerg[1], M. Østergaard[1], T. Jensen[2], K. Hørslev-Petersen[3], K. Stengaard-Pedersen[4], P. Junker[5], T. Ellingsen[6], P. Ahlquist[7], H. Lindegaard[5], A. Linauskas[8], A. Schlemmer[9], M.Y. Dam[6], I. Hansen[10], T. Lottenburger[11], C.G. Ammitzbøll[4], A. Jørgensen[4], S. Krintel[1], J. Raun[3], M. Hetland[1].
*[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet; [2]Department of Endocrinology, Hvidovre Hospital, Copenhagen; [3]King Christian X Hospital for Rheumatic Diseases, South Jutland Hospital, Gråsten; [4]Department of Rheumatology, Aarhus University Hospital, Aarhus; [5]Department of Rheumatology, Odense University Hospital, Odense; [6]Diagnostic Centre, Silkeborh Regional Hospital, Silkeborg; [7]Department of Medicine, Vejle Regional Hospital, Vejle; [8]Department of Rheumatology, Vendsyssel Hospital, Hjørring; [9]Department of Rheumatology, Aalborg University Hospital, Aalborg; [10]Department of Rheumatology, Viborg Regional Hospital, Viborg; [11]Department of Rheumatology, Vejle Regional Hospital, Vejle, Denmark*

**Background:** Rheumatoid arthritis (RA) is characterised by progressive destruction of joint bone and loss of periarticular bone mineral. Hand bone loss (HBL) measured by Digital X-ray Radiogrammetry (DXR) has been proposed as a sensitive outcome measure for treatment effect and as a potential predictor of subsequent radiographic progression in RA patients.
**Objectives:** To investigate the effect of adding adalimumab to a methotrexate and intra-articular triamcinolone treat-to-target strategy on one-year HBL ($HBL_{one\text{-}year}$) in early RA and to determine if $HBL_{6months}$ is associated with radiographic progression after two years.
**Methods:** In a clinical trial (OPERA) of 180 treatment-naive early RA patients (1), bone mineral density (BMD) was estimated from hand radiographs with Digital X-ray radiogrammetry (DXR) at baseline, after 6 months (n=90) and 12 months (n=70) of follow-up. Baseline and two-year radiographs were scored according to the Sharp/van der Heijde method. Baseline characteristics and $HBL_{6months}$ (0–6 months changes in DXR-BMD) were investigated as predictors of structural damage by univariate linear ($\Delta$Total Sharp/van der Heijde Score (TSS) as dependent variable) and logistic (+/– radiographic progression ($\Delta TSS>0$) as dependent variable) regression analyses. Variables with $p<0.10$ were included in multivariable models.
**Results:** In 70 patients with available $HBL_{one\text{-}year}$ data, $HBL_{one\text{-}year}$ was median (InterQuartileRange (IQR)) -1.9 (-3.3; -0.26 mg/cm$^2$) in the placebo-group and -1.8 (-3.6; 0.06) mg/cm$^2$ in the adalimumab-group, p=0.98,Mann Whitney. Increased HBL (compared to general population reference values (2)) was found in 26/37 and 23/33 patients in the placebo- and adalimumab-groups, Chi-sq=0.99. In 90 patients with $HBL_{6months}$ data and two-year radiographic data, $HBL_{6months}$ was independently associated with $\Delta$TSS after two years ($\beta$=-0.086 (95% Confidence Interval= -0.15; -0.025) TSS unit/mg/cm$^2$ increase,p=0.006), and borderline associated with presence of radiographic progression ($\Delta TSS>0$) (OR 0.96 (0.92–1.0), p=0.10).
**Conclusions:** In early RA, adding adalimumab to a methotrexate-based treat-to-target strategy had no impact on $HBL_{one\text{-}year}$, which was increased in both treatment groups. $HBL_{6months}$ was independently associated with $\Delta$TSS after two years.

## FRI0536 A NEW SYSTEM FOR INVESTIGATING CAPILLARY MORPHOLOGY AND BLOOD FLOW IN SYSTEMIC SCLEROSIS

M. Berks[1], G. Dinsdale[1], A.K. Murray[1], T. Moore[2], S. Rhodes[1], C. Taylor[1], A. Herrick[1,2]. *[1]University of Manchester, Manchester; [2]Salford Royal NHS FT, Salford, United Kingdom*

**Background:** Nailfold videocapillaroscopy (NVC) captures high-magnification images of capillaries, allowing non-invasive assessment of systemic sclerosis [SSc] related microvascular disease. We have developed a state-of-the-art NVC system to enable faster and easier acquisition of high quality static images and produce video sequences in which red blood cell velocity can be measured. The system uses novel software to make fully automated quantitative estimates of capillary morphology and blood flow velocity, eliminating the need for (subjective) clinician input to image interpretation.
**Objectives:** To apply the new system in a case-control study to: 1) assess system usability 2) test how well automated measures of capillary morphology differentiate between healthy controls (HC), subjects with primary Raynaud's phenomenon (PRP) and patients with SSc 3) investigate capillary blood flow velocity as a new quantitative measure for NVC.
**Methods:** 112 participants were recruited into the study (50 HC, 12 PRP, 50 SSc). Panoramic video sequences were taken for all 10 digits, each comprising 10,000 – 20,000 frames (size: 640x480 px, spatial resolution: 1$\mu$m/px, frame rate: 120 frames/s). The frames were processed and registered to produce a static panorama of the whole nailfold ($\sim$2–5mm wide). The analysis software automatically detected and measured capillary structural properties in this image[1], before using in-focus frames at each capillary to create video sequences for blood flow velocity estimation (Fig 1). Capillary-level measurements were averaged across all 10 nailfolds to produce subject-level parameters: capillary density, mean capillary width, maximum capillary width, shape score, derangement and mean flow velocity. For each parameter one-way ANOVA and Tukey's range test were used to check for group differences, and the area under ROC curve ($A_z$) used to measure separation between HC/PRP and SSc.
**Results:** ANOVA tests showed significant group-wise differences for all parameters. Table 1 shows group means and $A_z$ for each parameter.

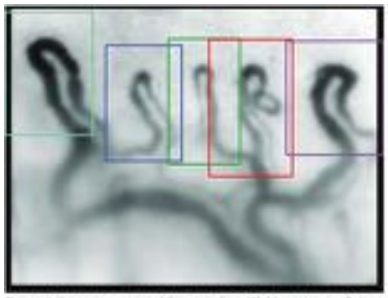

**Figure 1:** Segment extracted from whole nailfold panorama. Coloured boxes show capillaries detected by analysis software. Within each box the width and shape of the capillary is measured using the static image. A video sequence of in-focus frames is then extracted for each box and used to estimate capillary blood flow velocity.

**Conclusions:** The new system successfully generated high-quality video sequences, and allowed fast panoramic imaging of the whole nailfold. Automatically extracted capillary morphology parameters matched both clinical expectations and previous study results[1,2] and show considerable promise as outcome measures for SSc. Preliminary flow results suggest reduced blood velocity is associated with abnormal morphology and thus lower in SSc patients, further work is needed to corroborate this.

## FRI0537 AUTOMATED JOINT SPACE WIDTH MEASUREMENT AND DIGITAL X-RAY RADIOGRAMMETRY IN EARLY RA

M. Platten[1], Y. Kisten[1], J. Kälvesten[2,3], L. Arnaud[1], K. Forslind[4,5], R. van Vollenhoven[1,6]. *[1]Department of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Karolinska Institute, Stockholm; [2]Medicine and Health Sciences, Center for Medical Image Science and Visualization (CMIV), Linköping University; [3]Sectra AB, Linköping; [4]Section of Rheumatology, Department of Medicine, Helsingborg Hospital; [5]Section of Rheumatology, Department of Clinical Sciences, Helsingborg, Sweden; [6]Departments AMC, READE and VUmc, Amsterdam Rheumatology & Immunology Center (ARC), Amsterdam, Netherlands*

**Background:** Despite technological advancements and the availability of ultrasound and magnetic resonance imaging modalities, conventional radiography still remains the main imaging tool in Rheumatoid Arthritis (RA) patient management (1). One of the validated methods of radiographic scoring in RA, the modified Sharp van der Heijde (SHS) method, has much strength but is time-consuming, observer-dependent, and requires training, and is therefore seldom used in clinical practice (1, 2). Automated digital methods have been developed for analysing radiographs and may provide useful information on Joint Space Width (JSW) and/or Bone Mineral Density (BMD).
**Objectives:** To assess the feasibility and correspondence of fully automated digital measurements of JSW with conventional methods in early RA.
**Methods:** Patient characteristics and radiographic reports scored by the SHS method of 119 early RA patients were acquired from the SWEFOT database. From this cohort, 96 patients had both baseline and follow-up JSW and BMD measurements. Fully automated bilateral BMD of metacarpal diaphyses 2–4 and JSW of MCP joints 2, 3 & 4 (Sectra, Linköping, Sweden) were assessed. Additionally, JSW was compared to the joint space narrowing (JSN) score. Multilevel mixed models taking into account correlations between joints of the same hand, contralateral hand and repeated visits were used. Furthermore, these models were adjusted for height, age, gender and BMI.
**Results:** We studied 119 early RA patients (78% female), with an average age of 54 ±14.4 years. In 576 joints, patients with both baseline and follow-up JSW and BMD measurements, a significant reduction from baseline to 1 year was shown in the mean JSW (0.169 ±0.019cm to 0.166 ±0.019cm, $p<0.01$) and mean BMD (0.583 ±0.068g/cm$^2$ to 0.566 ±0.074g/cm$^2$, $p<0.01$). Significant correlations between JSW and BMD were observed at baseline ($r=0.32$, $p<0.01$) and 12-months ($r=0.35$, $p<0.01$). Inverse correlations emerged between automated JSW and SHS Joint Space Narrowing (JSN) assessments at baseline ($r=-0.29$, $p<0.01$) and 12-months ($r=-0.24$, $p=0.014$). JSWs of undamaged (JSN=0) joints were wider than damaged joints (0.168cm [95% CI: 0.170–167] versus 0.154cm [95% CI: 0.163–0.146]). Similarly the unadjusted multilevel model showed significant differences in JSW between undamaged (0.168cm [95% CI: 0.172–0.164]) and damaged joints (0.163cm [95% CI: 0.168–0.158cm]), $p<0.01$. This difference remained significant in the adjusted model (0.166cm [95% CI: 0.170–0.161] versus 0.162cm [95% CI: 0.168–0.156], $p<0.05$).

**Patient Demographic data of SWEFOT population versus study cohort**

| Demographic | SWEFOT patients (N=487) | Study Patients (n=119) | p-value |
|---|---|---|---|
| Female sex; n [%] | 344 (70.6) | 93 (78.2) | 0.13 |
| ACPA pos; n [%] | 310 (63.7) | 60 (57.7) | 0.25 |
| RF pos; n [%] | 333 (68.4) | 76 (65.0) | 0.47 |
| DAS28; mean (SD) | 5.73 (1.01) | 5.64 (0.95) | 0.39 |
| ESR, mm; mean (SD) | 39.8 (28.1) | 37.5 (24.3) | 0.45 |
| CRP, mg/l; mean (SD) | 33.7 (42.4) | 34.8 (38.1) | 0.69 |
| HAQ; mean (SD) | 1.19 (0.58) | 1.18 (0.56) | 0.95 |
| SHS ; mean (SD) | 4.54 (8.01) | 4.49 (8.20) | 0.74 |
| JSN; mean (SD) | 2.63 (7.08) | 2.45 (5.68) | 0.50 |
| ES; mean (SD) | 1.91 (3.75) | 2.03 (3.70) | 0.34 |

**Conclusions:** Digital JSW may have potential as a quick and observer-independent measure of cartilage damage in early RA.

## FRI0538 VALIDATION OF A SEMI-AUTOMATIC ALGORITHM FOR DEFINING CORTICAL BREAKS IN FINGER JOINTS USING HIGH-RESOLUTION PERIPHERAL QUANTITATIVE CT BY MICROCT

M. Peters[1], A. Scharmga[1], A. van Tubergen[1], B. van Rietbergen[2], R. Weyers[3], D. Loeffen[3], J. Van den Bergh[1], P. Geusens[1]. *[1]Rheumatology, MUMC, Maastricht; [2]Biomedical Engineering, TUE, Eindhoven; [3]Radiology, MUMC, Maastricht, Netherlands*

**Background:** High-Resolution peripheral QCT (HR-pQCT) imaging has a higher sensitivity in the detection of breaks compared to conventional radiography (1). Cortical bone in the finger joints is very thin (≈100μm) and it is therefore possible that the HR-pQCT is not able to detect these thin structures. An automatic algorithm that is based on binary images can therefore falsely identify these regions as breaks. To investigate the extent of this error, cortical break detection on HR-pQCT was compared to that on μCT with a higher resolution.
**Objectives:** To investigate the proportion of falsely detected breaks with a semi-automatic algorithm on HR-pQCT compared to μCT.
**Methods:** Nineteen finger joints of ten human female cadaveric index fingers (mean age ± SD; 85.1 ± 9.6 years) with unknown medical history were imaged by HR-pQCT and μCT (82 and 18μm isotropic voxel sizes, respectively). A semi-automatic algorithm was applied to HR-pQCT and μCT for the detection of cortical breaks. First, the outer margin of the bone structure was contoured. Second, the bone within 0.25mm from this contour was selected as cortical region. Last, different sizes for defining a cortical break (>0.50mm, >0.66mm and >0.82mm) were applied and evaluated. μCT images were registered to HR-pQCT in order to compare the locations of the detected breaks. The false discovery rate (FDR) of breaks detected on HR-pQCT was calculated, with μCT as reference.
**Results:** The number of breaks depended on the image modality and chosen break size, and varied between 0.8 and 20.8 breaks per joint (table 1).

Table 1. Comparison of the breaks detected on HR-pQCT and μCT by the algorithm using different break sizes

| Minimal break size | Number of breaks per joint[1] (n=19 joints) | | FDR of HR-pQCT[2] | |
|---|---|---|---|---|
| | HR-pQCT | μCT | μCT same break size | μCT break size of >0.50mm |
| >0.50mm | 14.2±11.6 | 20.8±19.4 | 37.9% | 37.9% |
| >0.66mm | 4.9±4.7 | 4.1±4.8 | 50.0% | 6.4% |
| >0.82mm | 2.4±2.5 | 0.8±1.1 | 86.7% | 4.4% |

[1]Mean ± SD; [2]μCT as reference.

The locations of the detected breaks on HR-pQCT and μCT generally correspond well (Fig 1-I). On HR-pQCT, however, breaks may be detected as large breaks, whereas on μCT these large breaks appear to represent a combination of several small breaks (Fig 1-II). With larger break diameters as a cut-off for both techniques, this resulted in the detection of breaks on HR-pQCT which were not detected on μCT. Therefore, the FDR for the detection of a break of the

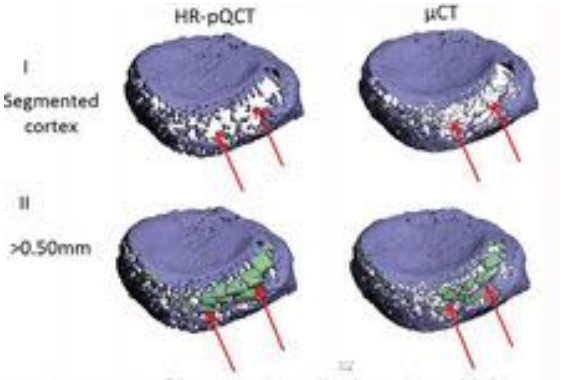

*Figure 1.* Binary images of the segmented cortex (I) and a visual output (II) of the phalangeal base of the algorithm as performed on HR-pQCT (left) and μCT (right). The cortex is shown in purple (I-II), cortical breaks are shown in white (I-II), and cortical breaks >0.50mm are shown in green (II). The red arrows indicate regions of which the μCT detects thin cortices which were not detected on HR-pQCT (I). This led to the detection of large breaks on HR-pQCT and multiple smaller breaks on μCT (II)

same size was sufficient for small breaks (37.9%), but poor for large break sizes (86.7%). However, when comparing a larger break on HR-pQCT with the smallest minimal break size on μCT it was found that only 4.4% of the detected breaks on HR-pQCT were falsely detected (table 1).

**Conclusions:** Because of its limited resolution, a single break region detected on HR-pQCT can appear as several smaller breaks on μCT. When accounting for this effect, however, excellent agreement is found between cortical break detected with the algorithm using HR-pQCT and μCT. We thus conclude that the use of HR-pQCT in combination with our semi-automatic algorithm is a promising tool for early detection and monitoring of the number of small cortical breaks in finger joints.

## FRI0539 RELIABILITY OF A SEMI-AUTOMATIC ALGORITHM IN THE DETECTION OF CORTICAL BREAKS IN FINGER JOINTS USING HIGH RESOLUTION PERIPHERAL QUANTITATIVE CT

M. Peters[1], A. Scharmga[1], J. de Jong[1], A. van Tubergen[1], R. Weijers[2], D. Loeffen[2], B. van Rietbergen[3], J. van den Bergh[1], P. Geusens[1].
*[1]Rheumatology; [2]Radiology, MUMC, Maastricht; [3]Biomedical Engineering, TUE, Eindhoven, Netherlands*

**Background:** Conventional radiography (CR) is considered the gold standard for diagnosis and monitoring of erosions in rheumatoid arthritis (RA). However, CR is less sensitive in the detection of erosions than high resolution peripheral quantitative CT (HR-pQCT) in hand joints (1). The visual scoring of these erosions is, however, laborious. Therefore an automatic method could be timesaving. We previously developed a semi-automatic algorithm for HR-pQCT that is able to detect cortical breaks. However, the intra-operator reliability of our algorithm was not yet tested on the joint level for different break sizes, and neither on a single break level.

**Objectives:** To test the intra-operator reliability of the algorithm on HR-pQCT images on the joint level and on a single break level for different break sizes.

**Methods:** Nineteen finger joints of ten human female cadaveric index fingers (mean age ± SD; 85.1 ± 9.6 years) with unknown medical history were imaged by HR-pQCT (82μm voxel size). A semi-automatic algorithm was developed for the detection of cortical breaks, taking into account various break sizes. First, the automatically detected contours were manually adapted twice by the same operator several weeks apart. Second, bone within 0.25mm from this contour was selected as the cortical region. Last, different sizes for defining a cortical break (>0.50mm, >0.66mm and >0.82mm) were applied. Breaks that were detected by the algorithm using both contours, and overlapped with at least 30 voxels were counted as matching breaks. The proportion of matching breaks was calculated as a measure of reliability for a single break. Intraclass correlation coefficients (ICCs) were calculated as a measure of reliability on the joint level.

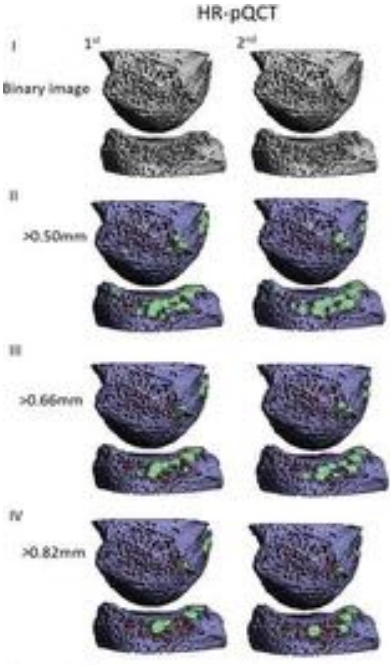

Figure 1. Binary images (I) and the visual outputs (II-IV) of an MCP joint of the designed algorithm as performed on the HR-pQCT after the first and second time contouring. The cortex is shown in purple, the trabecular bone in red, and the cortical breaks are shown in green (II-IV).

**Results:** The number of breaks depended on the chosen break size, and varied between 2.4 and 14.2 per joint. The locations of the detected breaks from the first and second time contouring generally corresponded well for all break sizes (Fig. 1). The agreement on a single break level was substantial for all break sizes (≥67.7%), with the highest agreement for breaks >0.66mm (80.9%).The agreement on the joint level was high for all break sizes (ICC≥.84, p<0.01) and excellent for breaks >0.66mm (ICC ≥.95, p<0.01) (table 1).

Table 1. Number of breaks and intra-observer reliability of breaks detected on the HR-pQCT images

| Minimal break size | HR-pQCT 1st* (n=19 joints) | HR-pQCT 2nd* (n=19 joints) | ICC# | Proportion of matching breaks$ |
|---|---|---|---|---|
| >0.50mm | 14.9±12.6 | 14.2±11.6 | 0.91 (0.79–0.97) | 67.7% |
| >0.66mm | 5.1±5.2 | 4.9±4.7 | 0.95 (0.87– 0.98) | 80.9% |
| >0.82mm | 2.6±3.2 | 2.4±2.5 | 0.84 (0.62–0.93) | 73.3% |

Number of breaks detected for different break sizes. *Mean ± SD, #ICC (95% CI), and $ with HR-pQCT 2nd as reference. SD = Standard Deviation, ICC = Intraclass Correlation Coefficient, 95% CI =95% Confidence Interval.

**Conclusions:** The intra-operator reliability of the algorithm was excellent at the joint level and very good of the single break detection for all break sizes. Therefore, the use of HR-pQCT in combination with our semi-automatic algorithm is a promising tool for early detection and monitoring of the number of small cortical breaks in finger joints.

## FRI0540 EVALUATION OF NAILFOLDVIDEOCAPILLAROSCOPY IN CENTRAL SEROUS CHORIORETINOPATHY

M.K. Erol[1], A. Balkarli[2], D. Toslak[1], D. Durmaz[1], B. Dogan[1], E. Baskan[1], S. Altun[3], M. Bulut[1], V. Cobankara[4]. *[1]Department of Ophtholmology; [2]Rheumatology, Antalya training and research hospital, Antalya; [3]Department of Ophtholmology, Gulhane Military Medical Academy, Ankara; [4]Rheumatology, Pamukkale University Hospital, Denizli, Turkey*

**Background:** Nailfold videocapillaroscopy (NVC) is a diagnostic tool to evaluate micro-vasculature. Presence of choroidal vasculopathy is apparent in central serous chorioretinopathy (CSCR).

**Objectives:** In this study, it was aimed to assess capillaroscopic findings of nailfold in patients with CSCR. To best of our knowledge, there is no study assessing NVC findings in CSCR in the literature.

**Methods:** Sixty-one patients with CSCR who met inclusion criteria and 82 age- and sex-matched healthy controls were included to the study. A videocapillaroscopy device with 200x magnification was used for capillaroscopic assessment.

**Results:** The mean age was 48.79 ± 11.146 years in the patient group (13 female, 48 male) whereas 49.38 ± 9.02 years in the control group (17 female, 65 male). The age and gender were comparable in the patient and control groups (p=0.727 and p=0.933, respectively). The capillary count was found to be decreased in the patient group compared to control group. No significant correlation was found between capillary count and choroidal thickness (p=0.551; r=-0.081). In the patient group, the frequencies of major capillaroscopic findings including capillary ectasia, aneurysm, micro-hemorrhage, avascular area, tortuosity, neo-formation, bizarre capillary, bushy capillary, meander capillary and extravasation were found to be increased in the patient group. However, no significant correlation was detected between capillaroscopic findings and disease type and presence of attacks.

Table 1. Capillaroscopic findings of patient and control groups

| Parameter | Patients (n=61) | Controls (n=82) | p |
|---|---|---|---|
| Capillary count, median (min-max) | 10 (7–12) | 11 (9–13) | <0.001 |
| Capillary ectasia, n (%) | 12 (19.7) | 0 (0) | <0.001 |
| Aneurysm, n (%) | 3 (4.9) | 0 (0) | 0.023 |
| Mega-capillary, n (%) | 1 (1.6) | 0 (0) | 0.427 |
| Micro-hemorrhage, n (%) | 6 (9.8) | 0 (0) | 0.001 |
| Tortuosity, n (%) | 47 (77) | 4 (4.9) | <0.001 |
| Avascular area, n (%) | 5 (8.2) | 0 (0) | 0.003 |
| Neo-formation, n (%) | 30 (49.2) | 0 (0) | <0.001 |
| Bizarre capillary, n (%) | 33 (54.1) | 3 (3.7) | <0.001 |
| Bushy capillary, n (%) | 30 (49.2) | 0 (0) | <0.001 |
| Meander capillary, n (%) | 6 (9.8) | 0 (0) | 0.001 |
| Extravasation, n (%) | 9 (14.8) | 0 (0) | <0.001 |

**Conclusions:** This is first study in which nailfold capillary assessment was

performed in patients with CSCR and we detected major capillaroscopic changes. These findings suggest that CSCR can be systemic microvasculopathy. Further studies are needed to clarify the diagnostic and prognostic value of capillaroscopy in CSCR.

## FRI0541 A CROSS-SECTIONAL, INTERNATIONAL SURVEY ON NON-INVASIVE TECHNIQUES TO ASSESS THE MICROCIRCULATION IN PATIENTS WITH RAYNAUD'S PHENOMENON (SUNSHINE SURVEY)

N. Ughi[1], G. Dinsdale[2], V. Smith[3], Y. Allanore[4], I. Foeldvari[5], A. Sulli[6], M. Cutolo[6], A.L. Herrick[2], F. Ingegnoli[1] on behalf of SUNSHINE Study Group and the EULAR Study Group on Microcirculation in Rheumatic Diseases.
*[1]Division of Rheumatology, Gaetano Pini Institute, Department of Clinical Sciences & Community Health, University of Milan, Milan, Italy; [2]Centre for Musculoskeletal Research, Salford Royal NHS Foundation Trust, The University of Manchester, Academic Health Science Centre, Manchester, United Kingdom; [3]Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium; [4]Paris Descartes University and Cochin Hospital, AP-HP, Paris, France; [5]Hamburger Zentrum für Kinder- und Jugend Rheumatologie, Klinikum Eilbek, Hamburg, Germany; [6]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

**Background:** Microcirculatory impairment in patients with Raynaud's phenomenon (RP) may be assessed by different techniques, but real-life data concerning their roles and current usage are not available.
**Objectives:** To obtain an overview of the specific techniques which may be used for the assessment of adult patients with RP in clinical and research settings: nailfold videocapillaroscopy (NVC), dermoscopy, stereomicroscopy, and digital USB microscopy, laser Doppler flowmetry, imaging, and anemometry/velocimetry, laser Speckle Contrast Analysis (LASCA), thermographic imaging, upper limb arterial Doppler ultrasound.
**Methods:** This survey was conducted online between October and December 2015 on behalf of EULAR study group on Microcirculation in Rheumatic Diseases (SG_MC/RD). Emails with a link to the survey were sent to physicians from the European Scleroderma Trials and Research group (EUSTAR) and SG_MC/RD mailing lists. Of those e-mailed, 418 were physicians looking after adult patients, and this group was considered in the following descriptive analysis.
**Results:** Of the 418 eligible physicians, 107 completed the survey, giving an overall response rate of 25.6%. Among the respondents 89 (83.2%) were rheumatologists, 74 (69.2%) European; 87 (81.3%) were practising for more than 10 years and 50% looked after between 31 and 60 patients per year with primary and/or secondary RP. The most routinely performed technique was NVC (63/107, 58.9%) both by rheumatologists and non-rheumatologists (54/89, 60.7% and 9/18, 50.0%). NVC was reported as the most available technique (93/107, 86.9%), and available in the place of work in 78/107 (72.9%) among both rheumatologists and non-rheumatologists. Nailfold capillaroscopy was the most frequently performed by the physician him/herself by using different types of equipment relating to availability: NVC 64/94 (68.0%), dermoscopy 38/63 (60.3%), stereomicroscopy 31/42 (73.8%), and digital USB microscopy 34/39 (87.1%). Most rheumatologists reported high levels of "appropriateness" for NVC in both clinical and research settings for global assessment (86/88, 97.7% clinical setting, 87/88, 98.9% research setting), and differential diagnosis of primary and secondary RP (clinical and research setting both 84/87 96.5%). In clinical setting NVC showed the highest percentage of appropriateness for monitoring primary RP (84/88, 95.4%), RP secondary to connective tissue diseases other than systemic sclerosis (82/87, 94.2%) and to systemic sclerosis (87/87, 100%). All techniques other than capillaroscopy reached a consensus lower than 2/3 of respondents based on their knowledge/experience. In research setting, all techniques were judged as potentially useful with a consensus more than 2/3 of respondents.
**Conclusions:** Of all the different techniques upon which opinion was sought, nailfold capillaroscopy was the one most used by physicians looking after adult patients in both clinical and research settings, the majority of whom use NVC in their everyday practice. The low proportion of clinicians using other techniques suggests that these are currently confined to specialist centres.

## FRI0542 BIOELECTRICAL IMPEDANCE ANALYSIS IS NOT A VALID METHOD FOR THE ASSESSMENT OF BODY COMPOSITION IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Konijn[1], L. van Tuyl[1], B. Dijkstra[1], I. Bultink[1], M. van der Schueren[2], W. Lems[1,3]. *[1]Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical Center; [2]Nutrition and Dietetics, VU University Medical Center; [3]Rheumatology, Amsterdam Rheumatology and immunology Center, Reade, Amsterdam, Netherlands*

**Background:** Rheumatoid cachexia (i.e. loss of fat free mass (FFM) and gain in fat mass (FM)) is often observed in chronic rheumatoid arthritis (RA) patients, with deleterious effects on morbidity and functional capacity [1,2]. In addition, the use of glucocorticoids is associated with increase in FM. Therefore, careful assessment of body composition is important in RA patients. Dual-energy X-ray absorptiometry (DXA) is a valid and reliable method to assess body composition, but is also expensive, time-consuming, invasive and thus not feasible for everyday use. Bioelectrical impedance analysis (BIA) is a relatively cheap, rapid, and non-invasive method to assess body composition in clinical practice, however BIA has not been validated in RA patients.
**Objectives:** To validate BIA against two different, widely used DXA devices for the assessment of body composition in patients with RA.
**Methods:** This cross-sectional validation study was performed in RA patients who visited study center A or B in the context of the COBRA-light extension studyl. Body composition was assessed by DXA (study center A: Hologic Delphi; study center B: GE Lunar IDxa) and BIA (Quadscan 4000) on the same day, and recorded as FM, FM%, FFM and FFM%. Agreement between both methods was assessed by paired t-tests, Bland-Altman plots and intra-class correlation coefficients (ICC), in which DXA was used as reference method.
**Results:** Of the 149 extension study patients, 43 patients (63% women, mean age 56 years, mean disease duration 5 years) were assessed by both DXA and BIA at the same day, and were included in this validation study. In study center A (n=25), BIA overestimated FM by 0.2 kg (p=0.71), and significantly underestimated FFM by 2.2 kg ($p<0.001$). FM% and FFM% were respectively over- and underestimated by 1.1% (both p=0.05). In study center B (n=18), BIA systematically underestimated FM by 3.1 kg, and overestimated FFM by 2.2 kg; FM% and FFM% were respectively under- and overestimated by 3.6% (all: $p<0.001$). Bland-Altman plots showed wide limits of agreement for all assessments in both study centers (Figure 1). These limits of agreement, indicating measurement error on individual level, were approximately 8 kg for FM and FFM assessments in both study centers. The ICC's, indicating measurement error on group level, showed good agreement in study center A (>0.90) and moderate-to-good agreement in study center B (>0.85).

Figure 1. Bland Altman plots of the assessment of Fat Mass and Fat Free Mass by DXA and BIA per study center in RA patients (n=43)

**Conclusions:** This study showed that BIA is an invalid method for the assessment of body composition in RA patients, both at individual and group level, and that errors depend on the DXA device used as reference method.

## FRI0543 RAMIFICATIONS IN NAILFOLD CAPILLAROSCOPY, RISK FACTORS AND PROGNOSTIC IMPLICATIONS

N. Val Dominguez, M.D.C. Freire Dapena, A. Argibay Filgueira, A. Rivera Gallego, A. Sousa Dominguez, R. Lorenzo Castro, A. Soto Peleteiro, P. Dieguez Pena, M. Estevez Gil, C. Vazquez Triñanes. *Thrombosis and Vasculitis Unit, Hospital Alvaro Cunqueiro. University Hospital of Vigo, Vigo, Spain*

**Background:** Presence of ramifications (RM) (capillaries from whose central axis lateral branches emerge) in the nailfold capillaroscopy is generally seen in patients with advanced microvascular damage and is a characteristic feature of scleroderma and dermatomyositis. Nevertheless they are also seen in patients without defined disease, so that it can be an inespecific finding whose potential role in the evolution of the patient is unclear.

**Objectives:** To analyze the risk factors and the prognostic implications associated with the presence of RM in the capillaroscopy. Analyze the risk factors associated with RM in patients who we perform a capillaroscopic in our hospital.
**Methods:** We reviewed all the capillaroscopies performed in our systemic autoimmune diseases outpatient between January 2013 and December 2015. We reviewed the clinic and epidemiological characteristics, capillary pattern, diagnosis and evolution of all the patients and we analyzed their relation with the presence of RM.
**Results:** In this period we performed a capillaroscopy to 226 patients, 48 (21.2%) of which had RM. In the RM group (39 women, 9 men), mean age was 51.38 years, with no significant differences in gender distribution and in age compared to the no-RM group (p 0.394 and 0.694 respectively). 78 of our patients were smokers (34.5%), 61 (27%) had history of arterial hypertension, 71 (31.4%) had hypercholesterolemia and 13 (5.8%) diabetes mellitus, with no differences between both groups (p 0.380, 0.265, 0.501 and 0.867 respectively).
We found 6 patients with digital ulcers, any of them with RM (p 0.197). Patients with idiopathic thromboembolic disease were 5 (2.21%), only 1 with RM (p 0.466). 182 patients (80.5%) presented Raynaud's phenomenon (RP) with a mean duration of 8.59 years, 37 of which had RM (p 0.497). Among patients with RP in which the final diagnosis was primary RP (46, 20.53%) only 3 (6.25%) had RM (p 0.006). Patients that finally were diagnosed with any collagen vascular disease were 135 (59.73%), 37 of wich had RM (p 0.01). In this group 6 patients had systemic lupus erythematosus, 32 systemic sclerosis, 5 antiphospholipid syndrome, 6 Sjögren syndrome, 2 mixed connective tissue disease and 67 undifferentiated connective tissue disease. We found no differences between RM and no-RM groups separately analyzing each of these diagnoses (p 0.426, 0.466, 0.223, 0.191, 0.293 and 0.148 respectively).
With respect capillaroscopic findings we found no correlation with the presence of dilatations (p 0.193), megacapilaries (p 0.418) or hemorrhages (p 0.888) but we did with other suggesting advanced microvascular damage as capillary loss (p 0.018) and presence of tortuosities ($p<0.001$) and with the sclerodermic capillaroscopic pattern (p 0.003).
**Conclusions:** Presence of RM identifies patients at risk of secondary RP, especially with underlying connective tissue diseases. So, the presence of RM in patients with not clear diagnostic force us to have specially attention with them because they have risk to develop a connective tissue disease in the future.

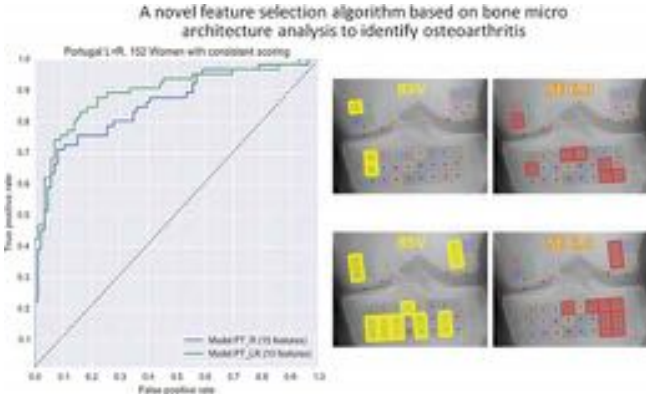
## FRI0544 IMPACT OF EDUCATION IN MUSCULOSKELETAL ULTRASONOGRAPHY: GOOD TO EXCELLENT RELIABILITY RESULTS IN MODIFIED US7 SCORING SYSTEM AFTER ONE YEAR OF CONTINUING EDUCATION SINCE BASIC OR INTERMEDIATE LEVEL OF TRAINING



P. Hanova[1], J. Zavada[1], J. Hurnakova[1], H. Mann[1], M. Klein[1], O. Sleglova[1], M. Olejarova[1], O. Ruzickova[1], S. Forejtova[1], M. Komarc[2], J. Gatterova[1], K. Pavelka[1]. *[1]Instit. of Rheumatology; [2]Instit. of Biophysics and Informatics, Prague, Czech Republic*

**Objectives:** To estimate the time to reach reliable results in a larger group of rheumatologists at onset of their musculoskeletal ultrasound (MSUS) training in modified 7-joints scoring system (US7).
**Methods:** US7 has been shown a useful tool to estimate activity of rheumatoid arthritis (RA) in daily clinical practice. The system has been extensively described including an atlas. Targets of the US7 include synovitis (in B-mode and Power Doppler (BM+PD)), tenosynovitis (BM+PD) and erosive changes of 7 joints (wrist, MCP II+III, PIP II+III, MTP II+V) on the dominant site. We used a modification of the original US7 published, assessing both palmar and dorsal view of MCP and PIP joints. 9 rheumatologists with basic/intermed. level of MSUS underwent a training in general MSUS+US7. At month 1, reliability testing in scoring of static pictures was performed. At months 3 and 12, two reliability-testing sessions were organized. 4 patients with various stages of activity and disease progression of RA were repeatedly scanned, in 2 rounds per session. Sonographers were blind to all patients' data. 2 US machines were used for each session and the setting was fixed before the start. Smoking or drinking alcohol was not allowed. Each patient was investigated by the same US machine in the same daytime in each round of a testing session. Inter-/intra-observer agreement was calculated for each modality of US7 (synovitis score in BM+PD, tenosynovitis score in BM+PD, erosion score) by using non-weighted Cohen kappa (intra-observer agreement) and Light's kappa (inter-observer agreement).
**Results:** At month 1, mean intra- and inter-observer agreement in scoring of static images was reached; $\kappa$=0,61 and 0,60 respectively (good). At month 3, mean inter-observer reliability was low ($\kappa<0.2$), intra-observer reliability varied within interval $\kappa$(0.02;1). As the education continued, mean inter-observer agreement achieved $\kappa$=0,6 (good), intra-observer agreement varied within interval $\kappa$ (0.6;1) (good-excellent).
**Conclusions:** Ultrasound is an operator dependent technique. The level of experience necessary to obtain reliable results in modified US7 (as an example of easy and well determined US method) was achieved after 12 months of low intensity training with direct supervision of a specialist on demand. Low intensity training is in the authors' experience the most frequently used method among beginners in MSUS. Scoring of static images was reliable already after 1 month. Although the probe positions in US7 are well defined, the inter-/intra-observer reliability in scoring of self-obtained images was none in month 3 and the difference leading to good results in month 12 must have been achieved in this later period of training. The difference between higher intra-observer and none inter-observer agreement in month 3 suggests that direct supervision of a specialist in MSUS in this stage of education would lead to quicker progress and better results in achieving reliability among the group members.

## FRI0545 A NOVEL FEATURE SELECTION ALGORITHM BASED ON BONE MICRO ARCHITECTURE ANALYSIS TO IDENTIFY OSTEOARTHRITIS

R. Ljuhar[1], B. Norman[1], D. Ljuhar[1], T. Haftner[1], J. Hladuvka[2], M. Bui Thi Mai[2], H. Canhão[3], J. Branco[3], A.M. Rodrigues[3], N. Gouveia[3], S. Nehrer[4], A. Fahrleitner-Pammer[5], H.-P. Dimai[5]. *[1]Braincon Technologies; [2]VRVis Research Competence Center, Vienna, Austria; [3]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [4]Center for Regenerative Medicine & Orthopedics, Danube University, Krems; [5]Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria*

**Background:** Texture information of the subchondral bone area of 2D radiographs represents a promising possibility for evaluating the state of osteoarthritis (OA) in addition to traditional clinical means such as visual and semi-quantitative assessments.
**Objectives:** Algorithms based on fractal analysis have shown to be capable of identifying differences in trabecular bone structure. However such features are likely to vary within the subchondral bone area and therefore the appropriate selection of the region of interest (ROI) plays a crucial role for the result of the analysis. Thus, a feature selection algorithm is being applied in order to determine ROIs that enable an optimum discrimination between patients with and without OA.
**Methods:** The study included 152 standardized knee radiographs from 66 female patients with OA, and 86 controls. Subchondral bone micro architecture was assessed by using both fractal analysis and a Shannon Entropy (SE) algorithm at predefined regions of the proximal tibia and the distal femur. For fractal analysis the distinct parameter Bone Structure Value (BSV) was defined. The selected area of the proximal tibia involved a matrix of 3x8 ROIs, whereas a 2x2 matrix was defined for each condyle of the distal femur. SE and the BSV were calculated for each of the 32 ROIs, respectively. Based on these 64 variables, a feature selection algorithm was applied to determine the variables that showed the best discrimination power between Case and Control subjects.
**Results:** By combining the BSV and SE, the odds ratio increased significantly from 3.08 (95% CI: 1.78–5.30) to 14.82 (95% CI: 6.69–32.83) when using 15 features, and to 39.75 (95% CI: 15.41–102.51) based on 10 features. By using the selected 10 features the accuracy was found to be 0.86. This showed to be a significant improvement compared to the accuracy achieved when calculating a single mean value for the 3x8 ROIs of the proximal tibia alone (0.62 vs. 0.86).

**Conclusions:** The application of a feature selection algorithm in accordance with the combination of the two texture analysis methods shows a significant improvement with respect to the discrimination power between subjects with and without OA. The high odds ratios confirm that reliable results can be achieved by combining the BSV and the SE. This novel algorithm for the assessment of bine micro architecture may not only be useful in osteoarthritis subjects but also for the early prediction and assessment of other degenerative bone diseases like osteoporosis and rheumatoid arthritis.

## FRI0546 THE POWER DOPPLER RESULT IN RHEUMATOID ARTHRITIS DEPENDS ON THE POSITION OF HANDS DURING ULTRASOUND EXAMINATION

R. Husic, A. Lackner, J. Hermann, M.H. Stradner, C. Dejaco. *Rheumatology, Medical University of Graz, Graz, Austria*

**Background:** Power Doppler (PD) ultrasound is used to assess joint inflammation in rheumatoid arthritis (RA). The extent of PD signals is influenced by several factors such as technical settings, room temperature and other variables.
**Objectives:** The aim of this study was to examine the relevance of the position of hands (extended versus neutral position) for PD ultrasound results in RA using a 2D semi-quantitative and a 3D quantitative analysis method.
**Methods:** Cross-sectional study of 42 consecutive RA patients with active disease according to clinical ($\geq$1 tender and/or swollen joint) and ultrasound examination ($\geq$1 joint with PD grade $\geq$1). Ultrasound examination was performed at dorsal sites of wrists and MCPs (bilaterally) by 1 (out of 2) investigators blinded to clinical results. An Esaote MyLab Twice ultrasound device was used with an 18-MHz linear transducer (2D-US) and a 4–13 MHz volumetric three-dimensional ultrasound probe (3D-US). For 2D-US, PD abnormalities were subjectively graded from 0 to 3. For 3D-US, the probe was placed at MCPs in a longitudinal direction over the extensor tendon and the joint space and at wrist over the lunate bone. Automatized image acquisition was conducted and the percentage of PD pixels within the region of interest (ROI, 100 slides, total width 8.5 mm) was calculated using the integrated 3D software.
Ultrasound examination was first performed with patients' hands in a neutral position (i.e. slight flexion of the fingers - only the wrist, thumb and finger tips touching the table), subsequently in an extended position (i.e. all palm and inner finger area touching the table).
**Results:** Out of the 42 RA patients, 66.7% were female. Median age was 57.5 (range 19–86) years. Patients had a median of 6 (0–23) swollen and 8 (0–45) tender joints, median SDAI was 22.1 (5.1–48.3).
In neutral position, a positive 2D-US PD result was found in 192/420 (45.7%) joints. A score of 1, 2 and 3 was observed in 42 (21.9% of all PD positive joints), 139 (72.4%) and 11 (5.7%) joints, respectively. 3D-US PD findings correlated well with 2D results, with median pixel values being 0.4 (range 1.0–1.9), 1.1 (0.2–7.4) and 2.3 (0.3–7.2) in joints with 2D-US scores of 1,2 and 3, respectively.
Changing the position from neutral to extended resulted in the disappearance of PD signals in 55/192 joints (28.7%, $p<0.001$, assessed with 2D-US). In detail, 29/42 joints with a PD score 1 in neutral position became PD negative in extended position (minus 69%, $p<0.001$). Out of those 139 joints with a PD score 2 in neutral position, 26 (18.7%) and 78 (56.1%) changed to scores of 0 and 1 in extended position, respectively. A PD score 3 was found to change to score of 1 and 2 at 4 (36.4% out of 11) and 5 (45.5%) joints, respectively.
Median 3D-US count was reduced from 0.9 (range 0.1–7.4) in neutral position to 0.2 (0.0–1.7, $p<0.001$) in extended position.
Inter-reader agreements for 2D-US and 3D-US results were good [ICC 0.82 (95%CI 0.69 to 0.90)] and [ICC 0.75 (0.27–0.93)] as was the intra-reader reliability for 3D-US [ICC 0.79 (0.38–0.94)].
**Conclusions:** A standardized approach for the ultrasound examination of RA patient is essential to produce reliable results. Our study demonstrates a significant reduction of PD scores by extended vs. neutral position of hands.

## FRI0547 MAGNETIC RESONANCE IMAGING JOINT SPACE NARROWING IS AN INDEPENDENT PREDICTOR OF RADIOGRAPHIC AND MRI DAMAGE PROGRESSION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

S. Møller-Bisgaard[1,2], B. Ejbjerg[2], I. Eshed[3], K. Hørslev-Petersen[4], M. Hetland[5], A.G. Jurik[6], H. Thomsen[7], T. Torfing[8], K. Stengaard-Pedersen[9], P. Junker[10], N.S. Krogh[11], T. Center, Ramat Gan, Israel; [4]Dept. of Rheum, King Chr. X'th Hosp., Graasten; [5]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Cph; [6]Dept. of Radiol, Aarhus Hosp., Aarhus; [7]Dept. of Radiol, Herlev Hosp., Cph; [8]Dept. of Radiol, Odense Hosp., Odense; [9]Dept. of Rheum, Aarhus Hosp., Aarhus; [10]Dept. of Rheum, Odense Hosp., Odense; [11]ZiteLab ApS, Cph; [12]Dept. of Rheum, Vejle Hosp., Vejle; [13]Dept. of Rheum, Gentofte Hosp., Cph; [14]Dept. of Epi, Odense University, Odense; [15]Dept. of Rheum, Hvidovre Hosp., Cph., Denmark*

**Background:** Magnetic Resonance Imaging (MRI) osteitis and synovitis have been identified as predictors of structural damage progression in rheumatoid arthritis (RA)[1,2], but the predictive value of MRI joint space narrowing (JSN, a measure of cartilage damage) and tenosynovitis (TS) needs further investigation.
**Objectives:** To investigate the predictive value of baseline MRI inflammatory and damage parameters on 2 year MRI and X-ray damage progression in an early RA (eRA) cohort following a non biologic treat-to-target strategy.
**Methods:** In 129 eRA (<6months) patients from the double-blind randomized CIMESTRA trial (methotrexate, intraarticular betamethasone and cyclosporine (CYA)/placebo CYA) contrast-enhanced MRIs of the non-dominant wrist and X-rays of hands and feet were performed at baseline and after 2 years. MRIs were evaluated according to the RAMRIS scoring system for osteitis, synovitis, erosion (ES), JSN, for TS[3] and X-rays according to the Sharp/van der Heijde method, with known chronology by two experienced radiologists. Potential predictive baseline variables (MRI osteitis, synovitis, TS, ES, JSN, X-ray ES and JSN, DAS28, gender, age, anti-CCP, smoking status) were tested in univariate linear regression analyses with 2-year change in MRI total damage score, Total Sharp Score (TSS), and MRI and X-ray JSN and ES scores as dependent variables. Significant variables ($p<0.05$) were included in multiple regression analyses with backward selection.
**Results:** Independent predictors of structural damage progression are presented in table 1.
If MRI JSN was not included in the model, MRI osteitis score was statistically significant independent predictor of X-ray progression (coefficient 0.32, p=0.001, vs TSS progression).
**Conclusions:** This trial is the first to report that MRI JSN independently predicts both X-ray and MRI damage progression in early RA. Further studies are needed to confirm early MRI-determined cartilage damage as predictor of progressive joint destruction in RA.

## FRI0548 RESPONSIVENESS OF A NEW MRI SCORING METHOD BASED ON THE CANADA-DENMARK DEFINITIONS OF LESIONS IN THE SPINE AND THE SPARCC MRI SPINE INFLAMMATION INDEX IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

S. Krabbe[1], M. Østergaard[1], I.J. Sørensen[1], B. Jensen[1], J. Møller[2], L. Balding[2], O.R. Madsen[1], K.H. Asmussen[1], G.P. Eng[3], S.J. Pedersen[1]. *[1]Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Frederiksberg, Gentofte and Hillerød; [2]Department of Radiology, Herlev and Gentofte Hospitals; [3]Department of Rheumatology, Køge Sygehus, Denmark*

**Background:** The Spondyloarthritis Research Consortium of Canada (SPARCC) Spine Inflammation Index is a well-established MRI scoring system for vertebral body inflammation.(1) It does not take the exact anatomical location of lesions into account. The Canada-Denmark (CanDen) MRI definitions were developed to allow detailed anatomical evaluation of inflammatory and structural lesions of the vertebral bodies as well as the posterior segments in patients with axial spondyloarthritis (axSpA).(2–3)
**Objectives:** The aim of this study was to assess the distribution of scores and the responsiveness of this new method, which combines the CanDen MRI definitions into a scoring system, as compared with the SPARCC Spine Inflammation Index in an axSpA randomized controlled trial.
**Methods:** For each disco-vertebral unit, inflammatory lesions of vertebral bodies (VB) in the anterior and posterior corners on central sagittal slices were scored

as 1 (small) or 2 (large). Non-corner lesions were scored as 2 (small) or 4 (large). Antero-lateral and postero-lateral inflammatory corner lesions in lateral sagittal slices were scored as 1. Inflammatory lesions in the posterior segments (PS) were each scored as 1. Fat (4), erosion and new bone formation were scored in a comparable way (details not shown due to length restrictions).
49 patients with axSpA and indication for TNFα inhibitor were randomized to placebo or adalimumab 40 mg sc. eow for 6 weeks. MRI of the spine was scored according to CanDen definitions and SPARCC by an experienced reader blinded to the clinical data. Responsiveness was assessed by standardized response mean (SRM) and Guyatt's responsiveness index (GRI). Values ≥0.8 represent a large degree of responsiveness.
**Results:**

Table 1. The distribution of CanDen and SPARCC scores at baseline as median, range, and inter-quartile range (IQR) is shown

| Measure (range) | Median | Range | IQR | SRM | GRI** |
|---|---|---|---|---|---|
| CanDen inflammation (total) (0–582) | 5 | 0–72 | 2–12 | 0.6 | 1.4 |
| CanDen inflammation (VB) (0–456) | 5 | 0–64 | 2–12 | 0.6 | 1.5 |
| CanDen inflammatory lesions (PS) (0–126) | 0 | 0–14 | 0–0 | 0.3 | 0.8 |
| CanDen fat infiltration (0–502) | 2 | 0–35 | 0–8 | 0.1 | 0.4 |
| CanDen bone erosion (0–480) | 0 | 0–8 | 0–0 | 0.2 | NA* |
| CanDen bone spurs (0–460) | 0 | 0–137 | 0–0 | NA* | NA* |
| SPARCC MRI Spine Inflammation Index | 6 | 0–65 | 2–14 | 0.6 | 1.5 |
| BASDAI | 6.3 | 4.2–9.8 | 5.3–7.2 | 1.1 | 1.3 |

SRM and GRI for changes week 0 to 6. *Not computable due to SD=0 in denominator. **Mean change score in adalimumab group divided by the SD of change scores in placebo group.

**Conclusions:** A new anatomy-based scoring system for spine inflammatory and structural lesions was described, demonstrating similar responsiveness as the SPARCC method. Further studies are needed to investigate the additional value of assessing posterior segments.

### FRI0549 CONE-BEAM CT, A NEW LOW-DOSE 3 D IMAGING TECHNIQUE FOR ASSESSMENT OF BONE EROSIONS IN RHEUMATOID ARTHRITIS: RELIABILITY ASSESSMENT AND COMPARISON WITH CONVENTIONAL RADIOGRAPHY

Y. Aurell[1], M. Malac[1], M.L. Andersson[2,3], K. Forslind[3,4]. *[1]Radiology, Sahlgrenska University Hospital, Gothenburg; [2]Spenshults Research and Development Centre, Halmstad; [3]Dep. of Clinical Sciences, Section of Rheumatology, Lund University, Lund; [4]Dep. of Medicine, Section of Rheumatology, Helsingborg's Lasarett, Helsingborg, Sweden*

**Background:** Early and accurate detection of erosive joint changes is important when validating and monitoring rheumatoid arthritis (RA). Magnetic resonance imaging (MRI) and ultrasound (US) have shown to be more sensitive than conventional radiography (CR) but have the drawbacks of being expensive (MRI) or difficult to learn (US). In several studies these methods have been compared to multidetector computed tomography (MDCT), which can be considered a reference method for detecting erosions but has several disadvantages, for example the exposure to ionising radiation. With the newly developed cone-beam CT (CBCT) which is dedicated for imaging of the extremities, these disadvantages can be minimized. The radiation dose is low, about 10% of the effective dose of MDCT, comparable to an extra CR exposure.
**Objectives:** To assess the intra-and interobserver agreement of erosions detected and scored with CBCT. To compare CBCT with CR for assessment of bone erosions in patients with established rheumatoid arthritis.
**Methods:** 30 patients (23 females, 7 males) with established RA – median disease duration (min-max) 15 (14–15) year – who had CR performed according to the Better AntiRheumatic PharmacOTherapy (BARFOT) study protocol were examined also with extremity CBCT (hands and feet) at the same occasion. Bone erosions were scored twice according to RA MRI score (RAMRIS), on digital images in three planes from the CBCT by two observers. The radiographs were scored by a third observer with Sharp van der Heijde Score (SHS). Disease activity was assessed with disease activity score of 28 joints (DAS28). Remission was defined as DAS28<2.6. Comparisons between groups was performed using Mann-Whitney U test. Correlations were performed with Spearman correlation test and intra class correlation coefficient (ICC) was calculated.
**Results:** The median age (min-max) was 54 (27–75) and median DAS28 (min-max) 2.25 (0.63–6.49). All 30 patients showed erosions on CBCT and 26 on CR. The correlation between CBCT and CR was 0.77 (p<0.001). Intra-and interobserver reliability for erosions scored by CBCT was excellent for both hands and feet for the two observers (ICC 0.90–0.97).The CBCT erosion scores of 16 patients in remission was median RAMRIS (min-max) 9 (1–67) vs. 21 (2–224), p=0.077 for 11 patients not in remission. The results for CR were for patients in remission median SHS (min-max) 12 (0–97) and those not in remission 40 (6–151), p=0.034. The median (min-max) numbers of eroded joints were 8 (1–40) with CBCT vs. 2 (0–20) with CR for patients in remission and for those not in remission 16 (2–68) with CBCT, vs. 7 (0–34) with CR. There were significantly more eroded joints detected by CBCT, p=0.002.
**Conclusions:** CBCT is a new low-dose 3 D imaging technique, which has high reproducibility and is more sensitive than CR in detecting erosions. CBCT has a potential to become a useful tool in detecting and follow up of erosions in patients with RA.

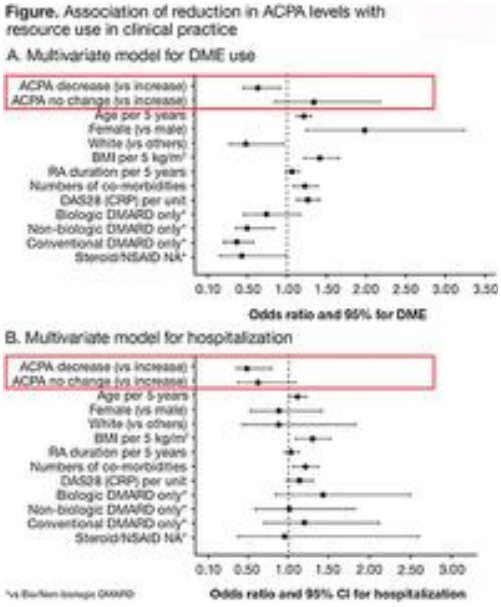
## Epidemiology, health services and outcome research

### FRI0550 REAL-WORLD TREATMENT PATTERNS AMONG RHEUMATOID ARTHRITIS PATIENTS WHO SWITCH FROM A TUMOR NECROSIS FACTOR INHIBITOR TO ANOTHER MEDICATION

B. Chastek[1], J.R. Curtis[2], L.K. Becker[1], P. Mahajan[3], C. Chen[4]. *[1]Optum, Eden Prairie MN; [2]University of Alabama at Birmingham, Birmingham AL; [3]Sanofi, Bridgewater NJ; [4]Regeneron Pharmaceuticals, Tarrytown NY, United States*



**Background:** When a patient with rheumatoid arthritis (RA) fails initial treatment with a tumor necrosis factor inhibitor (TNFi) because of inadequate response or lack of tolerability, switching to another TNFi or to a non-TNFi is recommended, but this is based on limited evidence.[1,2]
**Objectives:** This study examined real-world treatment patterns between patients with RA who switched from a TNFi to another TNFi (TNFi cyclers) compared with those who switched from a TNFi to a non-TNFi (non-TNFi switchers).
**Methods:** The data source was an administrative claims database from a large managed care organization of commercial and Medicare Advantage patients in the United States. The "index claim" was the first TNFi (adalimumab, certolizumab pegol, etanercept, golimumab, or infliximab) claim between January 2010 and February 2014 after ≥6 months of continuous enrollment pre-index. Eligible patients were aged ≥18 years at index with RA and no other autoimmune condition for which the study drugs could be used. The study included patients who subsequently switched either to another TNFi or to a non-TNFi (abatacept, tocilizumab, or tofacitinib) within 12 months post-index and had ≥12 months of additional follow-up. Each patient had 1 of 4 treatment patterns in the 12 months after the initial switch: (1) switched to a third TNFi or non-TNFi; (2) restarted the second therapy after a treatment gap of ≥45 days without switching; (3) discontinued the second therapy without switching or restarting; or (4) persisted with the second therapy without switching, restarting, or discontinuing. Adherence was defined as a proportion of days covered (PDC) of ≥80% for the second therapy.
**Results:** Of 32,272 adult patients with RA who received ≥1 biologic, 1432 met all study criteria, including 379 non-TNFi switchers and 1053 TNFi cyclers. Most patients (81%) were female. Non-TNFi switchers were older (54.0 vs 51.1 y; $P<0.001$) and less likely than TNFi cyclers to be commercially insured (82% vs 90%; $P<0.001$). In the 12 months after the initial switch, non-TNFi switchers were significantly more likely than TNFi cyclers to persist on the second medication (51% vs 44%; $P=0.021$) and significantly less likely to switch to a third TNFi or non-TNFi (29% vs 37%; $P=0.006$); non-TNFi switchers and TNFi cyclers had similar rates of restarting therapy after a ≥45-day treatment gap (6% vs 8%; $P=0.325$) and discontinuation without restarting or switching therapy (14% vs 11%; $P=0.185$). In the 12 months after the initial switch, non-TNFi switchers were significantly more likely than TNFi cyclers to have high adherence (≥80% PDC) to the second medication (45% vs 38%; $P=0.021$).
**Conclusions:** Among patients with RA, those who switched from a TNFi to a non-TNFi were more likely than TNFi cyclers to be persistent on the second medication in the first year, had greater adherence to the second medication, and were less likely to switch therapy again in the first year. The implications for clinical treatment outcomes deserve further study.

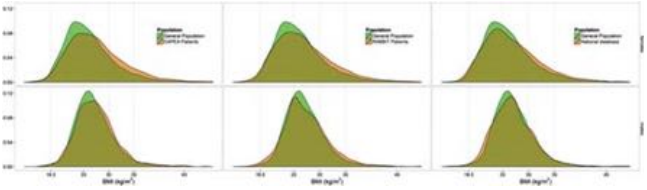
## FRI0551 EVALUATION OF CHANGE IN ANTI-CITRULLINATED PEPTIDE AUTOANTIBODY LEVELS IN CLINICAL PRACTICE AND ASSOCIATION WITH RESOURCE USE

E. Alemao[1], Z. Guo[1], C. Iannaccone[2], M. Frits[2], N. Shadick[2], M. Weinblatt[2].
*[1]Bristol-Myers Squibb, Princeton; [2]Brigham and Women's Hospital, Boston, United States*

**Background:** Testing for anti-citrullinated peptide antibodies (ACPA) has become standard in RA diagnosis in clinical practice, partly due to improved assay specificity compared with detection techniques for antibodies against RF.[1] ACPA concentration, beyond ACPA positivity, is indicative of more aggressive radiographic progression.[2] However, there is limited information on the association between changes in ACPA levels in clinical practice and resource use measures.
**Objectives:** To evaluate the association of changes in ACPA levels with resource use (durable medical equipment [DME] use/hospitalizations) in clinical practice.
**Methods:** Patients enrolled in the Brigham and Women's Hospital Rheumatoid Arthritis Sequential Study (BRASS) Registry, established in 2003, were analysed. BRASS primarily comprises patients with established RA who were evaluated semi-annually for multiple, clinical patient-reported outcomes and resource utilization parameters. The current analysis is based on patients enrolled in the BRASS registry who had ACPA values at baseline and at follow-up visits. ACPA levels were measured by well-documented and validated ELISAs from Inova Diagnostics (San Diego, CA), until its discontinuation in 2011, and Euro-Diagnostica (distributed by IBL-America, Minneapolis, MN) thereafter. Annual mean ACPA change from baseline (CFB) to 12 months was calculated and categorized as decrease (1+ unit decrease), no change (>–1 to <1 unit change) or increase (1+ unit increase). DME use of canes, wheelchairs, walkers and commodes as well as hospitalizations were assessed every 6 months. Multivariate regression analyses controlling for baseline covariates were conducted to evaluate associations between ACPA CFB and resource use measures defined by DME and hospitalizations.
**Results:** A total of 840 patients (64%) in BRASS had ACPA values at baseline and follow-up and were included in the current analysis. A decrease in ACPA levels was observed in 42.6% (n=358) of patients, 18.1% (n=152) had no change and 39.3% (n=330) had an increase. There were no significant differences in baseline characteristics between the three groups, except for BMI; patients with RA with an increase in ACPA levels had significantly lower BMI at baseline. In univariate analyses, the percentages of patients with DME use were 23.8, 30.5 and 29.8% in the groups with a decrease, no change and an increase in ACPA levels, respectively. Similarly, the percentages of patients with hospitalizations were 13.7, 13.9 and 21.3%, respectively. After controlling for baseline covariates, the odds ratio for DME use over 12 months in patients who had an ACPA decrease (vs increase) was 0.60 (95% CI 0.41, 0.89; p=0.011), and the odds ratio for hospitalization was 0.49 (95% CI 0.32, 0.75; p=0.001; Figure).

**Figure.** Association of reduction in ACPA levels with resource use in clinical practice



**Conclusions:** A reduction in ACPA levels was associated with a reduction in DME use and hospitalizations.

## FRI0552 PATIENTS WITH RHEUMATOID ARTHRITIS ARE MORE OBESE THAN THE GENERAL POPULATION ALREADY AT DISEASE ONSET: A COLLABORATIVE ANALYSIS FROM THREE LARGE GERMAN RA DATABASES

K. Albrecht[1], A. Richter[1], J. Callhoff[1], D. Huscher[1], G. Schett[2], A. Zink[1].
*[1]Epidemiology Unit, German Rheumatism Research Center, Berlin; [2]Department of Internal Medicine, Erlangen, Germany*

**Background:** METARTHROS (Metabolic impact on joint and bone disease) is a nation-wide German network to investigate the interaction between inflammatory and metabolic diseases.
**Objectives:** To compare the distribution of the body mass index (BMI) in early and established rheumatoid arthritis (RA) with representative data from the general population.
**Methods:** The distribution of the BMI was determined with baseline data from the early arthritis cohort CAPEA and the biologics register RABBIT as well as with data of patients enrolled in the National database of the Collaborative Arthritis Centers in 2013. BMI categories of <18.5 kg/m$^2$ (underweight), 18.5 to <25 kg/m$^2$ (normal weight), 25 to <30 kg/m$^2$ (overweight), and ≥30 kg/m$^2$ (obesity) were used. The results were stratified by age and sex and were compared to the German Ageing Study. The association of the BMI with sociodemographic features and markers of disease activity were analysed with non-parametric tests and linear models.
**Results:** The data of 1,207 (CAPEA), 12,230 (RABBIT) and 3,424 (National database) patients were evaluated. The mean age was 56/56/62 years, the mean disease duration 13 weeks/9.9 years/13.5 years and the mean DAS28 score 5.1/5.2/3.1 units, respectively. In all cohorts, obesity was more frequent (23.8%/23.4%/21.4%) than in the general population (18.2%), remaining in the age groups <70 years, independent of disease duration and more prominent in females (Fig.1). Current smoking was inversely associated with BMI. Linear analyses revealed no significant association between BMI and DAS28.
Fig.1 Distribution of the BMI in CAPEA, RABBIT and the National database

**Conclusions:** A higher prevalence of obesity, already seen at disease onset, supports a pathogenic role of obesity in the development of RA. This difference is more pronounced in females than in males. Patients in the cohorts with longer disease duration did not show a higher prevalence of obesity than those with recent onset RA, indicating that obesity may rather be a risk factor than a consequence of RA.

## FRI0553 OBESITY AND THE RISK OF SYSTEMIC LUPUS ERYTHEMATOSUS IN THE NURSES' HEALTH STUDIES

S.K. Tedeschi, M. Barbhaiya, B. Lu, S. Malspeis, J.A. Sparks, E.W. Karlson, K.H. Costenbader. *Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, United States*

**Background:** Obesity in the U.S. has increased to an alarming extent over the past four decades. Obesity is related to risk of several autoimmune diseases, possibly via generation of adipokines and inflammatory cytokines. Prospective studies of obesity and systemic lupus erythematosus (SLE) risk are lacking however.
**Objectives:** To prospectively evaluate the association between obesity and SLE risk
**Methods:** We conducted a prospective cohort study of women in the U.S. Nurses' Health Studies (NHS, 1976–2012, age 30–55 at baseline; NHSII, 1989–2013, age 25–42 at baseline). Incident SLE was confirmed by American College of Rheumatology 1997 criteria. Body mass index (BMI, kg/m$^2$) was reported at baseline and on biennial questionnaires. Cumulative average BMI (18.5 to <25 [normal (ref)], 25 to <30 [overweight], ≥30 [obese]) was the primary exposure. Cox proportional hazards models estimated hazard ratios (HR) and 95% confidence intervals (CI) for SLE by cumulative average BMI category, adjusting for covariates (Table). Analyses were conducted in each cohort; results were meta-analyzed with a DerSimonian-Laird random effects model. Sensitivity analyses: 1) excluded

women with cancer, and 2) started in 1988 (NHS)/1989 (NHSII) when obesity prevalence in the U.S. was most steeply increasing.
**Results:** We identified 154 SLE cases in NHS and 113 cases in NHSII. At baseline, obesity was present in 8.4% (NHS) and 11.8% (NHSII); mean age was 42.7 (SD 7.1) years (NHS) and 34.4 (SD 4.6) years (NHSII); 92% were White in each cohort. Obesity was significantly associated with SLE risk among women in NHSII, but not NHS (Table). In NHSII, a strong dose-dependent relationship between BMI and SLE risk was observed. After meta-analysis, obese women had a non-significantly elevated SLE risk compared to normal weight women (p trend 0.02). Results were similar in sensitivity analyses excluding women with cancer (HR 1.48, 95%CI 0.93–2.37, p trend 0.03). In analyses starting in 1988/1989, obese women had an increased SLE risk (meta-analyzed HR 1.76, 95%CI 1.19–2.58) compared to normal weight women (p trend <0.01).

Risk of SLE by cumulative average BMI category among 114,536 women in the Nurses' Health Study (NHS, 1976–2012) and 109,245 women in the Nurses' Health Study II (NHSII, 1989–2013)

| | Cumulative average BMI, kg/m$^2$ | | | p trend |
|---|---|---|---|---|
| | 18.5 to <25 | 25 to <30 | ≥30 | |
| NHS (n=154 cases) | | | | |
| Cases/P-Y | 89/1,989,864 | 47/897,609 | 18/381,108 | |
| Adjusted HR (95% CI)* | 1.00 | 1.28 (0.89–1.84) | 1.14 (0.67–1.92) | 0.37 |

| Cases/P-Y | 154/3,357,896 | 66/1,475,564 | 47/774,433 | |
| Adjusted HR (95% CI)* | 1.00 | 1.02 (0.61–1.71) | 1.49 (0.91–2.43) | 0.02 |

P-Y: person-years.*Adjusted for age, questionnaire cycle, race, household income, smoking, alcohol intake, oral contraceptive use, age at menarche, menopausal status and post-menopause hormone use p for heterogeneity = 0.039.

**Conclusions:** Obesity was associated with a significant 88% increase in SLE risk in the younger cohort, NHSII, but did not significantly elevate SLE risk in NHS subjects. Meta-analysis revealed a non-significant 49% increased risk of SLE in obese women. We observed a stronger obesity-associated SLE risk when analyses started in 1988/1989 in both cohorts. The discrepant results between the cohorts are not fully understood and deserve further study.

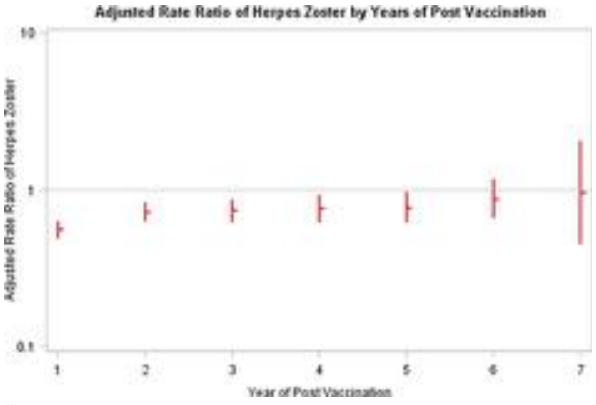
## FRI0554 POVERTY MODIFIES THE EFFECT OF RACE ON TOTAL KNEE ARTHROPLASTY OUTCOMES



S.M. Goodman[1], M.L. Parks[2], M.H. Bogardus[1], M. Zhang[3], J.T. Nguyen[3], Y.-Y. Lee[3], M.P. Figgie[2], L.A. Mandl[1], A.R. Bass[1]. *[1]Rheumatology; [2]Orthopedics; [3]Biostatistics, Hospital for Special Surgery, New York, United States*

**Background:** Race is an important predictor of total knee arthroplasty (TKA) outcomes in the United States; however analyses of race can be confounded by socioeconomic factors.
**Objectives:** To analyze the interaction between race and community poverty as it effects patient reported outcomes after TKA.
**Methods:** We identified all patients undergoing TKA enrolled in a hospital based registry between 2007 and 2011, living in three adjacent states. Using geocoding we linked individual-level registry data including WOMAC pain and function to U.S. census tracts (CT) data. We constructed a multivariate linear mixed effect model within multilevel frameworks to assess the interaction between race and CT poverty on 2-year WOMAC outcomes.
**Results:** Of 4225 TKA patients, 194 (4.6%) were black. Baseline WOMAC scores were statistically but not clinically significantly worse for blacks than for whites (WOMAC Pain 49 vs. 55, p<0.0001; WOMAC Function 47 vs. 54, p<0.0001; 100=best). Fewer blacks had a college education or above (45% vs. 62%, p<0.0001), and blacks had higher BMI (33 vs. 30, p<0.001) and more comorbidities than whites (44% >1 comorbidity vs. 27%, p<0.0001). More blacks lived in high poverty neighborhoods (37% vs. 3.5%, p<0.0001). Controlling for multiple potential confounders, our model demonstrated that whites and blacks from census tracts with <10% poverty have similar 2-year WOMAC scores. With increasing community poverty, pain and function worsened; from census tracts with >50% poverty blacks had clinically meaningful worse pain and function compared to whites (Table 1).
**Conclusions:** We have found a significant differential effect of poverty on 2-year outcomes after TKA when stratified by race. Overall WOMAC scores are minimally but not significantly worse for blacks than whites. However, while outcomes among whites do not vary much between high and low poverty census tracts, the effect of high poverty levels was disproportionally associated with worse TKA outcomes among black Americans. Since a higher proportion of blacks live in high poverty areas, this finding has important implications. Efforts to improve TKA outcomes among U.S. blacks will need to investigate both the impact of individual patient-level factors and community-level poverty.

## FRI0555 LONG TERM EFFECTIVENESS OF HERPES ZOSTER VACCINE AMONG PATIENTS WITH AUTOIMMUNE AND INFLAMMATORY DISEASES

H. Yun[1], F. Xie[1], J.W. Baddley[2], K. Winthrop[3], L. Chen[1], J.R. Curtis[1]. *[1]Clinical Immunology and Rheumatology; [2]Med-Infectious Diseases, University of Alabama at Birmingham, Birmingham; [3]Infectious Diseases, Oregon Health & Science University, Portland, United States*

**Background:** Recent results from long-term follow-up of healthy older participants of the Shingles Prevention Study (SPS) demonstrated that the herpes zoster (HZ) vaccination lost most of its benefit after approximately 10 years. However, the duration of protection among patients with autoimmune or inflammatory (AI) diseases is unclear.
**Objectives:** Current study aimed to evaluate the duration of HZ vaccine effectiveness in preventing HZ among older patients with autoimmune diseases.
**Methods:** Using Medicare data from 2006–2013 for patients with AI diseases, this retrospective cohort study identified patients who had HZ vaccination. To control for confounding, patients without HZ vaccination were matched 2:1 to vaccinated patients on year of vaccination, age, gender, race, type of AI diseases, and use of biologics, DMARDs and glucocorticoids. Follow up began one month after vaccination and ended at: HZ, death, loss of coverage or 12/31/2012. We calculated HZ incidence rates for each year and used Poisson regression to calculate the adjusted risk ratio of HZ for each year.
**Results:** Of 59,627 vaccinated patients with AIs matched to 119,254 unvaccinated AI patients, we identified 1,242 and 3,183 HZ events during follow-up respectively. Incidence rates among vaccinated increased from 0.75 per 100 person years (PY) during the first year post vaccination to 1.36 during the 6th year post. After multivariable adjustment, vaccinated patients had a significantly lower risk of HZ compared to unvaccinated patients through 5 years but not beyond.

Figgure 1

**Conclusions:** Among patients with autoimmune diseases, the effectiveness of HZ vaccination waned over time, and a significant benefit to reduce HZ risk compared to non-vaccinated patients was found only through 5 years post vaccination.

## FRI0556 DOES LEAVING POVERTY REDUCE NEWLY ACCUMULATED DAMAGE IN SLE?

E. Yelin, L. Trupin, J. Yazdany. *Medicine, UCSF, San Francisco, United States*

**Background:** Several studies indicate that persons with SLE in poverty experience increased levels of accumulated damage compared to the non-poor. However, it is unknown as to whether leaving poverty reduces the amount of newly accumulated damage and over what time frame.
**Objectives:** Describe impact of permanently leaving poverty on newly accumulated damage and the duration of time until the effects of poverty are attenuated.
**Methods:** We used the UCSF Lupus Outcomes Study (LOS), a national longitudinal sample of persons with SLE interviewed annually. The survey collects data to assess whether individuals are ≤125% of the US Federal poverty level as well as a validated self-report battery of accumulated damage, the Brief Index of Lupus Damage (BILD)[1]. We used linear regression to analyze the impact of having left poverty permanently versus having remained in poverty or never having been in poverty and effect of # of years out of poverty on change in BILD between the 2009 and 2014, with and without adjustment for covariates. Covariates are listed in the footnote to Table 1, below.
**Results:** 2009 LOS interviews included 750 persons with SLE, of whom 587 were interviewed through 2014. Of the 587, 461 (80%) were never in poverty between 2009 and 2014, 51 (9%) remained poor throughout, and 67 (12%) left poverty permanently. In 2009 mean BILD was 1.95 (std dev, 2.00), range 0–13; by 2014, mean BILD increase was 1.44 (std dev 1.71), range 0–13, a clinically meaningful increment in damage. Table 1 summarizes change in BILD as a function of having left poverty and for how long and shows that persons who left poverty experience similar levels of accumulated damage as those never in poverty; this occurs by 2–3 years after leaving poverty.
**Conclusions:** Leaving poverty is associated with reduced levels of newly accumulated damage as soon as 2–3 years later, even when taking into account disease, demographics, medical care, and health behaviors. These results indicate that clinicians should be attentive to the burdens associated with poverty and that public policies to alleviate poverty not specifically geared to persons with SLE may contribute to the reduction of new damage in SLE.

## FRI0557 THE ASSOCIATION BETWEEN BODY MASS INDEX AND MRI-DETECTED INFLAMMATION; PARADOXICAL EFFECTS IN RHEUMATOID ARTHRITIS, OTHER ARTHRITIDES AND SYMPTOM-FREE CONTROLS

L. Mangnus[1], W.P. Nieuwenhuis[1], H.W. van Steenbergen[1], M. Reijnierse[2], A.H.M. van der Helm-van Mil[1]. *[1]Department of rheumatology; [2]Department of radiology, LUMC, Leiden, Netherlands*

**Background:** Generally, an increased body mass index (BMI) is associated with higher inflammatory markers. Within rheumatoid arthritis (RA) it has been observed that a high BMI is associated with less severe radiographic joint damage.[1–4] The biologic mechanism underlying this association is unidentified.
**Objectives:** As joint damage is the consequence of inflammation, and because MRI is sensitive in detecting local inflammation, this study aimed to explore the association between BMI and MRI-detected inflammation in patients with RA, other arthritides and symptom-free persons recruited from the general population.
**Methods:** We studied 202 RA patients, 170 patients with other inflammatory arthritides from the Leiden Early Arthritis Clinic cohort and 193 symptom-free persons from the general population.[5] At baseline, all participants underwent a contrast-enhanced 1.5T MRI of the dominant or most painful MCP, wrist and MTP joints. Each MRI-scan was scored by two readers on synovitis, BME and tenosynovitis. The sum of the scores yielded the total MRI- inflammation score. Linear regression models (on log transformed MRI-data) were used for associations with the total MRI-inflammation score and Spearman's correlations for correlations with separate inflammatory features as they were non-normally distributed.
**Results:** A higher BMI was associated with higher MRI-inflammation scores in symptom-free persons ($\beta$=1.029, p=0.040) and arthritides other than RA ($\beta$=1.082, p<0.001). These $\beta$'s indicate an 1.029 fold and an 1.082 fold increase in MRI-inflammation with every point increase in BMI (Figure). However, in RA patients a higher BMI was associated with lower MRI-inflammation score ($\beta$=0.969, p=0.005). Similar results were seen when correcting for age and gender. Evaluating the different inflammatory features separately showed that BMI was correlated with higher synovitis and tenosynovitis scores in symptom-free persons (respectively $\rho$=0.17, p=0.016 and $\rho$=0.16, p=0.027) and in arthritides other than RA (respectively $\rho$=0.40, p<0.001 and $\rho$=0.26, p<0.001). This is in contrast to RA where a higher BMI was correlated with lower synovitis scores ($\rho$=-0.18, p=0.010) and was not correlated with tenosynovitis ($\rho$=-0.10, p=0.15). Similarly, BMI was positively correlated with BME in other arthritides ($\rho$=0.16, p=0.048)) and negatively correlated with BME in RA ($\rho$=-0.23, p=0.001).

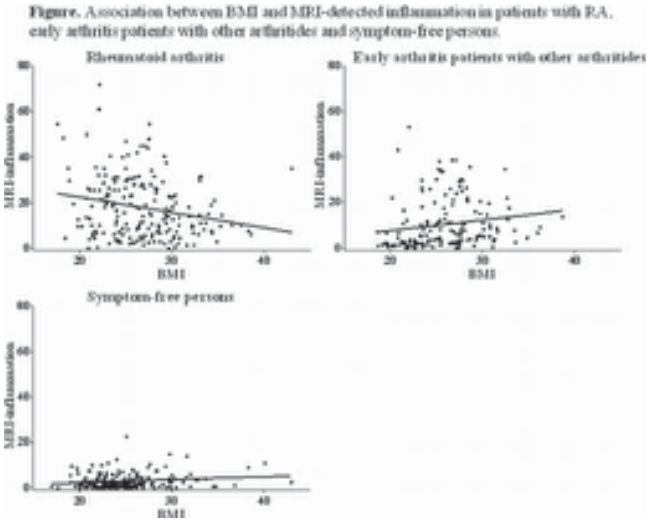

**Figure.** Association between BMI and MRI-detected inflammation in patients with RA, early arthritis patients with other arthritides and symptom-free persons

**Conclusions:** The association between BMI and MRI-detected inflammation differs in patients with RA compared to patients with other arthritides and symptom-free controls. Within RA a higher BMI is associated with less MRI-detected synovitis and BME; this might explain the previously observed association of BMI with less radiographic damage.

**Abstract FRI0556** – Table 1. Effect of leaving poverty and years out of poverty on change in BILD damage index between 2009 and 2014 in SLE, with and without adjustment for disease, demographic, and health care characteristics and health behaviors

| Leaving poverty | | Never in poverty | Left poverty permanently | Remained in poverty | |
|---|---|---|---|---|---|
| | | Data in cells represent level of newly accumulated damage (BILD) between 2009 and 2014 | | | |
| | Unadjusted* | 1.33 | 1.41 | 2.08 | |
| | Adjusted* | 1.24 | 1.08 | 1.90 | |
| Years out of poverty | | 5–11 years | 2–3 years | 1 year | Remained in poverty |
| | Unadjusted* | 1.24 | 1.44 | 2.43 | 2.31 |
| | Adjusted* | 1.04 | 1.26 | 2.31 | 2.06 |

Variables in adjusted models include age, gender, race/ethnicity, level of educational attainment, disease duration, specialties of principal and other physicians for SLE, managed care vs. fee-for-service insurance, pass rates of ≥85% in SLE quality indicators, smoking status (past, current, never), and body mass index. *Leaving poverty and # of years out of poverty significantly related to level of new damage accrual between 2009 and 2014 (p<0.05).

## FRI0558 RHEUMATOID ARTHRITIS PREVALENCE IN EUROPE, A EULAR-ENDORSED SURVEY

M.I. Zlatkovic-Svenda[1], A. Saraux[2], T. Tuncer[3], J. Dadoniene[4], D. Miltiniene[4], E. Gilgil[3], R. Stojanovic[1], F. Guillemin[5]. *[1]Institute of Rheumatology, University of Belgrade School of Medicine, Belgrade, Serbia; [2]Rheumatology, University Hospital, Brest, France; [3]Department of Physical Medicine, Rehabilitation and Rheumatology, Akdeniz University Faculty of Medicine, Antalya, Turkey; [4]Institute of experimental and Clinical Medicine, Vilnius University, Vilnius, Lithuania; [5]Inserm CIC-EC 1433, Nancy University Hospital, and Université de Lorraine, EA 4360 APEMAC, Nancy, France*

**Background:** Various rheumatoid arthritis (RA) prevalence estimates have been reported across Europe, but differences in methodology made it difficult to disentangle true heterogeneity (1). A unique RA prevalence survey method, comprising similar sampling and results interpretation, was needed.
**Objectives:** to estimate the RA prevalence in France, Turkey, Lithuania and Serbia using a unique methodology and to use direct method for standardization of results with reference to the European Standard Population.
**Methods:** In a first detection phase, a unique Questionnaire covering signs, symptoms, self-reported diagnosis and classification criteria for RA (ACR 1987) (2), previously translated and validated for each of the participating countries, was conducted on population sample. Two-stage random sampling was implemented on seven areas covering 20 counties in France, seven geographical regions covering 25 administrative provinces in Turkey, two largest cities- Vilnius and Kaunas in Lithuania and two geographical regions covering four counties in Serbia. In a second confirmation phase, diagnoses were confirmed by rheumatologists. Results were standardized by age and sex using the European Standard Population, defined as EU-27+EFTA, based on the 2010 estimates.
**Results:** Detection Questionnaire was administered by telephone on 15219 persons in France (3), 6558 in Lithuania (4) and 6213 in Serbia (1), with 64.7%, 64.7% and 63.3% response rate, respectively. In Turkey, Questionnaire was administered face-to-face on 4012 persons. Diagnoses were confirmed for 32 cases in France (93.7% female), 25 in Turkey (92.0% female), 39 in Lithuania (100.0% female) and 23 in Serbia (82.6% female). Overall standardized RA prevalence estimates are given in Table 1.

Table 1. Age- and sex-standardized RA prevalence, % (95% CI) for France, Lithuania, Turkey and Serbia, 18 years and older

| | Men | Women | Total |
|---|---|---|---|
| France | 0.15 (0.02–0.29) | 0.42 (0.26–0.58) | 0.29 (0.17–0.40) |
| Lithuania | 0.00 (0.00–0.00) | 1.01 (0.68–1.34) | 0.50 (0.38–0.63) |
| Turkey | 0.13 (0.00–0.31) | 1.02 (0.59–1.45) | 0.57 (0.31–0.84) |
| Serbia | 0.19 (0.00–0.38) | 0.52 (0.27–0.76) | 0.35 (0.18–0.53) |

**Conclusions:** Age- and sex-standardized RA prevalence estimates in France were in line with Serbia, but lower than in Turkey and Lithuania. Standardized RA prevalence estimates in men were similar for all countries, up to 0,19%. Standardized women RA prevalence was largely heterogenous, resulting in diverse overall European RA prevalence, from 0,29% to 0,57%. The use of a unique survey method with similar sampling and case ascertainment has shown genuine heterogeneity of the RA prevalence in women across Europe.

## FRI0559 LATITUDE GRADIENTS INFLUENCE THE AGE OF ONSET OF RHEUMATOID ARTHRITIS: A WORLDWIDE SURVEY

C. Ramos-Remus[1,2], A. Ramirez-Gomez[2], V. Brambila-Barba[2], A. Barajas-Ochoa[2], J.D. Castillo-Ortiz[2], J.M. Sanchez-Gonzalez[1] on behalf of GEO-RA group. *[1]Vicerrectoria Academica, Universidad Autonoma de Guadalajara; [2]Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara, Mexico*

**Background:** The effects of latitude gradients on diseases serve as surrogates for environmental factors to generate hypotheses for further testing. The age of onset in rheumatoid arthritis (ao-RA) is one important outcome predictor. Some reports suggest that ao-RA may be different depending on latitude gradients.
**Objectives:** To assess the ao-RA at preselected cities worldwide.
**Methods:** A proof-of-concept, worldwide survey. We selected major cities in each 15° quadrant (latitude and longitude) worldwide and found rheumatologists' contact information through rheumatology associations (e.g. ACR, PANLAR). An invitation e-mail was sent to rheumatologists requesting to directly interview 20 consecutive RA patients (ACR criteria) who attended their clinics about ao-RA. A second e-mail with instructions and a data-log sheet was sent to those who accepted. The information was limited to patient ID (initials or consecutive numbers), date of birth (month and year), date of RA diagnosis and date of RA onset (when the patient first noted a swollen joint). This data was considered nonsensitive, so no informed consent was required as per local regulations. Our goal was to have 3 participating rheumatologists in each selected city from 40 countries around the world. Statistical analysis: intra-city consistency was considered if no significant differences in ao-RA among rheumatologists' data were found (non-parametric tests). Then the ao-RA was compared per latitudes (each 10°) and longitudes by continents, and worldwide (one-way ANOVA with post-hoc Scheffé for multiple comparisons). Frequency distribution per ao-RA etary groups (10 year intervals) was also analyzed by country and quadrant. Significant differences were set at $p<0.05$.
**Results:** Data from 2,481 patients were obtained from 126 rheumatologists in 78 cities in 42 countries. Intra-city variability could be assessed in 29 (37%) cities, and consistency was ascertained in 72.5% of these. The overall frequency distribution by age group showed that in 28% of patients the disease started before 35 yrs of age, 23% between 36 and 45, 26% between 46 and 55, 15% between 56 and 65, and 8% after 65 yrs of age; the mean ao-RA was 44±14 years (95% CI 44 to 45) and 84% were women. The linear chart of the mean ao-RA by worldwide latitudes showed a U shape, with the first peak in southern latitudes (>30°), the second peak in northern latitudes (>41°) and the base at the Tropic of Cancer. The ao-RA was 9 years older in northern latitudes when compared to the Tropic of Cancer (48 ± 15 vs. 39 ± 12 years, $p<0.001$), and the proportion of patients with ao-RA after the age of 55 was also higher (38% vs. 20%, $p<0.001$); these figures were consistent when analyzing data by continent.
**Conclusions:** RA should be considered a disease mainly affecting young people, with almost one-third beginning before age 36 and half before the age of 45 worldwide. ao-RA appears to be influenced in some way by latitudes, mainly in the Tropic of Cancer (younger) and northern latitudes (older). Studies to assess environmental factors in these latitudes may be worth pursuing further.

## FRI0560 THE INCREASE IN THE NATIONWIDE INCIDENCE OF INFLAMMATORY RHEUMATIC DISEASES IN FINLAND DURING THIS MILLENNIUM

V. Rantalaiho[1,2], H. Kautiainen[3], L. Virta[4], K. Puolakka[5]. *[1]Centre for Rheumatic Diseases, Tampere University Hospital; [2]School of Medicine, University of Tampere, Tampere; [3]Department of General Practice, University of Helsinki, Helsinki; [4]Social Insurance Institution, Turku; [5]Department of Medicine, South-Karelia Central Hospital, Lappeenranta, Finland*

**Background:** With the growing knowledge, the diagnostic and therapeutic opportunities of most inflammatory rheumatic diseases have intensified during the recent decades. This has led to improved functional outcomes in the vast majority of patients, but also to a certain dependency of specialist care in these patients, which, in the face of the current decreasing numbers of practicing rheumatologists raises concerns about the abundance of the health care resources. Some earlier reports have shown a decreasing incidence of rheumatoid arthritis (RA) in Eastern Finland; however there is no data on other diagnoses, and the experience from clinical practice contradicts these findings. Thus, to be able to optimally meet the future needs of rheumatological therapy, the total burden of new inflammatory rheumatic diseases needs to be assessed.
**Methods:** From the Finnish nationwide register maintained by the Social Institute of Insurance (SII) we collected data on all patients granted a new special reimbursement on medications for various inflammatory rheumatic diseases from January 1st 2000 to December 31st 2014. The diagnoses were: juvenile arthritis (all patients aged 0–16 years with ICD-10 diagnosis M02-M46), and for patients >16 years, seropositive rheumatoid arthritis (RA) (M05), seronegative RA (M06), spondylarthritis (M45-M46), unspecified arthritis (M13) and psoriatic arthritis (L40.5). The total number of new patients and the incidences for each diagnosis /100 000 patient years in these age groups were counted in 3-year cohorts.
**Results:** During the observation time altogether 54 658 patients (61.7% female) with a new diagnosis of a rheumatic disease and an initiated treatment were identified. The total incidence of inflammatory rheumatic diseases increased linearly from the first cohort's 63/100 000/patient years to the last cohort's (2012–14) 76/100 000/patient years, and the absolute yearly number of newly

diagnosed patients increased 1.39-fold during the follow-up. The characteristics of each diagnosis group are presented in the Table.
**Conclusions:** The total burden new of rheumatic diseases has increased during this millennium. The incidence of seropositive RA has remained stable and only that of seronegative RA has decreased slightly. However, the incidence unspecified and psoriatic arthritis, as well as spondylarthritis has increased clearly. Thus, with increasing numbers of new patients the recourses for rheumatological treatment should increase accordingly to face their needs.

## FRI0561 HEALTHCARE RESOURCE UTILIZATION AND INFECTION RISK IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT COMORBIDITIES

A. Teeple[1], M. Ryan[2], L. Muirheid[2], L. Ellis[1]. [1]*Janssen Scientific Affairs, LLC, Horsham;* [2]*CTI Clinical Trial & Consulting, Cincinnati, United States*

**Background:** Rheumatoid Arthritis (RA) patients have increased risk of infection and comorbidities[1]. Understanding healthcare resource utilization (HRU) and infection risk associated with comorbidity burden in RA may facilitate awareness of outcomes and development of care coordination strategies in RA.
**Objectives:** To estimate the differences in HRU and odds of an all-cause infection claim in RA patients with comorbidities compared to RA patients without comorbidities.
**Methods:** RA patients identified by ICD-9 CM codes (714.xx) were identified in a transactional U.S. healthcare claims database (Symphony Health) between years 2003 to 2013. RA patients with continuous clinical activity for 1 year after the first observed RA diagnosis (index date) were included. HRU and all-cause infection claim occurrence were measured 1 year post- index. The proportion of patients with ≥1 comorbidity (Comorbidity Cohort; CC) and those without any comorbidities (No Comorbidity Cohort; NC) were summarized using descriptive statistics. The odds of developing an infection and magnitude of HRU were estimated using multivariable logistic and gamma log-link regression models, respectively. Additional independent variables used in the models included age, gender, race, region, household income, medical payer and biologic medication use.
**Results:** 645,158 RA patients were identified using the inclusion criteria (30% NC; 70% CC). The average age for the NC group was 56 years at RA index and 75% were female. The CC group was similar in age and gender –mean age was 58 years at RA index and 77% were female. On average, the CC group had 3 comorbidities per patient (range 1 to 18). CC patients with ≥4 comorbidities were more than 2 times as likely to have an infection claim compared to NC patients ($p<.0001$). Patients with ≥10 comorbidities had the highest odds ratio (OR) for an all-cause infection claim (9.81 OR $p<.0001$) compared to NC patients. The risk for an infection claim increases by an average of 61% for each additional comorbidity. Females were more likely to develop infection compared to males (1.41 OR $p<.0001$). Furthermore, the odds of an infection claim increased as comorbidity burden increased ($p<.0001$). Biologic use did not significantly increase the odds of an infection claim in CC patients when comorbidities were controlled for in the model (OR 1.01; p=0.1938). HRU models estimated that each additional comorbid condition was associated with approximately 43% higher total costs and 41% increase in outpatient days.
**Conclusions:** Comorbidity burden in RA patients is associated with higher total healthcare resource and costs and higher odds of having a medical billing claim for infection. While controlling for comorbidity burden, biologic use did not significantly increase the odds of all cause infection healthcare claims.

## FRI0562 ATTRITION AND PARTICIPANT CHARACTERISTICS IN A RHEUMATOID ARTHRITIS COHORT

A. Cesta[1], X. Li[1], M. Tatangelo[2], C. Bombardier[3]. [1]*Ontario Best Practices Research Initiative;* [2]*University of Toronto;* [3]*Research Institute, University Health Network, Toronto, Canada*

**Background:** The generalizability and validity of longitudinal observational studies is contingent on participant characteristics. If attrition is not random, it is important to identify any systematic differences between patients who continue to participate versus those who drop out.
**Objectives:** The purpose of this analysis was to compare characteristics of rheumatoid arthritis (RA) patients who continue to participate in the Ontario Best Practices Research Initiative (OBRI) to those of patients who have dropped out prior to reaching their 3 yr follow up.
**Methods:** Currently, 61 rheumatologists in Ontario (51% of active rheumatologists in Ontario) recruit patients into the OBRI. As of January 2015, 1533 patients had consented and were eligible to participate. 175 (11.4%) patients dropped out before reaching their 3 yr follow up assessment.
Among the drop outs, 109 (7.1%) withdrew consent, 38 (2.5%) were lost to follow up, and 28 (1.8%) refused to reconsent after 2 yrs of follow up. In addition to the drop outs, 38 (2.5%) patients had died. 1320 (86.1%) patients remained active participants. Patient characteristics and disease activity at enrollment were compared in the 175 patients who dropped out versus the 1320 patients who continued to participate. A survival curve was generated to look at time of drop out over the 3 year follow up period.
**Results:** Compared to patients who dropped out, patients who continued to participate had higher household incomes, lower disease activity scores, and were more likely to be taking a biologic at the time of enrollment (Table 1). The survival curve shows that the majority of patients drop out within the first two years (Figure 1).

Table 1. Patient Characteristics and Disease Activity at Time of Enrollment into OBRI

| | Patients who dropped out (N=175) | Active patients (N=1320) |
|---|---|---|
| Age, mean (SD) | 57.1 (15.4) | 56.9 (12.6) |
| Female, N (%) | 125 (75%) | 1041 (79%) |
| White, N (%) | 140 (88%) | 1133 (91%) |
| Education, N (%) | | |
| > High school | 146 (87%) | 1191 (92%) |
| *Household income, N (%) | | |
| ≥50,000 | 48 (28%) | 515 (39%) |
| Employment (full time), N (%) | 75 (45%) | 615 (52%) |
| Having private insurance, N (%) | 101 (60%) | 848 (68%) |
| Duration of disease (yrs), mean (SD) | 7.8 (9.9) | 9.2 (9.8) |
| *DAS28 (0–9.4), mean (SD) | 4.9 (4.4) | 4.4 (1.6) |
| *HAQ (0–3), mean (SD) | 1.44 (0.78) | 1.22 (0.76) |
| *Pain Score (0–3), mean (SD) | 1.76 (0.89) | 1.48 (0.87) |
| *RADAI (0–10), mean (SD) | 4.8 (2.2) | 4.0 (2.2) |
| Number of co-morbidities, mean (SD) | 2.3 (1.9) | 2.5 (2.1) |
| *RA medications | | |
| Biologic therapy, N (%) | 13 (8%) | 200 (15%) |

*$p<0.05$.

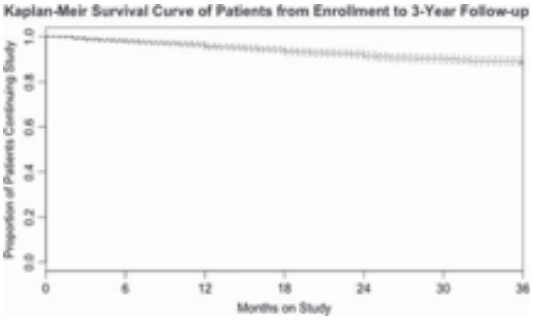

Figure 1

**Conclusions:** Patients with higher disease activity at enrollment were more likely to drop out. The OBRI attrition rate was 11.4% during the first three years of follow up, with 4.7% of patients dropping out in the first year, 3.5% in the second year and 3.2% in the third year. OBRI attrition rates were lower than those reported in the BRASS cohort (4.31% per 6 month follow up cycle) 1 and the ARAMIS cohort (6% per year) 2. The lower number of drop outs in the OBRI cohort could be attributed to the time invested in rheumatologist site visits by our study monitors and the biannual followup by our OBRI telephone interviewers.

## FRI0563 IT'S MORE THAN DRYNESS AND FATIGUE: THE PATIENT PERSPECTIVE ON HEALTH-RELATED QUALITY OF LIFE IN PRIMARY SJÖGREN SYNDROME - A QUALITATIVE STUDY

A. Lackner[1], A. Ficjan[1], J. Unger[2], W. Graninger[1], C. Dejaco[1]. [1]*Department of Rheumatology & Immunology, Medical University Graz, Graz;* [2]*FH Joanneum Bad Gleichenberg, Bad Gleichenberg, Austria*

**Background:** Patients with primary Sjögren Syndrome (PSS) are affected by glandular and extraglandular manifestations leading to physical and mental impairment. How these factors affect the health related quality of life (HRQL) of these patients is largely unexplored.
**Objectives:** This qualitative study was conducted to investigate patients' perspectives and needs influencing HRQL in PSS.
**Methods:** We recruited 20 consecutive PSS patients fulfilling the American-European consensus classification criteria out of the PSS cohort of the Medical University Graz, Austria. A total of 6 focus group sessions were performed.

A discussion guide with four open-ended questions was developed containing all elementary components of HRQL (physical, mental, social, daily life). All interviews were audio-recorded and transcribed verbatim. A modified meaning condensation procedure was used to analyse the data.

**Results:** All patients were female, the mean age was 61 (SD ±8) years and mean disease duration was 5 (±2) years. The focus group sessions took on average 58 ±13 minutes. The number of patients in each group ranged from three to four.

The interview analysis resulted in 484 meaning units, 254 subconcepts and 87 concepts. The identified concepts were grouped into three dimensions: physical dimension, psychological & emotional challenges and social life & daily living. An inter-dependency of the three dimensions was identified.

The concepts most commonly reported belonged to the physical dimension: pain, dryness and complaints related to these two symptoms. Patients frequently mentioned consequences of dryness including recurrent inflammation of eyes and ears, loss of sense of smell and taste, sleeping disturbances and the inability to eat and chew.

In the dimension psychological & emotional challenges, the most frequently mentioned concepts were "being worried about the future", "a long symptom to diagnosis lag" and "the feeling of being an encumbrance for their families". Concepts like dependency on relatives in daily life, difficulties at work and financial burden were classified within the dimension of social life & daily living.

**Conclusions:** We found that three interrelated dimensions (physical dimension, psychological & emotional challenges and social life & daily living) best reflected patients' experiences and feelings related to PSS. HRQL in PSS patients was influenced not only by dryness rather psychological and social burden clearly impacted the patients.

**Disclosure of Interest:** None declared

## FRI0564 SERUM URIC ACID TESTING PRACTICES OVER FIVE YEARS AMONG INCIDENT GOUT CASES

A. Benis[1], D. Jaffe[2], N. Flores[3], H. Gabay[1], R. Morlock[4], A. Klein[5], D. Teltsch[6], J. Chapnick[7], B. Feldman[1], M. Leventer-Roberts[1]. *[1]Clalit Health Services; [2]Kantar Health, Tel Aviv, Israel; [3]Kantar Health, Foster City; [4]Ardea Biosciences, Inc., San Diego; [5]AstraZeneca Pharmaceuticals, Gaithersberg; [6]Evidera, Lexington; [7]Kantar Health, Horsham, United States*

**Background:** Gout is a chronic inflammatory disorder associated with elevated levels of serum uric acid (sUA), resulting in urate crystal deposits in soft tissues. Uncontrolled gout can lead to bone erosion and joint destruction, kidney stones, and uric acid nephropathy. Gout is treatable with medication and lifestyle change. Long-term sUA monitoring is needed to confirm that patients are achieving target levels (≤6 mg/dL, or <5 mg/dL in more severe cases).[1–3]

**Objectives:** To describe incident gout cases and characterize these patients by subsequent sUA testing practices during 5 consecutive years.

**Methods:** Data from Clalit Health Services were used to identify incident cases of gout (1/1/2003–31/12/2009) among members ≥25 years old with continuous enrollment in Clalit for 1 year prior to and 5 years subsequent to diagnosis (index date). Cases were identified based on the following criteria: a) 1 diagnosis of gout from a hospital or specialist visit; or b) ≥2 diagnoses of gout from a general practitioner (GP) visit and either elevated sUA (>6 mg/dL) or a purchase of colchicine or allopurinol. Cases were excluded if a member was concurrently diagnosed with a disease known to affect sUA (eg, renal insufficiency, cancer, Familial Mediterranean Fever). sUA testing practices during the 5-year follow-up period were defined as: full (≥1 test per year), moderate (≥1 test per year for 3 or 4 years), poor (≥1 test per year for 1 or 2 years) and no testing (no tests performed). Demographics, clinical characteristics, comorbidities, concurrent medications, and healthcare utilization were examined and stratified by testing practices. Chi-square tests and one-way ANOVAs were used to test for differences by testing practices.

**Results:** We identified 15,598 incident gout cases meeting the inclusion criteria. Mean age was 59.3±14.5 years, 79.7% were male, and 35.7% were of higher socioeconomic status. Patients' clinical history indicated that 15.2% were current smokers and 32.4% were obese. Prevalence of pre-existing comorbidities including CVD, diabetes and hypertension was 26.8%, 20.8%, and 52.5% respectively, and mean Charlson Comorbidity Index was 0.9±1.3. The distribution of annual sUA testing over the 5-year follow up in this cohort was: 5,445 (34.9%) patients had full testing, 6,678 (42.8%) had moderate testing, 3,196 (20.5%) had poor testing, and 279 (1.8%) had no testing. At the end of follow-up, 25.6% of patients' last documented sUA was ≤6 mg/dL. Among patients in the groups with sUA ≤6 or ≥10 mg/dL, close to 39% had full testing, while among those with sUA between 6.1–9.9 mg/dL, full testing ranged from 31.6%–35.7%.

**Conclusions:** Consistent with previous findings, gout patients in Clalit were on average older adults, predominately men and with concurrent comorbidities. Over three-quarters of newly diagnosed gout patients performed an annual sUA testing during at least 3 of the 5 years of follow-up. Further study is required to assess the association between regular testing and health outcomes.

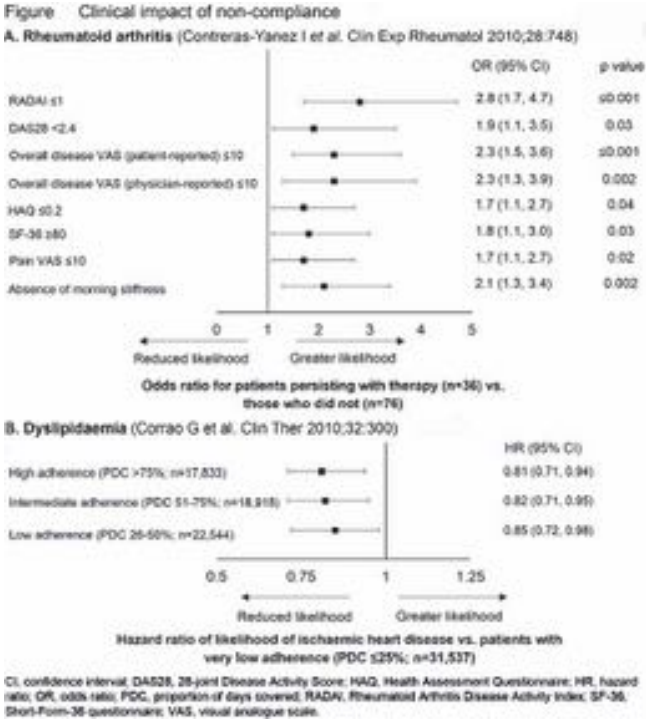
## FRI0565 INFLUENCE OF ROUTE OF ADMINISTRATION/DRUG FORMULATION AND OTHER FACTORS ON COMPLIANCE WITH TREATMENT IN RHEUMATOID ARTHRITIS AND DYSLIPIDAEMIA

B. Fautrel[1,2], A. Balsa[3], P. Van Riel[4], M. Casillas[5], J.-P. Capron[6], C. Cueille[6], I. De La Torre[5]. *[1]Pierre et Marie Curie University, Sorbonne Universités; [2]Rheumatology Dept, Pitié Salpêtrière Hospital, Paris, France; [3]Rheumatology Dept, Hospital Universitario de La Paz, Madrid, Spain; [4]3Scientific Institute for Quality of Healthcare, Radboud University, Nijmegen, Netherlands; [5]Lilly S.A, Madrid, Spain; [6]Lilly France, Neuilly-sur-Seine, France*



**Background:** Poor compliance with drugs for rheumatoid arthritis (RA) can lead to treatment failure, delayed recovery, disease progression and a need for more aggressive therapy. Understanding factors associated with poor compliance has potential to improve treatment outcomes.

**Objectives:** A comprehensive review was performed to investigate: the effect of route of administration on drug compliance in RA; compliance with oral drugs in RA compared with that in a non-pain-related disease (dyslipidaemia); the effect of poor compliance on clinical outcomes; the relationship between compliance and economic outcomes, such as healthcare resource utilisation and costs; and the impact of patient education/support programmes on compliance.

**Methods:** Comprehensive database searches and searches of the reference lists of relevant publications were performed to identify studies investigating drug compliance in adults with RA being treated with conventional synthetic or biologic agents. Similar searches were performed for studies of patients with dyslipidaemia being treated with statins. Studies had to be published after 1998 and in English, and had to involve ≥6 months of follow up. Compliance data were extracted and compared between the different routes of drug administration in RA, and between the two diseases for oral agents.

**Results:** A total of 33 and 22 papers underwent data extraction for RA and dyslipidaemia, respectively. The definitions and range of compliance values across studies was wide, making comparisons between drug formulations and diseases difficult. Within the constraints of the analysis, compliance and persistence rates were broadly similar for the different routes of drug administration in RA (compliance for intravenous [i.v.], subcutaneous [s.c.] and oral drugs, respectively: 68%, 59–73% and 33–107% [some patients took extra doses] at 6 months; 38–64% [i.v.] and 16–97% [s.c.] at 1 year; and 58–71% [oral] at 2 years). Compliance with oral drugs was also broadly similar across the two diseases (for RA: 33–107% at 6 months, 58–71% at 2 years; for dyslipidaemia: 40–100% at 6 months, 72–75% at 2–3 years). Poor compliance had clinical consequences

Figure Clinical impact of non-compliance

in both diseases: greater disease activity, pain and functional disability in RA, and increased serum cholesterol levels and risk of ischaemic heart disease in dyslipidaemia (Figure). The only factors associated with compliance/persistence across both diseases were age, race and the extent of copayment/out-of-pocket expenses. Over 1–3 years, poor compliance with biologic RA drugs led to increased resource use and medical costs but lower total direct costs due to reduced biologic (s.c. and i.v.) drug costs. By contrast, poor compliance with dyslipidaemia drugs resulted in increased total direct costs. For RA, compliance improved with patient education/support.

**Conclusions:** The route of drug administration and the symptomatic (pain) nature of the disease do not appear to be dominant factors for drug compliance in RA.

## FRI0566 ATTRIBUTES OF THE SUBCUTANEOUS BIOLOGIC THERAPY PREFERRED BY PATIENTS WITH RHEUMATIC DISEASE AND SATISFACTION WITH THE TREATMENT. RHEU LIFE SURVEY

C.M. González[1], L. Carmona[2], F.J. de Toro[3], M.J. Arteaga[4], S. Fernández[4], L. Cea-Calvo[4], E. Batlle[5]. *[1]HGU Gregorio Marañón; [2]I. de Salud Musculoesquelética, InMusc, Madrid; [3]Instituto de Investigación Biomédica de A Coruña, la Coruña; [4]Medical Affairs, Merk Sharp & Dohme, Madrid; [5]Departamento de Salud Sant Joan, Alicante, Spain*

**Background:** Preferences of patients and satisfaction with the medication are important to improve adherence and outcomes.

**Objectives:** In patients with rheumatoid arthritis (RA), axial spondyloarthritis (SpA) and psoriatic arthritis (PsA), we explored the attributes of drugs preferred by them, and the degree of satisfaction with the current medication.

**Methods:** RHEU-LIFE was a survey to patients >18 years-old with RA axial SpA or PsA treated with subcutaneous (SC) biological drugs, from 50 outpatient rheumatology hospital clinics. Patients responded anonymously to the survey. They ranked 5 treatment attributes from 1 (the most important) to 5 (the least important), and expressed their satisfaction with each one from "very satisfied" to "very dissatisfied".

**Results:** The survey was given to 1000 patients, 592 responded (59.2%, mean age 51.7 years, 42.4% men and 57.6% women; underlying disease RA: 304 (54.2%), axial SpA: 141 (25.1%), PsA: 116 (20.7%), not identified: 31. The biological drug was first (60.4%), second (26.8%) and third or more (13.5%). The attributes mentioned most frequently as "the most important" were normalization of quality of life (QoL) and symptoms control (43.6% and 32.5%, table). The importance was similar in patients with different diseases or treated with first, second or third biologic. The percentage "satisfied" or "very satisfied" was high for every attribute (80% or higher, table) and similar between patients with different conditions. The percentage "satisfied" or "very satisfied" with symptoms control and normalization of QoL was greater in those receiving the first biologic (87.8% and 85.7%) and lower with the third or more (78.4% and 72.0%, both $p<0.05$). No differences were found for the rest of the attributes.

Treatment attributes. Importance and satisfaction reported by patients with rheumatic diseases

| Treatment attributes | Importance* | | | | | % satisfied or very satisfied |
|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | |
| Continuous symptom control | 35.2% | 20.1% | 19.2% | 14.4% | 11.1% | 85.7% |
| Well tolerated | 21.5% | 20.2% | 27.9% | 18.2% | 12.2% | 81.0% |
| Rapid action | 19.2% | 20.6% | 21.2% | 22.5% | 16.5% | 79.8% |
| Convenience /ease of administration | 19.1% | 12.6% | 14.9% | 19.1% | 34.4% | 86.5% |
| Normalisation of quality of life | 43.6% | 19.9% | 13.6% | 8.9% | 14.0% | 81.7% |

*1 = the most important; 5 = the least important. The sum of percentages is not 100% because some patients scored various attributes as importance "1".

**Conclusions:** Patients with rheumatic diseases treated with SC biological drugs give more importance to normalization of the quality of life and symptom control than to tolerability, speed of action and the comfort or easeness of use, and express a high degree of satisfaction with their current treatment, especially those receiving therapy with a first biologic.

## FRI0567 TRENDS IN ANNUAL CONSULTATION INCIDENCE OF CLINICAL OSTEOARTHRITIS BETWEEN 1992-2013 IN UK PRIMARY CARE: ANALYSIS OF THE CLINICAL PRACTICE RESEARCH DATALINK

D. Yu, G. Peat, J. Bedson, K. Jordan. *Research Institute for Primary Care & Health Sciences, Keele University, Newcastle Under Lyme, United Kingdom*

**Background:** Recent trends and future projections in the population burden of osteoarthritis and primary joint arthroplasty rates across Europe point to a growing challenge for population health and health services. However there are few studies on whether the rate of new cases presenting to primary care is also increasing, and no published national studies in the UK.

**Objectives:** To determine the temporal trend in annual consultation incidence of clinical OA in UK primary care between 1992–2013.

**Methods:** We used the Clinical Research Practice Datalink (CPRD), a nationally representative database of primary care electronic health records (650 practices, 5 million population) to estimate the annual consultation incidence of clinical OA. To allow for known variation in codes used in primary care for coding osteoarthritis we using established Read codelists to define a new case of clinical OA as a recorded diagnosis of OA or, in adults aged over 45 years, a recorded non-specific peripheral joint pain code likely to reflect OA. Incident cases of OA in each calendar year had a coded record of clinical OA during the year, and no such record in the previous 3 years. Additionally we excluded cases with a record of a systemic inflammatory disease, spondyloarthropathy, or crystal disease in the previous 3 years or following 1 year, or a record of another specific non-OA diagnosis (soft-tissue disorders, other bone/cartilage diseases) at the same joint in the six months period before or after the recorded OA consultation. Prevalent OA cases identified in the previous 3 years were excluded from the denominator for each year to establish the at-risk population. Incidence density based on exact person time was applied to estimate annual incidence. Annual incidence was estimated for each year between 1992–2013 for any OA and for joint-specific (knee, hip and hand) OA, overall (all ages) and stratified by gender and age). Overall and gender estimates were age-standardised to the population of England in 2013. Sensitivity analyses included restricting the analysis to practices continuously registered with CPRD between 1992 and 2013, and to diagnosed OA only.

**Results:** Annual consultation incidence of clinical OA decreased from 30.7 per 1000 person-years (95% CI: 30.7–30.8) in 1992 to 28.4 (28.4–28.5) in 1999, then increased to 41.2 (41.1–41.2) in 2009 before decreasing to 32.8 (32.8–32.9) in 2013. The corresponding estimates among females were 36.2 (1992), 33.8 (1999), 48.7 (2009) and 39.2 (2013); for males, 25.3 (1992), 23.2 (1999), 34.1 (2009), and 26.8 (2013). Similar temporal trends in annual incidence were observed within each age-stratum and for knee and hip. There was a different pattern for incidence of hand OA which continuously increased from 1.9/1000 in 1992 to 4.9 in 2013. Similar trends were seen when restricting analysis to practices continuously registered with CPRD. Incidence of diagnosed OA decreased steadily from 2004.

**Conclusions:** We found no evidence of a sustained increase in the age-standardised consultation incidence of clinical osteoarthritis in UK primary care over recent years, a finding that held across a range of case definitions and sensitivity analyses.

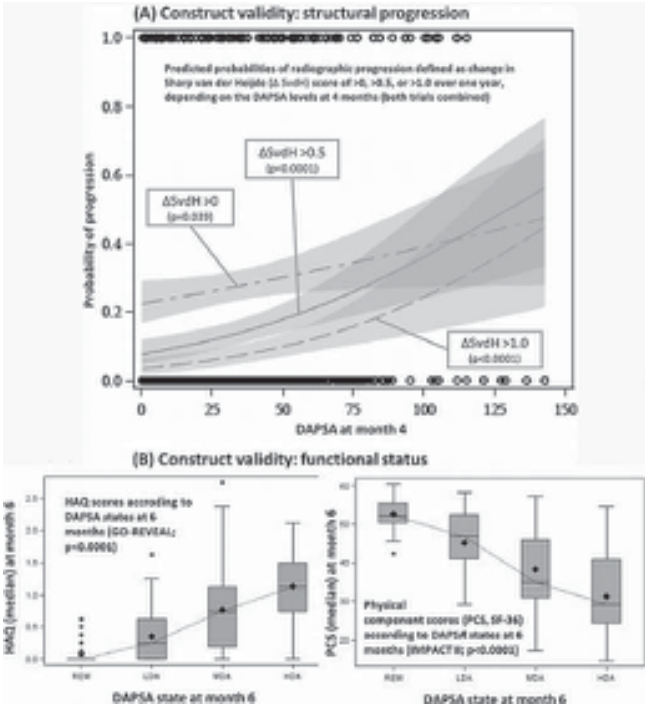
## FRI0568 DISEASE ACTIVITY STATES OF THE DAPSA, A PSORIATIC ARTHRITIS SPECIFIC INSTRUMENT, ARE VALID AGAINST THE CONSTRUCTS OF FUNCTIONAL STATUS AND STRUCTURAL PROGRESSION

D. Aletaha, F. Alasti, J.S. Smolen. *Division of Rheumatology, Medical University Vienna, Vienna, Austria*

**Background:** The Disease Activity index for PSoriatic Arthritis (DAPSA) was developed and validated. It is a composite measure of swollen and tender joint counts, patient global and pain assessment and an acute phase reactant. Recently, also DAPSA disease activity states were developed using clinical trial data and observational data (1). However, the validity of these states in regards to important outcomes of the disease has not yet been determined.



**Objectives:** To assess if different DAPSA disease activity states are associated with different degrees of functional impairment and/or different extents of joint damage progression in patients with psoriatic arthritis (PsA).

**Methods:** We used data from two pivotal trials of TNF-inhibitors in PsA, the IMPACT II (n=134) and the GO-REVEAL (n=313) trials. At 4 months, we identified patient in DAPSA remission (REM, ≤4), low disease activity (LDA, ≤14), moderate disease activity (MDA, ≤28), and high disease activity (HDA, >28). We then determined the rate of structural progression (defined as Sharp van der Heijde, SvdH, score increase of >0, >0.5, and >1 point from baseline to end of year 1) across these four disease activity groups. We also correlated DAPSA levels at 4 months with changes in SvdH change scores from baseline to year 1.

We also studied functional construct validity of the DAPSA states by assessing median scores of the Health Assessment Questionnaire Disability Index (HAQ; GO-REVEAL study only), and of the physical component scale of the Short Form-36 (PCS, SF-36; IMPACT II study only), across the different DAPSA states at 6 months.

**Results:** We identified 313 from GO-REVEAL and 134 from IMPACT II, with a mean (SD) baseline DAPSA of 44.7 (17.8) and 48.7 (26.3). The probability of progression according to different DAPSA scores is depicted in panel A of the Figure, separately for three cutpoints of progression. For all three analyses, the link between DAPSA and the probability of progression was significant

(progression >0: p=0.039; progression >0.5 and >1.0: p=0.0001 for both). This association was also seen when we compared patients in the four disease activity states at four months for their actual rate of progression, e.g., the proportion of patients with progression of >1 over one year was 3.7% among DAPSA remitters and 15.1% among patients with DAPSA HDA (p=0.0004).
We also confirmed functional construct validity by using HAQ scores in one trial (GO-REVEAL), and the SF-36 PCS in the other (IMPACT II). As can be seen in panel B of the Figure, the HAQ and PCS scores across the four groups were highly significantly different (p<0.0001 for both).

**Conclusions:** The definition of traditional disease activity states on the scale of the DAPSA, a PsA specific disease activity instrument, shows high validity against important constructs in PsA. This is important, and validates these DAPSA endpoints for future use in clinical trials, or as targets in clinical practice.

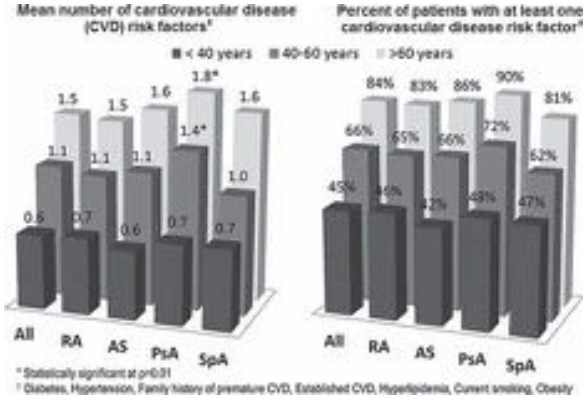
## FRI0569 REMISSION AND LOW DISEASE ACTIVITY MATRIX TOOL: RESULTS IN REAL-WORLD RHEUMATOID ARTHRITIS PATIENTS UNDER GOLIMUMAB



D. Rosa-Gonçalves, R. Fonseca, F. Aguiar, T. Martins-Rocha, M. Bernardes, L. Costa. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** Cost-effectiveness of treatments in rheumatoid arthritis (RA) is of growing importance thus, the ideal is to have a tool that help us to select patients most likely to respond to biotechnological drugs.
**Objectives:** To assess the relationship between predicted disease states and the observed amount of improvement applying the remission and low disease activity (LDA) matrix tool presented by MSD as a poster at EULAR 2015[1] to our patients receiving golimumab (GLM).
**Methods:** We identified RA patients who had done GLM as first biological therapy in our hospital. Demographic and clinical data at baseline and at 6 months were collected. The calculation of remission or LDA rates at 6 months of GLM treatment was made based on the proposed prediction matrix tool. Patients were divided into 2 groups by their predicted remission rate at 6 months: lowest chance if <30% and greatest if ≥30%. Thereafter, we compared the amount of improvement in DAS28-4v, tender joint count (TJC), HAQ and Patient Global Assessment of Disease Activity Visual Analog Scale (PGA-VAS) scores observed in each group during 6 months of treatment with GLM.
**Results:** At our hospital, 239 patients with RA are under biological therapy. Of these, 20 had GLM as the first biological agent. Most patients were females (n=16, 80%) and mean age (SD) at start of biological therapy was 50 (11.8) years. Most were non-smoking (n=15, 78.9%). Only 2 patients had rheumatoid factor and anti–citrullinated protein antibodies negative and mean disease duration was 9.5 (5.6) years. The mean of DAS28 4v was 5.71 (1.16). At 6 months we found that only one patient had inactive disease, the remaining showed moderate (n=12) or high (n=4) disease activity; 6 patients did not have EULAR response. When we applied the matrix tool, we found that in these cases only three and one case had less than 20% predicted rate of remission and LDA, respectively. We observe that patients with lowest chance of remission had greater improvement in DAS28-4v, TJC, HAQ, and PGA-VAS scores than those with highest chance, during 6 months of treatment: 1.80 vs 0.54, 8.13 vs 0.27, 0.44 vs 0.26 and 19.63 vs 15.91, respectively (p<0.05 only for DAS28-4v and TJC).
We found 9 cases (45%) of drug discontinuations at 6 months, 8 of which for primary failure and 1 for adverse event (at 1 month). Of the patients that remained under GLM at 6 months, 9 remained beyond 12 months of treatment, 4 of which have achieved remission.
**Conclusions:** The application of the remission and LDA matrix tool in our sample showed contradictory results with regard to the predictive ability of remission or LDA rate at 6 months. On the other hand, our results reinforce that EULAR response may be a more appropriate goal of treatment than LDA or remission in a subgroup of patients.

## FRI0570 PRESENCE OF CARDIOVASCULAR DISEASE RISK FACTORS ACROSS DIFFERENT INFLAMMATORY JOINT DISEASE ENTITIES: RESULTS FROM THE NOCAR PROJECT

G. Wibetoe[1], E. Ikdahl[1], S. Rollefstad[1], I.C. Olsen[1], F. Krøll[2], D.M. Soldal[3], T.K. Kvien[1], G. Haugeberg[4], A.G. Semb[1]. *[1]Dept. Rheumatology, Diakonhjemmet Hospital, Oslo; [2]Hospital for Rheumatic Diseases, Lillehammer; [3]Dept. Rheumatology, Hospital of Southern Norway, Kristiansand; [4]Dept. Rheumatology, Martina Hansens Hospital, Bærum, Norway*

**Background:** EULAR recommendations for cardiovascular disease (CVD) risk management in inflammatory joint diseases (IJD) advocate annual CVD risk assessment. Knowledge of the most prevalent CVD risk factors in the different IJD diagnoses may enable tailoring of efficient CVD preventive strategies for these high risk patients.
**Objectives:** 1) Evaluate prevalence of CVD risk factors in IJD patients and estimate 10-year risk for fatal CVD using the Systemic COronary Risk Evaluation (SCORE). 2) Investigate possible differences in CVD risk factor distribution across IJD entities.
**Methods:** In the nationwide NOrwegian Collaboration on Atherosclerosis in patients with Rheumatic joint diseases (NOCAR) project, annual CVD risk assessment is implemented in clinical practice of 11 rheumatology centres. IJD patients ≥30 years of age are eligible for inclusion. CVD risk factors and established CVD are recorded. The estimated CVD risk by SCORE was compared across IJD diagnoses for males and females individually, using analysis of variance, stratified by decennial age. Number of CVD risk factors, determined by presence of diabetes, hypertension, family history of premature CVD, hyperlipidemia (total cholesterol >8 mmol/L and/or low-density lipoprotein cholesterol >6 mmol/L), current smoking or obesity (body mass index ≥30kg/m$^2$), was counted for each patient. Frequency of CVD risk factors for the whole cohort was estimated and compared across the four major entities, using age and sex adjusted logistic regression analyses.
**Results:** Of the 2647 patients included in the 3 initial centres (Rheumatoid arthritis [RA]: n=1696, ankylosing spondylitis [AS]: n=445, psoriatic arthritis [PsA]: n=376, other spondyloarthritides [SpA]: n=130), 58.0% were females and the median (inter-quartile range [IQR]) age and disease duration were 57.4 (46.8–66.8) and 8.0 (3.8–15.9) years, respectively. The median (IQR) SCORE estimate was 1.4% (0.4–2.9) for the total population. The calculated CVD risk by SCORE was comparable across diagnoses, apart from male AS patients with a lower estimated CVD risk (p=0.01). Prevalence of CVD risk factors were comparable across all the IJD diagnoses, except for PsA patients who had significantly more CVD risk factors in the two oldest age groups (p=0.01). The percentage of patients

with at least one CVD risk factor and the mean number of risk factors for each patient are presented in the Figure. In detail, CVD risk factor rates were: family history of premature CVD: 17.5%, established CVD: 9.8%, current smoking: 19.6%, hypertension: 53.2%, obesity: 17.9%, diabetes: 6.7% and hyperlipidemia: 1.3%. PsA patients were more obese (p=0.001), more often hyperlipidemics ($p<0.05$), had more diabetes ($p<0.001$) and hypertension ($p<0.0001$), and were less frequently smokers (p=0.04). RA patients were more often smokers (p=0.02) and hypertensive (p=0.01).

**Conclusions:** In a large, multicentre cohort of IJD patients, a high prevalence of CVD risk factors was revealed, also in young patients. Interestingly, the risk factor burden was comparable in the 3 age categories across all IJD. Hence, CVD risk factor recording is essential in all IJD, and especially for PsA patients who had the largest CVD risk factor burden compared to the other IJD diagnoses.

## FRI0571 THE ASSOCIATION BETWEEN COMORBIDITIES AND DISEASE ACTIVITY, FUNCTIONAL ABILITY AND QUALITY OF LIFE IN PATIENTS WITH SPONDYLOARTHRITIS: RESULTS FROM THE MULTI-NATIONAL ASAS-COMOSPA STUDY

E. Nikiphorou[1], S. Ramiro[2], R. Landewé[3], A. Molto[4], M. Dougados[4], F. Van den Bosch[5], D. van der Heijde[2]. *[1]Whittington Hospital, London, United Kingdom; [2]LUMC, Leiden; [3]ARC, Amsterdam, Netherlands; [4]Paris Descartes University, Paris, France; [5]Ghent University Hospital, Ghent, Belgium*

**Background:** Comorbidities in rheumatoid arthritis are known to add to the burden of disease and its complexity, with implications on disease outcomes and prognosis. In Spondyloarthritis (SpA), the impact of comorbidities on outcomes is less well studied; yet, their prevalence is high.

**Objectives:** To investigate the relationship between the comorbidity burden in SpA as measured by the Rheumatic Disease Comorbidity Index (RDCI) and: (1) disease activity; (2) function; (3) quality of life.

**Methods:** Analysis was based on data from the ASAS COMOrbidities SPA study, ASAS-COMOSPA, a cross-sectional, multinational study involving 22 countries across four continents. Patients fulfilling the ASAS SPA criteria were included. Comorbidities were computed according to the Rheumatic Diseases Comorbidity Index (RDCI), which includes ischaemic heart disease, stroke, hypertension, lung disease (COPD), malignancy, fractures, depression, diabetes and gastrointestinal disease; range 0–9 (higher score indicating higher comorbidity burden). Univariable, followed by multivariable multilevel mixed-effects linear regression models were used to investigate the relationship between the RDCI and ASDAS(CRP), BASDAI, patient global, BASFI, and EQ5D, adjusting for clinical confounders (table). Patients were nested into their country of origin, which formed the basis of the multilevel analysis.

**Results:** A total of 3558 patients were included in the study; 66% males, mean age 43 (SD 14), median disease duration 5 years (IQR 11) and mean RDCI 0.72 (1.08). An increase in RDCI was associated with higher BASFI, BASDAI, ASDAS and patient global score and lower EQ5D (all $p<0.001$) (see table). For instance a patient with an RDCI score of 2 compared to 0 had on average 0.7 point higher on the BASFI, one point higher on the BASDAI and patient global, 0.24 units higher on the ASDAS and a 0.06 points lower on the EQ-5D.

Table 1. Relationship between comorbidities and disease outcomes

| OUTCOME | RDCI (β [95% CI]) |
|---|---|
| BASFI[$] | 0.34 [0.27–0.40] |
| BASDAI[£] | 0.53 [0.45–0.61] |
| ASDAS^ | 0.12 [0.09–0.16] |
| Patient's Global Assessment of Disease Activity^ | 0.45 [0.36–0.53] |
| EQ5D** | –0.03 [–0.04 to –0.02] |

*All models adjusted for age; gender; the presence of axial vs peripheral disease. [$]Model also adjusted for disease duration; level of education; BMI; smoking status; ASDAS. [£]Model also adjusted for level of education; BMI; CRP. ^ Model also adjusted for level of education; BMI. **Model also adjusted for BASFI, ASDAS.

**Conclusions:** Higher comorbidity burden is independently associated with worse outcomes in SpA as reflected by higher disease activity, worse functional and quality of life measures. The results highlight the need for promptly identifying and treating comorbidities in SpA. As with emerging evidence in RA suggesting failure to achieve treat-to-target principles in the presence of comorbidities, it is possible that comorbidities also hinder the achievement of therapeutic goals in SpA.

## FRI0572 SOCIAL AND EMOTIONAL IMPACT OF RHEUMATIC DISEASES IN PATIENTS TREATED WITH SUBCUTANEOUS BIOLOGICAL THERAPY. RHEU LIFE SURVEY

E. Batlle[1], C.M. González[2], L. Carmona[3], A.I. Torralba Gómez-Portillo[4], L. Cea-Calvo[5], M.J. Arteaga[5], F.J. de Toro[6]. *[1]Departamento de Salud Sant Joan, Alicante; [2]HGU Gregorio Marañón; [3]I. de Salud Musculoesquelética, InMusc; [4]ConArtritis (Arthritis National Coordinator Association); [5]Medical Affairs, Merk Sharp & Dohme, Madrid; [6]Instituto de Investigación Biomédica de A Coruña, la Coruña, Spain*

**Background:** Rheumatic diseases impair patients' everyday life but this is rarely assessed in clinical studies.

**Objectives:** To describe the social and emotional impact perceived, as a consequence of the disease, by patients with rheumatoid arthritis (RA), axial spondyloarthritis (SpA) and psoriatic arthritis (PsA) treated with biological drugs.

**Methods:** RHEU-LIFE was a survey to patients with RA, axial SpA and PsA from Spain. Rheumatologists from 50 outpatient hospital clinics handed the survey to 20 consecutive patients >18 years-old who attended the clinic, they completed the survey at home and returned by pre-paid post mail. Patients were surveyed on the perceived impact of their rheumatic disease on five areas: 1) quality of life in general; 2) emotional state; 3) work or daily activity; 4) personal relations and 5) life of their families, responding with the options "no impact", "some", "moderate" or "severe".

**Results:** The survey was given to 1000 patients; 592 responded (response rate 59.2%, mean age 51.7 years [SD 13.2], 42.4% men and 57.6% women). Patients' disease were RA (n=304, 54.2%), axial SpA (n=141, 25.1%) and PsA (n=116, 20.7%). 31 patients did not identify their disease. The percentage of patients who considered that the disease moderately or severely affected the different areas is shown in the table. A higher percentage of women vs men declared that the disease moderately or greatly affected all the areas (table). Similarly, aged patients described a greater impact than those who were younger (table). No differences were observed with regard to the disease, with similar percentages of patients with RA, axial SpA or PSA declaring "moderate" or "severe" impact in all areas (all, $p>0.1$).

Percentage of patients who declared that the impact of the disease is "moderate" or "severe" effect in the different areas

| | All | Gender | | | Age | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | Men | Women | p | <43 | 43–52 | 53–61 | >61 | p |
| Quality of life | 52.1% | 45.3% | 56.7% | 0.007 | 34.1% | 51.1% | 60.5% | 58.5% | <0.001 |
| Emotional | 41.0% | 36.2% | 44.6% | 0.004 | 30.4% | 44.6% | 45.4% | 39.7% | 0.018 |
| Work or daily activity | 49.2% | 40.5% | 55.9% | <0.001 | 33.3% | 47.5% | 59.8% | 55.0% | <0.001 |
| Personal relations | 26.0% | 19.6% | 30.4% | 0.014 | 15.6% | 28.3% | 30.8% | 27.5% | 0.017 |
| Life of family | 32.3% | 25.5% | 37.7% | 0.001 | 17.0% | 34.5% | 40.0% | 36.2% | 0.003 |

**Conclusions:** Patients with RA, axial SpA and PsA treated with biological drugs describe a significant impact in their quality of life, work or daily activity, emotional state, personal relations and life of their families, especially women and elderly patients. The impact was ranked similarly regarding the baseline disease.

**Acknowledgement:** This survey was financed by Merck Sharp & Dohme of Spain and endorsed by the patients' association ConArtritis (Arthritis National Coordinator).

**Disclosure of Interest:** None declared

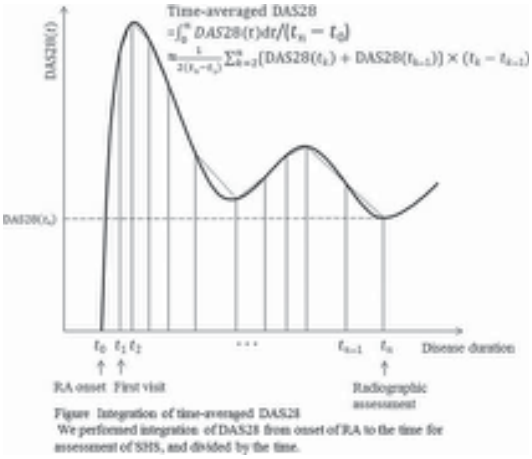
## FRI0573 INTEGRATION OF TIME-AVERAGED DAS28 FITS BETTER JOINT DESTRUCTION IN RHEUMATOID ARTHRITIS THAN ONE-TIME DAS28 AND IDENTIFIES A SIGNIFICANT JOINT-DESTRUCTIVE ASSOCIATION OF HLA-DRB1*04:05 WHICH IS INDEPENDENT OF ACPA AND DAS28

H. Tsuji[1], C. Terao[2], K. Yano[3], K. Ikari[3], M. Hashimoto[4], M. Furu[4], H. Ito[5], T. Fujii[4], W. Yamamoto[6], N. Yamakawa[7], K. Ohmura[1], A. Taniguchi[3], S. Momohara[3], H. Yamanaka[3], F. Matsuda[2], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology; [2]Department of Center for Genomic Medicine, Kyoto University Graduate School of Medicine, Kyoto; [3]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo; [4]Department of the Control for Rheumatic Diseases; [5]Department of Orthopedic Surgery, Kyoto University Graduate School of Medicine, Kyoto; [6]Department of Health Information Management, Kurashiki Sweet Hospital, Kurashiki; [7]Department of Immunology and Rheumatology, Katsura Hospital, Kyoto, Japan*

**Background:** Disease Activity Score 28 (DAS28) is one of correlates of joint destruction in rheumatoid arthritis (RA) as well as genetic components, RA-related autoantibodies, and disease duration. Joint destruction is considered to reflect the cumulative history of the disease activities, but one-time DAS28 is used in many studies. Relationship among the correlates is still unclear, while we previously showed that HLA-DRB1*04:05 is associated with joint destruction independently of anti-citrullinated protein antibody (ACPA).

**Objectives:** We hypothesized the superiority of time-averaged DAS28 to one-time DAS28 to fit the model to assess joint destruction. We also hypothesized that DRB1*04:05 might be associated with joint destruction independently of ACPA and DAS28.

**Methods:** We recruited RA patients in the KURAMA (n=204) and IORRA cohort (n=557) whose data of modified Sharp/van der Heijde score (SHS), consecutive DAS28, and other correlates of SHS were available. We calculated time-averaged DAS28 and modeled SHS using time-averaged DAS28 and the other covariates. We randomly picked up DAS28 in each patient and constructed 1000 sets of DAS28 to model SHS. We empirically evaluated fitting of the model using time-averaged DAS28 among the 1000 models using one-time DAS28. Next, we analyzed an association between DRB1*04:05 and SHS of ACPA (+) patients in KURAMA (n=100) and IORRA (n=472).
**Results:** In conditioned for the autoantibodies and disease duration, the time-averaged DAS28 showed significant improvement of model fitting in comparison with one-time DAS28 ($R^2$ in KURAMA: p=0.037, $R^2$ in IORRA: p=0.001). Generalized linear regression model in ACPA (+) patients showed a significant association between DRB1*04:05 and SHS (overall p=0.0002) in conditioned for time-averaged DAS28 and the other covariates. We observed this significant association even in patients whose time-averaged DAS28 was in low disease activity or remission.



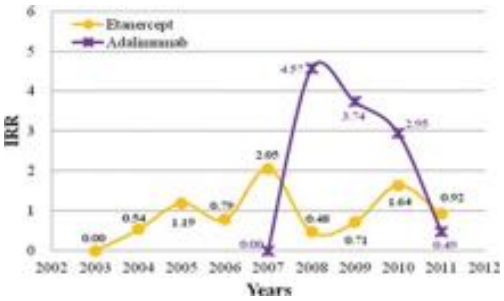


Figure Integration of time-averaged DAS28
We performed integration of DAS28 from onset of RA to the time for assessment of SHS, and divided by the time.

**Conclusions:** Time-averaged DAS28 fits SHS better than one-time DAS28 and usage of time-averaged DAS28 as a covariate would increase the power of studies to identify novel correlates of SHS. DRB1*04:05 demonstrates an association with joint destruction which is independent of ACPA and even DAS28 by using time-averaged DAS28, suggesting necessity of strong treatment for RA patients carrying DRB1*04:05 even when they are in low disease activity or remission.

## FRI0574 ONE-YEAR TUBERCULOSIS RISK IN RHEUMATOID ARTHRITIS PATIENTS INITIATING TUMOR NECROSIS FACTOR-α INHIBITOR FROM 2003 TO 2011 IN TAIWAN: A NATIONWIDE POPULATION-BASED COHORT STUDY

H.-H. Chen[1], Y.-M. Chen[1], K.-L. Lai[2], C.-H. Lin[1], D.-Y. Chen[3], C.-H. Lim[4], C.-J. Tsai[5]. *[1]Department of Medical Research; [2]Division of Allergy, Immunology and Rheumatology; [3]Department of Medical Education, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China; [4]Rheumatology Unit, Department of Internal Medicine, Pulau Pinang General Hospital, Georgetown, Malaysia; [5]Medical Division, AbbVie Biopharmaceuticals GmbH Taiwan Branch, Taipei, Taiwan, Province of China*

**Background:** Use of tumor necrosis factor-α inhibitor (TNFi), especially monoclonal antibody, may increase the risk of tuberculosis (TB) infection in patients with rheumatoid arthritis (RA). The emergence of active TB in RA patients receiving TNF-α inhibitor showed a biphasic pattern. The strategy of latent TB infection (LTBI) screening and treatment theoretically may reduce TB reactivation, which mainly contributes to the first phase of TB emergence. In Taiwan, etanercept and adalimumab were approved for RA treatment in 2003 and 2007 respectively.
**Objectives:** To examine the 1-year risk of TB infection in RA patients initiating TNFi therapies as compared to RA patients not treated with TNFi in Taiwan stratified by treatment initiation year (2003 to 2011).
**Methods:** Data was collected retrospectively using the 2003–2012 claim data from the Taiwanese National Health Insurance Research Database. We enrolled all treated RA patients initiating TNFi therapy as the study cohort, and those who never received TNFi therapy as the comparison cohort from 1st January 2003 to 31st December 2011. All patients were followed up for one year after starting treatment. The diagnosis of TB was identified using ICD-9-CM and the prescription of at least 2 anti-TB drugs within 6 months of TB diagnosis made. The 1-year TB risk of TNFi users compared with non-TNFi users was shown as incident rate rations (IRR) with 95% confidence intervals (CI) and adjusted hazard ratios (aHRs) using Cox's regression analysis after adjustment of potential confounders including age, sex, disease duration, TB history, comorbidities and concomitant medications, further stratified by the year of treatment initiation.
**Results:** A total of 46,668 RA patients were included; 40,678 (87.2%) in non-TNFi and 5,990 (12.8%) in TNFi group. A total of 163 1-year TB events were reported; 136 in non-TNFi group and 27 in TNFi group with 1-year TB incidence rate of 369 and 504 per 100,000 patient-years respectively. The 1-year TB risk was higher in TNFi users compared with non-TNFi users (IRR, 1.37; 95% CI, 0.71–2.07; aHR, 7.27; 95% CI, 3.65- 14.48). As shown in Figure 1, the IRR of TB within one year in adalimumab users compared with non-TNFi users peaked in 2008 (IRR, 4.57) and was lowest in the 2011 group (IRR, 0.49). Other significant risk factors of 1-year TB infection included age≥65 years (aHR, 1.52, 95% CI, 1.09–2.10), male (aHR, 1.81, 95% CI, 1.31–2.51) and prior TB infection (aHR, 29.28; 95% CI, 18.62–46.05).

**Conclusions:** The 1-year risk of TB in RA patients initiating TNFi was significantly higher than non-TNFi users. During 2008–2011, the 1-year TB IRR in adalimumab users compared with non-TNFi users dropped from 4.57 to 0.49, which might be explained by increasing physician/patient awareness with LTBI screening and treatment.

## FRI0575 THE UNMET NEED IN THE NORWEGIAN DISEASE-MODIFYING ANTIRHEUMATIC DRUG REGISTRY

I.C. Olsen[1], T.K. Kvien[1], E. Lie[1], R. Vasilescu[2], G. Wallenstein[3], S. Strengholt[4]. *[1]Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [2]Pfizer Inc, Brussels, Belgium; [3]Pfizer Inc, Groton, United States; [4]Pfizer Inc, Capelle aan den IJssel, Netherlands*

**Background:** Until 2012, the Norwegian disease-modifying antirheumatic drug (NOR-DMARD) registry included patients (pts) initiating treatment (trt) with conventional synthetic DMARDs (csDMARDs) and biologic DMARDs (bDMARDs). The revised NOR-DMARD protocol, implemented 2012–2013, includes bDMARDs only.
**Objectives:** Describe the outcomes of methotrexate (MTX) therapy and define the unmet need for further trt options for RA pts after MTX failure in the NOR-DMARD registry.
**Methods:** These analyses are based on data from two phases (P) of the NOR-DMARD registry: P1 – pts on csDMARDs and bDMARDs (2007–2011); P2 – pts on bDMARDs only (2012–2015). Using different selection criteria from P1 pts, MTX trt outcomes were assessed as follows: % of pts with inadequate response (IR) to MTX (defined as disease activity score 28–4 erythrocyte sedimentation rate [DAS28]>3.2 at 6 months [mo]); reasons for MTX discontinuation (D/C); % of MTX-IR pts remaining on trt despite DAS28>3.2 or DAS28>5.1. ACR20/50/70 and EULAR good/moderate response rates were assessed using P1 and P2 data in pts receiving bDMARDs as monotherapy (mono), +MTX or +other csDMARDs. Results are presented using descriptive statistics from non-imputed observations.
**Results:** P1 and P2 included a total of 2698 and 709 RA trt courses, respectively. Of 780 MTX-naïve pts starting MTX mono in P1, 429 (42.9%) had DAS28>3.2 at 6 mo; 381 of the 780 pts had available DAS28 data at Mo 12, and 30.9% pts had DAS28>3.2 at 12 mo. Furthermore, 58.2% of pts who had DAS28>3.2 at 6 mo remained at DAS28>3.2 at 12 mo. 1364 pts were treated with any csDMARDs in P1, 28/1364 pts had DAS28>5.1 for two consecutive visits and remained on trt.
In P1 pts previously exposed to MTX starting any trt other than MTX mono (N=1388), 1005 pts had a reason for MTX D/C listed; 489/1005 (48.7%) pts D/C due to side effects.
P1 included 1331 bDMARD trt courses: 279 (21.0%) as mono, 938 (70.5%) +MTX and 114 (8.6%) +other csDMARD. In P2 there were 709 trt courses with

bDMARDs: 229 (32.3%) as mono, 413 (58.3%) +MTX and 67 (9.3%) +other csDMARD. In P1, bDMARD mono pts had slightly higher baseline disease activity and slightly worse patient-reported outcomes. In P2, baseline demographics and characteristics were generally similar across trt groups (gps). EULAR and ACR responses at Mo 6 were generally comparable across trt gps in P1, although the bDMARD+other csDMARD gp had numerically higher ACR70 and lower EULAR good responses vs other gps. In P2, ACR20 and ACR50 responses were generally similar between bDMARD trt gps at Mo 6. At Mo 6, numerically more pts on bDMARD mono (18.4%) achieved ACR70 vs bDMARD+MTX (10.7%) and bDMARD+other csDMARD (5.9%); similar results were also observed for EULAR good/moderate responses. % of pts with DAS28 remission at Mo 6 were 54.4% for bDMARD mono; 45.7% for bDMARD+MTX; and 50.0% for bDMARD+other csDMARD (Table).

Efficacy endpoints at Month 6 in Phase 1 and Phase 2 populations for patients with RA treated with bDMARDs

| | bDMARD monotherapy | bDMARD + MTX | bDMARD + other csDMARD | All |
|---|---|---|---|---|
| *Phase 1 data (2007–2011)* | | | | |
| ACR70, n/N (%) | 20/160 (12.5) | 91/610 (14.8) | 11/64 (17.2) | 122/846 (14.4) |
| EULAR good/moderate, n/N (%) | 80/122 (65.6) | 331/487 (68.0) | 31/48 (64.6) | 442/657 (67.3) |
| EULAR good, n/N (%) | 57/122 (46.7) | 164/487 (33.7) | 11/48 (22.9) | 232/657 (35.3) |
| *Phase 2 data (2012–2013)* | | | | |
| ACR70, n/N (%) | 9/49 (18.4) | 27/253 (10.7) | 1/17 (5.9) | 37/319 (11.6) |
| EULAR good/moderate, n/N (%) | 34/44 (77.3) | 140/218 (64.2) | 8/11 (72.7) | 182/273 (66.7) |
| EULAR good, n/N (%) | 22/44 (50.0) | 89/218 (40.8) | 6/11 (54.6) | 117/273 (42.9) |
| Change in DAS28-4(ESR), mean (SD), [n] | -2.0 (1.7) [44] | -1.2 (1.4) [198] | -1.6 (1.2) [11] | -1.3 (1.5) [253] |
| DAS28-4(ESR) categories, n (%) | | | | |
| In remission (<2.6) | 25 (56.8) | 111 (45.7) | 7 (58.8) | 143 (47.2) |
| LDA (≥2.6 to ≤3.2) | 5 (10.9) | 42 (17.3) | 4 (28.6) | 51 (16.8) |
| MDA (>3.2 to ≤5.1) | 13 (28.3) | 74 (30.5) | 2 (14.3) | 89 (29.4) |
| HDA (>5.1) | 3 (6.5) | 16 (6.6) | 1 (7.1) | 20 (6.6) |
| Sustained remission: in remission at both Month 3 and Month 6 | 12/51 | 53/220 | 4/20 | 73/291 |

bDMARD, biologic disease-modifying antirheumatic drug; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DAS, disease activity score; ESR, erythrocyte sedimentation rate; EULAR, European League Against Rheumatism; HDA, high disease activity; LDA, low disease activity; MDA, moderate disease activity; MTX, methotrexate; SD, standard deviation

**Conclusions:** Data from the NOR-DMARD registry showed that >40% of MTX-treated pts had not achieved DAS28 low disease activity 6 mo. Despite pts advancement to bDMARDs, almost 50% failed to reach DAS28 remission at follow-up. This demonstrates substantial unmet medical need for pts with moderate to severe RA. Trt grp comparisons will be further explored.

## FRI0576 ECONOMIC IMPACT OF LOWER-LIMB OSTEOARTHRITIS WORLDWIDE: A SYSTEMATIC REVIEW OF COST-OF-ILLNESS STUDIES

J.H. Salmon[1], A.C. Rat[2], J. Sellam[3], M. Michel[1], J.P. Eschard[1], F. Guillemin[4], D. Jolly[5], B. Fautrel[6]. *[1]Rheumatology, Hôpital Maison Blanche, CHU Reims, Reims cedex; [2]Rheumatology, CHU de Nancy, Hôpitaux de Brabois, Vandoeuvre-lès-Nancy; [3]Rheumatology, Saint-Antoine Hospital, Assistance Publique - Hôpitaux de Paris (AP-HP), Paris; [4]Apemac, EA4360, Université de Lorraine, Université Paris Descartes, Nancy; [5]Department of Research and Innovation, Hôpital Robert Debré, CHU Reims, Reims; [6]Rheumatology, Pitié-Salpêtrière Hospital, Assistante Publique - Hôpitaux de Paris (AP-HP), Paris, France*

**Background:** Lower limb osteoarthritis (OA) is an expanding public health problem owing to the aging of the population and increase in obesity prevalence. Knowledge of the economic burden is limited.

**Objectives:** An overview of the economic consequences – overall costs as well as cost breakdown (direct and indirect) – of hip and knee osteoarthritis (OA) worldwide.

**Methods:** A systematic literature search of EMBASE, MEDLINE, Scopus and Cochrane databases for articles was performed independently by 2 rheumatologists who used the same predefined eligible criteria. Papers without abstracts and in languages other than English or French were excluded. Extracted costs were converted to an annual cost and to 2013 euros (€) by using the Consumer Price Index of the relevant countries and the 2013 Purchasing Power Parities between these countries and the European Union average.

**Results:** A total of 45 abstracts were selected, and 32 articles were considered for the review. The studiedpopulations were heterogeneous: administrative, hospital and national health survey data. Annual total costs per patient ranged from 0.7 to 12 k€, direct costs per patient from 0.5 to 10.9 k€ and indirect costs per patient from 0.2 to 12.3 k€. The weighted average annual costs per patient living with knee and hip OA were 11.1, 9.5 and 4.4 k€ for total, direct and indirect costs, respectively.

**Conclusions:** This review highlights the heterogeneity of studies and lack of methodologic consensus to obtain reliable cost-of-illness estimates for lower-limb OA. However, costs induced by the disease seem substantial and deserve to be more extensively explored.

**Disclosure of Interest:** None declared

## FRI0577 A NATIONAL ELECTRONIC HEALTH RECORD-ENABLED REGISTRY IN RHEUMATOLOGY: THE ACR'S RHEUMATOLOGY INFORMATICS SYSTEM FOR EFFECTIVENESS (RISE)

J. Yazdany[1], S. Kazi[2] on behalf of Research & Publications Subcomittee. *[1]Medicine/Rheumatology, University of California, San Francisco, San Francisco; [2]UT Southwestern, Dallas, United States*

**Background:** In 2014, the ACR launched the Rheumatology Informatics System for Effectiveness (RISE), a national electronic health record (EHR)-enabled registry. RISE passively collects data from EHRs of participating practices, provides advanced quality measurement and data analytic capacities, and can be used to fulfill national quality reporting requirements. Here we detail the characteristics of practices participating in RISE, patient characteristics and performance on several nationally endorsed quality measures.

**Methods:** RISE is a national Qualified Clinical Data Registry (QCDR), allowing collection of data on quality of care without individual patient informed consent.

| Characteristic | Total N (N = 239,302) |
|---|---|
| Age at last encounter, mean (SD) | 59 (± 16.1) |
| Sex | |
| Female, n (%) | 179,069 (74.8) |
| Male, n (%) | 60,225 (25.2) |
| Missing, n (%) | 8 (0.003) |
| Race, n (%) | |
| White | 145,944 (60.9) |
| Black | 18,339 (7.7) |
| Asian | 3,408 (1.4) |
| American Indian/Alaskan Native | 974 (0.2) |
| Native Hawaiian/Pacific Islander | 116 (0.05) |
| Other | 23,901 (10.0) |
| Missing | 40,573 (17.0) |
| Insurance/Payer type (at last encounter), n (%) | |
| Medicare | 70,804 (29.6) |
| Medicaid | 3,914 (1.6) |
| Commercial | 114,269 (47.8) |
| Other | 4,220 (1.8) |
| Missing | 46,115 (19.3) |
| U.S. Region, n (%) | |
| Midwest | 29,114 (12.2) |
| Northeast | 32,085 (13.4) |
| Southeast | 91,727 (38.3) |
| Southwest | 50,239 (21.0) |
| West | 11,022 (4.6) |
| Missing | 25,064 (10.5) |
| Selected Diagnoses (ICD9 code at last encounter), n (%) | |
| Rheumatoid arthritis (ICD 9 714.0, 714.1, 714.2, 714.3x | 60,364 (25.2) |
| Sjogren's syndrome (710.2) | 15,800 (6.6) |
| Systemic lupus erythematous (ICD9 710.0) | 13,940 (5.8) |
| Psoriatic arthritis (696.0) | 13,550 (5.7) |
| Gout (ICD9 274.xx) | 9,887 (4.1) |
| Spondyloarthropathy (ICD9 720.xx) | 8,890 (3.7) |
| Systemic sclerosis (ICD9 710.1) | 2,754 (1.2) |
| Vasculitis (ICD9 446.0, 446.1, 446.2x, 446.4, 446.5) | 2,845 (1.1) |
| Dermatomyositis or polymyositis (710.3, 710.4) | 2,366 (1.0) |
| Sarcoidosis (ICD9 135) | 1,548 (0.6) |
| Smoking, n (%) (last encounter) | |
| Never | 142,962 (59.6) |
| Current | 24,913 (10.4) |
| Former | 47,879 (20.0) |
| Missing | 23,548 (10.5) |
| Blood pressure, mmHg, mean (SD) (last encounter) | |
| Systolic | 125.4 (±16.5) |
| Diastolic | 78.2 (±9.7) |
| Diastolic>90 OR Systolic>140, n (%) | 34,961 (14.6) |

Participating practices enter a Data Use Agreement with the ACR, after which local data are mapped, validated and uploaded regularly to the central registry. Practices can access an analytics dashboard that allows review of up-to-date information on quality measures by provider and practice as well as national benchmarks. RISE currently includes data on numerous quality measures regarding rheumatoid arthritis (RA), drug safety, osteoporosis prevention and treatment, low back pain, and preventive health care (e.g. smoking, blood pressure management). We analyzed data between October 1, 2014 and September 30, 2015 to characterize practices and patients captured in RISE. We also calculated performance on several RA quality measures endorsed by the National Quality Forum (DMARD use, disease activity measurement, functional status measurement).

**Results:** During the dates examined, RISE included data on 239,302 patients, including 60,354 with RA (Table). Three hundred twelve clinicians across 55 sites contributed data to RISE. Characteristics of patients in RISE are summarized in the Table. For the subset of patients with RA, 50.7% of patients had a disease activity score recorded, 53.2% had a functional status score recorded, and 82.1% were taking a DMARD, as defined by national quality measures. For DMARDs, 34.4% of patients with RA were on brand name biologic or small molecule drug at their last encounter, and 67.0% were receiving a non-biologic DMARD.

**Conclusions:** The ACR's national EHR-enabled registry will provide critical infrastructure for improving quality of care in rheumatology and will serve as a unique data source to generate new knowledge regarding rheumatic disease. Data validation and mapping is ongoing and RISE will be available to both the research and clinical community to use to advance rheumatology.

## FRI0578 PATIENT AND CLINICIAN REPORTED OUTCOMES FOR PATIENTS WITH NEW PRESENTATION OF INFLAMMATORY ARTHRITIS: OBSERVATIONS FROM THE UK NATIONAL CLINICAL AUDIT

J. Ledingham[1], N. Snowden[2], J. Galloway[3], A. Rivett[4], J. Firth[2], E. Macphie[5], N. Kandala[6], I. Rowe[4], Z. Ide[4], E. Dennison[7] on behalf of BSR National Audit Project Working Group. *[1]Portsmouth Hospitals NHS Trust, Portsmouth; [2]Pennine MSK Partnership, Oldham; [3]King's College London; [4]British Society for Rheumatology, London; [5]Lancashire Care NHS Foundation Trust, Preston; [6]University of Portsmouth, Portsmouth; [7]Southampton University, Southampton, United Kingdom*

**Background:** Early inflammatory arthritis (EIA) services have undergone substantial reconfiguration in recent years with the recognition of a window of opportunity early on in the disease course as well as the introduction of treat-to-target disease modifying anti-rheumatic drug strategies. As part of a national UK audit into the management of EIA data were collected on patients presenting with inflammatory arthritis for the first 3 months of specialist care.

**Objectives:** Here we report the response to treatment at a national level in terms of clinical outcomes.

**Methods:** All individuals >16 years presenting to specialist rheumatology services in England & Wales with suspected new onset IA were recruited. Clinician & patient derived assessments of outcome were collected with consent at baseline and after 3 months of specialist care. Data collected included the Disease Activity Score (DAS28), the Rheumatoid Arthritis Impact of Disease (RAID) questionnaire (a validated patient reported outcome measure assessing pain; functional capacity; fatigue; physical/ emotional wellbeing; quality of sleep and coping) and impact upon work status.

**Results:** 97% of hospital trusts in England and Wales participated. 6,354 patients with suspected early inflammatory arthritis were recruited between 1st February 2014 to 31st January 2015. Of these 2896 were diagnosed with RA (defined by the presence of polyarticular disease (>5 joints involved) or pauciarticular disease with positive cyclic citrullinated peptide antibody); this represented >40% of estimated expected incident RA cases. At first specialist assessment DAS28 was reported for 91% of RA patients: mean DAS28 was 5.0 (44% of patients a DAS28>5.1 indicating severe disease). The mean RAID score was 5.6 (range 0 not affected to 10 (most affected).

After 3 months of specialist care mean DAS28 reduced to 3.5 with 62% achieving a meaningful reduction in DAS28 of >1.2 units. 24% of patients achieved DAS remission. The mean RAID score after 3 months was 3.6; the mean reduction in RAID score was 2.6 and did not meet the minimum clinically important level of 3. Of the working patients aged 16–65 years providing data 7%, 5%, 16% and 37% reported that they were unable to work, needed frequent time off work, occasionally and rarely needed time off work due to their arthritis respectively. 19% reported never being asked about their work by clinicians.

**Conclusions:** Although there are data that suggest the severity of RA has diminished in recent years, this audit confirms that at presentation RA remains a disease with significant patient burden. Acknowledging that this audit only captures the first 3 months of care, the results demonstrate important achievements in RA care in contrast to what might have been expected for RA in previous decades. However, less than a quarter of patients achieved remission and improvements in RAID scores were below the accepted minimum clinically important difference within the first 3 months.

**Disclosure of Interest:** None declared

## FRI0579 WHAT IS THE VARIABILITY OF HAQ OVER TIME IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ANTI-TNF?

R. Arendse[1], B. Haraoui[2], D. Choquette[2], J. Kelsall[3], P. Baer[4], D. Sholter[5], W.G. Bensen[6], M.J. Bell[7], M. Teo[8], E. Rampakakis[9], E. Psaradellis[9], B. Osborne[10], C. Tkaczyk[10], K. Maslova[10], F. Nantel[10], A.J. Lehman[10]. *[1]University of Saskatchewan, Saskatoon; [2]Institut de Rhumatologie de Montréal and University of Montreal, Montreal; [3]St. Paul's Hospital, Vancouver; [4]Ontario Medical Association, Scarborough; [5]University of Alberta, Edmonton; [6]St Joseph's Healthcare, Hamilton; [7]Sunnybrook Health Sciences Centre/University of Toronto, Toronto; [8]Penticton Regional Hospital, Penticton; [9]JSS Medical Research, Montreal; [10]Janssen Inc., Toronto, Canada*

**Background:** The Health Assessment Questionnaire (HAQ) remains the gold standard for measuring patient-reported functional status in rheumatoid arthritis (RA) and is included among the measures suggested by the American College of Rheumatology for making treatment decisions in routine care. We have previously shown that significant variability exists in the correlation of individual HAQ questions with patient-reported and clinical outcomes.

**Objectives:** The aim of this analysis was to assess, in routine care, the timelines of HAQ improvement as compared to clinical improvement and to examine possible differences in the improvement of individual questions.

**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, or psoriatic arthritis with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included RA patients treated with IFX who were enrolled since 2002 or with GLM enrolled since 2010. Time to achieving minimal important difference (MID; $\Delta \geq 0.22$) in HAQ, HAQ$\leq$1, minimal disease (MD) in individual HAQ questions (no or some difficulty), CDAI low disease activity (LDA), or CDAI remission was assessed with the Kaplan-Maier estimator of the survival function and cox regression.

**Results:** 1205 patients (75.3% female) were included with mean (SD) age of 56.0 (13.6) years and disease duration of 8.4 (8.9) years at baseline. Mean (SD) HAQ and CDAI were 1.55 (0.72) and 33.8 (17.4), respectively. Statistically significant and clinically meaningful improvements in both HAQ and CDAI were observed over time. The cumulative probability of achieving HAQ MID, HAQ$\leq$1, CDAI LDA, and CDAI remission by 12 months was 69.5%, 54.5%, 54.1%, and 18.1%, respectively. Time to achieving HAQ MID [Hazard Ratio (95% CI): 3.6 (3.2–4.2)], HAQ$\leq$1 [2.9 (2.6–3.4)], and CDAI LDA [3.1 (2.7–3.6)] was significantly lower as compared to CDAI remission.

With respect to individual HAQ questions, at baseline, the most predominant usual activities that patients were unable to do were taking a tub bath (27.9%), reaching and getting down a 5-pound object from the head (21.8%), and doing chores such as vacuuming or yard work (23.2%). In accordance, time to having no or some difficulty in these activities was significantly higher compared to the remaining HAQ items.

**Conclusions:** The results of this analysis show that the timelines for achieving HAQ targets in routine care is comparable to that of achieving CDAI LDA. Significant differences were observed in terms of improvement in individual HAQ items with the inability to take a tub bath, getting heavy overhead objects down, and doing chores being the most persistent.

## FRI0580 COMORBIDITY BURDEN AND MEDICATION USE BETWEEN PSORIATIC ARTHRITIS PATIENTS WITH MODERATE-TO-SEVERE PSORIASIS VS. THOSE WITH MINIMAL SKIN PSORIASIS IN THE US

J.F. Merola[1], V. Herrera[2], J.B. Palmer[2]. *[1]Brigham and Women's Hospital, Harvard Medical School, Boston; [2]Novartis Pharmaceuticals Corporation, East Hanover, United States*

**Background:** Psoriatic arthritis (PsA) is often presented with psoriasis (PsO). However, the severity of PsO among PsA patients varies, which may affect the comorbidity burden in this population.

**Objectives:** This study aimed to assess the comorbidity burden and medication use between PsA patients with moderate-to-severe PsO vs. those with minimal skin PsO.

**Methods:** Adults (18–64 years) with $\geq$2 claims for PsA (ICD-9-CM: 696.0) that were $\geq$30 days apart were selected from the Truven Health MarketScan claims database (data cut period 07/2009–06/2014). The index date was a randomly selected date after the first PsA claim. All patients were required to have $\geq$12-month continuous eligibility before (baseline period) and after (study period) the index date. Patients in the PsA+moderate-to-severe PsO group were required to have 1) $\geq$2 claims for PsO (ICD-9-CM: 696.1) that were $\geq$30 days apart, *and* 2) $\geq$1 PsO claim and $\geq$1 systemic therapy/phototherapy in the study period. PsA patients were classified into the PsA+minimal skin PsO group if they did not have any PsO claim or phototherapy in the data cut period, *or* had $\geq$1 PsO claim but

no evidence of systemic therapy or phototherapy in the data cut period. Patient demographics as of the index date, comorbidities, and medication use during the study period were compared between these two groups. Wilcoxon rank sum tests were used to compare continuous variables and Chi-square tests were used to compare binary variables. Bonferroni correction was used to adjust for multiple comparisons.

**Results:** A total of 10,495 patients with PsA+moderate-to-severe PsO and 15,503 patients with PsA+minimal skin PsO were included in this study. Mean age and percent male were comparable (48.46±10.29 vs. 49.92±10.05 years; 48.2% vs. 46.7%). Compared to patients with PsA+minimal skin PsO, those with PsA+moderate-to-severe PsO had slightly higher rates of chronic pulmonary disease (23.6% vs. 21.4%) and liver disease (excluding fatty liver) (15.1% vs. 10.7%), but lower rates of co-prevalent rheumatic disease (5.1% vs. 7.0%) and rheumatoid arthritis (32.2% vs. 35.7%). Patients with PsA+moderate-to-severe PsO also had significant higher rates of several PsA-associated comorbidities, including anxiety (18.8% vs. 15.8%), depression (23.2% vs. 20.1%) and obesity (21.5% vs. 15.9%) (all $p<0.0001$). Patients with PsA+moderate-to-severe PsO had significantly higher rates of all-cause medication use (99.9% vs. 94.7%) and larger number of unique medications filled (13.38 vs. 11.28) than patients with PsA+minimal skin PsO (both $p<0.0001$). Significant differences were also observed in the mean number of unique medications filled between these two groups for PsA-related medications (2.78 vs. 2.14), non-PsA-related medications (10.60 vs. 9.14), antidepressants (0.60 vs. 0.55), and antidiabetics (0.30 vs. 0.25) (all $p<0.0001$).

**Conclusions:** PsA patients with moderate-to-severe PsO had a higher comorbidity burden compared to those with minimal skin PsO, and also incurred significantly more medication use overall and related to PsA and specific comorbid conditions.

## FRI0581 VALIDATION OF THE DANISH VERSION OF THE STANFORD HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX AND DETERMINATION OF THE MINIMAL CLINICALLY IMPORTANT DIFFERENCE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS USING THE RASCH MEASUREMENT MODEL

L.M. Ørnbjerg[1], K. Christensen[2], A. Tennant[3], M. Hetland[1]. *[1]DANBIO registry and Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases; [2]Department of Biostatistics, Copenhagen University, Copenhagen, Denmark; [3]Schweizer Paraplegiker-Forschung, Schweizer Paraplegiker-Forschung, Nottwil, Switzerland*

**Background:** The Stanford Health Assessment Questionnaire Disability Index (HAQ-DI) is a widely used patient reported outcome for functional disability measurement in rheumatoid arthritis (RA). Minimal clinically important differences (MCIDs) have previously been calculated based on the original ordinal HAQ-DI scores resulting in a dependence of the MCIDs on baseline scores (1). This causes limited generalizability and validity of the proposed MCIDs. The Rasch measurement model provides a transformation of these ordinal scores to an underlying latent scale with interval scale properties. This requires adequate fit of HAQ-DI data to the model.

**Objectives:** 1) To examine the internal construct validity of the Danish version of the HAQ-DI (scored without correction for devices) and 2) to determine a MCID of the HAQ-DI in a cohort of RA patients initiating anti-rheumatic treatment in clinical practice based on the transformed linear logit scale of the HAQ-DI.

**Methods:** RA patients registered in the DANBIO registry at the out-patient clinic at Center for Rheumatology and Spine Diseases, Copenhagen, Denmark were included in the study if HAQ-DI and Patient Global Visual Analogue Scores (PtGl) scores were available at a baseline visit and after > three months of follow-up after initiation of a) first synthetic Disease Modifying Anti Rheumatic Drug (sDMARD) (if disease duration <12 months) or 2) first biological drug (if disease duration >12 months). The Rasch model was fitted to HAQ-DI data at baseline and follow-up and item fit evaluated in separate analyses by comparing observed and expected item-restscore correlations (2). MCID was calculated as the median changes of A) the original and B) logit HAQ-DI score in the group of patients who had improved by 15–30 mm (ie. minimal improvement) on a 0–100 mm PtGl scale.

**Results:** 362 RA patients were included in the study (Table 1). HAQ-DI data showed acceptable fit to the Rasch model as no significant evidence of misfit was disclosed at the first time-point and only a single misfitting item (the "Grip" sub-item, p=0.01) was identified at the second time-point. Consistent item ranking across time indicated instrument invariance. Changes in ordinal and logit HAQ-DI scores were strongly correlated (Spearmans rho =0.935, $p<0.001$), but the association between them is not completely linear. Sixty-one patients had an improvement > MCID on the logit scale (0.48), but no improvement on the ordinal scale (MCID 0.250), while no patients had the opposite pattern.

**Conclusions:** The Danish version of the HAQ-DI scored without correcting for devices showed acceptable internal construct validity and thus a MCID based on a linear transformed scale could be calculated for this study (0.48). Application of the logit MCID classified an additional 17% of patients as having achieved a MCID compared to the MCID calculated on the ordinal scale. This finding has potential implications for the use of ordinal-based MCID and the powering of future studies.

Clinical characteristics of the study population grouped by change in Patient Global VAS from baseline to follow-up.

## FRI0582 FLUCTUATING LEVELS OF RHEUMATOID FACTOR PREDICT PROGRESSION OF RHEUMATOID ARTHRITIS, BUT NOT INDEPENDENT OF DISEASE ACTIVITY

M. Unger[1], F. Alasti[1], G. Supp[1], P. Studenic[1], J. Smolen[1,2], D. Aletaha[1]. *[1]Department of Medicine 3, Division of Rheumatology, Medical University Vienna; [2]2nd Department of Medicine, Hietzing Hospital, Vienna, Austria*

**Background:** The presence of rheumatoid factor (RF) is associated with progression of joint damage in patients with rheumatoid arthritis (RA). RF levels may change during the course of therapy[1], but it is not clear, if such changes also reflect a change in prognosis of RA.

**Objectives:** Here, we aimed to investigate whether fluctuation of RF levels is an independent marker of progression of RA.

**Methods:** We identified 239 RA outpatients based on classifiable RA by the 2010 ACR/EULAR classification criteria, the presence of at least two available radiographs of hands and feet (2–4 years apart), the availability of repeated measurements of RF (at least two/year), and positive initial RF levels (≥50 IU/ml; for the possibility of fluctuation). Radiographic images were scored using the modified Sharp/van der Heijde (SvH) method. A total of 375 radiographic intervals could be included, since some of the patients had more than one included observation periods.

Logistic regression analysis was used to examine the effect of fluctuating RF levels (expressed as standard deviation of all RF measurements between the two radiographs) on significant damage progression (defined by an average increase of ≥3 on the SvH score per year); results were adjusted for mean RF levels over time, disease activity (expressed as Simplified Disease Activity Index – SDAI), percentage time on biologics and already existing radiographic damage.

**Results:** Mean (SD) RF levels were 351.4 (618.7) IU/ml at baseline and 253.7 (424.2) IU/ml at the time of the second radiograph ($p<0.001$). Mean and standard deviation of RF levels within each patient were on average 298.9 (515.0) and 128.7 (233.8), respectively. Mean time-integrated levels of disease activity (SDAI) were of 9.7 (7.0), and patients received biologic therapy over 32.4 (40.8) % of the observed time. Pre-existing damage was 41.1 (52.4) points on the SvH score.

Univariate logistic regression showed a clear association of higher standard deviations of RF levels with radiographic progression (p=0.015). When adjusting this effect for mean RF levels, disease activity (time-integrated levels of SDAI), percentage time on biologics and already existing radiographic damage, the association of standard deviation of RF levels on radiographic progression was lost (p=0.087), whereas disease activity ($p<0.001$) and pre-existing damage (p=0.001) showed high significance.

When adjusting for each of these predictors individually, the association remained unchanged when tested against time on biologics only (p=0.016), or pre-existing damage only (p=0.048). Even adjusting for mean RF levels only left a significant independent association (p=0.032), while the mean RF levels were not significant (p=0.146). Only when adjusted for time-integrated disease activity, standard deviation of RF lost significance on the association with radiographic progression (p=0.126; Table).

**Conclusions:** Fluctuations of RF levels are associated with radiographic progres-

| Predictors of Progression | | Wald | Sig. |
|---|---|---|---|
| Crude | SD of RF | 5.890 | 0.015 |
| Adjusted for Mean of RF, Disease Activity, Time on Biologics, Pre-existing damage | SD of RF | 2.922 | 0.087 |

| | Damage | 16.178 | <0.001 |

sion in RA. This effect is independent of mean RF levels over time, but seems to be associated with, or a consequence of, disease activity. Further studies need to explore the direction of causality of these observations.

## FRI0583 THE DECLINING BURDEN OF ABSENTEEISM DUE TO RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS IN SLOVENIA

P. Došenović Bonča[1], I. Eržen[2], D. Marinšek[1], M. Tomšič[3]. *[1]University of Ljubljana, Faculty of Economics; [2]National instute of Public Health; [3]Department of Rheumatology, Ljubljana University Medical Centre, Ljubljana, Slovenia*

**Background:** In Slovenia, evidence on the indirect costs of rheumatoid arthritis (RA) and ankylosing spondylitis (AS) is scarce.

**Objectives:** To analyse changes in sick leave for RA and AS patients in Slovenia in the 2000–2014 period.

**Methods:** National Institute of Public Health collects absenteeism data. Sick leave data for the entire population of Slovenia was used to conduct a comparative analysis of sick leave indicators (number of cases, share of lost working days, index of temporary disability measuring the number of lost days relative to the number of employees, frequency of spells reflecting the number of absenteeism cases relative to the number of employees and severity indicating the average length of absence from work) for RA and AS patients in Slovenia in the 2000–2014 period. Data were analysed using t-tests for equality of means and Chi-Squared tests of distribution uniformity. Chain indexes were used to determine average annual changes of the studied indicators.

**Results:** Over the period 2000–2014, the number of days lost per employed worker for RA declined by over 13% and by nearly 82% for AS. For all musculoskeletal disorders (MSDs) this indicator declined by nearly 20% while for all diseases combined by nearly 16%. For RA, the average annual decline in temporary disability and severity equalled 1%. The index of temporary disability for all MSDs also declined by slightly over 1% annually on average, severity on the other increased on average by 0.32% annually. For all diseases combined temporary disability declined annually by 1.6% and severity by 1.3% on average. The changes were considerably better for AS given that temporary disability and severity declined for 11.5% and 4.7% annually on average, respectively. The frequency index for RA increased after economic crisis in 2009 while the average annual decline for AS reached 7%. The average annual declines for all MDSs and all diseases combined were much lower reaching 1.5% and 0.3%, respectively.

For both RA and AS the mean values of all studied sick leave indicators with the exception of severity statistically significantly differ between genders ($p<0.001$). For RA sick leave indicators are higher for women while for AS absenteeism indicators are less favourable for men. This result is in line with the gender structure of RA and AS diagnosed patients (1:3 male to female ratio for RA and 3:1 male to female ratio for AS). There are also statistically significant differences ($p=0.000$) in the number of absenteeism cases between three age brackets (20–34, 35–49 and 50–64 years) for both RA and AS. For RA differences between age groups in severity are not statistically significant. For AS the younger population has statistically significantly lower severity indicators while for the upper two age brackets differences are not statistically significant.

**Conclusions:** Results indicate that indirect costs of RA and AS are declining. A more comprehensive estimation of indirect costs requires, however, also the assessment of presenteesim costs. The decline in the burden of absenteeism was larger for AS in comparison to RA. Patients diagnosed with AS are on average notably younger than RA patients. This implies that innovative treatment and disease management practices can prevent larger productivity losses created by absenteeism.

## FRI0584 THE VICIOUS CIRCLE OF EDUCATIONAL LEVEL, RHEUMATOID ARTHRITIS, AND RISK OF POVERTY - RESULTS OF A CROSS-SECTIONAL MULTICENTER STUDY IN GERMANY

M. Zänker[1,2,3], U. Schwill[1], C. Bielecke[1,2], A. Jacobi[2,3,4], K. Sokoll[2,4], G. Zeidler[5], A. Scheibert[5], P. Reutermann[2,6], M. Bohl-Bühler[7], J.M. Engel[8], U. Prothmann[9], M. Backhaus[10]. *[1]Immanuel Klinikum Bernau Heart Center Brandenburg, Bernau; [2]Rheumatic Disease Center, Northern Brandenburg; [3]Brandenburg Medical School; [4]Ruppiner Kliniken, Neuruppin; [5]Johanniter-Krankenhaus, Treuenbrietzen; [6]KMG Elbtalkliniken, Bad Wilsnack; [7]Rheumahaus, Potsdam; [8]MVZ Epikur, Bad Liebenwerda; [9]Knappschaftkrankenhaus, Püttlingen; [10]Park-Klinik Weißensee, Berlin, Germany*

**Background:** Compared to the general population, patients with rheumatoid arthritis (RA) are threatened by poverty due to treatment-related expenses, disability, and early retirement. Also, lower socio-economic state is associated with increased prevalence and severity of RA. The underlying mechanisms are still unclear.

**Objectives:** To evaluate the risk of poverty of RA-patients in an unselected community-based cohort in the German states of Brandenburg and Saarland, and to investigate interrelationship between educational level, socio-economic state and disease severity.

**Methods:** Cross-sectional multicenter study consecutively recruiting RA-patients in outpatient-clinics in Brandenburg and Saarland. Inclusion criteria were written consent and diagnosis of RA fulfilling ACR/EULAR-criteria. Using anonymised questionnaires, equivalised disposable income (EDI = total net income of a household divided by the number of equalised household members) was calculated. Risk of poverty was defined as <60% of the median EDI in Germany. Additionally, treatment-related expenses and effects of RA on social life were evaluated.

**Results:** Of all 910 returned questionnaires (return rate 88%), 882 (97%) were evaluable (666 from Brandenburg and 215 from Saarland). The mean±SD age of all patients was 61±12 years, 71% were female, mean functional capacity (FFbH) was 72±23%, rate of biologic treatment was 41%, and 21% were active smokers. Median monthly EDI of RA-patients was 1239€ (IQR 869–1654), 88% of the median EDI in Germany (1413€). The rate of RA-patients at risk of poverty was significantly higher compared to the population in Germany (27% vs. 16%, $p<0.001$). Of the RA-patients, 414 (52%) had approved disability and 136 (21%) got early retirement at a mean age of 55±11 years. Of all patients, 25% waved a drug prescription at some point due to financial reasons. The RA-subgroup at risk of poverty waived prescriptions even more often (37% vs. 18%, $p<0.001$), had a higher rate of active smokers (27% vs. 19%, $p=0.009$) with more pack-years (5.1±10.9 vs. 3.5±9.6, $p=0.034$), had worse functional scores (FFbH 64±25% vs. 75±22%, $p<0.001$) and higher rates of early retirement (30% vs. 17%, $p<0.001$) compared to the patients without poverty risk. Patients with an university degree had less functional impairment (mean FFbH 84±18% vs. 71±23%, $p<0.001$), lower early retirement rates (7% vs 22%, $p=0.004$) and older age at retirement (59±7 vs. 55±12years, $p=0.023$) than patients without a degree. These findings were not associated with different smoking rates, nutrition type, oral hygiene, exposure to agricultural or silica dust, or early diagnosis of RA.

**Conclusions:** RA-patients in this study had an almost doubled risk of poverty compared to the general population. Poverty reduces compliance to treatment resulting in a vicious circle. Lower educational level is associated with more severe disease course of RA, but the underlying mechanisms need further elucidation.

## FRI0585 IMPORTANCE AND LEVEL OF IMPLEMENTATION OF THE EULAR/EUMUSC.NET STANDARDS OF CARE FOR RA IN THE NETHERLANDS: SIMILARITIES AND DISCORDANCE BETWEEN PATIENTS AND HEALTH CARE PROFESSIONALS

M. Hifinger[1,2], Y. van Eijk[1], P. Putrik[2], S. Ramiro[3], A. Woolf[4], J. Smolen[5], M. Stoffer[5], T. Uhlig[6], R.H. Moe[6], M. Saritas[7], M. van de Laar[8], H. Vonkeman[8], M. de Wit[9], M. Janson[10], A. van der Helm-van Mil[10], A. Boonen[1,2]. *[1]Maastricht University Hospital; [2]Maastricht University, Maastricht; [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [4]Royal Cornwall Hospital, Cornwall, United Kingdom; [5]Medizinische Universität Wien, Wien, Austria; [6]Diakonhjemmet Hospital, Oslo, Norway; [7]Laurentius Hospital, Roermond; [8]University of Twente, Enschede; [9]VUMC, Amsterdam; [10]Leiden University Medical Center, Leiden, Netherlands*

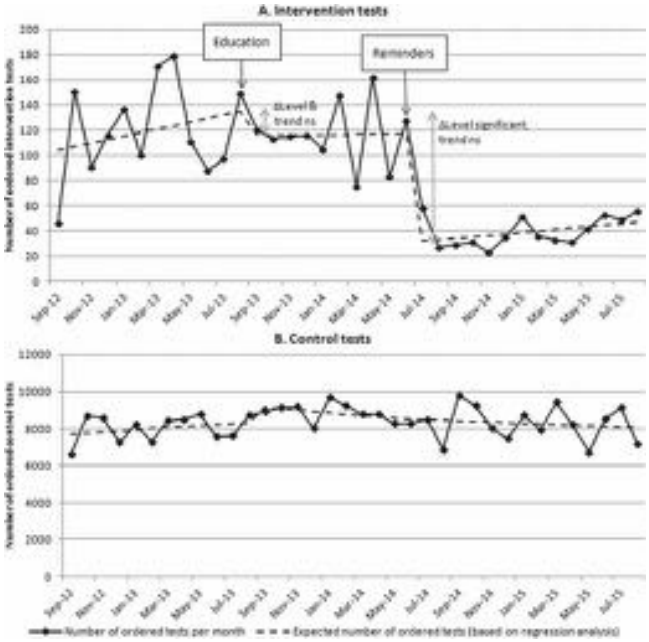
**Background:** To harmonize care, the core concepts of RA care have been formulated in the 16 EULAR/EUMUSC.net standards of care (SOC). To further empower RA patients and help them to monitor their disease, SOC have been converted into a patient checklist. Yet, the SOC have never been applied to patients and health care professionals (HCP) in a daily practice setting.

**Objectives:** To assess the importance, level of implementation and implementation gap of the 16 EULAR/EUMUSC.net SOC among patients with RA and HCPs in the Netherlands.

**Methods:** Dutch patients with RA from two hospitals, rheumatologists as well as nurses of the Dutch Society of Rheumatology completed a questionnaire on the importance and level of implementation (0–10 numeric rating scale (NRS);

10=highest, best) of each SOC. An implementation gap, identifying the SOC with a higher need for implementation, was calculated for all individual SOC: (maximal implementation (10) – reported implementation) X reported importance. Patients completed a NRS on global disease activity. Comparisons across subgroups were analysed with Mann-Whitney test.
**Results:** Overall, 217 patients and 91 HCPs (52 rheumatologists and 39 nurses) were included. The 3 SOC with the highest importance and implementation scores were similar for patients and HCPs, and showed almost no implementation gap (table). While for both patients and HCPs the implementation gap for alternative therapies was high, it should be noted that its perceived importance was relatively low (patients: 6.5 (3.2) and HCPs 6.2 (2.2)). The remaining important implementation gaps referred to SOC with a low implementation, but a high importance, for both patients and HCPs (table). Within patients, perceived level of implementation of most of the SOC was lower in those with higher disease activity. No important differences were found between subgroups according to gender, age, disease duration, education or health literacy.

**Table: The top three Standards of Care in RA for importance, implementation and implementation gap**



| | Patients (N=217) | Health Care Professionals (N=91) |
|---|---|---|
| **Age in years** *(mean ± SD)* | 60 ± 11 | 49 ± 9 |
| **Gender** *(% female)* | 69 | 72 |
| **Top 3 ranked SOCs** Level of importance *(mean ± SD) (0-10)* | 1. Informed on contact if disease worsens *(9.3 ± 1.1)*<br>2. Treatment with DMARDs *(9.2 ± 1.4)*<br>3. Regular re-appraisal if treatment target not achieved (9.1 ± 1.4)<br>3. Self-management of pain (9.1 ± 1.4) | 1. Treatment with DMARDs (9.2 ± 0.8)<br>1. Information on contact if disease worsens (9.2 ± 1.0)<br>2. Informed on treatments, benefits and risks (9.1 ± 0.8) |
| Level of implementation *(mean ± SD) (0-10)* | 1. Treatment with DMARDs (9.3 ± 1.2)<br>2. Regular re-appraisal if treatment target not achieved (9.1 ± 1.4)<br>3. Informed on contact if disease worsens (9.0 ± 1.6) | 1. Informed on contact if disease worsens (9.1 ± 1.3)<br>2. Treatment with DMARDs (8.9 ± 1.1)<br>3. Regular re-appraisal if treatment target not achieved (8.7± 1.3) |
| Implementation Gap different calculation *(mean ± SD) (0-100)* | 1. Informed on alternative therapies (and limited evidence) (30.2 ± 18.3)<br>2. Informed on personalised physical exercise (21.9 ± 20.1)<br>3. Access to trustful sources of information (21.5± 16.1) | 1. Treatment plan for patients (25.7 ± 18.7)<br>2. Informed on alternative therapies (and limited evidence) (23.6 ± 13.4)<br>3. Early diagnosis by specialist (22.3 ± 16.2) |

**Conclusions:** In the Netherlands, patients and HCPs share similar opinions on the most important aspects of RA care and agree these SOC are appropriately implemented. However, HCPs identified a need for improvement with regard to early diagnosis and providing a treatment plan to the patient. Patients experienced an unmet need in personalized exercise and access to trustful information. This audit of care using SOC identified areas for improvement for care that should be addressed.

## FRI0586 THE EFFECTS OF AN EDUCATIONAL MEETING AND SUBSEQUENT COMPUTER REMINDERS ON THE ORDERING OF LABORATORY TESTS BY RHEUMATOLOGISTS: AN INTERRUPTED TIME SERIES ANALYSIS

N. Den Broeder[1], N. Boers[1], N. Lesuis[1], E. Piek[1], S. Teerenstra[2], M. Hulscher[3], R. van Vollenhoven[4], A. den Broeder[1]. *[1]Rheumatology, Sint Maartenskliniek; [2]Health Evidence, section Biostatistics; [3]IQ healthcare, Radboud Institute for Health Sciences, Nijmegen, Netherlands; [4]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Karolinska Institute, Stockholm, Sweden*

**Background:** Excessive use of diagnostic laboratory does not only constitute a waste of resources, it may also result in an increased rate of false positives which may lead to further unnecessary testing, unnecessary treatment, and increased anxiety in both patients and physicians. Still, many clinicians order irrelevant laboratory tests despite the available information about unnecessary test utilization.
**Objectives:** To examine the effects of an educational meeting and subsequent computer reminders on the number of ordered laboratory tests.
**Methods:** Using interrupted time series analysis we assessed whether trends in the number of laboratory tests ordered by rheumatologists between September 2012 and September 2015 at the Sint Maartenskliniek (the Netherlands) changed following an educational meeting (September 2013) and introduction of computer reminders into the Computerized Physician Order Entry System (July 2014). The reminders functioned as follows: whenever a clinician tried to order one of the intervention tests a pop-up message appeared explaining in which specific rheumatology-related situation the test was indicated or not, and asked for a reason for ordering the test. The analyses were done for the set of tests on which both interventions had focussed (intervention tests; complement, cryoglobulins, immunoglobins, M protein) and for a set of tests unrelated to the interventions, included as a control (alanine transferase, anti-cyclic citrullinated peptide, C-reactive protein, creatine, haemoglobin, leukocytes, mean corpuscular volume, rheumatoid factor and thrombocytes). Secondary outcomes were the percentage of abnormal intervention test results and the percentage of valid reasons provided with the intervention test orders, as judged by two experts.
**Results:** At study start 101 intervention tests and 7660 control tests were ordered per month by the rheumatologists. After the educational meeting both the level and trend of ordered intervention and control tests did not change significantly. After implementation of the reminders, the level of ordered intervention tests decreased with 85 tests (95%>CI -133 to -37, p<0.01), though the trend did not change significantly (1.06, 95%>CI -6.2 to 8.3, p=0.77). The level and trend of control tests did not change following the introduction of reminders. Of the reasons given for ordering the intervention tests after the introduction of reminders, only 34% was deemed valid by two experts. Interestingly, the percentage of abnormal results in the intervention tests did not change significantly after the introduction of the reminders (17.4% before introduction of reminders compared 18.4% after introduction (p=0.73)), nor was it different in those cases were the reason for ordering the test was judged as valid (18.8%).

**Conclusions:** The educational meeting alone was not effective in decreasing the number of ordered intervention tests, but subsequent introduction of computer reminders did result in a large decrease of those tests. Therefore, we recommend using computer reminders additionally to education if reduction of inappropriate test use is aimed for.

## FRI0587 EVALUATION OF THE IMMUNE RESPONSE TO VACCINES IN PATIENTS ON BIOLOGICAL THERAPY. PRELIMINARY DATA OF RIER STUDY

P. Richi[1], T. Navío[2], L. Cebrian[3], L. Lojo[2], L. Gonzalez[4], M. Salido[5], P. Castro[5], A. Jiménez[1], M.D. Martín[6], J. Yuste[7], J. Llorente[8], I. Thuissard[9], D. Sanz[9], S. Muñoz-Fernández[1]. *[1]Rheumatology, Hospital Universitario Infanta Sofía; [2]Rheumatology, Hospital Universitario Infanta Leonor; [3]Rheumatology, Hospital Infanta Leonor; [4]Rheumatology, Hospital Universitario del Tajo; [5]Rheumatology, Hospital Universitario Infanta Cristina; [6]Laboratorio BR Salud; [7]Bactereology, Centro Nacional de Microbiología Instituto Carlos III; [8]Pharmacy, Hospital Universitario Infanta Sofía; [9]Post-graduate and Research, Universidad Europea, Madrid, Spain*

**Background:** Patients with rheumatic diseases on biological therapy have a greater risk of infections. Vaccination recommendations have been established, but, the effectiveness of vaccines in these patients is not well known, and it seems to depend on the different types of treatment used.
**Objectives:** To evaluate the response of vaccines against A and B Influenza, hepatitis B and pneumococcus in patients on biological treatment.
**Methods:** Patients with inflammatory arthopathies, psoriasis (Pso), inflammatory bowel disease (IBD) or connective tissue diseases (CTD) that were on or were going to initiate biological therapy, were included. A and B influenza antibodies (Ab) were measured by ELISA. A good response was achieved when base-line titer was increased by four. Hepatitis B surface antibody (Hep B sAb) was measured by ELISA and considered positive with a final titer >10m IU/ml. Protection against pneumococcus serotypes 1, 3, 7F, 14, 19A and 19F was measured by an opsonophagocytosis killing assay (OPKA). Opsonization titers (OT) were defined as the serum dilution that kills 50% of bacteria.
**Results:** 280 subjects were included, 167 women (59.6%), with a average age of 49.5±13.2 years. 35% were Rheumatoid Arthritis patients, 33.9% had spondiloarthropathies, 16.8% Psoriatic Arthritis, 5.4% Pso, 2.9% IBD and 6% other diagnostics. 84% of patients were on anti-tumor necrosis factor therapies, 8.9%

on Rituximab, 5% on tocilizumab, 1.4% on abatacept and 1.4% received other biologics. 45.4% of subjects were also on DMARDs and 18% on corticosteroids. A good response to influenza A vaccine was achieved in only 3.7% of patients for A influenza and 3.2% for type B, even though the majority of patients showed detectable titers of Ab in sera. 75% of patients had been vaccinated against hepatitis B before beginning the biological therapy. More than 90% of patients vaccinated against hepatitis B during the study achieved a good response. 40% of subjects showed OT against 3 or more pneumococcal serotypes.

**Conclusions:** The response from patients on biological therapy to the influenza vaccine is lower than expected. Comparative studies between these patients and those without biological treatment and healthy people are needed. There is a considerable amount of patients that have not received hepatitis B vaccine before the beginning of the biological treatment, although the response to this vaccine is good. Pneumococcal vaccine is successful in a considerable proportion of subjects. It is worth insisting on its administration.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3503

## FRI0588 COMPARING THE BURDEN OF ILLNESS OF PATIENTS WITH TOPHACEOUS AND NON-TOPHACEOUS GOUT IN FRANCE, GERMANY, ITALY, SPAIN, AND THE UK

P. Khanna[1], E. Tafesse[2], S. Baumgartner[3], A. Walker[4], R. Morlock[3]. *[1]University of Michigan, Ann Arbor; [2]AstraZeneca Pharmaceuticals, Gaithersburg; [3]Ardea Biosciences, Inc., San Diego, United States; [4]AstraZeneca Pharmaceuticals, Luton, United Kingdom*

**Background:** Gout is a common inflammatory arthritis and its worldwide prevalence is increasing. EULAR and American College of Rheumatology guidelines recommend a target sUA <6 mg/dL, with a target of <5 mg/dL in those with more severe symptomatic disease. Patients with significant crystal burden are assumed to have higher humanistic and economic burden of illness.

**Objectives:** To describe patient and treatment characteristics and resource utilization in gout patients with and without tophi.

**Methods:** Data were assessed from a survey of physicians and in-depth patient chart audits from France, Germany, Italy, Spain and the UK. Severity of gout was measured by physician global assessment. Flares, organ/joint damage and tophi were abstracted from the clinical chart. Type/dose of xanthine oxidase inhibitor, length of current treatment, physician type and patient sociodemographic factors were identified. Anonymized patients were included. Patients with a diagnosis of tophaceous gout were compared to all other gout (non-tophaceous) patients. Demographic characteristics and comorbidities, sUA levels, and use of colchicine for acute flares during the 12-month study period were compared using chi-square or Fisher's exact tests.

**Results:** Of the 1260 patients identified with gout, 327 (25.95%) had physician-confirmed tophaceous gout and 933 (74.05%) had non-tophaceous gout. Patients with tophi were older (62.3 vs 58.6 years old; $p<0.001$), had gout for a slightly longer period of time (2.8 vs 2.5 years; $p<0.001$), reported more flares (3.4 vs 1.7 per year; $p<0.001$), and were more likely to have joint damage (45.3% vs 10.5%; $p<0.001$). There were significantly higher levels of comorbidities in patients with tophi including cardiovascular disease ($p<0.001$), chronic obstructive pulmonary disease ($p<0.001$), congestive heart failure ($p<0.001$), diabetes ($p=0.011$), depression ($p=0.001$), hypertension ($p<0.001$), osteoarthritis ($p<0.001$) and Stage III ($p<0.001$) and Stage V ($p=0.016$) chronic kidney disease. Patients with tophi were more likely to be treated with a urate-lowering therapy (87.5% vs 78.6%; $p<0.001$). Patients with tophi were less likely to be using allopurinol (56% vs 68%; $p<0.001$) and more likely to be treated with febuxostat (22.9% vs 7.9%). There was no difference in the use of NSAIDs; however, patients with tophi were more likely to take colchicine (46.5% vs 33.7%; $p<0.001$) and steroids (27% vs 10%; $p<0.001$). Patients with tophi were less likely to reach the ideal treatment goal of sUA targets of <6 mg/dL and no flares (17% vs 27%; $p<0.001$) or <5 mg/dL and no flares (6% vs 14%; $p<0.001$). Patients with tophi made more gout-related office visits (6.07 vs 4.51; $p<0.001$) and a greater proportion made ≥1 gout-related emergency visit (27.2% vs 9.5%; $p<0.001$), hospitalization (12.8% vs 3%; $p<0.001$) or had a gout- related surgery (3.1 vs 1.2; $p=0.022$).

**Conclusions:** Patients with tophaceous gout have significantly greater burden of disease and greater frequency of comorbidities than patients with non-tophaceous gout. Preventing the development of tophi or resolving crystal burden by treating to guideline targets remains a rarely achieved goal for patients with and without tophi.

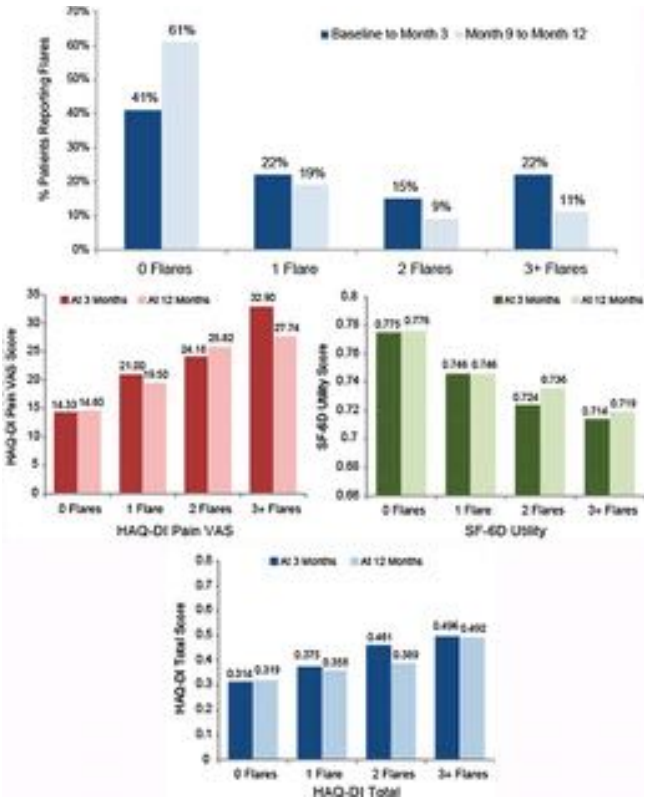
## FRI0589 THE IMPACT OF GOUT FLARES ON PATIENT-REPORTED ASSESSMENTS OF PAIN AND DISABILITY



P. Khanna[1], S. Baumgartner[2], J. Robinson[2], E. Tafesse[3], R. Morlock[2]. *[1]University of Michigan, Ann Arbor; [2]Ardea Biosciences, Inc., San Diego; [3]Astrazeneca, Wilmington, United States*

**Background:** Lesinurad (RDEA594) is a selective uric acid reabsorption inhibitor (SURI) investigated for the treatment of gout in combination with xanthine oxidase inhibitors. In two Phase 3 clinical trials examining lesinurad in combination with allopurinol, patients with non-tophaceous gout demonstrated a reduction in gout flares over the 12-month study periods.

**Objectives:** Investigate the relationship between gout flares and patient-reported assessments of pain and disability during the first 3 and last 3 months of two 1-year clinical trials assessing lesinurad in non-tophaceous gout patients with inadequate response to standard of care (NCT01510158 and NCT01493531).

**Methods:** CLEAR 1 and CLEAR 2 were 12-month, randomized, double-blind, phase III trials to evaluate lesinurad (200 mg or 400 mg oral, daily) in combination with allopurinol (ALLO) vs ALLO + placebo. Gout flares were collected using an electronic patient diary and all flares reported in the diary were assessed. Patient-reported assessments of pain and disability included a Global Pain Scale and the HAQ-DI. A global measure of health utilty, the SF-6D, was derived from the SF-36v2. A pooled analysis of non-tophaceous patients in CLEAR 1 and CLEAR 2 assessed patient-reported measures for those with 0 flares, 1 flare, 2 flares and 3 or more flares, across treatment arms, during the first 3 months of the study (months 1 to 3) and during the final 3 months of the study (months 10 to 12), irrespective of treatment.

**Results:** Patients in the CLEAR 1 and CLEAR 2 clinical trials (N=1062) were primarily male (94.8%), mean±SD age was 51.5±11.1 years and duration since gout diagnosis was 11.1±9.1 years. Most patients (87.8%) received ALLO 300 mg (range: 200–900 mg) daily. Irrespective of treatment, during the first 3 months of the study 41%, 22%, 15% and 22% patients reported 0, 1, 2 and 3 or more flares, respectively. During the final 3 months of the study 61%, 19%, 9% and 11% patients reported 0, 1, 2 and 3 or more flares, respectively. For both the HAQ-DI and Pain VAS, during the first 3 months and last 3 months of the study, the best (lowest) HAQ-DI and Pain VAS scores were reported in patients with 0 flares and the worst (highest) scores were reported in patients with 3 or more flares. The best (highest) SF-6D health utility scores, during the first 3 months and last 3 months of the study, were found in patients with no flares and the worst (lowest) scores were found in those with 3 or more flares.

**Conclusions:** Non-tophaceous patients with the lowest number of flares, during the first and last 3 months of treatment, reported the most favorable HAQ-DI, pain and health utility measures. A majority of patients experiences zero flares during the final 3 months of the study period.

## FRI0590 EARLY RECRUITMENT TO "CLOUDY WITH A CHANCE OF PAIN"; FROM WEBSITE HITS TO SMARTPHONE APP DOWNLOADS

R. Patel[1], J. Sergeant[1], J. McBeth[1], D. Schultz[2], C. Sanders[3], L. Cook[1], J. Ainsworth[3], W. Dixon[1]. *[1]Arthritis Research UK Centre for Epidemiology; [2]Centre of Atmospheric Science; [3]Centre for Primary Care, University of Manchester, Manchester, United Kingdom*

**Background:** Traditionally, participant recruitment for observational studies occurs by clinical teams identifying and approaching eligible patients. The current digital age, with increasing access to the web via PCs, tablets and smartphones provides an exciting alternative recruitment strategy. However, it is not clear whether studies can successfully recruit large numbers of participants in this way. "Cloudy with a Chance of Pain" is a national prospective population study which utilises participant's own smartphones to connect daily symptoms and hourly local weather using global positioning system (GPS) and is recruiting participants without the involvement of their clinical teams.
**Objectives:** To describe website activity and subsequent participant enrolment in the first week of recruitment following two national television broadcasts featuring the study.
**Methods:** Cloudy with a Chance of Pain was featured on BBC Two's "Trust Me I'm a Doctor" (20th January 2016) and BBC One's "Breakfast" (26th January 2016). Potential participants were directed to the study website www.cloudywithachangeofpain.com. The landing page described the project in text and video, after which interested visitors were directed to click through each item of an eligibility questionnaire (age ≥17 years, have arthritis or other chronic pain, resident in the UK, own a smartphone). If eligible in all 4, they were instructed to download the study app. Following download, participants were required to consent and then complete a baseline questionnaire. Google Analytics was used to evaluate the pattern and frequency of website traffic since launch. Enrolment data was provided by the data custodians and app developers, uMotif. Results are reported as mean (SD) or number (%).
**Results:** Within one week of launch, there were 84,494 visits from 22,732 visitors to the landing page of the website. There were 22,046 views of the "Take Part" page. The "take part" eligibility questionnaire was completed on 18,631 occasions. Of those, 15,836 (85%) were determined eligible. 5,683 participants successfully enrolled after following instructions to download the app and provide consent. 4,433 (78%) participants were female. The mean age was 49 (13). Figure 1 demonstrates cumulative enrolment within the first 7 days of launch. 48% of all enrolees registered within 3 hours of either the first or second TV broadcast.

**Conclusions:** Early recruitment to this study has been highly successful without any involvement of clinical teams. Although high website activity has been enabled by national media coverage, we have noted an excellent conversion rate (>33%) from website activity to app downloads without offering personal support or incentives. This confirms that direct participant recruitment using website information and smartphones is a novel and potentially successful approach to patient recruitment to observational studies.

## FRI0591 HYPERURICEMIA AND THE RISK FOR CARDIOVASCULAR DISEASE: INDIVIDUAL PATIENT META-ANALYSIS OF 77,045 INDIVIDUALS ENROLLED IN 15 EPIDEMIOLOGIC STUDIES

S. Baumgartner, R. Morlock. *Ardea Biosciences, Inc., San Diego, United States*

**Background:** Even though well-designed literature-based meta-analyses have confirmed the link between hyperuricemia and the risk for cardiovascular disease (CVD), it is known that study-level analyses can lead to biased assessments, and use of aggregated summary values has some limitations for explaining the heterogeneity. An individual patient data (IPD) meta-analysis offers several advantages including more accurate adjustment for confounders and better accounting of study heterogeneity.
**Objectives:** To perform unadjusted and risk-adjusted IPD meta-analysis of the association between hyperuricemia and prevalent CVD using data from diverse epidemiologic populations in the United States.
**Methods:** Baseline subject level data from 15 epidemiologic studies evaluating CVD risk conducted by the US National Heart Lung and Blood Institutes were pooled. Individuals who reported gout and using gout medications were excluded. Unadjusted and adjusted logistic regression analyses were performed. CVD was defined by self-reported physician diagnosis of myocardial infarction or stroke. Multivariable analyses adjusted for age, sex, sex-urate interaction, body mass index, smoking, total cholesterol, blood pressure, and diabetes mellitus.
**Results:** Overall, 50,966 men (66.1%) and 26,082 women (33.9%) were studied. The mean (standard deviation) age and serum urate (sUA) concentration were 49 (14) years and 5.9 (1.6) mg/dL, respectively. The overall proportion of participants with sUA >6.0 mg/dL was 44.3% and those with sUA >7 mg/dL was 22%. The prevalence of CVD was 7.7% among those with sUA ≤6 mg/dL and 9.8% among those with sUA >6 mg/dL ($p<0.001$). The unadjusted (77,045 observations) and adjusted (age-gender adjusted, 77,045 observations; multivariable adjusted, 66,234 observations) logistic regression models indicated significant association between hyperuricemia and the risk for CVD. For sUA >6.0 mg/dL compared to ≤6.0 mg/dL, odds ratios (95% confidence intervals) were 1.31 (1.24, 1.37), 1.37 (1.20, 1.56), and 1.60 (1.42, 1.81) in the adjusted, age-gender adjusted, and multivariable adjusted models, respectively. For each mg/dL increase in sUA, odds ratios were 1.13 (1.12, 1.15), 1.24 (1.20, 1.28), and 1.20 (1.15, 1.24), respectively.
**Conclusions:** These IPD meta-analyses confirm the results of literature-based meta-analyses that hyperuricemia is associated with elevated risk for CVD. Although the results of individual epidemiologic studies may vary due to differences in the risk profile, age, gender, and other risk factors, overall, the association between hyperuricemia and CVD appears to be robust.

## FRI0592 MAINTAINING MENTAL HEALTH IN OLDER PEOPLE WITH MUSCULOSKELETAL PAIN: A LONGITUDINAL COHORT STUDY

S. Baker[1], C.A. Chew-Graham[1], R. Wilkie[1], J. McBeth[1,2]. *[1]Research Institute for Primary Care & Health Sciences, Keele University, Staffordshire; [2]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom*

**Background:** Reporting troublesome pain doubled the risk of the onset of depression in older people[1]. However the majority (84%) of those with troublesome pain remained free of depression. Social participation (SP) (i.e. recreational and functional activities involving interaction with others) has been linked to good mental health. Whether SP (and its associated pathways; social support (SS), eudaimonic wellbeing (EW; a sense of purpose and meaningfulness in life) and physical activity (PA)) is associated with maintaining mental health in older adults with troublesome pain is not known.
**Objectives:** To test the hypothesis that among older people with troublesome pain higher levels of SP explain why some older people maintain good mental health, and if any role of SP remains once that through SS, PA and EW is accounted for.
**Methods:** Data were from a nationally representative population-based prospective (baseline, 2 and 4 year follow up) cohort study of community-dwelling people aged ≥50 years; the English Longitudinal Study of Ageing (ELSA; n=2654). At baseline participants were asked "are you often troubled with pain?" (response options yes/no). Mental health was classified at baseline and 4 years using the 8-item Centre for Epidemiologic Studies Depression scale (CESD-8) with scores <4 indicating "good mental health". SP at 2 years was defined using a multidimensional latent class model and coded as low or high participation. Path analysis assessed the total, direct and indirect (via SP) effects of pain at baseline on CESD-8 score at 4 year follow-up adjusted for age, gender, socioeconomic status, baseline CESD-8, self-rated health and limiting illness. In a multiple parallel pathways analysis EW (derived from CASP-19), SS and PA (using established ELSA measures) were then entered into the model. Not being troubled by pain was the referent category and results were expressed as odds ratios (OR) with 95% confidence intervals (95% CI).
**Results:** 1475 (55.6%) were female, median age 62 years (interquartile range: 57–69) and 863 (32.5%) reported being often troubled by pain at baseline. Having pain at baseline was associated with a 70% decreased odds of good mental health (total effect OR 0.30; 95% CI (0.23, 0.38)). Among those with pain at

baseline those with high SP at 2 years were 3 times more likely to have good mental health at 4 years (2.97; (2.29, 3.86)). After adjusting for confounders there was no indirect effect for SP (1.00; (0.98, 1.01)). In a multiple parallel pathways analysis there was a strong indirect effect for EW (0.53; (0.36, 0.73)) and no indirect effect through PA or SS.
**Conclusions:** In older people with pain high EW was associated with good mental health 4 years later. Interventions that aim to increase EW may improve mental health outcomes in older people with pain.

## FRI0593 A SYSTEMATIC LITERATURE REVIEW OF THE PREVALENCE OF PSORIATIC ARTHRITIS

T. Ágh[1], Z. Vokó[1], O. Heisel[2], S. Chiva-Razavi[3], M. Barbeau[3], L. Szilberhorn[1], P. Keown[2]. *[1]Syreon Research Institute, Budapest, Hungary; [2]Syreon Corporation, Vancouver, British Columbia; [3]Novartis Pharmaceuticals Canada Inc., Dorval, Quebec, Canada*

**Background:** Psoriatic arthritis (PsA) is a heterogeneous multifaceted inflammatory arthritis associated with psoriasis (PsO). PsA causes a substantial disease burden and has a significant societal health impact. Accurately determining the prevalence of PsA can be difficult due to variations in disease presentation over time, changes in disease classification and specialty of the treating physician.
**Objectives:** To perform a systematic literature review of the prevalence of PsA and to identify potential determinants of the prevalence of PsA.
**Methods:** A systematic literature search of English-language articles was conducted in October 2015 using MEDLINE, EMBASE and CINAHL, and was limited to articles published between 2009 and 2015. The systematic literature review was conducted by two independent reviewers in compliance with the PRISMA Statement.
**Results:** Thirty-nine studies (23 clinical studies, 10 database analyses, and 6 population-based surveys) were included. In most of the studies (n=38), the diagnosis of PsA was made by physicians using different classification criteria: Classification Criteria for Psoriatic Arthritis (CASPAR) criteria (n=14), CASPAR and Moll and Wright (M&W) criteria (n=2), CASPAR and Gladman modification of M&W criteria (n=1), CASPAR and Assessment of Spondyloarthritis International Society criteria (n=1), classification criteria for PsA not reported (n=20). In the reviewed articles, only point prevalence rates for PsA were reported. The point prevalence of PsA ranged between 0.02% to 0.67% in the adult population, and 3% to 42% in patients with PsO, with rates differing across countries. PsA seemed to be most prevalent in the 50–59 years age-group. PsA was more common among first-degree relatives of patients with PsA and also showed marked differences between different ethnic groups (showing the highest prevalence in the Caucasian population). The results of studies on gender differences were conflicting: some reported that PsA was more frequent in men and others that it occurred more frequently in women. In the studies reviewed, the majority of PsA patients had peripheral symptoms without axial involvement; polyarthritis seemed to be more prevalent than oligoarthritis. Findings of studies estimating the prevalence of PsA in PsO patients suggested that 29% to 41% of PsO patients attending dermatology clinics had undiagnosed PsA.
**Conclusions:** The high variance of prevalence rates can be explained with the differences in study populations, diagnostic methods and classification criteria of PsA. The prevalence of PsA seemed to be mostly affected by age and genetic factors. Findings of the epidemiological studies measuring the prevalence of PsA in PsO patients suggested that a large proportion of patients with PsO seen in dermatology centers might have PsA that had not been previously diagnosed. Given that untreated PsA may result in irreversible joint damage, increased awareness of this condition among PsO patients may be a critical step in reducing disability in this patient population. Further research is needed to better understand the occurrence of PsA.

## FRI0594 ASSOCIATION OF GOUT DIAGNOSIS WITH INCREASED RISK OF JOINT REPLACEMENT: A POPULATION-BASED COHORT STUDY OF OVER 250,000 PATIENTS

S. Perreault[1], A.B. Klein[2], R. Morlock[3]. *[1]Faculty of Pharmacy, University of Montreal, Montreal, Canada; [2]AstraZeneca, Gaithersburg; [3]Ardea Biosciences, Inc., San Diego, United States*

**Background:** Gout is the most common cause of inflammatory arthritis in men and older women, and there are very few studies on the rate of joint replacement among patients with diagnosed gout compared to those without gout.
**Objectives:** To assess the risk of joint replacement among patients with diagnosed gout compared to patients without gout diagnosis, and the predictors.
**Methods:** This was a population-based study with cohort study design in a cohort of older adults. We first identified all subjects aged >66 years between January 1, 1995 and December 31, 2009. A study cohort of 252,255 individuals was reconstructed using the Quebec RAMQ and MedEcho administrative databases. Patients with gout diagnosis were defined only if they met *all* of the following criteria: 1) gout defined by *ICD-9 or ICD-10 or exposure of specific gout treatment*. The date of cohort entry of patients with gout was defined as the first date of established gout during follow-up. The primary outcome was incident joint replacement rate defined by a composite endpoint representing patients with a medical procedure in the hip, femur and basin, knee, ankle/foot, hand/finger, shoulder and humerus, forearm and elbow, or wrist. Potential predictive factors examined included gout diagnosis, cardiovascular diseases, cerebrovascular disease, peripheral vascular disease, diabetes, kidney disease, pulmonary disease, dementia, rheumatic disease, and gastrointestinal disease.
**Results:** The incident rate of joint replacements was at 2.67 (95% CI: 2.57–2.77) and 1.92 (1.90–1.94) per 100 person-years among patients with diagnosed gout and those without a gout diagnosis, respectively ($p<0.0001$). Major predictors of total joint replacements were gout diagnosis (31%), advanced age (42%), cerebrovascular disease (13%), acute renal failure (10%), respiratory disease (12%), rheumatic disease (43%), and gastrointestinal disease (10%). Significant predictors of drug exposure are NSAIDs, intra-articular corticosteroids and narcotic use. Noted limitations included the limited ability to adjust for clinical severity and the potential of residual confounding factors.
**Conclusions:** Gout disease was associated with a significant, 31% increase risk of joint replacement in older adults. Further research should be conducted to confirm this potential associated risk.
**Acknowledgement:** This study was funded by AstraZeneca.
**Disclosure of Interest:** S. Perreault: None declared, A. Klein Employee of: AstraZeneca, R. Morlock Employee of: Ardea Biosciences, Inc., a member of the AstraZeneca Group

## FRI0595 RESPONSIVENESS AND TEST-RETEST RELIABILITY OF NEW DISEASE ASSESSMENT INSTRUMENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN RELATION TO SLEDAI-2K

W.W. Chatham[1], C.E. Collins[2], N. Gaylis[3], H. Busch[4], E. Hautamaki[5], S. Narayanan[5]. *[1]University of Alabama, Birmingham, Birmingham, AL; [2]MedStar Washington Hospital Center, Washington, DC; [3]AARDS Research, Inc., Aventura, FL; [4]Science & Research Institute, Inc., Jupiter, FL; [5]Global Evidence, Value & Access, Ipsos Healthcare, Washington, DC, United States*

**Background:** Several new simplified Disease Assessment Instruments/Indices (DAIs) in Systemic Lupus Erythematosus (SLE) are in different stages of development to aid easy use in daily clinical practice, including SLE Activity Tracking Evaluation Tool (LAST; 14 items; includes medications, Physician Global Assessment (PhGA) 0–10 scale, Patient Global Assessment (0–10 scale), C3/C4/anti-dsDNA measures), Clinical LAST (C-LAST; 11 items; similar to LAST, without lab measures), Total Lupus Activity Score (TLAS; 30 items on lupus symptoms, with 15 each of physician clinical & patient self-assessments), and Simple Disease Assessment for People with Lupus Erythematosus (SIMPLE; 17 items; includes patient self-assessment of lupus symptoms, Lupus Impact Tracker, steroid medication, C3/C4/proteinuria).
**Objectives:** To assess responsiveness and test-retest reliability of the DAIs between baseline (BL) and 3mo assessments.
**Methods:** This is a prospective real-world observational cohort study of SLE patients receiving standard care in two private and two academic sites in the US. Respective portions of DAIs (incl. SLEDAI-2K & PhGA (0–3 scale) (in all sites) & BILAG-2004 (in academic sites)) are completed by physicians and patients at four time points: BL/3mo/6mo/12mo. Responsiveness was assessed by analyzing within-person change in scale scores and effect size (mean change divided by standard deviation of BL score) between BL and 3mo in relation to change in clinical status, as measured by SLEDAI-2K scores, categorized as “improved”, “no change”, or “worsened”, and test-retest reliability was assessed by Spearman correlation coefficient ($r_s$) comparing BL and 3mo scores among those with “no change” in SLEDAI-2K scores. Correlations ($r_s$) between BILAG-2004 and other DAI scores were assessed.
**Results:** In total, 201 patients (mean age: 45 yrs; female: 91%; Black/African American: 56%; Hispanic: 10%) were enrolled in the study; 149 patients with BL baseline and 3mo data were evaluated. Within-person change/effect size among the *Improved* group (n=54): LAST = -6.4/-0.537, C-LAST = -5.6/-0.536), TLAS

= -1.7/-0.234, SIMPLE = -4.1/-0.359, PhGA (0–10) = -1.3/-0.655, PhGA (0–3) = -0.7/-0.915; *No change (n=55):* LAST = -0.7/-0.055, C-LAST: -0.5 /-0.049, TLAS: 1.7/.159, SIMPLE: -1.3/-0.114, PhGA (0–10) = -0.2/-0.080, PhGA (0–3): -0.02/-0.025; *Worsened (n=40):* LAST = 4.1/0.323, C-LAST = 2.9/0.265, TLAS = 4.8/0.449, SIMPLE = 1.9/0.170, PhGA (0–10) = 1.0/0.495, PhGA (0–3) = 0.4/0.480. Test-retest reliability was ($r_s$; all $p<0.0001$): LAST = 0.713, CLAST = 0.684, TLAST = 0.778, SIMPLE = 0.757, PhGA (0–10) = 0.639, PhGA (0–3) = 0.503). At 3mo, BILAG-2004 correlated with DAIs as (r/n): LAST = 0.465/59 (p=0.0002), C-LAST = 0.391/59 (p=0.0022), TLAS = 0.280/56 (p=0.0366), SIMPLE = 0.627/56 ($p<0.0001$), PhGA (0–10) = 0.553/59 ($p<0.0001$), PhGA (0–3) = 0.507/71 ($p<0.0001$).

**Conclusions:** Test-retest reliability showed moderate-to-strong correlations between baseline and 3mo assessments. For the "improved" and "worsened" groups (per SLEDAI-2K change), effect sizes indicated a small to medium effect, whereas the "no change" group had effect sizes indicative of no change; mean within-person change scores were directionally responsive to clinical change. Most DAIs had moderate correlation to BILAG-2004.

## FRI0596 RHEUMATOID ARTHRITIS RISK ALLELES, HLA-DRB1 HAPLOTYPES, AND RESPONSE TO TNFI THERAPY – RESULTS FROM A SWEDISH COHORT STUDY

X. Jiang[1], J. Askling[1], S. Saevarsdottir[1], L. Padyukov[1], S. Viatte[2], T. Frisell[1].
*[1]Karolinska University Hospital, Stockholm, Sweden; [2]Arthritis Research UK Epidemiology Unit, Center for Musculoskeletal Research, Institute of Inflammation and Repair, manchester, United Kingdom*

**Background:** Tumour necrosis factor inhibitors (TNFi) have proven successful in suppressing both inflammation and joint damage in rheumatoid arthritis. Still, predictors of response are largely lacking, to increase our understanding of the disease-driving biology and response to treatment. Several pharmacogenetics studies, including five GWAS, have been conducted to identify genetic predictors to TNFi response, but few markers have reached genome-wide significance or withstood replications.

**Objectives:** By taking a genetic risk score approach, combining information contained in individual RA risk markers, amino acids, and haplotypes, we may be able to better predict treatment response to TNFi.

**Methods:** We linked recent onset RA patients from the Swedish EIRA study (genotyped with the Illumina Immunochip array) to prospectively recorded data on treatment and clinical characteristics in the nationwide Swedish Rheumatology Register (SRQ). The cohort was defined as those who started TNFi as first biological DMARD treatment 2000–2012, and had at least one return visit with recorded DAS28 within 2–8 months after TNFi start (N=867). Based on previous reports, we identified established RA genetic risk factors: 76 RA risk loci, 4 amino acid polymorphisms at *HLA-DRB1* (position 11, 13, 71, 74), and calculated 16 haplotypes based on the amino acids. We calculated risk scores for the 76 SNPs, the 4 amino acids, and the haplotypes, by weighting SNP alleles/amino acid residues/copies of haplotype by their published log-odds. The association of RA risk scores and individual established genetic risk factors with DAS28-based EULAR response and a number of clinical disease activity measures at the evaluation visit closest to 5 months after initiation was estimated using logistic and linear regression models.

**Results:** All risk scores were good predictors for RA, in particular for ACPA-positive RA. We found, however, no association for any of the risk scores, or SE, in achieving good/moderate EULAR response in RA overall, nor in any RA subset. When evaluating each of the 76 SNPs, individual amino acid residues and haplotypes separately, we found that the number of SNPs with significant associations to response for TNFi was not higher than expected by chance (5/76 SNPs had $p<0.05$ in ACPA-positive RA, 4/76 in ACPA-negative RA). Similarly, despite the borderline significant association for some residues in ACPA-positive RA (glycine at position 11, serine and tyrosine at position 13) and in ACPA-negative RA (proline at position 11, arginine at position 13), none survived correction for multiple testing. In addition, none of the haplotypes, neither those based on 4 amino acids (11/13/71/74) nor those based on 3 amino acids (11/71/74), were significantly associated with EULAR response. With regard to the changes in individual disease activity measures, no associations were identified except that the risk scores may explain a small proportion of variance in HAQ changes.

**Conclusions:** Identified RA risks genes, amino acids, and haplotypes in our study do not predict response to TNFi therapies, neither individually nor when groups together into scores.

**Disclosure of Interest:** None declared

## FRI0597 SYSTEMATIC REVIEW OF CONSUMER PERCEIVED HEALTH INFORMATION NEEDS REGARDING BACK PAIN

Y.Z. Lim, M. Seneviwickrama, F.M. Cicuttini, D. Urquhart, A.E. Wluka.
*Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

**Background:** Low back pain (LBP) is very common. Being one of the most common presenting complaints for doctor visits, in the Global Burden of Disease study, it was ranked highest in terms of causing disability, and 6th in terms of overall burden, despite current available guidelines to manage LBP [1,2]. As optimal management requires coordination with patient expectations, understanding the consumer's perceived health information needs is important to optimize health outcomes for LBP.

**Objectives:** To identify consumer perceived health information needs regarding LBP.

**Methods:** A comprehensive search of MEDLINE, EMBASE, CINAHL and PsycINFO was performed (1990 to December 2014). Core search terms were developed around consumers' perspective of needs relating to health information relating to LBP. Data regarding design and methodology were extracted. Emergent themes were identified to provide a systematic review of the existing literature.

**Results:** 2638 papers were identified, of which 37 articles were relevant (Fig 1); 33 used qualitative methods, 7 used quantitative methods, and 3 used mixed methods. Participants, mainly with chronic LBP, were mostly recruited from primary practice but also from pain clinics, hospital, rehabilitation centers, specialist spine clinics and the general public. The quality of the literature was variable, with few studies specifically addressing the review question. However, many results were consistent. The 2 major areas of need, identified in at least 2 studies, related to

1) Information content: Consumers wanted general information about LBP to better understand it, with emphasis on obtaining a specific diagnosis and cause for LBP, which underscored the perceived need for imaging to acquire a diagnosis. Patients also wanted information regarding prognosis, including future disability and effect on work capacity, potential precipitation of flares. General information on LBP management, including pharmacological and non-pharmacological strategies, pain management, flare management and prevention, self-management strategies and support services for LBP were desired. They valued individualized information that did not conflict with their lived experience, life goals and beliefs.

2) Information delivery: Patients valued high quality information that was valid and trustworthy. Information needed to be delivered in a suitable tone and in understandable language, without medical jargon. They wanted to know how to find information about LBP.

**Conclusions:** This review highlights the mismatch between consumer health information needs and current health care providers' management. Widespread community wide interventions may be required to address community beliefs and expectations about back pain in order to improve consumer understanding of LBP. Addressing consumer perceived needs more effectively and integrating this into the management of LBP may improve patient outcomes regarding LBP.

FRI0598 **RELATIONSHIP OF JOINT HYPERMOBILITY WITH LOW BACK PAIN AND LUMBAR SPINE OSTEOARTHRITIS: A COHORT STUDY**

Y.M. Golightly[1], A.P. Goode[2], R.J. Cleveland[1], A.E. Nelson[1], M.T. Hannan[3], H.J. Hillstrom[4], V.B. Kraus[2], T.A. Schwartz[1], J.B. Renner[1], J.M. Jordan[1]. *[1]University of North Carolina, Thurston Arthritis Research Center, Chapel Hill, NC; [2]Duke University, Durham, NC; [3]Hebrew SeniorLife, Boston, MA; [4]Hospital for Special Surgery, New York, NY, United States*

**Background:** Low back pain (LBP) and osteoarthritis (OA) of the lumbar spine are common causes of disability. The contribution of joint hypermobility (range of motion greater than normal at most joints) to LBP and lumbar spine OA is not well known.
**Objectives:** This cross-sectional study examined the relationship of joint hypermobility with LBP and lumbar spine OA in a large cohort in the United States.
**Methods:** Of the 2146 participants with Beighton (hypermobility) data collected from 2003 to 2010, 1864 had complete LBP and lumbar spine radiographic data available for analyses. For the Beighton criteria, one point was given for each completed maneuver: passive dorsiflexion right/left fifth finger 90+ degrees, passive apposition right/left thumbs to forearm, right/left elbow hyperextension 10+ degrees, right/left knee hyperextension 10+ degrees, and palms on floor during forward trunk flexion with knees extended. The total score ranged from 0 (unable) to 9 (performed all maneuvers). A Beighton score $\geq$4 was defined as hypermobility. Presence of LBP was based on pain, aching or stiffness of the low back on most days. Each lumbar spine radiographic level was graded for disc space narrowing (DSN) and osteophytes (OST) in a semi-quantitative fashion (0–3) according to the Burnett Atlas. Radiographic lumbar spine OA (rOA) was defined as the presence of DSN and OST grade 1+ at the same lumbar level. Symptomatic lumbar spine OA (sxOA) was defined as presence of rOA with LBP. Associations of LBP and lumbar spine OA with hypermobility (Beighton $\geq$4) and each individual Beighton maneuver were estimated using separate logistic regression models, controlling for gender, race, age, body mass index (BMI), and history of low back injury. Interactions were examined between hypermobility and each covariate ($p<0.10$ considered statistically significant).
**Results:** Participant characteristics were: mean age 66 years (standard deviation [SD]±10), mean BMI 31 (SD±7) kg/m$^2$, 65% women, 33% African American, 2% low back injury, 6% hypermobility, 40% LBP, 59% rOA, and 25% sxOA. Adjusted results are summarized in the Table. Although not statistically significant, the adjusted odds of rOA were 18% lower among participants with vs. without hypermobility, while the odds of LBP and sxOA were 30% and 20% higher, respectively. Fifth finger dorsiflexion was inversely associated with LBP (35% lower odds) and sxOA (21% lower odds). The elbow maneuver was positively associated with LBP (41% higher odds), but inversely associated with rOA (28%); a similar, but not statistically significant, pattern was seen for the knee maneuver. The trunk flexion maneuver was inversely associated with LBP, rOA, and sxOA. No interactions of hypermobility and covariates were noted.

**Table. Adjusted* odds ratios (aOR) and 95% confidence intervals (CI) for association of hypermobility and lumbar spine outcomes.**

| | Lumbar Spine Outcome | | |
|---|---|---|---|
| **Hypermobility Measure** | Back Pain | Radiographic Osteoarthritis | Symptomatic Osteoarthritis |
| | aOR (95% CI) | aOR (95% CI) | aOR (95% CI) |
| Beighton Score, ≥4 / <4 | 1.30 (0.89, 1.90) | 0.82 (0.56, 1.22) | 1.20 (0.78, 1.84) |
| Fifth finger dorsiflexion, yes/no | 0.65 (0.54, 0.79) | 1.17 (0.96, 1.43) | 0.79 (0.63, 0.98) |
| Thumb apposition, yes/no | 0.80 (0.42, 1.52) | 0.88 (0.46, 1.66) | 0.86 (0.41, 1.84) |
| Elbow hyperextension, yes/no | 1.41 (1.05, 1.90) | 0.72 (0.53, 0.98) | 1.20 (0.86, 1.68) |
| Knee hyperextension, yes/no | 1.29 (0.79, 2.09) | 0.85 (0.52, 1.39) | 1.28 (0.75, 2.18) |
| Trunk flexion, yes/no | 0.38 (0.23, 0.63) | 0.67 (0.43, 1.03) | 0.38 (0.20, 0.73) |

*Adjusted for age, gender, race, low back injury, and body mass index

**Conclusions:** Joint hypermobility (specifically elbow and knee maneuvers) appears to be positively associated with LBP but inversely related to lumbar spine rOA. The trunk maneuver may reflect the musculotendinous (hamstring) flexibility more than ligamentous laxity, suggesting that greater hamstring flexibility is linked to a reduced occurrence of LBP and lumbar spine OA. Longitudinal studies may elucidate the role of joint hypermobility in lumbar spine outcomes.

## Education

FRI0599 **CLINICIAN TRAINING IN MOTIVATIONAL COMMUNICATION SKILLS: THE IMPACT OF THE LANGUAGE OF CHANGE PROGRAM AMONG RHEUMATOLOGISTS FROM ACROSS CANADA**

K. Lavoie[1,2,3,4], M. Bell[5,6], T. Taylor[7], R. Arendse[8], M. Saum[9], D. Faucher[9], M. Shawi[9], M. Camerlain[10]. *[1]Université de Quebec á Montréal; [2]Université de Montréal; [3]Hôpital du Sacré-Coeur de Montréal; [4]Montreal Behavioural Medicine Centre, Montreal; [5]Sunnybrook Health Sciences Centre; [6]University of Toronto, Toronto; [7]Dalhousie University, Halifax; [8]University of Saskatchewan, Saskatoon; [9]Janssen, Toronto; [10]Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, Canada*

**Background:** Motivational communication (MC) is an evidenced-based communication style designed to enhance patients' intrinsic motivation to engage in a healthy lifestyle and adhere to treatment. Due to its efficacy and popularity, the demand for physician training has risen markedly over the past decade. Despite the widespread dissemination of these programs, there is little empirical data on the extent to which they impact physician knowledge and attitudes.
**Objectives:** This study assessed the impact of a 1.5 hour introduction to MC workshop (phase I of Language of Change) on MC attitudes among rheumatologists.
**Methods:** This was a single group pre-post intervention trial. The MC training program, called *The Language of Change*, was developed by rheumatology and behavior change experts. The program being assessed consisted of 1 live workshop (a 1.5 hour introductory session) delivered by an MC expert alongside a dermatologist/nurse, to 53 rheumatologists from across Canada. Participants completed a battery of validated questionnaires measuring MC motivation, self-efficacy, outcome expectancies, and short term (30 day) intention to change, at baseline and after the session. T-tests were conducted to assess the effects of the introductory workshop on each questionnaire.
**Results:** Analyses revealed significant post introductory workshop effects on motivation to use MC (+.87, $p<.0001$), MC self-efficacy (+1.37, $p<.001$), outcome expectancies (including perceived program usefulness [+.73, $p<.002$], pertinence [+.65, $p<.001$], effectiveness [+.94, $p<.0001$], potential to benefit physicians [+.72, $p<.0001$] and potential to benefit patients {+.82, $p<.0001$]), and short term (30 day) intention to change (pre=42%, post=66%).
**Conclusions:** This study indicates that a 1.5 hour introductory workshop on MC significantly increased motivation to use MC and MC self-efficacy, and had a uniformly positive impact on outcome expectancies and intention to use MC in practice. Results suggest that even low doses of MC training may impact healthcare professional attitudes and intention to change.

FRI0600 **FEARS AND BELIEFS OF PEOPLE LIVING WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS OR PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW**

P.E. Palominos[1], L. Gossec[2], N. Andrade[1], A. Gasparin[1], F. Igansi[1], R. Chakr[1], R. Xavier[1]. *[1]Rheumatology Department, Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [2]Rheumatology Department, Pitié Salpêtrière Hospital, Paris, France*

**Background:** Despite the growing interest of rheumatologists into the patients' perspective in the last decade (1) and the wide use of patient-reported outcomes in the assessment of Rheumatoid Arthritis (RA) (2,3) and Spondyloarthritis (SpA) (4), the main fears and beliefs of these group of patients and their consequences on treatment outcomes are unclear.
**Objectives:** To assess the main fears and beliefs of people with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) from different continents and their effect on treatment outcomes;
**Methods:** A systematic literature review was conducted in Pubmed/Medline. All original articles published up to December 2014, reporting fears and/or beliefs of adult patients with RA, AS or PsA were analyzed. Fears and beliefs were collected by two independent researchers and grouped in categories.
**Results:** Of the 293 publications identified, 70 were analyzed, corresponding to 19,161 RA, 1,693 AS/Spondyloarthritis and 202 PsA patients. No article reported fears and/or beliefs of people living in Latin America, Africa or Oceania. Fears were reported in 19 articles of which 9 (47.4%) reported fears related to pharmacological therapy. Beliefs were reported in 59 articles: beliefs about the rheumatic disorder were found to affect the impact of disease (in N=24 articles, 40.7% of articles assessing beliefs), beliefs about therapy were sometimes linked to adherence (N=11, 18.6%) and beliefs about cause of disease influenced coping strategies and adherence (N=5, 8.5%). Beliefs mediated the emotional impact of disease in RA (N=9, 15.2%) and influenced functioning in AS and RA (N=4, 6.8%).
**Conclusions:** Patients' beliefs are linked to impact of disease and non-adherence

in RA, AS and PsA. Further research is needed on fears of PsA and AS patients and on fears/ beliefs of patients living outside Europe and North America.

## FRI0601 ROLE OF GROUP LEARNING TO IMPROVE REPRODUCIBILTY OF DAS-28 AMONGST HEALTHCARE PROFESSIONALS

S.S. Majeed[1], E.M. Clark[1,2] on behalf of Rheumatology Dept, North Bristol NHS Trust. *[1]Rheumatology, North Bristol NHS Trust; [2]University of Bristol, Bristol, United Kingdom*

**Background:** Interprofessional group learning is a valuable educational tool in multidisciplinary settings as it helps improve clinical care and encourages professionals to learn with, from and about each other (CAIPE, 2006). Disease activity in rheumatoid arthritis is assessed using the DAS28 scoring system; and changes in treatment are influenced by the result of the DAS28 score. In our Rheumatology Department DAS28 assessment is carried out by many members of our multidisciplinary team including doctors, nurses and pharmacists. This necessitates checking of, and ensuring reproducibility of DAS28 scoring amongst our team, to enable appropriate management of patients.

**Objectives:** We utilised educational theory to organise a group learning exercise to assess reproducibility of DAS-28 score and identify areas for improvement amongst multidisciplinary rheumatology healthcare professionals, based at a large general hospital in South West England.

**Methods:** Four patients with rheumatoid arthritis were selected for the exercise based on availability. All members of the multidisciplinary team assessed the patients using the DAS28. 13 professionals participated in this activity: six rheumatology consultants (two academics), three rheumatology specialist registrars, three rheumatology specialist nurses and one rheumatology specialist pharmacist. Median scores and coefficient of variation expressed as a percentage (CV, calculated by standard deviation/mean x 100) were calculated for each patients overall DAS28 score and the constituent parts. CRP levels were fixed for each patient.

**Results:**

| Patient | Tender Joint Count Median (CV) | Swollen Joint Count Median (CV) | VAS Median (CV) | DAS-28 Median (CV) |
|---|---|---|---|---|
| 1 | 17.5 (19.2) | 5.5 (42.0) | 75.5 (5.5) | 5.85 (5.5) |
| 2 | 6.0 (39.8) | 1.5 (138.9) | 24.0 (5.4) | 3.21 (17.3) |
| 3 | 0 (143.0) | 3.0 (52.9) | 34.5 (69.1) | 2.36 (20.1) |
| 4 | 0 (128.7) | 2.0 (38.5) | 9.0 (15.1) | 3.09 (14.2) |

**Conclusions:** Reproducibility of overall DAS28 scores and its constituent parts were generally poor according to the CV. No differences in reproducibility were seen when stratifying by professional group. All subcomponents of the DAS28 showed equally poor reproducibility. This may have important clinical implications for patient care, particularly when deciding on treatment escalation. This interprofessional learning exercise, deliberately bringing together all members of the rheumatology multidisciplinary team, has enhanced learning for all by identifying the following points: (1) no professional group is "better" than another when assessing DAS28; (2) standardisation of how we ask about the VAS subcomponent will be introduced immediately; (3) tender joints are to be classed as ones with any tenderness from reasonable palpation; and (4) clinical judgement should be used when assessing rheumatoid disease activity.

## FRI0602 BELIEFS ABOUT SUBCUTANEOUS BIOLOGICAL AND ORAL MEDICATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS. ARCO STUDY

C. Marras Fernandez-Cid[1], I. Monteagudo[2], J. Calvo-Alén[3], E. Raya Alvarez[4], T.R. Vázquez-Rodríguez[5], J.V. Tovar Beltrán[6], C. Díaz-Miguel Pérez[7], J.M. Ruiz Martín[8], R. Cáliz Cáliz[9], L. Cea-Calvo[10], S. Fernández[10], S. Martínez Pardo[11], G. Salvador Alarcón[11]. *[1]HUVA, Murcia; [2]HGU Gregorio Marañón, Madrid; [3]H. Txagorritxu, Araba; [4]HU San Cecilio, Granada; [5]HU Lucus Agusti, Lugo; [6]GHU Elche, Elche; [7]HU Ramón y Cajal, Madrid; [8]H. de Viladecans, Barcelona; [9]HU Granada, Granada; [10]Medical Affairs, Merk Sharp & Dohme, Madrid; [11]HU Mutua Terrassa, Barcelona, Spain*

**Background:** Patients' perception on the usefulness of their medicines is important to implement actions that increment confidence and minimize concerns.

**Objectives:** To describe the beliefs that patients with rheumatoid arthritis (RA) treated with subcutaneous (SC) biological drugs have on their oral and SC biological medications for RA.

**Methods:** ARCO is a cross-sectional study in RA patients >18 years-old on SC biological drugs from 42 Spanish hospitals. The beliefs on medication was assessed with the Spanish version of the Beliefs About Medicines Questionnaire (BMQ), obtaining their agreement with each statement through a Liker scale from 1 (strongly disagree) to 5 (strongly agree). The BMQ score was obtained subtracting the "concerns subscale" score from that of the "necessity scale"

**Results:** 364 patients were included (mean age 54.9 years [SD 12.5]; 77.5% women, median RA duration 7.8 years). The mean scores of the BMQ for the oral and SC biological medication were 5.60 (SD 5.03) and 5.22 (SD 5.43) respectively; the median for both was 5 (p = NS). For the oral medication, 84.4% of the patients scored higher in the necessity subscale than in the concerns subscale, whereas for the SC biological the percentage was 78.3%. Some 73.3% scored necessity > concerns for both drugs, whilst 4.4% scored necessity < concerns for. In the necessity subscale, the highest score for the oral medications was "My health, at present, depends on my medicines" and for SC "My medicines protect me from becoming worse" (table). In the concerns subscale, the highest score was "I sometimes worry about the long-term effects of my medicines" for both groups of drugs (table).

Percentage who responded "agree" or "strongly agree" to the BMQ statements (%)

| | Oral | SC biological |
|---|---|---|
| Necessity scale | | |
| My health, at present, depends on my medicines | 92.2 | 87.5 |
| My life would be impossible without my medicines | 86.5 | 76.6 |
| Without my medicines I would become very ill | 89.3 | 78.8 |
| My health in the future will depend on my medicines | 82.6 | 69.9 |
| My medicines protect me from becoming worse | 88.4 | 88.9 |
| Concerns scale | | |
| Having to take medicines worries me | 58.3 | 48.8 |
| I sometimes worry about the long term effects of my medicines | 77.5 | 73.0 |
| My medicines is mystery to me | 43.4 | 50.2 |
| My medicines disrupts my life | 24.2 | 19.8 |
| I sometimes worry about becoming too dependent on my medicines | 50.6 | 45.6 |

**Conclusions:** RA patients show strong positive beliefs about the necessity of their medicines for RA, although a substantial percentage also describes concerns. The beliefs are similar for oral and SC biological medicines. Rheumatologists should contribute to improve aspects related to specific patients' concerns.

**Acknowledgement:** The ARCO study was funded by Merck Sharp & Dohme Spain.

**Disclosure of Interest:** None declared

## FRI0603 PATIENTS' PRIORITIZATION OF PATIENT-CENTERED EDUCATION AND RESEARCH TOPICS IN RHEUMATIC DISEASE

W.B. Nowell[1], S. Ginsberg[1], P. Higginbotham[2], B. Johnson[2], R. O'Beirne[2], M. Safford[2], J. Willig[2], J.R. Curtis[2]. *[1]Global Healthy Living Foundation, Upper Nyack; [2]University of Alabama at Birmingham, Birmingham, United States*

**Background:** While healthcare provider priorities often coalesce around clinical concerns, little has been done to explore the most pressing educational concerns among rheumatic disease patients.

**Objectives:** To identify healthcare education topics most important to patients with inflammatory arthritis and other rheumatic conditions.

**Methods:** Participants were recruited from within the membership registry of the rheumatology patient community, CreakyJoints, to participate in one of six nominal groups held in June 2015. Each of the six groups generated a set of educational topics or questions ("items"), and then rank-ordered them within each focus group. Items were aggregated into common topic groups, redundant items de-duplicated, and then categorized into common topic groups and themes. Based on the qualitative work, a survey describing items from all nominal groups was created and deployed more widely to the CreakyJoints membership. Demographics and other disease-related features were captured.

**Results:** From the nominal groups, 8 educational themes emerged that were related to 28 unique educational topics (see Table 1). Overall, "Lifestyle changes

and patient environment modifications" was the most valued theme, receiving 14% of votes. Medication data (drug dosing, interactions, performance, etc.), physician selection, and knowledge of disease/disease progression were also strongly emphasized at 12%, 11%, and 10%, respectively. Themes of least interest included friend/family/community support, financial concerns (including insurance), and social interactions, with nominal group vote percentages of 3%, 2%, and 1%, respectively.

Among 400 participants who completed the survey, mean (SD) age was 55 (11.5) years with 86% being women and 82% being white. Participant health conditions (not mutually exclusive) included rheumatoid arthritis (74%), osteoarthritis (45%), fibromyalgia (26%), osteoporosis (18%), psoriatic arthritis (8%), lupus (5%), and ankylosing spondylitis (5%). The top 10 items rated as "Extremely Important" by a majority of patients were: How arthritis affects more than just your joints (86%); What are the signs that the medication is not working (84%); Importance of knowing about how the disease will progress, even if the news is bad (83%); What are the side effects of available drugs, and how do the drugs interact with each other (82%); What are the available medications and treatments for your case (80%); How to understand the results of tests used to monitor your condition (79%); How to find the right rheumatologist (76%); How to take an active role in decisions about your care (76%); How your life will change as your disease progresses (74%); and How to speak up and help manage your care when your perspective is different from your doctor's (73%).

**Table 1:** Top-ranked rheumatic disease educational concern themes, topic group and items.

| Theme | Topic Group Example | Item Example |
|---|---|---|
| Lifestyle Changes & Patient Environment Modifications | Dietary Choices | What would be good food alternatives for reducing flares |
| Medication Data (Dosing, Effects, Limitations) | Drug Effects | Drugs take a couple of months to work; don't expect an immediate fix |
| Physician Selection | Finding the Right Specialist | Make sure to have a proper diagnosis by a rheumatologist |
| Knowledge of Disease & Disease Progression | Disease Progression | What to look for that indicates the condition is getting worse |
| Reliable Resources | Individual Research Resources | It is important to educate yourself and do your own research |
| Asking for Help & Extent of Limitations | Asking for Help | Don't be afraid to ask for help when you are having a flare |
| Coping | Emotional | Dealing with the mental and emotional problems that come with the condition |
| Personalized Disease needs Personalized Treatment | Individualized Treatment Options | What are all medications/treatments available to you for your case in particular |
| Alternative Treatments | Alternative Treatments | What alternative therapies that might be helpful (i.e. acupuncture and biofeedback) |
| Self-Advocation and Voicing Concerns | Self-Advocation | Be your own advocate in your disease; trust your instincts and speak up |

**Conclusions:** Patients with rheumatic diseases are concerned about a variety of topics, which include lifestyle changes/patient environment modifications, medication data, and physician choice. Patient-centered research should maximally respond to addressing questions of importance to patients, and this survey is a first step in identifying and prioritizing the topics that matter most to patients.

## FRI0604 THE EFFECT OF AN EDUCATIONAL INTERVENTION BASED ON CLINICAL SIMULATION IN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS DIAGNOSIS BY GENERAL PRACTITIONERS: A RANDOMIZED CLINICAL TRIAL

S.A. Mora Alfonso[1], D.G. Fernández[1], L.F. Sastre[2] on behalf of Hospital Universitario de la Samaritana. *[1]Rheumatology; [2]Society for Research, Education and Care in Rheumatic Diseases, INVEDER SAS. Bogotá, Colombia, Bogota, Colombia*

**Background:** Clinical simulation is a teaching strategy generally used in the medical field that has not been used in rheumatology education yet. This innovative idea will enable the basis of models designed hands-size providing a very accurate way to study the most important semiological findings, such those of the rheumatoid arthritis and its main distinction diagnoses (osteoarthritis - OA); the most challenging to evaluate among general practitioners. Clinical simulation models are protected under the patent certificate number 50152 of the Superintendency Industry and Trade of the Republic of Colombia

**Objectives:** To evaluate the effectiveness of a rheumatology educational tool based on clinical simulation designed for general practitioners, professionals who will improve the diagnosis of rheumatoid arthritis and osteoarthritis

**Methods:** Randomized clinical trial. The research subjects were randomly assigned to two different groups: The experimental group, and the control group. A) The experimental group: educational intervention in rheumatoid arthritis based on clinical simulation, B) Control group: educational intervention on basic aspects of diagnosis and treatment of osteoporosis. After four weeks of the educational intervention, members of the two groups faced an evaluation process that included four cases with real patients (two patients with rheumatoid arthritis and two patients with osteoarthritis), two cases with two clinical simulation models (a case of rheumatoid arthritis and an osteoarthritis case), and six virtual clinical cases (three rheumatoid arthritis cases and three osteoarthritis cases). At that point participants ascertained the detected semiological findings, establishing a complete diagnosis very helpful in order to corroborate the diagnosis if it is required.

**Results:** 160 physicians (80 from the active group and 80 from the control group), 89 were women (56%). The average age was 35.0 years (standard deviation 7.7 years). Clinical stimulation was considered to work successfully when a practitioner diagnosed accurately at least 10 out of 12 cases submitted under his examination. A difference of 81.3% (confidence interval 95% 72–90%) was found successfully, amount statistically significant in favor of the active group (88.8% vs 7.5%) ($p = <0.001$). A greater number of hits were found in the detection of the semiological findings in the active group compared with the control ($p<0.001$)

**Conclusions:** The present study showed the effectiveness of an educational intervention based on clinical simulation to improve the diagnostic approach in rheumatoid arthritis and osteoarthritis; this innovative idea opens the gate for a new horizon in the teaching of modern rheumatology. Moreover, the clinical simulation is a meaningful benefit for patients representing an improvement in the quality and use of health system resources.

**Disclosure of Interest:** None declared

## FRI0605 EFFECT OF AN EDUCATIONAL INTERVENTION BASED ON CLINICAL SIMULATION IN THE DIAGNOSIS OF SPONDYLOARTHRITIS (SPA) FROM GENERAL PRACTITIONERS, A STUDY BEFORE AND AFTER

S.A. Mora Alfonso[1], D.G. Fernández Ávila[2], L.F. Sastre[2]. *[1]Rheumatology; [2]Sociedad para la Investigación, atención y educación en enfermedades reumáticas INVEDER SAS. Bogotá, Colombia, bogota, Colombia*

**Background:** This paper wants to quantify the rate of improvement in the diagnosis of SPA among a group of general practitioners who receive an educational intervention based on clinical simulation in the rheumatology field

**Methods:** Intervention study before and after

**Results:** 102 general practitioners received an educational intervention based on clinical simulation. The topic of this educational intervention was Spondyloarthritis. A workshop that includes clinical simulation models of feet, fingers and a mannequin created for this purpose was created, based on the strategy of problem-based learning. The workshop lasted 5 hours, it was divided into two parts: the first was about the of the clinical approach of joint pain and lumbar pain diagnosis and relevant aspects of SPA. In this first part, besides the theoretical support for the diagnosis of SPA, participants viewed pictures of patients with spondylitis and peripheral involvement (enthesitis, dactylitis, arthritis) seeking to achieve awareness of their sense of sight with respect to the diagnostic approach to patients with suspected SPA and sought to strengthen the logical approach to be implemented when approaching this type of patients. The second part focused on clinical cases applied to clinical simulation models, applying the knowledge acquired during the theoretical phase. Participants made a several stations where they where they could appreciate for periods of 15 minutes each simulators of 3 feet, 6 simulators simulated fingers and a mannequin where they can identify entheses and psoriasis lesions, improving visual and tactile sensitivity in each semilogic findings for tehe diagnosis of SPA. The participants filled out an pre and post test, which included clinical cases with simulators and photographs of hands and feet of patients with suspected EAS. 102 participants (59% women), average age 32.3 years (SD 7.1). Improvement in the correct diagnosis of EAS of 47% (the correct diagnosis increased from 39% to 86%). Paraclinical application in the cases presented decreased significantly, from an average of 8–4 paraclinical requested by each clinical case presented. 98.5% of participants would recommend to other colleagues to make this workshop. 97.7% believe that this educational intervention will improve the diagnostic approach to patients with suspected SPA

**Conclusions:** The usefulness of clinical simulation in the field of rheumatology has been shown, given by an improvement in the diagnostic sensitivity for the diagnosis of EAS demonstrated

**Disclosure of Interest:** None declared

## FRI0606 THE METHOD USED TO SET PASS MARKS IN AN OBJECTIVE STRUCTURED CLINICAL EXAMINATION (OSCE) DETERMINES THE OVERALL PERFORMANCE OF CANDIDATES DURING AN ACCREDITATION PROCESS

V. Pascual Ramos, G. Medrano Ramírez, E. Solís Vallejo, A. Bernard Medina, D. Flores Alvarado, M. Portela Hernández, M. Maldonado Velázquez, L. Jara Quezada, L. Amezcua Guerra, J. López Zepeda, E. Álvarez Hernández, M. Saavedra Salinas, C. Arce Salinas on behalf of Mexican Accreditation Council for Rheumatology (MACR). *Consejo Mexicano de Reumatología, Distrito Federal, Mexico*

**Background:** The assessment of clinical competences during a national accreditation is a high-stakes process, and the pass mark needs to be settled through

robust methods [1]. Since 2012, the MACR certifies trainees in Rheumatology (TR) using both written (multiple-choice questions –MCQ- test) and clinical (OSCE) examinations [2]. For 2013 and 2014 accreditations, OSCE pass mark was set by absolute criterion referencing (APM), while a global rating of borderline performance (BPM) was added for the 2015 process.

**Objectives:** To compare the performance of TR during an OSCE according to APM and BPM, and to examine whether correlations between MCQ and OSCE evaluations are affected by OSCE pass mark selection.

**Methods:** Forty-three TR presented a MCQ test and an OSCE circuit including 15 stations. Each station (8 minutes long) was assigned to an evaluator who rated candidate performance as "fail", "borderline" or "above range" using a Likert scale and additionally filled a tailored-checklist. Mean checklist scores (maximum score of 10) from those TR rated as borderline was defined as the BPM for each station. Average of all BPM defined the overall OSCE BPM. A composite OSCE score was obtained for each candidate. Descriptive statistics was used and correlations were examined using Pearson's test and Mann Whitney U test.

**Results:** For MCQ test, pass mark was set by criterion as >5.7; OSCE-APM was defined as >6 and composite OSCE-BPM was calculated as >7.4. TR's performance varied depending on the pass mark selected. Mean MCQ test score was 6.6±0.6 with 5 candidates receiving a failing score; mean composite OSCE score was 7.4±0.6 and no candidate received a failing score according to CPM, while 21 (48.8%) received a failing score according to BPM.

The BPM score widely varied among stations, ranging from 4.5 to 9.5; candidate's performance also varied across stations and within each station depending on the pass mark; station 2 showed the lowest percentage of TR with APM-passing score (26%) or BPM-passing score (42%); the opposite figure was true regarding station 10 who showed the highest percentage of TR with a passing score (100% and 72%, respectively).

MCQ test score correlated with composite OSCE score (r=0.67, P=0.001). Those TR who obtained a passing score according to BPM had higher MCQ scores than those with a failing OSCE score: (median, Q25-Q75) 7.1 (6.4–7.3) vs. 6.3 (5.9–6.7), p=0.001. There were more candidates with a passing OSCE-BPM score distributed in the upper MCQ quartiles than TR with a failing OSCE score (P<0.001).

**Conclusions:** The way to set a pass mark for an OSCE strongly impacts the performance of TR during a national accreditation process but poorly affects correlations between clinical and written examinations.

## FRI0607 RHEUMATOLOGY TRAINING IN INDIA – A REFLECTION AND COMPARISON WITH UNITED KINGDOM

P. Das[1], A. Moorthy[2], B. Dharmanand[3]. *[1]Rheumatology, Kettering general hospital, Kettering; [2]Rheumatology, University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [3]Rheumatology, Sakra World hospital, Bangalore, India*

**Background:** Indian subcontinent is one of the largest growing economy in the world.The burden of rheumatic musculoskeletal disease among Indian population is overwhelmimg.Clearly,there is a demand for specialist rheumatology work force in India.In this era of biologics and biosimilars,rheumatology is an attractive speciality among aspirant doctors.Our previous observational studies have explored and identified the strength and weakness in the rheumatology training programme in UK,Canada[1] and South Asian countries[2]. We aim to explore the perception of rheumatology training among specialist and current trainees in India,and compare with UK training.

**Objectives:** 1.To explore the perception of rheumatology training in India.

2.To identify the strength and weakness and the areas of improvement in training programme in India.

**Methods:** This is an observational questionnaire based study. A pilot study was conducted with 32 questions during APLAR conference 2015 in India. The re-designed questionnaire was circulated electronically to rheumatology trainees across India through their training leads. Our survey was directed towards exploration of rheumatology curriculum including content, training and research opportunities and job prospect. The results were analysed through smart survey.

**Results:** Total respondents were n=77, 16% (40/240)from UK and 49% (37/75) from India. There were female predominance (55%) in UK and male predominance (71%) in India. Noted a wide variation in application process, structure and duration of training. In India, training duration is 6 years (3 yrs in GIM and 3 yrs in rheumatology), whereas it is 5 years for combined and 4 years for pure rheumatology in UK.The national rheumatology curriculum was designed by JRCPTB in UK, but multiple regional syllabus were followed in India with lack of adherence to national curriculum.

Trainees from both countries received weekly institutional teaching. UK trainees received structured supervision for joint injections, whereas Indian trainees received more training for crystal identification and immunological studies. Fewer cross speciality clinics were practised in India. Less exposure to MSK ultrasound skills was noted among the trainees, however the concept of MSK Ultrasound was clearly evolving in India.

Postgraduate research programmes and opportunities were available in UK, whereas Indian trainees need to complete a formal supervised dissertation project as a part of postgraduate qualification.

Mandatory training for generic skills were lacking in India. Training records were maintained electronically in UK and by paper log book in India. Although speciality exit exam was mandatory in both countries, the format was different including MCQ based in UK and theoretical and practical based in UK.

**Conclusions:** 1. This is the first study comparing rheumatology training between UK and India.

2. Lack of structured Curriculum and homogenous rheumatology training exist in India.

3. Harmonisation of rheumatology training in India is essential, matched with developed nations.

## FRI0608 SIMULATION FOR JOINT INJECTION AND ASPIRATION. COLLABORATING OUR EXPERIENCES, WHAT HAVE WE LEARNT?

S. Shabbir[1], K. Shah[2], J. Mukherjee[3], M. Carby[4]. *[1]ST3 North West Thames; [2]CT2 North West Thames; [3]ST7 North West Thames; [4]Consultant Harefield Hospital, London, United Kingdom*

**Background:** We present a knee injection and aspiration course, with simulated rheumatology clinical scenarios targeting core medical trainees. Simulation should be a core part of the curriculum, providing a safe learning environment, as hands on rheumatology exposure is often limited.

**Objectives:** 1. To review and compare two different rheumatology practical teaching courses.

2. To highlight important rheumatology cases presenting on the acute medical take, and achieve the requirements on the core medical training curriculum.[1]

3. With training emphasis on service provision, to provide organised targeted teaching.[2]

**Methods:** Eight core medical trainees were recruited to a knee aspiration and injection course at a cardiothoracic specialist centre (no on-site rheumatology). There was a pre-course assessment, pre-course handout, followed by a practical demonstration on a knee manikin[3] by a competent teacher. Each trainee underwent assessement: Directly Observed Procedures – DOPs assessment. Pre- and post- course surveys evaluated confidence. Six months later, a second cohort of eight trainees were recruited, and the session was delivered by a rheumatology registrar. There was a brief lecture, followed by a demonstration. Trainees also underwent one-to-one assessment with SimMan® (scenarios: prosthetic joint septic arthritis and haemoptysis secondary to TB reactivation following anti-TNF treatment).

**Results:**

– Trainee experience prior to teaching: Cohort 1: 12.5% no experience. 37.5% seen but not attempted. 50% performed with supervision only. Cohort 2: 25% no experience. 37.5% seen but not attempted. 37.5% performed with supervision only.
– Confidence pre- and post teaching: Cohort 1: Initially only 40% had confidence in aspirating a knee joint. *Increased to 80%.* Cohort 2: Initially 34% had confidence in aspirating a knee joint. *Increased to 85%.*
– 100% trainees identified correct anatomical landmarks, proving that clinicians possess the knowledge but are limited by experience and resources.
– Outcomes were suprisingly largely unchanged despite involving a rheumatology registrar.

**Conclusions:** - Opportunities to gain practical experience are infrequent. This affects trainees rotating through multiple training centres. Trainee confidence is increased through simulation, however simple organised teaching sessions are currently not readily available.

– Limitations: Small cohorts, inconsistent outcomes due to two sessionsbeing delivered by different people. It is dfficult to directly compare the cohorts, as cohort 2 included SimMan®. However confidence was slightly increased with this, showing that simulation is an effective learning tool.
– This program may be targeted at rheumatology specialist trainees too.

## FRI0609 FIFTEEN-YEAR TREND IN INFORMATION ON THE INTERNET FOR PATIENTS WITH RHEUMATOID ARTHRITIS: EVOLVING, BUT WITH OPPORTUNITIES FOR IMPROVEMENT

J.D. Castillo-Ortiz [1], J.D.J. Valdivia-Nuno [1], A. Ramirez-Gomez [1], J.J. Castaneda-Sanchez [1], J.M. Sanchez-Gonzalez [2], C. Ramos-Remus [1,2].
[1] *Unidad de Investigacion en Enfermedades Cronico-Degenerativas;*
[2] *Vicerrectoria Academica, Universidad Autonoma de Guadalajara, Guadalajara, Mexico*

**Background:** Rheumatoid arthritis (RA) may lasts for decades, so patient education is very important. There has been an increase in RA patients seeking information on the Internet during the last 15 years.
**Objectives:** a) To assess the content, authorship, scope, readability and quality of the information currently available on the Internet in relation to RA; b) To compare it with a report published in 2001 [1] (2001-referent study); c) To assess the current positioning of websites posted by universities, hospitals, and medical associations.
**Methods:** We recreated the method used for the 2001-referent study assessing information on the Internet using the phrase "rheumatoid arthritis" in WebCrawler. All websites and pages were critically assessed for relevance, scope, authorship, type of publication, and financial objectives. Differences between studies were considered significant if 95% confidence intervals did not overlap. Additionally, we added a Google search following the same method, with a particular assessment of Internet pages posted by medical institutions regarding content quality (DISCERN instrument), readability (Flesch-Kincaid Grade Level test), and accessibility (the order of appearance).
**Results:** The search returned 316 hits using WebCrawler (85% were considered relevant). There were significant differences between the current studies and the 2001-referent studies (WebCrawler). There were increases in information sites (82% vs. 36%) and RA-specific discussion pages (59% vs. 8%), and decreases in advertisements (2% vs. 48%) and alternative therapies (27% vs. 45%). Google searches had significantly lower relevance (58% vs. 85%), more news articles (18% vs. 7%), more "only RA discussed" pages (76% vs. 59%), and less "alternative therapy" pages (19% vs. 27%) when compared with WebCrawler. Concerning the content quality of Internet pages, 37% were rated as good and 36% unbiased. Among the first 300 hits, 30 (10%) were posted by medical institutions, 17 from the United States, five from the United Kingdom, four from Australia, and one each from Canada, Malaysia, Spain and the Netherlands. The Mayo Clinic appeared as the top result, the Arthritis Foundation (United States) 3rd, the National Institute of Arthritis and Musculoskeletal and Skin Diseases (United States) 7th, the American College of Rheumatology 8th, and the Arthritis Research (UK) in 14th position. Regarding readability, 7% of these Web pages required six years of schooling, 27% between seven and nine years, 27% between 10 and 12 years, and 40% 12 years of schooling or more.
**Conclusions:** It seems that information on the Internet has evolved in this fifteen-year period. Medical institutions are better positioned now. However, there are still areas for improvement, such as content quality, leadership from medical institutions, and readability of information.

## Genomics, genetic basis of disease and HLA/T cell recognition

### SAT0001 IDENTIFICATION OF SJÖGREN'S SYNDROME RISK LOCI NEAR TNFAIP3 AND PRDM1

C. Lessard[1,2], H. Li[1,2], J.A. Ice[1], I. Adrianto[1], A. Rasmussen[1], D.M. Lewis[2], L. Radfar[2], D.U. Stone[2], C.G. Montgomery[1], N.L. Rhodus[3], R.H. Scofield[1,2], A.D. Farris[1], R. Omdal[4], M. Wahren-Herlenius[5], I. Alevizos[6], T. Witte[7], R. Jonsson[8,9], M. Rischmueller[10,11], L. Ronnblom[12], X. Mariette[13], W.-F. Ng[14], G. Nordmark[12], K.L. Sivils[1,2] on behalf of UK Primary Sjögren's Syndrome Registry. *[1]Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation; [2]University of Oklahoma Health Sciences Center, Oklahoma City; [3]University of Minnesota School of Dentistry, Minneapolis, United States; [4]Stavanger University Hospital, Stavanger, Norway; [5]Karolinska Institutet, Stockholm, Sweden; [6]National Institute of Dental and Craniofacial Research, NIH, Bethesda, United States; [7]Hannover Medical School, Hannover, Germany; [8]Haukeland University Hospital; [9]University of Bergen, Bergen, Norway; [10]The Queen Elizabeth Hospital; [11]The University of Adelaide, Adelaide, Australia; [12]Uppsala University, Uppsala, Sweden; [13]Hopitaux Universitaires Paris-Sud, Paris, France; [14]Newcastle University, Newcastle upon Tyne, United Kingdom*

**Background:** Sjögren's syndrome (SS) is a complex autoimmune disease with both environmental and genetic factors playing important roles in its etiology.
**Objectives:** The goal of this study was to replicate 8 suggestive loci that failed to exceed the genome-wide significance (GWS) threshold of 5x10E-8 in our previously published work: *TNFAIP3*, *PTTG1*, *PRDM1*, *DGKQ*, *FCGR2A*, *IRAK1BP1*, *ITSN2*, and *PHIP*.
**Methods:** Our previous study included 1638 SS cases and 6754 population controls. In the current study, we genotyped an additional 282 SS cases and 2576 population controls yielding a total of 1920 SS cases and 9330 controls. Analysis was done using logistic regression accounting for ancestry and gender.
**Results:** Two regions exceeded the GWS threshold. Association has been previously established with SS to a risk haplotype spanning the *TNFAIP3* coding region described in lupus; however, we identified a novel independent effect ~230kb 5' of *TNFAIP3* (rs6933404 $P_{meta}$=6.85x10E-9, OR=1.28) originally described in rheumatoid arthritis. Association was observed for the haplotype spanning the *TNFAIP3* coding region peaking at rs58721818 (P=4.77x10E-4), which is not correlated with rs6933404 ($r^2$=0.02; D'=0.49). Bioinformatics data provided limited support that rs6933404 is the functional variant in this region; however, another variant on this haplotype also surpassing GWS, rs6927172, modifies 8 transcription factor binding sites, and is located within an enhancer element in $CD4^+CD25^-IL17^+$ PMA-Ionomycin stimulated Th17 primary cells by the Epigenetics Road Map Project. A variant in the region of *PRDM1* also surpassed the GWS threshold (rs526531 $P_{meta}$=1.70x10E-8, OR=1.25). Two additional variants on this haplotype exceeded GWS, but no clear candidate functional variant has emerged based on bioinformatics data. Of the 6 remaining suggestive regions, *PTTG1*, *DGKQ*, and *FCGR2A* continue trending towards GWS.
**Conclusions:** These data now establish 2 new SS risk loci, *TNFAIP3* and *PRDM1*. *TNFAIP3*, which codes for the protein A20, is a negative regulator of NF-kB. *PRDM1*, which codes for the protein BLIMP1, is a transcription factor that regulates interferon-beta locus and plasma cell differentiation. Additional studies are needed to determine how these association signals function in the human genome and contribute to SS etiology.

### SAT0002 SPECIFIC PREMATURE EPIGENETIC AGING OF CARTILAGE IN OSTEOARTHRITIS

A. Gonzalez[1], L. Vidal-Bralo[1], Y. Lopez-Golan[1], A. Mera-Varela[1], I. Rego-Perez[2], S. Horvath[3], Y. Zhang[4], Á. del Real[5], G. Zhai[4], F.J. Blanco[2], J.A. Riancho[5], J.J. Gomez-Reino[1]. *[1]Instituto Investigacion Sanitaria-H Clinico U de Santiago, Santiago de Compostela; [2]INIBIC-Complejo H U A Coruña, A Coruña, Spain; [3]David Geffen School of Medicine, U of California Los Angeles, Los Angeles, United States; [4]Faculty of Medicine, Memorial U of Newfoundland, St. John's, Canada; [5]H U M Valdecilla-IDIVAL, U de Cantabria, Santander, Spain*

**Background:** Accelerated aging may be a component of osteoarthritis (OA) as shown by changes observed at the level of cartilage (local) in multiple studies. Systemic changes of biological aging have been much less studied, but accelerated telomere shortening (a biomarker of biological aging) has been described in the blood of patients with hand OA (1). In addition, some studies report increases in age-related comorbidities, frailty and mortality in patients with OA, which are consistent with sytemic premature aging. The recent discovery of an epigenetic biomarker of biological age consisting in DNA methylation age measures (DmAM) provides a new opportunity to address these questions.
**Objectives:** We aimed to explore the local and the systemic components of biological aging in OA using epigenetic DmAM biomarkers.
**Methods:** Three tissues were investigated: blood with 890 samples (182 controls without OA, 206 clinical hand OA, 229 severe knee OA and 273 severe hip OA), bone from femoral heads (45 controls without OA and 33 severe hip OA) and cartilage from tibial plateau or femoral heads (31 controls without OA and 36 severe OA). Two DmAM were used: a novel DmAM based on 8 CpG selected from previous work (2) and analyzed by quantitative minisequencing for blood; and the multi-tissue age estimator by Horvath (3), which is based on 353 CpGs analyzed with Illumina Methylation arrays, for bone and cartilage. Accuracy of the 8 CpG DmAM was evaluated with correlation and mean absolute difference (MAD) to age. Differences in DmAM (ΔDmAM) between OA patients and controls were evaluated with ANOVA adjusting for age and sex.
**Results:** OA cartilage showed an accelerated epigenetic aging of 3.7 years in relation with cartilage from controls without OA (Table 1). By contrast, no significant difference was observed in bone from OA patients (Table 1).
The new DmAM for blood based on 8 CpG was accurate as shown in data sets from controls, two from previous studies and the 182 controls without OA from the current study ($R^2 \geq 0.52$, $p < 10^{-16}$, MAD≤7.3 years). Therefore, it was applied to compare the controls without OA with the OA patients. None of the three groups of patients, hand OA, knee OA or hip OA, showed accelerated aging in blood (Table 1).

Table 1. Specific accelerated DmAM in OA cartilage compared with control cartilage

| Tissue | OA set | ΔDmAM (95% CI) | *P*-value |
|---|---|---|---|
| Cartilage | Knee/hip | 3.66 (1.06 to 6.26) | 0.008 |
| Bone | Hip | 0.04 (–1.80 to 1.87) | 0.34 |
| Blood | Hand | 0.01 (–1.10 to 1.12) | 0.98 |
| | Knee | 0.04 (–0.94 to 1.02) | 0.93 |
| | Hip | –0.72 (–1.70 to 0.25) | 0.11 |

**Conclusions:** OA cartilage showed premature biological (epigenetic) aging according to DNA methylation changes. This effect was cartilage-specific, excluding a systemic component, since it was not observed in bone tissue or in blood.

### SAT0003 THE ROLE OF 12/15-LIPOXYGENASE IN THE PATHOGENESIS OF OSTEOPOROSIS IN MICE

E. Jeziernicka[1], P. Bielecki[2,3], E. Sacharzewska[3,4], J. Niklinski[4], K. Kowal[3,5], O. Kowal-Bielecka[6]. *[1]Center for Osteoporosis; [2]Department of Otolaryngology, Provincial Specialist Hospital in Bialystok; [3]Department of Experimental Allergology and Immunology; [4]Center of Experimental Medicine; [5]Department of Allergology and Internal Medicine; [6]Department of Rheumatology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland*

**Background:** The pathogenesis of osteoporosis is complex and involves age-related factors and inflammation. 12/15-lipoxygenase (12/15-LOX) plays a key role in the regulation of inflammatory response and has been shown to contribute in bone metabolisms. However, the exact role of 12/15-LOX in the pathogenesis of osteoporosis is not clear.
**Objectives:** We aimed to investigate the impact of genetic deletion of *12/15-LOX* on 1) bone mineral density (BMD) and 2) serum balance between osteoprotegerin (OPG) and RANK ligand (RANKL), the two proteins known to be involved in bone remodelling, in mice.
**Methods:** The whole body BMD was measured using dual-energy X-ray absorptiometry (DEXA) bone densitometer equipped with software for evaluation of small animals (Hologic Discovery, USA) in 40-weeks old 12/15-LOX knockout mice and their age- and sex-matched wild-type littermates (C57Bl mice). Serum concentrations of OPG and RANKL were measured using commercially available ELISA kits (R&D Systems and USCN Life Science Inc., respectively).
**Results:** The mean whole body BMD was significantly lower in female 12/15-LOX knockout mice as compared with age-matched female C57Bl mice ($p < 0.01$). No significant differences were found in the mean whole body BMD of male 12/15-LOX knockout mice as compared with their age-matched male wild-type littermates.
No significant difference could be found in the mean serum concentration of OPG between 40-weeks old female 12/15-LOX knockout and C57Bl mice. However, in younger (8-weeks old) female C57Bl mice the mean serum concentration of OPG was significantly higher as compared with female 12/15-LOX knockout mice of the same age as well as compared with female 40-weeks old C57Bl or 12/15-LOX knockout animals ($p < 0.01$ for all comparisons).
There were no significant differences in the mean serum concentration of RANKL between female 12/15-LOX knockout mice and their wildtype littermates.
**Conclusions:** The results of our study indicate that 12/15-LOX plays a role in age-related osteoporosis in female mice, possibly through regulation of OPG-RANKL balance. Further studies should address the role of hormonal status on 12/15-LOX interactions with OPG-RANKL pathway.

## SAT0004 GENOMIC STRATIFICATION BY HLA-DRB4 EXPRESSION IDENTIFIES INNATE AND ADAPTIVE IMMUNE PATTERNS AS DIFFERENTIAL PREDICTORS OF RESPONSE TO METHOTREXATE IN RHEUMATOID ARTHRITIS

B.A. Stuhlmüller on behalf of Transcriptomics & Bioinformatics. *Rheumatology and Clinical Immunology, Charité University Hospital, Berlin, Germany*

**Background:** Variability of clinical course and response to therapy in RA suggests differences in molecular mechanisms depending on stage and sub-entity of the disease. Most dominant molecular discriminators are HLA-DR4 shared epitope (SE), and the status of rheumatoid factor (RF) and anti-citrullinated protein antibody (ACPA) development, all indicating subentities with influence on severity and outcome.
**Objectives:** Early RA prior to methotrexate (MTX) treatment was investigated to exclude major therapeutic influence. By comparing whole blood transcriptomes between subsequent responders and non-responders we aimed to unravel molecular mechanisms with influence on MTX outcome of RA.
**Methods:** Whole blood of 52 patients with early RA was obtained in the HITHARD and in the ArthroMark study. Clinical characteristics assessed at baseline and after 16 weeks included RF, ACPA, DAS28 and EULAR response for classification in good (GR), moderate (MR) and non-responders (NR). Total RNA was globin reduced and processed according to standard protocols for hybridization to U133 Plus 2.0 microarrays. Biostatistical methods included MAS5.0 and RMA algorithms with limma, lasso and Wilcoxon tests. For functional interpretation, expression of candidate genes was tested in various blood cell types and stimulation conditions using own and GEO reference transcriptomes. Marker selection was validated by qPCR with commercial primers and four different housekeeping genes.
**Results:** Different biostatistical approaches favored MAS5.0 algorithms for marker selection. Comparison between good and non-responders in unselected patients revealed insufficient discriminatory power. Generating different subgroups defined by gender, status of RF, ACPA, SE, HLA-DRB4 or DQA1 identified molecular patterns with a strong discrimination between GR and NR in HLA-DRB4$^-$ patients. All other subgroups did not improve pattern selection. In HLA-DRB4$^-$ patients, genes increased in GR were related to phagocytes and bone marrow activation whereas genes increased in NR were associated with lymphocyte activity. In HLA-DRB4$^+$ patients, patterns of adaptive immunity were again related to non-response but frequently combined also with innate patterns. Receiver-operating-characteristics (ROC) with the top 20 markers in HLA-DRB4$^-$ and DRB4$^+$ subgroups revealed AUC<0.96 and AUC<0.91 for response and AUC<0.98 and AUC<0.99 for non-response associated genes, respectively. Technical validation by qPCR with the 16 top candidates confirmed AUC-values up to 0.97 for prediction in the HLA-DRB4$^-$ group and reached AUC up to 0.89 in HLA-DRB4$^+$ patients.
**Conclusions:** Genetic stratification revealed transcriptional patterns that indicate different molecular pathomechanisms in RA depending on response to MTX therapy. Interestingly, the group responding to MTX was dominated by phagocyte but not lymphocyte activity, which may indicate an important contribution of innate triggers to the pathomechanisms in RA.

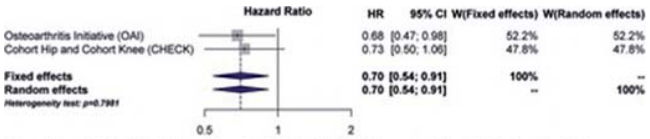
## SAT0005 A META-ANALYSIS AND A FUNCTIONAL STUDY WITH TRANSMITOCHONDRIAL CYBRIDS CONFIRM THE ROLE OF THE MTDNA HAPLOGROUPS IN THE DEVELOPMENT OF INCIDENT KNEE OSTEOARTHRITIS. DATA FROM CHECK AND OAI

I. Rego-Pérez[1], M. Fernández-Moreno[1], A. Soto-Hermida[1], M.E. Vázquez-Mosquera[1], E. Cortés-Pereira[1], S. Relaño[1], T. Hermida-Gómez[1], S. Pértega[2], N. Oreiro[1], C. Fernández-López[1], R. Garesse[3], F.J. Blanco[1].
*[1]Rheumatology; [2]Clinical epidemiology, Instituto de Investigación Biomédica de A Coruña, A Coruña; [3]Departamento de Bioquímica, Insittuto de Investigaciones Biomédicas Alberto Sols, Madrid, Spain*

**Background:** In the last years the study of the mitochondria in the context of osteoarthritis (OA) attracted much attention. In the present work we aim to analyze the role of the mtDNA haplogroups in the development of incident knee OA in well-characterized study cohorts
**Objectives:** To analyze the influence of the mtDNA haplogroups in the rate of incident knee OA in the prospective cohorts of CHECK and OAI and to perform functional analysis with transmitochondrial cybrids to explore the consequences of the mitochondrial background in the pathogenesis of Osteoarthritis
**Methods:** The influence of the haplogroups in the development of incident knee OA at eight years in 2579 subjects from the Osteoarthritis Initiative (OAI) and 635 subjects from the Cohort hip and Cohort knee (CHECK) was assessed. A subsequent meta-analysis was conducted to strengthen the association of these individual studies.
Transmitochondrial cybrids carrying the haplogroups J and H were constructed to study the influence of the mitochondrial background in different OA-related features.
**Results:** The haplogroup J significantly associates with a decreased risk of incident knee OA in subjects from the OAI (HR=0.680;95%CI=0.470–0.968;p<0.05) and CHECK (HR=0.728;95%CI=0.469–0.998;p<0.05). The subsequent meta-analysis including 3214 cases showed that the haplogroup J significantly associates with a lower risk of incident knee OA (HR=0.702;95%CI=0.541–0.912;p=0.008) (Figure 1).



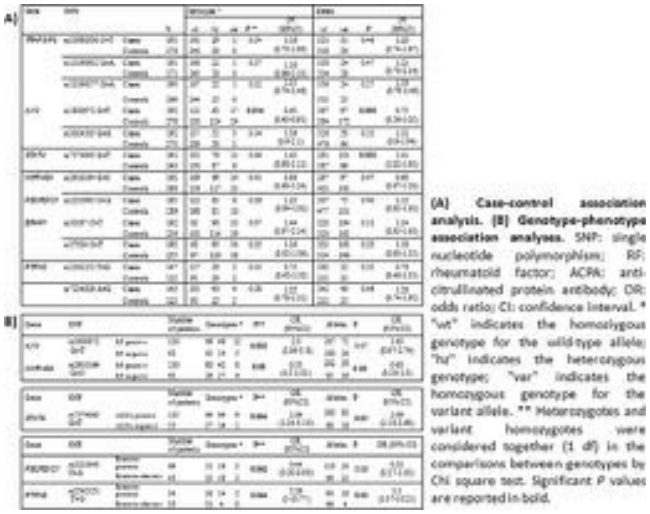


Figure1. Forest plot of individual associations involving the mtDNA haplogroup J and the risk of incident knee OA

Compared with the haplogroup H, haplogroup J shows a lower free radical production, specially peroxide/peroxynitrite (52.51±11.34 vs 41.26±7.48;p<0.05) and superoxide (8.58±3.0 vs 4.25±0.9;p<0.05), a higher cell survival under oxidative stress conditions (29.63±3.3 vs 56.45±7.36;p<0.05), a lower grade of apoptosis (7.35±3.78 vs 4.69±1.68;p<0.05) as well as a lower expression of the mitochondrially-related pro-apoptotic gene BBC3 (3.3-fold;p<0.05), a higher lactate production (64.22±10.76mg/dl vs 51.42±6.85mg/dl;p<0.05) and a lower expression of the mitochondrial biogenesis-related gene PGC1-α (2-fold;p<0.05)
**Conclusions:** The haplogroup J reduces the risk of incident knee OA. This mitochondrial variant constitute a protective phenotype against the development of OA, emerging as a powerful OA biomarker and even leading to the consideration of the mitochondrion as a potential therapeutic target in OA
**Acknowledgement:** We'd like to acknowledge to the participants of CHECK and OAI cohorts
**Disclosure of Interest:** None declared

## SAT0006 POLYMORPHISMS IN STAT4, IL10, PSORS1C1, PTPN2 AND MIR146A GENES ARE DIFFERENTLY ASSOCIATED WITH NEGATIVE PROGNOSTIC FACTORS IN ITALIAN PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS

P. Conigliaro[1], C. Perricone[2], C. Ciccacci[3], S. Rufini[3], P. Triggianese[1], C. Politi[3], A. Latini[3], G. Novelli[3], P. Borgiani[3], R. Perricone[1]. *[1]Clinic of Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata; [2]Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma; [3]Department of Biomedicine and Prevention, Genetics Section, University of Rome Tor Vergata, Rome, Italy*

**Background:** Rheumatoid Arthritis (RA) is a systemic autoimmune disease resulting in chronic inflammation of the synovium and consequent cartilage and bone erosion. RA is strongly associated with the presence of rheumatoid factor (RF) and consists of clinical subsets of anti-citrullinated protein antibody (ACPA)-positive and negative patients. Several genes have been proven to contribute to the disease susceptibility and they may be associated with a particular pattern of disease and with the response or toxicity to therapy. It is important to identify novel genomic biomarkers associated not only with disease susceptibility but also able to detect early those patients with negative prognostic factors who may benefit from a more aggressive therapeutic approach.
**Objectives:** This study was designed to evaluate whether the most relevant single nucleotide polymorphisms (SNPs) associated with RA and other autoimmune disorders are related to RF, ACPA, and clinical phenotype in a cohort of biologic-naïve Italian RA patients.
**Methods:** A total of 192 RA patients [female n=147 (76.5%), age 54.1 ± 13.2

**(A) Case-control association analysis. (B) Genotype-phenotype association analyses.** SNP: single nucleotide polymorphism; RF: rheumatoid factor; ACPA: anti-citrullinated protein antibody; OR: odds ratio; CI: confidence interval. * "wt" indicates the homozygous genotype for the wild-type allele; "hz" indicates the heterozygous genotype; "var" indicates the homozygous genotype for the variant allele. ** Heterozygotes and variant homozygotes were considered together (1 df) in the comparisons between genotypes by Chi square test. Significant *P* values are reported in bold.

years, disease duration 7.8 ± 9 years, positive RF n=130 (67.7%), positive ACPA n=137 (71.7%), 28 joint count disease activity score (DAS28) 5.2 ± 1.3, bone erosions at diagnosis n=69 (60%), disease modifying anti-rheumatic drugs (DMARDs) n=148 (77.1%)] were enrolled. 278 age-matched healthy controls were included. We analyzed a total of 12 SNPs in STAT4, IL10, PSORS1C1, PTPN2, ERAP1, TRAF3IP2 and MIR146A genes by allelic discrimination assays. Case-control association studies and genotype/phenotype correlation analyses were performed (Figure 1A-B).

**Results:** A higher risk to develop RA was observed for rs7574865 in STAT4 gene (P=0.035, OR=1.41). We observed a significant association between the variant alleles of rs1800872 in IL-10 gene and RA susceptibility. Subjects carrying the variant alleles (in heterozygous and homozygous status) showed a lower risk to develop RA in comparison with wildtype individuals (P=0.014, OR=0.63). The presence of RF resulted significantly associated with rs1800872 variant in IL10 (P=0.032, OR=2) while rs2910164 in MIR146A was protective (P=0.05, OR=0.55). ACPA were significantly associated with rs7574865 in STAT4 (P=0.004, OR=2.64). The SNP rs2233945 in PSORS1C1 gene was protective regarding the presence of bone erosions (P=0.042, OR=0.44) while rs2542151 in PTPN2 gene was associated with joint damage (P=0.044, OR=3.26).

**Conclusions:** Our results confirm that polymorphisms in STAT4 and IL10 genes confer susceptibility to RA. For the first time we described that SNPs in PSORS1C1, PTPN2 and MIR146A genes were differently associated with a severe disease phenotype in terms of autoantibody status and radiographic damage in an Italian RA population.

**Disclosure of Interest:** None declared

## SAT0007 GENETIC POLYMORPHISMS OF HLA-DRB1 ARE ASSOCIATED WITH DERMATOMYOSITIS AND ANTI-MDA5 ANTIBODIES IN CHINESE

Y. Wang[1], Z. Chen[2], L. Sun[1,2]. *[1]Department of Rheumatology and Immunology, Drum Tower Clinical College of Nanjing Medical University; [2]Department of Rheumatology and Immunology, The affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, China*

**Background:** Risk alleles at genome loci containing interferon induced with helicase C domain 1 (IFIH1) and human leukocyte antigen (HLA) genes closely associated with dermatomyositis (DM) in European population [1–3]. Autoantibody targeted to melanoma differentiation associated protein 5 (MDA5), a protein encoded by IFIH1, was associated with rapidly progressive interstitial lung disease (RP-ILD) and high mortality in DM [4].

**Objectives:** To estimate the associations between HLA and IFIH1 rs1990760 polymorphisms and susceptibility to DM and anti-MDA5 antibody expression in Chinese population.

**Methods:** HLA-DRB1and IFIH1 rs1990760 polymorphisms were determined in 102 DM patients and 400 healthy controls. Anti-MDA5 antibodies and ILD were evaluated by ELISA and high-resolution computed tomography (HRCT), respectively.

**Results:** Frequencies of HLA-DRB1*04:01 were significantly higher in DM (4.41% *vs* 0.63%, OR 7.34, 95%CI 2.84–18.95, *P* 0.00004, *Pc* 0.001), but the frequency of HLA-DRB1*14 (0.98% *vs* 5.88%, OR 0.16, 95%CI 0.05–0.55, *P* 0.004, *Pc* 0.049) was significantly lower than that of healthy controls. Compared with the healthy controls, HLA-DRB1*04:01 was associated with the development of ILD in DM (7.14% *vs* 0.63%, OR 12.23, 95%CI 4.97–30.10, *P* $5.03\times10^{-8}$, *Pc* $1.81\times10^{-6}$). The frequency of HLA-DRB1*09 (5.36% *vs* 18.48%, OR 0.25, 95%CI 0.10–0.63, *P* 0.003, *Pc* 0.042) was significantly lower in DM patients with ILD than in DM patients without ILD, suggesting it is a protective allele for ILD in DM. The frequencies of HLA-DRB1*04:01 (8.51% *vs* 0.63%, OR 14.79, 95%CI 6.17–35.45, *P* $1.53\times10^{-9}$, *Pc* $5.49\times10^{-8}$) and HLA-DRB1*12:02 (21.28% *vs* 10.00%, OR 2.43, 95%CI 1.43–4.14, *P* 0.001, *Pc* 0.037) were significantly increased in anti-MDA5 positives than in controls. Compared with anti-MDA5 negatives, the frequency of HLA-DRB1*12:02 (21.28% *vs* 4.55%, OR 5.68, 95% CI 2.22–14.48, *P* 0.0003, *Pc* 0.010) were significantly increased in anti-MDA5 positives. No association was observed between the IFIH1 rs1990760 and DM, anti-MDA5 antibody expression and ILD status.

**Conclusions:** HLA-DRB1 alleles, but not IFIH1 polymorphisms, may be associated with the susceptibility to DM, ILD involvement and anti-MDA5 expression in Chinese population.

## SAT0008 IL-17A GENE IMPLICATION IN SPANISH PATIENTS WITH RHEUMATOID ARTHRITIS

**Background:** Rheumatoid arthritis (RA) is an autoimmune pathology associated with increased risk of cardiovascular (CV) disease and subclinical atherosclerosis[1]. Consequently, both inflammatory diseases share common molecules involved in its pathogenesis. In this sense, interleukin 17A (IL-17A) is a pro-inflammatory cytokine involved in the regulation of immune responses and chronic inflammation[2].

**Objectives:** To evaluate the potential association between different IL-17A polymorphisms and CV events, as well as subclinical atherosclerosis, in a large cohort of Spanish RA patients.

**Methods:** Five IL-17A polymorphisms (rs4711998, rs8193036, rs3819024, rs2275913 and rs7747909) were genotyped by TaqMan assays in a 7900 HT Real-Time polymerase chain reaction system in 1,974 Spanish patients diagnosed with RA (fulfilling the 2010 American College of Rheumatology classification criteria for RA[3]), recruited from different Spanish hospitals. 318 patients (16.1%) had experienced CV events, and 822 had undergone carotid ultrasonography studies to assess subclinical atherosclerosis (presence/absence of plaques and carotid intima media thickness [cIMT]). The relationship between IL-17A alleles, genotypes and haplotypes and CV events, presence/absence of plaques and cIMT values was assessed. Results were adjusted for sex, age at diagnosis and traditional CV risk factors.

**Results:** No statistically significant differences were observed when allelic/genotypic frequencies of each IL-17A polymorphism were assessed regarding presence/absence of CV events, plaques or cIMT values. This was also the case when the five polymorphisms were combined to form haplotypes.

**Conclusions:** Our results do not confirm an association between the five IL-17A polymorphisms studied and the development of CV events or subclinical atherosclerosis in our cohort of Spanish RA patients.

## SAT0009 INVESTIGATION OF DIFFERENTIAL METHYLATION AS A POTENTIAL BIOMARKER OF METHOTREXATE RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Nair[1], D. Plant[1], S.M. Verstappen[1], J.D. Isaacs[2], A.W. Morgan[3], K.L. Hyrich[1], A. Barton[1], A.G. Wilson[4] on behalf of MATURA. *[1]ARUK Centres for Genetics and Genomics and Epidemiology, University of Manchester, Manchester; [2]Newcastle University, Newcastle-upon-Tyne; [3]University of Leeds, Leeds, United Kingdom; [4]University College Dublin, Dublin, Ireland*

**Background:** Methotrexate (MTX) is the first-line disease modifying anti-rheumatic drug (DMARD) for the treatment of rheumatoid arthritis (RA). By two years of treatment only 55% of patients remain on the drug, implying that many do not respond adequately or experience adverse effects (1,2). Therefore, identifying blood-based biomarkers that predict treatment response is an important research priority. DNA methylation is an epigenetic marker that modifies but does not alter DNA sequence, and should be considered for evaluation as potential biomarkers for treatment response. The mechanisms of action of MTX are unclear. However, it is thought that MTX promotes adenosine release and interferes with the intracellular methyl donor status leading to DNA hypomethylation (3).
**Objectives:** To identify differential DNA methylation signatures in whole blood, which may act as biomarkers predictive of response to MTX in patients with RA.
**Methods:** Epigenome-wide DNA methylation levels were measured using the HumanMethylation450 BeadChip (Illumina) in whole blood-derived DNA samples from individuals recruited to the Rheumatoid Arthritis Medication Study (RAMS), a one year observational study including patients with RA starting MTX for the first time, who had EULAR good response (n=36) or EULAR poor response (n=36) to MTX. DNA was taken from blood samples pre-treatment and following four weeks on therapy. Response was determined at six months using the DAS28 score. Differentially methylated positions (DMPs) were identified using linear regression, adjusting for gender, age, cell composition, and baseline DAS28 score.
**Results:** Although no probe reached study-wide significance, 16 DMPs suggestive loci were associated with MTX response in the pre-treatment samples (arbitrary $p<10^{-4}$), including a DMP close to the *IL6R* gene (cg15633035, $p=5.24x10^{-5}$). At four weeks, 20 DMPs were associated with response, with no overlap with the DMPs reported in the pre-treatment sample. In good responders, 10 DMPs were differentially methylated between pre-treatment and four week samples. In poor responders, 17 DMPs were differentially methylated between time-points. There was no overlap of DMPs between good and poor responders
**Conclusions:** These preliminary results suggest DNA methylation may provide a useful source of biomarkers of MTX response and now require replication in an independent dataset. Furthermore, investigation of differential methylation between baseline and four weeks reveals the potential of DNA methylation in pharmacodynamic modelling of MTX response. Further analysis is being conducted and significant findings will be validated in the total RAMS population using pyrosequencing.

## SAT0010 A TARGETED NEXT-GENERATION SEQUENCING GENE PANEL FOR AUTOINFLAMMATION

E. Omoyinmi[1], A. Standing[1], A. Keylock[1], D. Rowczenio[2], S. Melo Gomes[1], T. Cullup[3], L. Jenkins[3], K. Gilmour[3], D. Eleftheriou[1], H. Lachmann[2], P. Hawkins[2], N. Klein[1], P. Brogan[1]. *[1]Rheumatology; [2]National Amyloidosis Centre; [3]Great Ormond Street Hospital NHS Foundation Trust, UCL, London, United Kingdom*

**Background:** Monogenic autoinflammatory diseases (AID) are severe lifelong systemic inflammatory disorders with dysregulated innate immunity, causing significant morbidity, mortality, and economic burden. The number of AID is rapidly expanding. Securing a molecular diagnosis is of major importance for treatment, prognosis, and genetic counselling. Routine genetic screening is time-consuming, costly, and lacks sensitivity since only common disease harbouring exons of a minority of the known AID genes are currently tested using Sanger sequencing. Next-generation sequencing (NGS) offers the ability to rapidly and cost-effectively screen all exons of a gene panel containing hundreds of genes. This approach has not yet been routinely introduced in the UK for AID.
**Objectives:** To develop and evaluate the performance of a NGS gene panel for AID.
**Methods:** The Agilent SureDesign tool was used to design an NGS panel targeting 113 genes, grouped into 9 broad clinical phenotypes: AID; monogenic vasculitis/vasculopathy; complement defects; monogenic lupus; hemophagocytic lymphohistiocytosis (HLH); early-onset inflammatory bowel disease; autoimmune lymphoproliferative syndromes; monogenic stroke; and hereditary amyloidosis. The targeted region includes coding exons, conserved non-coding exons, upstream promoter regions, and splice sites. Captured and indexed libraries (QXT Target Enrichment System) were sequenced as a multiplex of 16 samples on an Illumina MiSeq sequencer in paired-end mode. Positive controls for panel validation comprised 19 DNA samples from patients with confirmed mutations in a variety of genes on the panel. We then applied the panel to test 29 prospective samples with suspected but unconfirmed monogenic inflammation. Read alignment, variant calling, and annotation were performed using Agilent SureCall v3.0 software.
**Results:** In the validation stage, our targeted panel detected all known mutations in the 19 positive control samples with an average read depth of 244X (+/–29X) across the captured genes. The panel was effective at detecting different types of variants, including rare and common single nucleotide variants (SNVs), insertion/deletions, splice-junction variants, upstream promoter region variants, and somatic mosaicism. Prospective testing of the panel in 29 patients revealed potential pathogenic variants in 14 of the 29 patients giving a detection rate of 48%. These included atypical patients with novel mutations in specific exons/genes, not currently routinely available for testing by Sanger sequencing in the NHS.
**Conclusions:** This study demonstrates the clinical utility of a comprehensive NGS-based targeted gene panel which was both highly sensitive and specific in detecting different sequence variants of clinical significance. We are currently integrating this panel into a routine diagnostic laboratory testing strategy for monogenic inflammation. This will facilitate accurate and timely molecular diagnosis, more targeted treatment, and ultimately better outcomes for our patients.

**Background:** Psoriatic arthritis (PsA) is an inflammatory arthritis that is associated with psoriasis. Although the majority of PsA genetic risk loci identified also confer risk for psoriasis, we have recently reported evidence of loci that are associated with PsA and not psoriasis, including an association at the *IL23R* locus which is also independent of a psoriasis variant at the same locus.
**Methods:** The PsA-specific SNP rs12044149, and the psoriasis SNP rs9988642 at the *IL23R* locus were genotyped in a cohort of 914 PsA cases and 6,945 controls from Spain, Crete, Germany and the UK, with the Life Technologies QuantStudio genotyping platform. Association testing was carried out using PLINK, and a meta-analysis was performed with PsA Immunochip data (1,962 cases, 8,923 controls). Genotype data was also available from the psoriasis WTCCC2 study (excluding known PsA, n=1,784) to compare effect sizes between PsA and psoriasis using multinomial logistic regression in Stata, and to directly compare PsA and psoriasis genotypes. Credible SNP sets were calculated for the PsA and psoriasis *IL23R* associations using the Bayesian refinement method, and functionally annotated.
**Results:** We replicated the association rs12044149 with PsA ($P=4.03x10^{-6}$), which remained significant when conditioning upon the psoriasis variant, rs9988642 ($P_{cond}=4.86x10^{-6}$), and reached genome-wide significance during

meta-analysis of the combined PsA dataset ($P_{meta}$=4.76x10$^{-20}$). Only a modest association was found for rs9988642 ($P$=0.04), with no genome-wide significance found during meta-analysis ($P$=4.61x10$^{-4}$). Within the psoriasis dataset, this association remained significant when conditioning upon rs12044149 ($P$=1.0x10$^{-07}$ vs. $P_{cond}$=1.63x10$^{-5}$). Effect estimates for rs12044149 were significantly different between PsA and psoriasis ($P$=2.0x10$^{-3}$), and direct comparison of genotypes for PsA and psoriasis found the risk allele to be significantly increased in PsA ($P$=4.52x10$^{-4}$, OR=1.3). Credible SNPs for rs12044149 mapped to promoter and enhancer regions within memory CD8$^+$ T cells, which we have previously reported to be critical for PsA.

**Conclusions:** We have successfully replicated a PsA-specific (associated with PsA but not psoriasis) risk variant at the *IL23R* locus in an independent cohort, confirming rs12044149 to be distinct from rs9988642 ($r^2$=0.02). This gives five PsA-specific associations that have now been identified.

## SAT0012 GENETIC ANALYSIS OF ABCG2 IN PRIMARY HYPERURICEMIA AND GOUT

B. Stiburkova [1,2], P. Simek [3], P. Cepek [1], K. Pavelcova [1,3], K. Pavelka [1]. *[1] Institute of Rheumatology; [2] Institute of Inherited Metabolic Disorders; [3] Department of Rheumatology, First Faculty of Medicine, Charles University in Prague, Prague, Czech Republic*

**Background:** The urate transporter *ABCG2* is one of the genetic determinants of serum uric acid concentrations[1].

**Objectives:** In the present study, we describe the identification and functional analysis of allelic variants in the *ABCG2* gene, a physiologically important urate transporter whose dysfunction plays a major role in pathogenesis of gout, in a cohort with primary hyperuricemia and gout.

**Methods:** The cohort consisted of 150 individuals: 32/118 primary hyperuricemics/gout. The definition of hyperuricemia was as follows: >420/360 μmol/l at two repeated measurements at intervals of at least 4 weeks in men/women. Gouty arthritis was diagnosed according to the 1977 preliminary criteria of the American College of Rheumatology for acute arthritis of gout. Patients suffering from secondary gout were excluded. We analyzed 15 exons of *ABCG2* gene by PCR amplification and sequenced directly. The functional analysis of identified allelic variants is in process (HEK cells).

**Results:** In the *ABCG2* gene, 16 intronic sequence variants were detected. In the case of c.689+1G>A, related to an individual with severe gouty phenotype, two abnormal splicing variants were identified: a) r.[532_689del]; b) r.[532_689del], r.[944_949del]. Identified deletions lead to frameshift and premature stop codon introduction[2].

From the nine exon variants detected, there were seven non-synonymous: p.V12M (*rs2231137*), p.Q141K (*rs2231142*), p.R147W (*rs372192400*), p.T153M (*rs753759474*), p.F373C (*rs752626614*), p.T434M (*rs769734146*) and p.D620N (*rs34783571*). Heterozygous p.V12M variant was detected in seven individuals. Heterozygous variant p.R147W, p.T153M, p.F373C and p.D620N was detected once, variant p.D620N was detected twice also in heterozygous state. Variants p.R147W, p.T153M, p.F373C and p.T434M were *in silico* predicted using Polyphen, Sift and Provean program as a probably damaging. The p.Q141K, previously functionally characterized allelic variant with a strong effect on uric acid secretion impairment, was in cohort of hyperuricemic/gout patients presented with significantly higher allele frequency MAF=0.19 (42 heterozygotes/5 homozygotes), than in population of European origin (MAF=0.09) and world-wide population (MAF=0.12).

**Conclusions:** Our results show that genetic factor *ABCG2* should be considered as one of the common risks for hyperuricemia/gout. In clinical practice, *ABCG2* dysfunction can be estimated easily by genotyping and these findings will help to recognize a trait of hyperuricemia at a very early stage.

## SAT0013 JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATION OF PTPN22 RS2476601 SNP IS SPECIFIC TO FEMALES IN A GREEK POPULATION

G.N. Goulielmos [1], R. Chiaroni-Clarke [2,3], D.G. Dimopoulou [4], M.I. Zervou [1], M. Trachana [5], P. Pratsidou-Gertsi [5], E. Myrthianou [1], A. Garyfallos [4], J. Ellis [2,3]. *[1] Medical School, University of Crete, Heraklion, Crete, Greece; [2] Genes, Environment and Complex Disease, Murdoch Childrens Research Institute, Parkville; [3] Department of Paediatrics, University of Melbourne, Parkville, Victoria, Australia; [4] Rheumatology Unit, 4th Department of Internal Medicine, Aristotle University of Thessaloniki, Hippocration Hospital; [5] Pediatric Immunology and Rheumatology Referral Center, 1st Department of Pediatrics, Aristotle University of Thessaloniki, Thessaloniki, Greece*

**Background:** Juvenile idiopathic arthritis (JIA) is an autoimmune disease characterized by persistent chronic arthritis [1] and is believed to be influenced by both genetic and environmental factors. *PTPN22* single nucleotide polymorphism (SNP) rs2476601 has been recently reported in an Australian study to be restricted to females and to not be observed in males [2].

**Objectives:** Considering that a significant source of inconsistency amongst the literature on autoimmune disease susceptibility genes stems from an inability to replicate genetic findings across different racial or ethnic groups, we attempted to confirm the female-specific association of rs2476601 in a homogeneous Greek population.

**Methods:** The sample set consisted of 128 (70.3% female) Caucasian JIA patients and 221 (28.1% female) healthy controls from Northern Greece. Genotyping for the *PTPN22* rs2476601 (*Xcm*I) was performed by restriction fragment length polymorphism (RFLP) analysis [3]. Logistic regression or the Gart (Woolf) method were used to estimate ORs and 95% CIs. Analyses were performed using Stata v13 (StataCorp, College Station, TX, USA).

**Results:** The rs2476601 was genotyped in 128 Caucasian JIA patientsand 221 healthy controls from Northern Greece. Overall, *PTPN22* was associated with increased risk of JIA in this Greek sample (OR =2.3, 95% CI 1.1 – 5.1, p=0.038). Sex-stratified analyses showed that, once again, the risk association was restricted to females (Female: OR =19.9, 95% CI 1.2 – 342, p=0.0016; Male: OR =1.1, 95% CI 0.3 – 3.1, p=0.94) confirming the prior findings. Given that the sex bias differs by JIA subtype, ideally we would have liked to test for these associations in individual subtypes; however, small sample size prevented us from performing these analyses with any statistical certainty.

**Conclusions:** This data demonstrated that the sex-specific pattern of association detected is broadly applicable to different populations, and provided further impetus to undertake studies to understand the crucial role of rs2476601 in the mechanisms leading to disease's development preferentially in females. Our work is of interest given the importance of comparative studies in populations of differing ethnic and/or racial origin in any attempt to conclusively define the genetic architecture of JIA and the magnitude of the effects of specific risk alleles globally.

## SAT0014 ASSOCIATION OF HLA GENES IN SYSTEMIC SCLEROSIS WITH INTERSTITIAL LUNG DISEASE

H.M. Kwon [1], E.Y. Song [2], Y.J. Lee [3], J.K. Park [1], E.Y. Lee [1], Y.W. Song [1], E.B. Lee [1]. *[1] Division of Rheumatology, Department of Internal Medicine; [2] Laboratory Medicine; [3] Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

**Background:** Interstitial lung disease (ILD) is associated with a significant morbidity and mortality in systemic sclerosis (SSc). Many studies have reported the association between human leukocyte antigen (HLA) alleles and increased risk of SSc, but the associated between ILD in SSc and HLA alleles remains unclear.

**Objectives:** The aim of this study was to investigate the association of HLA class I and HLA class II with ILD in Korean SSc cohort.

**Methods:** A total of 170 SSc patient (105 SSc patients with ILD and 65 SSc patients without ILD) were enrolled at Seoul National University Hospital from 1988 to 2014. Two hundred one healthy participants from Korean Marrow Donor Program (KMDP) were recruited as controls. Demographic information, clinical skin subset (limited vs. diffuse), SSc-specific autoantibodies (anti-topoisomerase I (ATA), anti-centromere (ACA), anti-ribonucleoprotein (RNP)), and internal organ involvement (ILD, pulmonary arterial hypertension, gastrointestinal, renal involvement) of the enrolled patients were characterized. ILD were diagnosed based on the findings of the chest computed tomography. HLA-A, -B, -C,-DQB1,-DRB1, and -DPB1 typing were performed PCR amplification with directly sequencing from extracted genomic DNA.

**Results:** HLA-B*52:01, C*12:02, DRB1*15:02, DPB1*09:01, and DPB1*13:01 alleles were more frequent in SSc patients with ILD than healthy controls. However, the frequencies of these genes did not differ between SSc patients with and without ILD (Table). ATA positive SSc was associated with HLA-B*52:01,

C*12:02, DRB1*15:02, DPB1*09:01, and DPB1*13:01 alleles compared to ATA negative SSc and DPB1*09:01 showed the highest odds ratio for ATA (OR =23.08).

Table 1. HLA frequencies in patient with systemic sclerosis with ILD and without ILD compared to healthy controls

| HLA alleles | SSc_Total (N=170) | ILD(+)SSc (n=105) | ILD(–)SSc (n=65) | Control (N=201) | SSc Total vs. Control $P_c$ | ILD(+)SSc vs. Control $P_c$ | ILD(–)SSc vs. Control $P_c$ |
|---|---|---|---|---|---|---|---|
| B*52:01 | 23 (13.5) | 20 (19.0) | 3 (4.6) | 9 (4.5) | 0.076 | <0.001 | 1.000 |
| C*12:02 | 23 (13.5) | 20 (19.0) | 3 (4.6) | 9 (4.5) | 0.046 | <0.001 | 1.000 |
| DRB1* 15:02 | 29 (17.1) | 24 (22.9) | 5 (7.7) | 14 (7.0) | 0.074 | <0.001 | 1.000 |
| DPB1* 09:01 | 22 (12.9) | 18 (17.1) | 4 (6.2) | 9 (4.5) | 0.045 | <0.001 | 1.000 |
| DPB1* 13:01 | 52 (30.6) | 38 (36.2) | 14 (21.5) | 25 (12.4) | <0.001 | <0.001 | 1.000 |

Abbreviation: HLA, human leukocyte antigen; SSc, systemic sclerosis; ILD, interstitial lung disease; OR, odds ratio; $P_c$, corrected $P$ by Bonferroni correction. $P_c$ of ILD(+)SSc vs. ILD(–) SSc: HLA-B*52:01 ($P_c$=0.304), C*12:02 ($P_c$=0.184), DRB1*15:02 ($P_c$=0.407), DPB1*09:01 ($P_c$=0.570), DPB1*13:01 ($P_c$=0.660).

**Conclusions:** SSc patients with ILD have several specific HLA genes compared with healthy controls and the frequencies of these HLA genes were significantly higher in ATA-positive SSc as well. Therefore, ATA positivity and ILD are associated with ceratin HLA class I and II in SSc patients.

## SAT0015 NOVEL AND RARE MUTATIONS LINKED TO POLYAUTOIMMUNITY

A. Johar [1], J.C. Sarmiento-Monroy [2], A. Rojas-Villarraga [2], M.F. Silva-Lara [1], H.R. Patel [1], R.D. Mantilla [2], C. Mastronardi [1], M. Arcos-Burgos [1,2], J.-M. Anaya [2]. *[1] Genome Biology Department, John Curtin School of Medical Research, ANU College of Medicine, Biology & Environment, The Australian National University, Canberra, Australia; [2] Center for Autoimmune Diseases Research (CREA), Universidad del Rosario, Bogota, Colombia*

**Background:** Polyautoimmunity (i.e., the presence of two or more autoimmune diseases in a single patient) and familial autoimmunity (i.e., diverse autoimmune diseases in a nuclear family) represent extreme phenotypes ideal for identifying major genomic variants contributing to autoimmunity (1–3). Whole Exome Sequencing (WES) and linkage analysis are well suited for this purpose due to its strong resolution upon familial segregation patterns of functional protein coding and splice variants (3).

**Objectives:** The primary objective of this study was to identify potentially autoimmune causative variants using WES data from extreme pedigrees segregating polyautoimmunity phenotypes.

**Methods:** DNA of 47 individuals across 10 extended and multigenerational pedigrees, ascertained from probands affected with polyautoimmunity and familial autoimmunity, were selected for WES. Variant calls were obtained through Genome Alignment Tool Kit (GATK) algorithm; filters for prioritizing major functional were applied and later implemented for genetic linkage analysis. Sanger sequencing corroborated variants with significant linkage.

**Results:** Novel and mostly rare variants harbored in *SRA1, MLL4, ABCB8, DHX34* and *PLAUR* genes showed significant linkage (LOD scores are >3.30). The strongest signal was in *SRA1*, with a LOD score of 5.48. Network analyses indicated that *SRA1* and *PLAUR* both contribute to regulation of apoptotic processes.

**Conclusions:** Novel and rare variants in genetic linkage with polyautoimmunity were identified throughout WES. Genes harboring these variants might be major players of autoimmunity.

**Background:** Rheumatoid arthritis (RA) is an autoimmune inflammatory disease associated with accelerated atherosclerosis and increased cardiovascular (CV) disease. Elevated levels of the C-reactive protein (CRP) are related to an increase risk of coronary artery disease [1] and stroke [2]. Recently, PCR, GCKR, HNF1A, LEPR, ASCL1 and NLRP3 have been associated with CRP levels in non-rheumatic population [2].

**Objectives:** We aimed to determine the potential role of these genes in the development of CV disease and subclinical atherosclerosis in patients with RA.

**Methods:** Genotyping was performed in 2,384 Spanish RA patients by TaqMan assays. Subclinical atherosclerosis was determined by carotid ultrasonography (US) in 1,193 patients.

**Results:** No statistically significant differences were found when PCR, GCKR, HNF1A, LEPR, ASCL1 and NLRP3 were assessed according to the presence/absence of CV disease. It was also the case when patients were stratified according the presence/absence of subclinical atherosclerosis.

**Conclusions:** Our results do not confirm an association between these genes and the development of CV disease and subclinical atherosclerosis in patients with RA.

## SAT0017 SYNOVIAL FLUID MIR-223 EXPRESSION LEVELS IN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS PATIENTS

R. Shumnalieva [1], D. Kachakova [2], S. Monov [1], R. Kaneva [2], Z. Kolarov [1], R. Rashkov [1]. *[1] Clinic of rheumatology; [2] Molecular Medicine Center, Medical University - Sofia, Sofia, Bulgaria*

**Background:** Synovial hypertrophy and synovitis could be seen in both rheumatoid arthritis (RA) and inflammatory osteoarthritis (OA) as a consequence of deregulated pro-inflammatory cytokine production. Abnormal local microribonucleic acids (miRNAs) production that regulate the inflammatory milieu in the synovial joints has been reported in several studies. Due to their stability miRNAs are widely explored as potential diagnostic biomarkers for both diseases as well as for disease activity and treatment response.

**Objectives:** The objective of our study was to evaluate the role of expression levels of miR-223 in the synovial fluid (SF) of RA and OA patients as diagnostic biomarker in the clinical practice.

**Methods:** Total RNA including miRNAs was isolated from SF of 48 RA, 16 OA and 11 healthy controls (HCs) by using RNeasy Protect Cell Mini kit (according to manufacturer's protocol). Reverse transcription was performed in order to synthesize cDNA by using miScript II RT kit. Expression of miR-223 was analyzed by relative quantitation method $2^{\wedge-(\Delta\Delta Cq)}$. As reference control for normalization RNU6B gene was used. Data were analyzed by SPSS. The results were compared to HCs as well as between the two disease groups.
**Results:** In SF miR-223 was overexpressed in 79.17% of the RA ($p=1.64 \times 10^{-3}$) and in 62.50% of OA patients (p=0.885) when compared to HCs. SF miR-223 levels were upregulated in 77.08% of the RA when compared to OA patients ($p=6.2 \times 10^{-3}$). In order to evaluate the diagnostic accuracy of miR-223 expression levels in SF to distinguish patients with RA or OA from HCs as well as between the two diagnostic groups receiver operating characteristic (ROC) curve analysis was constructed using RQ values. Expression levels of miR-223 in SF could discriminate RA patients from HCs with high diagnostic accuracy since area under the curve (AUC) was 0.841 (95 CI: 0.724–0.958; $p=4.6 \times 10^{-4}$) with 87.5% sensitivity and 72.7% specificity. ROC curve analysis showed that OA patients could not be well distinguished from HCs (AUC =0.631; 95 CI: 0.417–0.845) probably due to the small sample size but SF miR-223 levels could be used to discriminate OA from RA with the following AUC =0.693 (95% CI: 0,493–0.893) and with 68.8% sensitivity and 66.7% specificity.
**Conclusions:** SF miR-223 level could serve as potential diagnostic biomarker for RA as it could distinguish RA from both HCs as well as inflammatory OA. Larger sets are needed to confirm the diagnostic accuracy of miR-223 in RA.

## SAT0018 PRELIMINARY ANALYSIS REVEALS AN INTERFERON SIGNATURE IS ASSOCIATED WITH NON-RESPONSE TO ETANERCEPT IN RHEUMATOID ARTHRITIS PATIENTS

S.L. Smith[1], D. Plant[2], S. Eyre[1], K. Hyrich[1], A.W. Morgan[3], A.G. Wilson[4], J. Isaacs[5], A. Barton[1,2]. *[1]Centre for Genetics and Genomics, Arthritis Research UK, The University of Manchester; [2]NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust and University of Manchester, Manchester; [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds; [4]UCD School of Medicine and Medical Science, Conway Institute, University College Dublin, Dublin; [5]NIHR Newcastle Biomedical Research Centre, Newcastle upon Tyne NHS Foundation Trust and Newcastle University, Newcastle upon Tyne, United Kingdom*

**Background:** The treatment of rheumatoid arthritis (RA) has changed considerably over the last couple of decades, particularly since the introduction of biological therapies; however, a considerable proportion of patients fail to respond satisfactorily (30–40%). Early and effective treatment is known to correlate with better long-term outcomes and there is an unmet clinical need for predictors of response which can be used to stratify patients prior to treatment; so that those prone to non-response can be offered alternative options. We hypothesis that gene expression profiles of RA patients about to commence treatment with the biological drug etanercept will provide such a biomarker.
**Objectives:** To identify gene expression biomarkers which discriminate between good-responders (R) and non-responders (NR) to etanercept in RA patients.
**Methods:** 72 RA patients about to commence treatment with etanercept were chosen for analysis from the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS) longitudinal cohort. Using the established EULAR classification criteria this equated to 34 R (28-joint disease activity score (DAS28) of $\leq$3.2 and improvement of $>$1.2) and 38 NR (DAS28 $>$5.1 and improvement $<$0.6 or between 0.6–1.2) patients at 3-months follow-up. Total RNA was extracted from pre-treatment whole blood previously collected into TEMPUS/PaxGene blood tubes upon recruitment to BRAGGSS. Following biotin labelling and RNA amplification (Illumina TotalPrep RNA Amplification Kit), cRNA was hybridised to Illumina HumanHT-12 v4 Expression BeadChips targeting over 47,000 probes. GenomeStudio software summarised the bead level data, followed by QC and differential expression analysis using the Bioconductor package Limma.
**Results:** Using a fold-change (FC) cut-off of $>$1.2 between R and NR and p-value $<$0.05, 82 probes were differentially expressed; 33 up-regulated in NR and 49 up-regulated in R prior to treatment with etanercept. Interestingly, of the probes up-regulated in NR, an interferon (IFN) signature was observed, including the type-I IFNs, *IFITM3* (FC 1.53, p-value=0.01), *MX1* (FC 1.45, p-value=0.02) and *IFI44L* (FC 1.28, p-value=0.04) and a type-II IFN, *BTN3A2* (FC 1.38, p-value $9.6 \times 10^{-05}$). Of note, expression of *PTPRC*, a previously reported treatment response gene, was found to be up-regulated in R as compared to NR prior to treatment (FC 1.24, p-value=0.03).
**Conclusions:** The preliminary results suggest that an IFN signature prior to etanercept treatment is indicative of non-response in RA patients. These results are encouraging in that an IFN signature has consistently been associated with RA and clinical outcome to biological therapies. However, to the best of our knowledge this is the first study to observe an IFN signature correlating with response to etanercept. More in-depth analysis is ongoing using packages such as WGCNA (weighted correlation network analysis) and Matrix eQTL to further explore these associations.

## SAT0019 TUMOR NECROSIS FACTOR-α -308 A/G GENE POLYMORPHISM IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: RELATION TO DISEASE ACTIVITY, DAMAGE AND DISABILITY

I.I. El Gazzar[1], H.M. Fathi[2], T.A. Gheita[1], A.M. Nour El-Din[3], E. Abdel Rasheed[4], R.H. Bassyouni[5], S.A. Kenawy[6]. *[1]Rheumatology and Clinical Immunology, Faculty of Medicine, Cairo University, Cairo; [2]Rheumatology, Faculty of Medicine, Fayoum University, Fayoum; [3]Pediatrics; [4]Clinical Pathology, National Research Centre (NRC), Giza; [5]Medical Microbiology and Immunology, Faculty of Medicine, Fayoum University, Fayoum; [6]Clinical Pharmacology, Faculty of Pharmacy, Cairo University, Cairo, Egypt*

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease of childhood and an important cause of disability[1]. Its cause remains unknown, but likely includes complex interactions between genes and environmental exposures resulting in dysregulation of the immune system[2]. TNF-α is a cytokine with an important role in inflammation and immune function[3]. Several single nucleotide polymorphisms (SNPs) have been identified within the region of the TNF-α gene but only very small minority have proven functional consequences and were associated with JIA susceptibility[4]
**Objectives:** To evaluate the clinical significance of serum levels of tumor necrosis factor alpha (TNFα) and -308 A/G promoter polymorphism in JIA patients and find any association to the subsets, clinical and laboratory features, disease activity and damage as well as functional disability
**Methods:** Forty-eight JIA children and 30 controls were included in the present study. Juvenile arthritis disease activity score in 27 joints (JADAS-27) was calculated, juvenile arthritis damage index (JADI) assessed and Childhood Health Assessment Questionnaire (CHAQ) to measure the functional status. Serum TNF-α was assayed by ELISA and gene (-308) promoter polymorphism determined by polymerase chain reaction.
**Results:** The 48 JIA children (mean age: 11.5±2.8 years) were 13 systemic, 17 oligoarticular and 18 polyarticular onset. The serum TNF-α was significantly higher in patients (90.4±6.3 ng/ml) compared to control (3.5±2.6 ng/ml) ($p<0.0001$) with a tendency to be higher in the polyarticular subtype. All controls had TNF-α -308GG alleles. The frequency of GG genotype tended to be higher in systemic onset compared to oligoarticular and polyarticular subtypes. The serum TNF-α significantly correlated with JADAS-27 (r=0.32, p=0.03) and CHAQ (r=0.37, p=0.01) and negatively with the presence of GG alleles (r=-0.48, p=0.001). The GG alleles were significantly negatively associated with C-reactive protein (r=-0.32, p=0.03) with a tendency to negatively correlate with JADAS-27, CHAQ and JADI-extrarticular (r=-0.28, p=0.06; r=-0.25, p=0.09 and r=-0.25, p=0.09 respectively).
**Conclusions:** There is evidence of a possible influence of the –308 SNP promoter position on the production of TNF-α, the severity of JIA which may consequently influence the response to anti-TNF-α treatment.

SAT0020 **ASSOCIATION OF HLA-DP/DQ AND STAT4 POLYMORPHISMS WITH ANKYLOSING SPONDYLITIS IN A CHINESE POPULATION**

X. Liu, L. Wang, B. Yang. *Department of Lab Medicine, West China Hospital, Sichuan University, Chengdu, China*

**Background:** Ankylosing spondylitis (AS) is a highly heritable complex inflammatory arthritis disease. Genetic factors are thought to be crucial in the pathogenesis of ankylosing spondylitis. However, few studies were performed to investigate the relationship between HLA-DP/DQ and STAT4 polymorphisms and AS susceptibility.
**Objectives:** To further explore the associations of the four SNPs (HLA-DP rs3077, HLA-DP rs9277535, HLA-DQ rs7453920 and STAT4 rs7574865) with the risk and clinical characteristics of AS in a Chinese Han population. And also to analyze the linkage disequilibrium (LD) in HLA gene and the association between the HLA haplotypes and the susceptibility to AS.
**Methods:** 400 patients with AS and 379 age- and sex-matched healthy controls in a Chinese population were included. All the four SNPs were genotyped using polymerase chain reaction high resolution melting (HRM) analysis. Allele, genotype, and haplotype frequencies were compared between AS patients and controls. Besides, stratification analyses of HLA-DP/DQ and STAT4 polymorphisms and risk for AS were also performed.
**Results:** No significant difference was observed between AS patients and healthy controls in the allele frequency of rs3077, rs9277535 and rs7574865. However, there was a significant association between the HLA-DQ rs7453920 G/A variant and AS patients, with minor allele A correlated with a reduced risk of AS (allelic frequency, OR=0.44, 95% CI: 0.31–0.62, p=3.0E-06; dominant model, OR =0.42, 95% CI: 0.29–0.62, p=7.0E-06). Moreover, the haplotypes block AAA and GGA in the HLA gene significantly correlated with reduced risk of AS (AAA: OR =0.38, 95%CI: 0.22–0.66, p=0.0004; GGA: OR=0.41, 95% CI: 0.24–0.69, p=0.0006).

**Conclusions:** This is the first study demonstrating the relationship between HLA-DQB2 rs7453920 and the risk of AS in a Chinese population. Besides, this study revealed that LD blocks around HLA–DP/DQ are strongly associated with AS susceptibility. This research sheds new light on the significant relationship between the SNPs in the HLA gene and the risk of AS.

## Innate immunity in rheumatic diseases

SAT0021 **TYPE 2 INNATE LYMPHOID CELLS ARE RAPIDLY AND PERSISTENTLY RECRUITED IN EXPERIMENTAL FIBROSIS AND THEIR COUNTS CORRELATE WITH THE SEVERITY OF SKIN AND LUNG FIBROSIS IN SYSTEMIC SCLEROSIS**

T. Wohlfahrt[1], S. Weber[1], M. Englbrecht[1], C. Dees[1], C. Beyer[1], O. Distler[2], G. Schett[1], J. Distler[1], A. Ramming[1]. *[1]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen, Germany; [2]Center of Experimental Rheumatology and Zurich Center of Integrative Human Physiology, University Hospital Zurich, Zurich, Switzerland*

**Background:** Type 2 innate lymphoid cells (ILC2s), are recently identified as population of cells with lymphoid morphology lacking re-arranged antigen-specific receptors.
**Objectives:** We aimed to evaluate the contributive role of ILC2s in the pathogenesis of systemic sclerosis (SSc), in particular their levels and correlations with fibrotic manifestations in SSc and various fibrotic mouse models.
**Methods:** Human blood samples and skin sections (69 patients with SSc and 47 healthy controls) as well as skin and lung tissue of various fibrotic mouse models were analyzed by flow cytometry and immunohistochemistry using two complementary panels of markers each. ILC2s were further phenotyped for activation and homing parameters. ILC2 counts were correlated with clinical manifestations of SSc
**Results:** Significantly elevated numbers of ILC2s were detected in the skin (10-fold increase) and blood (4-fold increase) of SSc patients by two independent established sets of ILC2 markers compared to healthy controls. In contrast to circulating ILC2s, skin-resident ILC2s express various activation markers and stained positive for skin homing markers. Furthermore, our data suggest that ILC2s might be involved in the pathogenesis of fibrosis in SSc by showing multiple associations of ILC2 counts with fibrotic manifestations in SSc patients. Significantly higher frequencies were observed in diffuse cutaneous (dc)SSc patients compared to limited cutaneous SSc (lcSSc). The modified Rodnan Skin Score (mRSS) positively correlated with ILC2 counts and pulmonary involvement. In parallel, we detected significantly elevated numbers of ILC2s in the fibrotic skin of bleomycin-induced and DNA topoisomerase I-induced mice compared to control mice. Moreover, in the tight-skin (Tsk)-1model of fibrosis resembling less inflammatory stages of SSc significantly increased ILC2 counts were detected compared to control mice. Kinetic analyses revealed an early upregulation of ILC2s in experimental models of fibrosis. In contrast to lineage positive lymphocytes that peak at early inflammatory stages of fibrosis, however disappear over time, ILC2s persist also in later stages of established fibrosis.
**Conclusions:** Here, we provide first evidence for a role of ILC2s in the pathogenesis of SSc by demonstrating increased ILC2 counts in the skin and blood of human SSc patients. These findings were indirect supported by elevated numbers of ILC2s in the fibrotic skin and lung sections of various mouse models for SSc, reflecting different pathophysiological aspects of the disease. Proliferation of ILC2s in the fibrotic skin, the activated state of dermal ILC2s and correlations of ILC2 counts with dermal and pulmonary fibrosis together with supporting findings of these cells in fibrotic areas of murine skin and lung samples suggest a central role of ILC2s in the pathogenesis of fibrosis.

SAT0022 **S100A8/A9 IS A POTENT SERUM AND IMAGING BIOMARKER TOOL FOR ASSESSING JOINT INFLAMMATION AND DESTRUCTION IN SERONEGATIVE EXPERIMENTAL ARTHRITIS**

E.J.W. Geven[1], S. Abdollahi-Roodsaz[1], A. Sloetjes[1], M.I. Koenders[1], D. Foell[2], J. Roth[3], T. Vogl[3], P.L.E.M. van Lent[1]. *[1]Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands; [2]Department of Pediatric Rheumatology and Immunology; [3]Institute of Immunology, University of Münster, Münster, Germany*

**Background:** Seronegative joint diseases, including psoriatic arthritis and juvenile idiopathic arthritis, are characterized by the lack of autoantibodies, which are relevant biomarkers for predicting disease activity in rheumatoid arthritis. Promising alternative biomarkers are the Damage Associated Molecular Patterns (DAMPs), S100A8, S100A9 and the heterodimer S100A8/A9. These proteins are specifically expressed and released by infiltrating phagocytes and may therefore serve as relevant biomarkers for joint inflammation and destruction in seronegative arthritis.
**Objectives:** In this study we determined the biomarker potential of serum S100A8/A9 and in vivo imaging of synovial S100A8 to asses joint inflammation and damage in the IL-1 receptor antagonist deficient (IL-1Ra$^{-/-}$) mice, a mouse model for seronegative arthritis in which serum autoantibodies are not correlated to disease activity.
**Methods:** Serum levels of S100A8/A9 and various cytokines were monitored during arthritis development in IL-1Ra$^{-/-}$ mice using ELISA and Luminex and were correlated to macroscopic and microscopic parameters for joint inflammation and

damage. Local S100A9 expression and matrix metalloproteinase (MMP) mediated cartilage damage in the ankle joints were investigated by immunohistochemistry. In addition local S100A8 and activated MMPs were monitored in vivo by optical imaging using anti-S100A8-Cy7 and AF-489-Cy7, a specific tracer for activated MMPs.

**Results:** Starting at week 8, serum levels of S100A8/A9 were significantly increased (1640 ± 1008 ng/ml at week 16) in IL-1Ra$^{-/-}$ mice compared to WT BALB/c control mice (429 ± 191 ng/ml, $P$ =0.005) and strongly correlated to joint swelling (r =0.766, $P$<0.0001), while serum levels of IL-1β, IL-6, TNFα, IL-17, IL-4 or IFN-α did not. In addition, high serum S100A8/A9 levels at week 10 were predictive for increased joint swelling at week 16 (r =0.576, $P$ =0.0002). Next to macroscopic swelling, increased serum S100A8/A9 also correlated to microscopic cell influx (r =0.794, $P$ <0.0001) and was reflected by local expression of S100A9 within the synovium, indicating the activated synovial lining as the source of increased serum S100A8/A9. Local expression of S100-DAMPs could also be monitored non-invasively by in vivo optical imaging using anti-S100A8-Cy7. Next to a biomarker for inflammation, S100-DAMPs may also be used for assessing joint damage. Indeed, arthritic IL-1Ra$^{-/-}$ mice showed increased cartilage damage (r =0.687, $P$ <0.0001) which coincided with MMP-mediated neoepitope (VDIPEN) expression and in vivo imaging of activated MMPs.

**Conclusions:** These findings underline the potential of S100-DAMPs as a systemic and local biomarker in seronegative arthritis, not only for assessing inflammation but also joint damage.

**Disclosure of Interest:** None declared

## SAT0023 ARTERY TERTIARY LYMPHOID ORGANS OCCUR IN GIANT CELL ARTERITIS

F. Ciccia[1], A. Rizzo[2], R. Alessandro[1], G. Guggino[1], S. Croci[3], S. Raimondo[1], A. Cavazza[3], C. Salvarani[3], G. Triolo[1]. *[1]University of Palermo; [2]Azienda Ospedaliera Villa Sofia Cervello, Palermo; [3]Arcispedale Santa Maria Nuova, Reggio Emilia, Italy*

**Background:** Arteries are immuno-privileged sites. In advanced atherosclerotic lesions, however, adventitial lymphoid infiltrates, sometimes aggregated in lymphoid follicles (the so called artery tertiary lymphoid organs, ATLO), occur together with marked neoangiogenesis and lymphangiogenesis, and with the extensive induction of high endothelial venules.

**Objectives:** To investigate if tertiary lymphoid organs (TLO) are present in GCA and their formation is associated with the ectopic expression of constitutive lymphoid tissue-homing chemokines.

**Methods:** RT-PCR, immunohistochemical and immunofluorescence analysis were used to determine the presence of ectopic TLO in GCA and the expression of chemokines/chemokine receptors and cytokines involved in lymphoneogenesis in the artery samples obtained from 50 GCA patients and 30 controls. The presence of lymphatic conduits, of follicular dendritic cells (FDC) precursors and lymphoid tissue inducer cells was also investigated. Finally, expression of CXCL13 and BAFF by isolated vascular smooth muscle cells was evaluated before and after stimulation with toll like receptors agonists and cytokines.

**Results:** Artery TLO (ATLOs) were observed in the media layer of 60% of GCA patients in close proximity to neo-formed PNAD+ high endothelial venules. Pesence of ATLOs was independent by the number of infiltrating mononuclear cells, the age of patients and the presence of atherosclerosis. ATLO formation was also accompanied by the expression of CXCL13, BAFF, APRIL, IL-7 and IL-17. CXLC13 and BAFF expression was manily observed in the context of ATLOs, in VSMC and endothelial cells of neo-formed high endothelial cells. IL-7 and IL-17 expression levels were significantly correlated with the levels of CXCL13 and BAFF. The presence of follicular dendritic cells (FDC) precursors and of lymphoid conduits was demonstrated by confocal microscopy analysis and immunohistochemistry, respectively. Stimulation of VSMC with TLR agonists (LPS and poly-IC) and pro-inflammatory cytokines (IL-1b, IL-6, IFN-g and IL-17) resulted in the up-regulation of BAFF and CXCL13.

**Conclusions:** ATLOs occur in the inflamed arteries of GCA patients possibly representing the immune sites where immune responses toward unknown arterial wall-derived antigens may be organized.

**Disclosure of Interest:** None declared

## SAT0024 EPIGENETIC ANALYSIS OF LPS-INDUCED TOLERANCE IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS AND MACROPHAGES

K. Klein[1], R.E. Gay[1], C. Kolling[2], L.-L. Lin[3], N. Bostanci[4], G. Belibasakis[4], B.A. Michel[1], S. Gay[1], C. Ospelt[1]. *[1]Center of Experimental Rheumatology, University Hospital Zurich, Schlieren; [2]Schulthess Clinic, Zurich, Switzerland; [3]Inflammation and Immunology Research Unit, Pfizer, Cambridge, United States; [4]Institute of Oral Biology, Center of Dental Medicine, Universtiy of Zurich, Zurich, Switzerland*

**Background:** In macrophages, repeated stimulation of Toll-like receptor (TLR) 4 leads to a tolerant state of the cell which protects inflamed tissues from damage. We have recently shown that rheumatoid arthritis (RA) synovial fibroblasts (SF) lack these protective mechanisms and maintain the secretion of inflammatory cytokines and matrix degrading metalloproteinases (MMPs) after repeated LPS stimulation.

**Objectives:** To investigate mechanisms behind LPS tolerizable and non-tolerizable effects in RASF and macrophages.

**Methods:** RASF, and *in vitro* differentiated peripheral blood derived macrophages from healthy donors were treated with LPS (100 ng/ml) for 24h and then re-stimulated with low doses of LPS (10 ng/ml) for another 24h. The expression levels of interleukins (IL), chemokines, MMPs, retionoic acid-inducible gene 1 (RIG1), melanoma differentiation associated protein-5 (MDA5) and 2'-5'-oligoadenylate synthetase (OAS1) were analyzed by multiplex immunoassays on the Luminex®200 platform, ELISAs or quantitative Real-time PCR. Nuclear factor-κB (NF-κB) and activator protein-1 (AP-1) promoter activities in RASF (n=4) were evaluated by Dual-Luciferase reporter assays after repeated stimulation with LPS. The levels of histone 3 (H3) and H4 acetylation (H3ac, H4ac) as well as H3 lysine 4 trimethylation (H3K4me3) in promotor regions of tolerizable (OAS1, RIG1) and non-tolerizable (IL6, IL8) genes in SF (n=6–7) and macrophages (n=5) were analyzed by Chromatin Immune precipitation (ChIP).

**Results:** Multiplex protein platform and ELISAs revealed that most of the IL and chemokines were tolerizable in macrophages and non-tolerizable in supernatants from RASF after repeated LPS stimulation. A lack of tolerizable effects of RASF was also found for MMP1 and MMP3, whereas the anti-viral response genes OAS1, RIG1 and MDA5 were tolerizable in RASF and macrophages. Reporter gene activities for NF-κB and AP-1 were similar in single and double stimulated RASF, excluding potential differences in the activation of these transcription factors as underlying mechanisms for tolerizable/non-tolerizable effects in RASF. The levels of the activating histone marks H3ac and H3K4me3 were decreased by LPS double compared to single stimulation of SF and macrophages in promoter regions of OAS1 and RIG1. These chromatin marks were not changed or even increased in promoter regions of IL6, IL8 and MMP1 in RASF. Interestingly, AcH3 levels in an IL6 (-525/-349) and an IL8 (-80/-25) promoter region were increased in RASF (IL6: single LPS: 1.38; double LPS: 1.5; IL8: single LPS: 0.17 double LPS: 0.24) but decreased in macrophages (IL6: single LPS: 1.55; double LPS: 1.14; IL8: single LPS: 0.61 double LPS: 0.51).

**Conclusions:** Epigenetic modifications on gene promoters contribute to differences in tolerization between RASF and macrophages. Since many pro-inflammatory cytokines and MMPs are *non*-tolerizable genes in RASF, epigenetic enzymes that maintain the aggressive phenotype of RASF in persistent inflammation are future therapeutic targets.

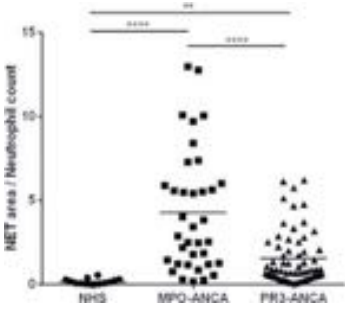
## SAT0025 ENHANCED CAPACITY OF MPO-ANCA COMPARED TO PR3-ANCA FOR INDUCING NEUTROPHIL EXTRACELLULAR TRAPS

T. Kraaij[1], S. Kamerling[1], J. Bakker[2], C. Pusey[3], H.U. Scherer[4], R. Toes[4], T. Rabelink[1], C. van Kooten[1], O. Teng[1]. *[1]Nephrology; [2]Clinical Chemistry, LUMC, Leiden, Netherlands; [3]Imperial College, London, United Kingdom; [4]Rheumatology, LUMC, Leiden, Netherlands*



**Background:** Neutrophil extracellular traps (NETs) are hypothesized to play an important role in the pathogenesis of ANCA associated vasculitis (AAV). On the one hand NETs can be part of the antigenic load in ANCA patients because NETs are covered with proteinase 3 (PR3) and myeloperoxidase (MPO) proteins (1). Presence of PR3 and MPO in a proinflammatory environment can induce ANCA autoantibody formation. On the other hand PR3- and MPO-ANCA autoantibodies by themselves have NET-inducing capabilities (1–3). The latter common pathway to induce NET release is intriguing taking into account the diverse clinical phenotype of granulomatosis with polyangiitis (GPA) versus microscopic polyangiitis (MPA).

**Objectives:** The present study aimed to better characterize the NET-inducing capabilities of PR3-ANCA and MPO-ANCA by using a novel assay to quantify NET release. This assay uses highly sensitive, 3-dimensional confocal laser scanning microscopy (3D-CLSM) to quantify in vitro NET release upon incubation with PR3- and MPO-ANCA.

**Methods:** Sera from 62 PR3+ patients, 36 MPO+ patients and 14 healthy subjects were collected. To induce and quantify NET release, healthy PKH-labelled neutrophils were seeded in a 96-well plate and stimulated with 10% sera. After 3¾ hours, cells were incubated with Sytox green for 15 minutes to stain NETs. NET release was imaged by automated 3D-CLSM and quantified with digital image analysis. NET release was represented as NET area corrected for neutrophil count. NET release was correlated with PR3- and MPO-ANCA titers as well as with clinical disease characteristics.

**Results:** Both MPO-ANCA and PR3-ANCA sera induced significant NET release (mean ± SEM for MPO-ANCA 4.29 ± 0.60, p<0.0001 and 1.56 ± 0.20 for

PR3-ANCA, $p<0.01$) as compared to NHS (0.17 ± 0.04). Moreover, MPO-ANCA induced significantly higher NET release than PR3-ANCA ($p<0.0001$) (Figure 1). NET release did not correlate with either MPO-ANCA titers ($r=0.17$, $p=0.35$) or PR3-ANCA titers ($r=-0.04$, $p=0.79$). We, then, categorized according to ANCA serotype and NET release.

**Conclusions:** We here demonstrate that MPO-ANCA has significantly enhanced NET-inducing capabilities compared to PR3-ANCA, which is independent of ANCA serum titers. These data point to a direct pathogenic role of ANCA autoantibodies in the perpetuation or relapse of AAV disease. Future studies will need to investigate whether ANCA-induced NET release can be a functional test to identify pathogenic from non-pathogenic ANCA in AAV patients.

## SAT0026 PRO-RESOLVING AND CARTILAGE-PROTECTIVE ACTIONS OF RESOLVIN D1 IN INFLAMMATORY ARTHRITIS

L. Norling[1], S. Headland[1], J. Dalli[2], H. Arnardottir[2], H. Jones[1], O. Haworth[1], C. Serhan[2], M. Perretti[1]. *[1]Barts and The London School of Medicine and Dentistry, London, United Kingdom; [2]Brigham and Women's Hospital and Harvard Medical School, Boston, United States*

**Background:** Dietary supplementation with fish oils has proved efficacious in reducing joint pain, swollen joint count and NSAID usage in RA patients, yet there is an unmet need to determine how they act. Omega-3 PUFA, which are abundant in fish oils are precursors to a new genus of protective bioactive lipids comprised of lipoxins, resolvins, protectins and maresins (collectively termed specialised pro-resolving mediators (SPM)).

**Objectives:** We hypothesised that SPM may offer a molecular mechanism for the beneficial effects of omega-3 consumption in RA patients. We tested the anti-arthritic potential of a specific SPM; Resolvin D1 (RvD1), in an inflammatory polyarthritis model and investigated novel mechanisms of action.

**Methods:** Metabololipidomic profiling on murine arthritic joints or human synovial fluids was performed by LC-MS/MS. Murine arthritis was induced by transfer of K/BxN serum. Mice were treated with 100ng AT-RvD1 daily either prophylactically or therapeutically ensuing overt signs of arthritis. Histology and flow cytometry was performed to assess joint leukocyte infiltrate. Human chondrocyte micromasses were cultured to assess chondroprotective actions of RvD1.

**Results:** Arthritic joints obtained from mice supplemented with an omega-3 rich diet contained elevated levels of protective SPM, and human RA synovial fluid analyses with LC-MS/MS revealed physiologically active levels of RvD1. Mice treated with a stable epimer of RvD1 (17*R*-RvD1) exhibited significantly attenuated arthritis severity, cachexia, hind-paw oedema and paw leukocyte infiltration and shortened the remission interval. Mechanistically, metabololipidomic profiling in arthritic joints revealed AT-RvD1 significantly reduced $LTB_4$, $TXB_2$ and prostaglandin biosynthesis, whilst selectively enhancing levels of protective SPM. AT-RvD1 stimulated genes associated with cartilage matrix synthesis, exhibited chondroprotection *in vitro* and direct intra-articular treatment prevented arthritis induced cartilage degradation. Joint protective actions of AT-RvD1 were abolished in ALX *(fpr2/3)* null mice, indicating the essential role of this receptor in mediating AT-RvD1 actions.

**Conclusions:** These studies indicate that this SPM offers a valuable therapeutic approach for inflammatory joint diseases including RA.

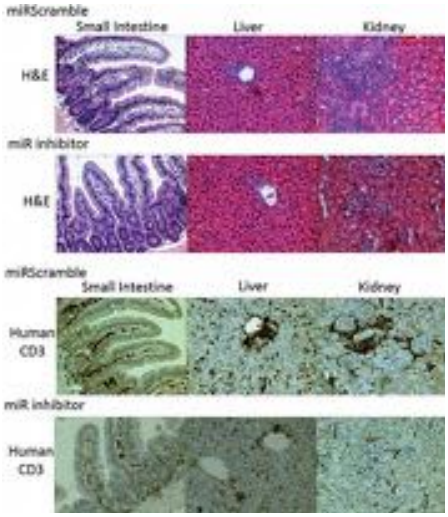
## SAT0027 INHIBITION OF TLR7 AND TLR8 SIGNALING BY ANTAGONIZING MICRO-RNA DERIVED FROM EXTRACELLULAR VESICLES SUPPRESSES INFLAMMATION IN A NOVEL HUMAN-MOUSE CHIMERIC MODEL OF LUPUS



N.A. Young, G. Valiente, J. Hampton, H. Steigelman, W. Jarjour. *Rheumatology and Immunology, The Ohio State University Wexner Medical Center, Columbus, United States*

**Background:** Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease affecting multiple organs and displaying a heavy female predominance during reproductive years. Our previous studies have demonstrated that toll-like receptor (TLR)7 and TLR8 are significantly up-regulated in peripheral blood mononuclear cells (PBMCs) of SLE patients and induced with estrogen treatment. While the conventional role of TLR7 and TLR8 involves binding to single-stranded RNA of viral origin to stimulate innate inflammatory responses, recent work has identified specific micro-RNAs (miRs) capable of activating these receptors that are packaged and secreted in exosomes.

**Objectives:** The goal of this study was to explore the therapeutic potential of using a cocktail of miR antagonists to block TLR7 and TLR8 inflammatory pathways induced by extracellular vesicle (EV)-derived miRs in SLE.

**Methods:** PBMCs from active SLE patients were adoptively transferred into immunodeficient NOD-scid IL-2rγ (null) mice to produce chimeras using a similar protocol we have previously established for Sjöjren's syndrome. PBMCs were treated with a cocktail of locked nucleic acid miR antagonists or nonsense, scrambled RNA control prior to injection. Blood was collected for both flow cytometry and cytokine analysis and tissues were processed for histopathological examination by H&E and immunohistochemistry.

**Results:** 21 days after adoptive transfer, human T-cells (CD4+ and CD8+), B-cells, monocytes, and NK cells were all successfully recovered from whole blood of chimeric mice at similar levels in both treatment groups. However, miR inhibition reduced levels of human IL-2, IL-6, IL-10, and TNF-α when compared to scramble (control) treatment. Although histopathological analysis revealed little to no inflammation in the skin and ear, miR inhibition blocked the robust responses detected in the small intestine, liver, and kidney with scramble RNA (control) treatment. Immunohistochemical analysis of the infiltrates confirmed the presence human CD3+ T-cells in these tissues and further demonstrated the suppression of inflammation following miR inhibition.

**Conclusions:** These results establish a novel chimeric model to study SLE and provide a platform to further explore the therapeutic efficacy of suppressing EV-encapsulated miRs that bind to TLR7 and TLR8 to induce autoimmune-mediated inflammatory responses.

## SAT0028 CIRCULATING SURFACTANT PROTEIN-D (SP-D) MOLECULAR SIZE PROFILE DIFFERS BETWEEN PATIENTS WITH UNTREATED AXIAL SPONDYLOARTHRITIS AND HEALTHY CONTROL SUBJECTS

H.L. Munk[1,2], D. Fakih[3,4], G.L. Sorensen[4], Q. Tan[5], L. Christiansen[5], A.F. Christensen[6], L. Ejstrup[7], A.G. Loft[6,8], K.O. Kyvik[2], R. Jounblat[3,9], U. Holmskov[4], P. Junker[1,2]. *[1]Department of Rheumatology, Odense University Hospital; [2]Department of Clinical Research, University of Southern Denmark, Odense, Denmark; [3]Laboratory of Immunology, Faculty of Public Health, Lebanese University, Fanar, Lebanon; [4]Department of Cancer and Inflammation Research, Institute of Molecular Medicine; [5]Department of Epidemiology, Biostatistics and Biodemography, University of Southern Denmark, Odense; [6]Department of Internal Medicine, Vejle Hospital, Vejle; [7]Department of Rheumatology, Esbjerg Hospital, Esbjerg; [8]Department of Rheumatology, Aahus University Hospital, Aahus, Denmark; [9]Department of Biology, Faculty og Sciences II, Lebanese University, Fanar, Lebanon*

**Background:** Surfactant protein-D (SP-D), an innate immune defence molecule of the collectin family has immune modulatory and anti-microbial effects and is expressed in lungs and on mucosal surfaces. The molecule consists of subunits ordered as trimers, dodecamers and even higher multimers. In healthy adults genes are responsible for the majority of the quantitative variation of SP-D in serum as well as its molecular size distribution[1]. High Molecular weight (HMw) SP-D is suggested to have anti-inflammatory properties, while low Mw (LMw) variants lack this capacity. In spondyloarthritis (SpA) SP-D correlates negatively with hsCRP and positively with patient global assessment. LMw variants have been shown to prevail in serum during inflammatory flares in chronic obstructive pulmonary disease.

**Objectives:** To investigate the distribution of SP-D HMw and LMw variants in serum among patients with SpA and controls according to the Met11Thr polymorphism.

**Methods:** 34 patients with SpA (age 22–63) according to the ASAS criteria, receiving NSAIDs only and 57 healthy controls (age 10–75) were included (Table 1). Total SP-D in serum was measured by ELISA and SNP rs721917 was genotyped. SP-D molecular size distribution was assessed using gel filtration chromatography. Integration of the area under the curves was performed to determine the ratio between HMw and LMw SP-D in serum.

**Results:** SP-D in SpA was in the normal range, 1092 ng/ml (725;1541) vs. controls, 910 ng/ml (494; 1682). Whereas the ratio of HMw:LMw serum SP-D was lower in SpA patients, 0.38 (0.18;0.53) compared to controls 1.49 (0.37; 3.24) even when adjusting for the Met11Thr polymorphism, gender, age, BMI and smoking (Table 2).

Tabel 1. Characteristics of patients and controls

| | SpA (n=34) | Control (n=57) | P-value |
|---|---|---|---|
| Sex (% male) | 71% | 42% | <0.0001 (Fisher test) |
| Age (y) | 36.4 (33.3- 39.6) | 39.7 (35.8–43.6) | 0.13 (Unpaired t-test) |
| Smoker | 32% | 51% | 0.006 (Fisher test) |
| BMI (kg/m$^2$) | 25.3 (23.7–26.9) | 25.6 (24.0–27.3) | 0.69 (Mann-Whitney test) |
| HLA-B27 | 82% | – | – |
| NSAID | 88% | – | – |
| Met11/Met11 | 8 (24%) | 21 (37%) | |
| Met11/Thr11 | 19 (58%) | 18 (32%) | |
| Thr11/Thr11 | 6 (18%) | 18 (32%) | |
| SP-D (ng/ml) | 1092 (725; 1541) | 910 (494; 1682) | 0.35 |
| H/L Mw SP-D ratio | 0.38 (0.18; 0.53) | 1.49 (0.37; 3.24) | 0.0004 |

Age, BMI: mean with 95% CI. SP-D and H/L Mw SP-D ratio: median with 25 and 75% percentile. Mann-Whitney test was used to compare SP-D levels and H/L Mw SP-D ratios.

Tabel 2. Ratio of HMw and LMw serum SP-D ratio between controls and SpA according to Met11Thr polymorphism

| H/L Mw SP-D ratio | Control | SpA | Difference | 95% CI | P-value |
|---|---|---|---|---|---|
| Met11/Met11 | 4,14 | 1,38 | –2,76 | –3.60 to –1.93 | P<0.001 |
| Met11/Thr11 | 1,51 | 0,36 | –1,15 | –1.84 to –0.46 | P<0.001 |
| Thr11/Thr11 | 0,22 | 0,06 | –0,16 | –1.15 to 0.83 | P>0.05 |

**Conclusions:** The molecular size distribution of circulating SP-D in patients with SpA is skewed towards preponderance of small size molecular variants. SpA related disease mechanisms may disrupt the multimeric state of SP-D, thereby amplifying the inflammatory burden of the disease.

## SAT0029 DECTIN-1 MEDIATES ABERRANT INNATE AND ADAPTIVE IMMUNE RESPONSE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M.Y. Mok, I.K. Lam, Y. Lo, D. Luk, W.C. Lau, W.K. Chan. *Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong*

**Background:** Dectin-1 is a c-type lectin receptor that signals via syk and is involved in anti-fungal immunity. Dectin-1 was found to trigger experimental inflammatory arthritis, and likely play a role in the pathogenesis of some autoimmune diseases.

**Objectives:** To examine (1) dectin-1 expression on circulating CD14+ monocytes in patients with systemic lupus erythematosus (SLE), (2) the effects of dectin-1 stimulation in ROS production by lupus monocytes and (3) syk signaling and cytokine profile of dectin-1 stimulated lupus monocyte-derived dendritic cells (MDDCs).

**Methods:** SLE patients with active and inactive diseases and healthy subjects were recruited. MDDCs were derived from peripheral monocytes in the presence of IL-4 and GM-CSF. Dectin-1 agonists including curdlan, zymosan and toll-like receptor agonists $Pam_3CSK_4$ (TLR2) and LPS (TLR4) were used to stimulate monocytes and/or MDDCs. Dectin-1, ROS and phosphorylated-syk (p-syk) were measured by flow cytometry. Cytokine profile was measured by and multi-bead immunoassay.

**Results:** The percentage of dectin-1 expressing monocytes was significantly lower in active SLE patients (64.5±24.3%) compared to inactive patients (89.6±7.2%) and healthy controls (91.7±9.5%) (both $p<0.001$). The absolute count of dectin-1 expressing monocytes correlated significantly and inversely with SLEDAI (r=-0.40, $p<0.001$), anti-dsDNA antibody level (r=-0.29, p=0.004), C3 (r=0.35, p=0.001) and C4 (r=0.24, p=0.02). Despite this, ROS production upon stimulation by dectin-1 agonists was comparable between these 3 groups. Stimulation of dectin-1 led to activation and maturation of MDDCs with upregulation of HLA-DR and CD86 (all $p<0.001$). SLE MDDCs showed higher p-syk activation compared to normal MDDCs upon dectin-1 stimulation (6.0±2.0 vs 2.8±1.0%, $p<0.001$). Curdlan-stimulated MDDCs produced higher levels of IL-1β, IL-23 and TNF-α. Adding TLR2 agonist to curdlan, SLE MDDCs produced significantly higher level of IL-1β (327.1±51.5 vs 125.3±88.5, p=0.009) and IL-6 (median 39.8 vs 21.7, p=0.03) compared to normal MDDCs. Combination of TLR4 agonist and curdlan induced IL-12 and TNF-α in normal MDDCs whereas lupus MDDCs produced predominant IL-6 and TNF-α.

**Conclusions:** Active SLE patients had significantly lower circulating dectin-1 expressing CD14+ monocytes which produced comparable level of ROS upon stimulation compared to inactive patients and healthy subjects. Dectin-1 agonists led to activation, maturation and higher p-syk activation in SLE MDDCs. Concomitant dectin-1 and TLR2 stimulation induced production of Th17 promoting cytokines, among which IL-1β and IL-6 were significantly higher in SLE compared to normal MDDCs.

## SAT0030 ACTIVE PMR AND GCA IS ASSOCIATED WITH CHANGES IN MONOCYTE SUBSET COMPOSITION

Q. Wang, K. van der Geest, Y. van Sleen, W. Abdulahad, J. Westra, A. Boots, E. Brouwer. *Rheumatology and Clinical Immunology, Universitity Medical Center Groningen, Groningen, Netherlands*

**Background:** Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are two closely related syndromes affecting older people. Pro-inflammatory cytokine IL-6 is found increased in both GCA/PMR patients and in the aged healthy population [1]. Pro-inflammatory monocytes, identified by CD16 and CD14 expression, increase with age and are potent producers of IL-6 [2]. Importantly, monocyte-derived macrophages have been identified in the inflamed arteries of GCA and contribute to the immunopathology of GCA [3]. Yet, peripheral monocyte subsets are less well studied in GCA and PMR patients.

**Objectives:** To assess the distribution of different monocyte subsets in newly diagnosed GCA and PMR patients before and after glucocorticoid (GC) treatment as well as the presence of CD16+ monocytes/macrophages in GCA temporal artery biopsies.

**Methods:** Peripheral blood samples of 24 newly-diagnosed GCA patients, 22 newly-diagnosed PMR patients and 24 age-matched, healthy controls (HCs) were studied. In a prospective, longitudinal study design, samples were obtained from 17 GCA and 15 PMR patients who were in remission after 3 month of treatment with GCs. Absolute numbers of total monocytes and non-classical ($CD14^{dim}CD16^{bright}$), intermediate ($CD14^{bright}CD16^{dim}$) and classical ($CD14^{bright}CD16^{-}$) monocytes were determined by truecount and flow cytometry. Immunohistochemical staining for detection of CD16 and CD68 was performed on sections of TAB from 15 GCA patients. Co-localization of CD16 and CD68 cells was performed using immunofluorescence.

**Results:** Total numbers of circulating monocytes were increased in newly-diagnosed GCA and PMR patients compared to age-matched HCs. Following 3 months of GC treatment, monocyte numbers normalized in PMR patients. When analysing absolute numbers of non-classical, intermediate and classical monocytes, we found the classical monocytes increased in newly-diagnosed GCA and PMR. GC treatment in GCA and PMR decreased numbers of non-classical

and intermediate monocytes but not classical monocytes. CD16 + cells were readily identified in GCA TABs. CD16 staining was detected in macrophage rich area's as evidenced by CD68 staining. Double Immunofluorescence using CD16 and CD68 showed the presence of double positive CD16+ CD68+ macrophages in GCA lesional tissue.
**Conclusions:** We show that peripheral monocyte numbers are modulated in active GCA and PMR. Treatment with GCs decreased CD16+ monocytes in GCA/PMR. CD16+ macrophages were readily detected in inflamed temporal artery biopsy tissue. The data may suggest a role for CD16+ monocytes in the pathogenesis of GCA/PMR.

## Rheumatoid arthritis - etiology, pathogenesis and animal models

### SAT0031 PREVALENCE, SENSITIVITY AND SPECIFICITY OF ANTIBODIES AGAINST CARBAMYLATED PROTEINS IN A LARGE COHORT OF ITALIAN RHEUMATOID ARTHRITIS PATIENTS

A. Pecani, C. Alessandri, F.R. Spinelli, T. Colasanti, M. Pendolino, C. Barbati, R. Mancini, F. Conti, G. Valesini. *Department of Internal Medicine and Medical Specialties, Rheumatology Unit, Sapienza University of Rome, Roma, Italy*

**Background:** Beside Rheumatoid Factor (RF) and anti-citrullinated peptide antibodies (ACPA), crucial biomarkers in the diagnosis of Rheumatoid Arthritis (RA), antibodies against carbamylated proteins (anti-CarP) have been recently identified in the sera of RA patients [1, 2]. Despite the interesting data presented up to now regarding anti-CarP in the sera of RA patients, the specificity and sensitivity of these new autoantibodies have not been addressed yet [3].
**Objectives:** To evaluate prevalence, sensitivity and specificity of anti-CarP compared to ACPA and RF, in a large cohort of RA patients, normal healthy subjects (NHS) and other disease controls.
**Methods:** A total of 607 frozen stored sera from 309 patients with established RA diagnosed according to the 2010 ACR/EULAR criteria, 98 NHS and 200 patients with other rheumatic conditions were evaluated. Sera were collected from consecutive unselected patients attending outpatient clinics of our department for clinical evaluation. The disease control group included patients with Systemic Lupus Erythematosus (SLE) (n=83), Sjögren's syndrome (SS) (n=45), systemic sclerosis (SCL) (n=51), and osteoporosis (OP) (n=21). Anti-CarP antibodies were detected by a modified solid phase "home-made" ELISA as described by Shi et al. using carbamylated foetal calf serum (FCS) as antigen [4]. ACPAs were detected using a second-generation ELISA (anti-CCP) kit (Delta Biologicals) while IgM RF was determined as part of routine analysis by immunonephelometry (Behering, Marburg, Germany).
**Results:** Anti-CarP antibodies were detected in 117 (34.4%) of RA patients, ACPA in 190 (61.4%) while RF in 202 (65.3%) of them. Two (2.04%) of the NHS were positive for anti-CarP, one (1.02%) for ACPA and three for RF (3.06%). Among disease controls, anti-CarP antibodies were detected in 14 (16.8%) of the SLE patients, 14 (31.1%) of SS patients, 3 (5.8%) of SCL patients and 2 (9.5%) of patients with OP. ACPAs resulted positive in 15 (18.07%) of the SLE patients, 11 (24.4%) of SS patients, 1 (1.9%) of SCL patients and 2 (9.5%) of patients with OP. On the other hand RF was detected in 19 (22.8%) of the SLE patients, 23 (51.1%) of SS patients, 18 (35.2%) of SCL patients and 4 (19.04%) of patients with OP. All data are summarised in Figure 1. To note, the sensitivity of anti-CarP, ACPAs and RF was 46.8%, 61.8% and 64.4% respectively while specificity was recorded as 91.95%, 89.93% and 76.51% respectively.

**Figure 1.** Anti-CarP antibodies in the sera of patients with rheumatoid arthritis, normal healthy subjects and disease control group.

Horizontal line corresponds to cut-off value.

Anti-CarP = antibodies against carbamylated proteins; NHS= normal healthy subjects; RA=rheumatoid arthritis; SLE=systemic lupus erythematosus; SS=Sjogren Syndrome; SCL= scleroderma; OP=osteoporosis.

**Conclusions:** Anti-CarP antibodies determined by the reactivity to carbamylated FCS, are predominantly present in RA but can also be detected in other rheumatic conditions. The prognostic relevance of anti-CarP antibodies in these latter patients should be further determined. Among the three autoantibodies studied, anti-CarP antibodies showed a slightly higher specificity but a relatively low sensitivity.

### SAT0032 PRO-RESOLVING MEDIATORS ISSUED FROM APOPTOTIC CELL EFFEROCYTOSIS (SUPERMAPO) MODULATE APC PROPERTIES TOWARD A TOLEROGENIC PROFILE: EFFICACY IN THE TREATMENT OF COLLAGEN- INDUCED ARTHRITIS

F. Bonnefoy [1], R. Vallion [1], M. Couturier [1], A. Daoui [1], E. Toussirot [2,3], S. Perruche [1]. *[1] INSERM UMR1098, Etablissement Français du Sang; [2] Clinical Investigation Center Biotherapy; [3] Rheumatology, University Hospital, Besançon, France*

**Background:** Pro-resolving mediators produced by macrophages eliminating apoptotic effector cells during the resolution of inflammation have been shown to stop inflammation, favor tissue repair and return to homeostasis. In immune-mediated inflammatory diseases such as rheumatoid arthritis (RA), one may believe that reintroducing pro- resolving mediators would allow the control of the disease. We have developed a cell culture system of macrophages and apoptotic cells that mimics this phase of resolution. The supernatant of this cell culture system called SuperMApo (SUPERnatant issued from Macrophage APOptotic cell culture) is enriched in pro-resolving factors including anti- inflammatory cytokines like TGF-b.
**Objectives:** to evaluate the effects of SuperMApo in the treatment of collagen-induced arthritis (CIA).
**Methods:** SuperMApo is obtained after 48h of culturing macrophages from peritoneal cavity with apoptotic cells obtained from thymus after X-ray irradiation. CIA was used as a model of RA. SuperMApo (200 μL of 5x concentrated SuperMApo, IV, for 2 days) was injected in score 8 CIA mice. The effect of SuperMApo was first evaluated on APC and T cells from naive mice in terms of phenotype, profile and properties such as maturation of APC before or after TLR-ligand stimulation and T cell polarization assays. Then, SuperMApo was evaluated in vivo in CIA mice.
**Results:** Macrophages, cDC and pDC submitted to SuperMApo demonstrated robust insensitivity to TLR ligand-induced activation, particularly in terms of co-stimulatory molecules expression. Spleen cells cultured with SuperMApo demonstrated a strong Treg increase. This was confirmed using naive CD4+CD25– T cells cultured in the presence of SuperMApo showing Foxp3 expression. CIA mice received 2 injections of SuperMApo (over 48h) and demonstrated a significant long term decrease of CIA (joint score before and after SuperMApo: 8–10 and 1–4, respectively; sustained response to 60 days). This clinical improvement was associated with a higher suppressive function of Treg. Treg transfer from mice treated by SuperMApo to arthritic mice induced joint improvement. Finally, we tested SuperMApo effect on PBMC issued from 4 patients with RA, with and without TLR ligand activation. Our results were that monocytes from 3 patients showed a decreased inflammatory phenotype after overnight exposure to SuperMApo (CD80, CD86, CD40 and HLA-DR expression).
**Conclusions:** these data demonstrated that macrophages eliminating apoptotic cells produced pro-resolving mediators affecting APC properties therefore allowing the control of arthritis in the CIA model.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4715

### SAT0033 CIRCULATING PLATELETS IS ACTIVATED AND ASSOCIATED WITH DISEASE ACTIVITY OF PATIENTS WITH RHEUMATOID ARTHRITIS

H. Yasuoka, M. Kato, K. Yoshimoto, K. Yamaoka, T. Takeuchi. *Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Physiologically, platelets can distribute systemically by circulation and contribute to hemostasis after activation [1]. Activated platelets acquire functional abilities of adhesion, and morphological changes, and releasing ingredients or small vesicles called microparticles (MP) [2]. On the other hand, recent reports have been shown that platelets include a lot of humoral factors such as chemokines, cytokines and growth factors [3], suggesting that platelets

and MPs can be vectors for transferring these factors to the lesions and contribute to disease processes such as inflammation [4].
**Objectives:** To examine the hypothesis that platelets is involved in the pathogenesis of Rheumatoid arthritis (RA), we investigated the activation status of circulating platelets and the association with clinical characteristics using a brief evaluation system.
**Methods:** Fifty-seven patients with RA were involved and 7 primary Sjogren's syndrome (pSS), 4 systemic lupus erythematosus (SLE), and 16 healthy controls were examined as controls. Fractions of platelets and microparticles were determined by the size less than 1mm in diameter using forward and side scatter of flow cytometry with Megamix® beads. Activated platelets were detected by $CD41^+CD62P^+$ population in the platelet fraction. Platelet-derived MPs were determined $CD41^+annexinV^+$ population in microparticle fraction. Activation status of platelets was examined by the ratio of CD62P-positive to negative platelet population. Proportion of platelet-derived MPs was examined by the ratio of platelet-derived MPs to platelets population. Correlation of activation status of platelets, MP and clinical parameters of patients with RA were also examined.
**Results:** Proportion of activated platelets and that of MPs were higher in RA compared to HC ($P<0.001$, $P<0.00001$, respectively). Serial analysis of 6 patients, who were treated with methotrexate and/or biologics and achieved improvement of disease activity at 12 week after the treatment, revealed significant decrease of these proportions ($P<0.03$). On the other hand, these parameters were comparable between HC and pSS or SLE. In patients with RA, proportion of activated platelets and those of MPs were correlated each other ($P<0.0001$). Interestingly, proportion of activated platelets and MPs were positively correlated with clinical parameters of patients with RA such as serum CRP ($P<0.05$, $P<0.05$, respectively), erythrocyte sedimentation rate ($P<0.03$, $P<0.05$, respectively), and CDAI ($P<0.05$, $P<0.05$, respectively), which were markers of disease activity. Whereas, no correlation was observed with age, sex, tender- and swollen-joint count, HAQ, nor MMP-3.
**Conclusions:** In patients with RA, platelets are activated and their activation status is correlated with the inflammatory markers and disease activity, suggesting that activation of platelets can contribute to the process of systemic chronic inflammation in the pathogenesis of RA.

## SAT0034 NICOTINE IS A POTENT DRIVER OF NETOSIS AND ACCELERATES COLLAGEN-INDUCED ARTHRITIS

J. Lee[1,2], A. Luria[3], C. Rhodes[3], H. Raghu[2,3], O. Sharpe[2,3], W. Robinson[2,3], J. Sokolove[2,3]. *[1]Rheumatology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of; [2]Immunology/Rheumatology, Stanford University School of Medicine; [3]VA Palo Alto Health Care System, Palo Alto, United States*

**Background:** Cigarette smoking is a major risk factor for rheumatoid arthritis (RA). The contribution of nicotine, the most ubiquitous and addictive component in the traditional as well as electronic cigarettes (e-cigarettes), to the development of RA remains unclear. Recent evidences implicate aberrant Neutrophil Extracellular Trap (NET) formation in the pathogenesis of RA.
**Objectives:** This study was undertaken to investigate the effect of nicotine on NETosis and its ability to potentiate arthritis in a murine model of RA.
**Methods:** Human neutrophils were incubated with nicotine in the presence of DNA-binding dye (Sytox) to quantify NETosis. In parallel, levels of NET-associated myeloperoxidase (MPO)/DNA complexes were measured using a novel NET-specific ELISA. Immunofluorescent staining was used to perform microscopic kinetic analysis of NETosis and to assess the presence of nicotinic acetylcholine receptors (nAChRs) in these neutrophils. NETosis were measured after stimulating neutrophils with GTS-21 ($\alpha$7-specific nAChR agonist) or mecamylamine (an AChR antagonist). Finally, the effect of systemic nicotine exposure on arthritis development and progression was investigated using subcutaneous osmotic nicotine pumps in the collagen-induced arthritis (CIA) mouse model.
**Results:** Neutrophils derived from current smokers displayed significantly higher level of spontaneous- and PMA-induced NETosis as measured by Sytox assay and by NET-specific ELISA. In line with this, nicotine enhanced NETosis in a dose-dependent manner in vitro. Furthermore, incubation with APCA-immune complexs or TNF-$\alpha$ facilitated priming of neutrophils to undergo nicotine-induced NETosis. Immunofluorescent staining revealed that nicotine induced robust formation of NET-like structure in these neutrophils. Cell surface staining with an $\alpha$7-specific agonist ($\alpha$-bungarotoxin) and anti-$\alpha$7-specfic antibody demonstrated co-localization on the plasma membrane. Nicotine-induced NETosis was reproduced when stimulated with GTS-21 and was abrogated when neutrophils were pretreated with mecamylamine. A significantly increased arthritis score as measured by paw swelling and thickness was observed in CIA mice treated with nicotine compared with vehicle treated controls.
**Conclusions:** Our data indicate that nicotine is a potent inducer of NETosis and may play an important role in the initiation and propagation of RA. Furthermore, our study provides molecular evidence for public awareness and clinical guidance against the use of nicotine-containing products including e-cigarettes in patients with RA.
**Disclosure of Interest:** None declared

## SAT0035 REGULATORY CD4+ T-CELL LEVELS AND ANTI CITRULLINATED PROTEIN ANTIBODY REPERTOIRE AS BIOMARKERS FOR ARTHRITIS DEVELOPMENT IN SEROPOSITIVE ARTHRALGIA PATIENTS

K. Janssen[1], J. Westra[2], P. Chalan[2], A. Boots[2], M. de Smit[3], A.J. van Winkelhoff[3,4], A. Vissink[1], E. Brouwer[2]. *[1]Department of Oral and Maxillofacial Surgery; [2]Department of Rheumatology and Clinical Immunology; [3]Center for Dentistry and Oral Hygiene; [4]Department of Medical Microbiology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands*

**Background:** Early diagnosis and treatment of rheumatoid arthritis (RA) is of paramount importance for achieving a better disease outcome. Seropositive arthralgia patients (SAP), positive for anti citrullinated protein antibody (ACPA) and/or rheumatoid factor (RF) with (a history of) arthralgia, have a "high risk" of developing RA. Therefore it is necessary to understand which preclinical immunological factors play a role in the progression towards RA in SAP since this could help identify individuals earlier and result in early intervention.
**Objectives:** This prospective study aimed at identifying whether altered regulatory T-cells (Tregs) levels and subsets, besides a broadened ACPA response, are biomarkers for RA development in SAP.
**Methods:** Thirty-four consecutive SAP were prospectively assessed every 6 months for at least 2 years. Every visit, peripheral blood mononuclear cells (PBMCs) were isolated and stored. At inclusion, peripheral Treg ($CD4^+CD25^+FoxP3^+$) levels and Treg subsets, defined as $CD45RA^+FoxP3^{low}$ naive Treg cells (Fr I), $CD45RA^-FoxP3^{high}$ activated Treg cells (Fr II) and cytokine producing $CD45RA^-FoxP3^{low}$ non-Treg cells (Fr III), were compared to age and sex matched healthy controls (HC, n=16) and treatment naive RA patients (n=12). SAP that developed RA during follow-up were compared to non-switchers on Treg levels and functional Treg subsets. To assess broadening of the IgG and IgA ACPA repertoire in serum, reactivity was measured against citrullinated peptides from fibrinogen, $\alpha$-enolase and vimentin.
**Results:** Total Treg levels were similar between HC, SAP and RA patients. Although functional Treg subsets Fr I and Fr II were comparable between groups, Fr III was increased in SAP compared to HC ($p=0.01$). Fourteen (41%) SAP developed RA during follow-up. Their Treg levels were comparable to those of non-switched SAP. At RA diagnosis, Treg levels in switched SAP were not changed compared to 6 months before. Switched SAP displayed an extended IgG ACPA repertoire compared to non-switched SAP ($p=0.046$).
**Conclusions:** Total and functional Treg levels do not indicate development of RA in SAP, in contrast to an extended IgG and IgA ACPA repertoire. Hence, there is presumably no contribution of altered Treg levels leading to the loss in suppression of autoimmunity in RA pathology.
**Disclosure of Interest:** None declared

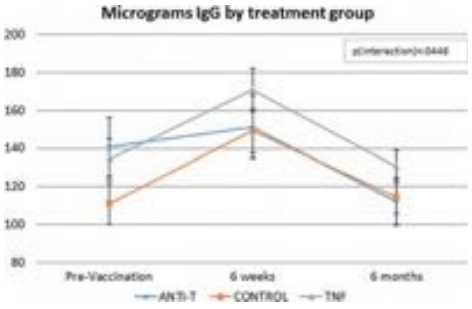
## SAT0036 BRAIN IGF1 RECEPTOR SIGNALING CONTROLS BEHAVIOR OF ARTHRITIC MICE

K. Andersson[1], L. Leifsdottir[1], M. Erlandsson[1], S. Töyrä[1], M. Pekna[2], M. Pekny[2], K. Olmarker[3], M. Bokarewa[1]. *[1]Dept rheumatology and inflammation research, Inst Medicine; [2]Dept of Clinical Neuroscience and Rehabilitation, Inst of Neuroscience and Physiology; [3]Dept of Medical Chemistry and Cell Biology, Inst of Biomedicine, Göteborg, Sweden*



**Background:** Insulin-like growth factor (IGF-1) signaling is essential for development and function of the brain. It helps to improve neuronal plasticity in response to stress, and recently it has been reported to mediate depression [1]. In rheumatoid arthritis (RA), depression is a serious comorbidity with a tight connection to functional disability and early mortality [2]. The serum levels of IGF-1 and the local expression of its receptor (IGF-1R) in inflamed joints are affected in RA [3]. However, the brain IGF-1R signaling in arthritis and its consequences for behavior has not been studied previously.
**Objectives:** In this study we analyze how arthritis affects IGF-1R expression and activity in the brain and its relation to behavioral changes.
**Methods:** Arthritis was induced in DBA/1 mice by immunization with collagen type II. Development of arthritis was followed clinically. One group was treated with shRNA targeting IGF1R, second group obtained control shRNA, and naïve healthy siblings comprised the control group. Behavioral pattern of each mouse was registered by filming at different stages. Protein and mRNA levels of IGF-1R, CD68 and IL-1b were measured in different parts of the brain with IHC and real-time PCR. Serum IGF-1 and IL6 were analyzed with a sandwich ELISA. We

validated the findings from experimental arthritis with a cohort of 235 patients with established RA.
**Results:** In RA patients, the arbitrary measure of pain (VAS) was mainly associated with depression index (FIQ, r=0.46), fatigue (r=0.44), and disability index (r=0.68) rather than to RA activity (DAS28, r=0.36). In mice, arthritis decreased locomotion and rearing, corresponding to the depressive-like behavioral pattern. Severity of arthritis and decreased mobility correlated with the increased mRNA levels of inflammatory cytokine IL-1, and a marker of activated microglia CD68. We observed a decreased expression of IGF-1R and a remarkable reduction in the number and regularity of the Purkinje cells in the cerebellum accompanied by an accumulation of phosphorylated tau along these cells. Arthritis increased serum levels of IGF-1, which correlated with behavioral pattern in arthritic mice. When the IGF1R signaling was inhibited with shIGF1R-treatment, the arthritic mice showed aggravation of the depressive-like behavior, including increased immobility time, which was no longer correlated to severity of arthritis.
**Conclusions:** Depression and functional disability aggravate pain experience in RA patients. Arthritis-induced inhibition of IGF-1R expression and signaling provide molecular mechanism of depression in RA.

## SAT0037 DURATION OF IMMUNE RESPONSE TO INFLUENZA VACCINATION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICAL AGENTS

N. Yuklyaeva[1], D.A. Lawrence[2], D. Raddatz[1], J. Kasten-Jolly[2], M. Scribani[1], J. Victory[1], J. Tirrell[1], A.A. Chaudhary[1], S. Sornprom[1], A. Sanguankeo[1]. *[1]Bassett Medical Center, Cooperstown; [2]Wadsworth Center, NewYork State Department of Health, Albany, United States*

**Background:** After influenza vaccination, limited data is available to prove effective anti-influenza status at the end of the season[1].
**Objectives:** To assess the strength and duration of response to trivalent influenza vaccine (A-California/07/2009(H1N1), A/Texas/50/2012 (H3N2), B/Massachusetts/02/2012) in patients with rheumatoid arthritis (RA) receiving biological agents.
**Methods:** Sera were collected prior to vaccination, and 4–6 weeks and 5–6 months thereafter. The vaccine was given in the age-appropriate dose recommended by the manufacturer. Antibody response to vaccination was measured by detection of vaccine-specific IgG using ELISA. Hemagglutination inhibition assay (HIA) was used to determine patients who were seroprotected (titer>1:40) prior to vaccination, and patients seroconverted (≥4-fold increase) post-vaccination[2].
**Results:** Study comprised of 88 subjects, 16 in Anti-T cell agent (abatacept) group, 35 in anti-TNF (adalimumab, certolizumab, etanercept, golimumab, infliximab) group and 37 were age-matched healthy controls. When tested by HIA, all subjects fulfilled the criteria for seroprotection prior to vaccination and only one patient failed to seroconvert by the end of the season. Levels of vaccine-specific IgG (mean±SE) for each of the groups with respect to each time point were: control group pre-vaccination 111.07±11.05 μg, 6 weeks post-vaccination 149.19±11.76 μg and 6 months post-vaccination 114.62±8.94 μg; Anti-T-cell group pre-vaccination 140.93±15.41 μg, 6 weeks post vaccination 151.33±16.4 μg and 6 months post vaccination 112.22±12.47 μg; Anti-TNF group pre-vaccination 134.33±10.63 μg, 6-weeks post vaccination 170.96±11.31 μg and 6-months post vaccination 130.67±8.6 μg. The three-way ANOVA model produced a statistically significant two-way interaction of diagnostic group*time (p=.0446) indicating a differential pattern of antibody response across the groups, with a more moderate slope between pre-vaccination and 6 weeks post-vaccination among the Anti-Tcell group as compared to the other two groups. Statistically significant positive correlations were found between baseline titer and titer at 6 weeks and 6 months post-vaccination for each of the three diagnostic groups tested individually. There was no correlation between RA and treatment duration with antibody titers at 6 weeks and 6 months post-vaccination.

**Conclusions:** The study suggests that anti-Tcell therapy may affect the strength and duration of IgG-mediated immune response and protection may fade away before the end of the influenza season. At the same time, response of patients on anti-TNF therapy was comparable to the control group. HIA results indicated all patients were seroprotected at the baseline and nearly all seroconverted whereas ELISA analysis helped reveal the more subtle dynamics of the immune response.

## SAT0038 CONFIRMATION OF SEROLOGICAL ANTIBODIES AGAINST NOVEL CITRULLINATED PROTEINS IN EARLY RHEUMATOID ARTHRITIS

P. Schulz-Knappe[1], P. Budde[1], A. Lueking[1], P. Schriek[1], H. Goehler[1], H.-D. Zucht[1], J. Detert[2], G.-R. Burmester[2], M. Schneider[3], J. Richter[3], S. Vordenbäumen[3]. *[1]Science, Protagen AG, Dortmund; [2]Charité University Medicine, Charité, Berlin; [3]Policlinic of Rheumatology, Heinrich-Heine-University, Düsseldorf, Germany*

**Background:** Rheumatoid Factors (RF) and autoantibodies against citrullinated proteins (ACPA) are part of the diagnosis of rheumatoid arthritis (RA). Unfortunately these analytes lack sensitivity especially in early phases of RA. By way of screening proteins from a human protein library of over 7,000 proteins we discovered over 20 novel citrullinated antigens targeted by ACPAs in CCP positive as well as in 5–10% of CCP negative RA patients suggesting added diagnostic potential.
**Objectives:** To challenge novel human proteins as biomarkers for early RA which exhibited reactivities in citrullinated format against early and late RA patient serum samples we set to analyze sufficiently large, new cohorts of patients with early and established RA against the candidate proteins both in their citrullinated and non-citrullinated form. We also planned to veify single antigen performance by comparison to established benchmark proteins and marketed assays.
**Methods:** 34 novel citrullinated antigens were analyzed in serum samples from independent cohorts of 300 CCP positive and 151 CCP negative patients with early RA, 100 healthy volunteers and 50 patients with established RA. All samples were analyzed in a multiplexed, bead-based array on Luminex FlexMAP3D, compared to reactivities against known citrullinated proteins (vimentin, fibrinogen, enolase) and subsequently in 3 commercially available anti-CCP-assays.
**Results:** We confirmed novel citrullinated antigens targeted by ACPAs as markers of RA. The citrullinated antigens are highly reactive compared to their non-citrullinated forms in mature RA and in CCP positive samples of patients with early RA. 4 single antigens reach high overlap to established CCP-Assays each with >75% sensitivity at 97% specificity. Increased reactivity of novel antigens was identified in up to 10% of CCP negative samples suggesting the presence of additional citrullinated epitopes not present in commercial CCP assays used in this study.
**Conclusions:** Novel citrullinated antigens discovered by large scale "omics" screening via Luminex bead based arrays were confirmed in novel samples of early and established RA, especially in CCP positive samples. Reactivity in 10% CCP negative samples suggests added diagnostic value.

## SAT0039 ENDOGENOUS GLUCOCORTICOID PRODUCTION BY THE ENZYME 11BETA-HYDROXYSTEROID DEHYDROGENASE TYPE 1 IS INCREASED WITH INFLAMMATION IN MUSCLE, WHERE IT SUPPRESSES INFLAMMATORY CYTOKINE OUTPUT AND PROTECTS AGAINST MUSCLE WASTING IN VIVO

R.S. Hardy[1], Z. Hussain[1], M. Pearson[1], A. Filer[1], C. Buckley[1], G. Lavery[2], M. Cooper[3], K. Raza[1]. *[1]Institute of Inflammation and Aging; [2]Institute of Metabolism and Systems Research, The University of Birmingham, Birmingham, United Kingdom; [3]ANZAC Research Institute, University of Sydney, Sydney, Australia*

**Background:** Local generation of endogenous glucocorticoids (GCs) by the enzyme 11beta-Hydroxysteroid Dehydrogenase Type 1 (11beta-HSD1) with inflammation has been shown to be an important anti-inflammatory pathway in both

acute and chronic inflammatory disease. Whilst beneficial within inflamed tissues such as the rheumatoid synovium (through suppression of pro-inflammatory pathways), the inflammatory regulation and impact of 11beta-HSD1 on neighbouring tissues such as muscle remain poorly defined.
**Objectives:** To characterise the inflammatory regulation of 11beta-HSD1 in muscle during systemic inflammation and examine its functional consequences on muscle inflammation and wasting in vitro and in vivo using primary human tissue and a transgenic murine model of polyarthritis.
**Methods:** Inflammatory regulation of 11beta-HSD1 was examined in primary myotube culture and ex vivo muscle biopsies isolated from human donors and from transgenic TNF overexpressing (TNF-tg) mice, as a model of systemic polyarthritis. Inflammatory cytokine output, myotube viability and markers of inflammatory muscle wasting were measured following exposure to endogenous GCs activated by 11beta-HSD1. The contribution of 11beta-HSD1 to muscle status in vivo was examined in the TNF-tg mouse on an 11beta-HSD1 global null background.
**Results:** In both human and murine primary muscle culture, 11beta-HSD1 mRNA and activity were significantly increased in response to the pro-inflammatory cytokine TNFa (mRNA; 7.6 fold, $p<0.005$, activity 4.1 fold, $p<0.005$). 11beta-HSD1 mRNA and activity were evident in ex vivo biopsies of murine and human muscle from tibialis anterior and quadriceps. This expression was augmented in response to TNFa and in muscles harvested from TNF-tg mice relative to wild type controls. Endogenous GCs activated by 11beta-HSD1 suppressed pro-inflammatory cytokine output of IL-6, TNFa, and IFNg, but had little impact on markers of muscle wasting and cell viability in myotube culture. To delineate the contribution of 11beta-HSD1 to suppression of inflammation and muscle wasting in vivo, we generated a TNF-tg mouse on an 11beta-HSD1KO background. These animals had more marked muscle wasting with reduced muscle weight relative to body weight (TNF-tg; 13.45%; TNF/11bKO, 36.2%; $p<0.005$), smaller compacted muscle fibres and increased pro-inflammatory gene expression.
**Conclusions:** This study demonstrates that in muscle, as observed in tissues such as the rheumatoid synovium, 11beta-HSD1 and endogenous glucocorticoid activation are markedly increased in response to inflammation. Whilst concerns have been raised that excess levels of GCs may contribute to factors such as muscle wasting, in this model, local endogenous glucocorticoid activation appears to be overwhelmingly anti-inflammatory in nature and protective in regards to inflammatory muscle wasting in vivo.

## SAT0040 THE ACTIVE METABOLITE OF LEFLUNOMIDE, A77 1726, ATTENUATES ARTHRITIS SEVERITY IN MICE WITH SPONTANEOUS ARTHRITIS VIA INDUCTION OF HEME OXYGENASE-1

S.-J. Moon[1], H.-S. Kim[2]. *[1]Division of Rheumatology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of; [2]Division of Rheumatology, Department of Internal Medicine, The Soonchunhyang University Seoul Hospital, Seoul, Korea, Republic Of*

**Background:** Rheumatoid arthritis (RA) is a debilitating, chronic autoimmune polyarthritis, characterized by synovial hypertrophy and inflammatory cell infiltration. Although the pathogenesis of RA is not understood clearly, altered oxidative stress is considered to play a critical role during the development and perpetuation of the disease. Although the pathogenesis of RA is not understood clearly, altered oxidative stress is considered to play a critical role during the development and perpetuation of the disease. Over the course of evolution, defensive mechanisms against oxidative stress have been developed. One major mechanism in the cellular defense against oxidative stress is activation of the nuclear-related factor 2 (Nrf2), a key transcription factor that contributes to the maintenance of cellular redox homeostasis. One of the major stress-responsive players regulated by Nrf2 is the antioxidant enzyme heme oxygenase-1 (HO-1). Nrf2 signaling has received recent attention as a participant in the pathogenesis of RA. Leflunomide is an oral drug that inhibits de novo pyrimidine synthesis by inhibiting dihydroorotate dehydrogenase. Leflunomide exerts immunoregulatory properties and is useful in RA treatment. Despite the clinical usefulness of the drug, the underlying mechanisms of the drug remain elusive.
**Objectives:** We investigated the antiarthritis effects and mechanisms of action of the active metabolite of leflunomide, A77 1726, in interleukin-1 receptor antagonist-knockout mice (IL-1Ra-KO mice).
**Methods:** To assess the therapeutic effect of A77 1726 on symptom severity in the IL-1Ra-KO mouse model, 14–15-week-old male IL-1Ra-KO mice were treated with 10 mg/kg or 30 mg/kg A77 1726. On day 42 after the first A77 1726 injection, the spleen was removed from each mouse in the different groups. Histologic analysis of the joints was performed using Safranin O, toluidine blue, and immunohistochemical staining. Sandwich ELISA kits were used to measure the amounts of IL-1β, TNF-α and malondialdehyde in sera obtained from the mice. The epxression of HO-1 in splenocytes was analyzed by immunostaining and western blotting.
**Results:** A77 1726 reduced the arthritis severity and cartilage destruction. The joints isolated from A77 1726-treated mice showed decreased expression of inducible nitric oxide synthase, nitrotyrosine, TNF-α, and IL-1β. Interestingly, HO-1 expression was significantly higher in splenic CD4+ T cells isolated from A77 1726-treated mice compared with those from vehicle-treated mice. A77 1726 treatment in Jurkat cells significantly increased nuclear HO-1 activity. Proteome profiler array revealed that A77 1726 slightly activated the phosphorylation of Akt in Jurkat cells. The ability of A77 1726 to induce HO-1 was diminished when Akt activity was blocked.
**Conclusions:** We suggest that the inhibitory effects of A77 1726 on joint inflammation and oxidative stress occur through Akt-dependent HO-1 induction in CD4+ T cells.

## SAT0041 MICRORNA-146A AN IMPORTANT REGULATOR OF LOCAL BONE DESTRUCTION IN INFLAMMATORY ARTHRITIS

V. Saferding[1], A. Puchner[1], E. Goncalves-Alves[1], M. Hofmann[1], S. Hayer[1], P. Georgel[2], M.M. Koenders[3], G. Schabbauer[4], J.S. Smolen[1], G. Steiner[1], K. Redlich[1], S. Blüml[1]. *[1]Rheumatology, Medical University of Vienna, Vienna, Austria; [2]Centre de Recherche en Immunologie et Hématologie, Université de Strasbourg, Strasbourg, France; [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands; [4]Physiology, Medical University of Vienna, Vienna, Austria*

**Background:** MicroRNA (MiR-) 146a plays an important role in the regulation of the innate immune response and has also been shown to suppress cancer development in myeloid cells. Although in late stages of arthritis elevated expression of miR-146a in synovial tissue of rheumatoid arthritis patients was detected, the level of this miRNA was found to be down regulated in early disease, but its role in the development of inflammatory arthritis is still elusive.
**Objectives:** To analyse the role of miR-146a in arthritis using two different disease models hTNFtg and K/BxN serum transfer arthritis and the regulatory function of this miRNA in fibroblasts and immune cells.
**Methods:** We induced K/BxN serum transfer arthritis in wild type and miR-146a$^{-/-}$ mice. As a second inflammatory arthritis model we crossed miR-146a deficient into hTNFtg mice. Disease severity was assessed clinically and histologically in both arthritis disease models. Blood of arthritis animals was analysed by flow cytometry. Serum cytokine levels were measured by Elisa. RNA expression levels were measured by qPCR. Proliferation of fibroblasts was analysed histologically and by $^{3}$[H]thymidine incorporation.
**Results:** Absence of miR-146a leads to increased clinical signs of the induced serum transfer arthritis. In line, higher serum levels of the proinflammatory cytokines IL-12 and IL-6 were measured in miR-146a deficient compared to wt mice. When we crossed miR-146a$^{-/-}$ into hTNFtg mice, histological examination revealed a significant increase in synovial inflammation and even more striking a more than twofold increase in local bone destruction due to increased generation of osteoclasts in the tarsal joints in miR-146a$^{-/-}$/hTNFtg mice compared to hTNFtg mice. Interestingly, systemic bone loss was comparable in hTNFtg compared to miR-146a$^{-/-}$/hTNFtg mice, suggesting an important local role of miR-146a. Indeed, we detected increased levels of IL-1β, TRAF6 and RANKL and decreased expression of OPG locally in the paws of miR-146a$^{-/-}$/hTNFtg compared to hTNFtg mice. Analysing the content of myeloid cells in the blood of arthritis diseased mice, revealed significantly increased numbers of circulating CD11b$^{+}$ as well as CD11c$^{+}$ cells in mice lacking miR-146a. Bone marrow transplants demonstrated a pivotal role for miR-146a in mesenchymal cells in controlling local osteoclast generation and bone destruction. Moreover loss of miR-146a leads to enhanced proliferation of synovial fibroblasts *in vitro* and *in vivo*.
**Conclusions:** These data demonstrate an important mitigating role of the miR-146a in inflammatory arthritis, most importantly in local bone destruction, by controlling mesenchymal expression of osteoclastogenic factors. This shows an important anti-inflammatory role of miR-146a, which might possibly be exploited for therapeutic purposes.

## SAT0042 DISENTANGLING THE ROLE OF HYPOXIA-INDUCIBLE FACTOR 1 AND 2 IN THE ADAPTION PROCESS OF HUMAN MICROVASCULAR ENDOTHELIAL CELLS TO PATHOPHYSIOLOGICAL HYPOXIA

M. Hahne[1,2,3], P. Kunath[1,2], M. Mursell[1,2], C. Strehl[1,2], G.-R. Burmester[1], F. Buttgereit[1], T. Gaber[1,2]. *[1]Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin; [2]German Rheumatism Research Center (DRFZ); [3]Miltenyi Biotec GmbH, Berlin, Germany*

**Background:** Angiogenesis is a prominent feature of the pathogenesis of RA. Although new blood vessels deliver oxygen to the augmented inflammatory cell mass, the neovascular network is dysfunctional and fails to restore tissue oxygen

homeostasis, so that the inflamed joint remains markedly hypoxic. At a cellular level, hypoxia is detected by a mechanism that regulates the amount of hypoxia-inducible factor (HIF)-1α and -2α. After translocation to the nucleus, HIF-1α or HIF-2α subunit bind its partner HIF-1β to form a functional, heterodimeric transcription factor, HIF-1 and HIF-2, which activate a gene program associated with angiogenesis, glycolysis, and adaptation to pH.
**Objectives:** The distinct functions of HIF-1 and HIF-2 in the hypoxia-induced angiogenesis and metabolic switch of endothelial cells are still unknown and therefore aim of this study.
**Methods:** Therefore, we investigated the adaption of Human Microvascular Endothelial Cell (HMEC)-1 to pathophysiologic hypoxic conditions (1% $O_2$). Angiogenesis assay and cytokine analyses were conducted to describe angiogenesis. Gene expression and ATP/ADP measurements were performed to visualize the bioenergetic switch under hypoxia. shRNA-technology enabled a specific knockdown of either HIF-1α or HIF-2α or the combination of HIF-1α and HIF-2α, in order to identify distinct functions of both transcription factors, which were assessed via microarray analysis.
**Results:** Hypoxia induced angiogenesis and a bioenergetic switch from oxidative phosphorylation towards glycolysis. Knockdown of either HIF-1α or HIF-2α leads to a reduced angiogenesis *in vitro*. Although HIF-1α and HIF-2α show overlapping functions during adaption of HMEC-1 towards hypoxia reduction of HIF-1α resulted in a diminished cellular energy supply due to a reduction in hypoxia-induced glycolytic enzyme gene expression thereby not altering pro-angiogenic factors VEGF, VEGF receptor 1 and 2, and IL8. In contrast, reduction of HIF-2α resulted in a reduction of hypoxia induced pro-angiogenic VEGF and IL8 gene and protein expression but induction of VEGFR1 without altering glycolytic enzyme gene expression. Finally, the results of HIF-1α/HIF-2α combined knockdown demonstrate that the lack of both factors significantly reduced cell survival as compared to the scramble control thereby diminishing both gene expression of pro angiogenic factors and glycolytic enzymes.
**Conclusions:** Our results indicate distinct but also overlapping functions of HIF-1α and HIF-2α in ECs which are of high interest regarding the intervention of tumour growth but also the chronicity of the inflammatory process in RA. Finally we clearly demonstrate a major impact of HIF-1α and HIF-2α on angiogenesis mediated either via the expression of pro-angiogenic factors in case of HIF-2α or via the glycolytic switch in case of HIF-1α. At least both are essential for endothelial cellular function. These findings open new possibilities for therapeutic approaches by targeting the specific hypoxia induced factors.

## SAT0043 INHIBITORY POTENTIAL OF SPECIFIC MONOCLONAL ACPAS IN TWO MOUSE SUBSPECIES GENETICALLY SEPARATED ABOUT ONE MILLION YEARS AGO

C. Grimm[1], B. Marklein[1], K. Rosenberger[1], Z. Konthur[2], G.R. Burmester[1], K. Skriner[1]. *[1]Department of Rheumatology and Clinical Immunology, Humboldt University and Free University; [2]Hennigsdorf, Germany, Drug Response Dx GmbH, Berlin, Germany*

**Background:** Rheumatoid arthritis is believed to be induced by environmental, genetic and immunological factors. Monoclonal Anti-citrullinated protein autoantibodies ACPA target different proteins and their role in RA is still largely unknown
**Objectives:** As a prerequisite to identify genetic factors involved in rheumatoid arthritis, we analyzed the susceptibility of PWD Mus musculus musculus subspecies, separated from Mus musculus domesticus about one million years ago to collagen antibody-induced arthritis (CAIA) and the role of ACPA antibodies in the CAIA model of arthritis.
**Methods:** Collagen antibody-induced arthritis (CAIA) was induced by administration of collagen antibodies followed by lipopolysaccharide injection. Two genetically distinct mouse strains, representatives of the subspecies *Mus musculus domesticus* and *Mus musculus musculus* as well as their F1 hybrids, and consomis strains thereof were analyzed for the development of clinical and histological signs of arthritis upon CAIA treatment. ACPA antibodies were tested by adding it to the CAIA cocktail and their autoantigenic profile was generated using protein macroarrays previously described (Leidinger et al., 2009; Lin et al, 2007; Ludwig et al. 2008).
**Results:** The wild-derived mouse strain PWD/Ph was highly susceptible to CAIA induced arthritis, whereas the classical laboratory strain C57BL/6J was resistant. Mice carrying chromosomes 5 or 12 from PWD on a B6 background display a B6-like phenotype in the CAIA model as well as the F1 hybrids (B6xPWD and PWDxB6) implicating the presence of dominant resistance modifiers in the C57BL/6J genetic background. The two mouse strains differ highly in their autoantigenic profile and the PWD strain show decrease of B-cells and IgA, IgG, IgM levels. Injecting specific monoclonal ACPAs reactive with the citrullintated H1 and H4 were able to block the CAIA induced arthritis. This inhibition can be explained in part by the inhibition of osteoclasts via a Toll 9 activation. DNAse treatment of ACPA immune complex blocks the the osteoclast inhibition in vitro in a dose dependent manner. Moreover TLR2 activation via P. gingivalis LPS and lipomannan treated animals show a 80% reduction of arthritis score compared to E. coli LPS in a C57BL/6J CAIA model. Anti-collagen specific antibodies are increased in both strains B6 and PWD when arthritis is induced.Rheumatoid factor RF was not detected in PWD or B6 mice before and after the CAIA-treatment nor in the LPS-treated control animals. Interestingly, the commercial CCP2 ELISA detected ACPA in some animals regardless of the treatment. Using the arginine and citrulline containing peptides as control shows that this response is directed to the arginine containing peptide and in most of the animals citrullination downregulates the antigenicity of the autoantibody targeted peptides.
**Conclusions:** The *Mus musculus musculus* derived mouse strain PWD/Ph is highly susceptible to arthritis development in the CAIA model. TLR2 activation blocks CAIA and specific ACPAs are able to block Osteoclast activation via TLR9 activation and may be used as therapeutic antibodies in the future that protect from RA development.

## SAT0044 ROBUST THERAPEUTIC EFFICACY OF MATRIX METALLOPROTEINASE-2 CLEAVABLE FAS-1-RGD PEPTIDE COMPLEX ON CHRONIC INFLAMMATORY ARTHRITIS

E.J. Nam, J.H. Kang, K.H. Sa, S. Sung, H. Al Faruque, J.S. Eun, N.R. Kim, Y.M. Kang. *Kyungpook National University Hospital, Daegu, Korea, Republic Of*

**Background:** Transforming growth factor-β-inducible gene-h3 (βig-h3) is an ECM protein, which consists of integrin-interacting structures including four homologous fas-1 domains and an Arg-Gly-Asp (RGD) motif, is abundantly found within synovial tissues and fluid of rheumatoid arthritis (RA). In the pathogenesis of RA, βig-h3 intensifies inflammatory processes by facilitating adhesion and migration of fibroblast-like synoviocyte (FLS) via binding to αvβ3 integrin. Based on these functions, fragmented peptides of βig-h3 have been developed as therapeutic agents for chronic inflammatory arthritis. Expression of MMP-2 is highly upregulated within the invasive pannus and associated with radiographic erosions in RA. Therefore, therapeutic agents that are transformable via introducing cleavable linkage by locally enriched MMP-2 within the pannus tissue would enhance targetability and therapeutic efficacy on chronic inflammatory arthritis.
**Objectives:** To investigate whether MMP-2 cleavable peptide complex consisted of fas-1 domain and RGD peptide blocks the interaction between βig-h3 and resident cells and leads to the amelioration of inflammatory arthritis.
**Methods:** We designed βig-h3-derivatives, including the fourth fas-1 domain truncated for H1 and H2 sequences of mouse (MFK00) and MMP-2-cleavable peptide complex (MFK902). MMP-2 selectivity was examined by treatment with a series of proteases. MFK902 efficacy was determined by the adhesion and migration assay with NIH3T3 cells *in vitro* and collagen-induced arthritis (CIA) model *in vivo*. The mice were treated intraperitoneally with MFK902 at different dosages (1, 10, or 30 mg/kg).
**Results:** MFK902 was specifically cleaved by active MMP-2 in a concentration-dependent manner. Both MFK00 and MFK902 revealed a dose-dependent inhibition of βig-h3-mediated adhesion of fibroblasts and were similarly effective at a lower concentration (1 μM), compared with RGD peptide. In the migration assay, a very high concentration of RGD peptide (500 μM) reduced fibroblast migration by less than 50%. The lowest effective concentration of MFK00 for inhibition was 1 μM with the $IC_{50}$ of 13.56 ± 1.28 μM. The $IC_{50}$ of cell migration for MFK902 was 4.56 ± 0.25 μM with the degree of inhibition higher than 2 fold at 1 μM and higher than 5 fold at 20 μM. In *in vivo* assay with a murine CIA model, treatment with all dosages of MFK902 resulted in a slower onset of arthritis, followed by less steep increase of clinical arthritis index up to day 50 with significantly lower scores, compared with controls. On day 50, the incidence of arthritic paws for the control group was 94%, whereas those for 1, 10, and 30 mg/kg groups with MFK902 treatment were 54, 41, and 38%, respectively. MFK902 ameliorated histopathologic deterioration and reduced the expression of inflammatory mediators in parallel with improvement of clinical features. In addition, a favorable safety profile of MFK902 was demonstrated *in vivo*.
**Conclusions:** The present study reveals that the MMP-2-cleavable peptide complex, based on βig-h3 structure, was a potent and safe therapeutic agent for chronic inflammatory arthritis and provides a reliable evidence for the MMP-2-cleavable mechanism as a tissue-targeted strategy to treat rheumatoid arthritis.

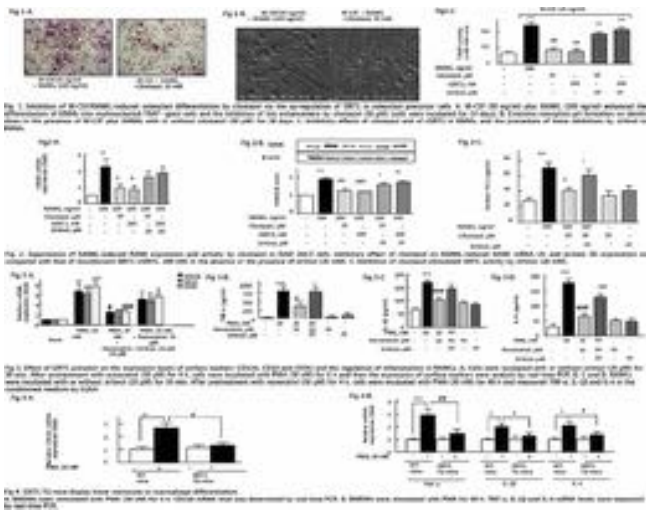
## SAT0045 ANTIBODIES DIRECTED AGAINST ENDOGENOUS AND EXOGENOUS CITRULLINATED ANTIGENS PRE-DATE THE ONSET OF RHEUMATOID ARTHRITIS

L. Johansson[1], F. Pratesi[2], M. Brink[1], L. Ärlestig[1], C. D'Amato[2], D. Bartaloni[2], P. Migliorini[2], S. Rantapää-Dahlqvist[1]. *[1]Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden; [2]Clinical and Experimental Medicine/Immunology, University of Pisa, Pisa, Italy*



**Background:** Anti–citrullinated-peptid/protein antibodies (ACPA) have been detected in individuals pre-dating symptom onset of rheumatoid arthritis (RA), with an initial limited spectrum of reactivities that gradually broadens to different citrullinated substrates typical of RA (1,2). The recent discovery of NETs as source of citrullinated antigens, and namely citrullinated histones H3 and H4 (3). We have previously described deiminated sequences contained in EBV-derived

proteins EBNA1 and EBNA2 as specific targets of ACPA in sera from patients with RA (4).
**Objectives:** The aim was to analyze the evolution of the antibody response predating the symptom onset using citrullinated exogenous (viral peptides) and self (H4 peptides) antigens as substrates to detect ACPA.
**Methods:** A cohort of 521 individuals sampled before symptoms of RA, and 272 population controls were identified as being donors to the Medical Biobank of Northern Sweden; 241 plasma samples from early RA-patients were also collected. ACPA were detected by ELISA on viral citrullinated peptides derived from Epstein-Barr-virus-encoded protein (EBNA1) and EBNA2 (VCP1 and VCP2) and on histone 4 derived peptides (HCP1 and HCP2).
**Results:** Anti-VCP1 antibodies were detected in 10.4% of the pre-symptomatic individuals as compared with 36.1% in early RA; anti-VCP2 in 17.1% vs. 52.3%; anti-HCP1 in 10.2% vs. 37.3%; anti-HCP2 in16.3% vs. 48.5%. Anti-VCP and -HCP concentrations were significantly increased in pre-symptomatic individuals as compared with controls ($p<0.001$) and increased approaching symptom onset. ACPA specific for HCP or VCP appeared simultaneously (median (Q1-Q3) 5.3 (2.9–8.9) years before symptom onset). Combination of anti-VCP1, -VCP2 and–HCP2 and negativity for -HCP1 yielded a high risk ratio (OR=18.70; 95%CI 2.53–138.47; $p<0.004$). Anti-VCP2 and -HCP2 antibodies were associated in pre-symptomatic individuals with HLA-SE in particular DRB1*0401 but not with the *PTPN22* T-allele. Three PADI3/PADI4 single nucleotide polymorphisms (rs3003444, rs7542629 and rs11800688) were significantly associated with anti-HCP1 antibodies after Bonferroni corrections.
**Conclusions:** Anti-VCP and -HCP antibodies predate symptom onset and predict disease development, but no hierarchy of citrullinated epitopes is clear of the ACPA response. These results suggest that no inciting citrullinated antigen so far described is common to all RA patients; rather data suggest a stochastic mechanism in ACPA production. Anti-HCP1 antibodies were associated with PADI polymorphisms.

## SAT0046 REGULATION OF SIRT1 MAYBE A PIONEERING STRATEGY IN TREATMENT OF RHEUMATOID ARTHRITIS

S.Y. Lee[1], W.T. Chung[1], S.W. Lee[1], S.Y. Park[2]. *[1]Rheumatology of Internal Medicine, Dong-A University Hospital; [2]Pharmacology, Pusan national university, Pusan, Korea, Republic Of*

**Background:** Monocyte maybe a dual role in rheumatoid arthritis (RA) development, because of differentiation to macrophages in joint and osteoclasts in bone so, blocking of monocyte differentiation maybe effective target in RA treatment.
**Objectives:** In this study, we interrupted monocyte differentiation to macrophages and osteoclasts via SIRT1 blocking and proposed pioneering treatment of RA.
**Methods:** In this study, monocytes from synovial fluid of RA patients (RAMCs), THP-1 monocytes, bone marrow–derived monocytes (BMDCs) from mice and RAW 264.7 cells were studied. PMA-induced expression of macrophages surface markers (CD11b, CD14 and CD36), proinflammatory cytokines (TNF-α, IL-1β and IL-6) secretion and differentiation of BMDCs from SIRT1 TG mice were measured after administration of resveratrol, which was reversed by sirtinol, an inhibitor of sirtuin proteins. In addition, RANKL [receptor activator of nuclear factor kappa B (RANK) ligand]-induced RANK expression in bone marrow–derived monocyte/macrophage precursors (BMMs) and RAW 264.7 cells were treated cilostazol and this was blocked by sirtinol (a SIRT1 inhibitor) in vitro and in a mouse model of collagen-induced arthritis (CIA).

**Results:** PMA-induced expression of macrophages surface markers (CD11b, CD14 and CD36) and proinflammatory cytokines (TNF-α, IL-1β and IL-6) secretion was inhibited by resveratrol. BMDCs from SIRT1 TG mice were inhibited differentiation by PMA than control BMDCs from C57BL/6 mice. These effects were associated with decrease in proinflammatory cytokines (TNF-α, IL-1β and IL-6) secreation by decreasing mRNA expression in BMDCs from SIRT1 TG mice. Further, resveratrol suppressed the PMA-induced PU.1 activation, which is critical transcription factor for macrophages differentiation. SIRT1 inhibits monocytes to macrophages differentiation through the down-regulates PU.1 activity and cilostazol elevated SIRT1 mRNA and protein levels in 12–24 h and increased SIRT1 activity, and these effects were also inhibited by sirtinol. Furthermore, the RANKL-induced nuclear expression of PU.1 was suppressed by cilostazol. In addition, marked RANKL-induced RANK immunofluorescence staining in Raw264.7 cells was strongly attenuated by cilostazol and by rSIRT1, and these attenuations were prevented by sirtinol. Extensive RANK staining of knee synovial tissues in a mouse model of collagen-induced arthritis (CIA) was also markedly reduced by cilostazol (30 mg/kg/day), and in BMMs both RANKL- and M-CSF-induced differentiation of BMMs to multinucleated $TRAP^+$ giant cells and resorption pit formation were inhibited by cilostazol in association with a decrease in TRAP (a marker enzyme of osteoclasts) activity.
**Conclusions:** SIRT1 have dual a role in anti-osteoclast formation BMMs of RA bone and inhibiting differentiation monocyte to macrophage in RA synovium. so, SIRT1 maybe a perfect strategy for RA treatment.

## SAT0047 LOCAL CRYOTHERAPY DOWN-REGULATES LOCAL AND SYSTEMIC IL-6 AND IL-17 PATHWAYS IN ADJUVANT-INDUCED ARTHRITIS

X. Guillot[1,2], H. Martin[2], K. Maguin-Gaté[2], S. Py[3], C. Demougeot[2], D. Wendling[1], N. Tordi[2]. *[1]Rheumatology Department, Besançon University Hospital, Besançon; [2]FDE EA4267, FHU INCREASE, Bourgogne Franche-Comté University, Besançon; [3]INSERM-CIC 1431, Besançon University Hospital, Besançon, France*

**Background:** Cryotherapy is widely and empirically used in an adjuvant and symptomatic setting in inflammatory rheumatic diseases, with a low level of evidence [1].
**Objectives:** The aim of this work was to evaluate local and systemic anti-inflammatory effects of local cryotherapy (LC) in adjuvant-induced arthritis (AIA), comparing 2 techniques (ice and cold gas spray). We considered clinical (arthritic score and ankle diameter) and biological effects on IL-6, IL-17A, IL-1β, TNF-α local and systemic levels.
**Methods:** Arthritis was induced by a single Mycobacterium butyricum injection in male Lewis rat tails (day 0). At the onset of arthritis (day 11), rats were treated either by 30 minute-ice applications on hind paws (in cages lined with ice pops – n=10) or by 2 minute-cold gas pulverizations on both hind paws (n=9) twice a day for 14 consecutive days. Ten non-treated AIA rats were used as controls. At day 24 (the day after the last cold application), hind paws were grinded in order to measure cytokine gene expression levels by Q-RT-PCR. Plasmatic levels of the same cytokines were also measured in plasma by cytometry (Multiplex Magpix® ebioscience). IL-6 plasma levels were measured by ELISA (rat IL6 platinum ELISA, BMS625®, ebioscience).
**Results:** Ice application significantly reduced the mean arthritic score and ankle diameter from day 6 to day 14 ($p<0.001$) and globally throughout the 14 day treatment period (2-way ANOVA: $p<0.001$) compared to non-treated AIA controls. Cold gas first aggravated arthritis at days 11–12 ($p<0.01$) then improved clinical inflammation at days 21–24 ($p<0.001$). Skin temperature after LC didn't differ between treatment groups. Both techniques significantly reduced IL-6, IL-1β, IL-17A gene expression levels in hind paws at day 24 compared to non-treated AIA (by 60%, 87% and 50% respectively, $p<0.001$, $p<0.001$ and $p<0.05$). Cytokine gene expression levels correlated positively with hind paw arthritic score and ankle diameter. Conversely, LC had no effect on TNF-α gene expression in hind paws. LC also significantly reduced IL-17A plasmatic protein levels at day 24 (Ice: 47±3pg/ml versus 132±15pg/ml; n=9; $p<00001$ – cold gas: 89±12pg/ml versus 132±15pg/ml; $p<0.02$) and IL-17A plasmatic levels correlated positively with arthritic score, ankle diameter and negatively with weight gain. Ice also reduced IL-6 plasmatic levels (118±20pg/ml versus 197±60pg/ml; $p<0.05$). LC had no effect on TNF-α nor IL-1β plasmatic levels.
**Conclusions:** These results demonstrate in vivo previously unknown therapeutic and anti-inflammatory effects of 14 day-LC in AIA. We observed both local (at the gene level in treated hind paws) and systemic (at the protein level in plasma)

down-regulation of key cytokine pathways critically involved in the pathogenesis and severity of inflammatory rheumatic diseases. LC local and systemic anti-inflammatory effects were mainly IL-6/IL-17A-driven and TNF-α-independent in this model.

## SAT0048 OVEREXPRESSION OF CCL18 PROMOTES MIGRATION AND ACTIVATION OF FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS

Y.-Q. Mo[1], J. Jing[1], J.-D. Ma[1], C. Deng[2], L.-F. Chen[1], D.-H. Zheng[1], L. Dai[1].
*[1]Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University; [2]Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou, China*

**Background:** CC chemokine ligand 18 (CCL18) has been reported overexpressed in numerous inflammatory disorders since 1997. However, its functional receptor, phosphatidylinositol transfer membrane-associated phosphatidylinositol transfer protein 3 (PITPNM3), has not been discovered until 2011 by our colleagues. Multiple functions of CCL18 besides its chemotactic activity were then identified, including promoting cytokine production, migration/invasion of cancer cells, type I collagen production by human fibroblasts of lung or skin. The effect on the pathogenesis of rheumatoid arthritis (RA) remains unclear.
**Objectives:** To explore the expression of CCL18 in RA patients and its effect on RA fibroblast-like synoviocytes (FLS).
**Methods:** CCL18 in serum and synovial fluid was measured by ELISA. Synovial tissue was obtained by closed-needle biopsy for H&E and immunohistochemistry staining, and FLS culture *in vitro*. Expression of PITPNM3 on cell membrane was detected by western blot. Cell proliferation was identified by cell counting kit (CCK-8) and migration ability was analyzed by transwell assay. Cytokines (IL-1β, IL-6, IL-17A, TNF-α, GM-CSF), chemokines (CCL2, CCL3, CCL5, CCL8) and MMP3 in culture supernatant were measured by Cytometric Bead Array (CBA) or ELISA.
**Results:** (1) Serum CCL18 of 51 active RA patients was 112 ng/mL (IQR, 85–132), which was significantly higher than healthy controls ($n$=11, 64 ng/mL (IQR, 36–70), $p<0.001$, Figure 1A). Eighteen RA patients had synovial fluid and CCL18 in synovial fluid was 1229 ng/mL (IQR, 934–1540) which was significantly higher than corresponding serum level ($p<0.001$) and synovial fluid CCL18 of osteoarthritis patients ($n$=7, 33 ng/mL (IQR, 25–229), $p$=0.001). (2) Immunohistochemistry staining showed CCL18-positive cells in lining and sublining area of RA synovium (n=48), which were significantly greater than osteoarthritis synovium (both $p$=0.001, Figure 1B∼D). Double-immunocytofluorescent staining showed vimentin-positive RA-FLS *in vitro* expressed PITPNM3 (Figure 2A) and western blot of membrane protein showed the expression of PITPNM3 protein on RA-FLS. (3) RA-FLS was incubated with different concentrations of CCL18 (0, 100, 250, 500 ng/mL) and CCK-8 proliferation assay showed no significant impact throughout 9 days (Figure 2B). Transwell assay showed that the migration ability of RA-FLS was significantly enhanced after stimulation of CCL18 (500 ng/mL) for 48 hours (Figure 2C). IL-6, CCL2 and MMP3 in culture supernatant were significantly increased after stimulation of CCL18 (500 ng/mL) for 48 hours (Figure 2D∼F).

Figure 1 CCL18 expression of rheumatoid arthritis (RA) patients and the control groups in serum (A), synovial fluid (A) and synovium (D). CCL18 expression in representative synovium from a RA patient (B, according to a 4-scale semiquantitative score, 4 scores for lining and 3 scores for sublining) and an OA patient (C, 3 scores for lining and 2 scores for sublining). In panels B and C, immunohistochemical stains of CCL18 with DAB as chromogen (brown), with original magnification of ×400.

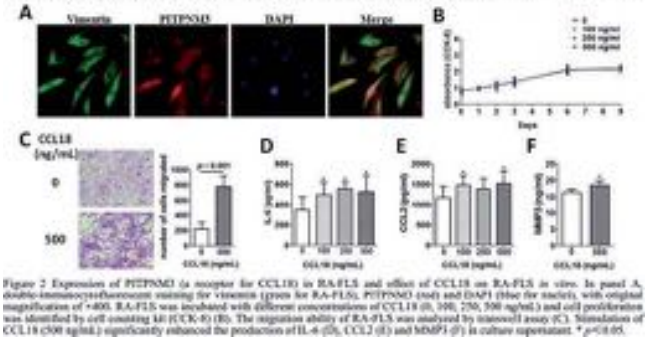

Figure 2 Expression of PITPNM3 (a receptor for CCL18) in RA-FLS and effect of CCL18 on RA-FLS *in vitro*. In panel A, double-immunocytofluorescent staining for vimentin (green for RA-FLS), PITPNM3 (red) and DAPI (blue for nuclei), with original magnification of ×400. RA-FLS was incubated with different concentrations of CCL18 (0, 100, 250, 500 ng/mL) and cell proliferation was identified by cell counting kit (CCK-8) (B). The migration ability of RA-FLS was analyzed by transwell assay (C). Stimulation of CCL18 (500 ng/mL) significantly enhanced the production of IL-6 (D), CCL2 (E) and MMP3 (F) in culture supernatant. * $p<0.05$.

**Conclusions:** Our preliminary results show overexpression of CCL18 in synovial tissue and fluid of RA patients can stimulate migration and activation of RA-FLS probably through the interaction between CCL18 and PITPNM3.

## SAT0049 CIRCULATING CD45+ CD34+ CD11B+ CELLS ARE IMMATURE FIBROCYTES AND THE LEVEL CORRELATES WITH THE NUMBER OF MONONUCLEAR CELLS THAT IN VITRO DIFFERENTIATE TO MATURE FIBROCYTES: A POTENTIAL NEW MARKER FOR INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS

S.A. Just[1], C. Nielsen[2], J.R. Davidsen[3,4], N. Bjerring[3], E.K. Hejbøl[5], S.W.K. Hansen[6], H.D. Schrøder[5], I.M.J. Hansen[7], T. Barington[2], H. Lindegaard[1]. *[1]Rheumatology; [2]Clinical Immunology; [3]Respiratory Medicine; [4]South Danish Center of Interstitial Lung Diseases; [5]Clinical Pathology, Odense University Hospital; [6]Institute of Molecular Medicine, University of Southern Denmark, Odense; [7]Medicine, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark*

**Background:** Circulating fibrocytes express both hematopoietic (CD45+ CD34+), and mesenchymal markers (Collagen+). The circulating "immature" fibrocytes can differentiate to "mature" fibrocytes in the target organ and there produce fibrosis components. Chronic inflammatory stimuli mediate differentiation of fibrocytes in diseased organs as observed in idiopathic pulmonary fibrosis (IPF) and asthma, where the levels of circulating fibrocytes correlated to disease severity. In Rheumatoid Arthritis (RA), interstitial lung disease (ILD) is an fibrotic disease manifestation with limited treatment options.
**Objectives:** 1) To demonstrate that circulating CD45+ CD34+ CD11b+ cells can express Procollagen and thereby show that these markers can be used to identify circulating fibrocytes. 2) To measure the levels of CD45+, CD34+, CD11b+ cells in patients with RA, Fibrotic ILDs, severe asthma and in healthy controls (HC). 3) To compare the levels with number of peripheral blood mononuclear cells (PBMC) that differentiate to mature fibrocytes *in vitro*.
**Methods:** CD45+, CD34+, CD11b+ cells from 4 patients were isolated by cell sorting, and stained for Procollagen. 30 patients (10 of each RA, fibrotic ILDs: IPF or non-specific interstitial pneumonitis, severe asthma) and 10 HC were included. Current medication, disease activity, lung function and radiographic data were collected. In 100 μL of lysed blood cells were enumerated by flowcytometry. Further, PBMC were isolated and cultured for 5 days. Coverslips from two wells were stained and mature fibrocytes counted and reported as fibrocytes per $10^6$ PBMC originally added to the well.
**Results:** A higher fraction of sorted CD45+ CD34+ CD11b+ cells stained positive for Procollagen, compared to CD45+ CD34+ CD11b- cells. All groups had higher level of CD45+ CD34+ CD11b+ cells compared to HC (all $p<0.05$). HC had a median of 1.02 cells/μL (IQR 0.71–1.32), RA 2.38 (IQR 1.93–4.39), asthma 3.45 (IQR 2.25–8.08) and fibrotic ILDs 5.89 (IQR 2.86–10.2). The number of CD45+ CD34+ CD11b+ cells correlated to number of PBMC that *in vitro* differentiated to mature fibrocytes, overall (r=0.62, p=0.0006), notably in the RA group (r=0.92, p=0.0005), the level of CD45+ CD34+ CD11b- cells did not.
**Conclusions:** This study supports that the markers CD45+ CD34+ CD11b+ can be used to identify immature fibrocytes, as they can express Procollagen and are more abundant in fibrotic diseases compared to HC. Further, the level correlates to the number of PBMC that differentiate to mature fibrocytes *in vitro*. The results indicate that circulating CD45+, CD34+, CD11b+ cells could be involved in the development of organ fibrosis, and thereby be a biomarker of early fibrosis development in RA ILD. Associations to inflammatory markers, pulmonary function and disease activity will be presented at the conference.

## SAT0050 RESIDENT NON-CLASSICAL MONOCYTES ARE CRITICALLY IMPORTANT FOR TISSUE DESTRUCTION IN ARTHRITIS

A. Puchner[1,2], V. Saferding[2], M. Bonelli[2], S. Hayer[2], B. Niederreiter[2], C.-W. Steiner[2], E. Goncalves-Alves[2], Y. Mikami[3], N. Binder[4], M. Koenders[5], J. Smolen[2], K. Redlich[2], S. Blüml[2]. *[1]Rheumatology, Medizinische Universität Wien, Wien; [2]Rheumatology, Medical University of Vienna, Vienna, Austria; [3]Molecular Immunology and Inflammation Branch, National Institutes of Health, Bethesda, Bethesda, United States; [4]Medical University of Vienna, Vienna, Austria; [5]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands*

**Background:** Bone destruction in rheumatoid arthritis is mediated by osteoclasts, which are derived from precursor cells of the myeloid lineage. Although there is much known about mature osteoclasts, the identity of osteoclast precursor populations during arthritis is poorly understood. Blood monocytes can be subdivided in classical inflammatory monocytes ($CD115^+Ly6C^{high}CCR2^+$) and non-classical resident monocytes ($CD115^+Ly6C^{-/low}CCR2^-$) and especially classical monocytes have been implicated in mediating tissue damage in autoimmunity.
**Objectives:** To investigate the role of different monocyte populations in joint destruction.

**Methods:** HTNFtg mice were clinically scored once per week for grip strength and swelling. In addition, blood was collected every other week starting on week 4. Mice were sacrificed at week 10 - blood, spleen and bone marrow were collected for flow cytometry analysis. K/BxN Arthritis was induced in wild type mice, blood and spleen were collected 14 days after disease induction. HTNFtg/CCR2$^{-/-}$ and hTNFtg mice were analyzed histologically. Different monocyte subsets were Facs-sorted and cultured in the presence of RANKL and MCSF to induce osteoclasts. RNA sequencing of RANKL stimulated osteoclast precursor cells was performed.
**Results:** Here we show that hTNFtg mice lacking CCR2, which lack circulating classical inflammatory monocytes, show enhanced local bone erosion and osteoclast generation in chronic TNF driven arthritis. When we correlated the number of the two monocyte subsets in blood with histological signs of joint destruction the number of inflammatory monocytes did not correlate at all with those parameters. In contrast, the number of non-classical monocytes in blood significantly correlated with the extent of tissue damage in both hTNFtg arthritis and also K/BxN serum transfer arthritis. Histological examination revealed that while all infiltrating monocytes express CD115, only a small fraction of these cells express Ly6C, suggesting that the synovial infiltrate predominantly consists of Ly6C$^{-/low}$ monocytes. Upon sorting resident and from blood, we demonstrate that resident Ly6C$^{-/low}$ monocytes are more potent to form osteoclasts *ex vivo* than classical Ly6C$^{high}$ monocytes. Genome-wide transcriptome profiling revealed increased expression of genes which are required for pre-osteoclast fusion in RANKL-stimulated resident Ly6C$^{-/low}$ monocytes.
**Conclusions:** Non classical resident monocytes possess particular osteoclastogenic potential and their numbers in blood correlate with histological parameters of joint destruction in two different models of inflammatory arthritis. Therefore these cells may provide a biomarker for erosive inflammatory arthritis and even a possible target for therapeutical intervention.

### SAT0051 TRANSCRIPTION FACTOR SOX5 PROMOTES RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLAST MIGRATION AND INVASION BY REGULATING MMP9 EXPRESSION VIA DOWNREGULATED MIR-15A/MIR-16

W. Tan[1], Y. Shi[1], X. Feng[1], F. Wang[1], W. Xuan[2], M. Zhang[2]. *[1]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China; [2]Rheumatology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China*

**Background:** SOX5 is known as a transcription factor which primarily involved in the regulation of embryonic development, cell fate, and chondrogenesis. To date, little is known the effect of SOX5 on rheumatoid arthritis (RA). We previously reported association between younger age at onset of rheumatoid arthritis (RA) and a RANKL promoter SNP that conferred an elevated promoter activity after stimulation via binding to a transcription factor SOX5 (Arthritis Rheum 2010; 62(10):2864–75.). Subsequently, we confirmed that SOX5 could up-regulate RANKL expression in RA synovial fibroblast (SF) and participate in the bone erosion of RA.
**Objectives:** Here, we examine the effect of SOX5 on the migration and invasive characteristics of RA synovial fibroblasts.
**Methods:** Rheumatoid synovial fibroblasts cell line MH7A were treated with SOX5 small interfering RNA (SOX5-siRNA) and recombinant Adenovirus SOX5 expression vectors (Ad-SOX5). Migration and invasion and of RASF was assessed by transwell matrigel™ invasion chambers and collagen gel assays. Modulation of MMP9 expression in RASF was analyzed by real-time PCR, western blot, luciferase assay and Chromatin immunoprecipitation (ChIP). Collagen-induced arthritis (CIA) DBA/1 mouse locally injected with lentivirus-shSOX5 was used to examine the effect of SOX5 on MMP9 expression in vivo.
**Results:** Overexpression of SOX5 significantly induced cell migration, invasion and MMP-9 expression in RASF. Migration and invasion of RASF could be markedly decreased by silencing SOX5 expression but could be reverted by added the recombinant MMP9 cytokine into RASF. Overexpression of SOX5 enhanced the promoter activity of MMP9 in Hela cell. Chromatin immunoprecipitation (ChIP) showed approximately 3-fold enrichment of MMP9-specific DNA in anti-SOX5 immunoprecipitate in IL-6 treated MH7A, as compared to untreated cells. Silencing SOX5 resulted in significantly increased miR-15a/miR-16 expression in MH7A. The enhanced MMP-9 expression induced by Ad-SOX5 transfection could be inhibited by miR-15a/miR-16 mimics. Local silencing SOX5 in CIA mice inhibited the synovitis and bone erosion in CIA mice and accompanied by the markedly reduced MMP9 expression in synovium.
**Conclusions:** These findings indicated transcription factor SOX5 plays an important role in regulating the migration and invasion and production in RA SF by modulation MMP9 expression via downregulated miR-15a/miR-16, suggesting SOX5 as a potential therapeutic target for the treatment of RA.

## Rheumatoid arthritis - prognosis, predictors and outcome

### SAT0052 IS INFORMATION ABOUT THE REASON FOR PREVIOUS BIOLOGICS DISCONTINUATION USEFUL TO PREDICT THE EFFECTIVENESS OF A BIOLOGIC WITH A DIFFERENT MODE OF ACTION?

A. Finckh[1], D. Courvoisier[1], J. Gottenberg[2], M. Hernandez[3], F. Iannone[4], E. Lie[5], H. Canhão[6], K. Pavelka[7], M. Hetland[8], C. Turesson[9], X. Mariette[10], D. Choquette[11] on behalf of PANABA collaboration. *[1]University Hospital, Geneva, Switzerland; [2]University Hospital, Strassbourg, France; [3]Hospital Clinic of, Barcelona, Spain; [4]University Hospital, Bari, Italy; [5]Diakonhjemmet Hospital, Oslo, Norway; [6]University Hospital, Lisbon, Portugal; [7]University Hospital, Prague, Czech Republic; [8]University Hospital, Copenhagen, Denmark; [9]Skåne University Hospital, Malmö, Sweden; [10]University Hospital, Paris-Sud, France; [11]CHUM, Montreal, Canada*

**Background:** With more biological disease modifying antirheumatic drugs (bDMARDs) in rheumatoid arthritis (RA), switching between bDMARDs is becoming more frequent. Patients (Pts) discontinue bDMARDs for various reasons, including inadequate effectiveness (IE) and adverse events (AE). Observational data indicates that the reason for discontinuing a second TNF inhibitor is usually the same that led to the first TNFi discontinuation, suggesting that a change in bDMARD mode of action may be more favourable.
**Objectives:** To investigate the impact of specific reasons for discontinuing the previous bDMARD on the clinical response to abatacept (ABA), a bDMARD with a different mode of action.
**Methods:** This is a pooled observational database analysis of 10 prospective cohorts of RA pts treated with iv ABA. All pts with available information on the reason for discontinuation of the last bDMARD were included. Pts initiating ABA as a first bDMARD were excluded from the analysis. The predictor of interest was the reason for prior bDMARD discontinuation, categorized as IE, AE, or other. The primary endpoint was time to ABA discontinuation, defined as the time between drug initiation to last administration: 1) for any reason, and 2) specifically for AEs or IE. Cox regression was used to estimate hazard ratios (HRs) for drug discontinuation, adjusting for pts demographics, disease and treatment characteristics.
**Results:** Of the 2001 RA pts included, 1272 discontinued ABA during the 3639 patient-years of follow-up. 499 pts (24.9%) had stopped their last bDMARD for AEs, 1290 pts (64.5%) for IE, and 212 pts (10.6%) for other reasons. Pts who discontinued their prior bDMARD for IE were younger, more frequently RF positive, had lower BMI, shorter disease durations, higher baseline DAS28 and had less comorbidities than pts who stopped their previous bDMARD for other reasons.
There was no association between reason for discontinuing prior bDMARDs (AE, IE, or other) and overall ABA retention (log-rank p=0.78). ABA discontinuation for AEs was significantly associated with prior discontinuation of bDMARDs for AEs (log-rank $p<0.001$), and ABA discontinuation for IE was significantly associated with prior bDMARD discontinuation for IE (log-rank, p=0.02). In adjusted models, discontinuation of the prior bDMARD due to AE doubled the risk of AE-related discontinuation with ABA (HR 2.15, 95% CI: 1.63 – 2.84), compared to pts who had not discontinued their last bDMARD for AEs. IE on the prior bDMARD also tended to increase the risk of discontinuing ABA for IE (HR 1.15, 95% CI: 0.98 – 1.35), compared to pts without IE on their last bDMARD.
**Conclusions:** The same reason that led to discontinuing prior bDMARDs is likely to lead to the discontinuation of a new bDMARD with a different mode of action. Overall these results suggest that discontinuation is mostly explained by patient-specific characteristics (selection) and less by particular drug mechanism.

### SAT0053 C1M IS A SEROLOGICAL BIOMARKER FOR IDENTIFICATION OF STRUCTURAL PROGRESSORS IN RHEUMATOID ARTHRITIS; VALIDATION IN 3 PHASE III CLINICAL TRIALS

A.S. Siebuhr[1], A. Platt[2], M.A. Karsdal[1], A.-C. Bay-Jensen[1]. *[1]Biomarkers and Research, Nordic Bioscience, Herlev, Denmark; [2]AztraZeneca, Cambridge, United Kingdom*

**Background:** There is a need for reliable prognostic biomarkers in rheumatoid arthritis (RA) for identification of patients in urgent need of aggressive treatment. Serological assessment of type I collagen degradation (C1M) was demonstrated to be a biomarker for identification of RA disease progression in the phase 3[1] LITHE study. In the LITHE study C1M predicted JSN progression when corrected for confounders (including CRP and baseline level of joint space narrowing; JSN).
**Objectives:** To support serum C1M as a biomarker for RA structural progression.
**Methods:** Placebo groups were pooled (n=543) from the 24-week Phase 3, randomized, double-blind, placebo-controlled, parallel group studies of fostamatinib on a MTX background, OSKIRA 1, 2 and 3 (NCT01197521; NCT01197534;

NCT01197755). Patients who did not achieve ACR20 at week 12 were given active drug and were considered escapers. Radiographic progression was assessed by increase in JSN, erosion (ERN) or modified total sharp score (mTSS) after 24 weeks. Only 270 patients had radiographic assessment at both baseline and at 24 weeks. C1M was assessed in fasting serum at baseline (BL). One-way ANOVA was used to assess differences in BL demographics. Associations between BL demographics were investigated by Spearman's correlation. Multiple regression included age group, gender, disease duration, BMI, CRP and BL radiographic status. Non-normalized data was log-transformed.

**Results:** BL demographics of the 3 studies were comparable. 36% of patients were escapers, having BL elevated levels of C1M, CRP and disease activity compared to non-escapers (p=0.03, p<0.0001, p=0.006). 20% of all patients had radiographic progression by JSN, 24% by ERN and 31% by mTSS. BL CRP was significantly elevated in progressors compared to non-progressors (JSN p=0.02, mTSS p=0.005, ERN p=0.005). ERN progressors had a significantly increased level of C1M than non-progressors (p=0.02). JSN only progressors had significant increases in BL radiographic status compared to non-progressors (JSN p=0.003, mTSS p=0.007, ERN p=0.03).

At BL there was an association between C1M and radiographic status (JSN rho=0.14, mTSS rho=0.14, ERN rho=0.13,) and disease activity (DAS28 rho=0.44). In multiple regression the effect size β of C1M alone was -0.25, 0.90 and 1.18 for the association with the 24 week change in radiographic progression as determined by JSN, mTSS and ERN, respectively. Only for ERN the effect size reached statistical significance (p=0.0008). The beta value describes the effect of C1M on predicting the radiographic progression. The effect size decreased for JSN when adjusted for CRP (β=-0.68), but for both mTSS and ERN the effect was eliminated. When the other confounders were included the effect size decreased even further for JSN (β=-0.70).

| | Δ 24weeks | | | |
|---|---|---|---|---|
| **JSN** | | | | |
| | B | P | R2 | N |
| C1M | -0.25 | NS | 0.0008 | 270 |
| C1M, CRP | -0.68 | 0.044 | 0.008 | 270 |
| C1M, age group, gender, dis.dur, BMI, CRP | -0.71 | 0.036 | 0.01 | 270 |
| C1M, age group, gender, dis.dur, BMI, CRP, BL mTSS | -0.70 | 0.038 | 0.010 | 270 |
| **mTSS** | | | | |
| C1M | 0.90 | NS | 0.009 | 266 |
| C1M, CRP | -0.04 | NS | 0.02 | 266 |
| C1M, age group, gender, dis.dur, BMI, CRP | -0.01 | NS | 0.04 | 266 |
| C1M, age group, gender, dis.dur, BMI, CRP, BL mTSS | 0.17 | NS | 0.04 | 266 |
| **ERN** | | | | |
| C1M | 1.18 | 0.0008 | 0.04 | 266 |
| C1M, CRP | 0.64 | NS | 0.04 | 266 |
| C1M, age group, gender, dis.dur, BMI, CRP | 0.71 | NS | 0.06 | 266 |
| C1M, age group, gender, dis.dur, BMI, CRP, BL mTSS | 0.71 | NS | 0.08 | 266 |

Multiple regression analysis of the effect of C1M on predicting radiographic progression after 24 weeks. The beta-, p- and R2 and N value are given. Statistical significance was considered as p<0.05. C1M: MMP-degraded type I collagen. CRP: C-reactive protein, dis.dur: disease duration, BMI: body mass index, JSN: Joint space narrowing, mTSS: modified total sharp score, ERN: Erosion.

**Conclusions:** In this study we found that BL C1M was associated with structural status and disease activity and that BL C1M was a predictor of radiographic progression (JSN) after 24 weeks when adjusted for confounders. Secondly, escapers had higher level of C1M, CRP and disease activity indication a worse disease stage in escapers at baseline. This study provides supports C1M as an important emerging biomarker of progression in RA.

## SAT0054 FAVORABLE LONG-TERM OUTCOME OF EARLY INFLAMMATORY ARTHRITIS IN CLINICAL PRACTICE: HIGH BASELINE HAQ AND DAS28 AT 3 MONTHS PREDICT USE OF BIOLOGICS

A. Fanouriakis[1,2], I. Papalopoulos[1], E. Gergianaki[1], G. Spyrou[1], P. Rapsomaniki[2], M. Terizaki[1], N. Avgoustidis[1], A. Repa[1], D.T. Boumpas[2,3], P. Sidiropoulos[1]. *[1]Rheumatology, Clinical Immunology and Allergy, University Hospital of Heraklion, Heraklion, Crete; [2]Rheumatology and Clinical Immunology, 4th Department of Internal Medicine, "Attikon" University Hospital; [3]Joint Rheumatology Program, Medical School, National and Kapodestrian University of Athens, Athens, Greece*

**Background:** The course and natural history of early inflammatory arthritis (EA) varies widely and partly depends on the level of disease control in the early stages. Dedicated EA clinics follow a systematic targeted approach to improve long-term outcome of patients.

**Objectives:** To assess the long-term outcome of EA following care in a dedicated early arthritis outpatient clinic.

**Methods:** The "Early Arthritis (EA) Cohort" of the Department of Rheumatology of the University Hospital of Crete is a prospective cohort, which follows patients with inflammatory arthritis [RA, spondylarthritis or undifferentiated (UA)] of less than 6 months duration. Patients are followed quarterly for 2 years with systematic documentation of disease activity and function (measured by the DAS28 and HAQ, respectively), as well as for changes in therapy based on physician judgment. For the purpose of this study, we assessed long-term outcome (disease activity and function at 2 years) and examined prognostic factors for subsequent initiation of biologic agent.

**Results:** Out of 559 patients referred to the EA Clinic, a total of 317 had a final diagnosis of RA or UA and were included in the present analysis [83.0% women, mean (SD) age at disease diagnosis 53.7 (15.1) years, 28.5% positive for RF or/and ACPA, mean (SD) number of tender and swollen joints at baseline 6.9 (6.0) and 5.5 (5.5), respectively. Mean (SD) DAS 28 at baseline was 4.59 (1.38) and mean HAQ was 0.59 (0.51), with 33.9% of patients having high disease activity (DAS28>5.1) and 18.3% reporting a HAQ≥1. At 2 years of follow-up, mean (SD) DAS28 and HAQ were 3.63 (1.3) and 0.49 (0.48), respectively (p<0.001 compared to baseline values for both). Nevertheless, 38.3% of patients still had moderate and 13.8% high disease activity at 2 years, while 19.3% reported a HAQ>0.75.

During the course of follow-up, 34 patients received a biologic agent due to persistent high disease activity. In multivariate regression analysis, factors associated with initiation of biologic were HAQ at baseline [adjusted RR (95% CI) 4.91 (3.54–6.81)] and DAS28 at 3 months [adjusted RR (95% CI) 1.49 (1.15–1.93)].

**Conclusions:** Routine care with regular, objective documentation of disease activity and function is associated with satisfactory long-term outcomes in early inflammatory arthritis. Baseline impaired function and persistent disease activity at 3 months predict need for biologic treatment during follow-up.

**Disclosure of Interest:** None declared

## SAT0055 TREATMENT RESPONSE TO CONVENTIONAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (DMARDS) AND BIOLOGICS IN SEROPOSITIVE AND SERONEGATIVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: RESULTS FROM CATCH (CANADIAN EARLY ARTHRITIS COHORT)

B. Aberumand[1], V. Bykerk[2], O. Schieir[3], D. Lin[2], G. Boire[4], B. Haraoui[5], C.A. Hitchon[6], C. Thorne[7], D. Tin[7], E.C. Keystone[2], S. Jamal[8], J.E. Pope[9]. *[1]Medicine, Schulich School of Medicine and Dentistry, London; [2]Mount Sinai Hospital; [3]University of Toronto Dalla Lana School of Public Health, Toronto; [4]Medicine, Centre Hospitalier Universitaire de Sherbrooke (CHUS), Sherbrooke; [5]Medicine, University of Montreal Hospital Research Centre (CRCHUM), Montreal; [6]Medicine, University of Manitoba, Winnipeg; [7]Southlake Regional Health Centre, Newmarket; [8]University of British Columbia, Vancouver; [9]Schulich School of Medicine and Dentistry, London, Canada*

**Background:** Rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) status may affect treatment response in early rheumatoid arthritis (ERA).

**Objectives:** To investigate differences in treatment response to disease modifying anti-rheumatic drugs (DMARDs) and biologics in ERA in seropositive versus seronegative patients for RF and/or ACPA.

**Methods:** Data were obtained from The Canadian Early Arthritis Cohort (CATCH), a prospective multi-site study of patients with ERA who met 1987 or 2010 ACR/EULAR criteria for RA, had symptom duration <1 year, were not in remission at baseline and had RF or ACPA available, DAS28 scores at baseline and follow-up. Stratified multiple linear regression compared the effects of initial treatment with methotrexate (MTX) monotherapy, MTX combination therapy (defined as MTX plus one or more conventional DMARD), biologic therapy and other therapy on change in DAS28 (D DAS) at 3 and 6 month follow up in patients who were seropositive (RF + and/or ACPA+) and seronegative (RF- and ACPA-), patients who were RF positive and RF negative, and patients who were ACPA positive and ACPA negative, respectively. All multivariable models were adjusted for baseline age, gender, education, ethnicity, symptom duration, comorbidities, erosions and pain scores.

**Results:** 1068 patients had a baseline mean (SD) age of 53.3 (15.0), symptom duration of 5.8 (3.0) months, DAS28 of 5.2 (1.3) and 74% were female. A total of 867 (81.2%) patients were seropositive and 201 (18.8%) were seronegative (RF positive 759 [66%], RF negative 385 [34%], ACPA positive 539 [61%], and ACPA negative 349 [39%]). Relative to the other therapy group, better treatment response to methotrexate combination therapy at 3 months was observed for patients who were RF+ (β: 0.45 [95% CI -0.74 to -0.17]) vs. RF- (β: 0.29 [95% CI -0.14 to 0.71]) and the combined seropositive (β: -0.29 [95% CI -0.56 to -0.02]) vs. seronegative group (β: -0.12 [95% CI -0.69 to 0.44) but not patients who were ACPA+ (β: -0.06 [95% CI -0.41 to 0.30]) vs. ACPA- (β: -0.41 [95% CI -0.84 to 0.02]), after adjusting for covariates. Similar results were observed when analyses were repeated with change in DAS at 6-months as the outcome as patients

on methotrexate combination therapy who were RF+ (β: -0.47 [95% CI -0.81 to -0.13]) vs. RF- (β: 0.15 [95% CI -0.39 to 0.71]) and those that were seropositive (β: -0.32 [95% CI -0.65 to 0.00]) vs. seronegative (β -0.20 [95% CI -0.97 to 0.56]) responded better to treatment. Response to other treatment strategies did not significantly differ by antibody in any grouping (Table).

**Table**

| | Antibody | RF | | ACPA | | RF and ACPA | |
|---|---|---|---|---|---|---|---|
| | Treatment | Negative β (95% CI) | Positive β (95% CI) | Negative β (95% CI) | Positive β (95% CI) | Both Negative β (95% CI) | Either or Both Positive β (95% CI) |
| DAS28 over 3 months | MTX mono | 0.23 (-0.23, 0.70) | -0.14 (-0.44, 0.18) | -0.28 (-0.76, 0.21) | 0.17 (-0.23, 0.57) | -0.12 (-0.81, 0.57) | -0.05 (-0.35, 0.24) |

| | Biologic | -0.30 (-1.75, 1.16) | -0.37 (-1.19, 0.45) | -0.64 (-2.43, 1.16) | -0.48 (-1.29, 0.33) | -1.65 (-4.74, 1.44) | -0.44 (-1.18, 0.29) |
| | Other | Reference | Reference | Reference | Reference | Reference | Reference |
| DAS28 over 6 months | MTX mono | 0.17 (-0.45, 0.80) | -0.05 (-0.42, 0.32) | -0.05 (-0.67, 0.57) | 0.08 (-0.40, 0.57) | 0.19 (-0.77, 1.16) | 0.00 (-0.36, 0.36) |
| | MTX combo | 0.16 (-0.39, 0.71) | -0.47 (-0.81, -0.13) | -0.27 (-0.83, 0.28) | -0.15 (-0.58, 0.28) | -0.20 (-0.97, 0.56) | -0.32 (-0.65, 0.00) |
| | Biologic | -1.71 (-3.47, 0.04) | -0.92 (-1.85, 0.01) | -2.32 (-4.64, 0.00) | -1.05 (-2.02, 0.08) | -2.24 (-5.74, 1.27) | -1.09 (-1.98, 0.21) |
| | Other | Reference | Reference | Reference | Reference | Reference | Reference |

**Conclusions:** In ERA, RF and ACPA status affected treatment response to MTX combination therapy, with better changes in DAS28 at 3 and 6-months in seropositive compared with seronegative patients. Given the complexity of rheumatoid arthritis management, the study findings potentially have implications for identifying prognostic indicators that may help inform therapeutic decision-making.

## SAT0056 WHAT ARE THE REASONS OF DISCREPANCIES BETWEEN PATIENTS AND PHYSICIANS IN THEIR PERCEPTIONS OF RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND WHAT IS THE IMPACT OF THIS DISCORDANCE ON REMISSION, FUNCTION AND STRUCTURE AT 1 YEAR? RESULTS FROM THE ESPOIR COHORT

C. Gaujoux-Viala[1,2], N. Rincheval[2], L. Gossec[3], F. Guillemin[4], M. Dougados[5], J.-P. Daures[2], B. Combe[6]. *[1]Rheumatology, Nîmes University Hospital; [2]EA2415, Montpellier University, Nîmes; [3]Rheumatology, Pitié-Salpêtrière Hospital;GRC-UPMC 08 – EEMOIS, Paris; [4]Lorraine University, Paris Descartes University, EA 4360 Apemac, Nancy; [5]Rheumatology B, Cochin Hospital, Paris; [6]Rheumatology, Lapeyronie Hospital, Montpellier, France*

**Background:** Patients and physicians often differ in their perceptions of rheumatoid arthritis (RA) disease activity, as quantified by the patient's global assessment (PGA) and by the evaluator's global assessment (EGA). The quest for understanding the reasons for discrepancies in evaluations of disease activity becomes particularly important in the context of recent recommendations that define Boolean-based ACR EULAR remission as the treatment target.
**Objectives:** The objectives of this study were:
1) to explore the extent and reasons for this discordance
2) to determine if this discordance at baseline is associated with RA outcomes at 1 year (remission, function and structure) in early RA in daily clinical practice.
**Methods:** *Patients:* from the French cohort of EA ESPOIR (at least 2 swollen joints for less than 6 months, DMARD naïve), fulfilling the ACR-EULAR criteria for RA at baseline
*Analyses:* At baseline, agreement between PGA and EGA (Bland-Altman plot) was assessed. Multivariate linear regression was used to determine the patient and EA features independently associated with discordance (calculated as PGA – EGA). Logistic regression was used to analyze discordance as |PGA – EGA| $\geq$20. Multivariate logistic models were used to determine if discordance at baseline is associated with remissions (Boolean, SDAI and DAS28), functional stability (HAQ $\leq$0.5 and deltaHAQ $\leq$0.25) and absence of radiographic progression (delta Sharp score $<$1) after 1 year of follow-up.
**Results:** In 645 patients with ERA (mean age=48.8±12.2 years, 77% female, 48.7% ACPA+) agreement was better at both ends of the spectrum, especially for patients with high disease activity. Evaluation of disease activity yielded discordant scores between the patients and their physicians in 30% of our cohort: 153 patients (24%) had higher PGA scores, 41 patients (6%) had higher EGA scores, and 451 patients (70%) had concordant PGA and EGA scores (|PGA – EGA| $<$20).
In multivariate linear regression center-adjusted, higher PGA has been found to be associated with absence of fulfilling ACR 1987 revised criteria for RA (p=0.0005), higher levels of fatigue (p$<$0.0001) and lower number of swollen joint counts (SJC) (p=0.0022). With logistic regression center-adjusted, low number of SJC (OR [95% CI]: 1.92 [1.26–2.91]), low mental component of the SF-36 (OR [95% CI]: 1.82 [1.23–2.69]) and living alone (OR [95% CI]: 1.68 [1.09–2.58]) were associated with discordance between PGA and EGA.
In multivariate analyses, discordance at baseline was not associated with remission, function and structural progression at 1 year.
**Conclusions:** In early RA, the discordance between PGA and EGA is multifactorial with objective measures like low SJC and absence of ACR 1987 revised criteria for RA, but also patient reported outcomes like high level of fatigue and low mental status, and environmental factor: living alone. Discordance between PGA and EGA at baseline was not associated with RA outcomes at 1 year. Understanding the reasons for a discordant view of disease activity will help to facilitate the sharing of decision-making in the management of RA.

## SAT0057 LOW MORTALITY RATE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS FROM SOUTH ITALY

D. Iacono, G. Cuomo, V. D'Abrosca, I. Pantano, G. Valentini. *Department of Clinical and Experimental Medicine, Second University of Naples, Rheumatology Section, Naples, Italy*

**Background:** Rheumatoid arthritis (RA) is a chronic systemic inflammatory disorder associated with increased mortality (1), (standardized mortality ratio for all causes–SMR, being 1.47 in the last 50 years) (2).
**Objectives:** To investigate the mortality rate and predictive factors as assessed at admission in a cohort of RA patients followed at a South Italy tertiary centre.
**Methods:** RA patients admitted to the outpatient Clinic of a tertiary centre from 01/01/2008 to 31/12/2015 were investigated. Table 1 shows patients features (age, sex, disease duration, Simplified Disease Activity Index-SDAI index, Health Assessment Questionnaire-Disability Index-HAQ-DI, Rheumatoid Factor-RF and/or Anti-Citrullinated Cyclic Peptides Antibody-ACPA, concomitant comorbidity) as detected at baseline, and treatment during follow-up. RA patients mortality incidence rate (event/100person year) was calculated, baseline predictors of mortality were analyzed by univariate and multivariate cox-regression analysis.
**Results:** A total of 608 RA patients were included (497 women), median age 56.8 years, range 15–89.5. On December 31 2015, 589 out of patient were alive, 19 were known to have died and 7,3% had been lost to follow up. Mortality Incidence rate (MIR) in our cohort was 0.79 deaths/100 person-year, SMR with respect to Italian population was 0.79 (MIR in Italy 1/100 person-year). This feature might depend on the low prevalence of RF/ACPA positivity (69.13%) in our series. Cox regression analysis (univariate analysis) pointed out age at first visit (HR 1.14; p$\leq$0.0001), diabetes (HR 4.395; p=0.004) and a HAQ value$>$1 (HR 6.02; p=0.02) as independent predictors of mortality. On the contrary, female sex resulted to have a protective role (HR 0.349, p=0.027). At multivariate analysis, the only baseline independent predictor of mortality was age at admission (HR 1.17, 95% CI 1.01–1.35, p=0.026).

**Table 1. Clinical and epidemiological features of 608 RA patients at baseline**

| | |
|---|---|
| Sex F/M ratio | 497/111 |
| Age (yrs : median, range) | 56.8 (15-89.5) |
| Disease duration (yrs: median, range) | 9 (0.5–41) |
| RF positivity | 270/432 (62.5%) |
| ACPA positivity | 188/360 (52.2%) |
| FR and/or ACPA positivity | 318/460 (69.13% |
| Biologic drug treatment (n) (%) | 354/608 (58%) |
| DAS 28 (median, range) | 3.97 (0.56-7.29) |
| Media ±DS | 4.03±1.21 |
| SDAI (median, range) | 12.19 (0.03-45) |
| HAQ –DI (median, range) | 1 (0-3) |
| Arterial Hypertension | 246/608 (40.5) |
| Metabolic syndrome | 63/608 (10.4) |
| Diabetes Mellitus | 51/608 (8.4) |
| History and/or follow-up Cardiovascular Events | 41/608 (6.7) |

**Conclusions:** The present study points out a South Italian RA SMR lower than that in general Italian population and significantly lower than that reported in RA patients from other countries (2). This result can depend on the lower percentage of RF/ACPA positive patients in our cohort in respect to general population. Epidemiological studies on the sierological profile of South Italian RA patients are needed.

SAT0058 **CONSISTENCY OF RADIOGRAPHIC RESPONSES WITH SARILUMAB PLUS METHOTREXATE ACROSS SUBPOPULATIONS OF PATIENTS WITH RHEUMATOID ARTHRITIS IN A PHASE 3 STUDY**

D. van der Heijde[1], C. Fan[2], H. van Hoogstraten[2], E.K. Mangan[3], J. van Adelsberg[3], P.C. Miranda[4], M.C. Genovese[5]. *[1]Leiden University Medical Centre, Leiden, Netherlands; [2]Sanofi, Bridgewater; [3]Regeneron Pharmaceuticals, Tarrytown, United States; [4]Centros de Estudios Rheumatologicos Santiago, Centros de Estudios Rheumatologicos Santiago, Chile; [5]Stanford University Medical Center, Palo Alto, United States*

**Background:** The investigational drug sarilumab is a human monoclonal antibody directed against the interleukin 6 receptor.[1] The phase 3 MOBILITY study (NCT01061736) examined sarilumab + methotrexate (MTX) vs placebo + MTX in a double-blind, 52-week, randomized trial of patients with active, moderate-to-severe rheumatoid arthritis (RA) with inadequate response to MTX.[1] Both sarilumab doses (150 and 200 mg subcutaneously every 2 weeks [q2w]) demonstrated statistically significant improvements in signs and symptoms of RA, in physical function, and inhibition of radiographic progression. The most common treatment-emergent adverse events were infections, neutropenia, injection site reactions, and increased transaminases.

**Objectives:** In the present study, radiographic efficacy of sarilumab across subpopulations from MOBILITY was assessed.

**Methods:** To explore the consistency of radiographic response, treatment-by-subgroup interactions were assessed by rank ANCOVA for change in van der Heijde modified total Sharp score (mTSS) at week 52. A total of 19 subgroups were investigated (listed in Table footnote); those with $P \leq 0.2$ for interaction are presented. Radiographic progression was defined as mean change from baseline mTSS.

**Results:** Both doses of sarilumab showed less progression relative to placebo across all subgroups. Change in mTSS across subgroups based on rheumatoid factor and anti–cyclic citrullinated peptide status and demographic characteristics such as age, sex, and ethnicity appeared to be consistent with overall study findings. Subgroups with interaction $P \leq 0.2$ were prior use of biologics and baseline C-reactive protein (CRP), body mass index (BMI), RA disease duration, median mTSS, and smoking history (Table). In some groups (lower BMI, no prior biologic use, higher baseline CRP, no history of smoking, and high mTSS), the treatment effect increased, because there was greater progression in the placebo group relative to the sarilumab groups. The progression with sarilumab 200 mg q2w was consistently lower compared with sarilumab 150 mg q2w. Progression was substantially greater in placebo patients with baseline mTSS >25 compared with those with baseline mTSS ≤25. These differences were not observed in sarilumab-treated patients. Joint space narrowing and erosion score showed patterns similar to the total score. Overall, sample sizes were limited in some subgroups.

**Conclusions:** Sarilumab generally inhibited radiographic progression to a similar extent across a wide spectrum of subgroups. Nonetheless, the treatment effect appeared to be greater in subgroups with poor prognostic markers such as high levels of CRP and more structural damage at baseline, as well as in nonsmokers and patients with low BMI.

**Table.** Radiographic Progression (Mean Change From Baseline mTSS at Week 52) in MOBILITY Subgroups[a] With Treatment by Subgroup Interaction *P*≤0.2

SAT0059 **CRITERIA FOR CHOICE BY CLINCIANS OF THE THERAPEUTIC STRATEGY IN PATIENTS WITH INSUFFICIENT RESPONSE TO A FIRST ANTI-TNF: DATA FROM THE RANDOMIZED "ROC" CRITERIA**

E. Chatelus[1], C. Sordet[1], P. Ravaud[2], J. Sibilia[1], J.-E. Gottenberg[1] on behalf of the ROC Trial Investigators. *[1]University Hospital, Strasbourg; [2]Hotel Dieu, Paris, France*

**Background:** Therapeutic strategy after failure of a 1st anti-TNF (TNF-IR) is not codified in rheumatoid arthritis (RA). Little is known about the criteria for choice of a second biologic by clinicians.

**Objectives:** To determine whether patient's or disease characteristics guide clinicians for their choice of a second biologic in TNF-IR patients with RA

**Methods:** The ROC trial randomized patients with an insufficient response to a 1st anti-TNF to receive either a second anti-TNF or a non-TNF targeted biologic. Before randomization, the clinician's preference for the second biologic (either a non-TNF targeted biologic or a second anti-TNF) was collected. After randomization, the choice of the molecule within each arm was left to the clinician.

**Results:** The clinician's preference for the second biologic could be collected before randomization for 281 out of the 292 patients analyzed in the ROC trial. 151 clinicians would have preferred to prescribe a non-TNF targeted biologic, 72 a second anti-TNF and 58 clinicians had no preference.

Among baseline characterics of disease, only disease duration was significantly associated with the preference for non-TNF targeted biologics (median 8 [3–17] years for patients for whom clinicians would have chosen a non-TNF biologic versus 5 [1–13] years for patients for whom clinicians would have chosen a second anti-TNF, p=0.001). Other parameters (such as age, sex, body mass index, number of previous conventional DMARDs, seropositivity for

RF/ACPA, extra-articular invovement, CRP, ESR, DAS28-ESR at inclusion) has no significant impact on the clinician's choice.Cotreatment either with glucocorticoids, methotrexate or anopther conventional DMARD had no significant impact on the choice of clinicians either.
With regards to the choice of the mechanism of action in the non-TNF targeted group, clinicians significantly more frequently prescribed abatacept in patients with cardiovascular risk factors (70% of patients treated with abatacept had cardiovascular risk factors compared to 44% of patients treated with rituximab or tocilizumab) p=0.03). Clinicians prescribed significantly more frequently tocilizumab in patients with a high C-reactive protein value (median baseline value of 10.5 mg/l versus 5 mg/l in patients who received abatacept or rituximab) (p=0.01).
**Conclusions:** There is no characteristic patient's profile explaining the preference of clincians for a non-TNF biologic or a second anti-TNF in TNF-IR patients. Among non-TNF biologics, abatacept was more frequently prescribed in patients with cardiovascular risk factors and tocilizumab was more frequently prescribed in patients with a high C-reactive protein value.

## SAT0060 ACHIEVEMENT OF INDIVIDUAL IMPORTANT RESPONSE MEASURED BY DAS28DCRIT IN ACTIVE RHEUMATOID ARTHRITIS WHEN TREATED WITH TOCILIZUMAB: DATA FROM A LARGE PROSPECTIVE OBSERVATIONAL STUDY

F. Behrens[1,2], M. Köhm[1,2], M. Hofmann[3], G. Fliedner[4], C. Specker[5], H. Burkhardt[1,2]. *[1]CIRI/Rheumatology, Goethe-University; [2]Clinical Research, Fraunhofer IME Project group TMP; [3]Chugai Deutschland, Frankfurt; [4]Rheumapraxis, Osnabrück; [5]Rheumatology, St. Josef Hospital Essen-Werden, Essen, Germany*

**Background:** Normal fluctuations in results of disease activity measurements due to short-term situational effects and measurement errors are issues for evaluation of individual clinically meaningful therapeutic response in daily practice in patients with rheumatoid arthritis (RA). To address this aspect, we established earlier a statistical approach to determine a critical difference (dcrit) that defines valid criterion for response as assessed by the Disease Activity Score-28 joints (DAS28)[1]. With this study DCRIT criterion was used to measure clinical meaningful response in RA-patients treated with Tocilizumab (TCZ) in routine care.
**Methods:** The patient population was derived from a prospective noninterventional study in patients with active RA treated with TCZ. A total of 635 patients were analysed. 310 patients with stable disease and stable therapy (no change in TCZ, cDMARD, NSAID and prednisolone) for at least one year (from month 12 to 24 after TCZ initiation) were used to evaluate the previous established $DAS28_{dcrit}$ cut-off of 1.8 for response. To evaluate individual variations in DAS28 scores despite stable mean DAS28 without treatment changes, we subjected DAS28 scores at 12, 18 and 24 months to an ANOVA model to establish a 95% one sided confidence interval (95% CI) for normal fluctuations; this value was used to define the dcrit for individual changes. The total cohort was used to calculate percentage of achieving DAS28 dcrit-response.
**Results:** The mean baseline disease activity (DAS28) from the stable cohort was 5.52 and decreased to 2.51 (month 12). For the next treatment year, the mean DAS of the entire cohort was stable (month 15 2.44, 18 2.40, 21 2.44 and 24 2.46). The calculation of the dcrit cut-off in TCZ-monotherapy results in 1.81 which is within the range of dcrit values in other treatment regimes; for the population including combinational therapy, result was slightly higher (1.9). 70.5% of the patients achieved $DAS28_{dcrit}$, reflecting meaningful clinical response only arised from the treatment intervention after 12 weeks. The responders increased up to 76.0% at week 24 and 78.9% at week 52 (calculated based on dcrit cut-off 1.8). After 2-years of treatment 80.6% of the patients reach a stable $DAS28_{dcrit}$ response. If using the more conservative (1.94) the result reads as follows: 64.5% week 12, 73.8% week 24, 77.3% week 52, 77.6% at week 104.
**Conclusions:** The established critical differences for DAS28 ($DAS28_{dcrit}$) of 1.8 was confirmed in an independent cohort of TCZ-treated patients. The slightly higher value of critical difference in TCZ treated patients (especially in TCZ+DMARD) might be due to the unique effect of TCZ on one variable of DAS28 (ESR/CRP). For both cut offs (1.8 and 1.9) high percentages of patients achieved this level of response after initiation of TCZ-treatment.

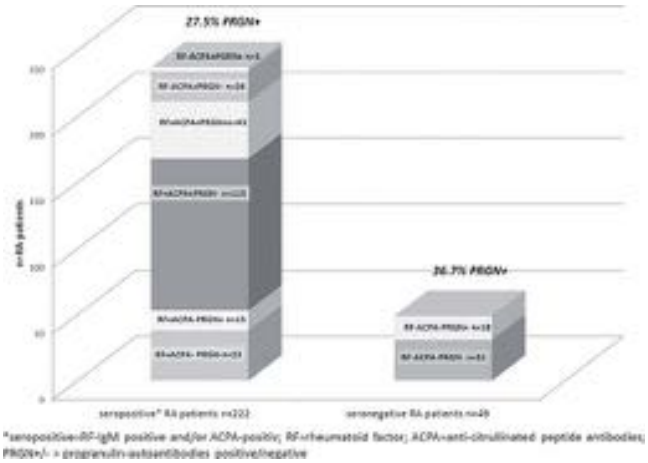
"Destra Secchia", Pieve di Coriano; [25]Pol. di Bari, Bari; [26]AO Rummo, Benevento; [27]U. of Florence, Firenze; [28]Sapienza U., Roma, Italy*



**Background:** Subclinical synovial inflammation detected by ultrasonography (US) in patients with rheumatoid arthritis (RA) in clinical remission relates to disease flare. The impact of tenosynovitis in this context is not known.
**Objectives:** To evaluate the association between US-detected tenosynovitis and synovitis in RA patients in clinical remission and flare over 12-months.
**Methods:** STARTER is a multicentre cohort study of the US Study Group of the Italian Society for Rheumatology. Participants were selected on the basis of a reliability exercise and the availability of high-end equipment. Patients with RA in clinical remission underwent clinical evaluation and US synovitis (-S) and tenosynovitis (-T) were assessed categorically for Grey Scale (GS) and power Doppler (PD) at 11 joints, extensor and flexor tendons in both hands and wrists. Patients were seen at 6 and 12 months. Flare within 12 months was defined as increase of $>1.2$ or $>0.6$ if final DAS28$>$3.2. The relationship between the presence of GS-T/-S, PD-T/-S was evaluated by logistic models, presented as odds ratios (OR) and 95% confidence interval (CI), adjusted for pre-specified confounders.
**Results:** 361 patients (72.3% f, mean age (sd) 56.1 (13.3), median disease duration (IQR) 7.1 years (3.6–13.5)) were included. 98/326 (30.6%) patients had a flare within 12 months. Considering US variables separately, only PD-S significantly predicted flare (OR 1.87 (1.12,3.14)). When the model included both –T and –S, only the concurrent presence of –T and –S predicted flare (PD-T+-S: OR 2.06 (1.04, 4.07); GS-T+-S: OR 2.27, (1.01,5.10)), while isolated –S and –T did not.
**Conclusions:** In patients with RA in clinical remission, US-detected synovial and tenosynovial inflammation identifies patients at risk of flare. US might help decisions on management in this population.

## SAT0062 TEST FOR SERUM PROGRANULIN AUTOANTIBODIES CAN REDUCE THE SERONEGATIVE STATUS IN RHEUMATOID ARTHRITIS BY ONE THIRD

G. Assmann[1], S. Zinke[2], M. Gerling[1], N. Fadle[1], D. Preuss[3], M. Pfreundschuh[1], L. Thurner[1]. *[1]Oncology, Hematology, Immunology, Rheumatology, University Medical School of Saarland, Homburg; [2]Rheumatology, Rheumatology Center Berling-Lichtenberg, Berlin; [3]Jose Carreras Institution, University of Saarland, Homburg, Germany*

**Background:** Progranulin autoantibodies (PGRNabs) have been previously described in sera of patients with different autoimmune diseases such as ANCA associated vasculitis, large vessel vaskulitis, Crohn's disease, polyarthritis including psoriatic arthritis and rheumatoid arthritis, whereas healthy controls and patients with different non-rheumatological disorders have shown a prevalence less than 1% [Ref.]. At primary diagnosis of rheumatoid arthritis as well as during the course of diseases at least 25% of RA patients have never developed serum RF or ACPA. Here we conducted a study on RA patients who were tested for RF, ACPA, and PRGNabs to evaluate the prevalence of serostatus in RA.
**Objectives:** Prevalence of serum PRGNabs in RA with stratification into seropositive RA patients with the proof of serum RF and/or ACPA and seronegative RA patients.
**Methods:** From Nov 2011 till Dec 2013 sera of 271 RA patients were collected and analyized for RF-IgM, ACPA-IgG, and PGRNabs with ELISA (as previously published) using a retrospective, blinded, non-randomized study design. All patients were on treatment with conventional DMARDS (n=165) or TNF inhibitors (n=106). All patients fullfilled the ACR criteria from 1987 and the revised diagnostic EULAR/ACR criteria from 2011. RA patients characteristics concerning age, gender, treatment history, radiological joint imaging, and duration of disease were availiable.
**Results:** The overall prevalence of PGRNabs in RA patients was 29,2%. 222

RA patients were seropositive for RF and/or ACPA, 49 RA patients were seronegative. Testing for PRGNabs resulted in significantly higher prevalence of PRGNabs in RF- and ACPA-seronegative RA patients compared to RA patients with seropositivity in at least one of serummarkers RF or ACPA (27.5% versus 36.7%, p=0.021, Chi2 test) [Figure]. The prevalence of PRGNabs in RF-positive RA patients were significant higher than in ACPA-positive RA (25.0% vs. 29,6%, p=0.019, chi2 test). The disease duration did not differ between in PRGNabs negative or positive RA patients (8.1 vs. 7.9 years).

**Conclusions:** PGRNabs are positive in more than 30% of sera of RA patients who are seronegative for RF-IgM and ACPA. These results suggest that testing for PRGNabs can reduce the seronegative status in RA patients. However, the data has to be confirmed by a larger validation cohort of RF and ACPA negative RA patients.

## SAT0063 REMOTE ASSESSMENT OF DAILY FLUCTUATIONS OF PATIENT-REPORTED DISEASE SYMPTOMS AND ACTIVITY IN RHEUMATOID ARTHRITIS: FEASIBILITY, COMPLIANCE AND ACCEPTABILITY

I. Gourley[1], C. Calderon[1], M. Beyer[1], L. Hamade[1], R. Margolies[2], K. Gilmer[1], T. Messina[1], O. Fields[1], D. Tisdale[1], M. Curran[1], A. Rowe[1]. *[1]Janssen R & D, LLC, Spring House; [2]Core Human Factors, Bala Cynwyd, United States*

**Background:** Existing clinical measures for Rheumatoid Arthritis (RA) patients, eg: Disease Activity Score (DAS)28 are labor-intensive and typically compiled once every three months by a physician. In contrast, wearable fitness activity trackers allow for continual measurement of activity and lifestyle events. If correlated to disease activity, use of data from "wearable" will provide an understanding of impact on activity on a more frequent basis than the physician-applied tests.

**Objectives:** The primary aim of this study was to determine feasibility, patient compliance and acceptance using an activity tracker together with a novel smartphone-based electronic Patient Reported Outcome (ePRO) app (Remote Access to RA [RA-RA] app developed in-house) for RA patients.

**Methods:** Smartphone users diagnosed with RA (n=15) were recruited to wear an activity tracker and use the RA-RA app daily for one week. The patients attended two study sessions. During the first session patients were dispensed the activity tracker. The investigator installed the activity tracker companion and the RA-RA apps on the patient's smartphone and provided instructions for their use. Patients wore the activity tracker for one week, and were asked to complete RA symptom questionnaires on a regular basis (eg:morning, evening, and weekly). During the study period, the activity monitor collected objective measures of patient activity while the RA-RA app collected patient reported outcome measures (eg: stiffness, sleep quality, joint pain). Blinded activity and RA symptom data were automatically transferred to and stored on a clinical electronic data capture system. During the second session, patients were interviewed regarding their experiences; likes, dislikes, difficulties, and provided feedback on the RA-RA app, activity tracker and its accompanying app. Patients also described any instances and reasons for non-compliance with using the app or wearing the activity tracker.

**Results:** Thirteen of fifteen patients successfully used the activity tracker and wore it for the duration of the study week.Overall, patients found the RA-RA app easy to use for tracking their RA symptoms and activity. Many patients reported that RA-RA accurately described their RA symptoms. Some patients experienced app errors and required assistance from study staff. Overall, patients liked the on-screen controls. Patients provided valuable feedback on interface design considerations (eg: keypad or the arrows for time entry). Preliminary analysis showed some correlation between duration of morning stiffness reported in the app and level of morning activity captured by the activity tracker.

**Conclusions:** Digital healthcare application, use of the activity tracker, and a smartphone-based ePRO is a feasible, easy to use and acceptable system for the collection of daily fluctuations of symptoms and activity in RA patients. Based on the results of this pilot study, the next trial will be in a clinical setting with RA patients receiving treatment. This study will establish correlation of patient's activity and ePRO information with the standard clinical information (ACR, DAS28, and HAQ), as well as serum and imaging biomarkers to determine disease activity and inflammation.

## SAT0064 THERAPY ADHERENCE, PRESCRIBED MEDICATIONS, DISEASE ACTIVITY AND PSYCHOSOCIAL CONSEQUENCES IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.G. Kuipers[1], M. Koller[2], F. Zeman[2], K. Müller[2], J.U. Rüffer[3]. *[1]Klinik für internistische Rheumatologie, Rotes Kreuz Krankenhaus Bremen, Bremen; [2]Center for Clinical Studies, University Hospital Regensburg, Regensburg; [3]German Fatigue Society, Cologne, Germany*

**Background:** Adherence to rheumatoid arthritis (RA) treatment is essential for therapeutic success.Factors contributing to therapy adherence and their consequences are under debate.

**Objectives:** To investigate the relationship between therapy adherence and disease activity as well as patients' quality of life.

**Methods:** The survey included a representative, nationwide sample of German physicians specialized in RA and patients with RA. The physician questionnaire assessed disease activity (DAS28), patients' adherence to therapy and medical prescriptions. The patient questionnaire assessed quality of life (SF-12), health education literacy (i.e., the understanding and use of medical information, HELP), activities of daily living (MDHAQ), fatigue (EORTC QLQ-FA13) and patients' listings of their medications. Adherence was assessed with a combined measure of physician rating (1= very adherent, 0 = less adherent) and the match between physicians' prescriptions and patients' accounts of their medications (1 = perfect match, 0 = no perfect match). Three groups of patients could be distinguished: high (very adherent according to physician and perfect medication match, n=180), medium (either high physician rated adherence or perfect medication match, n=279), and low (0 in both adherence criteria) (n=205). An ANOVA was used to analyze differences in continuous variables among the three groups.

**Results:** 671 pairs of patient and physician questionnaires were analyzed. Mean patients' age (73% female) was 60 years (SD=12). At the time of assessment, 67.2% the patients showed low disease activity (DAS28 <3,2), 28.8% moderate disease activity (DAS28 3,2 to 5,1), and 4.0% high disease activity (DAS28 >5,1). There was no relation between adherence and demographic variables. However, it was related to disease activity, numerous psychosocial variables and the number of prescribed medications (Table 1).

Table 1

| | Adherence | | | p |
|---|---|---|---|---|
| | High | Medium | Low | |
| DAS28* | 2.45 (1.11) | 2.80 (1.20) | 3.06 (1.26) | <0.001 |
| HAQ (Disability)* | 0.58 (0.62) | 0.76 (0.67) | 0.85 (0.74) | 0.001 |
| SF-12** | | | | |
| Physical | 43.20 (9.91) | 40.85 (10.95) | 39.61 (10.98) | 0.004 |
| Psychological | 50.42 (10.58) | 47.49 (11.37) | 46.47 (11.55) | 0.002 |
| Fatigue* | | | | |
| Physical | 2.18 (0.80) | 2.39 (0.85) | 2.45 (0.88) | 0.006 |
| Psychological | 1.71 (0.72) | 1.95 (0.85) | 2.02 (0.90) | 0.001 |
| Cognitive | 1.36 (0.46) | 1.50 (0.61) | 1.54 (0.68) | 0.011 |
| HELP* | | | | |
| Understanding medical information | 1.46 (0.54) | 1.54 (0.65) | 1.67 (0.78) | 0.008 |
| Use of medical information | 1.79 (0.70) | 1.94 (0.84) | 2.16 (0.91) | <0.001 |
| Communicative competence | 1.50 (0.53) | 1.58 (0.64) | 1.70 (0.75) | 0.012 |
| Number of prescribed medications | 3.71 (2.16) | 5.04 (2.74) | 5.69 (2.74) | <0.001 |

Data are presented using means and (standard deviations). *Lower values denote better performance, **higher values denote better performance.

**Conclusions:** This study showed that patient adherence to therapy was associated with less disease activity and higher levels of quality of life. Adherence was also dependent on the total number of prescribed medications. The effects were consistent across different psychosocial domains. The findings may help to detect patients who are at risk not to comply with treatment and eventually to optimize patient education and counseling.

**Background:** Achieving remission is the most important treatment goal in patients with rheumatoid arthritis (RA). With the development and wider use of highly effective disease modifying anti-rheumatic drugs (DMARD) about half of RA patients reach a state of disease remission, raising the question about tapering or stopping anti-rheumatic treatment.
**Objectives:** To assess the effect of a controlled DMARD tapering regimen on treatment costs and work productivity in RA patients in remission
**Methods:** 101 RA patients in sustained remission (DAS28 <2.6 for more than 6 months) enrolled in the multicenter randomized controlled RETRO Study were analyzed (1). Patients either continued DMARDs (arm1), tapered dose by 50% (arm 2) or entire stopped DMARDs after tapering (arm 3) for one year. Assessment of DMARD costs and work productivity was done every three months in all 101 patients including those remaining in remission and those relapsing a re-starting their original DMARD regimen.
**Results:** In RA patients treated with conventional DMARDs, baseline quarterly treatment costs of 154€ remained stable in arm 1 (156€), while decreasing to 81€ in arm 2 and 75€ in arm 3. In patients treated with biologic DMARDs quarterly treatment costs were 5708€ at baseline. They remained stable in arm1 (5533€) and decreased to 2855€ in arm 2 and 2668€ in arm 3. Overall DMARD costs were reduced by 327.292€ within one year, while outcome was very good

with patients either remaining in remission or immediately regaining remission when exposed to original DMARD regimen after relapse.
**Conclusions:** Controlled tapering of DMARD treatment leads to effective reduction of treatment costs in RA patients in sustained remission.

## SAT0066 THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE IN METHOTREXATE INCOMPLETE RESPONDERS PREDICTS CLINICAL RESPONSES TO NON-BIOLOGICAL VERSUS BIOLOGICAL THERAPY IN EARLY RA

K. Hambardzumyan[1], R.J. Bolce[2], S. Saevarsdottir[3], K. Forslind[4], J.K. Wallman[5], R.F. van Vollenhoven[1]. *[1]Unit of Clinical Therapy Research, Inflammatory Diseases, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; [2]Crescendo Bioscience, South San Francisco, United States; [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm; [4]Department of Clinical Sciences, Section of Rheumatology, Lund University, Helsingborg; [5]Department of Clinical Sciences Lund, Section of Rheumatology, Lund University, Lund, Sweden*

**Background:** In rheumatoid arthritis (RA), biological medications are marginally better than combination of conventional non-biological drugs such as methotrexate (MTX) with sulfasalazine and hydroxychloroquine (triple therapy [TT]) at group level [1–3]. Previously we have reported that multi-biomarker disease activity (MBDA) score measured after MTX monotherapy in MTX incomplete responders (MTX-IR) or the change of the MBDA score (ΔMBDA) from baseline (BL) to month 3 (M3) was predictive for a subset of patients with low versus high likelihood of subsequent response to TT or TNF inhibitor (TNFi) [4, 5].
**Objectives:** To evaluate a combination of the MBDA score at M3 and ΔMBDA (BL-M3) as a predictor of response to TT or TNFi in MTX-IR in early RA patients from the SWEFOT trial.
**Methods:** In the SWEFOT trial, patients started MTX monotherapy for 3 months and MTX-IR were randomised to TT or TNFi. We analysed 157 MTX-IR patients with complete data on the MBDA score at BL and M3, and DAS28 at year 1. The MBDA score between BL and M3 was compared by Wilcoxon Signed Rank test. Proportions of clinical responders (DAS28≤3.2) at year 1 among patients with high (>44 [validated cut-off] or >38 [non-validated, ROC curve-based cut-off]) MBDA score at M3 AND non-big decrease from BL to M3 (ΔMBDA≤20) were compared with other patients (MBDA≤44/≤38 OR/AND ΔMBDA>20) by $\chi^2$ test. Overall difference of the responses in the two therapy arms was analysed by Breslow-Day test (for homogeneity of odds ratio).
**Results:** Median (interquartile range) of the MBDA score at BL and M3 were 59 (49–73) and 46 (37–60), respectively (p<0.001). For patients with a high MBDA score (>44 or >38) and ΔMBDA≤20, the likelihood of response to TNFi was significantly greater than to TT (60% vs 30%, p=0.006, Figure 1A and 60% vs 33%, p=0.006, Figure 1B), whereas for other patients the likelihood of response was greater for TT than TNFi (63% vs 46%, p=0.134, Figure 1A, and 69% vs 41%, p=0.035, Figure 1B). The overall differences of the responses to the treatments based on >44 or >38 cut-offs were highly significant (p=0.003 and p=0.001, respectively; Figure 1A, B).

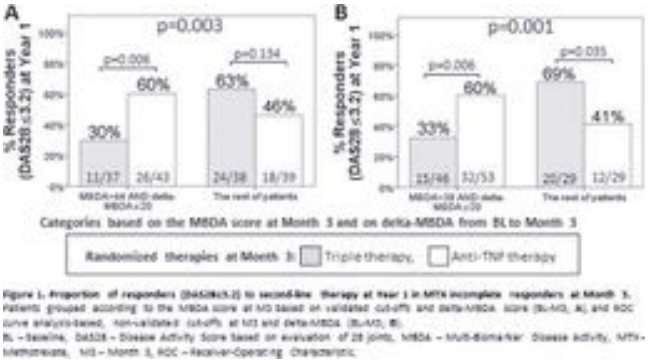

Figure 1. Proportion of responders (DAS28≤3.2) to second-line therapy at Year 1 in MTX-incomplete responders at Month 3. Patients grouped according to the MBDA score at M3 based on validated cut-offs and delta-MBDA score (BL-M3, A), and ROC curve analysis-based, non-validated (cut-offs) at M3 and delta-MBDA (BL-M3, B).
BL – baseline, DAS28 – Disease Activity Score based on evaluation of 28 joints, MBDA – Multi-Biomarker Disease Activity, MTX-IR – methotrexate, M3 – Month 3, ROC – Receiver-Operating Characteristic

**Conclusions:** In patients with early RA and incomplete response to MTX, MBDA score predicted the relative efficacy of subsequent treatment with triple therapy versus anti-TNF. Patients with high MBDA score after MTX monotherapy AND change in the MBDA score ≤20 had higher likelihood of responding to TNFi and the other patients had higher likelihood of responding to TT.

## SAT0067 RADIOGRAPHIC DAMAGE AND DISABILITY IN PATIENTS WITH RA IN RELATION TO DISEASE DURATION IN THE ERA OF BIOLOGICS. LONG-TERM RESULTS FROM THE SCQM COHORT

K.A. Heinimann[1], J. von Kempis[1], R. Sauter[2], M. Schiff[3], H. Schulze-Koops[4], R. Mueller[1]. *[1]Division of Rheumatology; [2]Clinical Trials Unit, Kantonsspital St. Gallen, St. Gallen, Switzerland; [3]University of Colorado, Denver, United States; [4]Rheumaeinheit, Medizinische Klinik IV, Klinikum der Universität München, Munich, Germany*

**Background:** Rheumatoid arthritis (RA) is an inflammatory disease with a chronic course over many years. Long-term observations in the late 90s have demonstrated that RA is associated with progressive articular destruction and increasing disability over the course of the disease. When biologic treatment was introduced, a lot of studies were able to show a favourable influence on disease activity, joint destruction, and disability. However, to our knowledge, no long-term studies have been conducted investigating the radiographic outcome and disability in this new era of treatment with biologics.
**Objectives:** To analyse patients with RA for radiographic damage, disability and disease activity dependent on disease duration.
**Methods:** We included all RA patients from the Swiss Clinical Quality Management in rheumatoid arthritis (SCQM) with at least one clinical visit and information on the disease duration available in the database. The primary endpoint was the association between the radiographic destruction, assessed by Ratingen erosion scores at the last clinical visit, and disease duration. This endpoint was investigated by a multiple negative binomial regression model which corrected for the effect of gender, age, rheumatoid factor (RF), ACPA and therapeutic status regarding the use of anti-TNF drugs and methotrexate (MTX), as possible confounding factors. Disease activity (DAS 28) and disability (HAQ DI) in dependence of disease duration served as secondary outcomes, analysed by using a multiple linear regression model with corrections for the same potential confounders as described for the primary endpoint.
**Results:** The original 52'753 records on 8'678 patients resulted in 6'526 evaluable observations for the Ratingen score. Disease duration ranged between less than 1 and more than 65 years, with a median disease duration of 8.3 years, and past or current use of anti-TNF drugs in 58.4% of patients. We found a significant association between disease duration and radiographic destruction with an average increase of Ratingen scores by 8.3% each year (95%CI from 8.1% to 8.6%). The most significant predictor for less radiographic destruction was a negative rheumatoid factor. During the first 5 years of the disease, clinical activity and disability decreased over time. While DAS 28-scores remained on a stable level in patients with a disease duration of more than 5 years (median DAS 28 of 2.8), HAQ-DI scores increased continuously by 0.018 for each additional year.
**Conclusions:** In this RA cohort, patients showed a continuous increase of articular destruction and physical disability in parallel to disease duration, despite treatment with biologics in the majority of patients. Even though in the era of biologics a satisfactory control of disease activity can be achieved in most patients, RA remains a progressive disease leading to joint destruction and physical disability.

## SAT0068 CIRCULATING MIR-126 IS A MARKER OF DISEASE ACTIVITY IN PATIENTS WITH EARLY RA BUT DOES NOT DIFFERENTIATE PATIENTS AT RISK OF DEVELOPING RA

K. Prajzlerová, R. Jandová, V. Hrušková, P. Hánová, H. Mann, K. Pavelka, J. Vencovský, L. Šenolt, M. Filková. *Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University in Prague, Prague, Czech Republic*

**Background:** We have previously shown differential expression of some circulating miRNAs in patients with early RA (ERA) and their potential as markers of disease activity and treatment response.
**Objectives:** We aimed to investigate differentially expressed circulating miRNAs in clinically suspect arthralgia patients with positive antibodies to citrullinated peptide antigens (ACPA) who are at high risk of developing RA and compared them to ERA and established RA.
**Methods:** The study included 20 ACPA+ arthralgia patients, 25 treatment naïve ERA patients who met the 2010 ACR/EULAR criteria (disease duration $<$6 months), 26 patients with highly active established RA prior anti-TNF treatment initiation and 24 healthy controls (HC). Clinical disease activity assessments (DAS28, SDAI) were performed. Ultrasound of 28 small joints was performed in ACPA+ arthralgia patients to evaluate subclinical synovitis. Total RNA from plasma was isolated using phenol-chloroform extraction. A comprehensive analysis of miRNAs was performed using TaqMan® Low Density Array (TLDA) in 5–6 samples in each group. The expression of miR-126 was further validated by single assays in remaining samples and normalized to an average of 2 spike-in C. elegans controls. dCt was used for relative quantification.
**Results:** Patients with arthralgia showed no clinical and ultrasound evidence of arthritis (grey scale and power Doppler for single joint $\leq$1) Of these, all were ACPA+, CRP 7.4±19.2 mg/l. Treatment naïve ERA patients had active disease (DAS28 5.7±1.3, CRP 20.7±23.2 mg/l), 60% were ACPA+. Patients with established RA all had high disease activity (DAS28 6.6±0.9, CRP 28.1±31.3 mg/l), 73% were ACPA+, had failed DMARDs therapy and were due to commence anti-TNF treatment. Out of the 380 miRNAs analysed by TLDA, 128 miRNAs were detected in HC, 129 in arthralgia, 44 in ERA and 25 in RA patients. TLDA analysis revealed 1.7x higher levels of miR-126 in ACPA+ arthralgia patients compared to HC, and 27x and 63x lower levels in ERA and RA compared to HC, respectively. These data were suggestive of significant dysregulation of miR-126 in patients with active polyarthritis compared to ACPA+ arthralgia. However, further validation showed no difference in miR-126 levels among HC, arthralgia and ERA patients but the levels were 2.6x lower in RA patients compared to HC (p=0.0037). The levels of miR-126 significantly negatively correlated with DAS28 (r=-0.460; p=0.047), SDAI (r=-0.535; p=0.018), SJC (r=-0.504; p=0.028), and TJC (r=-0.517; p=0.023) in treatment naïve ERA patients, but not in those with established disease. There was no correlation with CRP in any patient group.
**Conclusions:** Higher miR-126 levels reflect lower disease activity in treatment naïve ERA patients. We hypothesize that significant downregulation of miR-126 levels in RA patients may be modified by previous exposure to multiple treatments.

## SAT0069 THE VALIDATION ABOUT THE MEASUREMENT OF JOINT SPACE DISTANCE BY USING SUPER RESOLUTION IMAGE AND CURVE FITTING METHODS

K. Funahashi[1,2], T. Kojima[1], N. Takahashi[1], S. Asai[1], T. Takemoto[1], N. Asai[1], T. Watanabe[1], T. Goto[3], M. Shimizu[3], H. Kariya[3], N. Ishiguro[1]. *[1]Department of Orthopedic Surgery, Nagoya University School of Medicine, Nagoya; [2]Department of Orthopedic Surgery, Kariya Toyota General Hospital., Kariya; [3]Department of Electrical and Electronic Engineering, Nagoya Institute of Technology, Nagoya, Japan*

**Background:** Cartilage loss is irreversible progress, so physicians have to find the detection of joint space narrowing as early as possible. It is stated that physical disability in rheumatoid arthritis (RA) is associated with joint space narrowing rather than erosion [1], so early detection of progressive joint damage is the most important. But in DICOM which is the international standard for medical images, 1 pixel on radiographic images is 0.10 to 0.15 mm, so the detection of the change which is lower than that is impossible.To solve this problem, we previously developed new method measuring the joint space distance with the X-rays image which performed super-resolution image processing [2]. However, we did not validate the measured value by our methods.
**Objectives:** To validate the measurement of joint space distance by using super resolution image and curve fitting methods. We also evaluated whether the focus-film distance affected the measured value.
**Methods:** We producted phantom model (PM) of joint space that expressed metacarpophalangeal joint space 1mm by using 3D printer.The super-resolution images of PM with radiographs by using total variation regularization and shock filter were prepared (Fig. 1). We measured the distance of joint space by three methods, 1) conventional measurement; distance between two points, 2) measurement by using normal vector from the top of joint surface of phalanx bone, 3) measurement using joint space area calculated by integration method. Each method processed on MATLAB®. 2), 3) methods were processed by curve fitting method which create parabolic curve by choosing some points of joint surface.We measured the distance ten times to adjust the error of measurement.We took radiographs with the focus-film distance under conditions of 90cm, 100cm, 110 cm, respectively.
**Results:** Between the two points method, normal line method and integration method, the mean (standard deviation) of measured value under focus-film distance 90 cm was 1.033 (0.018), 0.964 (0.017), 0.939 (0.009), respectively. Under focus-film distance 100 cm, it was 0.963 (0.031), 0.969 (0.032) ,0.943 (0.025), respectively. Under focus-film distance 110 cm, it was 1.019 (0.026), 0.964 (0.018), 0.943 (0.015) , respectively. There were no significant differences with measured value between three methods under each focus-film distance. There were also no significant differences with each focus-film distance (Fig. 2).

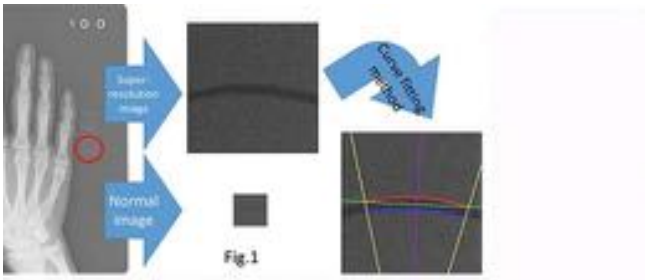

Fig.1

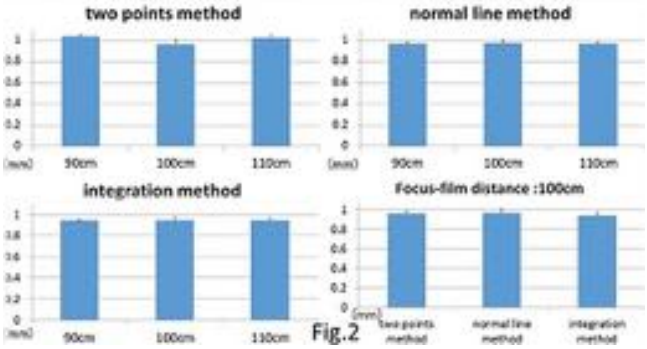

Fig.2

**Conclusions:** The measured value was not affected by a difference of the focus-film distance between 90cm to 110cm.We obtained the measured value, 0.937 – 0.970 by two methods, which were equal to 1mm of PM.The standard deviation was less than 0.032mm. We validated the measurement accuracy of curve fitting methods. We suggested that the possibility of early detection with joint space narrowing in rheumatoid arthritis patients by using super resolution image and curve fitting methods.

## SAT0070 PATIENTS WITH EARLY RHEUMATOID ARTHRITIS TREATED WITH REMISSION INDUCTION TREAT-TO-TARGET REGIMENS REPORT IMPORTANT EARLY AND LASTING HEALTH IMPROVEMENT: RESULTS FROM THE CARERA TRIAL

K. Van der Elst[1,2], D. De Cock[3], V. Stouten[4], J. Joly[1], P. Moons[2], P. Verschueren[1,4], R. Westhovens[1,4] on behalf of the CareRA Study Group.
*[1]Rheumatology, University Hospitals Leuven; [2]Department of Public Health and Primary Care, Academic Centre for Nursing and Midwifery; [3]Department of Development and Regeneration, Skeletal Biology and Engineering Research Centre; [4]Department of Development and Regeneration, Skeletal Biology and Engineering Research Centre, KU Leuven - University of Leuven, Leuven, Belgium*

**Background:** Patients' and healthcare providers' perceptions about treatment success can differ. Patient-reported health is therefore an important parameter to consider in daily care, especially in early rheumatoid arthritis (ERA), a disease stage where major health improvements can be realized, and patient adjustment is fully in progress.

**Objectives:** To explore patient-reported health of persons with ERA within the first treatment year.

**Methods:** The CareRA trial is a RCT rooted in daily practice, comparing remission induction treat-to-target regimens in ERA patients stratified in risk groups based on classical prognostic markers: in the high-risk group, patients were randomized to 1/3 intensive combination therapies with moderate-to-high-dose glucocorticoid bridging; in the low-risk group, patients were randomized to MTX monotherapy or MTX with moderate dose glucocorticoid bridging. The Short-Form 36 (SF36) questionnaire was used to assess 8 health dimensions at treatment initiation (BL), 4 months (W16) and 1 year (W52) later. Missing data were handled according to the SF36 user's manual. Differences in patient-reported health between risk and treatment groups, and between patients in remission (DAS28-CRP $<2.6$) or not were tested with Mann-Whitney U or Kruskal-Wallis.

**Results:** Participants (n=379) shared characteristics with a typical ERA population; 66.2% was in remission at W16. The SF36 scores improved in all treatment groups at W16 and no differences between or within risk groups were observed, except for the general health dimension, which differed at W16 ($p<0.001$) and showed a different evolution (p=0.047) across the high-risk treatment arms. At W52, only the physical functioning score differed across the low-risk treatment arms (p=0.024). The largest health improvement was seen over the first 4 treatment months, while scores remained stable up to W52. The largest mean improvements were observed within physical health domains, e.g. "role physical" (30.84±45.07); but patients also reported progress in the mental health dimensions, e.g. "vitality" (10.44±19.39). Nevertheless, some participants did not report any improvement, e.g. 26 patients (8.52%) perceived no change in "physical functioning" after 4 months and 36 patients (11.80%) reported lower scores (mean change = -12.31±15.31), regardless of being in remission or not at W16 (p=0.93). Patients in remission at W16 scored significantly better for "mental health" ($p<0.001$) at W16, and for "role emotional" ($p<0.001$) at W16 and in terms of 4-month change (p=0.01).

**Conclusions:** In our ERA population, important improvement in patient-reported health was seen at W16 lasting up to W52. Perceived health hardly differed between risk and treatment groups, which could be expected within a treat-to-target approach. Despite substantial improvements at group level, some patients did not perceive progress. Our future research will explore this particular subset, including also psychosocial health determinants, as these patients are likely to benefit from more tailored care interventions.

## SAT0071 NUMBER OF AUTOANTIBODIES ASSOCIATED WITH ALL-CAUSE MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Vidal-Bralo, A. Montes, R. Varela, M.D. Bóveda, E. Pérez-Pampín, J.J. Gómez-Reino, A. Gonzalez. *Instituto Investigacion Sanitaria-Hospital Clinico Universitario de Santiago, Santiago de Compostela, Spain*

**Background:** Patients with rheumatoid arthritis (RA) show higher mortality rates than the general population (1). The increase has been correlated with several features as the long-term activity of the disease, corticosteroid use and autoantibody seropositivity. Regarding autoantibodies, an increase in mortality has been associated with rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA), but there is not consensus on the relative role of them. Recently, the anti-carbamylated protein antibodies (anti-CarP) have also been associated with increased mortality in RA patients (2), but in the early RA patients that were studied only RF seemed to be independently associated with all-cause mortality.

**Objectives:** The aim of this study was to determine the association of RF, ACPA and anti-CarP autoantibodies with all-cause mortality in patients with established RA.

**Methods:** Patients with established RA were recruited from 2001 to 2009 and followed until November 2015. Full data were available for 274 patients and only this subset was included in the present analysis. Anti-CarP was assessed by homemade ELISA with in vitro carbamylated fetal bovine serum (3). Cox proportional hazards regression models for all-cause mortality were used adjusting for age, sex and smoking status, and hazard ratios (HR) of ACPA, anti-CarP and FR positivity were obtained in antibody-specific and -combination models.

**Results:** At recruitment, patients showed the following characteristics: age =68.6 years (SD=7.95), disease duration =16.1 years (11.28), RF =61.8%, ACPA =66.4%, anti-CarP =40.2%, ever smokers =19.7%. At the end of the study 171 patients have died (62.4%). Age and smoking at recruitment showed increased hazard ratios for all-cause mortality, whereas gender was not associated.

Each of the three RA autoantibodies was associated with increased all-cause mortality in antibody-specific analysis with very similar HR: RF =1.59 (1.03–2.44, p=0.036), ACPA =1.57 (1.01–2.45, p=0.046), and anti-CarP =1.60 (1.07–2.39, p=0.024). The similarity of effects was also observed in the combined analysis including a variable for each of the antibodies, with the following HR: RF =1.30 (0.79–2.14), ACPA =1.22 (0.72–2.05), and anti-CarP =1.37 (0.88–2.13), none of them significant. Therefore, it seemed appropriate to consider the three autoantibodies as additive factors: the additive showed HR for the number of autoantibodies =1.29 (1.08–1.56, P=0.007) per each additional antibody.

**Conclusions:** The three RA autoantibodies were associated with increased all-cause mortality without clear differences between them, making it appropriate to consider the antibodies as additive factors contributing to risk stratification. This additive contribution is similar to the described for other aspects of RA activity and severity where patients with the largest number of autoantibodies are the most affected.

## SAT0072 ULTRASOUND IS ASSOCIATED WITH LATE PHASES PRECEDING THE CLINICAL ONSET OF RHEUMATOID ARTHRITIS IN INDIVIDUALS GENETICALLY AT RISK

L. Brulhart[1], D. Alpizar-Rodriguez[2], P. Zufferey[3], S. Bas[2], D. Gascon[4], C. Lamacchia[4], P. Roux-Lombard[4], E. Ciubotariu[5], M.J. Nissen[4], C. Gabay[4], A. Finckh[2]. *[1]Rheumatology, HNE, la Chaux-de-Fonds; [2]Rheumatology, HUG, Geneva; [3]Rheumatology, CHUV, Lausanne; [4]HUG, Geneva, Switzerland; [5]Hopital du Sacré-Coeur, Montréal, Canada*

**Background:** Identifying pre-clinical phases of rheumatoid arthritis (RA) is challenging. Musculoskeletal ultrasound (US) is more sensitive than clinical assessment for the detection of synovitis. US abnormalities have been associated with subsequent joint inflammation in patients with anti-citrullinated peptide antibodies (ACPA) without clinical synovitis (SJ)[1].
**Objectives:** To identify US abnormalities associated with the recognized phases of RA development[2] in individuals at increased risk for RA.
**Methods:** This is a nested cohort study within an ongoing prospective study of individuals genetically at risk of developing RA, namely first degree relatives of patients with RA (FDR). Individuals without clinical evidence of RA were enrolled, and then followed-up yearly. We included in this analysis all individuals with available ACPA status (anti-CCP 2, 3.0, or 3.1) and US assessment. The US examination was conducted according to the validated SONAR score[3] and performed by US trained rheumatologists blinded to clinical and biological data. According to previous publications[4], inflammatory activity on US (active US) was defined as a Bmode score ≥9 and at least one synovitis of grade 2 or 3, or a Doppler score ≥2. We used logistic regression to analyze univariable and multivariable associations between US findings and specific phases preceding RA development and other patient characteristics.
**Results:** A total of 269 FDRs were analyzed, of which 97 (36%) had an active US as defined above. Individuals with an active US tended to be older (years median (IQR): 51 (41–59) vs 47 (35–57), OR: 1.0, 95% CI: 1.0–1.0, p<0.05), with no difference in sex, body mass index and tobacco smoking. In univariable analyses, there was a strong correlation between an active US and the presence of 'unclassified arthritis' (≥1 SJ on physical examination) (OR:2.6, 95% CI:1.4–4.9). No association was demonstrated with genetic risk factors (presence of shared epitope), systemic autoimmunity (ACPA positivity) or self reported symptoms in the absence of arthralgia or SJ (Table 1). In the multivariable analyses, the relation between US and 'unclassified arthritis' remained significant (OR:2.4, 95% CI:1.3–4.5).

Table 1. Phases of RA development[2]

| n(%) | Non-active US (n=172) | Active US (n=97) | Univariable OR (95%CI) |
|---|---|---|---|
| Shared epitope (1 or 2 copy) | 58 (34) | 27 (28) | 0.8 (0.4-1.3) |
| ACPA without arthralgia or SJ | 8 (5) | 6 (6) | 1.4 (0.5 – 4.0) |
| Arthralgia or CSQ+3 without SJ | 11 (6) | 6 (6) | 1.0 (0.3-2.7) |
| ACPA and arthralgia without SJ | 9 (5) | 6 (6) | 1.2 (0.4-3.5) |
| Unclassified arthritis (≥1 SJ) | 23( 13) | 28 (29) | 2.6 (1.4-4.9)[a] |

SJ: swollen joint, CSQ: Connective Tissue Disease Screening Questionnaire, (a) P<0.05

**Conclusions:** In individuals at risk of RA, active US was strongly associated with the presence of "unclassified arthritis". There was no association between US findings and earlier identified phases of RA development. These data suggest that in individuals at increased risk for RA, without obvious disease, US may identify imminent RA. These findings support the usefulness of US in a screening strategy for imminent RA.

## SAT0073 GOOD THERAPEUTIC RESPONSE WITH BIOLOGICS BUT PATIENTS' AND PHYSICIANS' OPINION ARE DIFFERENT. DATA FROM THE AUSTRIAN BIOREG REGISTRY

M. Herold[1,2], G. Eichbauer-Sturm[3], R. Puchner[4], B. Rintelen[5], F.S. Singer[2], B.F. Leeb[5]. *[1]Internal Medicine VI, Medical University of Innsbruck, Innsbruck; [2]BioReg Austria, Vienna; [3]Rheumatologist in private practice, Linz; [4]Rheumatologist in private practice, Wels; [5]Lower Austrian State Hospital Stockerau, 2nd Department of Internal Medicine, Karl Landsteiner Department of Clinical Rheumatology, Stockerau, Austria*

**Background:** The discordance between patients and physicians in estimation of patients' global health is well known especially from RA patients. We tried to find out whether differences in global health estimation are the same in patients with different diseases using data of the Austrian biologic registry.
**Objectives:** The aim of this evaluation was to elucidate the amount of differences between PGA (Patient Global disease Activity) and EGA (Evaluator's Global disease Activity) in patients with rheumatoid arthritis (RA), spondylarthritis (SpA) and psoriatic arthritis (PsA) at baseline and at control visits every six months after inclusion in *BioReg*.
**Methods:** Data were extracted from the Austrian *BioReg* registry (http://www.bioreg.at) which was initiated in 2009 to document patients treated with one of the nine biologics (abatacept, adalimumab, anakinra, certolizumab, etanercept, golimumab, infliximab, rituximab, tocilizumab) approved in Austria. Patients with ongoing biologic therapy as well as biologic-naïve patients starting biologic therapy can be included (baseline, BL). Further documentation is recommended about every six months (V1, V2 up to V11). Meanwhile, 1663 patients (rheumatoid arthritis (RA) n=948, ankylosing spondylitis (SpA) n=400, psoriatic arthritis (PsA) n=267, other disease n=48) have been documented. Estimation of global health is done using a visual analogue scale (VAS with 100 mm, 0 = no disease) by patients (PGA) and by physicians (EGA) at every visit.
**Results:** VAS (median values of BL; V1; V2; V3; V4; V5) of patients with RA showed differences between PGA (30; 20; 22; 20; 20; 20) and EGA (15; 7; 10; 10; 10) as well as in SpA (PGA 39; 30; 26; 30; 30; 20 and EGA 20; 10; 10; 10; 10; 10) and in PSA (PGA 30; 10; 12; 20; 20; 10 and EGA 20; 10; 5; 10; 10; 10). Median values of inflammation's laboratory markers (ESR in mm/1st hour and CRP in mg/l) were always within the normal range (ESR and CRP in RA 5; 12; 14; 12; 14; 14 and 2,0; 2,0; 2,2; 2,0; 2,0; 2,0; in SpA: 7; 7; 7; 8; 7; 7 and 1,5; 1, 5; 1,7; 1,4; 1,2; 1,1 and in PsA 8; 8,5; 9; 9; 10; 10 and2,0; 1,7; 1,4; 1,0; 1,0; 1,0).
**Conclusions:** As described for RA we also saw in patients with RA but also in SpA and PsA, that physicians' estimation of global health is always better than patients' values at all visits. We suppose that physicians focus primarily on signs of active inflammation and less on general feeling. The normal values of ESR and CRP support this assumption.

## SAT0074 NO NEED TO DETECT ANTI-DRUG ANTIBODIES IN PATIENTS TREATED WITH TNF INHIBITORS

M. Herold[1], L. Boso[2], T. Haueis[2], W. Klotz[1], G. Zangerl[3]. *[1]Department of Internal Medicine VI, Medical University of Innsbruck, Innsbruck; [2]Landeskrankenhaus Bludenz, Bludenz; [3]Rheumatologist in private practice, Zams, Austria*

**Background:** Formation of anti-drug antibodies (ADA) might be responsible for sub-therapeutic serum drug levels resulting in a lack of clinical response. The need to test ADA levels in patients treated with a TNF inhibitor is the subject of discussion (1, 2).
**Objectives:** ADA levels were measured in patients treated with ADL or ETN or IFX to check immunogenicity in patients receiving various TNF inhibitors and clarify whether ADA measurement reflects treatment output.
**Methods:** Frozen serum samples from patients with rheumatoid arthritis (RA), spondylarthritis (SpA) and psoriasis arthritis (PsA) and treated with adalimumab (ADL; n=41) or etanercept (ETN; n=42) or infliximab (IFX; n=42) were selected. All patients were receiving continuous care of one of the authors. Anti-ADL, anti-ETN or anti-IFX levels were tested with commercially available assays (*Grifols Deutschland GmbH*) according to the manufacturer's instructions. Drug levels were also determined with assays from the same manufacturer.
**Results:** Among ADL-treated patients we found 8/41 (20%) to be positive for ADA. In the ETN group elevated ADA levels were found in 3/42 (7%) patients; in the IFX group 8/42 (19%) patients had positive ADA levels. High ADA concentrations did not always correlate with diminished therapeutic response. Among ADA positive patients 3/8 in the ADL group (1 of each disease), 3/3 in the ETN group (RA 2, SpA 1) and 5/8 in the IFX group (RA 1, PsA 3, SpA 2) continued the given therapy

with good response. The three positive ETN patients showed only borderline elevated ADA levels.
**Conclusions:** ADA levels were more often found in patients treated with ADL or IFX than with ETN. These results agree with those of previous studies (3) and might indicate differences in immunogenicity between these three TNF inhibitors. Nevertheless positive ADA levels did not always indicate failure of therapy. The low incidence of ADA levels, the high cost of ADA assays and the absence of a need to change therapy based on ADA levels have to be considered before ADA analysis is ordered within a routine control.

## SAT0075 VALIDATION OF THE RHEUMATOID ARTHRITIS PREDICTION RULES FOR THE DISEASE DEVELOPMENT IN PATIENTS WITH JOINT PAIN FROM WEST SWEDEN

R. Pullerits[1,2], S. Bratt[1], M. Turkkila[1], M. Erlandsson[1], M. Bokarewa[1,2].
*[1]Department of Rheumatology and Inflammation Research, Institution of Medicine, The Sahlgrenska Academy at Gothenburg University; [2]Department of Rheumatology, Sahlgrenska University Hospital, Gothenburg, Sweden*

**Background:** Rheumatoid arthritis (RA) is a joint destructive disease, which leads to physical disability. There is no cure of RA today. Thus, recognition of RA at preclinical stages is essential for successful treatment.
**Objectives:** To validate and improve known prediction rules aiming at early recognition of clinically suspect arthralgia and diagnosis of RA.
**Methods:** Medical records of 241 first-time patients with clinically suspect joint pain were evaluated for RA diagnosis by the 2010 EULAR/ACR criteria (1) and by the RA prediction rules (13-points, Amsterdam (2)); and 16-points clinical assessment (Leiden (3)) and prospectively followed during 29–47 months. All the patients were a part of the inception cohort of 5455 patients whose samples were tested for RF and/or ACPA during 12 consecutive months at the Laboratory of Clinical Immunology at the University Hospital of Gothenburg. Patients with known diagnosis of RA, other rheumatic disease and chronic pain conditions were excluded. The utility of arthritis-specific autoantibody status (ACPA and/or RF) and the family history for RA prediction were analyzed.
**Results:** The RA criteria applied to the records of the first visit identified 24% of patients as RA (EULAR score mean 7.6), 30% as undifferentiated arthritis (UA, EULAR score mean 3.6), while the remaining 45% of the patients were characterized as arthralgia (EULAR score mean 2.3). The 13-point and 16-point prediction rules allocated RA patients to the high-risk group with comparable sensitivity of 78% and 91%. The significant correlation between the two models was present in UA (r=0.398; p=0.0005) and arthralgia (r=0.411; $p<0.0001$) groups, but not in RA (r=0.0007, ns). Specificity for RA diagnosis at the first visit was higher in the 13-point rule (90.5%), however it was not discriminative between the arthralgia and UA groups. The clinical 16-point assessment discriminated successfully between RA/UA and between UA/arthralgia groups. The 16-point assessment allocated 50% of patients with UA to the high-risk group, which affected specificity. During the follow-up period, 23 cases of new RA and 5 UA were registered. The sensitivity of the 16-point assessment at the first visit was 60%, similar for the antibody-positive and for antibody–negative cases. The sensitivity of the 13-point rule was 21% (p=0.003), and was selective for the antibody-positive cases. At the first visit, subjects with family history of RA were over-represented in the arthralgia group (p=0.022). At follow-up only 1 of them developed UA.
**Conclusions:** Both prediction rules are shown to be sensitive identify RA patients at assessment. The clinical 16-point assessment has prospective sensitivity for new cases. This is shown independently of autoantibody status and family history of RA.

## SAT0076 UTILITY OF SURVIVIN MEASUREMENTS FOR EARLY RECOGNITION OF CLINICALLY SUSPECT ARTHRALGIA AND DIAGNOSIS OF RHEUMATOID ARTHRITIS IN WEST SWEDEN

M. Bokarewa[1,2], M. Turkkila[2], S. Bratt[2], M. Erlandsson[2], R. Pullerits[1,2,3].
*[1]Department of Rheumatology, Sahlgrenska University Hospital; [2]Department of Rheumatology and Inflammation Research, Institution of Medicine, The Sahlgrenska Academy at Gothenburg University; [3]Department of Clinical Immunology, Sahlgrenska University Hospital, Gothenburg, Sweden*

**Background:** Recognition of rheumatoid arthritis (RA) at preclinical stages is essential for successful treatment, long-term functional ability and survival. Available serological markers of the disease are restricted to acute-phase reactants and presence of autoantibodies - rheumatoid factor (RF) and ACPA. Although specific, these markers cover less than a half of the patients with RA. Oncoprotein survivin has been recently identified as a marker of severe RA frequently associated with progressive joint damage and poor response to antirheumatic treatment (1). A pilot study on the samples from the Nordic Biobank showed that survivin could predict development of RA several months ahead of clinical symptoms (2).
**Objectives:** To validate the utility of survivin measurements for early recognition of clinically suspect arthralgia and diagnosis of RA in the epidemiological setting.
**Methods:** The first-visit patients with joint pain from the inception cohort of 5455 subjects tested for RF and/or ACPA during 12 consecutive months at the Laboratory of Clinical Immunology at the University Hospital of Gothenburg, were evaluated for RA diagnosis by the 2010 EULAR/ACR criteria (3). Patients with known diagnosis of RA, other rheumatic disease and chronic pain conditions were excluded. The subjects not fulfilling RA diagnosis at the first visit were prospectively followed during 29–49 months. The utility of survivin measurement and arthritis-specific autoantibody status (ACPA and/or RF) for RA diagnosis were analyzed.
**Results:** The total of 385 patients were included in the study. RA criteria applied to the records of the first visit identified 17% of patients as RA. Additional 21% of patients were recognized as undifferentiated arthritis (UA), while the remaining 62% of the patients were characterized as arthralgia. Majority of the RA patients were survivin positive (52%) with an overlap for antibodies (RF and/or ACPA) in 88%. The UA and arthralgia groups had low prevalence of patients positive for survivin (p=0.018) and for autoantibodies (p=0.002). During the follow-up period, 23 cases of new RA and 5 new UA were registered. The incidence of new cases was significantly higher among the survivin-positive patients and corresponded to the increased risk compared to survivin-negative (p=0.008). The combination of survivin and autoantibodies increased further the risk for development of the disease compared to negative patients (RR 4.05[ 1.73–9.20], p=0.002). The presence of isolated survivin was also associated with higher risk of RA (RR 2.55 [1.14–5.71], p=0.028), while no increase in RA risk could be shown for the isolated presence of autoantibodies.
**Conclusions:** This prospective study showed in the epidemiological setting that the presence of survivin was associated with an increased risk of RA. Combination of survivin and autoantibodies further increased this risk.

## SAT0077 PROGNOSTIC FACTORS FOR ABATACEPT RETENTION IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A JAPANESE MULTICENTER REGISTRY

M. Hanabayashi[1], N. Takahashi[2], Y. Yokota[1], H. Miyake[1], T. Kojima[2], N. Ishiguro[2] on behalf of TBCR. *[1]Department of Orthopaedic Surgery, Ichinomiya Municipal Hospital, Ichinomiya; [2]Department of Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** In recent years, it has been reported that baseline anti-cyclic citrullinated peptide (CCP) antibody positivity is associated with a better response and retention rate in patients with rheumatoid arthritis (RA) [1,2]. However, there have been few reports describing the association of prognostic factors with the long-term clinical results represented by drug retention rate.
**Objectives:** The aim of this study was to identify prognostic factors for abatacept (ABT) retention in clinical routine practice using data from a Japanese multicenter registry system for RA patients treated with biological DMARDs.
**Methods:** All eligible RA patients who underwent ABT therapy from October 2010 through to March 2015 (n=513) were prospectively registered in the Tsurumai Biologics Communication Registry (TBCR). Potential prognostic factors such as

baseline demographics and disease characteristics were analyzed using Log-rank test. Variables with a p value of <0.20 were included in the multivariable analysis using a Cox proportional hazard model.
**Results:** The overall retention rate was 58.2% (95% CI; 0.49 - 0.66) at 4 years. Based on Log-rank test, previous biologics treatment (naïve vs. switch), Steinbrocker stage (1–2 vs. 3–4), RF status (negative vs. positive), anti CCP antibody status (negative vs positive) and concomitant MTX use (user vs. non-user) were eligible to enter the multivariate model (Table 1). Multivariable analysis revealed that patients had a significantly lower risk of ABT discontinuation if they were biologic-naïve (HR; 0.57, 95%CI; 0.35 - 0.91) and anti-CCP antibody positive (HR; 0.57, 95%CI; 0.32 - 0.99) (Table2). Furthermore, we divided anti-CCP antibody status into three categories (<4.5; negative, 4.5 - <100; low titer, ≥100; high titer) and examined the relationship between titer and retention rate. Kaplan-Meier curve indicated that the retention rate in high titer group was lower than that in low titer group (Figure 1).

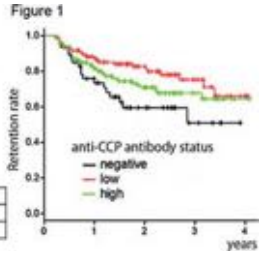

Table 1

| Variables | Log-rank |
|---|---|
| naïve vs. switch | p<0.001 |
| stage (1-2 vs.3-4) | p=0.086 |
| RF (negative vs. positive) | p=0.159 |
| anti CCP antibody (negative vs. positive) | p=0.035 |
| MTX (user vs.non-user) | p=0.060 |

Table 2

| Variables | adjusted HR (95% CI) | p-value |
|---|---|---|
| naïve vs. switch | 0.568 (0.354 - 0.912) | 0.019 |
| anti CCP antibody (negative vs. positive) | 0.567 (0.323 – 0.995) | 0.048 |

Figure 1

**Conclusions:** This study demonstrated that baseline anti-CCP antibody positivity is associated with a better long-term retention of ABT therapy. But additional therapeutic intervention would be necessary for patients with high titer to improve the short- and long-term clinical results of ABT.

## SAT0078 PROSPECTIVE OBSERVATIONAL STUDY TO EVALUATE THE USE OF MUSCULOSKELETAL ULTRASONOGRAPHY TO IMPROVE RHEUMATOID ARTHRITIS MANAGEMENT: CANADIAN EXPERIENCE (ECHO)

M. Stein[1], E. Rampakakis[2], J.S. Sampalis[2], W. Bensen[3]. *[1]Rheumatology, McGill University, Montreal; [2]JSS Medical Research, St.Laurent; [3]Charlton Medical Centre, Hamilton, Canada*

**Background:** Musculoskeletal Ultrasound (MSUS) has been shown to be superior to clinical examination in the detection of synovitis in patients with Rheumatoid Arthritis (RA), and can be used to improve diagnostic accuracy [1] and potentially monitor disease changes in order to make treatment decisions aimed at optimizing patient care. Since the creation of the Canadian Rheumatology Ultrasonography Society (CRUS) in 2010, an increasing number of rheumatologists has been trained in the use of MSUS.
**Objectives:** The overall study objective is to compare the effectiveness of MSUS to Routine Care (RC) as a disease management tool in patients with moderate-to-severe RA for whom a change in treatment is indicated. The study also assessed the predictive power of US assessments.
**Methods:** Descriptive interim analysis of the "Echo" study, a prospective two-cohort, quasi-experimental study of patients diagnosed with active moderate-to-severe RA managed either with MSUS or as per RC. In order to be eligible for the study patients must require a change in treatment as per the judgment of the treating physician. Patients are followed for 1 year with assessments at baseline, 3, 6, 9, and 12 months. Outcome measures of interest include CDAI Remission, DAS-28 Remission and DAS-28 Low Disease Activity (LDAS).
**Results:** A total of 339 patients (70.1% female) with a mean (SD) age of 58.7 (11.79) years and disease duration of 7.4 (10.2) years were enrolled, without any significant differences between treatment groups. There were no differences between the two treatment groups with respect to the study outcomes. However, higher total US Erosion Scores at baseline were associated with lower rates of LDAS at 9 months (OR =0.810; P=0.047) and 12 months (OR =0.808; P=0.078) and lower rates of DAS-28 Remission at 9 months (OR =0.811; P=0.60); higher total synovitis GREY scale at baseline was associated with a lower rate of LDAS at 6 months (OR =0.913; P=0.014) and DAS – 28 Remission at 3 months (OR =0.911; P=0.074)
**Conclusions:** MSUS assessments can be useful predictors of future disease remission in patients with RA. The impact of MSUS on disease management and clinical outcomes requires further study.

## SAT0079 CHARACTERIZATION OF RA PATIENTS WITH A DAS28 RESPONSE TO ADALIMUMAB THERAPY BY IMPROVEMENT IN PAIN: A GERMAN NONINTERVENTION STUDY

M. Köhm[1,2], E. Scharbatke[3], E. Stemmler[4], G. Greger[4], F. Behrens[1,2], B. Wittig[4]. *[1]Rheumatology, Goethe-University; [2]Clinical Research, Fraunhofer IME Project group TMP, Frankfurt; [3]Rheumatology/Immunology, Universitätsklinik Würzburg, Würzburg; [4]AbbVie Deutschland GmbH&Co.KG, Wiesbaden, Germany*

**Background:** In daily clinical practice, therapeutic responses (eg, Disease Activity Score-28 joints [DAS28]) are not always associated with improvements in pain in patients with rheumatoid arthritis (RA).
**Objectives:** To evaluate pain responses in RA patients with a DAS28 response to adalimumab (ADA) therapy.
**Methods:** We analyzed data from two large German multicenter observational studies of patients with active RA who initiated ADA therapy during routine clinical care. Patients were classified on the basis of significant responses in DAS28 and pain (on a scale of 0=best; 10=worst), as determined by statistical analyses of the critical difference for individual improvement.[1] Patients with a significant DAS28 improvement at month 12 (≥1.8 points from baseline) and significant pain improvement (≥3 points from baseline) were compared with patients with a significant DAS28 response, but no significant reduction in pain. Outcomes included fatigue, patient global assessment (PGA), and physician global assessment (MDGA) (all on a scale of 0=best to 10 = worst) and function as assessed by the Funktionsfragebogen Hannover questionnaire (FFbH; % remaining function).
**Results:** Of 5745 patients in the full analysis set, 1509 patients had available data on pain and a significant DAS28 response at month 12. Of these patients, 1038 had a significant improvement in pain and 471 did not. Baseline characteristics and concomitant medications were similar between the two groups (Table). After 24 months of ADA therapy, both groups had similar swollen and tender joint counts and levels of inflammatory markers. Patients with both DAS28 and pain responses had better functional status at month 12 than patients without an improvement in pain (mean FFbH=76.0% vs 68.8%; $P<0.0001$), despite lower mean baseline values (56.8% vs 63.8%). Significant differences ($P<0.0001$ for all) in favor of patients with pain responses were also observed in mean values for fatigue (2.8 vs 4.2), PGA (3.0 vs 4.5), and MDGA (2.3 vs 2.9) at month 12.
**Conclusions:** Approximately two-thirds of patients with a significant therapeutic response to ADA at month 12 also have a significant improvement in pain. There were no obvious differences in baseline characteristics between patients with or without improvements in pain. Patients with improvements in both DAS28 and pain have significantly less fatigue and significantly improved function and global disease activity at month 12 compared with patients who have a DAS28 response, but no improvement in pain.

## SAT0080 EQUIVALENCE OF DIFFERENT VERSIONS OF THE HEALTH ASSESSMENT QUESTIONNAIRE (HAQ) ACROSS SOCIO-ECONOMIC FACTORS IN THE MULTI-NATIONAL QUEST-RA STUDY

M. Hifinger[1,2], S. Norton[3], S. Ramiro[4], P. Putrik[1,2], T. Sokka-Isler[5], A. Boonen[1,2]. *[1]MUMC; [2]Maastricht University, Maastricht, Netherlands; [3]King's College London, London, United Kingdom; [4]LUMC, Leiden, Netherlands; [5]Jyväskylä Central Hospital, Jyväskylä, Finland*

**Background:** Several studies reported socio-economic (SE) gradients in physical function as assessed by HAQ. It is however not known whether this reflects true differences in physical function among socio-economic groups, or whether differential interpretation of HAQ items across SE groups biases item responses.
**Objectives:** To investigate differential item functioning (DIF) across SE factors (age, gender, education and work status) when assessing physical function in RA patients across the different composite HAQ scores.
**Methods:** Data from the Questionnaires in Standard Monitoring of Patients with Rheumatoid Arthritis (QUEST-RA), comprising 8,891 patients from 30 countries (mean age 55 years, 81% females) were used. Physical function in daily activities

was assessed using a set of 30 individual items from the different HAQ versions (Stanford HAQ, HAQ-II, modified HAQ (MHAQ) and multi-dimensional HAQ (MDHAQ)). SE factors comprised age, gender, education (years), and work status (yes or no).

DIF was investigated using item response theory models implemented in a latent variable modelling framework, with models equivalent to ordinal logistic regressions having answers on each HAQ as outcome and SE factors as well as the latent trait function as predictors. Scores for 4 composite HAQs were recalculated and adjusted for DIF by methods similar as above, but simultaneous modelling all previously identified items exhibiting DIF. To assess the impact of DIF on associations between SE factors and composite HAQ scores, multilevel mixed effect linear regression models were estimated with individuals nested in country. Models were adjusted for SE factors, disease activity score in 28 joints (DAS28)) and a comorbidity index (Rheumatic diseases comorbidity index (RDCI)). Changes in the strength of association between SE-factors and HAQ or for DIF-adjusted HAQ were investigated by comparing β-coefficient of the SE factors in the models.

**Results:** Relevant DIF (defined as OR $>1.1$ or $<0.90$, ($\Delta \geq 10\%$)) in HAQ items was found for the SE factors age (n=13 items), gender (n=26 items) and work status (n=20 items), whereas education influenced only few items (n=7) (table) (table). Adjustment of composite HAQs for DIF resulted in an increase of HAQ scores, indicating influence of individual item DIF on the composite scores (table). In regression models all SE factors remained significantly related to all composite HAQ before or after adjusting for DIF. Changes in coefficients of regression models were overall negligible, except for gender (all HAQ versions). β-coefficients for gender increased by up to 0.07 (70% coefficient change), indicating several items have for women a different meaning, independent of their underlying level of functional limitation.

Table: Differential item functioning (DIF) of health assessment questionnaire across socio-economic factors

| | Health Assessment Questionnaire HAQ version | | | | DIF (Odds Ratio (OR), 95% CI) | | | |
|---|---|---|---|---|---|---|---|---|
| HAQ item, short description | HAQ | MHAQ | MDHAQ | HAQ-II | Age (per 10 years) | Education (standardized OR, SD=4.1 years) | Gender (reference: male) | Employment status (reference: not working) |

## SAT0081 THE DIAGNOSTIC AND PREDICTIVE VALUE OF ANTI-ACETYLATED PEPTIDE ANTIBODIES (AAPA) IN RHEUMATOID ARTHRITIS PATIENTS STARTING THEIR FIRST DMARD TREATMENT ON METHOTREXATE

P. Studenic[1], S. Blüml[1], H. Bang[2], M. Unger[1], K. Raza[3], D. Aletaha[1], J. Smolen[1], G. Steiner[1]. *[1]Rheumatology, Medical University Vienna, Vienna, Austria; [2]Orgentec Diagnostika, Mainz, Germany; [3]Centre for Translational Inflammation Research, University of Birmingham, Birmingham, United Kingdom*

**Background:** Anti-acetylated-peptide antibodies (AAPA) have recently been described in rheumatoid arthritis (RA) patients and may be used as a further diagnostic marker in patients with undifferentiated arthritis (1).

**Objectives:** To determine the prevalence of AAPA in a cohort of RA patients starting their first conventional synthetic DMARD treatment (csDMARD). In addition, we aimed to evaluate the usefulness of AAPA as potential predictors of clinical response to methotrexate (MTX) therapy.

**Methods:** We measured IgG and IgA AAPA by ELISA using two acetylated peptides derived from vimentin. We tested by regression, parametric and non-parametric analyses of disease activity measures if AAPA show potency for predicting response to MTX.

**Results:** Among 110 patients starting treatment on MTX, 74.5% were positive for IgG and/or IgA AAPA: 49% were positive for either IgA or IgG antibodies and 25.5% were IgA/IgG double positive. In comparison, 63.6% of the patients were positive for either RF or ACPA (measured by the CCP assay). In the AAPA positive patients; in total, 26.4% of the patients showed IgA antibodies and 73.6% were positive for IgG AAPA. Importantly, of the 36.4% of patients negative for both RF and ACPA (double negative), 55% were positive for IgG and/or IgA AAPA, and the remaining 45% (i.e. 16% of the total cohort) were completely seronegative (triple-negative; see table). When comparing triple negative patients with the AAPA positive double-negative ones, no significant difference in baseline characteristics was found but a trend that patients with more seroreactivities showed higher composite disease activity scores. Analyzing the clinical response to MTX, AAPA positive double-negative patients showed a significantly greater relative SDAI change after 6 months compared to triple-negative patients (p=0.028; median (IQR): -44.6% (-58.5 - -28.90) vs. 5.26% (-23.9 - 55.5%). In addition, there was a significantly greater relative change in CRP and erythrocyte sedimentation rate in AAPA positive double-negative patients.

In a backward regression model only RF could significantly be associated with the SDAI response, leading to + 30% relative change in SDAI (p=0.024). Status of ACPA and AAPA as potential predictors had to be excluded. Furthermore, RF positive patients showed larger relative changes in CRP, ESR, SDAI, CDAI and DAS after 6 months of MTX treatment

Table 1. Crosstable of status of RF, ACPA and anti-acetylated peptide antibodies (AAPA)

| | Anti-acetylated peptide antibodies | | | Total |
|---|---|---|---|---|
| | Negative | IgA or IgG positive | IgA and IgG positive | |
| Negative | 16.4% | 16.4% | 3.6% | 36.4% |
| RF | 3.6% | 3.6% | 2.7% | 10% |
| ACPA | .9% | 1.8% | 0.9% | 3.6% |
| RF+ACPA | 4.5% | 27.3% | 18.2% | 50% |
| Total | 25.5 | 49.1 | 25.4 | 100% |

**Conclusions:** AAPA commonly occur in RA patients and were, in fact, the most prevalent autoantibodies in our cohort. Measuring AAPA in addition to RF and ACPA reduced the prevalence of seronegative patients by more than 50%. These AAPA positive but RF and ACPA negative patients responded significantly better to MTX. Therefore, AAPA positivity in RF and ACPA negative patients identifies a subgroup of patients with a more favourable response to MTX.

## SAT0082 BIOLOGICAL THERAPY AND IMPROVEMENT OF DISEASE ACTIVITY IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS IN A SPECIALIZED CENTER

P. Santos-Moreno[1], L. Villarreal[2], G. Ballesteros[1], J. Bello[1], E. Castillo[1], R. Giraldo[1], D. Gomez[1], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Rheumatology; [2]Psychology; [3]Health services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Biological therapy is useful to prevent clinical and radiological progression in patients with rheumatoid arthritis (RA) when there is a failure with conventional DMARD therapy. Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA). On the other hand a multidisciplinary care team (MCT) model was generated in order to improve outcomes.

**Objectives:** The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 24-month period in patients with biological DMARD therapy in a large cohort of patients from a Colombian specialized in RA center with a MCT model.

**Methods:** A descriptive retrospective study was performed. Records of patients using biologics from specialized in RA center were reviewed; those patients were followed-up under T2T standards. Clinical follow-up was according to DAS28: every 3–5 weeks (DAS28 $>5.1$), every 7–9 weeks (DAS28 $\geq 3.1$ and $\leq 5.1$), and every 11–13 weeks (DAS28 $<3.1$). Therapy had to be adjusted with DAS28 $>3.2$ unless patient's conditions don't permit it. A MCT model means that a patient should be seen by other specialties such as physiatrist, physical and occupational therapy, nutritionist and psychologist at least 3 times a year. We divided patients in three groups: low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission (REM). Descriptive epidemiology was

done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson's statistics.
**Results:** 370 patients were included in this study, 310 (83%) women and 60 (17%) men. Average age was 59 ± 9 years. The biological therapy was distributed: Infliximab 57 (15%), Abatacept 53 (14%), Adalimumab 53 (14%), Etanercept 52 (14%), Rituximab 46 (12%), Tocilizumab 46 (12%), Certolizumab 41 (11%), Golimumab 19 (5%). At 24 months was observed an increase in percentage of patients (up to 71%) in REM/LDA and a decrease in percentage of patients in MDA/SDA disease activity statistically significant. At beginning mean DAS28 was 4.3 ± 1.23 and after 24 months of follow-up mean DAS28 was 3.02 ± 0.72; the median was analyzed using t-Student assuming normality for DAS28 distribution; it showed improvement ($p<0.00$).

| ACTIVITY LEVEL | TIME 0 n (%) | 6 MONTHS n (%) | 12 MONTHS n (%) | 24 MONTHS n (%) |
|---|---|---|---|---|
| REM | - | 72 (19) | 137 (37) | 145 (39) |
| LDA | 73 (19) | 85 (23) | 73 (20) | 118 (32) |
| MDA | 195 (53) | 178 (48) | 142 (38) | 103 (28) |
| SDA | 102 (28) | 95 (9) | 17 (5) | 4(1) |

**Conclusions:** There was a global improvement of DAS28 in a cohort of RA patients receiving biological therapy followed and treated under recommendations of T2T strategy and MCT model; this revision shows the importance of T2T follow-up and treatment for this disease.

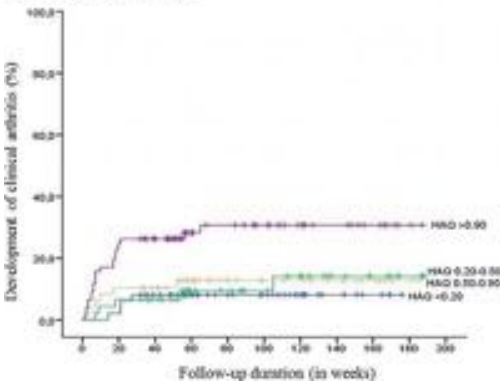
## SAT0083 ON THE RELATIONSHIP BETWEEN RHEUMATOID FACTORS, MONOCYTE SUBSETS AND FC RECEPTOR FUNCTION IN EARLY RA

P. Matt, U. Lindqvist, S. Kleinau. *Department of Medical Sciences, Rheumatology, Inst. Med. Sci., Uppsala University, Uppsala, Sweden*



**Background:** Immunoglobulins (Ig) and immune complexes (ICs) intervening with complement and Fc receptors (FcR) are important for the pathogenesis of rheumatoid arthritis (RA). Thus, B-cells are interesting targets for controlling chronic inflammation and autoantibody production (rheumatoid factors (RF) and ACPAs), especially in seropositive disease. In inflamed RA joints, accumulated FcR bearing monocytes/macrophages contribute to inflammation by cytokine release and antigen presentation. These cells consist of subpopulations with different features and may be defined by the composition of specific membrane receptors. However, the association between RA-specific antibodies and monocyte function in early RA is poorly studied.
**Objectives:** We have previously reported on altered monocyte FcR expressions, FcγR function and IgG load in an early RA cohort which reflected joint disease activity (ref). Here we were interested in evaluating the systemic B-cell activity in the same patients and related these findings to monocyte subpopulations, the FcγR function and to treatment response.
**Methods:** The sera of 20 early DMARD- and steroid naïve RA patients and 33 matched HCs were analyzed for Ig isotypes, IgG subclasses, the IgM, IgG and IgA RF isotypes and ACPA-IgG with standardized methods or with ELISA kits. Correlations of the Ig measurements with available data on the patients' monocyte FcγR function (eq. IgG1/IgG3 IC binding and TNFα production after IgG1/IgG3 stimulation) and monocyte subpopulations (defined by CD14/CD16 expression) were performed. The patients were evaluated before and after 3 months of treatment with methotrexate (MTX) and prednisolone (PRED). At follow up the individual treatment effect was determined using the EULAR response criteria. The distribution and the amount of the 3 RF isotypes among the responder groups were determined.
**Results:** The RA patients presented higher levels of total IgG, the IgG1 and IgG3, and all tested RF isotypes than the HCs. These findings correlated negatively with the monocyte FcγR function; high levels of all 3 RF isotypes reflected low IgG1-IC binding capacity, and high IgA-RF titers were associated with low monocytic TNFα release after IgG1- and IgG3-IC stimulation. These findings did not apply to the ACPA-IgG titers. A general observation of higher pre-treatment levels of Igs and auto-antibodies in the non responders was made, these individuals also maintained high levels of IgG3 and IgM-RF at follow up. Interestingly, an increase in the classical monocyte subset was seen in the non responders compared to the HC. And these non responders also had fewer non classical monocytes compared with the good responders. A good treatment response was observed in those patients who initially presented with few concurrent RF isotypes and low titers thereof.
**Conclusions:** In early naïve seropositive RA elevated specific IgG subclasses and RFs reflect an immune state of decreased monocyte FcγR function. An altered distribution of the monocyte subpopulations can be observed which may reflect the patients' treatment response. A good response to a combined MTX/PRED therapy is more likely to be observed in those patients who present low systemic B-cell activity.

## SAT0084 EVALUATION OF FUNCTIONAL DISABILITY IN PATIENTS WITH CLINICALLY SUSPECT ARTHRALGIA

R.M. Ten Brinck[1], H.W. van Steenbergen[1], L. Mangnus[1], L.E. Burgers[1], M. Reijnierse[2], T.W.J. Huizinga[1], A.H.M. Van der Helm–van Mil[1]. *[1]Rheumatology; [2]Radiology, Leiden University Medical Centre, Leiden, Netherlands*

**Background:** A phase of arthralgia precedes the emergence of rheumatoid arthritis (RA). This phase is not yet well characterized. The presence of MRI-detected subclinical inflammation has been identified in this phase and is correlated with RA development. However, it is unknown if patients with arthralgia at risk for RA (with and without subclinical inflammation) have functional limitations.
**Objectives:** This study assessed functional disability in patients with clinically suspect arthralgia (CSA) and the associations with MRI-detected inflammation and progression to clinical arthritis.
**Methods:** Between April 2012 and April 2015 patients were included in the CSA cohort. Patients with CSA were defined as having no clinical arthritis, with symptoms of hands or feet for <1 year and were considered to be at risk for RA by their rheumatologists based on their clinical presentation. At baseline, functional disability was assessed using HAQ scores and unilateral 1.5 T extremity MRIs of wrist, MCP and MTP joints were made. MRIs were scored on synovitis, tenosynovitis and bone marrow edema (BME) by two independent readers. The sum of these features yielded the total MRI-inflammation score. Pearson correlation coefficients, linear regression models, paired t-tests and Cox proportional hazards regression analyses were used.
**Results:** Of the 255 patients included, 77% were female and the mean age was 44.2 years. Median HAQ score was 0.50 at baseline and median duration of follow-up was 61 weeks. In univariable linear regression, a higher total inflammation score was significantly associated with a higher HAQ score (β=0.01, p=0.019). Of the individual types of inflammation, tenosynovitis showed the strongest correlation (β=0.04, p=0.003). When evaluating subclinical inflammation at specific hand joints in relation to HAQ-questions measuring hand function, significant correlations were observed. For instance, difficulties with opening previously opened jars was associated with MRI-inflammation score at the wrists (Pearson r=0.18, p=0.011). Patients that progressed to clinical arthritis had higher HAQ scores at presentation, than CSA-patients that did not progress (median HAQ scores 0.90 and 0.50 respectively). HAQ scores above 0.90 in particular were associated with arthritis development (HR=2.62, 95% CI: 1.06–6.47, p=0.036) as shown in the Kaplan-Meier plot (figure 1). An analysis of the patients that did develop arthritis revealed that median HAQ-scores were the same both at initial presentation with CSA and at conversion to clinical arthritis (median HAQ scores 0.90 and 0.68 respectively, paired t-test p-value = 0.751).

Figure 1. Kaplan -Meier One Minus Survival plot showing cumulative progression to clinical arthritis for CSA patients divided in four groups based on their baseline HAQ score.

**Conclusions:** CSA-patients already have functional limitations. The severity of functional disability is associated with the severity of local subclinical inflammation. CSA-patients that progressed to clinical arthritis had high HAQ scores at baseline and these HAQ scores did not increase when arthritis became clinically evident.

## SAT0085 DO SPECIFIC ACPAS OR OTHER AUTOANTIBODIES MEASURED BY A NOVEL ASSAY PREDICT RESPONSE TO METHOTREXATE MONOTHERAPY IN PATIENTS WITH EARLY DMARD-NAÏVE RA?

S. Saevarsdottir[1], L. Klareskog[1], M. Hansson[1], J. Eriksson[1], M. Johannesson[1], R. Holmdahl[1], K. Skriner[2], G. Serre[3], L. Mathsson-Alm[4], R.F. van Vollenhoven[1], D. van der Woude[5], R. Allaart[5], L. Alfredsson[1], I. McInnes[6], J. Rönnelid[1], J. Askling[1] on behalf of the BeTheCure Consortium. *[1]Karolinska Institutet, Stockholm, Sweden; [2]Charite University Medicine, Berlin, Germany; [3]Université de Toulouse, Toulouse, France; [4]Thermofisher, Uppsala, Sweden; [5]Leiden University Medical Center, Leiden, Netherlands; [6]University of Glasgow, Glasgow, United Kingdom*

**Background:** Antibodies against citrullinated peptide antigens (ACPAs) strongly predict the risk of developing RA. ACPA also seem to predict a more severe RA phenotype.
**Objectives:** Little is, however, known about the predictive value of specific ACPAs, or other autoantibodies (AAbs), in terms of response to methotrexate treatment.
**Methods:** A total of 20 AAbs were measured by a custom-made microarray assay based on the ImmunoCAP ISAC system (*Phadia AB, Uppsala, Sweden*), in baseline samples from patients participating in two randomized controlled trials (RCTs): Swefot, n=340; Improved, n=450). Validation was performed in two large inception cohorts (EIRA linked to the SRQ register, n=1481; Glasgow, n=384). All patients started methotrexate in monotherapy as their first DMARD. Response to methotrexate was defined as EULAR response at first follow-up visit (3–6 months). The likelihood of EULAR good or moderate (vs. no) response was calculated by logistic regression adjusted for potential confounders, and the proportion of patients positive for each AAb is provided (adj. OR, 95%CI; *% positive*).
**Results:** For the RCTs, 5 out of 20 AAbs were significantly associated with response in Improved, and 1 out of 17 in Swefot (fewer peptides on an earlier version of ISAC). *Fib36_52_cit* (citrullinated fibrinogen) was significantly associated with good/moderate response in both RCTs (Improved: adj.OR=2.27 (1.19–4.31), *32% positive*; Swefot: adj.OR=1.87 (1.06–3.29), *44% positive*). *Fib591_cit* (also citrullinated fibrinogen) was associated with good/moderate response in Improved (adj.OR=3.70 (1.27–10.76), *15% positive*) and a non-significant trend was observed in Swefot (adj.OR=1.65 (0.89–3.06), *30% positive*). *Vim60_75_cit* (citrullinated vimentin) was associated with response in Improved (adj.OR=1.85 (1.06–3.21), *46% positive*) but not in Swefot (adj.OR=1.06, *63% positive*). For *CEP_1*, a borderline significant association was observed in Improved (adj.OR=1.70 (0.96–3.00), *40% positive*) but not in Swefot (adj.OR=0.90, *51% positive*). Further, AAbs against citrullinated peptides named pept_Z2 and pept_5 were associated with response in Improved (adj.OR=1.81 (1.02–3.23), *41% positive*; and 2.25 (1.27–4.01), *44% positive*, respectively), while no association was observed in Swefot (adj.OR=0.98 and 1.17). Interestingly, none of the above associations were replicated in the inception cohorts (EIRA-SRQ, Glasgow), nor did we observe any trend for a dose-response association with response for the total number of positive AAbs.
**Conclusions:** Whilst two AAbs against citrullinated fibrinogen predict response to methotrexate in both early RA RCTs, neither these nor any other of the AAbs tested predicted response in the real-life population-based inception cohort setting. The reasons for the discrepant results are not yet clear, but our results highlight the importance of testing in multiple study populations and settings when identifying predictors to be used for clinical prediction.

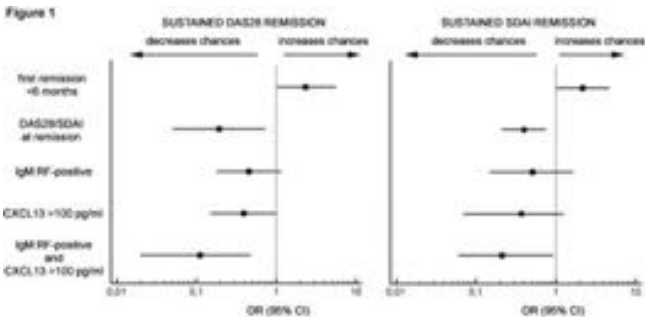
## SAT0086 THE SHORT-TERM AND LONG-TERM OF HUMERAL IMMUNE RESPONSES TO HEPATITIS B VACCINATION ARE IMPAIRED IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING CONVENTIONAL AND BIOLOGICAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS



S. Intongkam, M. Muthanugulwong, R. Pakchotanon, P. Narongroeknawin, P. Asavanabodee, S. Chaiamnuay. *Medicine, Phramongkutklao Hospital, Bangkok, Thailand*

**Background:** Hepatitis B vaccination is recommended for rheumatoid arthritis (RA) patients in many international guideline. However, the short-term and long-term efficacies of hepatitis B vaccination in RA patients that recieved conventional and/or biological disease-modifying anti-rheumatic drugs (cDMARDs and/or bDMARDs) are not clearly established.
**Objectives:** To assess the long term of immunogenicity of the hepatitis B vaccination in rheumatoid arthritis (RA) patients receiving cDMARDs and/or bDMARDs.
**Methods:** The study comprised 45 patients with RA, of whom 33 received cDMARDs and 12 received bDMARDs therapy (study group), and 9 subjects with age- and sex-matched healthy controls (control group). All subjects were vaccinated with 20 $\mu$g of recombinant hepatitis B vaccine (Euvax B®) at weeks 0, 4, and 24. Blood samples were collected 8 weeks and 12 months after receipt of the third vaccine dose to test for antibody to hepatitis B surface antigen (anti-HBs). Responders (seroprotection) were defined as anti-HBs level $\geq$10 mIU/mL. The study was approved by the ethic committee and institutional review board.
**Results:** Baseline characteristics of study and control groups were similar. Patients receiving cDMARDs tended to has lower proportion of seroprotection than control group (69.7% vs 100%, p=0.09) at 2 months and (57.57% vs 100%, p=0.016) 12 months after receipt of the third vaccine dose. Patients receiving bDMARDs had a significantly lower proportion of seroprotection compared with control group (50% vs 100%, p=0.02) at both 8 weeks and 12 months after receipt of the third vaccine dose. The proportion of seroprotection is significantly decreased between 2 months and 12 months in patients receiving cDMARDs (69.7% vs 57.57%, p=0.044) after completion of the third dose vaccine.
**Conclusions:** DMARDs both conventional and biological DMARDs therapy impaired short-term and long-term immunogenic response to hepatitis B vaccine.
**Disclosure of Interest:** None declared

## SAT0087 SERUM LEVELS OF CXCL13 REFINE THE PREDICTIVE ABILITY OF AUTOANTIBODIES TO IDENTIFY UNSTABLE REMISSION IN EARLY RHEUMATOID ARTHRITIS

S. Bugatti, A. Manzo, B. Vitolo, F. Benaglio, R. Caporali, C. Montecucco. *Division of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy*

**Background:** Early achievement and maintenance of disease remission improve long-term outcomes in patients with rheumatoid arthritis (RA), and eventually allow therapeutic withdrawal. Better knowledge of the prevalence and prognostic factors for sustained remission might improve patient care according to their individual profile. RA-specific autoantibodies are associated with a less favorable disease course, but their impact on the achievement and sustainability of remission upon treatment in early RA remains controversial.
**Objectives:** To evaluate whether additional B cell-related markers, such as serum levels of the B-cell chemoattractant CXCL13, predict different remission outcomes in patients with early RA.
**Methods:** We evaluated 205 RA patients from the Pavia early arthritis inception cohort not in remission at baseline with at least 2 years of follow-up, for whom baseline serum was available. Patients had arthritis of short duration ($<$12 months) and were treatment-naïve at presentation. After diagnosis, patients were initiated a treat-to-target regimen with methotrexate aiming at low disease activity and were seen at 2-months intervals for the first six months and then trimestrally. Levels of rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA) and CXCL13 were determined on baseline sera. Point remission was defined as the achievement of DAS28 remission ($<$2.6) or SDAI remission ($\leq$3.3) at any time within the first 12 months. Mean DAS28 $<$2.6 and mean SDAI $\leq$3.3 in the 3 visits following first remission (7–9 months) were regarded as sustained remission.
**Results:** 95/205 (46.3%) patients achieved point DAS28 remission and 69/205 (33.7%) point SDAI remission, with a median (IQR) time to remission of 6 (2–9) and 6 (4–9) months respectively. Male gender, younger age, a lower TJC28, better functional status, absence of radiographic erosions and use of prednisone were independent predictors of point remission. No significant effects of the autoantibody status and CXCL13 levels, alone or in combination, were seen. Irrespective of the remission criterion, more than half of the patients lost remission at follow-up (54.7% for DAS28, 62.3% for SDAI). Shorter time to remission and deeper remission were independent predictors of sustained remission (Figure 1). The ACPA status did not significantly impact the chance of sustaining remission. In contrast, both DAS28 and SDAI remission showed a trend to be less frequently maintained in RF-positive patients and in patients with baseline serum levels of CXCL13 $>$100 pg/ml (Figure 1). The combination of RF-positivity and high CXCL13 independently predicted failure to sustain remission with an adjusted OR (95% CI) of 8.49 (1.95 to 36.91) for DAS28 and 4.61 (1.01 to 24.67) for SDAI (Figure 1).

**Conclusions:** Disease remission is unfrequently maintained in early RA patients despite steered treatment strategies. B-cell autoimmunity does not significantly impact the chance of ever achieving remission. However, RF-positivity in combination with high CXCL13 identify a subgroup of patients at particularly high risk of losing remission in the short-term, irrespective of how early and how stringent remission is achieved.

SAT0088 **ANTI-JAK IS ANTI-FIBROTIC IN PATIENTS WITH RHEUMATOID ARTHRITIS**

S. Hirata[1,2], N.S. Gudmann[3], S. Kubo[1], M. Karsdal[3], A.C. Bay-Jensen[3], Y. Tanaka[1]. *[1]The First Department of Internal Medicine; [2]Department of Laboratory and Transfusion Medicine, University Hospital, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan; [3]Nordic Bioscience A/S, Herlev, Denmark*

**Objectives:** To quantify connective tissue turnover from type III collagen in response to 4 different types of intervention in rheumatoid arthritis (RA); methotrexate (MTX) combined with or without either tocilizumab (TCZ), tofacitinib (TOFA) or adalimumab (ADA) in RA.
**Methods:** 149 RA patients were treated with 1) MTX; 23, 2) ADA+MTX; 49, 3) TOFA+MTX; 27 or 4) TCZ+MTX; 50. Four specific neo-epitopes biomarkers were measured in the serum samples; C3M and PRO-C3 markers of type III collagen degradation and formation respectively.
**Results:** Tissue destruction measured by C3M increased in RA patients and was significantly correlated with total sharp score (SHS) as well as disease activity (DAS28) at baseline even after adjustment for covariates (rho=0.20, 0.33, p=0.018, <0.0001, respectively). PRO-C3 was also increased and the levels correlated with both SHS, and DAS28 (rho=0.22, 0.43, p=0.0067, <0.0001, respectively). Tissue destruction measured by C3M was reversed to healthy levels in all treatment after the treatment with MTX, ADA+MTX, TOFA+MTX or TCZ+MTX. However, JAK inhibition resulted in a decrease of PRO-C3, a sign of fibrogenesis, whereas MTX increased PRO-C3 in RA. (Figure)

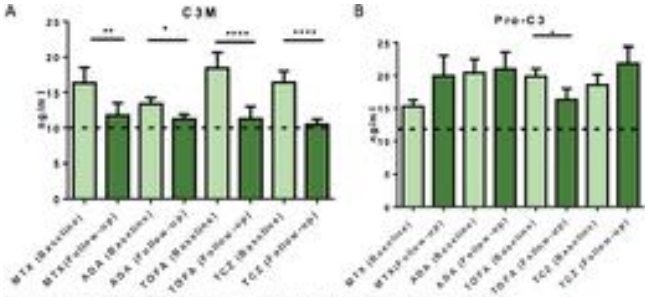

Figure: Evaluations of biomarker levels at baseline and follow-up: A) Type III collagen degradation evaluated by C3M. B) Type III collagen formation evaluated by PRO-C3. Difference between baseline and Follow-up was evaluated by mean of Wilcoxon match pairs signed rank test. The dashed line represents a reference level of healthy controls as provided by the manufacturer. *p≤0.05, ** p≤0.01, ***p≤0.001, ****p≤0.0001. Error bars are illustrated as SEM.

**Conclusions:** Interstitial tissue remodeling was increased in RA as compared to healthy controls. All four different intervention inhibited inflammation-driven tissue destruction to the same level, whereas only TOFA blocked fibrogenesis in RA patients, indicating that JAK inhibition could attenuate tissue fibrosis.

SAT0089 **ANXIETY AND DEPRESSION AMONG RHEUMATOID ARTHRITIS PATIENTS, AND ASSOCIATION WITH CLINICAL MEASUREMENTS AND PATIENT REPORTED DISABILITY AND TREATMENT SATISFACTION**

S. Peterson[1,2], N. Li[1,2], S. Blackburn[3], D. Kielar[2]. *[1]Janssen Immunology Global Commercial Strategy Organization, Horsham, PA; [2]Janssen Research & Development, LLC, Spring House, PA, United States; [3]Adelphi Real World, Bollington, United Kingdom*

**Background:** Rheumatoid arthritis (RA) has a substantial negative impact on patients' (pts) lives and is marked by pain and reduced mobility. In addition to RA articular manifestations, RA is often associated with important extra-articular manifestations, including anxiety and depression.[1]
**Objectives:** To describe pt self-reporting of anxiety and depression in pts with RA and to better characterize the association of anxiety/depression with disease activity, disability, and satisfaction with current treatment.
**Methods:** Descriptive analyses and multivariate linear and logistic regression analyses were performed using mood disorder data from the EU5 and US Adelphi RA Disease Specific Program. Presence of anxiety and depression was reported by pts that completed the EQ-5D anxiety/depression domain in the Patient Self Completion form. Multivariate models were run, controlling for pt age, gender, body mass index, and current disease severity, for each of the following measures: WPAI, HAQ-DI, DAS28 (ESR), and pt satisfaction with current treatment. WPAI, HAQ-DI, and DAS28 (ESR) data were evaluated using linear models, and pt-reported satisfaction were evaluated using logistic regression models.
**Results:** For the sample of pts included in the analysis (n=1,015), 38.4% of pts reported moderate or extreme anxiety/depression as their current health state. Pts with self-reported moderate (n=349) or extreme (n=41) anxiety/depression had greater work impairment, higher scores on the HAQ-DI, higher scores on the DAS28 (ESR), and a higher likelihood of being dissatisfied with their current treatment than those without stated depressed mood or anxiety. (n=625; Table). In multivariate analyses, significant differences were observed between the presence of pt-reported moderate anxiety/depression and higher WPAI scores ($P<0.001$), higher HAQ-DI scores ($P<0.001$), and lower pt-reported satisfaction with current treatment ($P<0.001$); significant differences were also observed between the presence of pt-reported extreme anxiety/depression and poorer results on the DAS28 (ESR) ($P=0.004$), HAQ-DI ($P<0.001$), and pt-reported satisfaction with current treatment ($P=0.001$), all compared to pts without anxiety or depression.

Table 1. Disease activity, disability, and treatment satisfaction in pts by self-reported anxiety and depression and severity

| Measure | No reported anxiety/depression (n=625) | Moderate anxiety/depression (n=349) | Extreme anxiety/depression (n=41) |
|---|---|---|---|
| Mean (SD) percent overall work impairment[a] | 18.3 (21.7) | 37.6 (26.4) | 36.4 (28.4) |
| Mean (SD) HAQ-DI score[a] | 0.6 (0.6) | 1.1 (0.7) | 1.5 (0.8) |
| Mean (SD) DAS28 (ESR)[a] | 3.4 (1.3) | 3.8 (1.5) | 4.8 (1.5) |
| Proportion dissatisfied with current treatment, % (n/n)[a] | 16.6 (96/579) | 36.0 (113/314) | 56.4 (22/39) |

[a] *P*-value for global test <0.0001.

**Conclusions:** Anxiety and depression represent a significant burden for pts with RA. In this analysis, pt-reported mood disorders were independently associated with work impairment, disability, pt satisfaction with current treatment, and clinical disease activity. These findings highlight the multi-dimensional impact of anxiety and depression as a key extra-articular manifestation of RA. Further research on optimal management of this key unmet medical need is warranted.

SAT0090 **THREE OUT OF EVERY FOUR PATIENTS WITH DMARD-NAIVE EARLY RHEUMATOID ARTHRITIS MEET DAS28 REMISSION AT 12 MONTHS IN FINLAND**

T. Rannio[1], J. Asikainen[1], P. Hannonen[1], T. Yli-Kerttula[2], P. Ekman[2], L. Pirilä[3], L. Kuusalo[3], M. Mali[3], M. Puurtinen-Vilkki[3], S. Kortelainen[3], J. Paltta[3], K. Taimen[3], M. Kauppi[4], K. Laiho[4], S. Nyrhinen[4], H. Mäkinen[5], P. Isomäki[5], T. Uotila[5], K. Aaltonen[6], H. Kautiainen[6], T. Sokka[7]. *[1]Rheumatology, Central Hospital of Central Finland, Jyväskylä; [2]Rheumatology, Central Hospital of Rauma, Rauma; [3]Rheumatology, Turku University Hospital, Turku; [4]Rheumatology, Päijät-Häme Central Hospital, Lahti; [5]Rheumatology, Tampere University Hospital, Tampere; [6]University of Helsinki, Helsinki; [7]Faculty of Health Sciences, University of Eastern Finland, Kuopio, Finland*

**Background:** Finnish national combination treatment trials [1,2] have demonstrated excellent outcomes in patients with early rheumatoid arthritis (RA)

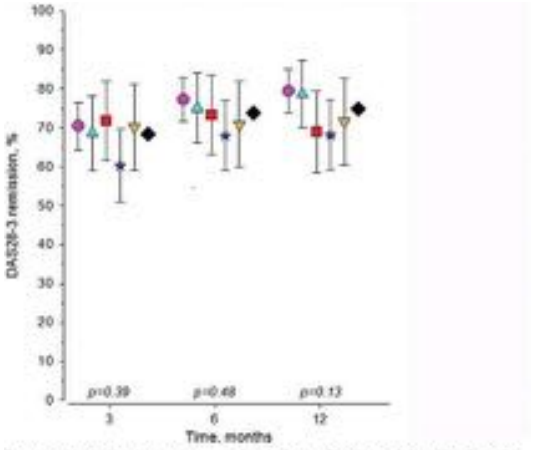

Figure 1. Remission proportions at 3, 6 and 12 months visits at 5 FIN-ERA clinics by DAS28-3 remission criteria.
*Values are percentage of RA patients with 95% CIs. Pink ball = Site A; Blue star = Site B; Turquoise triangle = Site C; Orange triangle = Site D; Red square = Site E. Black diamond = Entire cohort.

including 90% of patients reaching 28-joint Disease Activity Score (DAS28) remission. Whether similar results are reached in clinical praxis is not known.
**Objectives:** To assess what proportion of patients with dmard-naïve early rheumatoid artritis (RA) reach DAS28 remission over one year and remission variability across clinics in Finland
**Methods:** Patients with dmard-naïve inflammatory arthritis diagnosed as new early RA were recruited. Comparison among sites were made in proportion of patients in 28-joint Disease Activity Score with 3 variables (DAS28–3) remission. Repeated measures were analyzed using mixed models approach with appropriate distribution and link function.
**Results:** 611 patients were recruited at 5 sites: 67% female; the mean age (SD) at diagnosis was 57 (16) years; respective 71% and 68% were RF and AntiCCP positive; 23% had radiographic erosions. A total of 506 (83%) fulfilled the ACR/EULAR 2010 classification criteria for RA for further analyses. DAS28–3 remission was met by 68% and 75% at 3 and 12 mo, respectively. Clinic had no effect in remission when adjusted for confounders (Figure 1). At baseline, a total of 68% used MTX based combination therapy, and 31% used triple therapy with methotrexate, hydroxychloroquine and sulphasalazine. In multivariate analysis, the only independent predictors of DAS28–3 remission at 12 mo were lower baseline DAS28–3 (odds ratio 0.6, 95% confidence interval 0.4–0.7, $P<0.001$) and triple therapy as the initial treatment (odds ratio 1.8, 95% confidence interval 1.0–3.3, $P=0.048$).
**Conclusions:** Three out of every four dmard-naïve early RA patients are in remission in Finland after 1 year of diagnosis. High remission rates were achieved with use of csDMARDs in combinations for majority of patients. Treatment with triple therapy is a predictor of DAS28–3 remission also in real-life rheumatology settings.

## SAT0091 MAJOR CLINICAL CHARACTERISTICS OF CHINESE RHEUMATOID ARTHRITIS (RA) PATIENTS WITH SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) UNDER TREAT-TO-TARGET (T2T) RECOMMENDATIONS

X. Liu[1], F. Xiao[2], J. Yang[3], R. Mu[4], H. Wang[5], H. Wei[6], X. Xin[7], Y. Zhu[8], Y. Zhang[3], Y. Jia[2], L. Zhang[2], Y. Liu[2], M. Wang[2], X. Li[9]. *[1]Department of Rheumatology and Immunology, The Third Affiliated Hospital of Peking University, Beijing; [2]Medical Department, Shanghai Gothic Internet Technology Co., Ltd., Shanghai; [3]Central Hospital of MianYang, Mianyang; [4]People's Hospital, Beijing University Medical School, Beijing; [5]JiaXing First Hospital, JiaXing; [6]Department of Rheumatology, Northern Jiangsu People's Hospital, Yangzhou; [7]Ningbo First Hospital, Ningbo; [8]Weifang People's Hospital, weifang; [9]Department of Rheumatology and Immunology, The Second Affiliated Hospital of Shanxi Medical College, Taiyuan, China*

**Background:** Treat-to-target (T2T) is a widely accepted management strategy for rheumatoid arthritis (RA) to achieve defined outcomes (remission or low disease activity). Moreover, mobile applications of patient-centered care created by multidisciplinary teams have been used for disease management in rheumatology. Smart System of Disease Management (SSDM) is a series of applications system for chronic diseases management.
**Objectives:** To describe major clinical characteristics of Chinese RA patients using SSDM under T2T recommendation in real world.
**Methods:** The SSDM includes doctors' application system and patients' application system. The patient application system includes self-assessment (DAS28, HAQ), medication management, adverse events management and laboratory records. After data entry, patients can synchronize data to the authorized doctor. The data were collected online from 173 rheumatology centers that cover 27 provinces in China. All patients fulfilling the 1987 ACR (formerly the American Rheumatism Association) criteria for RA were recruited. The median of each variable was analyzed using t-test assuming normality for DAS28 distribution and the level disease activity was analyzed using Pearson's statistics.
**Results:** Since December 14th, 2014 to January 25th, 2016, 2,585 patients, 1,854 (71.7%) women and 731 (28.3%) men, participated in this study. Average age was 49.4 ±12.86 (15–90) years with mean disease duration of 8.9 years. The mean DAS28 scores was 4.03±1.54 (0.62–8.84) and the mean HAQ scores was 2.80±4.33 (0–24). At the Baseline, 19.5% of patients got remission, 12.9% low disease activity (LDA), 43.5% moderate disease activity (MDA) and 24.1% high disease activity (HDA). Clinical remission rate was negatively correlated with HAQ scores. For the entire cohort, the most commonly used treatment were conventional DMARDs (92.7%) include leflunomide (65.52%), hdroxychloroquine (48.52%), methotrexate (39.00%) and sulfasalazine (5.77%).
**Conclusions:** SSDM has provided demographic and clinical data of Chinese RA patients in real world practice. Clinical data and biologic samples would be valuable resources for future national and international studies.
**Disclosure of Interest:** None declared

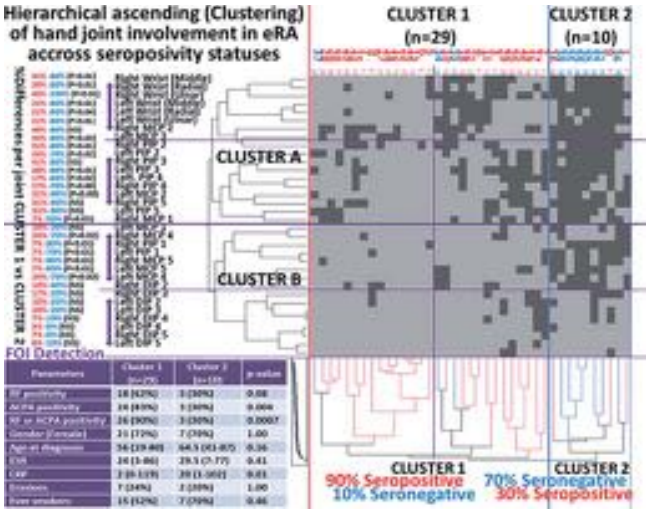
## SAT0092 PREVALENCE OF SUBCLINICAL INFLAMMATION IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAVE LOW DISEASE ACTIVITY

Y.-C. Chen, J.-F. Chen, T.-T. Cheng. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

**Background:** Studies using ultrasound (US) showed that a significant proportion of patients thought to be in clinical remission actually exhibited different grades of synovitis, and a subgroup of these patients suffered from flares and/or joint damage during follow-up[1].
**Objectives:** Evaluate joint inflammation by ultrasound in patients with different stages of rheumatoid arthritis as the primary endpoint measure.
**Methods:** Gray scale and power Doppler ultrasound were performed on the dorsal radio-scaphoid, dorsal radio-lunae, ulnar-triquetrium, and palmar radio-lunate joints of both wrists. The presence of synovitis, comorbidities, and use of disease modifying anti-rheumatic drugs were recorded. Patient with a bilateral wrist score sum (GSUS + PDUS) equal or greater than 4 was considered to have sonographic inflammation. A logistical regression model was used to identify factors associated with inflammation.
**Results:** There were 1248 patients (1010 females, 238 males; mean age: 59.61 ± 12.19 years). Synovitis was most common at the dorsal radio-lunate joint. Patients with high disease activity (DAS28 $>5.1$) had more sonographic inflammation than those with moderate or low disease activity. Most patients (57.4%) in complete remission (DAS28 $<2.6$) had subclinical synovitis (Table). Logistical regression analysis indicated that male sex, smoking, and liver disease are positively associated with inflammation and that advanced age, alcohol consumption, hypertension, gastrointestinal disease, and use of MTX, glucocorticoid, or a biological therapy are negatively associated with inflammation. Use of biological agents decreased the risk of inflammation by 40.9%.

Table 1

| DAS28 | 0 | 1 | 2 | 3 | ≧4 | Total |
|---|---|---|---|---|---|---|
| Complete remission, n (%) | 2 (1%) | 12 (5.9%) | 28 (13.9%) | 44 (21.8%) | 116 (57.4%) | 202 (100%) |
| Low disease activity, n (%) | 2 (0.9%) | 14 (6.5%) | 20 (9.3%) | 42 (19.6%) | 136 (63.5%) | 214 (100%) |
| Moderate disease activity, n (%) | 4 (0.6%) | 20 (3.1%) | 75 (11.5%) | 123 (18.8%) | 431 (66%) | 653 (100%) |
| High disease activity, n (%) | 10 (5.6%) | 8 (4.5%) | 20 (11.2%) | 21 (11.7%) | 120 (67%) | 179 (100%) |
| Total, n (%) | 18 (1.4%) | 54 (4.3%) | 143 (11.5%) | 230 (18.48%) | 803 (64.3%) | 1248 (100%) |



**Conclusions:** There was sonographic evidence of synovitis in most patients who were in complete remission. Regular monitoring of rheumatoid arthritis patients with ultrasound and DAS28 may help prevent disease flare-ups and joint destruction.

## SAT0093 HAND JOINT INFLAMMATION ON FLUORESCENCE OPTICAL IMAGING REVEAL DISTINCT PATTERNS IN SEROPOSITIVE AND SERONEGATIVE EARLY RHEUMATOID ARTHRITIS

Y. Kisten[1], E. af Klint[1,2], A. Levitsky[1], H. Rezaei[1,2], N. Györi[1], A. Karlsson[2], R. van Vollenhoven[1,3], L. Arnaud[1]. *[1]Department of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Karolinska Institute; [2]The Rheumatology Unit and Clinic, Karolinska University Hospital, Stockholm, Sweden; [3]Departments AMC, READE and VUmc, Amsterdam Rheumatology & Immunology Center (ARC), Amsterdam, Netherlands*

**Background:** Detection of abnormal Rheumatoid Arthritis (RA) related autoantibodies, Rheumatoid Factor (RF) and Anti-Citrullinated Peptide Antibody (ACPA), along with Musculoskeletal ultrasound (MSUS) play a critical role in the diagnosis of early RA (eRA). Fluorescence optical imaging (FOI) is an emerging modality designed for the hands and wrists that detects subclinical hand joint inflammation[1] and may therefore prove valuable in the assessment of eRA.
**Objectives:** Here, we analyzed the FOI results of eRA patients and investigate whether patterns of hand joint inflammation may distinguish seropositive from seronegative RA.
**Methods:** In FOI, Inflammation is considered positive, when altered microcirculation (capillary leakage/perfusion) is seen as abnormally increased focal optical signal intensities by visual inspection of the entire image series in real-time (360 seconds all 34 joints: 3 wrists, 5 MCPs, 5 PIPs and 4 DIPs, bilaterally are evaluated

using post-processing imaging techniques). Unsupervised ascending hierarchical clustering was used to identify clusters of patients with different patterns of joint involvement in FOI. The robustness of the clustering was verified using another clustering method (k-means), and agreement between the 2 methods was assessed using Cohen's kappa. Baseline clinical and biological characteristics of patients were compared between the clusters using non-parametric tests.
**Results:** Out of 1326 joints of 39 eRA patients (26 females; 9 with erosive RA; 54% RF+; and 69% ACPA+), 400 (30%) were considered positively inflamed by FOI. The mean (±SD) number of active joints detected by FOI was 10.3 ± 7.2. Clustering of joint involvement according to the FOI distinguished 2 separate clusters of patients: Cluster1 (n=29) and Cluster2 (n=10). The proportion of seropositive patients was significantly higher in cluster 1 versus cluster 2 (26/29 versus 3/10, $p<0.01$) (figure). The distribution of inflammation throughout the joints, except for right MCP2, PIPs 5, left MCP1 & DIPs in cluster 2 displayed distinguishable patterns ($p<0.05$) compared to cluster 1, which showed joint inflammation to be largely concentrated around wrists, right MCP2, bilateral MCP3, and to a lesser degree around PIPs 2–4, and left MCP2. The DIPs showed no significant differences between clusters.

**Conclusions:** Two separate patterns of inflammatory joint involvement may be distinguished in early RA, using fluorescence optical imaging. The proportion of seropositive patients was significantly different between these patterns, suggesting that FOI identifies patterns of joint involvement that are different for seropositive and seronegative RA.

## SAT0094 THE ASSOCIATION BETWEEN METHOTREXATE USE AND EFFECTS OF TREATMENT WITH A SECOND BIOLOGIC AGENT IN RHEUMATOID ARTHRITIS

Y. Ogawa, T. Kojima, N. Takahashi, K. Funahashi, N. Ishiguro. *Department of Orthopaedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** In general, the concomitant use of methotrexate (MTX) and biologic disease-modifying antirheumatic drugs (DMARDS) plays an important role in treatment for bio-naïve patients with rheumatoid arthritis (RA). However, it remains unclear whether concomitant use of MTX is related to the effects of treatment with second biologic DMARDS in RA patients for whom first biologic DMARDS therapy have failed.
**Objectives:** The objective of the current study was to determine whether, and if so to what extent, concomitant use of MTX was associated with the effects of treatment with second biologic DMARDS, especially in the context of whether or not tumor necrosis factor inhibitor (TNFi) had been used.
**Methods:** We used demographic and clinical data from the Tsurumai Biologics Communication Registry, which comprises Nagoya University and 20 affiliated hospitals in Japan. Patients aged 20–80 years who fulfilled the ACR 1987 revised classification criteria or the 2010 ACR/EULAR classification criteria for RA were selected; only those switching to second biologic DMARDS therapy were included. Multivariate logistic regression analysis was used to assess the association between MTX use and the possibility of sufficient response to second biologic DMARDS treatment, as defined by good response at week 16 in the EULAR response criteria, based on DAS28. Crude and adjusted odds ratios (ORs) and corresponding 95% confidence intervals (95% CIs) were calculated. Adjustment variables included sex, age, disease duration, whether or not TNFi had been used in RA treatments with first and second biologic DMARDS, use of MTX in first biologic treatment, and use of glucocorticoids in treatment with second biologic DMARDS. We determined the statistical significance of potential subgroup effect of whether or not TNFi had been used as second biologics by testing the significance of the interaction terms added to our multivariable models.
**Results:** The demographic and disease characteristics of the patients at baseline were comparable except for the proportion of TNFi between patients not using MTX (n=49) and those treated concomitantly with MTX (n=122). The mean age was 59 years; 86% were women. Patients had longstanding RA (mean 10.6 years), and the baseline DAS28 was 5.2. Among the patients, 68% received glucocorticoids. The mean dose of MTX was 8.0 mg/week in patients using MTX. The proportion of TNFi was 26.5% in patients not using MTX and 62.3% in those using MTX, respectively. A good response as per EULAR response criteria was identified in 14 (28.6%) patients not using MTX and 58 (47.5%) patients treated concomitantly with MTX. The crude OR for the association between concomitant use of MTX and the possibility of good response as per EULAR response criteria was 2.27 (95% CI 1.11–4.63) compared with nonuse of MTX. After adjustment for the aforementioned covariates, concomitant use of MTX was associated with an increased possibility of good response to biologic DMARDS compared with nonuse of MTX (OR 2.77, 95% CI 1.04–7.36). This multivariable adjusted effect estimate was not modified by whether or not TNFi had been used (P value for interaction greater than 0.05).

**Table 1.** Association between MTX use and the possibility of good response as per EULAR response criteria, as determined by binary logistic regression analysis*

| | Crude OR (95% CI) | Adjusted OR (95% CI)† |
|---|---|---|
| MTX not using | 1.00 (referent) | 1.00 (referent) |
| MTX using | 2.27 (1.11–4.63) | 2.77 (1.04–7.36) |

* OR = Odds ratio; 95% CI = 95% confidence interval. MTX = methotrexate
† Adjusted for sex, age, disease duration, whether or not tumor necrosis factor inhibitor had been used in treatments with first and second biologics, use of MTX in first biologic treatment, and use of glucocorticoids in treatment with second biologics.

**Conclusions:** This study demonstrated that concomitant use of MTX was independently associated with an increased possibility of good response to second biologic DMARDS regardless of whether or not TNFi had been used in RA treatment.

## SAT0095 LEUCINE-RICH ALPHA2-GLYCOPROTEIN IS A USEFUL BIOMARKER TO EVALUATE THE CLINICAL DISEASE ACTIVITIES OF RHEUMATOID ARTHRITIS UNDER TREATMENTS

Y. Hosono[1], M. Hashimoto[2], M. Fujimoto[3], S. Serada[3], M. Furu[2], H. Ito[2], C. Terao[4], W. Yamamoto[5,6], T. Fujii[2], T. Mimori[1], T. Naka[3]. *[1]Department of Rheumatology and Clinical Immunology; [2]Department of Control for Rheumatic Diseaseas, Graduate School of Medicine, Kyoto University, Kyoto; [3]Labolatory of Immune Signal, National Institute of Biomedical Innovation, Ibaraki; [4]Center for Genomic Medicine; [5]Department of Control for Rheumatic Diseaseas, Kyoto University Graduate School of Medicine, Kyoto; [6]Department of Health Information Management, Kurashiki Sweet Hospital, Kurashiki, Japan*

**Background:** Acute phase biomarkers such as erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) are usually used for the evaluation of the disease activity of rheumatoid arthritis (RA). However, these biomarkers are sometimes not useful in evaluating the disease activity of RA patients in daily clinical practice, because they often become within normal range after the initiation of treatments. Thus, new biomarker which reflects the disease activity of RA under the treatment is required. Leucine-rich-α2-glycoprotein (LRG) is a newly identified biomarker that reflects inflammation and is correlated with the 28-joint Disease Activity Score even in patients treated with IL-6 receptor antagonist.
**Objectives:** To assess whether serum LRG levels could be a biomarker to evaluate the disease activity of RA under treatments in daily clinical practice.
**Methods:** Serum LRG levels were measured by enzyme-linked immunoabsorbant assay in 370 consecutive RA patients who were under treatments in our facility in 2012. Disease activity was evaluated by Clinical Disease Activity Index (CDAI) that does not include ESR or CRP as components. Radiological joint destruction was evaluated by modified Total Sharp Score (mTSS). Multivaiate analysis of covariance (MANOVA) was used to assess the association between CDAI and LRG, ESR, CRP levels and the association between mTSS and LRG, ESR, CRP, disease duration, and anti-CCP antibody level.
**Results:** Among 370 patients, 71% were treated by methotrexate and 29% by biological DMARDs and average CDAI was 7.8±6.2 (low disease activity). After MANOVA analysis, LRG but not ESR or CRP showed the significant correlation with CDAI (LRG; effect size 0.034, p=0.0007, CRP; effect size 0.010, p=0.055, ESR; effect size 0.0053, p=0.18). LRG significantly correlated with the disease activities in RA patients, even when ESR or CRP levels were within normal range.

In addition, LRG showed the significant correlation with mTSS as well as disease duration and anti-CCP antibody level (LRG; effect size 0.019, p=0.017, disease duration; effect size 0.769, p<0.001, and anti-CCP antibody; effect size 0.036, p=0.0011), while ESR and CRP did not (ESR; effect size 0.0038, p=0.28, CRP; effect size 0.00073, p=0.64).
**Conclusions:** LRG is useful marker to evaluate the disease activity and to estimate the joint damage of RA patients under treatments in daily clinical practice independent of CRP and ESR levels.

## Rheumatoid arthritis - comorbidity and clinical aspects

### SAT0096 INDICATORS AND FREQUENCY OF HIP SYNOVITIS DETECTED BY ULTRASOUND IN RA

A.A. Negm[1], A.-S. Mohamed[1], A. Abonar[2], E. Abdulazim[1], S. AL Araby[1].
*[1]Rheumatology, Physical Medicine & Rehabilitation; [2]Clinical Pathology, Faculty of Medicine, Al-Azhar University, Cairo, Egypt*

**Background:** Large joints affection including the hip in RA has significant impact on patient's activity. Unfortunately, clinical detection of hip synovial hypertrophy and effusion is difficult, while Ultrasound is reliable and effective to compensate for such problem[1].
**Objectives:** Identify clinical and Laboratory characteristics associated with Ultrasonographic hip synovitis among RA Patients
**Methods:** We conducted an observational cohort study on 60 RA adult patients fulfilling the 1987 ACR classification Criteria for RA. Exclusion criteria include those with non- RA related Hip Arthritis (Degenerative, Traumatic, Metabolic and referred pain from the back). Grouping: Group I, 30 patients complaining of hip pain and Group II 30 without hip pain. All patients had full history and clinical examination including DAS28, SJC66, TJC68, Patient and Physician Global Assessment of disease activity (PTGA, PGA); and Lab includes ESR, CRP and RF. Ultrasound examination was done according to the standard EULAR guidelines.
**Results:** The following table shows the demographic, clinical and lab characteristics of both groups.

| | Group I | Group II | P-value |
|---|---|---|---|
| Female, n (%) | 22 (73) | 27 (90) | NS |
| Age, mean (SD), years | 32.7 (5.4) | 32.1 (5.9) | NS |
| RA Duration, (SD), years | 5.3 (3.1) | 4.8 (2) | NS |
| SJC 66, mean (SD) | 6.6 (2.5) | 5 (4.8) | NS |
| TJC 68, mean (SD) | 13.7 (4.9) | 10 (7.25) | 0.026 |
| VAS, mean (SD) | 6.6 (0.8) | 5.8 (1.1) | 0.003 |
| PTGA, mean (SD) | 7 (0.7) | 6.2 (1.2) | 0.001 |
| PGA, mean (SD) | 6 (0 .8) | 5 (1.2) | 0.002 |
| SJC 28, mean (SD) | 5.5 (2) | 3.3 (2.1) | <0.001 |
| TJC 28, mean (SD) | 10.5 (3.5) | 7 (3.5) | <0.001 |
| ESR, mean (SD) | 41.8 (13.6) | 35.4 (11.8) | NS |
| CRP, mean (SD) | 7.6 (5.9) | 5.2 (5.2) | NS |
| DAS 28, mean (SD) | 5 (0.65) | 4.2 (0.85) | <0.001 |

The initial intra-group analysis showed no statistically significant difference in all the measurable demographic, clinical and laboratory data between patients with Normal and Abnormal US. Except for duration of symptoms of hip pain in Group I (16.3±9.6 weeks in those with abnormal US vs 4.4±2.3 weeks in those with normal US Scan (P<0.001) by using point Biserial correlation. Regarding US, Synovial Hypertrophy/ effusion (Abnormal US) was found in 14 out of 30 patients (46.7%) in Group I and 10 out of 30 (33.33%) in group II with no significant difference (P=0.29).
Further whole group analysis showed that CRP was statistically significantly higher in patients with abnormal Hip US (24/60 patients) 8.25±5.25 mg/dl than those with normal Hip US (36/60 patients) 5.17±5.58 mg/dl (P=0.036). In addition, Knee effusion and synovial thickening detected by clinical examination was more frequent in patients with abnormal Hip US (than those with normal hip US, 41.7% vs 13.8% (P=0.015).
**Conclusions:** Hip joint is frequently affected in RA and searching for hip joint involvement should not be limited to those complaining of hip pain to exclude subclinical hip involvement.
Apart from CRP, duration of hip symptoms and knee affection, there was no significant correlation between abnormal US and demographics or laboratory data.

### SAT0097 EFFECTIVE CONTROL OF RHEUMATOID ARTHRITIS DISEASE ACTIVITY PREVENTS DEVELOPMENT OR ACCELERATION OF SUBCLINICAL ATHEROSCLEROSIS OVER 3 YEARS

A. Arida, A.D. Protogerou, G. Konstantonis, K. Fragkiadaki, G.D. Kitas, P.P. Sfikakis. *Rheumatology Unit, 1st Dept. of Propaedeutic Internal Medicine, Joint Academic Rheumatology Program, Athens University Medical School, Athens, Greece*

**Background:** Rheumatoid arthritis (RA) associates with increased cardiovascular disease (CVD) morbidity and mortality due to accelerated atherosclerosis, attributed to both classical risk factors and chronic inflammation.
**Objectives:** To examine whether effective inflammation control prevents development and/or modifies acceleration of subclinical atherosclerosis in RA.
**Methods:** Consecutive, non-diabetic RA patients (n=139), aged 61.3 (52.9–67.9) years, with RA duration 10 (5–17) years, followed-up at least every 4 months in our center and previously examined by ultrasonography for subclinical atherosclerosis, were prospectively re-evaluated after 3.2 (3.1–3.3) years. None had known CVD, malignancy, chronic renal failure, or other chronic or acute inflammatory disease at baseline. The only inclusion criterion in the prospective study was effective disease control during the follow-up period, determined arbitrarily as the presence of remission or of low disease activity (DAS28<3.2) for at least 75% of this period. Non-diabetic control individuals without CVD at baseline (n=251, aged 56.1 (44.9–56.1) years) were studied in parallel (median follow-up of 3.2 (3.1–3.3) years). Preclinical atherosclerosis was assessed as described in detail elsewhere [1,2].
**Results:** Formation of new atheromatic plaques in carotid and femoral arterial beds, reflecting atheromatosis, was evident in 22% of RA patients versus 28% of controls. Carotid intima-media thickness, reflecting arterial wall hypertrophy, increased per year by 0.010 (0.002–0.023) in RA versus 0.011 (0.002–0.023) in controls for the left common carotid artery and by 0.010 (0.002–0.023) in RA versus 0.011 (0.000–0.025) for the right common carotid artery. Pulse wave velocity, reflecting arterial stiffness, changed per year by 0.071 (-0.149- 0.275) in RA versus -0.015 (-0.247–0.184) in controls. Two of 139 patients versus 1 of 251 controls developed clinical CVD during follow-up. By multivariate analysis after correcting for age, gender, smoking, body mass index, hypertension, hyperlipidemia, as well as anti-hypertensive and lipid lowering therapies, no statistically significant differences for any of the evaluated markers of subclinical atherosclerosis were found between patients and controls.
**Conclusions:** Effective inflammation control seems to abrogate any RA-specific effect on the progression of atherosclerosis. Whether early and sustained disease control translates to the expected for the general population rates of cardiovascular morbidity and mortality in RA patients remains to be proven by large prospective cohort studies.

### SAT0098 RISK OF HOSPITALIZATION FOR SERIOUS BACTERIAL INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICS. ANALYSIS FROM THE RECORD STUDY OF THE ITALIAN SOCIETY FOR RHEUMATOLOGY

A. Bortoluzzi[1], G. Sakellariou[2], G. Carrara[3], M. Govoni[1], C.A. Scirè[3].
*[1]Department of Medical Science, Rheumatology Unit, University of Ferrara, Cona (Ferrara); [2]Division of Rheumatology, IRCCS San Matteo Foundation, Pavia; [3]Epidemiology Unit, Italian Society for Rheumatology, Milan, Italy*

**Background:** Biological disease modifying antirheumatic drugs (bDMARDs) are widely used in treating rheumatoid arthritis (RA). There are concerns regarding the risk of serious infections related to these treatments, and scarce information on the impact of co-treatments.
**Objectives:** To define the risk of serious infections in patients receiving bDMARDs, evaluating the effect of specific biologic agents and co-treatments in a large population-based sample of RA deriving from the administrative health database of the Lombardy region in Italy.
**Methods:** Data were extracted from health databases of the Lombardy Region in the period between 1/1/2004 and 31/12/2013. Patients with RA, identified through a rheumatologist certified diagnosis (exemption code 006.714.0) and treated with bDMARDs (abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab) were included. Hospitalizations for bacterial infections were evaluated by the hospital discharge forms in the period of exposure to each biologic drug with the following diagnosis ICD9CM: 049.* or 320.*, 054.3 or 323.*, 681.*682.*, 421.*, 481.*482.*, 590.*, 711.*, 730.0*730.2*, 038.* or 790.7. The association between biologic drugs exposure and hospitalization for bacterial infections was assessed by survival models for competing risks, with time-dependent covariates. Results were presented as hazard ratios (HR) and 95% confidence intervals (CI), crude and adjusted for pre-specified confounders

(sex, age, disease duration, Charlson comorbidity index, concomitant use of methotrexate, leflunomide, corticosteroids, NSAIDs, number of previous biologics and previous infections).

**Results:** 4656 RA patients who had at least one bDMARD prescription for a total of 7601 exposures were included. 3603 were women (77.4%) with a mean age at first bDMARD exposure of 55.7 years (12.7 ± SD) and with a modal disease duration over 5 years. The factors associated with hospitalization with a definite bacterial infection are shown in figure. Considering etanercept as reference, the adjusted HR for infection was equal to 0.29 (95% IC 0.10 - 0.82) for abatacept, while it was not significantly different compared to other bDMARDs.

**Conclusions:** Treatment with bDMARDs was not associated with an increase in hospitalized infection. The risk was lower with abatacept that confirmed to have a better safety profile.

**Disclosure of Interest:** None declared

## SAT0099 ADVOCATING FOR RHEUMATOID ARTHRITIS AND CARDIOVASCULAR HEALTH (ARCH): A SYSTEMS-BASED SCREENING INITIATIVE IN A US TERTIARY REFERRAL CENTER

B. Goldstein[1], D. Kim[2], P. Zelarney[3], S. Meadows[4], M. Stern[4], C. Egidio[4].
*[1]Rheumatology; [2]Cardiology; [3]Biostatistics; [4]Medicine, National Jewish Health, Denver, United States*

**Background:** Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular disease (CVD) as compared to the general population. Furthermore, RA patients have a comparable increased risk of CVD to that of diabetics and yet are not screened as well. The European League Against Rheumatism (EULAR) recommends that rheumatologists engage in assessing the CVD risks in RA patients, but there are currently no specific recommendations from the American College of Rheumatology (ACR). Multiple barriers such as limited time and lack of familiarity of CVD screening guidelines challenge the feasibility of this practice. Furthermore, recent data suggest that primary care providers fail to assess RA patients consistently or aggressively.

**Objectives:** The project aimed to increase RA patient awareness of CV risks, improve the process for screening and documenting CV risk factors. At National Jewish Health, a tertiary referral center, we implemented an integrated system to provide RA patients direct access to evaluation by a cardiologist for CVD risk assessment.

**Methods:** We reviewed the medical records of all RA patients presenting to our hospital for new or follow up appointment in 2015 when the rheumatology CVD risk assessments began. Charts were reviewed for: baseline characteristics, a chest commuted tomography (CT) scan that included cardiac imaging information and medication use. A board certified cardiologist reviewed the cardiac CT information for the presence or absence of coronary calcifications.

**Results:** There were 683 RA patients seen during the study interval and 251 were screened and referred for CV risk assessment. A significant number of patients are current or past smokers. (Table) The majority are seropositive and have normal lipid and hemoglobin A1C levels. We have recorded an MDHAQ on 75% of the RA patients and 39% have an ASCVD risk score. Prior to this project, we had not done routine assessments or recorded them in our electronic medical records. We found 104/251 (41%) of the patients had a chest CT available for review. 41/104 (39%) had some presence of coronary calcifications on chest CT and 39/104 (37%) were either on or started a statin.

**Conclusions:** RA patients seen in our tertiary hospital were effectively screened for CVD risk and aggressively treated, but we found that not all patients could be screened. Our institution was amenable to the practice changes and implementation among other hospitals may be a feasible option.

| | Total N = 251 | Women N =189 | Men N = 62 |

## SAT0100 ASSOCIATION BETWEEN CHRONIC PERIODONTITIS AND CLINICAL PROFILE OF RHEUMATOID ARTHRITIS

B. Rodríguez-Lozano[1], J.L. Garnier Rodríguez[2], J. González Febles[3], S. Dadlani[4], B. Tejera Segura[1], I. Ferraz Amaro[1], J.F. Díaz González[1], S. Bustabad Reyes[1]. *[1]Rheumatology, Hospital Universitario de Canarias., Prov. Santa Cruz Tenerife; [2]Odontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife; [3]Periodontology, UCM, Madrid; [4]Periodontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife, Spain*

**Background:** Recent clinical data show a clear association between periodontitis (P) and rheumatoid arthritis (RA). However, the literature is inconsistent whether severity of P is associated with RA activity; some studies haven't shown any or negative association.Nevertheless, there is one study[1] that has found a positive association between severity of P and activity of RA.

**Objectives:** 1) To describe if the severity of P affects the clinical expression and activity of RA.2) To define the characteristics of P in RA patients with high clinical activity.

**Methods:** Observational, cross-sectional, case-control study of adult RA patients (ACR/EULAR 2010) in a hospital Rheumatology Service,with at least 4 teeth, no dental prophylaxis or antibiotic intake 6 months before. Sociodemographic/anthropometric variables including smoking status, Graffar scale and stress level. RA variables: DAS28 (ESR & CRP), SDAI, titles RF/ACPA, extraarticular manifestations and comorbidities:o steoporosis (OP), diabetes mellitus (DM), dyslipidemia (DS), ischemic cardiovascular disease (ICD); glucocorticoid (GC),synthetic and biological therapy (DMARDs/BT). Periodontal Variables: plaque index (PI), bleeding on probing (BoP), probing pocket depth (PPD), recession (REC), clinical attachment level (CAL). Dental team: 2 periodontists/2 general dentists. Full mouth CAL, PPD and periapical x-rays were taken. CAL was classified according to the European Workshop in 2005 (Tonetti), into level 0 (absence), N 1T (mild), N2 T (severe). Statistical Analysis: t-student, Kruskal Wallis, Chi-square. Statistical program: Stata 13.1.

**Results:** 187 RA patients, F/M 78,6%/21,4%, mean age 54,4 yo, follow-up: 8,8 y. Early RA 18,72%. Positive F/ACPA: 74,19%/67,86%. Mean clinical activity: DAS28(ESR) 3,81/DAS28(CRP) 3,18/SDAI 14,49. Disease activity: remission 20, 86%, low 24,06%, moderate 45,45%, high 9,63%; RA treatment: GC therapy 47,06% (pred 2,85 mg/d)l; DMARDs monotherapy/combined: 53%/11,76%, BT 30%. Smoking: Current smoker (19,25%)/former smoker (24,6%); low socioeconomic status (36,36%), relative poverty (33,69%); annual dental prophylaxis: 43%; dyslipidemia: 53,47%, OP/osteopenia: 55,86%. P N2T in 69, 05% of patients with moderate/high activity vs 30,95% remission/low activity; 55,34% patients with P N1T showed RA remission/low activity ($p<0,001$). It has been found a strong association between severe P and moderate/high RA activity, with OR 57,649±37,403 (CI 95% 16,163–205,620). Patients with moderate/high RA activity presented increased values of all periodontal parameters compared to those with low activity ($p<0,005$). It has been observed an association between rheumatoid nodes, pleuritis and OP with severe P ($p=0,028$).

**Conclusions:** 1. High-activity RA is associated with severe P. 2. Patients with moderate and high activity RA have higher prevalence of both number and percentage of probing pocket depth ≥ de 5mm. 3. Presence of rheumatoid nodes and osteoporosis are related to severe P. 4. These results prompt an independent relationship between severe P and RA patients with high clinical disease activity.

## SAT0101 COULD THE FUNCTIONAL DISABILITY OF RHEUMATOID ARTHRITIS PATIENTS INFLUENCE IN THE DEVELOPMENT OF PERIODONTITIS?

B. Rodríguez-Lozano[1], S. Dadlani[2], J.L. Garnier Rodríguez[3], J. González Febles[4], L. Expósito Pérez[1], H. Sánchez Pérez[1], M. García González[1], S. Bustabad Reyes[1]. *[1]Rheumatology, Hospital Univeristario de Canarias, Prov. Santa Cruz de Tenerife; [2]Periodontology; [3]Odontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife; [4]Periodontology, UCM, Madrid, Spain*

**Background:** It has been suggested that functional disability in patients with rheumatoid arthritis (RA) could influence in hygiene procedure performance,promoting the development of periodontitis (P).However, this factor has been tested in few studies, with inconsistent data[1,2]. Hence, it has been implied both that functional disability has a possible role in P process risk (13,4%)[2],and that there is no higher plaque index[3] (PI) or no association between P severity and functional index by HAQ[4].
**Objectives:** 1)To test whether the functional ability of RA patients is associated with the presence of a more severe P.2) To describe the possible influence of functional disability on the development of P in terms of RA activity.
**Methods:** Observational,cross-sectional,case-control study,performed in adult RA patients (ACR/EULAR 2010) in a Rheumatology Service; and a control group with a non-inflammatory joint pathology,with at least 4 teeth,without dental prophylaxis or antibiotic intake 6 months before. RA activity was evaluated:DAS28 (ESR), DAS28(CRP) and SDAI, and patients were categorized by activity and functional disability (HAQ index).Periodontal parameters:PI (Silness and Löe,1964)[5],4 surfaces/tooth (0–3);bleeding on probing (BoP), probing pocket depth (PPD), clinical attachment level (CAL). Dental team:2 periodontists/2 general dentists (inter-observer variability<30%). Full mouth CAL,PPD and periapical x-rays were taken. CAL was classified according to the European Workshop 2005 (Tonetti):level 0 (absence), N1 T (mild), N2 T (severe). Statistical Analysis:t-student, Kruskal Wallis, Chi-square. Statistical program: Stata 13.1.
**Results:** 344 patients:187RA (147 F/40 M)and 157 control (101F/56M),mean age 54,9 (17,9), follow-up 8,8 years;18,72% patients with early RA. 83/187 (44,39%) RA patients presented a remission/low disease activity and 55,61%, moderate/high activity. 69,05% patients had P N2 T. Mean HAQ index was 0,76 (0,62), finding differences between patients with varied disease activity:p50 [p25-p75] 0,250 (0–0,750) in RA patients with remission/low activity vs 1,125 (0,625–1,5) those with moderate/high activity, p=0,000. There was no association between HAQ values and presence of P (OR 1,0003 IC 95% 0,999–1,001). Nevertheless, there was a gradually increase in PI values from control patients 0,56 (0,40), to remission/low RA activity 0,59 (0,37), RA moderate/high 0,86 (0,53), with statistically significant differences between consecutive categories (p<0,001 and p=0,001, respectively).
**Conclusions:** 1. No association was found between functional ability of RA patients measured by HAQ index and presence of a more severe P.2. An ascendant gradient in PI is observed related to RA clinical activity with significant difference, despite an acceptable preserved functional ability.3. These findings could strenghten an classic risk factor independent relationship between RA and P.

## SAT0102 INFLUENCE OF VACCINATION PROGRAM TO PREVENT ACUTE RESPIRATORY INFECTION IN RHEUMATOID ARTHRITIS

P. Rodriguez-Cundin[1], V. Calvo-Río[2], R. Blanco[2], L.C. Dominguez-Casas[2], N. Vegas-Revenga[2], C. Fernández Díaz[2], V. Portillo[2], F.M. Antolin[1], M.H. Rebollo-Rodrigo[2], M.A. Gonzalez-Gay[2]. *[1]Preventive Medicine; [2]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Spain*

**Background:** Patients with autoimmune rheumatic diseases such as rheumatoid arthritis (RA) are at increased risk for infections, especially respiratory type. Immunization is a recommended measure to reduce these complications.
**Objectives:** Assess the incidence of acute respiratory infections (ARI), defined as one that causes hospitalization, before and after inclusion in a systematic vaccination program.
**Methods:** Prospective study in a cohort of 294 patients diagnosed with RA, were included in the vaccination program. This program includes: seasonal flu vaccine (october to april), pneumococcal (combined regimen 13-valent and 23-valent) and Haemophilus influenzae B.
Only 7 patients (2.94%) refused vaccination.
The follow-up time was from October 1st, 2011 (starting date) to June 30th, 2015. Information on ARI episodes before and after immunization was collected from the Hospital Information System, reviewing hospital records.
**Results:** 287 RA patients (225 women/62 men) were vaccinated, with an average age of 58.1 ± 12.7 years. RA was characterized at the time of vaccination by the time of evolution of RA 93 ± 95.9 months; 154 (53.65%) positive RF, 97 (33.8%) erosive and 40 (13.9%) with extra-articular manifestations (7 with pulmonary fibrosis).

TABLE: SERIUS INFECTIONS POST-IMMUNIZATION

| | Age | sex | Biological Therapy At vaccination | Biological Therapy previus | Others Theraphys | Rheumatoid Factor | Serius Respiratory infections |
|---|---|---|---|---|---|---|---|
| 1 | 72 | W | No | Yes | Prednisone 30 mg/24h | - | Pneumonia(E. coli) |
| 2 | 45 | W | No | - | LFN | + | LRTI (Microbial culture negative) |
| 3 | 66 | M | No | Yes | CQ | - | Pneumonia (microbial culture negative) |
| 4 | 67 | W | No | No | - | - | LRTI (Microbial culture negative) |
| 5 | 48 | W | No | No | MTX Prednisone 10 mg/24h | + | LRTI (Microbial culture negative) |
| 6 | 63 | W | No | Yes | MTX Prednisone 10 mg/24h | + | LRTI (aspergillus fumigatus) |

Abreviatures: W: Woman; M: Man; LFN: leflunomide; CQ: chloroquine; MTX: methotrexate; LRTI: Lower Respiratory Tract Infections

Only 42 (14.6%) were not taking any immunosuppressive or immunomodulatory therapy at the time of immunization. 147 patients were treated with Disease Modifying Antirheumatic Drugs (DMARD's), mainly methotrexate, and 98 patients (34.1%) were with a TNFa inhibitor.
Regarding the ARI, before inclusion in the vaccination program, 20 (7%) patients in the cohort studied had been admitted into the hospital for this reason.
During follow-up, and subsequent immunization, only 6 of the 287 patients (2.1%) had ARI (Table 1). One of them had an ARI prior to vaccination program.
This reduction from 7% to 2.1% achieved statistically significant difference (p=0.0017).
**Conclusions:** Incorporating a program of systematic vaccination in RA patients appears to be an effective prophylactic measure to prevent the ARI.
**Disclosure of Interest:** None declared

## SAT0103 RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS IN A SWISS COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND AXIAL SPONDYLARTHRITIS

K. Lauper, P. Chevallier-Ruggeri, A. Finckh, C. Gabay. *Rheumatology, University Hospitals of Geneva, Geneva, Switzerland*

**Background:** Rheumatoid arthritis (RA) has been associated with an increased risk of cardiovascular (CV) morbidity and mortality. Recent data indicated that this could also be the case in psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA) patients.
**Objectives:** To compare the risk of major adverse cardiovascular events (MACE) in RA, PsA and AxSpa as of disease onset.
**Methods:** A mixed retrospective and prospective cohort study was conducted using data from patients included in the Swiss Clinical Quality Management (SCQM) registry. Patients diagnosed with RA, PsA, or AxSpA at an age of ≥18 years without a history of MACE (i.e., non-lethal myocardial infarction, non-lethal stroke and death from cardiovascular event) at the time of first articular symptoms or, if not available, at the time of diagnosis were included. The primary outcome was the incidence of first MACE, using self-reported or physician-reported data. For each patient we recorded the time in years from disease onset until either occurrence of first MACE or end of follow-up. The exposure of interest was the type of rheumatic disease: RA, PSA or AxSpA. In addition to sex and age at disease onset, we assessed traditional CV risk factors: known familial history of MACE before age 50, and presence of ever-hypertension, ever-diabetes, ever-hyperlipidemia, and ever-smoking. We applied Poisson regression to estimate and compare the incidence rates for MACE.
**Results:** 5311 patients (3068 RA, 1462 AxSpA, and 781 PsA patients) were eligible and contributed a total follow-up time of 37'459 years for RA, 19'818 for AxSpA, and 9'159 for PsA. Diseases started between 1950 and 2014 and differed significantly with respect to assessed CV risk factors (Table 1). A total of 98 RA, 28 AxSpA, and 11 PsA patients had experienced at least one MACE since disease onset. The unadjusted incidence rate of MACE per 1000 person-years was 2.62 for RA, 1.41 for AxSpA, and 1.20 for PsA (p=0.0011). After adjusting for traditional CV risk factors, age at disease onset, sex, and year of disease onset (categorized as: <1985, 1985–2000, or >2000) the significant difference between PsA and RA persisted (MACE incidence rate ratio (IRR): 0.45, 95% confidence interval (CI): 0.22- 0.91), while the difference between AxSpA and RA was decreased and no longer significant (IRR: 0.86, 95% CI: 0.5 -1.49). Because ever-hypertension, ever-diabetes, ever-hyperlipidemia, and ever-smoking may not reflect the status at time of disease onset, we analyzed the risk of MACE also with only adjusting for sex, age at disease onset, disease onset and family history of early MACE. The results (n=5311) were very similar, suggesting that especially age and sex are important confounders when comparing incidence rates across diseases. Male sex, older age at disease onset, a known family history of early MACE, ever-hypertension, and ever-hyperlipidemia were also significantly positively associated with the risk of MACE.

Table 1

| | AxSpa (n= 1462) | PsA (n=781) | RA (n=3068) | P-value |
|---|---|---|---|---|
| Age in yrs at disease onset, median (IQR) | 29 (23-39) | 39 (30-49) | 47 (37-56) | 0.0000 |
| Sex (male), n (%) | 804 (55) | 418 (54) | 768 (25) | 0.0000 |
| Family history of early MACE (< 50 yrs), n (%) | 173 (12) | 116 (15) | 357 (12) | 0.048 |
| Ever-hypertension, n (%) | 346 (26, n = 1326) | 276 (37, n=738) | 1141 (39, n= 2940) | 0.0000 |
| Ever-diabetes, n (%) | 63 (4, n=1417) | 50 (7, n= 759) | 214 (7, n= 3068) | 0.0021 |
| Ever-hyperlipidemia, n (%) | 208 (18, n=1185) | 163 (24, n = 668) | 663 (25, n=2668) | 0.0000 |
| Ever-smoking, n (%) | 892 (62, n = 1450) | 450 (58, n= 775) | 1700 (56, n= 3048) | 0.0012 |

IQR = Interquartile range
P-values are from a Kruskal-Wallis test for continuous or discrete variables and from a Fisher's exact test for categorical variables.

**Conclusions:** Taking into account traditional CV risk factors, age and sex, the type of rheumatic disease remained associated with risk of MACE. RA seems to convey a larger CV risk than PsA, while the difference between RA and AxSpA remains unclear.
**Disclosure of Interest:** None declared

## SAT0104 DEPRESSION AND ANXIETY IN PATIENTS WITH AN EARLY ARTHRITIS – A PILOT STUDY

D.C. Freier[1], V. Höhne-Zimmer[1], P. Klaus[1], T. Braun[1], D. Ducks[2], V. Köhler[1], R. Uebelhack[3], F. Buttgereit[1], G.-R. Burmester[1], J. Detert[1]. *[1]Department of Rheumatology and Clinical Immunology, Charité-University Medicine, Berlin; [2]University of Applied Sciences, Information sciences, Potsdam; [3]Department of Psychiatry and Psychotherapy, Charité-University Medicine, Berlin, Germany*

**Background:** The depression is with an average of 16% to 38% one of the most prevalent co-morbidities in rheumatoid arthritis (RA) as well as heart diseases or diabetes mellitus. Few studies investigate the clinical relevance of psychiatric disorders in an early disease stage of the RA and as if they may affect future outcomes in chronicity process.
**Objectives:** The aim was to evaluate the prevalence rates of depression and anxiety in an early arthritis (EA) cohort and the distribution across diagnosis groups and gender. Furthermore, we wanted to investigate whether certain disease parameters of an EA show differences between patients (pts) with normal scores versus (vs) pts with high scores in depression and anxiety to construe strategies for everyday practice by gathering such diseases at an early stage.
**Methods:** In a prospective cross-sectional survey, 176 pts with EA answered the Hospital Anxiety and Depression Scale (HADS). The suspicion of an EA was defined by at least one fluid joint and a disease duration from six weeks to maximum 12 months. We compared the standardized clinical routine assessment with disease activity score 28 (and clinical investigation of 68 joints), visual analogue scale (VAS) for pain and disability according the health assessment questionnaire (HAQ) with results of HADS in different diagnostic groups.
**Results:** The mean age of EA cohort was 50.4±16.1 years (♀ 69.3%, mean disease duration: 4.2±3.4 months). Pts assigned to the following groups: "Rheumatic diseases" (RD, n=108) with subgroups "Rheumatoid Arthritis" (RA, n=55) and "Non-rheumatoid arthritis" (NRA, n=53) and "Non-rheumatic diseases" (NRD, n=68). We found a positive global distress in 47.7% of EA pts. The score in RD group was 50.9% vs 42.6% in NRD group. In RA pts it was 49.1% vs 52.8% in NRA pts. The HADS average was as similar in all groups and if compared to gender. We found out that a positive distress score accompanied with significantly higher means of the tender joint count-68 (TJC, p=0.032), the VAS for pain ($p<0.000$) and HAQ ($p<0.000$). RA pts with positive distress score showed higher rates in HAQ (p=0.004) and pain-VAS (p=0.001). NRD pts with positive distress scores had also significant higher means of pain-VAS (p=0.033). Only the NRA group didn't show statistically significant differences.
**Conclusions:** There is an extremely high point prevalence, with almost 50%, of anxiety and depression for EA pts. If EA pts had positive HADS, three established standardized EA measurement instruments (HAQ, VAS for pain, TJC68) showed significantly higher average as if they had negative scores. To improve the treat-to-target concepts in clinical practice with a particular focus on comorbidities, further studies are required. The importance of early psychiatric-psychological interventions in the early stages of RA disease is unclear.

## SAT0105 INFLAMMATORY MARKERS IN RHEUMATOID ARTHRITIS – WHAT IS THE ROLE OF SERUM AMYLOID A PROTEIN?

D.R. Gonçalves, R. Fonseca, F. Aguiar, T. Martins-Rocha, M. Bernardes, L. Costa. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** Dissociation between the responses of a number of acute-phase proteins (APP) is well known. C reactive protein (CRP) levels have been used extensively to model disease activity in rheumatoid arthritis (RA). However, biologic therapy reduce CRP levels, even without associated reductions in RA disease activity. Serum amyloid A (SAA) also models RA disease activity and has been suggested as a better biomarker for RA disease activity.
**Objectives:** To determine if SAA levels had better correlation with conventional clinical and serological assessments in RA than CRP and ESR.
**Methods:** A cross-sectional study was performed. Samples were analyzed from RA patients under biologic therapy of a reference hospital in northern Portugal. We compared the correlation between SAA, CRP and ESR levels with swollen and tender joints counts (SJC and TJC), DAS28-4v, SDAI, CDAI, HAQ and visual analogue scale for pain (VAS-P). Correlation was calculated using the Spearman rank correlation (r). P-values $<0.05$ were regarded as significant.
**Results:** 173 patients were evaluated, 86.7% (n=150) were women. The mean (SD) age was 56 years (10.75). Mean disease duration was 16.31 years (8.87). Most of patients had positive serology (rheumatoid factor and/or anti-CCP antibody) (n=146, 84.4%). Ninety eight patients (56.6%) were under TNF antagonists, 23.7% (n=41) were under rituximab and the remaining under tocilizumab (TCZ).
SAA levels were moderately correlated with CRP levels ($r=0.49$, $p<0.001$) but there was no statistically significant correlation with ESR (r=0.03, p=0.75).
Correlation analysis of SAA and CRP levels with several conventional assessments showed (SAA and CRP, respectively): SJC - 0.17 vs 0.08, TJC - 0.18 vs 0.09, DAS28-4v - 0.32 vs 0.41, SDAI - 0.23 vs 0.18, CDAI - 0.18 vs 0.11, ESR – 0.32 vs 0.55; all p values $<0.05$ except SJC, TJC and SDAI for CRP values. There was no statistically significant correlation of these acute-phase protein with HAQ and VAS-P. ESR levels showed very weak correlation with all parameters ($p>0.05$), except with DAS28-4v ($r=0.58$, $p<0.001$).
We also noted that SAA levels were raised ($>6.4$mg/L) in 37.6% (n=65) of patients in which the CRP concentration was normal ($<0.3$mg/dL). However, only 6% (n=11) with normal SAA levels had raised concentrations of CRP. When evaluated SAA and CRP levels in patients with active disease (DAS28-4v $^3$2.6, SDAI$>$3.3 and CDAI$>$2.8) we found more patients with normal CRP values than SAA (62 vs 26, 82 vs 32, 84 vs 33, respectively).
Interestingly, when comparing the effects of biological therapy on APP we noted that in TCZ group the CRP, ESR and SAA levels were lower than in group under TNF antagonists and rituximab ($p<0.001$ for all, Mann-Whitney test).
**Conclusions:** The lack of a strong correlation between SAA and CRP or ESR levels coupled with their better correlation with markers of RA activity suggests that changes in their levels may provide a more sensitive indicator of disease activity, especially during treatment with biologic therapy.

## SAT0106 VALVULAR HEART DISEASE IN A MEXICAN MESTIZO COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY

D.A. Galarza-Delgado[1], J.R. Azpiri-Lopez[2], I.J. Colunga-Pedraza[3], R.I. Arvizu-Rivera[3], A. Martinez-Moreno[2], J.A. Cardenas-de la Garza[3], R. Vera-Pineda[2], L.E. Gonzalez-Carrillo[2], M.A. Ramos-Guzman[2], G. Serna-Peña[1], M.A. Garza-Elizondo[3], M.A. Benavides-Gonzalez[2]. *[1]Internal Medicine Department; [2]Cardiology Department; [3]Rheumatology Department, "Dr. José Eleuterio González" University Hospital, Monterrey, Mexico*

**Background:** Rheumatoid arthritis (RA) is associated with a higher rate of cardiovascular mortality. The prevalence of valvular heart disease (VHD) varies greatly in the published reports. Data in Mexican mestizo patients with RA is scarce.
**Objectives:** We aimed to evaluate the presence of VHD in a cohort of RA Mexican mestizo patients and compare it to matched controls.
**Methods:** An observational, comparative, case control study was designed. Patients with RA aged 40 to 75 years that fulfilled the 2010 ACR/EULAR criteria were included. Exclusion criteria included prior atherosclerotic cardiovascular disease (myocardial infarction, stroke and peripheral arterial disease) and overlap syndromes.
Patients were matched using age, sex and comorbidities. A standard transthoracic echocardiography was performed according to the American Society of Echocardiography guidelines. Valvular regurgitation was classified as mild, moderate or severe according to the European Association of Echocardiography and American Society of Echocardiography recommendations.
**Results:** A total of 56 patients and 28 controls were included in the final analysis. Characteristics of both groups are shown in Table 1. There was no statistical difference in sex, age, type 2 diabetes mellitus and body mass index between the two groups. VHD was reported in 45 (80.4%) RA-patients and 13 (46.4%) individuals in the control group ($p<0.003$). Statistical difference was found in mitral and tricuspid regurgitation ($p<0.001$ and $p<0.003$, respectively) in RA-patients when compared with the control group.
In the RA group, 5 (8.9%) showed mild aortic regurgitation; 28 had mild and 1 had moderate (50% and 1.8%, respectively) mitral regurgitation; 8 (14.3%) showed mild pulmonary regurgitation; 39 had mild and 4 had moderate (69.6% and 7.1%, respectively) tricuspid regurgitation. In the control group, 1 (3.6%) showed mild

aortic regurgitation; 3 (10.7%) had mild mitral regurgitation; 1 (3.6%) showed mild pulmonary regurgitation; 12 (42.9%) had mild tricuspid regurgitation.

Table 1. Clinical and Demographic characteristics

| | RA group (n= 56) | Control group (n=28) | P value |
|---|---|---|---|
| Women, n (%) | 54 (96.4%) | 27 (96.4%) | .845 |
| Age, mean ± SD | 56.01 ± 9.38 | 53.15 ± 6.27 | .922 |
| Hypertension, n (%) | 22 (39.3%) | 4 (14.3%) | .024 |
| Type 2 Diabetes mellitus, n (%) | 8 (14.3%) | 4 (14.3%) | > 999 |
| Smoking, n (%) | 6 (10.7%) | 0 (0.0%) | <.004 |
| Body mass index, mean ± SD | 28.51 ± 4.61 | 28.49 ± 4.54 | .538 |
| Valvular heart disease, n (%) | 45 (80.4%) | 13 (46.4%) | < 0.003 |
| Mitral valve regurgitation, n (%) | 29 (51.8%) | 3 (10.7%) | < 0.001 |
| Tricuspid valve regurgitation, n (%) | 43 (76.8%) | 12 (42.9%) | < 0.003 |
| Aortic valve regurgitation, n (%) | 5 (8.9%) | 1 (3.6%) | .658 |
| Pulmonary valve regurgitation, n (%) | 8 (14.3%) | 1 (3.6%) | .260 |

**Conclusions:** In our cohort, 80.4% of the RA-patients had VHD, with the tricuspid valve being the most affected (76.8%). Prospective studies are needed to evaluate the role of VHD in RA-patients morbi-mortality.

## SAT0107 SIMPLE PREDICTORS OF ABNORMAL 2H POSTLOAD GLUCOSE IN RA PATIENTS WITH NORMAL FASTING GLUCOSE

F. Ursini[1], S. D'Angelo[2], C. Tripolino[1], C. Bruno[1], L. D'Antona[1], K. Nicolosi[1], S. Naty[1], I. Olivieri[2], R.D. Grembiale[1]. *[1]Health Sciences, University of Catanzaro "Magna Graecia", Catanzaro; [2]Rheumatology Department of Lucania, San Carlo Hospital, Potenza, Italy*

**Background:** Rheumatoid arthritis (RA) is characterized by an excess of cardiovascular diseases (CVD) risk, similar to type 2 diabetes (T2DM). A recent meta-analysis confirmed an elevated prevalence and incidence of T2DM in RA [1]. In this context, the necessity to recognize early T2DM in RA is driven by the evidence that CVD risk factors tends to act synergistically, thus increasing the risk conferred by each single factor [2]. However, it's still difficult to select patients that need to underwent extensive diabetes investigation in the rheumatology setting.

**Objectives:** Aim of our work was to identify useful predictors of impaired glucose tolerance (IGT) and T2DM in RA patients with normal fasting glucose values in the rheumatology outpatient setting.

**Methods:** 100 RA patients satisfying ACR/EULAR 2010 criteria [3] were screened with FPG. Of these, 78 had normal (<100 mg/dL) FPG values and therefore were recruited. All patients underwent a 75g oral glucose tolerance test (OGTT) following World Health Organization (WHO) recommendations. According to 2-hours postload glucose values (2h-pG), patients were classified as normal (NGT) if 2h-pG <140 mg/dL, impaired glucose tolerance (IGT) if 2h-pG 140–200 mg/dL or T2DM if 2h-pG ≥200 mg/dL. Age, sex, body mass index (BMI), waist circumference (WC) and blood pressure were recorded. After overnight fasting, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), total and HDL cholesterol, triglycerides (TG) and uric acid were measured. The homeostasis model assessment of insulin resistance (HOMA-IR)[4] was calculated with the formula: glucose (mg/dL) x insulin (mU/L)/405. The triglycerides and glucose index (TyG index)[5] was calculated with the formula: *ln* (TG [mg/dL] x glucose [mg/dL]/2). The lipid accumulation product (LAP)[6] was calculated with the formula [WC (cm) – 58 for women or 65 for men] x TG (mmol/L). The visceral adiposity index (VAI) was calculated with the formula proposed by Amato et al [7].

**Results:** Of the 78 RA patients recruited 57 were NGT, 18 were IGT and 3 were T2DM. After correction for age, sex, BMI, and systolic blood pressure, 2h-pG correlated with diseases duration (R=0.25, p=0.04), ESR (R=0.27, p=0.02), lnTG/HDLc (R=0.24, p=0.04), HOMA-IR (R=0.29, p=0.01), LAP (R=0.28, p=0.02) but not with lnCRP, lnTG, fasting glucose, uric acid, TyG index or VAI. In addition 2h-pG category correlated only with LAP (R=0.33, p=0.005). When A1c% was set as dependent variable, it correlated with lnTG (R=0.26, p=0.03), fasting glucose (R=0.29, p=0.0), uric acid (R=0.26, p=0.03), TyG index (R=0.25, p=0.04), LAP (R=0.30, p=0.01).

**Conclusions:** In RA patients with normal fasting glucose, LAP correlates significantly with 2hPG and predicts abnormal glucose tolerance.

## SAT0108 METHOTREXATE AND ANTI-TNF TREATMENT IMPROVE ENDOTHELIAL FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND ANKYLOSING SPONDYLITIS

G. Deyab[1], I. Hokstad[2], M.C. Småstuen[3], S. Agewall[4], I. Hollan[2,5,6]. *[1]Lillehammer Hospital Trust; [2]Lillehammer hospitalfor Rheumatic Diseases, Lillehammer; [3]Oslo and Akershus University Collage; [4]Oslo University Hospital, Ullevål, Oslo, Norway; [5]Harvard Medical School; [6]Brigham and Women's Hospital, Boston, Boston, United States*

**Background:** Inflammatory rheumatic diseases (IRD) are associated with accelerated atherosclerosis, which progression is related to inflammation. One of the first stages in atherogenesis is endothelial dysfunction (ED).

**Objectives:** We wanted to examine the effects of methotrexate (MTX) and anti-tumor necrosis factor (TNF) treatment (with or without MTX co-medication) on endothelial function (EF) in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS).

**Methods:** From the data registry from PSARA (an observational study), we evaluated patients with RA (n=64), PsA (n=30) and AS (n=20) who completed a 6 month follow-up. All patients required treatment with either MTX monotherapy or anti-TNF±MTX, due to clinical indication. EF was assessed by finger plethysmography (RH-PAT): reactive hyperemia index (RHI) <1,67 was considered as ED. In patients with ED at baseline (n=40), we searched for change in EF after 6 weeks and 6 months of anti-rheumatic therapy.

**Results:** In IRD patients with ED, RHI improved from baseline to 6 weeks (mean change=0.56, p<0.005) and 6 months (mean change=0.46, p<0.005), with the greatest improvements within the RA subgroup in whom RHI significantly improved at both control visits. In PsA, RHI improved at both control visits, but the change was statistically significant only at the 6 months visits. AS patients had a statistically non-significant trend towards RHI improvement at both control visits. At 6 months, RHI improved more in the MTX group than in the anti-TNF±MTX group (mean change 0.74 vs. 0.24; p=0.010), and this difference remained statistically significant after adjustments for potential confounders. There was no significant difference between the treatment regimens at 6 weeks.Id significantly greater thhe The improvement in RHI was independent of changes in disease activity and of traditional CV risk factors.

**Conclusions:** Treatment with MTX and anti-TNF±MTX appears to relatively fast improve EF in IRD patients with ED, independently of improvement of disease activity. After 6 month, the EF improvement was more pronounced in the MTX users than in the anti TNF±MTX users. Among other factors, this might be due to a better effect of MTX on the vasculature, or due to differences in the MTX and anti-TNF±MTX populations.

It remains to be examined in further studies if the lack of significant effect of the treatment on ED in AS is due to specific features of vascular disease in AS, or due to other factors, such as Type-2 error.

## SAT0109 SUBCLINICAL ECHOCARDIOGRAPHIC CHARACTERISTICS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITHOUT OVERT CARDIAC DISEASE

G. Orsolini[1], O. Viapiana[1], G. Cioffi[2], A. Dalbeni[3], A. Giollo[1], E. Fracassi[1], F. Ognibeni[2], D. Gatti[1], M. Rossini[1]. *[1]Rheumatology Section, Department Medicine, University of Verona, Verona; [2]Department of Cardiology, Villa Bianca Hospital, Trento; [3]Internal Medicine Section, Department of Medicine, University of Verona, Verona, Italy*

**Background:** Patients with rheumatoid arthritis (RA) have an increased risk for cardiovascular (CV) disease, despite preserved left ventricular (LV) ejection fraction (EF). Changes in LV geometry, LV systolic dysfunction (LVSD) and the development of excessive left ventricular mass (LVM) are closely and consistently

associated with CV disease in several settings of patients such as those with arterial hypertension or type 2 diabetes mellitus, with preserved LVEF.
**Objectives:** The aim of this study was the evaluation of this subclinical parameters in patients with RA.
**Methods:** 198 outpatients with RA without overt cardiac disease were prospectively analyzed with echocardiography and compared with 198 matched controls. In all patient LV geometry (concentric remodeling or hypertrophy), LVEF, circumferential and longitudinal LVSD (respectively by stress-corrected midwall shortening [sc-MS] and Tissue Doppler mitral annular peak systolic velocity [S']) and the presence of inappropriately high LVM (iLVM)were evaluated.
**Results:** The patients with RA present higher prevalence respect to controls ofconcentric remodeling or hypertrophy, circumferential or/and longitudinal LVSD and iLVM as reported on table.

Table 1

| | RA | Controls | p |
|---|---|---|---|
| Concentric remodeling (%) | 74 | 18 | <0.001 |
| Hypertrophy (%) | 37 | 16 | <0.001 |
| LVEF (%) | 1 | 3 | NS |
| iLVM (%) | 64 | 15 | <0.001 |
| Circumferential LVSD (%) | 55 | 14 | <0.001 |
| Longitudinal LVSD (%) | 45 | 20 | <0.001 |
| C&L LVSD (%) | 28 | 6 | <0.001 |

By multiple logistic regression analysis, rheumatoid arthritis emerged as independent predictor of all this echocardiography alterations.
**Conclusions:** The patients with RA without overt cardiac disease have the same echocardiographyc characteristics what are associated with CV disease in hypertension and in diabetes mellitus. These findings may be clinically useful for identifying a subgroup of patients with RA at very high risk for adverse CV events (mostly heart failure). Longitudinal studies are needed to assess the prognostic role of this conditions in these patients and to test conceivable and useful pharmacological and/or non-pharmacological treatments.

## SAT0110 PREVALENCE OF SELF-REPORTED COMORBIDITIES IN RHEUMATOID ARTHRITIS OUT-PATIENT CLINIC PATIENTS

G. Haugeberg[1,2], B.-T.S. Fevang[3], D.M. Soldal[4], C. Gjesdal[3]. *[1]Rheumatology, Martina Hansens Hospital, Oslo; [2]INM, NTNU, Trondheim; [3]Rheumatology, Haukeland Hospital, Bergen; [4]Rheumatology, Sørlandet Hospital HF, Kristiansand, Norway*

**Background:** Patients with rheumatoid arthritis (RA) has been shown to be at increased risk for other diseases, in particular for osteoporosis, infections, cardiovascular diseases and malignancy. There are limited data on prevalence of comorbidities in unselected RA patient outpatient cohorts reflecting the magnitude of comorbidities in RA patients.
**Objectives:** To explore the prevalence of comorbidities in RA patients followed at outpatient clinics in Norway.
**Methods:** The RA patients were recruited from two outpatient clinics in Norway, one located in the southern and one in the western part of Norway. As part of clinical routine the RA patients at these two centers were monitored at ordinary visits by the use of the computer software tool GoTreatIT® Rheuma. Standardized data collection for disease activity measures, patient reported outcome measures (PROM) and treatment was registered as part of clinical routine. Patients also self-reported their comorbidities using the computer system. Patients with at least one visit in 2015 at the outpatient clinics were included.
**Results:** A total of 2437 RA patients were assessed, 1065 from the southern and 1372 from the western located center. Only minor differences were found between the two centers, for demographic, disease and treatment variables. Patient demographic and disease characteristics: mean age 62.7 (SD 14.1) years, BMI 25.9 (4.5) kg/m$^2$, education 11.8 (3.6) years, 70% females, current smoker 16.0% and 66.8% were RF+ and 73.5% were anti-CCP+. Measures reflecting disease activity: mean ESR 18.2 (14.4) mm/hr, CRP 7.0 (13.8) mg/dl, DAS28 2.4 (1.2) and CDAI 6.6 (7.0). Mean values for PROMs: Pain 32.7 (25.3) mm, fatigue 37.8 (29.8) mm. MHAQ 0.18 (0.42). Current user of mono synthetic disease modifying anti-rheumatic drugs (sDMARDs) 45.5%, mono biologic DMARDSs (bDMARDs) 10.4% and combination sDMARDs and bDMARDs 25.5%. Prednisolone was used by 40.8% of the patients.
Self-reported comorbidity data was available in 1616 of the 2437 (66.3%) patients. The percentage of patients reporting to have myocardial infarction was 3.9%, arterial hypertension16.5%, heart failure 1.2%, peripheral artery disease 1.7%, cerebrovascular disease 1.8%, osteoporosis 12.8%, chronic infections 3.7%, lymphoma 0.7%, melanoma 0.9%, other skin cancer 0.5%, other cancers 5.8%. Among the 123 patients who reported to have cancer 6.5% reported to have metastasis and 58.1% reported to have had ca treatment the last 5 years. Thyroid gland disease was reported by 8.0%, diabetes mellitus by 4.4% and peptic ulcer disease by 5.0%.
**Conclusions:** Our data gives an estimate of the prevalence of the most frequent comorbidities in RA patients seen in Norwegian outpatient rheumatology clinics. Osteoporosis and cardiovascular disease was the most frequent comorbidities. Both of these comorbidities have been shown to be more frequent in RA patients compared with the background population. Data on prevalence of comorbidities may contribute to an increased awareness improving overall patient care in RA.

## SAT0111 INCREASED INSULIN RESISTANCE AND IMPAIRED BETA-CELL FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS: COULD INFLAMMATION FULLY EXPLAIN THESE METABOLIC DISTURBANCES?

G.G. Ristic[1], V. Subota[2], D. Stanisavljevic[3], B. Glisic[1], M. Petronijevic[1], D. Stefanovic[1]. *[1]Department of Rheumatology and Clinical Immunology; [2]Institute of Medical Biochemistry, Military Medical Academy; [3]Institute of Medical Statistics, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

**Background:** Chronic inflammation, the basic feature of rheumatoid arthritis (RA), plays a major role in accelerated atherosclerosis through its influence on insulin resistance (IR), lipid status, and other risk factors.
**Objectives:** To investigate the level of IR and β-cell function in RA pts compared to healthy controls and evaluate whether inflammation can explain these metabolic disturbances.
**Methods:** The study population included 127 nondiabetic subjects (90 RA pts and 37 matched healthy controls). We determined body mass index (BMI), waist circumference (WC), presence of hypertension and metabolic syndrome (MetS). All pts were on disease modifying antirheumatic drugs (93.3% on methotrexate), 65.6% on steroids (median 5 mg/day, range 5–10, none on steroids >10 mg/day), and 27.8% on biologic therapy. Laboratory analyses included inflammation markers (SE, hsCRP, IL-6), glucose, insulin, and C peptide (as a marker of insulin secretion). IR was calculated using the updated-computer Homeostasis Model Assessment (HOMA2-IR), based on fasting plasma glucose and specific insulin concentrations. Serum specific insulin was measured by a sensitive ELISA, which employs a monoclonal antibody to insulin. The output of the HOMA2 model was calibrated to give IR of 1 as normal. Therefore, values were considered abnormal when HOMA2-IR was >1.
**Results:** Insulin resistance (HOMA2-IR>1) was detected in 67/90 (74.4%) of RA pts and in 20/37 (54.2%) of controls, p=0.025. RA pts had significantly higher concentration of specific insulin, C peptide and HOMA2-IR than healthy controls, while HOMA2-B was not statistically different. Importantly, both groups were comparable regarding all other factors known to affect glucose metabolism in the general population (age, WC, presence of hypertension or MetS). As it was expected we found significant differences in inflammation markers between RA pts and controls: ESR 29.5 (14–44) vs. 16.0 (10.0–20.0); hsCRP 5.5 (2.8–15) vs. 3.0 (1.8–3.9); IL-6; 7.4 (2.0–18.8) vs. 2.0 (2.0–2.4); p<0.000 for all. In logistic regression analysis, after adjustment for inflammation markers, statisticaly significant differences for HOMA2-IR and insulin became less important but still persisted (Table), while significance for C peptide disappeared.

Table 1. Impact of inflammation markers on the level of IR and β cell function

| Laboratory parameters | RA pts (N=90) | Controls (N=37) | P | P adjusted for ESR | P adjusted for CRP | P adjusted for IL-6 |
|---|---|---|---|---|---|---|
| Glucose (mmol/l) | 4.8±0.6 | 4.7±0.8 | ns | – | – | – |
| Insulin (pmol/L) | 68.5 (50.2–102.7) | 55.3 (36.0–69.1) | 0.008 | 0.030 | 0.048 | 0.035 |
| HOMA-S | 70 (46–100) | 84 (71.0–132) | 0.010 | 0.063 | 0.074 | 0.095 |
| HOMA2-IR | 1.4 (1.0–2.3) | 1.2 (0.8–1.4) | 0.008 | 0.028 | 0.046 | 0.031 |
| HOMA-B | 148 (116–190) | 141 (114–158) | 0.186 | – | – | – |
| C peptide (pmol/L) | 785 (520–1010) | 600 (450–880) | 0.046 | 0.199 | 0.078 | 0.058 |

**Conclusions:** RA pts had higher IR and impaired β-cell function in comparison to healthy controls. The persistence of statistical significance for IR after correction for inflammation markers, may implicate that the influence of inflammatory disease burden is important but not the only risk factor for IR in RA.
**Disclosure of Interest:** None declared

## SAT0112 THE EFFECT OF CARDIAC REHABILITATION PROGRAM ON DISEASE ACTIVITY, FUNCTIONAL OUTCOME AND CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. Peynirci Cersit[1], I. Yagci[1], S. Cersit[2], N. Inanc[3]. *[1]Physical Medicine and Rehabilitation, Marmara University School of Medicine; [2]Cardiology, Ministry of Health Kartal Kosuyolu Training and Research Hospital; [3]Rheumatology, Marmara University School of Medicine, Istanbul, Turkey*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by symmetric peripheral synovial joint involvement. The most common mortality cause in rheumatoid arthritis (RA) is cardiovascular diseases. Recent guidelines recommend assessment of cardiovascular risk, however the management of cardiovascular risk is not clear.
**Objectives:** The aims of the study were to find effect of cardiac rehabilitation on

**Abstract SAT0112** – Table 1

| Parameters | Groups | Baseline | 10th weeks | 24th weeks | F time | P value | F group | P value |

disease activity, functional status, fitness and cardiovascular risk score in patients with moderate disease activity.

**Methods:** Forty seven patients with RA who had filled ACR/EULAR 2010 classification criteria were enrolled to the study. The patients were randomized to cardiac rehabilitation (25 patients) and home based exercise program (22 patients) groups. The intervention in cardiac rehabilitation group included warming, bicycle ergometer, upper and lower extremity stregthening, cooling and stretching exercises. The patients had received cardiac rehabilitation three times a week for 10 weeks. Individualized home exercise program was given to cardiac rehabilitation group after 10th week. The patients in home exercise program were encouraged to do aerobic and strengthening exercises. The patients were evaluated at baseline, 10th and 24th week with exercise tolerance test, 6 minute walking test, DAS28 score, analysis of mSCORE risk profile, HAQ (Stanford Health Assessment Questionnaire), SF36 (Short Form-36) and Beck Depression Scale.

**Results:** There were significant improvement in the VO2 max, MET level, DAS28, HAQ, SF36- pain, Beck Depression Scale parameters in cardiac rehabilitation group when compared to home exercise group. There was no effect on mSCORE risk profile.

**Conclusions:** Cardiac rehabilitation improved physical fitness, functional outcomes and decreased disease activity but did not affect mSCORE risk profile. mSCORE risk analysis was seemed to be useful to evaluate cardiovascular risk for 10 years but not for appropriate tool for follow up of cardiac risk.

**Disclosure of Interest:** None declared

## SAT0113 IMPLEMENTATION OF THE TREAT-TO-TARGET STRATEGY LEADS TO DRAMATICALLY REDUCTION OF N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE LEVEL IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

I.G. Kirillova, D. Novikova, T. Popkova, Y. Gorbunova, E. Markelova, A. Volkov, E. Luchihina, N. Demidova, K. Kasumova, M. Kanonirova, G. Lukina, A. Novikov, E. Alexandrova, D. Karateev, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Objectives:** to study the effect of antirheumatic therapy administered in accordance with "treat-to-target" principles on NT-proBNP level in early rheumatoid arthritis (RA) patients (pts) during 18-month follow-up

**Methods:** A total of 66 early RA pts (ACR/EULAR criteria, 2010) were included in the study: 71% of women, age 56 [46;61] years, disease duration 6 [4;8] months; DAS28 5.3 [5.0;6.2], positive for ACCP (100%), RF (87%), without prior administration of DMARDs and glucocorticoides. The control group consisted of 27 healthy subjects, which were matched by sex and age. Methotrexate (MT) therapy was started in all pts with an escalation of the dose up to 30 mg/week subcutaneously. Incase of no remission 3 months (mon) later, MT was added with biologic therapy (BT): Adalimumab, Certolizumab pegol, Abatacept. After 18 mon 27 (41%) pts achieved remission. Antihypertensive therapy was administered in 51 (77%) pts: ACE inhibitors, ARBs, beta-blockers, calcium antagonists, diuretics. The normal range for NT-proBNP was less than 125 pg/ml.

**Results:** At baseline the concentration of NT-proBNP in early RA pts (125 [65;208] pg/ml) was higher than in control group (52 [40;69] pg/ml), $p<0,05$. In 32 (49%) RA pts NT-proBNP level were higher than normal. Pts with elevated NT-proBNP level compared to pts with normal one were older (60 [56;65] vs 50 [35;55] years), have a higher frequency of carotid atherosclerosis (85% vs 43%), coronary artery calcinosis (69% vs 22%), chronic heart failure (CHF) (20% vs 0%), ischemic heart disease (28% vs 5%), as well as a higher BMI (28 [24;31] vs 24 [22;29] kg/m$^2$), CRP (34 [13;78] vs 14 [3;41] mg/l), $p<0,05$ for all cases. The frequency of dyslipidemia, abdominal obesity, diabetes mellitus were not obtained between the groups. After 18 mon NT-proBNP level decreased from 125 [65;208] to 68 [33;115] pg/ml, $p<0,05$. There were also reduction in the number of pts with high NT-proBNP level from 49% to 21%, $p<0,05$. Pts who achieved remission showed a decrease in the number of pts with high NT-proBNP level (from 41% to 7%), $p<0,05$, and those who disease activity remained showed a decrease in the number of pts with high NT-proBNP level (from 54% to 31%), $p<0,05$. In group of MT+BT revealed a more pronounced decrease in NT-proBNP level (from 50% to 15%), $p<0,05$, than in group MT (46% vs 31%), $p>0,05$. The most pronounced decrease NT-proBNP level was in pts who achieved remission on MT+BT therapy (Tabl.1). There were correlation between $\triangle$NT-proBNP and $\triangle$CRP ($r=0,4$;$p<0,05$).

Table 1. The elevated NT-proBNP level depending on achieved RA activity and therapy

| | DAS28<2,6 (n=27) | | | | DAS≥2,6 (n=39) | | | |
|---|---|---|---|---|---|---|---|---|
| | MT (n=15) | | MT+BP (n=12) | | MT (n=11) | | MT+BP (n=28) | |
| | 0 mon | 18 mon | 0 mon | 18mon | 0 mon | 18 mon | 0 mon | 18 mon |
| NT-proBNP, n (%) | 5 (33%) | 2 (13%) | 6 (50%) | 0 (0%) | 7 (64%) | 6 (55%) | 14 (50%) | 6 (21%) |

**Conclusions:** At baseline NT-proBNP concentration in early RA pts were higher than in control group and its level correlated with age, traditional risk factors of cardiovascular disease (CVD), CVD, disease activity, markers of inflammation. Achieved remission especially in case of MT+BP therapy leads to a more pronounced reduction in NT-proBNP level. That can contribute to reduce the risk of CHF.

**Disclosure of Interest:** None declared

## SAT0114 THE IMPACT OF EDUCATION ON ADHERENCE TO TREATMENT WITH DISEASE MODIFYING ANTI-RHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS PATIENTS

I. Holc, A. Pahor, S. Gradišnik, K. Dai, M. Koren Krajnc, V. Kovačič Grobelšek, M. Dobnik. *Dept. of Rheumatology, UMC Maribor, Maribor, Slovenia*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disorder that typically affects small and medium sized joints in a symmetric manner. In RA joint damage with loss of function can occur. To reduce the risk of joint damage and functional impairment a high degree of adherence by patients to their prescribed regimen is necessary for optimal outcomes. However, poor adherence to drug is suspected in many patients.

**Objectives:** Identify potential determinants of adherence to disease modifying anti-rheumatic drugs (DMARDs) including the level of education in RA patients.

**Methods:** This survey was conducted in the outpatient Rheumatology department. 232 consecutive adult RA patients were included in a survey during their routine rheumatology appointments. RA patients fulfilled EULAR/ACR 2010 or ARA criteria for RA. Survey was designed to record adherence to different RA treatments using two questionnaires, one for a rheumatologist and one for a patient. The data from both questionnaires was entered into a database and statistically evaluated. All the analyses were performed in the R statistical software, version 3.2.2. (R Foundation for Statistical Computing, Vienna, 2015).

**Results:** The surveyed patient population was mostly female (79.7%) with a mean age of 59.3 years (SD=10, range 26–83). 64.3% of patients were rheumatoid factor (RF) positive. According to DAS-28, 7.5% of patients had high disease activity, 34.6% moderate, 21.1% low, and 36.8% patients were in remission. 62.8% of patients had secondary, 20.8% primary and 16.5% university degree of education. At the time of survey, 10% of patients were unemployed, 24% were working and 65.9% were retired. There were 63%, 73% and 88% patients with primary, secondary and university education, respectively, adherent to cs-DMARDS. Considering education there's borderline statistically significant difference in adherence in DMARDs' treatment ($p=0.0517$). The adherence to folic acid treatment was somewhat lower: 38%, 37% and 48% in patients with primary, secondary and university education, respectively. No impact of education on adherence was found in corticosteroid treatment group. No significances in adherence considering education were found in corticosteroid and folic acid treatment ($p=0.937$ in $p=0.629$). There seems to be no clear trend in adherence with respect to patient age, gender and marital status, while the unemployed patients seem to be less adherent in all therapies. We observed the lowest adherence in patients with high disease activity.

**Conclusions:** Education degree seems to be important factor considering adherence in RA patients treated with cs-DMARDS. The best adherence was observed in patients with highest education degree.

## SAT0115 CORRELATIONS BETWEEN RHEUMATOID ARTHRITIS ACTIVITY INDICES AND FACTORS AFFECTING ACUTE PHASE REACTANTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.H. Kim, I.A. Choi. *CHUngbuk National University Hospital, Cheongju, Korea, Republic Of*

**Background:** Assessment of disease activity is a key part of clinical decision in rheumatology care. High disease activity presented by DAS28 >5.1 is used as a cutoff for biologic use in many countries include Korea, while remission (DAS28 <2.6) is considered as a goal of therapy.
**Objectives:** We compared the DAS28ESR and DAS28CRP to other RA activity measures and were to find confounding factors affecting acute phase reactants to patients with rheumatoid arthritis to find best tool to access RA disease activity.
**Methods:** A cross-sectional study was conducted in 1120 patients with RA, using initial registration data from Korean Biologics Registry (KOBIO).
**Results:** In comparison of composite indices, DAS28CRP showed excellent correlation with SDAI (r =0.926, p<0.001), CDAI (r =0.901 p<0.001). DAS28ESR also showed good correlation with SDAI (r =0.875, p<0.001) and CDAI (r =0.886, p<0.001). In defining high disease activity, DAS28CRP showed an excellent agreement with DAS28ESR (kappa 1.000). However, in defining remission, DAS28CRP showed a fair agreement with DAS28ESR (kappa 0.317, 95%CI 0.137 to 0.497). Compared CDAI remission (≤2.8), DAS28ESR showed a fair agreement (kappa 0.331, 95%CI -0.014 to 0.675) and DAS28CRP showed a poor agreement (kappa 0.104, 95%CI -0.031 to 0.238).
In comparison of acute phase reactants to other disease activity measures, CRP showed low but significant correlation with SJC (r =0.132, p<0.001), TJC (r =0.087, p=0.004), SDAI (r =0.441, p<0.001), CDAI (r =0.134, p<0.001) and RAPID3 score (r =0.139, p<0.001). ESR also showed significant correlation with SJC (r =0.132, p<0.001), TJC (r =0.063, p=0.035), SDAI (r =0.233, p<0.001), CDAI (r =0.145, p<0.001) and RAPID3 score (r =0.166, p<0.001).
In correlation analysis using CDAI as controlled variable, ESR increased with age (r =0.110, p<0.001) and serum rheumatoid factor (r =0.105, p=0.001) but was not correlated with BMI, disease duration, and anti-CCP Ab titer. There was no difference in ESR according to the gender, smoking status, presence of diabetes mellitus, obesity (BMI ≥30) or low body weight (BMI <20).
In the same analysis, CRP was not correlated with age, BMI, disease duration, RF and anti-CCP antibody. It was higher in male compared to female (3.41 ± 3.60 vs 2.42 ± 4.08 mg/dL, p=0.001) and higher in ever-smoker compared to never-smoker (3.23 ± 3.46 vs. 2.48 ± 4.10 mg/dL, p=0.027). There was no difference in CRP according to the presence of diabetes mellitus, obesity (BMI ≥30) or low body weight (BMI <18.5).
**Conclusions:** Both DAS28CRP and DAS28ESR were well correlated with other activity indices and showed an excellent agreement in defining high disease activity. ESR increased with age but was less susceptible to gender or smoking status compared to CRP, suggesting DAS28ESR to be a more useful marker for inter-patient-comparison of RA disease activity.

## SAT0116 MORTALITY PROFILE OF PATIENTS WITH RHEUMATOID ARTHRITIS IN FRANCE AND ITS CHANGE IN 10 YEARS

J. Avouac[1], F. Amrouche[1], G. Rey[2], Y. Allanore[1]. *[1]Rheumatology A, Paris Descartes University, Paris; [2]CepiDc, INSERM, le Kremlin-Bicetre, France*

**Background:** Rheumatoid arthritis (RA) is associated with an excess of mortality. This risk depends on disease activity, severity and associated comorbidities.
**Objectives:** Our objective was to study the mortality profile of RA patients in France using multiple-cause-of-death analysis.
**Methods:** Data were collected between 2000 and 2011 in the French Epidemiological Center for the Medical Causes of Death database, and death certificates issued upon the death of an adult for whom RA was an underlying cause of death (UCD) or a non-underlying cause of death (NUCD) were evaluated using multiple-cause-of-death analysis. Sex, age, sex ratio, standardized mortality rates, as well as frequency of the various causes of death were assessed. For the main causes of death, the observed number of deaths in relation to the expected number of deaths (O:E ratio) was calculated.
**Results:** During the study period, 13,208 deaths related to RA were identified. RA was identified as the UCD in 4597 (35%) certificates. The number of certificates mentioning RA as the UCD decreased from 38 to 27% between 2000 and 2011. The mean±SD age at death was 79 ± 9 years (51% with ≥80 years). The female: male ratio was 3.2 and remained stable during the follow-up period. This ratio was significantly higher in the population where RA was the UCD (4.1 vs. 2.8 p<0.001). The mean standardized mortality rate was 0.25 per 1 million people (range 0.21–0.28), and remained stable throughout the period. When RA was the UCD (n=4,597), the main NUCDs were cardiovascular diseases (29%) and infectious diseases (22%). When RA was a NUCD (n=8,611), the most common UCDs were cardiovascular diseases (35% of certificates, including 877 patients with ischemic heart disease), neoplasms (15%), respiratory diseases (10%) and infectious diseases (7%). The overall O:E ratio was >1 for infectious (3.56), respiratory (1.40) and cardiovascular diseases (1.24), but was <1 for neoplasms.
**Conclusions:** This is the first national study using a multiple-cause-of-death analysis to study the mortality profile of patients with RA. Our results show that cardiovascular diseases are the most common UCD and NUCD associated with RA in France. These data strengthen the need to develop specific strategies for cardiovascular prevention to improve survival of patients with RA.

## SAT0117 QUALITY ASSESSMENT IN THE MANAGEMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS. IMPLEMENTATION OF THE "TREAT TO TARGET" STRATEGY

J.L. Andreu[1], M.A. Martín[2], J.J. Pérez-Venegas[3], J.-A. Román-Ivorra[4], H. Corominas[5], A. Gil[6], F. Sánchez-Alonso[2], T. Jiménez[6], M.A. Sánchez Ruiz[6]. *[1]Rheumatology, H.U. Puerta de Hierro, Majadahonda; [2]Unidad de Investigación, Sociedad Española de Reumatología, Madrid; [3]Rheumatology, Hospital de Jerez, Jerez; [4]Rheumatology, H.U. P. la Fe, Valencia; [5]Rheumatology, H.U. Moises Broggi, Barcelona; [6]Medicina Preventiva y Salud Pública, Universidad Rey Juan Carlos, Madrid, Spain*

**Background:** The current paradigm of optimal clinical management of patients with rheumatoid arthritis (RA) recommends reaching a state of remission or low activity of the disease, assessed by composite indexes of activity, by means of a tight control and a dynamic adjustment of available therapeutic options, using a "treat to target" strategy.
**Objectives:** The aim of this study is to assess the level of implementation of the "treat to target" strategy and other parameters of medical quality in clinical records (CRs) of RA patients in Spanish rheumatology departments.
**Methods:** Adult RA patients fulfilling 2010 ACR-EULAR criteria for RA and diagnosed between January 1st, 2010 and December 31st, 2013 in Spanish rheumatology departments were included. From every centre, 19 patients were randomly chosen from a computerized anonymized list provided by every department. Independent auditors assessed the CRs, verifying the fulfilling of the quality criteria included in an assessment tool specifically developed for this project. The study was approved by the ethic committees of every participant hospital. Descriptive statistics was used for the presentation of the results.
**Results:** A total of 856 CRs from 46 rheumatology departments were included. Patients' mean age was 54 years and 71% of patients were women. Mean duration of RA was 2 years. During the follow-up, 38% of patients reached a state of low disease activity, defined by DAS28 and/or SDAI. An explicit assessment of the disease activity as a determinant element considered to choose the therapy was recorded in 32% of the CRs. An optimal escalation of methotrexate dose was registered in 72% of the cases. Use of a composite disease activity score (DAS28, SDAI, CDAI) was reported in 61% of the cases. Disease activity monitoring every 6–8 months after reaching the therapeutic target was recorded in 73% of the cases. In 99% of the cases, the clinicians had registered patient's comorbidities and these associated conditions had been considered in planning the therapeutic approach and objective. In only 4% of the CRs, visits every 4 weeks using a composite activity score had been reported during the early stage while trying to reach remission after diagnosis. Starting a DMARD in the first two weeks after the first appointment with the rheumatologist was recorded in only 35% of the cases.
**Conclusions:** Currently, the implementation of the "treat to target" strategy is scarcely registered in clinical records of patients diagnosed with RA in Spanish rheumatology departments. A minority of patients is treated according to the "Treat to target" recommendations.
**Disclosure of Interest:** None declared

## SAT0118 DYSLIPIDEMIA IS UNDERTREATED IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM A LARGE COHORT OF RA PATIENTS IN DAILY CLINICAL PRACTICE

K. Thomas[1], A. Lazarini[1], E. Kaltsonoudis[2], A. Drosos[2], P. Katsimbri[1], D. Boumpas[1], P. Tsatsani[3], S. Gazi[3], E. Grika[1], P. Vlachoyiannopoulos[1], P.P. Sfikakis[1], K. Karagianni[4], L. Sakkas[4], L. Pantazi[5], K. Boki[5], T. Dimitroulas[6], G. Evangelatos[7], A. Iliopoulos[7], C. Georganas[8], P. Vounotrypidis[9], M. Areti[10], P. Georgiou[11], K. Mavragani[1], I. Bournazos[8], G. Katsifis[12], G. Kitas[1,13], D. Vassilopoulos[1]. *[1]Joint Rheumatology Program, University of Athens, Athens; [2]University of Ioannina, Ioannina; [3]KAT Hospital, Athens; [4]University of Thessaly, Larissa; [5]Sismanoglio Hospital, Athens; [6]Aristotle University, Thessaloniki; [7]NIMTS Hospital; [8]Private Practice, Athens; [9]Private Practice, Thessaloniki; [10]Private Practice, Livadia; [11]Agios Andreas Hospital, Patra; [12]Navy Hospital; [13]Hygeia Hospital, Athens, Greece*

**Background:** Existing guidelines advocate aggressive management of dyslipidemia in rheumatoid arthritis (RA) patients according to cardiovascular disease (CVD) risk scores generated for the general population (SCORE). More specific RA scores such as the ERS-RA score have not been extensively studied.
**Objectives:** To evaluate the use of lipid-lowering agents for CVD prevention (primary/secondary) in RA patients according to different CVD risk scores (SCORE, ERS-RA).
**Methods:** Prospective, multicenter (12 hospitals, 6 private offices), cross-sectional, epidemiological study in Greece (06/2015–01/2016, RA Study Group). Demographics, disease characteristics, treatment and comorbidities were collected and SCORE/ERS-RA were calculated.
**Results:** Among 1475 patients, 178 (12%) had CVD (44% coronary artery disease, 44% peripheral vascular disease, 27% stroke) and 43% were not receiving any hypolipidemic therapy. From those on therapy, only 12% achieved an LDL-cholesterol (LDL-C) level <70 mg/dl while 48% had LDL-C<100 mg/dl. 859 patients without CVD, diabetes or hypolipidemic therapy were further analyzed (79% women, mean age 59.5 yrs, mean disease duration 3.4 yrs, mean DAS28-ESR 3.4, mean HAQ 0.45). Complete data for SCORE calculation were available in 225/859 patients (26%). When stratified according to CVD risk, 31.5%, 66%, 2% and 0.5% of patients had a SCORE of <1% (low risk), ≥1 to <5% (moderate), ≥5 to <10% (high) and ≥10% (very high), respectively. In moderate risk (1–5%) patients, 78% had an LDL-C>100 mg/dl while among high or very high risk (≥5%) patients, 100% had an LDL-C>70 mg/dl (target groups for drug therapy). Among 996 patients (40–75 yrs old), without CVD events, there were 99 diabetic patients (10%) and less than half (48%) were on hypolipidemic therapy. For the rest, the ERS-RA score was calculated (619/897, 69% with available data); 50% of them (308/619) had a 10-year risk of ≥7.5% (therapeutic cutoff) but only 40% of patients in this group were being treated.
**Conclusions:** A substantial proportion of RA patients with established CVD or diabetes do not receive lipid-lowering therapy or they do not achieve therapeutic targets. Among those without CVD or diabetes, more than half belong to moderate to high CVD risk groups and are not receiving appropriate hypolipidemic therapy.

## SAT0119 COMPARISON BETWEEN CAROTID PLAQUE AND CAROTID INTIMA MEDIA THICKNESS TO DETECT SUBCLINICAL ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS

L. Riancho-Zarrabeitia[1], A. Corrales[1], M. Santos-Gómez[1], V. Portilla[1], R. Blanco[1], P. Dessein[2], M.A. González-Gay[1]. *[1]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [2]2Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa*

**Background:** Carotid plaque (CP) detected by ultrasonography and carotid intima-media thickness (cIMT) are useful surrogate markers for subclinical atherosclerosis and good predictors of cardiovascular disease in the general population and rheumatoid arthritis (RA).
**Objectives:** Our aim was to determine if cIMT may predict the presence of carotid plaques.
**Methods:** We evaluated 670 RA patients from NW Spain without previous history cardiovascular events. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7–12 MHz linear transducer and the *automated software guided technique radiofrequency – Quality Intima Media Thickness* in *real-time* (*QIMT*, *Esaote*, *Maastricht*, *Holland*). The cIMT was determined as the average of three measurements in each common carotid artery. The final cIMT was the largest average cIMT (left or right). Carotid plaque was defined according to the Manheim Consensus Conference criteria. Based on studies reported in non-rheumatic patients, a cIMT was considered as associated with high cardiovascular risk if it was ≥0.90 mm.
**Results:** Unilateral and bilateral carotid plaque frequency and cIMT values are summarized in table 1.
cIMT values were 0.619±0.105 mm in patients without plaques and 0.774 ± 0.161 mm in those with plaques (p<0.001).
Using 0.90 mm as the cIMT cut-off value for high cardiovascular risk, the sensitivity to detect carotid plaques was 21.2% and the specificity 99%. A ROC curve comparing the presence of carotid plaque and cIMT was performed, being the area under the curve 0.795.
The best cIMT cut-off point to determine the presence of plaques was considered as the one with the highest sensitivity and specificity. According to that, 0.670 mm was found to be the best cut-off point, being sensitivity and specificity for plaque detection 71.9% and 74% respectively. Positive predictive value for a cIMT ≥0.670 mm was 78.3% in our population, being 66.8% the negative predictive value.
Regarding bilateral plaques, a cIMT cut-off value of 0.90 mm had sensitivity of 27.7% and specificity of 96.6%. The ROC curve showed that the best cut-off point for bilateral plaque detection was also 0.670 mm with sensitivity 79.1% and specificity 64.2%.

Table 1

| Variable | | Variable | |
|---|---|---|---|
| Carotid plaque, n (%) | 379 (56.8) | Bilateral plaque, n (%) | 251 (37.6) |
| Unilateral plaque, n (%) | 128 (19.2) | cIMT (mean ±SD) mm | 0.71±0.16 |

**Conclusions:** In Spanish RA patients cIMT ≥0.670 mm is a good predictor of carotid plaques. Our study suggests the possibility of considering a cIMT lower than 0.90 mm as a predictor of high cardiovascular risk in RA.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4604

## SAT0120 COMPARISON BETWEEN CAROTID ULTRASONOGRAPHY AND CORONARY ARTERY CALCIFICATION SCORE TO DETECT SUBCLINICAL ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS

L. Riancho-Zarrabeitia[1], A. Corrales[1], J.A. Parra[1], M. Santos-Gómez[1], V. Portilla[1], P. Dessein[2], R. Blanco[1], M.A. González-Gay[1]. *[1]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [2]School of Physiology, University of the Witwatersrand, Johannesburg, South Africa*

**Background:** Carotid ultrasonography (CU) and coronary artery calcification score (CAC) evaluated by multidetector computed tomography (MDCT) scanner are useful in detecting subclinical atherosclerosis and are good surrogate markers of cardiovascular morbidity and mortality in general population and in rheumatoid arthritis (RA). In RA, a good correlation between both diagnostic methods has been demonstrated, being CU more sensitive for detecting subclinical atherosclerosis.
**Objectives:** Our aim is to determine the association between the presence of carotid plaque and CAC quantification, and, using the presence of carotid plaque as a reference, to determine the cut-off value of CAC score that better predicts subclinical carotid atherosclerosis.
**Methods:** We evaluated 127 RA patients without previous cardiovascular events. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), equipped with 7–12 MHz linear transducer and the *automated software guided technique radiofrequency – Quality Intima Media Thickness* in *real-time* (*QIMT*, *Esaote*, *Maastricht*, *Holland*). Carotid plaque was defined according to the Manheim Conference Consensus criteria. To determine CAC score, a CT Imaging of coronary arteries using a 32-slice MDCT scanner (Lightspeed, Pro 32, GE Healthcare, USA) was performed. A CAC score ≥100 was considered as a surrogate marker of very high cardiovascular risk.
**Results:** Unilateral and bilateral carotid plaque frequency and the mean CAC score in the different groups are summarized in table 1. Patients without carotid plaques had a mean CAC value of 23 ±49 [range 0–250], being 50 ±116 [0–569] in patients with unilateral plaque and 192± 302 [0–1205] in patients with bilateral plaques, being these differences statistically significant (p<0.001). Using a CAC score ≥100 as a marker of very high cardiovascular risk, the sensitivity to detect carotid plaques was very low (28%).
A ROC curve comparing the presence of carotid plaque and CAC quantification was performed, being the area under the curve 0.692. When we used CAC score value score ≥1 as the cut-off value to predict high cardiovascular risk, the sensitivity and specificity for the presence of carotid plaques increased (69.3% and 64.1%, respectively). Positive predictive value for CAC ≥1 was 81.3% in our population, being 48.1% the negative predictive value.
Regarding bilateral carotid plaques, the CAC score ≥100 had a sensitivity of 40%. ROC curve showed an area under the curve of 0.712. Using a CAC score value score ≥1 as the cut-off value to predict high cardiovascular risk, the sensitivity to determine the presence of carotid plaques increased to 76.4% but the specificity decreased to 54.2%.

| Variable | | Variable | |
|---|---|---|---|
| Age (mean ± SD) | 58, 57±9,7 | Bilateral plaque, n (%) | 55 (43,3) |
| Female, n (%) | 92 (72,4) | CAC (media ± DE) | 103,4±222,6 |
| Plaque No, n (%) | 39 (30,7) | CAC ≥1, n (%) | 75 (59) |
| Plaque Yes, n (%) | 88 (69,3) | CAC ≥100, n (%) | 26 (20,5) |
| Unilateral plaque, n (%) | 33 (26) | | |

**Conclusions:** A CAC score value score ≥1 is good predictors of carotid plaques, showing sensitivity close to 70%. Our data support the use of a CAC score

value score ≥1 instead of a CAC score ≥100 as the cut-off value to predict high cardiovascular risk in patients with RA.

## SAT0121 THE EFFECT OF TYPE 2 DIABETES ON DISEASE ACTIVITY IN MALE AND FEMALE RHEUMATOID ARTHRITIS PATIENTS

L. Nieuwenhuis, V. Brown, C. Popa, J. Fransen. *Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** Rheumatoid arthritis (RA) patients with comorbidities are likely to have higher disease activity (DAS28) scores than patients without comorbidities[1–3]. Diabetes has been recently suggested to associate with higher disease activity in a large group of RA patients[4]; however, it is still uncertain how baseline diabetes affects RA disease activity and remission percentages in RA[5]. This is important and information might be used to improve treatment strategies.
**Objectives:** To investigate the effect of having type 2 diabetes on DAS28 scores and RA remission percentages in male and female RA patients during the first year after RA diagnosis.
**Methods:** Data were retrieved from the prospective Nijmegen Early RA cohort. Patients fulfilled the ACR or ACR-EULAR classification criteria. The course of disease activity (DAS28) over the first year after RA diagnosis was the primary outcome. Secondary outcome was RA remission one year after diagnosis (DAS28 score <2.6)[6]. Presence of diabetes was defined by physician diagnosis. Statistical analyses comprised mixed linear models and logistic regression. Potential confounders included smoking, BMI, alcohol intake, age, HAQ score and rheumatoid factor at baseline. Gender was treated as effect modifier.
**Results:** 35 (4.2%) out of the 840 included patients had DM2 at baseline. Mean DAS28 values at baseline were 5.33 (SE 0.20) for diabetic and 5.04 (SE 0.05) for non-diabetic patients (p<0.21). At baseline only age was relevantly different between non-diabetic and diabetic patients in univariable analyses (53.8 (SE 0.50) versus 56.0 (SE 2.44) years, p=0.04), and was therefore included as confounder in the analyses. The difference in DAS28 scores during the first year after RA diagnosis between diabetic and non-diabetic patients is presented in Table 1.The parameter estimate of the interaction between gender and DM2 was -0.08 (SE 0.41), indicating no statistically significant interaction (p=0.85). Moreover, after one year, four (11.8%) diabetic and 186 (23.1%) non-diabetic patients were in remission. Table 1 presents the effect of DM2 on achieving remission one year after RA diagnosis, which was not statistically significantly different for males and females (parameter estimate 1.36, SE 1.24, p=0.28).

Table 1. Differences in DAS28 scores and OR for achieving RA remission during the first year after RA diagnosis between diabetic and non-diabetic patients

| | Crude effect | P | Adjusted effect* | P |
|---|---|---|---|---|
| Difference in DAS28 score (SE) | | | | |
| DM2 versus no DM2 | 0.00 (0.00) | 0.89 | 0.00 (0.00) | 0.95 |
| OR for achieving remission at 1 year after RA diagnosis (95% CI) | | | | |
| DM2 versus no DM2 | 0.44 (0.15–1.28) | 0.13 | 0.21 (0.03–1.59) | 0.13 |

*Adjusted for gender, age, and interaction between gender and DM2. α=0.05. CI, confidence interval; DM2, diabetes mellitus type 2; SE, standard error.

**Conclusions:** There was no large influence of having DM on baseline DAS28, response in DAS28 scores and remission percentages during the first year after RA diagnosis; this was the same for male and female patients.

## SAT0122 COMORBIDITIES IN A MEXICAN MESTIZO COHORT OF PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

L. Pérez-Barbosa[1], I.J. Colunga-Pedraza[1], J.C. Riega-Torres[1], R.I. Arvizu-Rivera[2], A. Martínez-Moreno[3], F.J. Torres-Quintanilla[2], M.A. Garza-Elizondo[1]. *[1]Rheumatology; [2]Internal Medicine; [3]Cardiology, Hospital Universitario, UANL, Monterrey, Mexico*

**Background:** Patients with rheumatoid arthritis (RA) are at an increased risk of comorbidities and it has been linked to a decrease in life expectancy in comparison with the general population. Early recognition and treatment of comorbidities is important.
**Objectives:** We aimed to evaluate the presence of comorbidities in a Mexican mestizo cohort of patients with early-RA.
**Methods:** A descriptive, cross-sectional study of patients with early-rheumatoid arthritis (disease duration <12 months) was designed. Information on comorbidities, weight, height and body mass index (BMI) was collected.
**Results:** Data of fifty patients was included in the final analysis, 46 (92.0%) of them were women. Patient's characteristics are shown in Table 1. Mean age was 44.3 ± 13.12 years. Mean disease duration was 6.09 ± 2.91 months. Tuberculosis (TB) infection was found in 12 (24.0%) patients, 7 (58.3%) of them were latent tuberculosis infection. Four cases of extra-pulmonary TB were reported. Hypertension was the second most prevalent comorbidity, being reported in 11 (22.0%) patients.

| Table 1. Patient's characteristics | |
|---|---|
| Women, n (%) | 46 (92.0%) |
| Age (yo), mean ± SD | 44.30 ± 13.12 |
| Disease duration (months), mean ± SD | 6.09 ± 2.91 |
| Body mass index, mean ± SD | 28.60 ± 5.48 |
| Type 2 diabetes mellitus, n (%) | 6 (12.0%) |
| Smoking, n (%) | 9 (18.0%) |
| Dyslipidaemia, n (%) | 4 (8.0%) |
| Hypertension, n (%) | 11 (22.0%) |
| Tuberculosis infection, n (%) | 12 (24.0%) |
| | n= 50 |

**Conclusions:** In this cohort of Mexican mestizo patients with early-RA, TB infection was found in 24.0% of the patients. Hypertension was the second most prevalent comorbidity in our cohort, being reported in 22.0% of the patients. Other cardiovascular heart disease risk factors were also reported. Early recognition of these comorbidities is needed because of the higher risk of cardiovascular heart disease in RA-patients in comparison to the general population.

## SAT0123 RADIOGRAPHIC SEVERITY OF RHEUMATOID ARTHRITIS IN LATIN AMERICAN PATIENTS: RESULTS FROM THE GLADAR COHORT

L. Massardo[1], F. Schweitzer[1], C. Pineda[2], B. Pons-Estel[3], M. Cardiel[4], E. Soriano[5], C. Galarza[6], R. Levy[7], M. Sacnum[3], C. Caballero-Uribe[8], W. Bianchi[9], H. Gonzalez[10], R. Montufar[11], R. Pinto[12], L. Ramirez[13], C. Zerbini[14], I. Laurindo[15], I. Barra[1] on behalf of GLADAR. *[1]Pontificia Universidad Católica de Chile, Santiago, Chile; [2]Instituto Nacional de Rehabilitacion, Mexico DF, Mexico; [3]Hospital Provincial de Rosario, Rosario, Argentina; [4]Hospital General Dr. Miguel Silva, Morelia, Michoacan, Morelia, Mexico; [5]Hospital Italiano de Buenos Aires y Fundacion Dr. Pedro M. Catoggio Para el Progreso de la Reumatología, Buenos Aires, Argentina; [6]Centro de Lupus, Cuenca, Ecuador; [7]Universidade do Estado do Rio deJaneir, Rio de Janeiro, Brazil; [8]Universidad del Norte, Barranquilla, Colombia; [9]Santa Casa, Rio de Janeiro, Brazil; [10]CM Imbanaco, Cali, Colombia; [11]ISSS, San Salvador, El Salvador; [12]UF Minas Gerais, Belo Horizonte, Brazil; [13]Universidad de Antioquia, Medellin, Colombia; [14]Hospital Heliopolis; [15]Universidad de Sao Paulo, Sao Paulo, Brazil*

**Background:** More radiographic damage occurs within the first year of rheumatoid arthritis (RA). Erosions occurring preferentially in feet and joint space narrowing (JSN) in wrists have been described in early RA. Little is known of radiographic progression in Latin American patients with early RA.
**Objectives:** To describe radiographic changes in a Latin American (LA) early rheumatoid arthritis (RA) multinational inception cohort at baseline, a multicenter observational study.
**Methods:** Patients were enrolled in GLADAR (*Grupo Latino Americano de estudio De Artritis Reumatoide)*, the largest longitudinal cohort of early RA (<1 year from onset) in LA, from 2004/2005–2008. Demographic and clinical data were obtained and sets of hand/wrist and foot radiographs were scored using the modified Sharp/ Van der Heijde scoring system.
**Results:** A total of 507 patients with radiographic readings were evaluated. The mean radiographic score was 23.37 at baseline visit; 56.2% had erosions and 97.8% joint space narrowing (JSN). Among patients with JSN, the mean score was 20.97. JSN occurred in hands/wrists (97%) and feet (72%), while erosions were observed in hands/wrists (42.8%) and feet (28.8%). X-rays of 253 patients were assessed after at one-year of follow-up; of 132 without erosions, 14.4% developed erosions; and 100% JSN. No significant differences were observed among patients who progressed according to socio-demographic features, use of DMARDS, use of prednisone and rheumatoid factor positivity.
**Conclusions:** This is the largest radiographic study of Latin American RA patients. Damage occurs early in the disease. Surprisingly, JSN is the most common radiographic change and occurs more often in hands/wrist. Further studies are needed to understand the meaning of the greater breakdown in cartilage compared to erosions in this population.

## SAT0124 RISK FACTORS OF VENOUS THROMBOEMBOLIC EVENTS IN PATIENTS WITH RHEUMATHOID ARTHRITIS (RA)

M.A. Satybaldyeva, N.S. Seredavkina, S. Glukhova, D. Karateev, T. Reshetnyak, E. Nasonov. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Venous thromboembolic events (VTE) such as deep vein thrombosis, thrombophlebitis and thromboembolism of pulmonary artery are an important clinical problem that concerns all spheres of medicine. Patients with chronic inflammatory diseases including RA have an increased risk of venous thromboembolism. It is important to determine risk factors of VTE in patients with RA (standard and associated with disease) for prevention of thrombosis.
**Objectives:** To determine prognostic risk factors of venous thromboembolic events in patients with rheumathoid arthritis.
**Methods:** 362 patients (F:302, M:61) with definite diagnosis of rheumathoid arthritis were analyzed, 53,7 ± 13,3 years old, duration of disease 12,4 ± 10,9 years. All patients were hospitalized in V.A. Nasonova Reasearch Institute of Rheumatology. Doppler ultrasound of lower limbs veins were done to patients with suspected thrombosis or with thrombosis in past history. Patients were divided in 2 groups: 1st Gr included patients with thrombosis in a moment or in past history – 34/362 (9,9%) and 2nd Gr - patients and without thrombosis – 328/362 (90,1%). Analysis of risk factors was done according to questionnaire survey and medical history. Disease activity was expressed as DAS28 score which is a composite score derived from tender joint count, swollen joint count, ESR and patient's global assessment of disease activity. Possible prognostic risk factors included age (>40 years, >60years, >75 years), body mass index (BMI) >30, smoking, pregnancy and childbirth, taking antifertility agents, immobilization, surgical treatment, traumas, fractures, diabetes mellitus, pulmonary diseases, cardiac failure, varicose vein disease, cancer, oral and intra-articular (<5 and >5 injections) introduction of glucocorticoids (GCs). In order to identify predictors of venous thromboembolic events we used multivariance analysis (discriminant function classification).
**Results:** Multivariance analysis showed that the thrombosis is mainly influenced by following factors: immobilization, cardiac failure, varicose vein disease, oral and intra-articular (>5 injections) introduction of GCs; weighted coefficients: 1,0; 0,92; 3,13; 0,02; 0,52. Function of prediction of thrombosis is suggested:
Z =1,0 * immobilization (Yes-1/No-0) + 0,92* cardiac failure (Yes-1/No-0) + 3,13* varicose vein disease (Yes-1/No-0) + 0,02* oral GCs (yes-1/No-0) + 0,52* intra-articular (>5 injections) introduction of GCs (Yes-1/No-0).
The value of function Z=1,65 divides patients with and without venous thromboembolic events, sensitivity 64%, specificity 82%, positive predictive relevance 80%.
**Conclusions:** Adverse prognostic factors of venous thromboembolic events in patients with rheumathoid arthritis are immobilization, cardiac failure, varicose vein disease, oral and intra-articular (>5 injections) introduction of GCs.
**Disclosure of Interest:** None declared

## SAT0125 TOCILIZUMAB ACHIEVES RAPID REDUCTION OF DISEASE ACTIVITY AND HAS BENEFICIAL EFFECTS ON BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS – RESULTS OF A PROSPECTIVE 5- YEAR STUDY

M. Höhle. *Orthopedic, internal, rheumatologic Center, Hamburg, Germany, Hamburg, Germany*

**Background:** Tocilizumab (TCZ) leads to a rapid improvement of the clinical course in patients with highly active rheumatoid arthritis (RA). However, a residual rheumatic activity can still be detected.1 RA is a known risk factor for osteoporosis related bone fractures.2 It is well established that TCZ has beneficial effects on bone remodeling.3
**Objectives:** The aim of this analysis was to investigate the effects of TCZ on bone mineral density in a real world patient population.
**Methods:** 50 rheumatoid factor positive patients with RA (17 male, age 20–72 years) who received TCZ as monotherapy since 2008 were prospectively investigated. At baseline and the following 4–6 clinical visits, DAS28 was determined and ultrasound performed. At baseline and every 6 months thereafter, biochemical parameters for bone metabolism and protein diagnostics were recorded. Once a year, the subjects underwent MRI, CT and DXA scan.
**Results:** In all 50 patients the DAS28 normalized at the latest by the 3rd infusion cycle of TCZ. The initial RAMRIS score of >5 was reduced to <2 after 6–18 months. Ultrasound revealed a decline of synovialitis and tenodynovialitis after 8 weeks and 12 months, respectively. At baseline in 22 women with early RA, axial QCT/DXA values and lateral DXA values were within reference. 3 patients with early RA had osteopenia, 2 had osteoporosis. Patients with manifest RA had a BMD in the reference range, 3 had osteopenia and 2 were diagnosed with osteoporosis. In 6 male patients, BMD values were within the reference range. 2 men with early RA had osteopenia and 2 had manifest osteoporosis. In 1 male patient with manifest RA, normal BMD values were documented. 2 men with manifest RA hat osteopenia and 4 had osteoporosis. 10 patients had vitamin D3 deficiency and were treated with vitamin D3. 2 patients with osteoporosis were treated with antiresorptive medication. In all patients, BMD values were within the reference range after 1 year of treatment with TCZ, despite 18% of patients presenting with a DAS score >2.7. 2 patients presented with pustular dermatosis in the palms. No allergic reactions were observed.
**Conclusions:** Treatment with TCZ leads to a rapid decline of inflammatory activity of the affected joints in patients with RA and minimizes cartilage destruction. TCZ showed a positive effect on bone remodeling and therefore BMD. Thus, the risk for the development of osteoporosis and its related fractures can be minimized by TCZ treatment. Furthermore, TCZ has a positive effect on BMD in manifest RA thus preventing sarcopenia. Temporary elevations of DAS28 during TCZ therapy do not negatively affect BMD.

## SAT0126 COMORBIDITIES AFTER DAILY CONCOMITANT TREATMENT WITH 10MG PREDNISONE OR PLACEBO IN THE 2-YEAR COMPUTER ASSISTED MANAGEMENT IN EARLY RHEUMATOID ARTHRITIS TRIAL-II

M.J. De Hair, M. Safy, N. Ijff, J.W. Jacobs, J.M. van Laar on behalf of the whole Society for Rheumatology Research Utrecht (SRU). *Department of Rheumatology & Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands*

**Background:** In the second Computer Assisted Management in Early Rheumatoid Arthritis (CAMERA–II) trial, patients initiated treatment with methotrexate (MTX) with randomized 10 mg/d prednisone (pred) or placebo (plac), given for 2 years [1]. Significantly more patients in the MTX+pred strategy arm than in the MTX+plac arm were erosion free at 2 years, and disease activity improved faster. The frequency of adverse events (AE) during the 2 year trial was comparable between the groups. There is paucity of data on long-term AEs after treatment with medium dose of glucocorticoids, however.
**Objectives:** To investigate the incidence of long-term AEs/comorbidities in early rheumatoid arthritis patients, who had been treated additionally with pred10 mg/day or plac in CAMERA-II.
**Methods:** After the 2 year trial, patients were followed according to a protocol in clinical care. The occurrence of AEs/comorbidities and the use of pred (it was the strategy to taper and stop it) was collected retrospectively from the medical charts. The incidence of long-term AEs/comorbidities in the former MTX+pred group was tested versus that in the former MTX+plac group using Fisher's Exact tests.
**Results:** Of the 236 patients included in the CAMERA-II trial, follow-up data was available of 218 patients: MTX+pred N=107, MTX+plac N=111; no longer followed according to protocol N=18. The median follow-up time after the end of the 2-year trial period was 6 (range 0–9) and 6 (0–11) years, respectively. 86 (80%) patients treated with pred could discontinue it after a median of 9 months after the end of the trial end. The percentage of patients with AEs/comorbidities is shown in Table 1. No statistically significant differences between the two groups were found.

Table 1. Percentage of new onset AEs/comorbidities after the trial in the former pred vs former plac group

| Comorbidity | MTX + pred (N=107) | MTX + plac (N=111) | p-value |
|---|---|---|---|
| ≥1 comorbidity | 36 | 36 | 1.00 |
| Hypertension | 4 | 10 | 0.11 |
| Diabetes Mellitus type II | 3 | 2 | 0.68 |
| Cardiovascular disease | 13 | 8 | 0.27 |
| Peptic ulcer | 1 | 0 | 0.49 |
| Cataract | 8 | 7 | 0.80 |
| Glaucoma | 0 | 1 | 1.00 |
| Fracture | 11 | 14 | 0.55 |
| Osteonecrosis | 0 | 0 | – |
| Mortality | 10 | 6 | 0.33 |

**Conclusions:** Of patients in the MTX+pred group during CAMERA-II, 80% could discontinue pred after the trial. There was no increased incidence of long-term AEs/comorbidities in the former MTX+pred group.

## SAT0127 CHILD OUTCOME AFTER CERTOLIZUMAB PEGOL EXPOSURE IN RHEUMATOID ARTHRITIS PREGNANCIES: A CASE SERIES REPORT

M. Meroni[1], V.L. Ramoni[2], A.L. Brucato[2], M. Limonta[3], M. Ostensen[4], M. Cutolo[5]. *[1]Rheumatology Unit, Internal Medicine Unit, Papa Giovanni XXIII Hospital; [2]Internal Medicine Unit, Papa Giovanni XXIII Hospital; [3]Rheumatology Unit, Papa Giovanni XXIII Hospital, Bergamo, Italy; [4]Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Trondheim, Norway; [5]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy*

**Background:** About 25% of pregnant RA patients remain active during pregnancy and need continuation of effective therapy to maintain low disease activity [1]. Recent evidence supports the use of TNF inhibitors (TNFi) to achieve these goals [2]. The overall safety of TNFi exposure during pregnancy has been demonstrated [3–4]. Certolizumab pegol (CZP) has received particular interest because of its low transplacental transfer, an advantage compared to several other TNFi [5]. A recent study analyzing CZP exposure during gestation has not shown harmful effects on pregnancy outcomes [6]. Since there are few data on child outcome, our case series adds observations on the safety of CZP in pregnancy.
**Objectives:** The study purpose consists in assessing CZP exposure safety during pregnancy in a group of RA patients.
**Methods:** During a 48 months period, we retrospectively evaluated 8 RA patients exposed to CZP in the 1st and/or the 2nd trimester of pregnancy. All patients had signed an informed consent regarding the potential risk of biologic agents for the fetus. Details regarding demographic and clinical presentation as well as pregnancy outcome and child health were collected. Data on child development during the first 6 months of life were obtained.
**Results:** The eight enrolled patients had been treated with CZP for 6 to 18 months. Three patients received methotrexate (MTX) and other TNFi (infliximab or etanercept) before pregnancy, which were discontinued 6–24 months before conception.
During pregnancy all patients were treated with the standard dose of CZP 200 mg every 2 or 3 weeks. In addition, all patients received low-dose prednisone ranging from 5±2.5 mg daily. Two subjects were in addition on sulfasalazine 500 mg x 3/day, and three others on hydroxychloroquine (HCQ) 200 mg twice daily. In 6/8 patients, CZP treatment was continued throughout the first trimester. In 2 cases high disease activity required continuation of CZP until the end of the second trimester.
No obstetric, neonatal or perinatal severe complication was observed. Except for one SGA child all neonates were healthy at birth. One child was hospitalized at the age of 4 months for disseminated Candida albicans infection, but recovered completely with amphotericin B treatment. All other children developed normally during the first 6 months of life. None of the newborn was breastfed, due to the lack of data on safety. All babies were vaccinated according to the mandatory Italian schedule (includes no live vaccine during the first 6 months of life); one child had the 5th month dose postponed to the 6th month of life.
**Conclusions:** The limits of our case series consist in the small numbers and the lack of measuring CZP levels in cord blood. However, our data add to the experience that CZP might be considered in pregnant RA patients when disease activity requires continuation of therapy throughout pregnancy.

## SAT0128 SECONDARY SJÖGREN'S SYNDROME IN RHEUMATOID ARTHRITIS: CHARACTERISTICS AND ASSOCIATION WITH JOINT DAMAGE

O. Akkar, L. Ichchou. *Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco*

**Background:** Rheumatoid Arthritis (RA) is often associated with secondary Sjögren's syndrome (SSs) with a prevalence ranging from 10 to 30 percent.
**Objectives:** The aim of this study was to evaluate the prevalence of SSs, characterize sSS patients and study the association between sSS and joint damage.
**Methods:** We conducted a cross-sectional study of RA patients, according to ACR/EULAR 2010 classification criteria, followed up at the Department of Rheumatology. Demographic characteristics and RA features of disease were collected. Pain was measured using a visual analogue scale (VAS). Disease activity was assessed by the Disease Activity Score (DAS 28). Functional disability was evaluated by the Health Assessment Questionnaire (HAQ). Joint destruction was assessed by the van der Heijde-modified Sharp Score. The diagnosis of SSs was made by a rheumatologist or confirmed by chart review. Data analysis was carried out using the SPSS 20 Software. $p<0.05$ was considered statistically significant.
**Results:** One hundred and four patients with a mean±SD age of 49.37 ± 13.21 years were enrolled. Eighty-nine percent were females. Mean±SD duration of symptoms was 10.88 ± 9.17 years. Rheumatoid factor was present in 75% of patients with RA. Seventeen patients (16.3%) had SSs. RA subjects with sSS had longer RA disease duration and higher sharp scores. VAS pain and functional disability were significantly higher in patients with sSS ($p<0.05$). The multivariate analysis showed that factors associated with joint destruction in patients with SSs were disease duration of RA (p=0.0001) and seropositivity by ACPA (P=0.006).
**Conclusions:** In our study, RA patients with sSS had worse joint damage, suggesting that sSS is a marker of a more aggressive disease. Therefore, it is important to screen sSS symptoms in patients with RA.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5077

## SAT0129 VITAMIN D STATUS AND ITS ASSOCIATION WITH DISEASE ACTIVITY, SEVERITY AND PHYSICAL DISABILITY IN RHEUMATOID ARTHRITIS PATIENTS

O. Akkar, L. Ichchou. *Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco*

**Background:** Vitamin D has immunomodulatory effects in a wide range of human autoimmune diseases; including Rheumatoid Arthritis (RA). Vitamin D deficiency is common in RA.
**Objectives:** The objective of this study was to evaluate vitamin D status in RA patients and assess the relationship between vitamin D levels, disease activity, severity and physical disability.
**Methods:** We included in this cross-sectional study patients with RA according to ACR/EULAR classification criteria, followed up at the Department of Rheumatology. Demographic characteristics and disease specific variables were collected. Disease activity was assessed by the Disease Activity Score (DAS 28). Functional disability was evaluated by the Health Assessment Questionnaire (HAQ). Joint destruction was assessed by the van der Heijde-modified Sharp Score. Serum concentrations of 25(OH) Vitamin D were measured. According to the GRIO recommendations, 25(OH)D insufficiency was defined as 25(OH)D ranging from 10 to 30 ng/mL, and deficiency as 25(OH)D $<10$ ng/mL. Data analysis was carried out using the SPSS 20 Software. $p<0.05$ was considered statistically significant.
**Results:** Seventy-tree patients with a mean±SD age of 52.04 ± 12.26 years were enrolled. Sixty-nine percent were females. Mean±SD duration of symptoms was 11.61 ± 8.43 years. The prevalence of 25(OH)D insufficiency and deficiency was 69.9% and 17.8% successively. The univariate analysis showed a significant correlation between 25(OH)D serum concentration, number of swollen joints (p=0.024) and disease activity (p=0.012). In multivariate analysis adjusted for age, Sharp score, and C-Reactive Protein, there was a significant correlation between 25(OH)D serum concentration and disease activity (p=0.048).
**Conclusions:** Vitamin D deficiency is highly prevalent and is associated with higher disease activity in our RA patients. Therefore, Vitamin D measurement and possibly vitamin D supplementation should be considered in the management of RA patients.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5083

## SAT0130 DRUG USAGE ANALYSIS AND COMPARATIVE MEDICATION EXPENSES IN PATIENTS WITH RHEUMATOID ARTHRITIS USING CONVENTIONAL OR BIOLOGICAL THERAPY

A. Aza[1], A. Cardozo[1], P. Santos-Moreno[2], L. Villarreal[3], G. Ballesteros[2], J. Bello[2], E. Castillo[2], R. Giraldo[2], D. Gomez[2], A. Lopez[4], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Health services; [2]Rheumatology; [3]Psychology; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** In the last years it has seen a marked improvement in the treatment of rheumatoid arthritis (RA) by using conventional DMARDs and more recently with the introduction of biologics; biological therapy is useful to prevent clinical and radiological progression in patients with RA but is associated with high costs and has impacted budget in Colombian health system.
**Objectives:** The purpose of this study was to assess drug usage of conventional treatment and biologic agents in terms of reduction of the Disease Activity Score 28 (DAS28) and comparative medication expenses associated in patients with moderate-severe RA during a 24 month period.
**Methods:** We conducted a real-world, retrospective, cross-sectional study, based on information from a specialized in RA center in Colombia where there is a model with therapeutic goals like T2T and a multidisciplinary approach. Subjects with moderate-severe disease activity received conventional treatment or biologic

therapy, and were followed-up and treated according to DAS28; therapy had to be adjusted with DAS28 >3.2 unless the patient's conditions did not allow it. Descriptive epidemiology was done and the overall drug costs were assessed and compared between the two types of therapies.
**Results:** 526 patients using conventional treatment were included, mean age 63.5 ± 11.8, 424 (80%) female and 102 (20%) male. These patients had a DAS28 on average 4.5 ± 1 at beginning and after 24 months 410 patients (78%) got remission/low disease activity status with a mean DAS28 2.57 ± 1. On the other hand, 303 patients using biologics were included, mean age 58.5 ± 9.4, 251 (82%) female and 52 (18%) male; after 24 months of observation 154 patients (50%) obtained remission/low disease activity status with a mean DAS28 of 2.6 ± 1. Cost of conventional DMARD treatment for RA in Colombia was about 850 US dollars/patient/year because mostly of patients have more than one DMARD; use of biologics cost $7,725 US dollars/year/patient, ranging between the cheapest biological and the most expensive ($4,878 and $12,774 US dollars/year respectively); that means conventional treatment is nine times cheaper in comparison with costs of biological therapy and possibly more effective.
**Conclusions:** This study showed that it is possible to decrease disease activity and obtain a significant cost-reduction in treatment of RA by using conventional DMARDs in a model with therapeutic goals like T2T and optimizing a multidisciplinary approach; the use of biologic therapies in the treatment of RA continues being evaluated but is associated with high costs; we show real-world data on drug utilization in patients with moderate-severe RA in a low income developing country. These observations could be used by decision makers in order to consider health decisions; nonetheless, further research based on cost-effectiveness analysis and cost-comparison is needed to verify these results.
**Disclosure of Interest:** None declared

## SAT0131 A LOOK TO THE WRONG DIAGNOSIS OF RHEUMATOID ARTHRITIS

N. Palacio[1], D. Buitrago-Garcia[2], C. Castro[2], P. Santos-Moreno[3], L. Villarreal[4], G. Ballesteros[3], J. Bello[3], E. Castillo[3], R. Giraldo[3], D. Gomez[3], A. Aza[5], A. Lopez[6], A. Cardozo[5]. *[1]Nursing; [2]Epidemiology; [3]Rheumatology; [4]Psychology; [5]Health services; [6]Pharmaceutical chemist, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** There is a lack of expertise in rheumatoid arthritis (RA) diagnosis in primary level of Colombian medical centers, leading to misdiagnosis; many times osteoarthritis (OA) and another rheumatic diseases are misdiagnosed as RA which derives in wrong treatment for patients with clinical and health economics implications.
**Objectives:** The aim of this study was to describe demographic and clinical characteristics of a cohort of patients with misdiagnosis of RA in a specialized center in Colombia.
**Methods:** A descriptive, cross sectional study. Were included patients who were referred from primary care centers to a RA specialized center in a 48 month period with presumptive diagnosis of this disease. Each patient was evaluated to confirm or rule-out diagnosis of RA as follows: a rheumatologist fulfilled a complete medical record including all previous data; it was assessed rheumatoid factor and anti-citrullinated antibodies, and other laboratories depending on each case. Also were made x-rays of hands and feet, and in some cases of persistent doubt about the diagnosis was requested comparative MRI of hands or/and feet. Frequencies and percentages were calculated for the demographic and clinical characteristics of the cohort of patients in which the diagnosis of RA was ruled-out.
**Results:** In 5176 patients was found a wrong diagnosis of RA. Of these misdiagnosed patients, 4.385 (85%) were women, and 791 (15%) men, with an average age of 59 ± 13 years old. Between differential diagnosis which were found in this cohort of misdiagnosed patients: osteoarthritis in 2930 patients (56.6%), systemic lupus erythematosus (SLE) in 369 patients (7.1%), Sjögren syndrome in 237 patients (4.6%), spondyloarthropathies in 135 patients (2.6%), gout in 95 patients (1.8%), and in 28.3% of cases other diagnoses including all kinds of soft tissue rheumatism.
**Conclusions:** Almost half patients with presumptive RA diagnosis in primary care centers in Colombia are misdiagnosed. The most important cofounding diagnosis was osteoarthritis and many patients were receiving DMARDs for treatment. For this reason there is an urgent need of education strategies for primary care physicians and the implementation of centers of excellence in RA, in order to conduct a proper diagnose and avoid clinical and health economics consequences of misdiagnosis.

## SAT0132 PRESENCE OF PSYCHOLOGICAL, SEXUAL AND SLEEP DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Santos-Moreno[1], L. Villarreal[2], G. Ballesteros[1], J. Bello[1], E. Castillo[1], R. Giraldo[1], D. Gomez[1], A. Aza[3], A. Lopez[4], A. Cardozo[3], N. Palacio[5], C. Castro[6], D. Buitrago-Garcia[6]. *[1]Rheumatology; [2]Psychology; [3]Health services; [4]Pharmaceutical chemist; [5]Nursing; [6]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** The rheumatoid arthritis (RA), as known, causes inability in various performance areas mostly in the musculoskeletal, but few is known about psychological, sleep and sexual problems.
**Objectives:** The aim of this study is to describe the socio-demographic profile of patients with RA in specialized RA clinic in Colombia, where we identified disorders in areas besides the physical or musculoskletal, like psychological, sexual and sleep.
**Methods:** A descriptive study was performed in a specialized clinic dedicated to care patients with RA. 1298 RA patients were included in the study, which were seen by the area of psychology; information was collected through semi-structured interviews and non-probability sampling, also using classificatory criteria of pathologies described in CIE 10 diagnostic manual, applying descriptive epidemiology for continuous variables, measure of central tendency and dispersion for qualitative and categorical variables through percentages and averages.
**Results:** Total sample of patients was 1298, 1048 (80%) were women and 250 (19%) were men. Patients had a DAS28 2.6 in average ± 1.1; mean age was 55.1 ± 8.8 years; 58% of patients were medium socio-economical level and the 34% were low socio-economical level; 59% were married, 18% were divorced, 14% is single and 6% were widowed. Related with the occupation, 25% were retired because age and 10% had handicap retirement pay; 24% were dedicated to housekeeping and 35% were working. Related to education 6% were illiterate, 44% had elementary school, 33% high school, 8% had a technical degree and only 7% had college level. According to CIE-10 739 patients (57%) had psychological disorders, 279 patients (21%) had sexual and 373 (28%) had sleep disorders.
**Conclusions:** According to these findings there is a high prevalence of patients with low-medium socio-economical levels in RA which shows a possible correlation of a socio-demographic unfavorable situation with presence of disease. Also there are high rates of psychological, sexual and sleep comorbidities, which implies that measures must be implemented in order to improve these areas of performance in patients with RA.

## SAT0133 MANAGEMENT OF CARDIOVASCULAR RISK FACTORS IN RHEUMATOID AND PSORIATIC ARTHRITIS: THE AUSTRALIAN RHEUMATOLOGY ASSOCIATION DATABASE (ARAD) HEART HEALTH SURVEY

P. Sinnathurai[1,2,3], A. Capon[1], R. Buchbinder[4,5], V. Chand[6], L. Henderson[1], M. Lassere[7,8], L. March[1,2,3]. *[1]Rheumatology, Royal North Shore Hospital; [2]Institute of Bone and Joint Research, Kolling Institute; [3]University of Sydney, Sydney; [4]Monash Department of Clinical Epidemiology, Cabrini Hospital; [5]Department of Epidemiology and Preventative Medicine; [6]Centre of Cardiovascular Research &Education in Therapeutics, Monash University, Melbourne; [7]Rheumatology, St George Hospital; [8]University of New South Wales, Sydney, Australia*

**Background:** Chronic inflammatory arthritis is associated with increased cardiovascular (CV) morbidity and mortality [1]. Furthermore, obesity is associated with a reduced chance of achieving low or minimal disease activity in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) [2,3]. EULAR guidelines recommend that patients with chronic inflammatory arthritis should receive screening and management for traditional CV risk factors [4]. Previous analysis showed that diabetes mellitus (DM) and high cholesterol were more common in patients with PsA than RA [5].
**Objectives:** To describe and compare current treatment patterns for CV risk factors in patients with RA and PsA in ARAD.
**Methods:** ARAD is a voluntary national registry. Participants with inflammatory arthritis complete questionnaires every 6 -12 months in online or paper format. An additional Heart Health Survey was sent to online participants, including questions about pharmacological management of CV risk factors, dietary modification and physical activity. Results from the survey were linked with ARAD.
**Results:** Out of 1973 online ARAD participants, 1254 (64%) responded to the Heart Health Survey. Unlike earlier analysis of the whole ARAD cohort, there were no significant differences in the prevalence of CV risk factors between the RA and PsA responders. Pharmacological or dietary management was utilised by all patients with DM. Most patients with hypertension received pharmacological treatment (RA 93%, PsA 94%). The majority of patients with hypercholesterolaemia also received pharmacological management (RA 69%, PsA 73%). However, utilisation of lifestyle modification for management of obesity was low. In obese patients, only 34% had made any dietary change for their health. 12% of obese patients with RA and 8% of obese patients with PsA had attended an exercise program. 63% of RA and 61% of PsA patients who were obese reported being physically inactive; undertaking less than 30 minutes of

moderate physical activity on 3 or more days of the week. In obese patients, 79% with RA and 62% with PsA reported that their arthritis limited their ability to engage in physical activity.

**Conclusions:** CV risk factors are common in this Australian cohort. Management of CV risk factors was similar between patients with RA and PsA. The majority of patients receive pharmacological management. However, lifestyle modifications appear to be underutilised in the management of obesity. Arthritis is reported as the main factor limiting respondents' physical activity.

## SAT0134 PERIODONTAL CONDITION AS A EARLY MANIFESTATION OF UNDIFERENCIATED ARTHRITIS

S. Giraldo Q[1,2], C. Romero-Sanchez[1,2,3,4], P. Chalem[5], J.M. Bello-Gualtero[1,2], L. Chila M[3], C. Rodriguez[3], C. Pacheco[6], W. Bautista-Molano[2], D.M. Castillo[3], J. Londoño[4], G.I. Lafaurie[3], G. Ballesteros M[7], R. Valle-Oñate[1,2,4]. *[1]Department of rheumatology and Inmunology, Hospital Militar Central; [2]School of Medicine, Universidad Militar Nueva Granada; [3]Unit of Oral Basic Investigation, Universidad El Bosque; [4]Spondyloarthropathy Group, Rheumatology Department, Hospital Militar/Universidad de la Sabana; [5]Foundation Institute of Rheumatology, Fernando Chalem, Bogotá, Colombia; [6]Research and Biomedicine of Chihuahua, S.C, Chihuahua, Mexico; [7]Health Foundation, Clinica El Bosque, Bogotá, Colombia*

**Background:** Periodontal disease (PD) and rheumatoid arthritis (RA) are two common chronic inflammatory diseases globally destructive. Recently, there has been increasing evidence that periodontal disease and rheumatoid arthritis share many biological and pathological features like the significant increase in acute phase reactants. It is important to demonstrate that periodontal inflammation can affect clinical index and variability of the patients with RA.

**Objectives:** To evaluate the association between clinical indices of PD and markers of activity in Colombian RA patients and individuals with first-degree relatives of patients with RA.

**Methods:** The rheumatologic condition and periodontal status of 73 individuals with rheumatoid early arthritis and 164 individuals first degree relative with RA patient were evaluated. *Porphyromona gingivalis (Pg),* IgG1, and IgG2 to *Pg* were determined. The C-reactive protein, erythrocyte sedimentation rate, rheumatoid factor-RF, anti-citrullinated protein antibodies, RA 33 antibodies and scales of RA activity were measured. The rheumatologic Scores and periodontal condition were evaluated by two experienced and calibrated periodontists and rheumatologist. The chi-square test was used to evaluate association between periodontal variables and RA activity indices. The study was approved by the Ethics Committee of the Universidad El Bosque and the Hospital Militar Central, Bogotá, Colombia.

**Results:** RA group showed 67.1% of periodontitis, of which 43.8% were classified as moderate and 15.1% as severe, positive RF in 49 patients (67.2%) and ACPAs (52%), RA patients had association between dental Plaque >30% with activity clinical index DAS28ESR (p=0.05), SDAI (p=0.008), Bleeding of probing with DAS28ESR (p=0.05), ESR (p=0.03) and CRP (p=0.03) and association between clinical attachment level with ACPAs (p=0.05), Furthermore first-degree relatives of patients with RA showed periodontal disease in a 70.1% classified as moderate 43.9% and 12.8% as severe, positive RF 18 (18%), and ACPAs (7.1%), was finding association between gingival index with activity clinical index DAS28ESR (p=0.05), CRP (p=0.03), ESR (p=0.005) and RAPID3 (p=0.05), association periodontal pocket deep with HAQ-DI score (p=0.05) and bleeding of probing with SDAI (p=0.05).

**Conclusions:** RA and PD share pathophysiological mechanisms that explain how greater commitment periodontal dental plaque index and periodontal pocket deep are directly related to indices of clinical activity of the joint disease. This would explain the persistence of elevated acute phase reactants with minimal or absent joint clinical manifestations.

## SAT0135 ACHIEVING FREEDOM FROM GLUCOCORTICOIDS MIGHT DECREASE RISK OF CLINICAL FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS: FIVE-YEAR FINDINGS OF THE TOMORROW STUDY

S. Anno[1,2], K. Inui[3], K. Mamoto[4], T. Okano[4], Y. Sugioka[5], M. Tada[6], T. Koike[2,5], H. Nakamura[4]. *[1]Department of Orthopaedic Surgery, Yodogawa Christian Hospital, Osaka; [2]Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama; [3]Department of Rheumatosurgery; [4]Department of Orthopaedic Surgery; [5]Center for Senile Degenerative Disorders (CSDD), Osaka City University Medical School; [6]Department of Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan*

**Background:** Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falls and fractures.

**Objectives:** The present study prospectively investigates correlations between decreasing doses of glucocorticoid (GC) and the incidence of clinical fractures in patients with RA based on the five-year findings of the TOMORROW study (UMIN000003876) that started in 2010.

**Methods:** We evaluated anthropometric parameters, bone mineral density, disease activity, RA medication, and the incidence of clinical fractures over a period of five years in 202 patients with RA (mean age, 58.6 years; mean disease duration, 14.0 years). We also assessed the effects of GC doses on the incidence of clinical fractures over the same period in patients with RA using multivariate regression analysis.

**Results:** The incidence of clinical fractures in patients with RA was 0.042/person-years (py). There were 87 RA patients (41.8%) treated with GC whose incidence rate and number of clinical fractures were significantly higher than those without GC treatment (27.4% vs. 11.9%; p=0.008; 0.063 vs. 0.012 py; p=0.012, respectively). After adjusting for fracture risk factors including age, sex, smoking, and body mass index, multivariate logistic regression analysis revealed that GC administered within the five-year period was a significant risk factor for clinical fractures (odds ratio [OR], 2.58; 95% confidence interval [CI], 1.22–5.44, p=0.013). A mean GC dose during the 5-year period of ≥2 mg/day increased risk for fractures in patients with RA (OR 3.48; Table 1). Although only reducing the GC dose did not decrease the risk of clinical fractures in patients with RA, risk was significantly lowered when the dose was reduced to zero within the five-year period (OR 0.21; Table 1).

Table 1. Odds ratios for fractures determined by multivariate logistic regression analysis in 87 patients with RA treated by GC

| | OR | 95% CI | *p* |
|---|---|---|---|
| History of fractures | 1.99 | 0.95–4.16 | 0.069 |
| Average GC dose (≥2 mg/day/5 y) | 3.48 | 1.19–10.21 | 0.023 |
| Only reducing GC within 5 y | 0.61 | 0.21–1.78 | 0.362 |
| Reducing GC to zero within 5 y | 0.21 | 0.07–0.65 | 0.006 |
| Bisphosphonate medication | 3.37 | 1.51–7.54 | 0.003 |
| Low BMD at thoracic vertebrae (<0.7 g/cm$^2$) | 4.44 | 1.69–11.64 | <0.001 |

RA, rheumatoid arthritis; GC, glucocorticoid; OR, odds ratio; CI, confidence interval; BMD, bone mineral density.

**Conclusions:** Medication with GC was a significant risk factor for clinical fractures, and low doses are apparently significantly associated with an increased frequency of fractures among patients with RA. However, reducing the GC dose to zero among RA patients within five-years could lower the risk for clinical fractures. We concluded that GC medication should be tapered to zero over a period of five years in patients after RA activity is controlled.

## SAT0136 PATIENTS WITH RHEUMATOID ARTHRITIS AND HIGH LEVELS OF ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODY UNDER TREATMENT WITH HIGH-DOSE GLUCOCORTICOID FREQUENTLY FALL: FIVE-YEAR FINDINGS OF THE TOMORROW STUDY

S. Anno[1,2], K. Inui[3], K. Mamoto[4], T. Okano[4], Y. Sugioka[5], M. Tada[6], T. Koike[2,5], H. Nakamura[4]. *[1]Yodogawa Christian Hospital, Osaka; [2]Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama; [3]Department of Rheumatosurgery; [4]Department of Orthopaedic Surgery; [5]Center for Senile Degenerative Disorders (CSDD), Osaka City University Medical School; [6]Department of Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan*

**Background:** Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk for falls. However, previous prospective studies have not included controls to clarify whether RA per se represents a risk factor for falls.

**Objectives:** The present study prospectively compares the five-year incidence of falls and risk factors influencing falls between patients with RA and controls based on the findings of the TOMORROW study (UMIN000003876) that started in 2010.

**Methods:** We compared anthropometric parameters, bone mineral density, disease activity, and the incidence of falls in 202 patients with RA (mean age, 58.6 years; medication with biological agents, 54.9%) and in 202 age- and sex-matched healthy volunteers (controls; mean age, 57.4 years) over a five-year

period. We also analyzed risk factors for falls in the patients using multivariate regression analysis.
**Results:** The rate of individuals who fell did not significantly differ between patients with RA (n=101, 50%) and Controls (n=91, 45%) within the five-year period. However, the incidence of falls was significantly higher in the patients than the controls (0.39 vs. 0.21/person-years (py); $p$ =0.002). Multivariate linear regression analysis adjusted for fall risk factors including age, sex, smoking, and body mass index, revealed the association of a history of falls at entry into the study and RA morbidity with the number of falls in all participants ($\beta$ =0.248, 0.144, $p$ <0.01, respectively). In addition, anti-cyclic citrullinated peptide antibody (CCP), matrix metalloproteinase (MMP)-3 levels, a history of falls at entry, mean MMP-3 values, disease activity score 28 (DAS28-CRP), modified Health Assessment Questionnaire (mHAQ) score and glucocorticoid dosage (GC) over five years were related to the number of falls among the patients (Table 1).

Table 1. Multivariate linear regression analysis of risk factors associated with number of falls sustained by patients RA

| | | RA | N=202 |
|---|---|---|---|
| | Number of falls | $\beta$ | $p$ |
| At the entry | Anti-CCP antibody (U/mL) | 0.295 | <0.001 |
| | MMP-3 (ng/mL) | 0.197 | 0.005 |
| | History of falls | 0.248 | <0.001 |
| | DAS28-CRP | 0.108 | 0.129 |
| | mHAQ | 0.137 | 0.061 |
| | Dose of GC (mg/day) | 0.009 | 0.900 |
| 5 years | Average MMP-3 (ng/mL) | 0.162 | 0.026 |
| | Average DAS28-CRP | 0.157 | 0.033 |
| | Average mHAQ | 0.150 | 0.043 |
| | Average dose of GC (mg/day) | 0.160 | 0.024 |

RA, rheumatoid arthritis; CCP, cyclic citrullinated peptide; MMP-3, matrix metalloproteinase-3; DAS28-CRP, disease activity score 28 with C-reactive protein; mHAQ, modified Health Assessment Questionnaire; GC, glucocorticoid.

**Conclusions:** The rate of individuals who fell did not significantly differ between the patients and controls, but the incidence of falls was significantly higher in the patients within the five-year period. A higher titer of anti-CCP, higher doses of GC, and a high anti-CCP level were the most significantly associated with an increased frequency of falls among patients with RA.

## SAT0137 HIGH DISEASE ACTIVITY AND GLUCOCORTICOID USE ARE ASSOCIATED WITH INCREASED RISK OF MYCOBACTERIUM TUBERCULOSIS INFECTION IN RHEUMATOID ARTHRITIS

S. Chaiamnuay, K. Chullapant. *Medicine, Phramongkutklao Hospital, Bangkok, Thailand*

**Background:** Rheumatoid arthritis (RA) increased risk of Mycobacterium Tuberculosis Infection (TB). Risk of TB infection in RA patients from Thailand, the country with moderate prevalence of TB infection (137/100,000 in general population) has not been studied.
**Objectives:** The aim of this study was to determine incidence and factors related TB infection in RA patients from Thailand.
**Methods:** All patients were diagnosed with RA according to American College of Rheumatology (ACR) 1987 and/or ACR and European league of Rheumatology 2010 between 2000 and 2015. Twenty Cases of TB infection diagnosed after having RA were identified. TB infection was diagnosed by WHO 2013 revision definition and confirmed by physicians. Four age and sex matched controls were selected from 355 RA patients from Thai Army Rheumatoid Arthritis Cohort. Demographic data, RA disease associated factors and risk factos for TB infection were collected. Incidence rate was calculated by incidence density. Univariable and multivariable analyses were performed to identify factors associated with TB.
**Results:** Twenty-nine TB cases and 116 controls were included and 85.60% were female. The mean age ± SD was 64.75±11.06 years and mean disease duration ± SD was 12.79±7.15 years. Rheumatoid factor and anti-citrullinated protein antibody were positive in 75.23 and 68.95%, respectively. Most patients (93.18%) were treated with synthetic DMARDs. The combination of biologic and synthetic DMARDs was used in 7.58% of the patients. Incidence of TB infection was 2,180/100,000 person-year. Cases were more likely to have higher disease activity, use higher dose of methotrexate, use higher dose of leflunomide and use higher dose of glucocorticoid than controls. The means ± SD of Disease activity28 score (DAS28), dose of methotrexate, dose of leflunomide and dose of glucocorticoid in cases and control were 5.26 ±1.73 vs 4.45 ±1.51 (p=0.027), 9.84 ±6.02 vs 6.47 ±5.62 mg/week (p=0.03), 15±9.26 vs 6.55±7.53 mg/day (p=0.06) and 6.17±5.18 vs 1.15±2.06 mg/day (p=0.005), respectively. In multivariate regression analysis, only high DAS28 and current use of prednisolone were independently associated with TB infection (Odd ratio, 95% CI of 4.95, 1.15–8.36 and 1.23, 1.04–1.44, respectively).
**Conclusions:** Incidence of TB infection in RA in this study was very high compared to general population in Thailand and other Asian countries such as Hong Kong and Korea. High RA disease activity and the use of glucocorticoid are independently associated with TB infection.

## SAT0138 LEFT VENTRICULAR FUNCTION AT 2-YEAR FOLLOW-UP IN TREATMENT-NAIVE RHEUMATOID ARTHRITIS PATIENTS IS ASSOCIATED WITH ANTI-CCP STATUS: A COHORT STUDY

B.B. Løgstrup[1], D. Masic[2], T.B. Laurbjerg[2], J. Blegvad[2], M. Herly[2,3], L.D. Kristensen[2], G. Urbonaviciene[2], A. Hedemann-Nielsen[4], T. Ellingsen[3,5,6]. *[1]Department of Cardiology, Aarhus University Hospital, Aarhus; [2]Diagnostic Center, Regional Hospital Silkeborg, Silkeborg; [3]Department of Rheumatology, Odense University Hospital, Odense; [4]Diagnostic Centre, University Research Clinic for Innovative Patient Pathways, Silkeborg Regional Hospital, Silkeborg; [5]Clinical Institute, University of Southern Denmark, Odense; [6]Danbio Registry, Glostrup, Denmark*

**Background:** In patients with rheumatoid arthritis (RA) the role of autoimmunity and especially auto antibody status and the time-course of left ventricular (LV) function is unknown.
**Objectives:** To assess LV function as well as the amount of coronary calcium by coronary computer tomography (CCT) in relation to anti-cyclic citrullinated peptide antibody (anti-CCP) status in a cohort of treatment-naive RA patients. Furthermore to assess changes in these parameters during a 2-year follow-up period.
**Methods:** Sixty-six steroid- and DMARD-naive RA patients (42 women) were included and treated with methotrexate according to the national guidelines. We assessed both the LV function by conventional echocardiography and speckle-tracking echocardiography. Furthermore, we performed CCT to estimate the amount and progression of coronary calcium. Patients were examined at he time of diagnosis and after 2-years of efficient anti-inflammatory treatment.
**Results:** All patients fulfilled the international criteria for RA. We found no clinical significant differences in LV function parameters during the 2-year follow-up period in the total population. However, we found that patients with a persistently elevated anti-CCP both had a significantly lack of improvement in S'(1±1.4 cm/s versus 0.2±0.9 cm/s; p=0.04) and had a worsening in global longitudinal systolic strain (GLS) (0.6±1.8% versus -1±2.8%; p=0.04) compared to patients with non-persistently elevated anti-CCP over a 2-year time period. Furthermore, we observed a significant correlation between ΔGLS over 2 years and anti-CCP at 2-year follow-up (r=0.36;p=0.006). It remained significantly correlated (p=0.008) after correction for relevant cofounders (age, gender, blood pressure, heart rate, and baseline GLS). The circumferential strain improved in the group with non-persistently elevated anti-CCP compared to the group with persistently elevated anti-CCP (-4.2±3.8% versus 0.3±1.9%; p=0.009). We observed a mean progression of calcium score during the 2-year follow-up period of 22.4±68.9. We observed no differences in progression in calcium score in patients with persistently elevated anti-CCP (n=12) versus not persistently elevated (n=32) (23.8±40.3 versus 22.6±68.9; p=0.96).
**Conclusions:** LV function and deformation is reduced in treatment-naive RA patients with persistently elevated anti-CCP. Deformation abnormalities is associated with the degree of anti-CCP positivity in a 2-year follow-up period. No differences in the amount of coronary calcium was observed according to inflammatory burden.
**Disclosure of Interest:** None declared

## SAT0139 MAXIMUM METHOTREXATE DOSE SEEM TO BE AN ONLY RISK FACTOR FOR DEVELOPMENT OF MTX-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS

T. Higuchi[1], Y. Higuchi[2], S. Fuke[3], T. Takagi[4], D. Suzuki[5], Y. Koyama[6]. *[1]Rheumatology, Japanise Red Cross Okayama Hospital; [2]Neuropsychiatry, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences; [3]Cardiology; [4]Orthopedics; [5]Dermatology; [6]Rheumatology, Japanese Red Cross Okayama Hospital, Okayama-shi, Japan*

**Background:** Since February 2011, an approved Methotrexate (MTX) dose for rheumatoid arthritis: RA treatment has been raised from 8mg/wk to 16mg/wk in Japan. Recently, we have an impression that incidence of MTX-associated lymphoproliferative disorders (MTX-LPD) are increasing.
**Objectives:** To investigate incidence and etiology of MTX-LPD.
**Methods:** All of adult patients receiving MTX for treatment of autoimmune diseases (n=244) in our hospital from May 2012, to August 2015 are surveyed. In each case, the possible risk factors for development of MTX-LPD including minimum MTX dose, maximum MTX dose, administration period, and cumulative dose were investigated in detail. In order to detect the important risk factors, Cox proportional hazards regression analysis (Cox model) were carried out.
**Results:** At baseline, the background of the patients were as follows: male-

to-female ratio was 4:3, age was 72.3±8.5 years, minimum MTX dose was 5.4±1.0mg/wk, maximum MTX dose was 10.9±3.6mg/wk, administration period was 274.4±379.7wk, and all cumulative dose was 1842.3±1358.1mg. By the end of 2015, seven of patients developed (six RA, one psoriatic arthritis: PsA). The incidence was accounted for 2.9% in all amenable patients by following up for 119 weeks on average. By Kaplan-Meier plots, incidence of MTX-LPD was 0.85% at up to 52weeks and 9.2% at up to 260weeks. Cox model analysis revealed that maximum MTX dose was the only independent risk factor for MTX-LPD development. The annual incidence of MTX-LPD increases 1.58 times with 1mg increment of MTX (p=0.009, 95%CI 1.12–2.25). The seven MTX-LPD cases include three DLBCL, two indeterminable, and one Hodgkin's lymphoma. The last one had both Follicular and Hodgkin's lesions. The EBV in blood level was significantly elevated in all checked cases, and EBER was positive in six specimens of five cases by histopathological inspection. All of the lymphoproliferative lesions regressed spontaneously after MTX was withdrawn.

**Conclusions:** In our cohort, the incidence of MTX-LPD was quite frequent as compared to previous Japanese report (0.5%; before 2011) or reports from worldwide (0.05–0.3%). It is of particular interest that the annual incidence of MTX-LPD increases 1.58 times with only 1mg increment of MTX a week. It is also notable that all of the lesions regressed spontaneously so far after cessation of MTX, and the connection with EBV infection was found in all investigated cases. Although our cohort is rather small, we believe that it is worth to survey why the incidence of MTX-LPD are increasing in Japan with a larger cohort study. It may reveal the etiology of MTX-LPD in detail.

## SAT0140 PREVALENCE OF REACTIVATION OF HEPATITIS B VIRUS (HBV) IN PATIENTS WITH RESOLVED HBV HEPATITIS ON IMMUNOSUPPRESSIVE THERAPY FOR RHEUMATIC DISEASE: MULTICENTRE PROSPECTIVE OBSERVATIONAL STUDY IN JAPAN

W. Fukuda[1], T. Hanyu[2], M. Katayama[3], A. Okada[4], S. MIzuki[5], M. Miyata[6], Y. Handa[7], M. Hayashi[8], Y. Koyama[9], K. Arii[10], T. Kitaori[11], H. Hagiyama[12], Y. Urushidani[13], T. Yamazaki[14], Y. Ikeno[15], T. Suzuki[16], S. Inokuma[16]. *[1]Cnter for Rheumatic Disease, Japanese Red Cross Kyoto Daiichi Hospital, Kyoto; [2]Department of Rheumatology, Nagaoka Red Cross Hospital, Niigata; [3]Department of Rheumatology, Osaka Red Cross Hospital, Osaka; [4]Department of Rheumatology, Department of Rheumatology, Nagasaki; [5]Department of Rheumatology, Matsuyama Red Cross Hospital, Matsuyama; [6]Department of Internal Medicine, Japanese Red Cross Fukushima Hospital, Fukushima; [7]Department of Rheumatology, Saitama Red Cross Hospital, Saitama; [8]Department of Orthopedics, Nagano Red Cross Hospital, Nagano; [9]Department of Rheumatology, Japanese Red Cross Okayama Hospital, Okayama; [10]Department of Internal Medicine, Japanese Red Cross Kochi Hospital, Kochi; [11]Department of Orthopedics, Japanese Red Cross Fukui Hospital, Fukui; [12]Department of Rheumatology, Yokohama City Minato Red Cross Hospital, Yokohama; [13]Department of Rheumatology, Matsue Red Cross Hospital, Matsue; [14]Department of Rehabilitation, Japanese Red Cross Kyoto Daini Hospital, Kyoto; [15]Department of Rheumatology, Nasu Red Cross Hospital, Ootahara; [16]Department of Allergy and Rheumatic Diseases, Japanese Red Cross Medical Center, Tokyo, Japan*

**Background:** Although the reactivation of hepatitis B virus (HBV) is recognized as a serious complication in patients with connective tissue disease (CTD) receiving immunosuppressive drugs (ISDs), the incidence and risk factors of reactivation remain controversial.

**Objectives:** We performed a multicentre, observational, prospective study across 16 Japanese Red Cross hospitals to clarify the prevalence and pathophysiology of HBV reactivation in patients with CTD. We report the results of 2-year observations in patients with resolved HBV infection.

**Methods:** Patients with CTD, treated with a dose of ≥5 mg/day prednisolone, and/or synthetic or biological ISDs, with negative HBs antigen and positive anti HBs and/or HBc antibody (Ab), were enrolled. HBV-DNA (RT-PCR) and related data were registered regularly.

**Results:** Among 1040 patients, including 950 rheumatoid arthritis, HBV-DNA was detected in 32 patients (1.75/100 person-years), and >2.1 log copy/ml was observed in 9 cases (0.49/100 person-years) over 1–2 years of observation. None of the reactivated patients, including six treated with a nucleic acid analogue, showed overt hepatitis. Low HBs Ab titres and advanced age seemed to be risk factors for HBV reactivation; however, reactivation was observed in 3 patients with positive HBs Ab and negative HBc Ab. The risk of reactivation among the different types of ISDs was not statistically different. The intervals from the start of ISD to reactivation were longer than previous reports (4–157 months, average 58.9 months).

**Conclusions:** HBV reactivation with ISD was 1.75/100 person-years in CTD patients with resolved HBV infection. Overt hepatitis was observed in none of the reactivated patients, and low HBs antibody titres and advanced age were risk factors for reactivation. Patients with positive HBs Ab and negative HBc Ab are not free from the risk of reactivation of HBV.

## SAT0141 CHANGES OF BONE DENSITY AND MICROARCHITECTURE IN RHEUMATOID ARTHRITIS PATIENTS WITH EARLY DISEASE: A ONE-YEAR STUDY WITH HR-PQCT

P.C. Wong[1], Y. Zhu[2], L. Qin[2], L.-S. Tam[3]. *[1]Medicine & Therapeutics, Prince of Wales Hospital; [2]Orthopaedics & Traumatology; [3]Medicine & Therapeutics, the Chinese University of Hong Kong, Shatin, Hong Kong*

**Background:** Periarticular and systemic osteoporosis is a major feature in patients with rheumatoid arthritis (RA). Bone loss in RA is considered to be a result of chronic inflammation, particularly at the early stage of the disease. High Resolution peripheral Quantitative Computed Tomography (HR-pQCT) is an in vivo 3D imaging modality dedicated to peripheral skeleton imaging. Whether a better controlling of the disease inflammation could lead to a preservation of vBMD and microarchitecture is to be determined.

**Objectives:** This one-year cohort study in RA patients with early disease (onset <2 years) aimed to compare changes of vBMD and bone microarchitecture indices at the distal radius and tibia between patients who achieved and those who did not achieve disease remission.

**Methods:** Forty-seven RA patients (age: 54.5±11.8 years) with disease onset <2 years and with active disease (Disease Activity Score in 28 joints [DAS28] ≥3.2) were recruited for this one-year study. Disease remission at 12 months was assessed as Simplified Disease Activity Score ≤3.3. HR-pQCT imaging of the distal radius and tibia was performed at baseline and 12 months.

**Results:** At 12 months, 20 patients achieved disease remission and 27 patients remained with activity disease. There was no significant difference in baseline DAS28 score (4.93 vs. 4.92, p>0.05) and age between the two groups. In patients who did not achieve disease remission, particularly at the distal radius, there were decreases in cortical and trabecular vBMD, cortical thickness and trabecular number, and increase in trabecular separation (Table 1). Increase in cortical porosity presented as the most prominent deterioration of bone microarchitecture (20%). Only changes in trabecular separation (2.87%) and cortical vBMD (-1.12%) achieve statistical significance. In patients who achieve disease remission, decrease in vBMD and deterioration in bone microarchitecture were in general to a lesser extent than their counterparts. In particular, there appeared to be a decrease in cortical porosity in these patients (-6.62%). However, there was no significant group-wise difference in changes of vBMD and microarchitectural indices (all p>0.05).

Table 1. Percentage changes of all HR-pQCT indices between two groups

| Variables | No remission (n=27) | Remission (n=20) | p-value |
|---|---|---|---|
| Radius | | | |
| Cortical vBMD | –0.19±1.76 | 0.63±3.19 | 0.269 |
| Trabecular vBMD | –2.41±7.30 | –3.06±7.22 | 0.765 |
| Cortical thickness | –1.12±4.51 | –0.11±3.43 | 0.407 |
| Cortical pore volume | 20.1±105 | –6.22±25.8 | 0.282 |
| Cortical porosity | 19.7±95.0 | –6.62±25.9 | 0.236 |
| Trabecular number | –2.21±8.34 | –0.55±7.31 | 0.483 |
| Trabecular thickness | 0.21±2.28 | –0.51±1.50 | 0.227 |
| Trabecular separation | 2.87±8.42 | 1.21±6.90 | 0.475 |
| Tibia | | | |
| Cortical vBMD | –1.12±3.07 | –0.90±1.58 | 0.773 |
| Trabecular vBMD | –0.13±2.69 | 0.11±1.57 | 0.718 |
| Cortical thickness | –0.34±3.49 | 0.39±2.51 | 0.432 |
| Cortical pore volume | 6.27±17.28 | 5.05±11.6 | 0.785 |
| Cortical porosity | 7.89±18.5 | 4.95±12.4 | 0.542 |
| Trabecular number | 2.20±7.71 | 1.72±8.85 | 0.843 |
| Trabecular thickness | –0.58±1.80 | –0.24±1.47 | 0.494 |
| Trabecular separation | –1.37±7.29 | –0.92±8.89 | 0.847 |

RA, rheumatoid arthritis; CCP, cyclic citrullinated peptide; MMP-3, matrix metalloproteinase-3; DAS28-CRP, disease activity score 28 with C-reactive protein; mHAQ, modified Health Assessment Questionnaire; GC, glucocorticoid.

**Conclusions:** There was a trend towards a preservation of vBMD and bone microarchitecture in RA patients who achieve disease remission. An early and better control of disease activity might reduce the future risk of osteoporosis in RA patients.

**Disclosure of Interest:** None declared

SAT0142 **TREAT-TO-TARGET PRACTICE USING ONLINE ASSESSMENT OF DISEASE ACTIVITY WITH SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILE TOOLS: A COHORT STUDY OF RHEUMATOID ARTHRITIS PATIENTS IN CHINA**

Y. Jing[1], W. Hongzhi[2], X. Xiafei[3], W. Hua[4], M. Rong[5], Z. Fengxiao[6], Z. Yun[7], Z. Jinmei[1], L. Xiaofeng[8], L. Hong[1], J. Yuhua[9], Z. Li[9], J. Xiaobing[9], L. Yuan[9], X. Fei[9]. *[1]Central Hospital of MianYang, Sichuan; [2]JiaXing First Hospital Department of Rheumatology, ZheJiang; [3]Ningbo First Hospital Department of Rheumatology, Zhejiang Ningbo; [4]Northern Jiangsu People's Hospital, Jiangsu; [5]People's Hospital, Beijing University Medical School, Beijing; [6]Hebei General Hospital, Hebei; [7]Weifang people's hospital, Shandong; [8]The Second Affiliated Hospital of Shanxi Medical College, Shanxi; [9]Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China*

**Background:** There are more than 5 million RA patients in China, but only 4,000 rheumatologists. T2T strategy are critical for the treatment of RA, but the Chinese doctors can hardly provide patients with a complete assessment in the clinic due to limited time. We have confirmed in a validation study that Chinese RA patients can master the use of SSDM for accurate DAS28 self-assessments after training[1].
**Objectives:** To explore the effectiveness of applying SSDM in improvement of disease activity after repeated self-assessment in Chinese RA patients.
**Methods:** The SSDM includes both doctors' and patients' application. After entry of lab test, treatment regiments, and executing DAS28 assessment by patients, all data can be synchronized to the authorized doctor' mobile tool. They can adjust treatment regiments base on these data. Since Aug. 2014 to Jan. 2016, 31 rheumatologists from 25 hospitals participated in the study. Patients were educated to measure DAS28 with SSDM on the baseline, and were asked to repeat the assessment once a month.
**Results:** 636 RA patients with repeated self-assessment of DAS 28 were recruited, 448 (70.4%) women and 188 (29.6%) men. Mean age was 45.26±13.17 (18 to 83) years, median duration of disease was 2.92 (0.08 to 50.42) years. Mean duration of self-assessment was 67.00±66.50 (2 to 371) days. Mean assessment times were 4.38±3.36 (2–20). Mean DAS28 score was 3.96±1.46 (0.62 to 8.29) at baseline and 3.58±1.45 (0.60 to 9.07) at the last assessment. Proportion of patients in remission, low, moderate and severe disease activity (Rem, LDA, MDA and SDA) was 19.03%, 13.36%, 45.28% and 22.33% respectively at baseline, and changed into 26.57%, 13.68%, 45.28% and 14.47% at the last assessment. The rate of T2T (DAS28$\leq$3.2) at the last assessment was higher than that of baseline significantly ($P<0.01$). The rate of SDA patients for last assessment was also significantly lower than baseline ($P<0.01$). To explore whether the frequency of self-assessment could influence disease activity, we stratified the times of DAS28 assessment among those who did not achieve clinical remission (DAS$>$2.6). 65 patients made only two assessments within 151.41±86.72 (48–372) days, whose mean DAS28 was 4.20±1.28 (2.64–7.39) at baseline and improvement of that was 0.49±1.46 (-4.31–4.25) at their last assessment. There were 61 patients making more than 5 times of self-assessment during 159.98±88.10 (28–343) days. Their mean DAS28 score was 4.27±1.13 (2.61–7.19) at baseline and improvement of that was 1.12±1.34 (-1.86–4.51) at the last assessment, which was significantly better than patients who had only two self-assessments (T=2.52, P=0.013).
**Conclusions:** Under regular self-assessment of DAS28 using SSDM, RA patients achieved better T2T result. SSDM can assist rheumatologists to rationally adjust treatment for RA patients.

SAT0143 **THE EFFECT OF TOTAL KNEE ARTHROPLASTY ON THE ARTHRITIS OF OTHER JOINTS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Y. Yonemoto, K. Okamura, C. Okura, T. Suto, K. Takagishi. *Department of Orthopaedic Surgery, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan*

**Background:** There have been some reports that total arthroplasty can improve the disease activity in RA patients. The RA disease activity is commonly assessed using composite measures. These include five components: inflammation markers, the swollen joint count, tender joint count, patient's global VAS and evaluator's global VAS. Therefore, total arthroplasty can improve all of these components if there is improvement of arthritis, even if it is only in the surgical site. It is still unclear whether the improvement of disease activity is only at the surgical site or includes other joints.
**Objectives:** The aim of this study was to assess the arthritis of systemic large joints at baseline and 12 weeks after TKA using 18FDG-PET (PET)/CT in patients with RA.
**Methods:** Seventeen RA patients who underwent TKA were included this study. We assessed the FDG-PET, CRP, ESR, MMP-3, DAS28-ESR, DAS28-CRP, CDAI, SDAI, HAQ-DI, HSS score and Knee ROM at baseline (just before TKA) and 12 weeks after TKA.
**Results:** The median age of the patients was 68 years old, and the disease duration was 23 years. Concomitant MTX and PSL treatment was being administered to 71% of the patients. One patient was treated with infliximab, two used etanercept, one used tocilizmab and two used abatacept. The CRP, MMP-3, all of the composite measurements, the HAQ and the knee function improved significantly 12 weeks after TKA. These data show the changes in the SUV of each joint. The SUV of the bilateral wrist joints decreased significantly 12 weeks after TKA. However, the SUV of other large joints were unchanged.
**Conclusions:** TKA can improve not only the ADL and knee function, but also the disease activity in RA patients. However, TKA has limited effectiveness against the arthritis of the joints not undergoing surgery.

## Rheumatoid arthritis - other biologic treatment

SAT0144 **SOLUBLE FORM OF GP130 MOLECULE, AN IL-6 INHIBITOR, CONTRIBUTES THE EFFICACY ON RA TO TOCILIZUMAB (AN ANTI-IL-6 RECEPTOR ANTIBODY) THERAPY**

K. Yoshizaki[1], S.N.J. Song[1], H. Itoh[1], M. Iwahashi[2], K. Uno[3]. *[1]The Institute of Scientific and Industrial Research, Osaka University, Osaka; [2]Higashi Hiroshima Memorial Hospital, Hiroshima; [3]Louis Pasteur Center for Medical Research, Kyoto, Japan*

**Background:** IL-6, one of the causes of key molecule in RA pathogenesis, is signaling through the two receptor systems, one is IL-6 binding molecule (IL-6R) and the other is gp130 molecule (gp130), a signal transducer. And we know the presence of soluble form of IL-6 receptor (sIL-6R) and gp130 (sgp130). SIL-6R is an IL-6 functional accelerator; however less is known about the function of sgp130.
**Objectives:** We want to know whether sgp130 is a regulator of IL-6 both in vitro and vivo. Tocilizumab, an anti-IL-6 receptor antibody, shows good effect as well as TNF-a inhibitors for the treatment of RA. However the efficacy is variable to each of patient. We want to know the reason of this variety caused by sgp130 molecule.
**Methods:** [In vitro] Hep3B, a hepatoma derived cell line, was stimulated with IL-6 or Hyper IL-6 (complex of IL-6/sIL-6R) and co-cultured with tocilizumab or complex of gp130-Fc. CRP mRNA induction was accessed after two days culture by real-time RT-PCR.
[In vivo] We performed with observation study. 88 RA patients (48 biologics naïve, 40 biologics non-naïve) were treated with tocilizumab over 16 weeks by every 4 week injection at dose 8mg/kg. 41 biologics in pretreatment serum was measured by Bio-Prex27 and Milliplex. The disease activity at 16 week was scored on DAS28-CRP. Multiple linear regression analysis were used to determine if any relationship existed between biologics and patient's week 16 DAS 28-CRP score.
**Results:** [In vitro] Gp130-Fc did not inhibited the IL-6 induced CRP, however inhibited the Hyper IL-6 induced CRP productions. This means, gp130-Fc specifically inhibited the stimulation with complex of IL-6/sIL-6R which stimulation could not be inhibited with tocilizumab.
[In vivo] 7 biomarker including sgp130 were predictive of the week 16 DAS28-CRP in naïve tocilizumab patients ($R2=0.646$, $P<0.0001$) while gp130, GM-CSF, IP-10 were predictive in non-naïve patients ($R2=0.486$, $P<0.001$). The most reliable marker is sgp130 (Estimated value -5.34).
**Conclusions:** 1) Sgp130 is a natural IL-6 inhibitor both in vitro and in vivo.
2) Higher level of sgp130 predicts the better outcome to tocilizumab therapy
3) Clinical efficacy might be resulted in the additive effects by the inhibition with tocilizumab (IL-6 binding inhibition on IL-6R) and the inhibition with sgp130, (IL-6/sIL-6R binding inhibition on gp130).
4) Prediction of individual RA patient's outcome to tociizumab therapy can be recognized by measuring biologics including sgp130 (most reliable marker) in pretreatment serum.
5) Opening the personalized medicine in RA field by measuring biomarker before therapy.

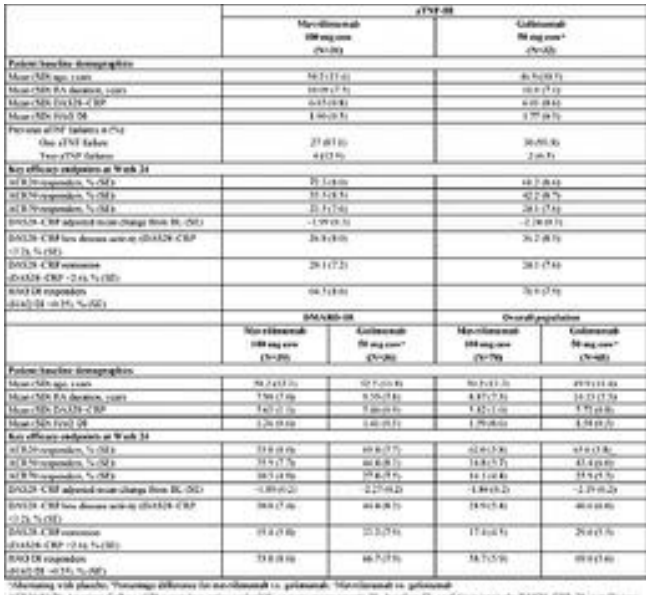
## SAT0145 EFFICACY AND SAFETY OF SIRUKUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DESPITE DISEASE-MODIFYING ANTI-RHEUMATIC DRUG TREATMENT: RESULTS OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

T. Takeuchi[1], C. Thorne[2], G. Karpouzas[3], S. Sheng[4], W. Xu[4], R. Rao[5], K. Fei[4], B. Hsu[4]. *[1]Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan; [2]University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; [3]Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA; [4]Janssen Research & Development, LLC, Spring House, PA, United States; [5]GSK Medicines Research Centre, Hertfordshire, United Kingdom*

**Background:** Sirukumab, a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, is under development for rheumatoid arthritis (RA) and other diseases.
**Objectives:** To evaluate efficacy and safety of sirukumab in patients (pts) with RA refractory to conventional synthetic disease-modifying anti-rheumatic drugs (DMARDs).
**Methods:** In this Phase 3 global study, 1,670 pts with active RA and inadequate response to DMARDs were randomized (1:1:1) to sirukumab subcutaneous (SC) 50mg q4w, sirukumab SC 100mg q2w, or placebo SC q2w. Pts on placebo with insufficient improvement (<20%) at Wks 18 or 40 or still on placebo at Wk 52 were re-randomized to receive blinded treatment in 1 of the 2 sirukumab doses. Co-primary endpoints were the proportion of pts achieving ACR20 at Wk 16 and change from baseline in modified van der Heijde/Sharp (vdH-S) radiographic damage mean score at Wk 52.
**Results:** For both co-primary endpoints, sirukumab 50mg q4w and 100mg q2w showed significant improvement vs placebo (Table; all $P<0.001$). All major secondary endpoints were met for both sirukumab doses. Significantly greater improvements were also observed in both the physical and mental component summary scores of the Short Form-36 (SF-36) Health Survey with both sirukumab doses vs placebo at Wk 52 (all $P<0.001$). Significantly more pts on sirukumab did not experience radiographic progression from baseline to Wk 52 (50mg q4w, 59.0%; 100mg q2w, 62.4%) than on placebo (45.5%; both $P<0.001$). Through Wk 52, incidences of treatment-emergent adverse events (AEs) and serious AEs, respectively, were numerically higher with sirukumab 50mg q4w (79.6% and 11.0%) and 100mg q2w (80.2% and 9.8%) vs placebo (65.5% and 6.8%). The most common AEs (≥8%) with sirukumab were elevated liver enzymes, upper respiratory tract infection, and injection site erythema, and nasopharyngitis.

Table 1. Key endpoints

| Endpoints | Placebo (n=556) | Sirukumab 50mg q4w (n=557) | Sirukumab 100mg q2w (n=557) |
|---|---|---|---|
| Primary endpoints | | | |
| ACR20 at Wk 16, n (%) | 147 (26.4) | 305 (54.8)[a] | 298 (53.5)[a] |
| vdH-S mean (SD) change from baseline at Wk 52 | 3.69 (9.25) | 0.50 (2.96)[a] | 0.46 (3.26)[a] |
| Major secondary endpoints | | | |
| HAQ-DI mean (SD) change from baseline at Wk 24 | −0.22 (0.53) | −0.43 (0.58)[a] | −0.46 (0.57)[a] |
| ACR50 at Wk 24, n (%) | 69 (12.4) | 168 (30.2)[a] | 185 (33.2)[a] |
| DAS28 (CRP) remission at Wk 24, n (%) | 31 (5.6) | 145 (26.0)[a] | 142 (25.5)[a] |
| Major clinical response at Wk 52, n (%) | 10 (1.8) | 30 (5.4)[a] | 50 (9.0)[a] |



[a] $P \leq 0.001$ vs placebo.

**Conclusions:** In DMARD-inadequate responders, sirukumab SC 50mg q4w and 100mg q2w reduced signs/symptoms of RA, inhibited radiographic progression, and improved health-related quality of life. The safety profile of sirukumab was consistent with the known safety profile of anti-IL-6 treatment.

## SAT0146 EARTH EXPLORER 2, A PHASE IIB EXPLORATORY STUDY EVALUATING EFFICACY AND SAFETY OF MAVRILIMUMAB, A FULLY HUMAN GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR RECEPTOR-ALPHA MONOCLONAL ANTIBODY, AND THE TUMOR NECROSIS FACTOR ANTAGONIST GOLIMUMAB IN RHEUMATOID ARTHRITIS

M. Weinblatt[1], I. McInnes[2], J. Kremer[3], P. Miranda[4], J. Vencovský[5], A. Godwood[6], M. Albulescu[6], D. Close[6], G. Burmester[7]. *[1]Brigham and Women's Hospital, Boston, United States; [2]University of Glasgow, Glasgow, United Kingdom; [3]The Albany Medical College, Albany, United States; [4]Centro de Estudios Reumatológicos, Santiago, Chile; [5]Institute of Rheumatology, Praha, Czech Republic; [6]MedImmune, Cambridge, United Kingdom; [7]Charité – University Medicine Berlin, Berlin, Germany*

**Background:** Mavrilimumab, a fully human monoclonal antibody targeting the granulocyte-macrophage colony-stimulating factor receptor-α, has demonstrated efficacy and safety in disease-modifying antirheumatic drug (DMARD)-inadequate responder (IR) patients (pts) with rheumatoid arthritis (RA).[1]
**Objectives:** Few head-to-head studies in tumor necrosis factor antagonist (aTNF)-IR assess alternative aTNFs vs. other agents; this Phase IIb exploratory study (NCT01715896) evaluates the efficacy and safety of mavrilimumab and golimumab in aTNF-IR and DMARD-IR pts.
**Methods:** This 24-week study enrolled pts with active RA (28-joint Disease Activity Score [DAS28]–C-reactive protein [CRP]/erythrocyte sedimentation rate ≥3.2); ≥4 swollen joints; inadequate response to ≥1 DMARDs and/or 1–2 aTNFs receiving concomitant methotrexate (MTX; 7.5–25.0 mg/week). Pts received subcutaneous mavrilimumab 100 mg every other week (eow), based on data from the Phase IIa study,[2] or golimumab 50 mg alternating with placebo eow. Key endpoints were ACR20/50/70 responses, DAS28–CRP <3.2 and <2.6, Health Assessment Questionnaire Disability Index improvement >0.22 at Week 24 and safety/tolerability. Treatment estimates for mavrilimumab and golimumab are presented with standard errors.
**Results:** Pts were randomized to mavrilimumab or golimumab (1:1) (Table). Data for pts receiving mavrilimumab 100 mg eow and golimumab 50 mg at Week 24 are shown for the aTNF-IR, DMARD-IR and overall strata (Table). The most common treatment-emergent adverse events (TEAEs) for mavrilimumab 100 mg and golimumab 50 mg were nasopharyngitis (5.7%, 1.5%), headache (4.3%, 2.9%), upper respiratory tract infection (4.3%, 2.9%), viral upper respiratory tract infection (4.3%, 2.9%), and hepatic enzyme increase (4.3%, 2.9%), respectively. Related serious TEAEs were pneumocystis pneumonia (n=1) and lung disorder (n=1) [both in golimumab-treated pts]. No deaths were reported and no significant pulmonary safety signals were identified.

**Conclusions:** In this exploratory study, mavrilimumab 100 mg eow and golimumab 50 mg demonstrated efficacy and an acceptable safety profile in DMARD-IR and aTNF-IR pts. The study was not powered to demonstrate statistical significance between mavrilimumab and golimumab. As mavrilimumab 100 mg eow has previously been shown to be suboptimal compared with 150 mg eow in DMARD-IR pts (EARTH EXPLORER 1),[1] additional studies are needed to establish the benefit of a higher dose in pts with moderate to severe RA and inadequate response to aTNF agents.

## SAT0147 SAFETY AND EFFICACY OF BI 655064, AN ANTAGONISTIC ANTI-CD40 ANTIBODY IN RHEUMATOID ARTHRITIS (RA) PATIENTS

S. Daniluk[1], R. Ptaszynski[2], U. Mueller-Ladner[3], A. Petrikova[4], H. Kellner[5], E. Dokoupilova[6], B. Kwiatkowska[7], R. Alten[8], C. Schwabe[9], B. Rosenstock[10], T. Doan[11], R. Thiedmann[10], F. Fleischer[10], J. Hilbert[12], S. Visvanathan[12], S. Padula[13], J. Steffgen[10]. *[1]ClinicMed Badurski and Partners, Bialystok; [2]Rheumatica, Warsaw, Poland; [3]Giessen University, Kerckhoff-Klinik, Bad-Nauheim, Germany; [4]CTCenter MaVe, Olomouc, Czech Republic; [5]Centre for Inflammatory Joint Diseases, Munich, Germany; [6]Medical Plus, Uherske Hradiste, Czech Republic; [7]Prof. Eleonora Reicher Memorial National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland; [8]Schlosspark klinik, Berlin, Germany; [9]Auckland Clinical Studies, Auckland, New Zealand; [10]Medicine, Boehringer Ingelheim, Biberach, Germany; [11]Clinical, Boehringer Ingelheim, Sydney, Australia; [12]Translational Medicine and Clinical Pharmacology, Boehringer Ingelheim, Ridgefield, United States; [13]Medicine, Boehringer Ingelheim, Ingelheim, Germany*

**Background:** Blocking the CD40-CD40L pathway may be a new emergent treatment for patients with RA. BI 655064 is a humanized, purely antagonistic anti-CD40 monoclonal antibody. In healthy volunteers, BI 655064 was well tolerated in doses up to 240 mg q1w s.c. for 4 weeks. Doses ≥120 mg resulted in persistent >90% CD40 receptor occupancy and >90% inhibition of CD40L-induced CD54 upregulation.
**Objectives:** BI 655064 was investigated in RA patients with prior inadequate response (IR) to a stable dose of MTX at ≥15 mg.
**Methods:** In this double-blind, randomized trial, RA patients (n=67) were treated with either 120 mg BI 655064 or placebo q1w (2:1, respectively) for 12 weeks as add-on to MTX. Patients were stratified based on region (Eastern Europe vs. Western Europe/New Zealand). Inclusion criteria were ≥6 swollen and ≥6 tender joints, CRP ≥8 mg/L or ESR ≥28 mm/1h. The primary efficacy endpoint was ACR20 response at week 12.
**Results:** Baseline variables of the 2 groups were comparable except mean baseline CRP, which was substantially lower in patients treated with BI 655064 (9.8 mg/L) vs. placebo (23.6 mg/L). Treatment was prematurely discontinued by 4 patients (9.1%) in the BI 655064 group and 4 (17.4%) in the placebo group. Adverse events (AE) were reported in 65.9% of BI 655064-treated patients vs. 78.3% of placebo-treated patients. Two SAEs were reported in each group, neither was considered drug-related. The most frequently reported AEs were nasopharyngitis (BI 655064: 13.6%, placebo: 21.7%) and headache (BI 655064: 6.8%, placebo: 13.0%). There were no relevant changes in safety-related laboratory parameters. Efficacy results of all patients (FAS), including a subgroup of patients with CRP > median (7.5 mg/L; upper limit of normal: 6.0 mg/L), are listed in the table.

Table 1

| | BI 655064 (N=44) | Placebo (N=22*) |
|---|---|---|
| ACR20 response % | 68.2 | 45.5 |
| ACR50 response % | 36.4 | 18.2 |
| Mean change† in DAS28-CRP @wk12 | –1.65 | –1.42 |
| **Subgroup with CRP > median** | **BI 655064 (N=17)** | **Placebo (N=16)** |
| Mean change† in DAS28-CRP @wk12 | –1.83 | –1.38 |
| CRP change from baseline, mean (SE) | –10.45 (3.54) | –3.90 (3.65) |

*1 patient excluded from efficacy analysis due to early use of i.v. steroids. †Adjusted for region, anti-TNF history and baseline CRP.

All 6 patients who had previously received anti-TNF therapy were in the BI 655064 group; 4 achieved an ACR20 and 2 achieved an ACR50 response. There was a median decrease in ESR and total rheumatoid factor in the BI 655064-treated group by 16 mm/h and 81.5 IU/mL, respectively, compared with a decrease of 9 mm/h and 0.2 IU/mL in the placebo group.
**Conclusions:** In this relatively small proof-of-clinical-concept trial, treatment of MTX IR RA patients with BI 655064 did not indicate a relevant safety concern and showed moderate efficacy, which might have been impacted by the relatively high placebo response rate and the imbalance in baseline CRP.

## SAT0148 IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES WITH OLOKIZUMAB TREATMENT IN PATIENTS WITH ACTIVE, MODERATE TO SEVERE RHEUMATOID ARTHRITIS WHO HAD FAILED PREVIOUS ANTI-TNF THERAPY: RESULTS FROM THE RA0056 DOUBLE-BLIND, RANDOMIZED CONTROLLED STUDY, AND RA0057, ITS OPEN-LABEL EXTENSION

M. Genovese[1], R. Fleischmann[2], D. Furst[3], N. Janssen[4], J. Carter[5], B. Dasgupta[6], C. Pitzalis[7], I. Vasyutin[8], T. Kaviarasu[9], A. Krotkova[8], P. Durez[10]. *[1]Stanford University Medical Center, Stanford; [2]University of Texas Southwestern Medical Center, Dallas; [3]UCLA, Los Angeles; [4]Houston Institute for Clinical Research, Houston; [5]University of South Florida Health, Tampa, United States; [6]Southend University Hospital, Westcliff-on-Sea; [7]Queen Mary University of London, London, United Kingdom; [8]R-Pharm CJSC, Moscow, Russian Federation; [9]Quintiles Inc, Bangalore, India; [10]Université Catholique de Louvain, Brussels, Belgium*

**Background:** Rheumatoid arthritis (RA) has a high patient (pt) burden with significant impact on health-related quality of life. Here we report the effect of treatment with olokizumab (OKZ), an interleukin-6 (IL-6)-targeting monoclonal antibody in development for the treatment of RA, on pt-reported outcomes (PROs) in the phase 2 randomized controlled trial (RCT) RA0056 and its open-label extension (OLE) RA0057.
**Objectives:** To assess the effect of OKZ treatment on PROs in pts with moderate to severe RA who have previously failed anti-TNF therapy.
**Methods:** RA0056 was a dose-ranging, multicenter, double-blind RCT (NCT01242488) that enrolled pts with active, moderate to severe RA (meeting 1987 ACR classification criteria and/or ACR/EULAR diagnostic score ≥6; ≥6 swollen and ≥6 tender joints; CRP ≥1.2x upper limit of normal). Pts were receiving stable dose MTX 12.5–25mg/week (wk) for ≥6 wks and were intolerant to, or had a previous inadequate response to, ≥1 anti-TNF ≤2 years prior to screening. Pts received 1 of 9 treatments: subcutaneous (sc) placebo (PBO) every 4 weeks (Q4W) or every 2 weeks (Q2W), intravenous (iv) tocilizumab (TCZ) 8mg/kg Q4W, or sc OKZ 60/120/240mg Q2W or Q4W. Pts who completed the 12-wk study were eligible for entry into the RA0057 OLE (NCT01296711), in which all pts received sc OKZ 120mg Q2W+MTX. Pts with ongoing serious adverse events were excluded. PROs included change from baseline in: Health Assessment Questionnaire-

[a] Both PBO dosing arms from the RCT are presented as combined data; [b] All OKZ dosing arms from the RCT are presented as combined data
BRAF-MDQ: Bristol Rheumatoid Arthritis Fatigue-Multi-Dimensional Questionnaire; EQ-5D VAS: EuroQoL-5 Dimensions Visual Analogue Scale; HAQ-DI: Health Assessment Questionnaire-Disability Index; OLE: open-label extension; PAAP: Patient's Assessment of Arthritis Pain; PtGADA: Patient's Global Assessment of Disease Activity; RCT: randomized controlled trial; SD: standard deviation

Disability Index, Pt's Global Assessment of Disease Activity, Pt's Assessment of Arthritis Pain, Pt Acceptable Symptom State, Pt's Global Impression of Change, Bristol Rheumatoid Arthritis Fatigue-Multi-Dimensional Questionnaire and EuroQoL-5D Visual Analogue Scale. All missing data were left as missing.
**Results:** 198 pts completed RA0056; 190 (114 OKZ, 40 PBO, 36 TCZ) enrolled in RA0057. At Wk12 of the RCT, OKZ-treated pts reported greater improvements in PROs compared to PBO pts, similar to TCZ pts (Table). These changes were maintained to Wk48 of the OLE both in pts receiving OKZ throughout (OKZ→OKZ) and in TCZ-pts switching to OKZ at OLE entry (TCZ→OKZ). PBO-pts reported improvements in PROs following switch to OKZ (PBO→OKZ).
**Conclusions:** Treatment with OKZ resulted in improvements in PROs in patients with moderate to severe RA, which were maintained up to Wk48 of OLE.

## SAT0149 RADIOGRAPHIC OUTCOMES IN PATIENTS ACHIEVING CLINICAL REMISSION OR LOW DISEASE ACTIVITY IN A PHASE 3 STUDY OF SARILUMAB PLUS METHOTREXATE IN PATIENTS WITH ACTIVE, MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS

D. van der Heijde[1], J. Simon[2], H. van Hoogstraten[3], E.K. Mangan[4], J. Fay[4], J. van Adelsberg[4], C. Fan[3], M.C. Genovese[5]. *[1]Leiden University Medical Centre, Leiden, Netherlands; [2]Köhler & Milstein Research, Yucatan, Mexico; [3]Sanofi, Bridgewater; [4]Regeneron Pharmaceuticals, Inc., Tarrytown; [5]Stanford University Medical Center, Palo Alto, United States*

**Background:** Clinical remission is an important treatment target of rheumatoid arthritis (RA), and it is important to understand its role as a surrogate for radiographic inhibition.[1,2] In the phase 3 MOBILITY study (NCT01061736), sarilumab (150 or 200 mg subcutaneously every 2 wks [q2w] + methotrexate [MTX]) demonstrated clinical and radiographic efficacy in adults with active, moderate-to-severe RA with inadequate response to MTX.[3] The most common treatment-emergent adverse events were infections, neutropenia, injection site reactions, and increased transaminases.
**Objectives:** The objective of this post hoc analysis was to examine differences in radiographic progression between patients in MOBILITY who did and those who did not achieve different definitions for remission or low disease activity (LDA).
**Methods:** Remission and LDA categories included CDAI $\leq$2.8 and $\leq$10, SDAI $\leq$3.3 and $\leq$11, and Boolean-based ACR/EULAR remission, which included tender joint count and swollen joint count (28-joint count) $\leq$1, CRP $\leq$10 mg/L, and patient global visual analog scale $\leq$10. Cutoffs for 28-joint disease activity score by C-reactive protein (DAS28-CRP) were $<$2.6 and $\leq$3.2. Differences in radiographic progression, defined as the mean change from baseline in modified total Sharp score (mTSS), between the treatment and placebo groups in these benchmarks were assessed using a 2-sided Cochran-Mantel-Haenszel test stratified by prior biologic use and region. Missing or postrescue radiographic data were imputed by a linear extrapolation approach for any patient with $\geq$1 postbaseline radiograph, but these patients were not counted as in remission or with LDA for clinical outcomes.
**Results:** Overall, a greater proportion of patients receiving either dose of sarilumab + MTX achieved remission or LDA and had significantly less radiographic progression than patients receiving placebo + MTX (Table). Regardless of treatment group, patients who achieved remission or LDA showed less radiographic progression at wk 52 than patients who did not (Table). In general, the progression in patients achieving remission was lower than in patients achieving LDA. Even if patients did not achieve remission or LDA, patients receiving sarilumab + MTX had less radiographic progression than those receiving placebo + MTX. Smaller mean changes in mTSS were observed with sarilumab 200 mg q2w compared with sarilumab 150 mg q2w. Similar findings were observed for erosion score and joint space narrowing.
**Conclusions:** Remission or LDA was associated with less radiographic progression irrespective of treatment, and remission was associated with less radiographic progression than LDA. Irrespective of whether patients achieved remission or LDA, sarilumab + MTX was associated with less radiographic progression than placebo + MTX.

## SAT0150 COMPARATIVE RISK OF MALIGNANCY WITH INITIATON OF ABATACEPT AND OTHER BIOLOGICS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A COHORT ANALYSIS OF A UNITED STATES CLAIMS DATABASE

S. Suissa[1], N. Baker[2], H. Kawabata[2], N. Ray[3], T. Simon[2]. *[1]McGill University, Montreal, Canada; [2]Bristol-Myers Squibb, Princeton, United States; [3]Mu Sigma, Bangalore, India*

**Background:** Patients with RA may be at an increased risk for malignancies compared with the general population, and treatment with TNF inhibitors have been reported to further increase this risk.[1] Abatacept, the first selective co-stimulation modulator for the treatment of RA, has a mechanism of action that is fundamentally different from that of other biologic agents.
**Objectives:** This cohort study aimed to compare the risk of malignancy between patients initiating abatacept and patients initiating other biologic treatments.
**Methods:** Adult patients diagnosed with RA in the MarketScan® Commercial and Supplemental Medicare database who initiated treatment with abatacept or another biologic treatment between 1 July 2006 and 30 September 2014 were eligible for inclusion in the analysis. Patients were required to have at least 180 days of continuous health plan enrolment prior to, and $\geq$1 day following, initiation of the qualifying RA treatment. Patients were presumed to have initiated a treatment if there was no claim for that particular drug in the 180 days prior to the index date. Therefore, patients initiating abatacept or another biologic treatment may be initiating a biologic for the first time or switching from one biologic to another. Malignancies were identified by International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes. Patients were followed from 180 days after the date of initiation of abatacept or another biologic treatment until occurrence of a malignancy (identified by ICD-9 code), end of enrolment in the database or end of data collection, whichever occurred first. Patients who had an ICD-9 code for a malignancy in the 6 months prior to or after the date of initiation were excluded. Crude incidence rates were calculated for each cohort. After matching each initiator of abatacept with 1 or 2 initiators of other biologic treatments on the propensity score, a Cox regression analysis was performed to estimate the hazard ratio.
**Results:** A total of 17,670 patients initiating abatacept and 50,641 initiating another biologic were identified. During an average follow-up of 1.4 years for abatacept initiators and 1.6 years for other biologic initiators, there were 1132 and 2933 patients with an incident event of malignancy, respectively. This resulted in incidence rates of 44 (95% CI: 42, 47) and 36 (35, 38) per 1000 person-years in abatacept initiators and other biologic initiators, respectively. The propensity score analysis resulted in 17,517 patients initiating abatacept matched with 32,277 patients initiating another biologic. After adjusting for prior biologic treatment, the hazard ratio of malignancy with abatacept relative to other biologic agents was

1.10 (0.98, 1.23). Hazard ratios for lung cancer, lymphoma, breast cancer and non-melanoma skin cancer were also similar between the two.
**Conclusions:** In this large, real-world study of patients treated for RA, the risk of malignancy was not significantly different for those who initiated abatacept compared with those who initiated other biologic agents.

## SAT0151 IMAGING AND HISTOPATHOLOGICAL CHANGES TO TOCILIZUMAB IN PATIENTS WITH MODERATE TO SEVERE RA: A SINGLE CENTRE RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED STUDY

A.S. Zayat, C. Wong, R. Cuthbert, Z. Ash, S.J. Bingham, P. Emery, M.H. Buch. *Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds University, Leeds, United Kingdom*

**Background:** Tocilizumab (TCZ) is a well-established biologic therapy in the treatment of rheumatoid arthritis (RA). There is limited data on imaging and synovial tissue histology changes.
**Objectives:** To evaluate level of response as defined by power Doppler (PD) ultrasound (US) and synovial tissue histology changes.
**Methods:** Patients with RA, inefficacy to minimum one DMARD +/– TNFi, with DAS28≥3.2 and knee synovitis amenable to synovial biopsy were recruited to this open-label 48-week study. Patients randomised to TCZ/methotrexate (MTX) for 48 weeks or placebo (PBO)/MTX for the first 16 weeks followed by TCZ/MTX until week 48. Clinical and US hand, wrist and knee assessments with US-guided knee synovial biopsy at baseline (BL), weeks 12 and 48 (biopsy optional). US was scored accrording to OMERACT 0–3 grey scale and PD synovitis scoring system. Synovial tissue was assessed for synovial inflammatory infiltrate, stromal cell density, synovial lining on 0–3 scale and overall synovitis (0–9 scale) determined.
**Results:** 15 patients recruited: 12 (80%) females; 9 received TCZ/MTX, 6 PBO/MTX. 2 patients withdrew at each arm, one due to TCZ infusion reaction. Week 16: 33% (3/9) TCZ/MTX achieved DAS28ESR-rem vs 0 PBO+MTX, latter remaining in moderate/high disease activity. Week 48: 92% (12/13) whole group in DAS28ESR-rem. US response: 38% (3/8) TCZ/MTX group who had BL PD synovitis in hand/wrist had absence of PD synovitis at week 16 vs none PBO/MTX group. All patients with abnormal BL PD in knees (median (IQR) PD score of 2 (0–9)) had improved week 48 PD score (median (IQR) PD score of 0 (0–1)). 13 patients (8 TCZ/MTX, 5 PBO/MTX) had synovial biopsies obtained weeks 0 & 12; 21/26 samples (80%) samples useable. No difference between pre- and week 12 synovitis score in both groups. Median (IQR) total synovitis score at BL and after week 12 respectively of 3 (2.75, 4.25) and 3 (2.5–4) in the TCZ/MTX group vs 6 (4,7) and 6 (4,6) in PBO/MTX group. BL total synovitis score did not predict early or late response.
**Conclusions:** TCZ/MTX was associated with significant clinical and imaging improvement compared to MTX alone. An absence of change in synovial infiltrate with TCZ/MTX at 12 weeks suggests a different mechanism for response compared to other anti-cytokine therapies such as the TNFi. Further histochemistry analysis and investigation may potentially determine mechanism and indicators of response on a tissue level.

## SAT0152 SAFETY OF SURGERY IN PATIENTS TREATED WITH TOCILIZUMAB FOR RHEUMATOID ARTHRITIS: DATA FROM THE REGATE REGISTRY

M. Locci[1], C. Lukas[1], B. Combe[1], F. Banal[2], G. Cormier[3], M. Couret[4], M. Dougados[5], R.-M. Flipo[6], C. Marcelli[7], T. Pham[8], S. Rist[9], E. Solau Gervais[10], J. Sibilia[11], J. Morel[1]. *[1]Hopital Lapeyronie, Montpellier; [2]Hopital d'instruction des armées, Metz; [3]CHD de la Roche sur Yon, la Roche sur Yon; [4]CH Valence, Valence; [5]Hopital Cochin, Paris; [6]CHRU Roger Salengro, Lille; [7]CU côte de Nacre, Caen; [8]Hopital Sainte Marguerite, Marseille; [9]CHR la Source, Orléans; [10]CHU la miletrie, Poitier; [11]Hopital de Hautepierre, Strasbourg, France*

**Background:** Rheumatoid Arthritis (RA) patients have a higher risk of post-operative complications compared with the general population, especially considering the risk of infection. It remains unclear whether use of biological DMARDs, including Tocilizumab (TCZ), is an independent risk factor for post-operative complications.To date, there is no evidence pointing to delayed wound healing or increased risk of post-operative infection in patients receiving TCZ.
**Objectives:** To evaluate safety and predictive factors of complications after surgery in rheumatoid arthritis patients receiving Tocilizumab in routine care.
**Methods:** Patients treated with TCZ for RA included in the French REGATE registry were included if they underwent surgery. When TCZ was interrupted more than 12 weeks prior to surgery, patients were excluded. Post-operative complications were defined as an adverse event occurring in the 12 weeks after surgery. Frequency of post-surgery complications was collected and compared in patients with and without complications in order to identify factors associated with complications. A second analyze was achieved in patients with post-operative infection (local or general). Qualitative variables were compared by Fisher's test and quantitative variables were compared by the Mann-Whitney test.
**Results:** Out of 1499 patients from the REGATE registry, a total of 167 patients underwent 175 surgical procedures: 103 orthopedic surgeries (58.9%) and 29 abdominal surgeries (16.6%). These patients were mainly women (84%), the mean age was 58.11±12.83 years, and the disease duration of 14.96±11.29 years. The mean delay between surgery and the last TCZ infusion was 4.94±1.74 weeks (median 4 weeks). Thirty-eight surgical procedures happened whereas the last TCZ infusion was less than 4 weeks ago. Fifteen patients experienced 15 complications (8.9%) with 10 severe infections, 1 intestinal obstruction, 1 RA flare, 1 delayed wound healing, 1 thromboembolic disorder and 1 hemorrhagic complication. Postoperative complications occurred after 7.8% of orthopedic surgeries (8 of 103) and 2.9% of abdominal surgeries (2 of 29). The 10 severe infections occurred mostly after orthopedic surgery (7/10). There was 7 surgical site infections (46.7%) and 3 general infections. In 5 patients, TCZ treatment was definitely stopped. In univariate analysis, leflunomide dose was significantly associated with postoperative complications (p=0.04). Steroids and previous Rituximab treatment in the year before surgery, tended to be associated with peri-operative complications (p=0.09 and 0.07 respectively). In multivariate analysis, considering patients with infectious complications, diabetes was significantly associated with an increased risk of infection (P=0.03, OR 8.01, 95%CI 1.29–49.71).
**Conclusions:** In routine practice, the postoperative period in TCZ treated patients seem to be safe when TCZ is stopped 1 month before surgery. Diabetes was significantly associated with an increased risk of post-operative infection in RA patients treated with TCZ.
**Disclosure of Interest:** None declared

## SAT0153 ABATACEPT PLUS METHOTREXATE CAN EFFECTIVELY AND SAFELY REGAIN THE TARGET OF REMISSION FOLLOWING RE-TREATMENT FOR FLARES AFTER DRUG-FREE WITHDRAWAL IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

P. Emery[1], G. Burmester[2], V. Bykerk[3], B. Combe[4], D.E. Furst[5], M.A. Maldonado[6], T.W. Huizinga[7]. *[1]University of Leeds, Leeds, United Kingdom; [2]Charité – University Medicine Berlin, Berlin, Germany; [3]Hospital for Special Surgery, New York, United States; [4]Service d'Immuno-Rheumatologie, Montpellier, France; [5]University of California Los Angeles, Los Angeles; [6]Bristol-Myers Squibb, Princeton, United States; [7]Leiden University Medical Center, Leiden, Netherlands*

**Background:** AVERT was a Phase IIIb, randomized, active-controlled study to evaluate the efficacy and safety of abatacept (ABA) treatment in three phases: treatment period (TP), withdrawal period (WP) and re-exposure period (RP). The TP and first 6 months (M) of the WP have previously been reported.[1]
**Objectives:** To describe efficacy and safety of re-treatment with ABA + MTX following RA disease flare after all treatment withdrawal.
**Methods:** MTX-naïve, anti-cyclic citrullinated peptide-2-positive patients (pts) with early RA (active synovitis in ≥2 joints for ≥8 weeks, DAS28 [CRP] ≥3.2 and symptom onset within ≤2 years) were randomized to 12M of weekly SC ABA 125 mg + MTX, ABA 125 mg monotherapy (mono) or MTX alone. Pts with DAS28 (CRP) <3.2 at M12 entered a 12M WP with no treatment, including corticosteroids. All pts with protocol-defined flare after 15M could receive open-label weekly SC ABA 125 mg + MTX 10–20 mg (RP) for 6M. Baseline for the RP was the last assessment within 30 days before the first re-exposure dose. For pts who entered the RP, time to first flare after withdrawal (Kaplan–Meier [KM] curves) and predictors of shorter times to flare (Cox proportional hazard model), and DAS28 (CRP) remission during re-exposure (adjusted logistic regression), were modeled.
**Results:** Most pts entered the WP (225/351); of 176 pts with DAS28 (CRP) <2.6 at 12M, only 12.3, 14.0 and 11.3% for ABA + MTX, ABA mono and MTX alone, respectively, maintained DAS28 (CRP) <2.6 free of all drugs at 24M. The KM curves for time to first flare during WP for pts entering the RP are shown (Figure). Corticosteroid use at study entry was associated with shorter time to flare. In total, 146 pts from all three groups entered the RP; baseline characteristics were similar to those of pts at study entry (mean RA duration ~0.5 yrs). Mean (SD) DAS28 (CRP) was 5.28 (1.37) at RP baseline and 2.41 (0.94) at the end of RP (mean change: –2.87 [0.13], n=120). In total, 76.6% (95/124) of evaluable pts had low disease activity (DAS28 [CRP] <3.2) on RP Day 169, with 62.9% (78/124) in remission (DAS28 [CRP] <2.6). Mean (SD) HAQ at RP entry was 1.40 (0.63), and 0.64 (0.57) at the end of the RP. Pt assessment of disease activity was significantly associated with DAS28 (CRP) remission during the RP. Over the 12M WP, the numbers (%) of serious AEs were 2 (2.4), 0 (0) and 5 (6.7), respectively; only one serious infection was reported (MTX alone; pyelonephritis; 337.4 pt-yrs). In the RP, no pts discontinued due to AEs and no serious infections were reported (292.2 pt-yrs). Overall rates of infections were 8.1 and 16.1 (incidence rate/100 pt-yrs) in the WP and RP. In the TP, incidence rates of infections were 116.6,

126.1 and 110.7/100 pt-yrs from 0–6M, and 64.6, 66.5 and 72.8/100 pt-yrs from 6–12M for ABA + MTX, ABA mono and MTX alone.

**Figure.** Time to first flare after study medication withdrawal
All treated patients entering the re-exposure period

**Conclusions:** Re-treatment with abatacept + MTX can effectively recapture prior remission following flare after complete withdrawal of therapy. The lower rate of infections in the RP versus initial TP suggests re-treatment is well tolerated.

## SAT0154 REASONS FOR DISCONTINUATION THE BIOLOGICAL TREATMENT IN CHRONIC INFLAMMATORY ARTHROPATHY

A. Martin Vila [1], R. Melero Gonzalez [2], N. Martinez Lopez de Catro [1,3], M. Álvarez Payero [1], M.R. Rodriguez [1], F. Maceiras Pan [2,3], C. Mouriño [2,3], M. Rodríguez López [2,3], I. Hernández Rodriguez [2], C. Barbazán Álvarez [2], M. Samartin Ucha [1,3], V. Balboa Barreiro [4], J. De Uña Álvarez [4], G. Piñeiro Corrales [1], J.M. Pego Reigosa [2,3]. *[1]Pharmacy; [2]Rheumatology, Eoxi Vigo; [3]Iridis Group, IBI; [4]Statistic, U. Vigo, Vigo, Spain*

**Objectives:** To analyze the reasons for discontinuation the biological treatment in a cohort of patients diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (PA), ankylosing spondylitis (AS) and other spondyloarthropathies (O) that have been treated with at least a biotech drug.

**Methods:** Retrospective observational study. All patients who had been treated with a biological drug for at least six months during the period between 01/01/2009 and 31/08/2014, for any of the previously specified indications were included. In addition to demographic data, all lines of treatment received from the diagnosis, and the reasons for discontinuation of those lines were analyzed. The adverse events categorized as reasons to treatment discontinuation were collected. The relationship between the reasons for discontinuation and the biological treatment was explored.

**Results:** We studied 484 patients with a mean age of 56 years (SD 14.4), 54.3% women. Disease distribution: 49% RA,21.5% PA, 22.6% AS and 6.9%O.Drug distribution:adalimumab 45.7% of patients,etanercept 29%,infliximab 12.7%,golimumab 2.6%,certolizumab 0.8%, abatacept 2.6%, rituximab 3.4% and tocilizumab 3%.Of a total of 765 lines of treatment, were analyzed all the finished lines:365.The reasons for discontinuation were:42.5% secondary failure,22.7% side effects,10.7% primary failure,6% clinical remission,1.9%, exitus, nonadherence 0.3% and other reasons for discontinuation 15.9%.Significant differences ($p<0.05$) were observed in the distribution of reasons for discontinuation based on biological treatment used.All comparisons between different drugs 2–2 were performed for each of the reasons for discontinuation, and the following differences were found.When adalimumab versus etanercept and versus infliximab is compare, it is more frequent the reason for discontinuation “clinical remission” in adalimumab than in etanercept or infliximab ($p<0.05$).When comparing etanercept versus infliximab is more often the reason for discontinuation “primary failure” with etanercept ($p<0.01$).

In the 50% of patients (P) with rituximab and in the 38.5% of P with abatacept the reason for discontinuation was an adverse event (AE), compared with 19% in adalimumab, 19.6% etanercept and 26.3% infliximab. Regarding the AE that were a cause for discontinuation:infusion reaction in 19P,general symptoms in 16P,bacterial infection in 12P,other types of skin toxicity 11P,anaphylaxis in 8P,liver toxicity in 4P,hematologic tumor in 2P,tuberculosis in 2P,psoriasiform reaction 2P,viral infectión 2P,interstitial disease 1P,solid tumor in 1P,psychiatric disorders in 1P,lipid abnormalities 1P,hematologic toxicity 1P and not collected in history in 2P.

**Conclusions:** The most common reason for discontinuation was "secondary failure" followed by “AE”,highlighting the infusion-related reactions and bacterial infections.The frequency of several of the reasons for discontinuation of treatment is different depending on the biological drug used.

Supported by an unrestricted grant from Pfizer.

## SAT0155 SIGNATURE OF INFLAMMATORY GENES IN B-CELLS AND DOUBLE NEGATIVE MEMORY PHENOTYPE AS BIOMARKERS OF RESPONSE TO TOCILIZUMAB

A.L. Fedele [1], B. Tolusso [1], S. Canestri [1], E. Gremese [1], C. Di Mario [2], G. Di Sante [2], S. Alivernini [1], G. Ferraccioli [1]. *[1]Institute of Rheumatology; [2]Institute of General Pathology, Catholic University of the Sacred Heart, Rome, Italy*

**Background:** Tocilizumab (TCZ) is an effective treatment in Rheumatoid Arthritis (RA) inducing modifications of B cell subsets in vivo.[1–3]

**Objectives:** To define whether the study of circulating B cell subsets could represent a possible tool to understand the pharmacological action of TCZ, helping the clinician to identify the best responders to IL6R blockade.

**Methods:** 70 RA patients (age 52.3±15.2 years, disease duration 8.5±10.1 years, 74.3% female) not responder to previous cDMARDs (n=39) and/or bDMARDS (n=31) were enrolled in the study, of which 19 (27.1%) with early RA (ERA) and 51 (72.9%) with a long-standing disease (LSRA). All patients were treated with TCZ at a dose of 8 mg/kg every 4 weeks. At each visit remission was evaluated according to ACR/EULAR criteria[4] and peripheral blood (PB) derived B cells were collected for the analysis of B-cell subsets distribution by FACS using IgD-CD27 classification[5]. Among them, PB-derived B cells from 13 bDMARDs naïve RA patients were analyzed for specific genes expression through RT-PCR.

**Results:** In RA cohort, 16.7% and 19.3% of TCZ-treated RA patients reached ACR/EULAR remission (SDAI$\leq$3.3) at 6th and 12th months FU. At TCZ baseline, a higher percentage of post-switched memory B-cells (p=0.005) together with plasmablasts ($p<0.001$) and a lower percentage of pre-switched memory B cells (p=0.01) were observed in RA patients compared to Healthy Controls (HC, n=45) mainly in bDMARDs naïve patients. After TCZ treatment, we showed an increase of pre-switched memory and a reduction of post-switched memory and double negative (DN) B cells in responders, more evident in patients reaching remission. In particular, patients reaching SDAI remission at 6 and 12 months of TCZ-treatment had a higher reduction of DN B cell subsets already after 3 months reaching a comparable value as in HC ($p<0.05$). At the multivariate analysis, a disease duration less than 12 months [OR (95%CI): 18.0 (1.6–203.9)], a moderate disease activity (SDAI$\leq$26) at baseline [OR (95%CI): 20 (1.7–250)] and a higher reduction of DN B cells at 3 months of FU [OR (95%CI): 1.05 (1.01–1.08)] arose as significant independent predictors of ACR/EULAR remission (SDAI$\leq$3.3) at 6th months of TCZ treatment. Finally, TCZ-treatment seems to influence B-cell genes expression inducing an up-regulation of proinflammatory molecules (TNF-alpha, IL6) genes, together with the related STAT3, SYK and ZAP-70 genes, in the earlier treatment phases (3 and 6 months respectively) and the subsequent down-regulation of their receptors (TNF-RII and IL6R). Interestingly, the expression of JAK1 decreased significantly at the 12th month, whereas that of JAK3 did not change at the different time points.

**Conclusions:** In our cohort of TCZ-treated RA patients, a significant reduction of DN memory B cells at the 3th month of FU has emerged as an early biomarker of remission afterwards. At the same time, profound effects at the JAK1 gene level occurred in B cells after TCZ treatment, even if an increase of Syk and ZAP-70 genes expression was observed, suggesting that B cells are not fully deactivated even after 6–12 months of treatment.

Blanco[1]. *[1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander; [2]Rheumatology, Clinic Hospital Santiago de Compostela, Santiago; [3]Rheumatology, Hospital la Princesa; [4]Rheumatology, Hospital Puerta del Hierro; [5]Rheumatology, Hospital 12 de Octubre, Madrid; [6]Rheumatology, Hospital de Donostia, Donostia; [7]Rheumatology, Hospital Ourense, Ourense; [8]Rheumatology, Hospital Bellvitge, Barcelona; [9]Rheumatology, Hospital de Basurto, Bilbao; [10]Rheumatology, Hospital Malaga, Malaga; [11]Rheumatology, Hospital Gemans Trias i Pujol, Badalona; [12]Rheumatology, Hospital la Fe, Valencia; [13]Rheumatology, Hospital Laredo, Laredo; [14]Rheumatology, Hospital de Alicante, Alicante; [15]Rheumatology, Clinic Hopital Lozano Blesa, Zaragoza; [16]Rheumatology, Hospital Rafael Menendez, Lorca; [17]Rheumatology, Hospital Can Misses, Ibiza; [18]Rheumatology, Hospital Universitario de Alava, Alava; [19]Rheumatology, Hospital Universitario de Navarra, Pamplona, Spain*

**Background:** Rheumatoid arthritis (RA) may associate with Interstitial Lung Disease (ILD). Disease-modifying anti-rheumatic drug (DMARD) or TNF alfa inhibitors (iTNF), had been involved in the ILD development as well as exacerbation of an existing one. Nowadays there is no consensus related to treatment.
**Objectives:** The aimed of this study is to evaluate efficacy and safety of Abatacept (ABA) treatment in patients with AR and ILD.
**Methods:** Multicentre study in patients with RA and ILD associated were treated with ABA. ILD was diagnosed by High Resolution Computed Tomography (HRCT). ABA was used at dose of 10 mg/kg/4 weeks iv or 125 mg/week sc. Its efficacy was evaluated according to the following measures:

a) Dyspnea classified by the Modified Medical Research Council (MMRC); Significant variability of 1 point and asymptomatic MMRC=0;
b) Pulmonary function test (PFT); Significant oscillations >10% in Forced Vital Capacity (FVC) and diffusing capacity of the lung for carbon monoxide (DLCO) >10%;
c) Imaging technique (HRCT);
d) Joint assessment (DAS28).

Quantitative variables were expressed as mean ± SD or as median (interquartile range) and compared with (Wilcoxon test) (Test Fisher) between the baseline and 3, 6 and 12 months.
**Results:** 34 individuals were included (19 women /15 men), patients with ILD associated to RA, with a mean age of 61,4 ± 9,8 years. The median duration of RA before ADA was initiated was 4,8 [0,86–13,12] (0–25) years, and had previously received an average 1,29±0,90 DMARDs. RA was seropositive in 24 cases (71%). ILD was associated with a DMARD: MTX (n=3), Etanercept (n=3), Adalimumab (n=3) y Certolizumab (n=1).
ABA was used in monotherapy in 14 patients and combined with other immunosuppressors in 20 patients: Leflunomide (LFD) (n=7), LFD and cyclosporine (n=1), Sulfasalazine (n=1), MTX (n=2), MTX with LFD (n=1), hydroxychloroquine (n=5), Hydroxychloroquine with LFD (n=2), Azathioprine (n=1).
A significant improvement of dyspnea was observed; patients who didn't have dyspnea, kept asymptomatic. FVC and HRCT showed a significant improvement during 6 to 12 months period. DLCO remained stable in the majority of the patients. RA (DAS28) activity also improved.
After follow up of 12,82±7,48 months, the most significant adverse effects were: pulmonary Infection (n=2), urinary infections (n=1), infusion reactions (n=1).
ABA was discontinued due to: Serious infections (n=2); join inefficacy (n=2), pulmonary inefficacy (n=1), infusion reaction (n=1).
**Conclusions:** ABA seems to be an effective and relatively safe treatment in patients with RA and associated ILD. This data should be verified again in prospective and randomized studies.

## SAT0157 TOCILIZUMAB SERUM TROUGH LEVELS CORRELATE WITH CLINICAL ACTIVITY IN RHEUMATOID ARTHRITIS

C. Tornero Marín[1], C. Plasencia[1], D. Pascual Salcedo[2], T. Jurado[2], M.B. Paredes[1], I. Monjo[1], E. Moral[1], A. Pieren[1], G. Bonilla Hernán[1], D. Peiteado[1], P. Bogas[1], L. Nuño[1], A. Villalba Yllan[1], E. Martín Mola[1], A. Balsa Criado[1]. *[1]Rheumatology; [2]Immunology, Hospital La Paz, Madrid, Spain*

**Background:** Tocilizumab (TCZ), a humanized anti-IL-6 receptor antibody, represents a new treatment strategy for RA patients.Several studies have demonstrated the association between high serum levels of TNF-inhibitors and a good clinical response in patients with RA. Little evidence exists on this relationship for other biological therapies.
**Objectives:** To evaluate the association between TCZ serum through levels and disease activity in a cohort of RA patients after one year of treatment with TCZ.
**Methods:** 34 RA patients treated with Tocilizumab were included. Clinical activity was assessed using the Disease Activity Score 28 (DAS28-ESR) and the Clinical and Simplified Activity Index (CDAI and SDAI), serological improvement by C-Reactive Protein- CRP- and Erythrocyte Sedimentation Rate-ESR, clinical improvement by the delta-DAS 28 and response to treatment using EULAR criteria at baseline and after one year of treatment. We stratified all patients into quartiles according to the tocilizumab levels (μg/ml) as follows: IQR1: <3,4, IQR2: 3,4–11,2, IQR3: 11,2–18,5 and IQR4 >18.5. A last observation carried forward analysis (LOCF) was performed at the first year of treatment, so patients that dropped out of the therapy before this period were included. Blood samples were collected just before intravenous (i.v) infusion. Serum drug levels were determined by a capture enzymelinked immunosorbent assay (ELISA).
**Results:** The baseline demographic and clinical characteristics are shown in Table 1. When patients were categorised into quartiles, IQR1 comprised 8 (24,2%) patients; IQR2, 7 (21,2%); IQR3, 8 (24,2%) and IQR4, 10 (30,3%). Clinical activity (DAS28, CDAI and SDAI) was statistically significant higher in patients with lower serum through levels at the first year [DAS28 (IQR1: 4,46 ±1,5, IQR2: 2,58 ± 0,87, IQR 3: 3,6± 0,79; IQR4: 2,17 ± 0,74; p=0,001), CDAI (IQR1: 23±13,9, IQR2: 7,72 ± 4,44, QIR 3: 13,38± 4,35, IQR4: 6,33 ± 4,62; p=0,003) and SDAI (IQR1: 19,46 ±15,5, IQR2: 9,51± 7,4, IQR3: 12,59 ± 6,31, IQR4: 4,55 ± 3,73; p=0,005)] and also was the number of swollen joints (IQR1: 7,5 ± 6,6, IQR2: 2,29 ±2,06, IQR3: 5,63 ± 4,3, IQR4: 1,1 ± 1,6, p=0,013) and tender joints (IQR1: 5,5 ± 5,7, IQR2: 1,71 ± 2,06, IQR3: 3,13 ± 2,8, IQR4: 0,8 ± 0,9, p=0,014). In addition, the EULAR reponse was worse in those patients with lower serum drug levels [non-responders: 4 (66,7%) in IQR1 vs 1 (16,7%) in IQR2 vs 1 (16,7%) in IQ3 vs 0 (0%) in IQR4, moderate responders: 3 (37,5%) in IQR1 vs 0 (0%) in IQR2 vs 4 (50%) in IQR3 vs 1 (12,5%) in IQR4 and good responders: 1 (5,3%) in IQR1 vs 6 (31,6%) in IQR2 vs 3 (37,5%) in IQR3 vs 9 (47,4%) in IQR4, p=0,006]. In terms of acute-phase reactants, the mean ESR tended to be higher in patients with lower TCZ levels (IQR1: 22,6±14,8 vs IQR2: 5,6±1,6 vs IQR 3: 9,4 ±3,5 vs IQR4: 6,4 ± 3,5, p=0,005), and also CRP levels (RIQ1: 10,2±17,4 vs RIQ2: 2,3 ± 3,4 vs RIQ3 0,56 ± 0,4 vs RIQ 4: 0,42 ± 0,66, p=NS)].

## SAT0158 RESPONSE AND RADIOGRAPHIC PROGRESSION IN BIOLOGIC-NAÏVE AND BIOLOGIC-EXPERIENCED PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SIRUKUMAB

C. Thorne[1], G. Karpouzas[2], T. Takeuchi[3], S. Sheng[4], W. Xu[4], S. Xu[4], R. Kurrasch[5], K. Fei[4], B. Hsu[4]. *[1]University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; [2]Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, United States; [3]Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan; [4]Janssen Research & Development, LLC, Spring House, PA; [5]GlaxoSmithKline, Collegeville, PA, United States*

**Background:** Efficacy and safety of sirukumab, a selective, high-affinity human monoclonal antibody to IL-6, have recently been evaluated in a global Phase 3 study in patients (pts) with active rheumatoid arthritis (RA) refractory to conventional disease-modifying anti-rheumatic drugs (DMARDs).

**Objectives:** To compare efficacy and radiographic progression of sirukumab in subgroups of pts with active RA despite DMARD treatment who previously received biologic therapy (biologic-experienced) and who previously only received synthetic DMARDs (biologic-naïve).

**Methods:** Pts were randomized (1:1:1) to sirukumab subcutaneous (SC) 50mg q4w, sirukumab SC 100mg q2w, or placebo SC q2w. Pts on placebo with insufficient (<20%) improvement at Wks 18 or 40 or still on placebo at Wk 52 were re-randomized to sirukumab treatment (1 of the 2 doses). The co-primary efficacy endpoints were: Wk 16 ACR20 response and Wk 52 change from baseline (BL) in modified vdH-S radiographic score. This post-hoc analysis compared efficacy for biologic-naïve and -experienced pts within biologic experience category for sirukumab vs placebo, and across experience category within sirukumab dose group.

**Results:** Improvements were observed in all outcomes for sirukumab vs placebo, regardless of prior biologic use (all $P<0.001$ within biologic experience categories; Table). 34.9% (583/1,670) of pts were prior biologic-experienced; efficacy with sirukumab was comparable for pts who had taken 1 or ≥2 prior biologics. At BL, compared with biologic-naïve pts, biologic-experienced pts had longer disease duration (mean, 11 vs 7 yrs; $P<0.0001$) and worse HAQ-DI scores (mean, 1.58 vs 1.49; $P=0.02$). No differences between prior biologic-naïve and -experienced pts were observed in either sirukumab dose group for the co-primary endpoints (both $P\geq0.1$) as well as for Wk 24 ACR50 response, DAS28 (CRP) remission, or Wk 52 mean DAS28 change from BL (all $P\geq0.1$).

**Conclusions:** Both sirukumab doses significantly reduced RA signs/symptoms and inhibited radiographic progression vs placebo within prior biologic use categories, with comparable efficacy observed between biologic-naïve and -experienced pts for both sirukumab doses.

## SAT0159 RESULTS OF A PHASE 1B STUDY OF THE SAFETY, TOLERABILITY, AND PHARMACOKINETICS OF THE MMP9 INHIBITOR GS-5745 IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

D.L. Gossage[1], B. Cieslarova[2,3], S. Ap[1], H. Zheng[4], S. Zhao[4], Y. Xin[4], P. Lal[4], G. Chen[1], V. Smith[4], J.S. Sundy[4]. *[1]Gilead Sciences Inc., Seattle, United States; [2]Pharmaceutical Research Associates, CZ, s.r.o; [3]First Department of Internal Medicine, Third Faculty of Medicine, Charles University, Prague, Czech Republic; [4]Gilead Sciences Inc., Foster City, United States*

**Background:** Active matrix metalloproteinase-9 (MMP9) degrades matrix proteins and promotes inflammation. MMP9 knockout mice are also protected from collagen-induced arthritis disease progression. Furthermore, elevated levels of MMP9 are present in the synovial fluid of patients with RA suggesting that targeting of MMP9 may have therapeutic benefit. GS-5745 is a humanized $IgG_4$ mAb that inhibits MMP9 activity with picomolar specificity.

**Objectives:** To determine the safety and tolerability of GS-5745 in adult subjects with RA. Secondary objectives were to investigate the PK of GS-5745, and to assess the effect of GS-5745 on RA disease activity measures.

**Methods:** This multi-center, randomized, double-blind, placebo-controlled study enrolled 18 subjects who met the ACR criteria for RA and had a mean screening CRP ≥8.0 mg/L. Subjects were randomized 4:1 to receive GS-5745 400 mg or placebo (PBO) infusions every 2 weeks for a total of 3 infusions. Concurrent biologic DMARD use was excluded, but subjects continued their stable conventional DMARD therapy. A 28 swollen and tender joint count, patient assessment of pain, and patient and physician global assessment of health were obtained.

**Results:** Eighteen subjects (15 active and 3 PBO) were enrolled and received 3 doses of GS-5745 or PBO. The median plasma half-life of GS-5745 was 5.7 days. Mean free plasma MMP9 levels in the GS-5745 cohort were reduced by 90% from 126.1 ng/mL at Baseline to 13.2 ng/mL (2.18) at Day 43; compared to a 17% increase from 76 ng/mL at Baseline to 89 ng/mL at Day 43 in the PBO cohort. DAS 28-CRP low disease activity or remission at Day 43 occurred in 4/15 patients receiving GS-5745 versus 0/3 receiving PBO There were no SAEs. All adverse events were of Grade 1 or 2 severity. AEs occurring in ≥10% of active treated subjects included hypertension and nasopharyngitis, both 13%. Changes in additional RA disease activity measures are shown in the tab:

**Conclusions:** Short term treatment with GS-5745 in patients with RA was well tolerated. Improvement in selected measures of RA disease activity was observed after 3 doses of GS-5745. Mean free plasma MMP9 was reduced by 90% compared to baseline in the GS-5745 group at Day 43. These results support further studies evaluating GS-5745 in RA.

**Acknowledgement:** We would like to thank study investigators Drs. E. Peterfai,

## SAT0160 CLINICAL AND RADIOGRAPHIC OUTCOMES AFTER 2 YEARS OF SARILUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. van der Heijde[1], J. van Adelsberg[2], J. Fay[2], H. van Hoogstraten[3], E.K. Mangan[2], N. Graham[2], C. Fan[3], A. Spindler[4], M.C. Genovese[5]. *[1]Leiden University Medical Centre, Leiden, Netherlands; [2]Regeneron Pharmaceuticals, Inc., Tarrytown; [3]Sanofi, Bridgewater, United States; [4]Universidad Nacional de Tucumán, Tucumán, Argentina; [5]Stanford University Medical Center, Palo Alto, United States*

**Background:** Sarilumab, an investigational human IL-6 receptor mAb, demonstrated statistically significant improvements in signs and symptoms of RA, physical function, and inhibition of radiographic progression in combination with MTX in the 1-year phase 3 MOBILITY study (NCT01061736).
**Objectives:** This analysis examined 2-year clinical and radiographic outcomes and safety in patients completing the MOBILITY study who continued in the open-label, long-term extension (OLE) study EXTEND (NCT01146652) and were treated with sarilumab 200 mg q2w.
**Methods:** Patients who participated in MOBILITY were initially randomized to placebo or sarilumab 150 or 200 mg subcutaneously for up to 1 year. Early rescue with open-label sarilumab 200 mg was allowed in case of insufficient response after wk 16. Following MOBILITY patients were eligible for enrollment in EXTEND, where all patients received active treatment (sarilumab 200 mg q2w after final dose selection) + MTX. Radiographs of patients who had a radiograph available at baseline and in the first and second year were centrally read by 2 readers independently. Linear extrapolation was performed if a patient had 2 postbaseline radiographs but was missing a radiograph at year 2. Analysis of clinical endpoints was based on all available data. Clinical endpoints were set to missing after early treatment discontinuation but not after rescue with open-label sarilumab. Statistical analysis was performed on the basis of patients' original randomized treatment assignment (placebo, or sarilumab 150 or 200 mg), regardless of whether the patient was rescued during the double-blind period (MOBILITY).
**Results:** Of the 1197 randomized patients enrolled in MOBILITY, 901 patients participated in EXTEND (Table). At year 2, disease activity (DAS28-CRP and CDAI) reached the same level regardless of initial treatment. In addition, at year 2, percentages of patients achieving DAS28-CRP $<2.6$ were similar in the 3 groups, and similar trends were observed for CDAI remission (CDAI $\leq 2.8$) (Table). Two-year radiographic data were available for 800 patients; linear extrapolation was used in 56 of these patients. mTSS scores at year 1 in initial placebo and sarilumab 150 and 200 mg groups were maintained through year 2 in the OLE (Table). TEAEs occurred in 86.3% of patients over 2 years, and SAEs occurred in 16.3% of patients. Over 2 years, death occurred in 7 patients (0.6%). Five deaths were classified as unrelated to treatment. Two deaths were assessed as possibly associated with sarilumab (streptococcal sepsis, possible stroke). The most common TEAEs ($\geq$5% in $\geq$1 treatment group) were neutropenia (17.8%), increased ALT (11.6%), and upper respiratory tract infections (11.1%).
**Conclusions:** Once active treatment with sarilumab 200 mg q2w was initiated after year 1, clinical response at year 2 was similar irrespective of prior treatment, and radiographic progression stabilized. Adverse events were consistent with the anticipated effects of IL-6 inhibition and the known safety profile of sarilumab.

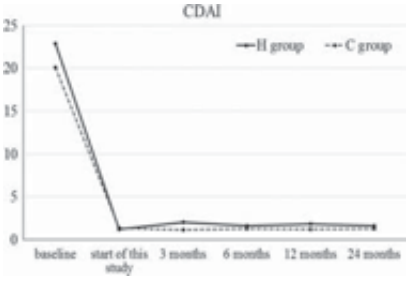
## SAT0161 THE RETENTION RATE OF ABATACEPT IN VERY ELDERLY PATIENTS (75 YEARS AND ABOVE) WITH RHEUMATOID ARTHRITIS, SINGLE-CENTER, RETROSPECTIVE, OBSERVATIONAL STUDY

E. Kikuchi, K. Uekubo, N. Aoki, T. Yoshioka, T. Okai. *Center for Rheumatology and Joint Surgery, Kawakita General Hospital, Tokyo, Japan*

**Background:** There are few data about the safety of biologics for very elderly rheumatoid arthritis patients.
**Objectives:** To analyze the retention rate of abatacept in very elderly patients with rheumatoid arthritis (RA).
**Methods:** Data was collected retrospectively from medical records of RA patients in our center. Abatacept was administered in 58 patients. We divided them into two groups of the very elderly group (over 75 years old) and the remaining group (under 75 years old). We analyzed the retention rate of each group by Kaplan-Meier curves and log-rank test.
**Results:** In *the very elderly group* (29 cases: 81.6±3.3 years, women: 89.7%, ACPA-positive: 86.2%, MTX use: 48.3%, oral steroid use: 31.0%), the cumulative retention rates in 12 and 24 months were both 0.558.
In *the remaining group* (29 cases: 63.4±10.7 years, women 89.7%, ACPA-positive: 86.2%, MTX use: 58.6%, oral steroid use: 37.9%), the cumulative retention rates in 12 and 24 months were 0.705 and 0.617 respectively.
There was no significant difference in the retention rates in the two groups (log-rank test, p=0.913). Abatacept was administered as the first biologics in 58.6% of the very elderly group, 31.0% of the remaining group respectively.
The main reasons for discontinuation of abatacept were hospitalization for infection (elderly: 3 cases, remaining: 2 cases) and hospitalization for gastrointestinal symptoms (elderly: 2, remaining: 0).



**Conclusions:** Our data suggested that abatacept can be used for a long period even for very elderly RA patients.

## SAT0162 BIOLOGICAL AGENT HOLIDAY THERAPY FOR RHEUMATOID ARTHRITIS IN PATIENTS WITH CLINICAL DISEASE ACTIVITY INDEX REMISSION

E. Torikai, M. Suzuki, Y. Matsuyama. *Orthopaedic surgery, Hamamatsu university school of medicine, Hamamatsu, Japan*

**Background:** The advancement in biological agents (Bio) and improvement in treatment strategy enabled patients with rheumatoid arthritis to achieve remission or to achieve low disease activity. On the other hand, the cost of Bio has become a major problem in health economics and for some patients Bio therapy is not affordable. In this situation, it is important for us to consider whether we should discontinue or extend the interval of Bio.
**Objectives:** To investigate Bio-holiday therapy for rheumatoid arthritis patients with clinical disease activity index (CDAI) remission.
**Methods:** Thirty seven rheumatoid arthritis (RA) patients with CDAI remission were included in this study. The patients were classified into two groups. Bio-holiday group (group H) consisted of 17 patients (etanercept (ETA) 5, golimumab (GLM) 8, tocilizumab (TCZ) 4 patients) where the patients were off from Bio if they achieved CDAI remission. Methotrexate was combined for all patient. They had to visit our clinic at least once in every two months, and were treated with Bio within 3 months after falling out of CDAI remission. They could be off from Bio again once they've reached CDAI remission. Bio group (group C) consisted of 22 patients (ETN 7, GLM 9, TCZ 6 patients). The mean ages of the two groups were 55.6 for H and 58.3 years old for C group and the mean disease duration were 4.45 and 4.96 years. There were no statistical differences between the backgrounds of both groups. CDAI, the van der Heijde-modified total sharp scores [1] (mTSS) and health assessment questionnaire [2] (HAQ) were compared between both groups.
**Results:** The mean withdrawal periods were 11.8 (GLM), 6.5 (ETN) and 10.0 months (TCZ) respectively. Two patients in group H and 3 patients in group C dropped out due to financial reasons. One patient in each group dropped out due to flare-up. None of the patients discontinue their therapy for adverse events in both groups. Except for one patient who dropped out from CDAI remission due to flare-up in H group, all the other patient were able to achieve CDAI remission without delay. There were no statistical differences in CDAI throughout the period of study (Figure). There were no statistical differences in ∆mTSS (group H -0.18/year and group C -0.24/year) and HAQDI (group H; 0.12, 0.08 and group C; 0.10, 0.08 at baseline and at final evaluation respectively).

**Conclusions:** We conclude that it is possible to keep disease activity, radiographic progression and physical function by Bio-holiday for RA patients with CDAI remission under tight control strategy. As the flare-up rate of RA patients with deep remission is not so severe, it is not difficult for us to restart Bio therapy and gain CDAI remission. In addition it is financially durable and thus we recommend bio-holiday therapy.

## SAT0163 LONG TERM TREATMENT WITH ABATACEPT OR TOCILIZUMAB DOES NOT INCREASE EPSTEIN-BARR VIRUS LOAD IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Massy[1], O. Muis-Pistor[1], M. Martin[2], I. Auger[2], M.-C. Guzian[1], S. Guis[1,3], J. Roudier[1,2], T. Pham[4], N. Balandraud[1,2]. *[1]Rheumatology 1, AP-HM, Aix Marseille University; [2]UMRs1097, INSERM, Marseilles; [3]CRMBM/CEMEREM UMR 7339, Aix Marseille University, Marseille; [4]Rheumatology 2, AP-HM, Aix Marseille University, Marseilles, France*

**Background:** Epstein-Barr Virus (EBV) is a widely disseminated lymphotrophic herpes virus implicated in a lot of benign and malignant disorders. In transplant patients, EBV load is enhanced because of immunosuppressive drugs (cyclosporine) and in a few cases, it can lead to lymphoproliferative disorders (LPD). An EBV load higher than 500 copies per 500 ng of DNA is a predictive factor of post transplant lymphoma [1,2] Similarly, immunity against EBV is particular in RA patients: the level of antibodies against EBV is higher in RA than in healthy controls [3], RA patients have a defective EBV specific supressor T cell function [4].The risk to develop a lymphoma is higher in RA patients than in controls. We have previously shown that: 1/ EBV load is 10 fold higher in RA patients than in controls [5] and 2/ Methotrexate and TNF alpha antagonists (immunosuppressive drugs used in RA patients) do not increase EBV load in RA [6].
**Objectives:** Here, we monitored EBV load over 3 years in patients with RA treated by 2 more recent biologics, Abatacept (CTLA4 Ig) a T cell activation inhibitor, or Tocilizumab, an anti IL6 receptor antibody.
**Methods:** EBV load in the peripheral blood mononuclear cells (PBMCs) from 55 patients under Abatacept (+/– Methotrexate) and 35 patients under Tocilizumab (+/– Methotrexate) was monitored from 6 months up to 3 years, by real time PCR. The influences of treatment duration and disease activity score 28 (DAS28) index on EBV load were analyzed.
**Results:** Neither Abatacept nor Tocilizumab significantly enhanced EBV load over time. None of our patients developed EBV associated lymphoma.
**Conclusions:** Long term usage of Methotrexate with Abatacept or Tocilizumab in patients with RA does not significantly influence EBV load in PBMCs.

## SAT0164 IMMUNE RECONSTITUTION 20 YEARS AFTER TREATMENT WITH ALEMTUZUMAB IN A RHEUMATOID ARTHRITIS COHORT: IMPLICATIONS FOR LYMPHOCYTE DEPLETING THERAPIES

F.A.H. Cooles[1], A.E. Anderson[1], T. Drayton[2], R.A. Harry[1], J. Diboll[1], L. Munro[1], N. Thalayasingam[1], A.J.K. Östör[2], J.D. Isaacs[1]. *[1]National Institute for Health Research Newcastle Biomedical Research Centre at Newcastle upon Tyne Hospitals Foundation Trust and Newcastle University, Newcastle upon Tyne; [2]Addenbrooke's NHS Trust, Cambridge, United Kingdom*

**Background:** Alemtuzumab, an anti-CD52 monoclonal antibody, was administered (cumulative dose range 1–420mg) to a cohort of patients with severe RA between 1991–94[1]. We previously reported significant delays in immune reconstitution detectable 12 years after administration[2].
**Objectives:** To perform the 20 year follow-up of our unique cohort with regards to morbidity, mortality, lymphocyte reconstitution, circulating cytokines and response to vaccination.
**Methods:** Mortality and morbidity data (Mar 2006–Jan 2015) were collected from death certificates, case notes or interview. Alemtuzumab patients were age, sex and disease duration matched with RA controls. For both groups circulating lymphocyte subsets ($CD4^+$ and $CD8^+$ naïve, central memory and effector memory T cells; naïve, memory and $CD5^+$ B cells and $CD19^+CD24^{hi}CD38^{hi}$ Bregs; NK Cells and NK T Cells) were quantified by multicolour flow cytometry. Serum IL-15 and IFN-$\gamma$ were measured by ELISA (MSD) and antigenic responses by generation of protective titres (as conventionally defined) following vaccination with influenza, Pneumovax II and combined diphtheria/tetanus/poliovirus vaccines
**Results:** 16 patients were alive at the time of this study, 9 agreed to interview, vaccines and peripheral blood analysis, a further 4 had case note review only and 3 were uncontactable. 8 matched RA controls were also recruited. Since our last review 10 patients had died with causes of death consistent with a population with long-standing RA. There was no suggestion of compromised immune function with no increase in new autoimmune conditions or severe infections in living patients. Alemtuzumab patients continued to demonstrate abnormalities in their lymphocyte compartment with persistent significant reductions in $CD4^+$ and $CD8^+$ central memory cells, $CD5^+$ B Cells and a new finding of significantly reduced naïve B cells when compared with previous analysis[2]. For the first time we examined $CD19^+CD24^{hi}CD38^{hi}$ Bregs which were also significantly reduced. Nonetheless vaccine responses were comparable between alemtuzumab recipients and controls. In addition, there were significantly higher IL-15 and IFN-$\gamma$ levels in the

serum of the alemtuzumab cohort. IL-15 levels inversely associated with $CD4^+$ total memory and central memory T cells.
**Conclusions:** In this unique patient cohort, after 20 years the effects of alemtuzumab treatment persist. Despite lymphocyte abnormalities, satisfactory vaccine responses are mounted and opportunistic infections remain absent. We hypothesise the reduced T-cell compartments trigger IL-15 via homeostatic mechanisms which, as a bystander effect, may activate NK cells causing IFN-$\gamma$ release. An activated NK compartment could explain the lack of opportunistic infections in patients with lymphocyte abnormalities for 20+ years.
As lymphodepleting therapies, including alemtuzumab, continue to be administered this work is important with regard to long term drug safety and stages of immune recovery.

## SAT0165 TOFACITINIB VERSUS BIOLOGIC TREATMENTS IN MODERATE TO SEVERE RHEUMATOID ARTHRITIS PATIENTS WHO HAVE HAD AN INADEQUATE RESPONSE TO NONBIOLOGIC DMARDS: SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS

E. Bergrath[1], G. Wallenstein[2], R. Gerbert[2], D. Gruben[2], C. Makin[1]. *[1]Mapi, Boston; [2]Pfizer Inc., Groton, United States*

**Background:** Rheumatoid Arthritis (RA) patients who are intolerant, show an inadequate response, or experience moderate/high disease activity despite traditional, non-biologic disease-modifying antirheumatic drugs (inadequate response [DMARD-IR] or second-line therapy patients) are often treated with a biologic agent (or "novel DMARDs") in Europe. Other treatments of interest, such as Janus kinase (JAK) inhibitors (a new class of DMARDs) are currently in development. Tofacitinib is an oral JAK inhibitor for the treatment of RA.
**Objectives:** The overall objective of this study was to compare the efficacy, and safety/tolerability of tofacitinib as monotherapy and combined with a DMARD relative to biological DMARDs (bDMARDs) and other novel DMARDs currently approved or being considered for approval by the European Medicines Agency (EMA) for second-line moderate-to-severe RA patients by means of a systematic literature review (SLR) and network meta-analysis (NMA) of randomized clinical trial (RCT) evidence.
**Methods:** MEDLINE®, EMBASE®, and Cochrane Central Registry of Controlled Trials databases were searched simultaneously to identify RCTs published in English between 1990 and March 2015. Population of interest included adults with moderate to severe RA who had responded inadequately or failed treatment with at least one traditional, non-biological DMARD. Treatments approved by the EMA for moderate-to-severe RA and investigational therapies were of interest and included: abatacept, adalimumab, anakinra, certolizumab pegol, etanercept, golimumab, infliximab, tocilizumab, baricitinib (investigational), and tofacitinib (investigational). Outcomes of interest were: American College of Rheumatology (ACR) response criteria (20/50/70), change from baseline in the Health assessment questionnaire (HAQ-DI), the Disease activity score (DAS-28) (change from baseline and categorical), and safety outcomes. Bayesian NMA models were simultaneously synthesized to obtain treatment effects for the outcomes of interest.
**Results:** 68 full-text articles and 11 conference abstracts corresponding to 45 RCTs were identified, the majority of which demonstrated a low risk of bias. Based on evidence synthesis of monotherapies, tofacitinib 5 mg twice daily (BID) and 10 mg BID monotherapy exhibited comparable efficacy, and safety/tolerability to other monotherapies. Based on evidence synthesis of combination therapies, tofacitinib 5 mg BID and 10 mg BID + DMARDs or methotrexate (MTX) were mostly comparable to other combination therapies in terms of efficacy based on DAS28 and ACR. In terms of safety, tofacitinib 5 mg BID + MTX or DMARDs was mostly comparable to other combination therapies, but less favorable versus some (with respect to withdrawals, infections, serious adverse events), and tofacitinib 10 mg BID + MTX or DMARDs was comparable to most, but less favorable in terms of withdrawals versus a few treatments.
**Conclusions:** Tofacitinib 5 mg BID and 10 mg BID, either as monotherapy or combined with DMARDs or MTX is comparable to other monotherapies and combination therapies respectively, based upon DAS28 and ACR response criteria. While monotherapies were also comparable in terms of safety, further research is recommended to firmly establish the comparative safety of the combination therapies.

## SAT0166 AN ANALYSIS OF LABORATORY RESULTS FROM 2 RANDOMIZED, DOUBLE-BLIND STUDIES OF SIRUKUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS REFRACTORY TO DISEASE-MODIFYING ANTI-RHEUMATIC DRUG TREATMENT

G. Karpouzas[1], C. Thorne[2], T. Takeuchi[3], Y. Tanaka[4], H. Yamanaka[5], M. Harigai[5], T. Ota[6], S. Sheng[7], W. Xu[7], S. Xu[7], R. Kurrasch[8], K. Fei[7], B. Hsu[7]. *[1]Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, United States; [2]University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; [3]Division of Rheumatology, Keio University School of Medicine, Tokyo; [4]University of Occupational and Environmental Health, Japan, Kitakyushu; [5]Institute of Rheumatology, Tokyo Women's Medical University; [6]Janssen Pharmaceutical K.K., Tokyo, Japan; [7]Janssen Research & Development, LLC, Spring House, PA; [8]GlaxoSmithKline, Collegeville, PA, United States*

**Background:** Agents intercepting the IL-6 pathway have been associated with abnormalities in liver enzymes, neutrophils, and platelets.
**Objectives:** To evaluate laboratory results from 2 Phase 3 studies (1 global, 1 Japanese) of sirukumab, a selective human anti-IL6 monoclonal antibody, in patients with active rheumatoid arthritis (RA), and to compare patients using concomitant methotrexate (MTX) or not.
**Methods:** In the global study, patients with active RA and inadequate response to disease-modifying anti-rheumatic drugs were randomly assigned (1:1:1) to sirukumab SC 50mg q4w, sirukumab SC 100mg q2w, or placebo SC q2w. Approximately 86% were taking MTX at baseline in the global study. In the Japanese study, 122 patients with active RA refractory to MTX or sulfasalazine were assigned (1:1) to monotherapy with sirukumab SC 50mg q4w or sirukumab SC 100mg q2w. Descriptive hematology and chemistry results through Wk 24 were summarized for the 2 sirukumab dose groups, and results were stratified by MTX use. No inferential statistical testing was conducted.
**Results:** As has been observed with other IL-6 pathway inhibitors, sirukumab was associated with increases in alanine transaminase (ALT) and aspartate transaminase (AST) and decreases in neutrophil and platelets. The proportion of patients with maximum toxicity grade $>1$ at Wk 24 for lab results of interest were similar across the sirukumab dose groups (Table). The proportion with increased ALT and AST grade $\geq 2$ ($>3$x Upper Limit of Normal) through Wk 24 was numerically greater for patients on concomitant MTX in the global study vs those not on MTX. Similarly, continued MTX exposure numerically amplified the effect of sirukumab treatment on liver test abnormalities in the 121 Japanese patients in the global study (on MTX), vs the Japanese monotherapy study. Neutrophil and platelet decreases were similar between groups with and without MTX.

Table 1. Proportion of patients (n [%]) on sirukumab with key lab abnormalities through Wk 24

| Sirukumab dose | CTCAE grade | Global study – with MTX | | Global study – no MTX | |
|---|---|---|---|---|---|
| | | 50mg q4w (n=562) | 100mg q2w (n=564) | 50mg q4w (n=86) | 100mg q2w (n=85) |
| ALT increased | 1 | 330 (58.7) | 312 (55.3) | 27 (31.4) | 33 (38.8) |
| | 2 | 32 (5.7) | 46 (8.2) | 2 (2.3) | 5 (5.9) |
| | 3 | 9 (1.6) | 20 (3.5) | 1 (1.2) | 0 |
| | 4 | 0 | 0 | 0 | 0 |
| AST increased | 1 | 266 (47.3) | 283 (50.2) | 22 (25.6) | 28 (32.9) |
| | 2 | 15 (2.7) | 20 (3.5) | 2 (2.3) | 1 (1.2) |
| | 3 | 1 (0.2) | 5 (0.9) | 0 | 0 |
| | 4 | 0 | 0 | 0 | 0 |
| Neutrophils decreased | 1 | 104 (18.5)[a] | 113 (20.1)[b] | 17 (19.8)[c] | 15 (17.6) |
| | 2 | 66 (11.8)[a] | 63 (11.2)[b] | 9 (10.5)[c] | 11 (12.9) |
| | 3 | 20 (3.6)[a] | 13 (2.3)[b] | 2 (2.3)[c] | 3 (3.5) |
| | 4 | 0 | 1 (0.2)[b] | 0 | 0 |

[a]n=561. [b]n=563. [c]n=85.

**Conclusions:** Numeric differences in abnormally elevated liver enzyme tests for RA patients treated with sirukumab were observed between patients on MTX and not on MTX, including patients from the global and Japanese studies. In these 2 Phase 3 studies, there was no clear dose-dependent effect on ALT, AST, neutrophils, or platelets between the 2 sirukumab doses.

## SAT0167 HEALTH-RELATED PHYSICAL AND EMOTIONAL WELL-BEING AND FATIGUE IMPROVE SIGNIFICANTLY WITH SIRUKUMAB TREATMENT: RESULTS OF A PHASE 3 STUDY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS REFRACTORY TO CONVENTIONAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

G. Karpouzas[1], C. Thorne[2], T. Takeuchi[3], K. McQuarrie[4], S. Sheng[4], W. Xu[4], S. Peterson[4], R. Ganguly[5], C. Han[4], K. Fei[4], B. Hsu[4]. *[1]Division of Rheumatology, Harbor-UCLA Medical Center, Torrance, CA, United States; [2]University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; [3]Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan; [4]Janssen Research & Development, LLC, Spring House, PA; [5]GlaxoSmithKline, King of Prussia, PA, United States*

**Background:** Rheumatoid arthritis (RA) may have a substantial negative impact on physical and emotional well-being and fatigue. Sirukumab, a selective, high-affinity human anti-IL6 monoclonal antibody, is being evaluated for RA treatment.

**Objectives:** To evaluate the effects of sirukumab on health-related physical and emotional well-being (based on Short Form-36 [SF-36] health survey) and fatigue (Functional Assessment of Chronic Illness Therapy [FACIT]-Fatigue scale) in patients (pts) with RA refractory to Disease-Modifying Anti-Rheumatic Drugs (DMARDs).

**Methods:** This Phase 3 study evaluated 2 sirukumab doses in pts with active RA and inadequate response to DMARDs. Pts were randomized (1:1:1) to double-blind treatment with sirukumab subcutaneous (SC) 50 mg q4w, sirukumab SC 100 mg q2w, or placebo SC q2w. In the placebo group, pts with <20% improvement at Wks 18 or 40 or still on placebo at Wk 52 were re-randomized to treatment with 1 of the 2 sirukumab doses. Pts completed the SF-36 and FACIT-Fatigue at baseline (BL) and Wks 8, 16, 24, 36, and 52. Clinically meaningful improvements from BL were defined as ≥5-point increase for the SF-36 physical and mental component summary (PCS and MCS) scores and ≥4-point increase for the FACIT-Fatigue score.

**Results:** Significantly greater mean increases (improvements) from BL in mean SF-36 PCS and MCS, all 8 SF-36 domain scores, and the FACIT-Fatigue score were observed for sirukumab 50mg q4w and 100mg q2w vs placebo at Wks 8, 16, 24, 36, and 52 (all $P<0.02$; Table). Also, significantly more pts achieved clinically meaningful improvements from BL in the SF-36 PCS and MCS scores (≥5-point increase) and the FACIT-Fatigue score (≥4-point increase) on sirukumab (both doses) vs placebo at Wks 8, 16, 24, 36, and 52 (all $P<0.05$).

Table 1. SF-36 and FACIT-Fatigue Outcomes at Wk 52[a]

| Outcome | Placebo (n=556) | Sirukumab 50 mg q4w (n=557) | Sirukumab 100 mg q2w (n=557) |
|---|---|---|---|
| Mean (SD) change from BL | | | |
| SF-36 PCS | 2.42 (6.81) | 5.66 (7.74)[b] | 6.16 (7.23)[b] |
| SF-36 MCS | 2.69 (9.57) | 5.35 (9.64)[b] | 4.77 (9.80)[b] |
| SF-36 domain scores | | | |
| Bodily pain | 3.91 (8.58) | 7.77 (8.41)[b] | 7.83 (8.70)[b] |
| General health | 2.04 (7.12) | 5.08 (7.86)[b] | 4.35 (7.49)[b] |
| Physical function | 1.44 (8.20) | 4.72 (9.20)[b] | 5.49 (8.68)[b] |
| Role-physical | 2.98 (8.40) | 5.79 (8.59)[b] | 6.09 (8.10)[b] |
| Vitality | 3.03 (8.87) | 6.17 (9.22)[b] | 6.49 (9.18)[b] |
| Mental health | 2.47 (9.24) | 5.20 (9.71)[b] | 4.67 (9.81)[b] |
| Role-emotional | 2.62 (11.34) | 5.70 (10.85)[b] | 5.16 (11.77)[b] |
| Social function | 2.80 (9.84) | 5.72 (10.07)[b] | 5.86 (9.47)[b] |
| FACIT-Fatigue score | 2.7 (9.6) | 6.7 (9.5)[b] | 6.8 (9.5)[b] |
| Proportion of pts achieving clinically meaningful improvement from BL | | | |

## SAT0168 CLINICAL REMISSION OUTCOMES WITH SARILUMAB PLUS CSDMARDS IN ACTIVE, MODERATE-TO-SEVERE RA PATIENTS WITH INADEQUATE RESPONSE TO TUMOR NECROSIS FACTOR INHIBITORS

G. Burmester[1], P. Hrycaj[2], C. Pacheco-Tena[3], H. van Hoogstraten[4], E.K. Mangan[5], Y. Lin[4], D. Bauer[4], J. Fay[5], J. Parrino[5], A. Kivitz[6]. *[1]Charité - University Medicine, Berlin, Germany; [2]Department of Rheumatology and Clinical Immunology, Poznań University of Medical Sciences, Poznań, Poland; [3]Universidad Autónoma de Chihuahua, Chihuahua, Mexico; [4]Sanofi, Bridgewater; [5]Regeneron Pharmaceuticals, Inc., Tarrytown; [6]Altoona Center for Clinical Research, Duncansville, United States*

**Background:** Clinical remission is an important treatment goal in rheumatoid arthritis (RA) and is associated with improved physical function and quality of life.[1,2] In the phase 3 TARGET study (NCT01709578), sarilumab (150 or 200 mg subcutaneously every 2 weeks + conventional synthetic disease-modifying antirheumatic drugs [csDMARDs]) demonstrated efficacy in adults with active, moderate-to-severe RA and inadequate response to tumor necrosis factor (TNF) inhibitors.[3] Infections, neutropenia, injection site reactions, and increased transaminases were among the most common treatment-emergent adverse events.[3]

**Objectives:** This analysis assessed the proportions of patients achieving clinical remission measured by 4 different disease activity measures in a difficult-to-treat patient population with active RA and inadequate response or intolerance to ≥1 prior TNF inhibitor(s).

**Methods:** Four definitions of remission were used: 28-joint disease activity score by C-reactive protein (DAS28-CRP) <2.6, clinical disease activity index (CDAI) ≤2.8, simplified disease activity index (SDAI) ≤3.3, and Boolean-based ACR/EULAR remission (tender and swollen joint counts [28 joints] ≤1, CRP ≤10 mg/L, and patient global visual analog scale ≤10 mm/100 mm). Differences in incidence of these benchmarks between the active treatment groups and placebo were assessed using 2-sided Cochran-Mantel-Haenszel tests stratified by geographic region and number of prior TNF inhibitors. Patients who started rescue medication or discontinued the study were considered not to be in remission (nonresponder imputation).

**Results:** Baseline demographic and disease characteristics were balanced among the 3 treatment groups. At week (wk) 12 and wk 24, the proportion of patients achieving DAS28-CRP <2.6, CDAI, SDAI, and Boolean-based remission was higher in the sarilumab-treated groups than in the placebo group (Table). At wk 24, a significantly greater proportion of sarilumab patients achieved DAS28-CRP <2.6 compared with placebo. In comparison with placebo patients, a greater proportion of sarilumab patients who achieved DAS28-CRP <2.6 or Boolean-based remission also had clinically meaningful improvements in Health Assessment Questionnaire–Disability Index (HAQ-DI) and Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) at wk 24 (Table).

**Conclusions:** Sarilumab induced remission (using a broad range of definitions) as early as 12 weeks after initiation of therapy in patients with an inadequate response to TNF inhibitors. Patients with remission generally had improvements in physical function and fatigue as well.

**Table.** Incidence of Clinical Remission in Patients With Inadequate Response to ≥1 Prior TNF Inhibitor at Weeks 12 and 24

## SAT0169 SUCCESSFUL EXTENSION OF TOCILIZUMAB INFUSION INTERVALS FROM 4 WEEKS TO 6 OR 5 WEEKS IN 90% OF RA PATIENTS WITH GOOD RESPONSE TO 4 WEEKS INTERVALS

H. Uda[1], O. Saiki[1,2]. *[1]Rheumatology, Higashiosaka City General Hospital, Higashiosaka; [2]Internal Medicine, Shiraishi Hospital, Imabari, Japan*

**Background:** A period of 4 weeks (w) has been recommended as the interval between tocilizumab (TCZ) infusions. The cost of TCZ is very high, which makes it difficult for all patients to receive TCZ because of the associated expenses.
**Objectives:** Treating the patients with TCZ, we experienced that longer intervals than 4w were also effective. We examined whether the intervals between TCZ infusions could extend from 4w to 6w or 5w.
**Methods:** The RA patients who had shown good response and maintained low disease activity (LDA) with 8mg/kg of TCZ infusions at 4w intervals were enrolled in the study. To the eligible patients, the intervals between TCZ infusions were extended to 5w at the same TCZ dose (8mg/kg). For the patients who could maintain LDA for 6 months and more at 5w interval of TCZ infusion, the intervals between TCZ infusions were extended to 6w. We followed the patients up for 2 years and more. Good response and LDA was defined as DAS-28CRP EULAR criteria.
**Results:** One hundred patients were enrolled in the present study, and 96 patients completed the study. 93 patients maintained LDA with 8mg/kg of TCZ infusion every 5w for 6 months and more and the rest of 7 patients could not keep LDA and the intervals between TCZ infusions were shortened to 4w. The 93 patients who maintained LDA with 8mg/kg of TCZ infusion every 5w were received 8mg/kg of TCZ infusion every 6 weeks, and 62 patients maintained LDA with 6w-interval. After 2 years follow-up, 96 patients could maintain LDA and 4 patients were dropped from the study. Among 96 patients who could maintain LDA, the intervals between TCZ intervals were 6w in 62 patients, 5w in 28 patients, and 4w in 6 patients, indicating that 90% of patients who had shown good response with 4w intervals could extend the intervals between TCZ infusions from 4w to 5w or 6w. The mean baseline DAS28-CRP score in patients who could maintain LDA with TCZ infusions at 6w intervals were 2.2 and was significantly lower than that at 4 weeks interval (2.6). The frequency of adverse events with TCZ infusions at 6 weeks intervals was lower than that at 4 weeks intervals.
**Conclusions:** The present study provides evidence that most of RA patients who showed good response to TCZ infusions at 4w could extend the intervals to 6w or 5w. This finding should be of great interest for both financial and labor reasons.
**Disclosure of Interest:** None declared

## SAT0170 BDMARDS MONO VS COMBO THERAPY IN RHEUMATOID ARTHRITIS. ANALYSIS OF A RHEUMATOLOGICAL SINGLE TERTIARY CENTER REAL-LIFE EXPERIENCE

I. Farina, E. Galuppi, B. Abdel Hafith, A. Lo Monaco, M. Govoni. *Department of Medical Sciences, UOL Rheumatology, Section of Haematology and Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna, Ferrara, Italy*

**Background:** Despite adavantages of biological combo therapy over biological mono for RA treatement and the limited approval of biologics as monotherapy (etanercept, adalimumab, certolizumab, tocilizumab), real life registries data revealed that approximately one-third of patients taking biologic agents are using them as monotherapy.
**Objectives:** To assess the prevalence of bDMARDs use as monotherapy (bDMARDs-mono) in a cohort of RA patients treated with bDMARDs attending a tertiary rheumatological center.To characterize the clinical profile of these patients, and to investigate factors related to monotherapy.
**Methods:** All patients with Rheumatoid Arthritis attending our center and receiving bDMARDs up to 31th january 2015 were retrospectively analyzed. Demographic, and clinical characteristics of each patient were recorded: age, gender, disease duration, drugs history and clinical disease activity (DAS28) at last visit.
**Results:** 341 RA patients receiving bDMARDS were included. F 160, M 123, mean age 59.98 ±12.54, disease duration 178.69±101.81 months. 197 patients were taking bDMARD as first line bio-therapy, 144 had been previously treated with one or more bDMARDs. 52% (n=179) of patients were receving bDMARD-mono with a mean disease duration 187.4±125.1 month; 48% (n=162) were bDMARDs-combo, 65% of them with MTX; mean disease duration 168.9±42.4 m. Biologic agents used as mono or combo are shown in table 1. 32% of bDMARDs-mono had discontinued csDMARDs before starting biological therapy, 68% after an average 50,4 months after starting bDMARDs ($p<0.001$). The most common

reasons for discontinuing csDMARDs were toxicity (55% of cases), with significant difference between those who stopped before and after starting bDMARDs (66% vs 48% respectively, p<0,02). 11% of patients discontinue csDMARDs because of nonspecific bad tolerance, 9% for inefficacy, 11% for others unspecified reasons. 25 patients (14%) on bDMARDs-mono stopped csDMARDs for clinical remission. Overall, 57% of RA patients were in clinical remission (DAS28 PCR <2.6) at the time of the inclusion in the study, without significant differece between the two groups (bDMARDs-mono vs combo). The use of bDMARDs-mono was more frequently observed in those patients with disease duration longer than 10 years (p<0,0001).

Tab 1. *Biologic approved in monotherapy for RA treatment

**Conclusions:** Biologic monotherapy for managing RA is widely used in our clinical practice especially in patients with long term disease. The proportion of patients (1/3) who start bDMARD-mono is quite similar to that reported in literature. On the other hand, most of patients arrive to bDMARDs-mono after starting biologic agent as the result of csDMARD witdrawal due to AE or intollerance to DMARDs and to a lesser extent because achieving good control of the disease since patient's preference is strongly oriented to csDMARD discontinuation rather than bDMARDs withdrawal or tapering.

## SAT0171 SERUM IL-33 INDEPENDENTLY PREDICTS RESPONSE TO RITUXIMAB IN RHEUMATOID ARTHRITIS: DATA FROM THE SMART AND REPLICATION COHORTS

J. Sellam[1], E. Rivière[2], A. Courties[2], P.-O. Rouzaire[3], B. Tolusso[4], E. Vital[5], P. Emery[5], G. Ferraciolli[4], M. Soubrier[6], M. Dougados[7], X. Mariette[2].
*[1]Rheumatology, Univ Paris 06, Saint-Antoine Hospital, AP-HP, DHU "Inflammation, Immunopathologyn Biotherapy", Paris; [2]Rheumatology, AP-HP Bicêtre Hospital INSERM U1184, le Kremlin Bicêtre; [3]Immunology, Clermont-Ferrand University hospital, Clermont-Ferrand, France; [4]Rheumatology, Catholic University of the Sacred Heart, Rome, Italy; [5]Rheumatology, LMBRU LTHT, LIRMM University of Leeds, Leeds, United Kingdom; [6]Rheumatology, Clermont-Ferrand University hospital, Clermont-Ferrand; [7]Rheumatology, AP-HP Cochin Hospital, Paris, France*

**Background:** In a transcriptomic study, we found that whole blood interleukin-33 (IL-33) mRNA expression is increased in patients with rheumatoid arthritis (RA) responding to rituximab (RTX) (1). Using one ELISA IL-33 kit (DuoSet, R&D) for protein assessment, we previously reported an association between serum IL-33 level and RTX response in a single cohort, but additional experiments have recently raised caution about accuracy of this kit for sera measurements (2). Recommendations from the manufacturer advice to use for human sera another assay (Quantikine, R&D).

**Objectives:** To replicate in different cohorts and with a more accurate ELISA assay the possible association between detectable serum level of IL-33 and response to RTX in RA patients.

**Methods:** Serum IL-33 level and B-cell biomarkers known to be associated with RTX response (rheumatoid factor [RF], anti-citrullinated cyclic peptide [anti-CCP] antibodies, high serum IgG level above upper limit normal >12.7 g/L) were assessed in 111 RA patients receiving a first course of 2 grams RTX in the SMART cohort (85% of patients with RF or anti-CCP) as well as, for replication, in 74 RA patients (including 32 patients from Leeds, UK and 42 from Clermont-Ferrand, France) treated with the same schedule in routine care (97% of patients with RF or anti-CCP). We performed uni- and multivariate analyzes to identify factors associated with a EULAR response at 24 weeks.

**Results:** At week 24, 84 (76%) and 54 (73%) patients reached EULAR response in SMART and in replication cohort, respectively. Serum IL-33 was detectable in 27/111 (24%) and 35/74 (47%) patients from SMART and replication cohort, respectively. In SMART, multivariate analysis indicated that auto-antibodies status (positive RF or anti-CCP) were associated with RTX response (OR 3.47 95%CI 1.04–11.60; p=0.04). The same trend was observed for high serum IgG (OR 2.82 95%CI 0.97–8.14; p=0.056) but not for serum IL-33. In the replication cohort, detectable serum IL-33 was independently associated with RTX response (OR 3.73, 95%CI [1.12–12.38]; p=0.03) with the same trend for auto-antibodies status (OR 32, 95%CI [0.69–999]; p=0.08), but without significant result for high serum IgG. When we combined both cohorts (n=185), the 3 parameters were associated with RTX response in multivariate analysis: presence of RF or anti-CCP (OR 3.27 95%CI 1.13–9.46; p=0.03), high serum IgG (OR 2.32, 95%CI 1.01–5.33; p=0.048) and detectable IL-33 (OR 2.40 95%CI 1.01–5.72; p=0.047). There was synergy between the 3 predictive factors since detection of IL-33 in patients having positive auto-antibodies and high IgG level improved likelihood of response (100% EULAR responders) compared with patients having only positive auto-antibodies and high IgG level (77% responders) or compared with those without any of these factors (55% responders) (Figure 1).

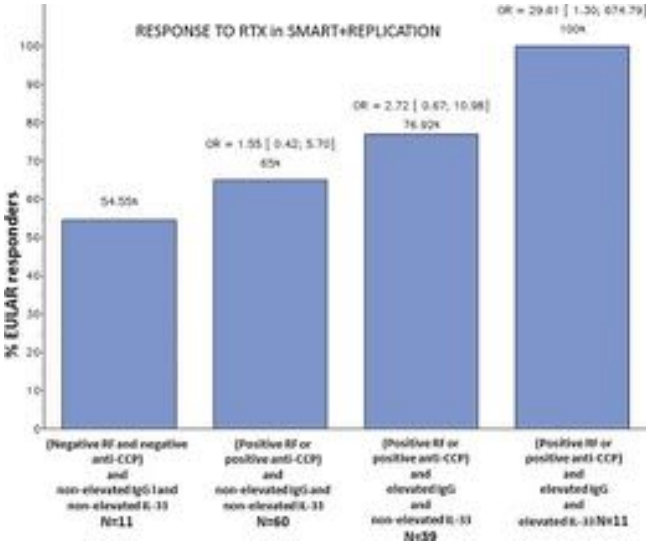

Figure 1

**Conclusions:** Using an accurate ELISA kit, serum IL-33 may predict clinical response to RTX, independently of and synergistically with auto-antibodies and serum IgG level

## SAT0172 COMPARISON OF EFFICACY AND SAFETY OF BIOLOGIC AGENTS BETWEEN ELDERLY-ONSET AND YOUNGER-ONSET RHEUMATOID ARTHRITIS

K. Fujita, Y. Yamamura, Y. Nomura, N. Shibutou, A. Ueno, K. Maruyama, T. Ombe, M. Hiramatsu, M. Yamamura. *Okayama Saiseikai General Hospital, Okayama, Japan*

**Background:** There are pathogenetic and clinical differences between elderly-onset rheumatoid arthritis (EORA) and young-onset rheumatoid arthritis (YORA).

**Objectives:** To compare the efficacy and safety of biologic agents between patients with EORA and those with YORA.

**Methods:** A total of 61 patients with RA, who started biologic agents after the age of 65 years, have been enrolled from April 2011 to August 2015, and divided into two groups according to the age at disease onset; i.e. EORA ≥65 years and YORA <65 years. Biologic agents were grouped into 3 classes; the TNF-alpha inhibitors (TNFi) including infliximab, etanercept, adalimumab, golimumab and certolizumab pegol, the CTLA4-Ig abatacept (ABT) and the IL-6 inhibitor tocilizumab (TCZ). Forty-four patients with EORA have received 64 biologic agents (36 women and 8 men; average ± SD age, 76.1 ± 5.7 years; disease duration, 2.0 ± 3.4 years; rheumatoid factor (RF)/anti-cyclic citrullinated peptide antibody (ACPA) positive, 63.6%/65.9%), and 17 patients have received 29 biologic agents (13 women and 4 men; average age, 71.2 ± 4.9 years; disease duration, 17.8 ± 13.9 years; RF/ACPA positive, 76.5%/70.6%). The disease activity was measured according as simplified disease activity index (SDAI), and the efficacy was determined by the induction rate of remission (SDAI ≤3.3) and low-disease activity (3.3 < SDAI ≤11).

**Table** SDAI in EORA or YORA patients during 6-month observation of biologic therapy.

| SDAI | Month 0 | | Month 3 | | Month 6 | |
|---|---|---|---|---|---|---|
| | EORA | YORA | EORA | YORA | EORA | YORA |
| ABT | 21.8±1.8 | 18.3±3.1 | 8.8±0.8 | 8.8±1.9 | 5.3±0.7 | 9.1±3.7 |
| TCZ | 28.6±4.0 | 30.1±4.8 | 8.3±1.4 | 13.1±2.7 | 4.0±0.9 | 11.5±1.8 |
| TNFi | 20.7±2.0 | 21.6±2.7 | 11.1±2.6 | 17.9±3.9 | 4.8±0.7 | 8.9±2.3 |
| Total | 23.5±1.6 | 21.8±2.0 | 9.5±1.1 | 13.4±2.0 | 4.7±0.4 | 9.6±1.9 |

SDAI: simplified disease activity index; EORA:elderly-onset rheumatoid arthritis; YORA: young-onset rheumatoid arthritis; ABT: abatacept; TCZ: tocilizumab; TNFi: TNF-alpha inhibitor.

**Results:** The EORA patient group did respond better to biologic agents than the YORA patient group; the SDAI was significantly lower in the former than in the latter. At present, there were no significant differences in responses to TNFi, ABT and TCZ between the 2 patient gourps (Table 1). Both patient groups developed adverse events during biologic therapy, and severe adverse events including cholecystitis, pulmonary cryptococcosis, diverticulitis, malignant lymphoma, Pneumocystis pneumonia, organizing pneumonia and so on.
**Conclusions:** The results indicate that biologic agents are similarly effective for both EORA and YORA patients, irrelevant to different classes, but patients with EORA appears to be more responsive to biologics than YORA patients, presumably due to their shorter disease duration.

**Background:** Plasma concentrations of lipoprotein (a) [Lp(a)], a lipoprotein with proatherogenic and thrombogenic properties, have a strong genetic basis, although high concentrations of Lp(a) have also been reported in the context of inflammation, as rheumatoid arthritis (RA) (1). There are few studies that evaluate the impact of biologic therapies on Lp(a) in RA (2), taking into account that with these new therapies a better control of inflammation is achieved.
**Objectives:** Evaluate the plasma concentrations of Lp(a) in Spanish RA patients on biologics therapy attending rheumatology outpatient clinics.
**Methods:** Baseline analysis of the CARMA project (CARdiovascular in rheuMAtology), a 10-year prospective study evaluating the risk of cardiovascular events in RA patients and other forms of inflammatory arthritis who attended rheumatology outpatient clinics at 67 hospitals in Spain. RA patients were classified into four categories: no biologic therapy, undergoing anti-TNF therapy, receiving anti-IL-6 receptor tocilizumab (TCZ), and other biologic therapies (rituximab or abatacept). A model of linear multivariate regression was built in which the dependent variable was Lp(a) concentration and the explanatory variable was biologic therapy. The model was adjusted for confounding factors.
**Results:** Seven hundred and seventy-five RA patients were analyzed. Total cholesterol and triglycerides concentrations were significantly higher in TCZ-treated patients. Nevertheless, no significant difference in the atherogenic index (TC/HDL-c) between TCZ-treated patients and patients without biological therapy was found. After adjusting for confounding factors, patients treated with biologic therapy had lower plasma concentrations of Lp(a) than those not undergoing biologic therapy. However, only TCZ-treated patients achieved statistically significant differences when compared with those not undergoing biologic therapy (β-coefficient: -0.303, 95% confidence interval: -0.558 to -0.047; p=0.02).
**Conclusions:** RA patients treated with tocilizumab, an inhibitor of interleukin 6 receptor, show lower plasma concentrations of Lp (a) compared to patients without biological therapy.

## SAT0174 EFFICACY OF SARILUMAB PLUS CSDMARDS IN RHEUMATOID ARTHRITIS PATIENTS WHO HAD AN INADEQUATE RESPONSE TO ONE OR MORE THAN ONE PRIOR TNF INHIBITOR

M.C. Genovese[1], G.da R.C. Pinheiro[2], E.K. Mangan[3], Y. Lin[4], J. van Adelsberg[3], H. van Hoogstraten[4], D. Thompson[3], R. Fleischmann[5]. *[1]Stanford University Medical Center, Palo Alto, United States; [2]Discipline of Rheumatology, Rio de Janeiro State University, Rio de Janeiro, Brazil; [3]Regeneron Pharmaceuticals, Inc., Tarrytown; [4]Sanofi, Bridgewater; [5]Metroplex Clinical Research Center, Dallas, United States*

**Background:** In the phase 3 TARGET study (NCT01709578), sarilumab (150 or 200 mg subcutaneously [SC] every 2 weeks [q2w] plus conventional synthetic disease-modifying antirheumatic drugs [csDMARDs]) demonstrated efficacy in adults with active, moderate-to-severe rheumatoid arthritis (RA) and inadequate response to tumor necrosis factor inhibitors (TNFis).[1] Consistent with IL-6 inhibition and the safety profile of SC sarilumab, infections, neutropenia, injection site reactions, increased lipids, and increased transaminases were among the most common treatment-emergent adverse events.
**Objectives:** This prespecified analysis examined whether the efficacy of sarilumab plus csDMARDs was affected by the number of prior TNFis.
**Methods:** Adults with active, moderate-to-severe RA with inadequate response or intolerance to ≥1 TNFi were randomized to receive placebo (n=181), sarilumab 150 mg q2w (n=181), or sarilumab 200 mg q2w (n=184) SC plus csDMARD(s) for 24 weeks.[1] Efficacy by number of prior TNFis (1 vs >1) was analyzed for the coprimary endpoints of ACR20 response at week 24 and mean change from baseline in Health Assessment Questionnaire–Disability Index (HAQ-DI) at week 12. Additional post hoc analyses evaluated the secondary endpoints of ACR50/70. Treatment-by-subgroup interactions were analyzed using a logistic regression model for ACR20 at week 24 and a mixed-effect model for repeated measures for HAQ-DI at week 12; treatment-by-subgroup interaction with $P<0.05$ was considered significant.
**Results:** A majority of patients (76.8%) reported prior use of only 1 TNFi; 23.2% of patients used >1 TNFi. Most patients discontinued TNFi treatment because of inadequate response (92.3%). ACR20 responses were numerically greater in patients receiving either dose of sarilumab in both the 1 and the >1 prior TNFi groups at week 24 relative to placebo patients (Table). Responses in placebo and sarilumab groups were numerically higher in the group that failed 1 TNFi. Similar results were observed with ACR50/70 responses. The mean change from baseline in HAQ-DI at week 12 was greater in sarilumab patients than in placebo patients in both prior TNFi exposure groups. Interaction test analyses indicated no significant treatment-by-subgroup effect in the proportion of patients with 1 or >1 prior TNFi who achieved ACR20 at week 24 ($P$=0.1215) or in mean change from baseline in HAQ-DI at week 12 ($P$=0.1767).

Table. Efficacy of Sarilumab Plus csDMARDs in Patients With 1 or >1 Prior TNFi Failure

| | Placebo + csDMARDs (n=181) | Sarilumab 150 mg q2w + csDMARDs (n=181) | Sarilumab 200 mg q2w + csDMARDs (n=184) |
|---|---|---|---|
| **ACR20 at week 24, n/N (%)** | | | |
| 1 TNFi | 49/132 (37.1) | 83/132 (62.9) | 82/133 (61.7) |
| OR (95% CI vs placebo) | — | 3.11 (1.85, 5.25) | 2.90 (1.73, 4.86) |
| >1 TNFi | 12/49 (24.5) | 18/49 (36.7) | 30/51 (58.8) |
| OR (95% CI vs placebo) | — | 1.82 (0.75, 4.43) | 4.66 (1.94, 11.21) |
| **ACR50 at week 24, n/N (%)** | | | |
| 1 TNFi | 30/132 (22.7) | 56/132 (42.4) | 58/133 (43.6) |
| OR (95% CI vs placebo) | — | 2.71 (1.55, 4.75) | 2.76 (1.60, 4.78) |
| >1 TNFi | 3/49 (6.1) | 11/49 (22.4) | 17/51 (33.3) |
| OR (95% CI vs placebo) | — | 4.69 (1.18, 18.68) | 8.75 (2.25, 34.04) |
| **ACR70 at week 24, n/N (%)** | | | |
| 1 TNFi | 13/132 (9.8) | 39/132 (22.7) | 24/133 (18.0) |
| OR (95% CI vs placebo) | — | 2.93 (1.41, 6.08) | 2.06 (0.99, 4.32) |
| >1 TNFi | 0/49 | 6/49 (12.2) | 6/51 (11.8) |
| OR (95% CI vs placebo) | — | NC* | NC* |
| **HAQ-DI at week 12** | | | |
| 1 TNFi | | | |
| LS mean change from baseline ± SE | -0.29 ± 0.05 | -0.44 ± 0.05 | -0.50 ± 0.05 |
| LS mean difference vs placebo (95% CI) | — | -0.15 (-0.28, -0.01) | -0.21 (-0.34, -0.07) |
| >1 TNFi | | | |
| LS mean change from baseline ± SE | -0.17 ± 0.08 | -0.54 ± 0.09 | -0.40 ± 0.08 |
| LS mean difference vs placebo (95% CI) | — | -0.37 (-0.59, -0.14) | -0.23 (-0.45, -0.01) |

ACR20/50/70, American College of Rheumatology 20%/50%/70% response; CI, confidence interval; csDMARD, conventional synthetic disease-modifying antirheumatic drug; HAQ-DI, Health Assessment Questionnaire–Disability Index; LS, least squares; NC, not computable; OR, odds ratio; q2w, every 2 weeks; SD, standard deviation; SE, standard error; TNFi, tumor necrosis factor inhibitor. *Odds ratios were not computable because no placebo patients with exposure to >1 TNFi achieved an ACR70 response.

**Conclusions:** Efficacy of sarilumab was observed in patients with inadequate response to TNFis, irrespective of the number of prior TNFi therapies. In harder to treat patients (ie, patients with prior exposure to >1 TNFi), sarilumab 200 mg was associated with a greater numerical trend in ACR20/50 when compared with sarilumab 150 mg.

## SAT0175 VALIDATION OF B CELL DEPLETION AS A PREDICTOR OF CLINICAL RESPONSE AND EFFICACY OF RETREATMENT OF NON-RESPONSE IN RHEUMATOID ARTHRITIS

M.Y. Md Yusof[1,2], J.B. Candelier[2], S. Dass[1,2], A. Rawstron[3], E.M. Vital[1,2], P. Emery[1,2]. [1]*NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust;* [2]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds;* [3]*Haematological Malignancy Diagnostic Service, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Rituximab has been licensed for the treatment of Rheumatoid Arthritis (RA) for over a decade. We previously showed that the initial depth of B cell depletion was associated with clinical response; 96% complete versus 74% incomplete depletion at 6 months (p=0.02)[1] and that retreatment of initial non-responders with incomplete depletion led to 72% response rate in cycle 2 (C2)[2].
**Objectives:** To validate B cell depletion after the first infusion as a predictor of response to rituximab (Project 1) and assess outcome of retreatment of first cycle non-responders (Project 2) as a basis for B cell monitoring during rituximab treatment.
**Methods:** The published discovery cohorts included 60 patients in Project 1 and 25 patients in Project 2. For this validation study, we analysed the subsequent consecutive 180 patients with RA treated with rituximab at a single centre. Each cycle of rituximab consisted of 2×1000mg infusions, repeated on clinical relapse. B cell subsets (naïve, memory and plasmablast) were measured at baseline, after first infusion of rituximab (2 weeks) and at early B cell repopulation (6 months) using a flow cytometry protocol optimized to detect low numbers of B cell subsets and plasmablasts. Complete depletion was defined as total B cell count $<0.0001\times10^9$/L. First cycle non-responders who had incomplete depletion at C1 were retreated at 6 months.
**Results:** 180 patients (female=147 (81%), median age at rituximab initiation 62 (IQR 51–71) years and median disease duration 10 (IQR 5–18) years were studied. 72 (40%) patients were biologic-naïve. In C1, 126 (70%) achieved moderate-good EULAR response. The complete depletion rate for C1 was 54%. Complete depletion was associated with response; p=0.027 (Table 1). 30 patients who were C1 non-responders and had incomplete depletion were retreated at 6 months. Of these, 20 (67%) had complete depletion and 20 (67%) responded in C2. Non-responders in C2 had trend to higher plasmablast numbers at retreatment than responders (p=0.14).

Table 1. B cell depletion and response in validation cohort

| Cohort | Project A | | | |
|---|---|---|---|---|
| | Depletion | Non response | Response | p |
| Validation (n=180) | Incomplete | 32/82 (39%) | 50/82 (61%) | 0.036 |
| | Complete | 23/98 (23%) | 75/98 (77%) | |
| Combined discovery + validation (n=240) | Incomplete | 46/117 (39%) | 71/117 (61%) | 0.003 |
| | Complete | 26/123 (21%) | 97/123 (79%) | |

**Conclusions:** We have validated that the depth of B cell depletion after the first infusion is a predictor of response to rituximab in RA. A high degree of response in C2 was also confirmed when C1 non-responders who had incomplete depletion were retreated. B cell subsets therefore should be monitored in the routine care of RA patients receiving rituximab and repeat infusions considered if early depletion is incomplete and clinical response poor.

## SAT0176 IL-6 BLOCKADE WITH TOCILIZUMAB DOES NOT SUPPRESS CD4+T CELL ACTIVATION AT 48 WEEKS OF THE TREATMENT

M. Murakami[1,2], T. Kuritani[2], N. Nishimoto[1,2]. [1]*Tokyo Medical University;* [2]*Osaka Rheumatology Clinic, Osaka, Japan*

**Background:** Rheumatoid arthritis (RA) is a common immflamatory autoimmune disease characterized by persistent synovitis and progressive destruction of cartilage and bone in multiple joints. The proportion of CD25+CD4+ T cells is increased in anti-citrullinated protein antibodies (ACPA) positive RA patients compared with ACPA negative RA patients. Abatacept (ABA), a biologic blocking T cell co-stimulation, decreased the proportion of CD25+CD4+ T cells and interleukin (IL)-6 levels in ACPA positive RA patients. It has been reported that CD25 expressions are increased by IL-6. Tocilizmab (TCZ) is a humanized anti-human IL-6 receptor antibody that has been developed to inhibit the IL-6 signal as a therapeutic agent.
**Objectives:** We aimed to investigate whether IL-6 blockade with TCZ decreases the proportion of CD25+CD4+ T cells.
**Methods:** Peripheral blood mononucleated cells (PBMCs) were obtained from 13 ACPA (+) RA patients at baseline, 24 and 48 weeks of TCZ treatment (male:female ratio = 0.077). Surface phenotypes and activation markers of T cells were analyzed with flow cytometory.
**Results:** DAS28-ESR and SDAI were significantly reduced at 24 and 48 weeks compared with those at baseline (DAS28-ESR: 4.87±1.25 at baseline; 1.99±1.13 at 24 weeks, $p<0.0001$; 1.61±0.70 at 48 weeks $p<0.0001$; SDAI: 20.75±9.56 at baseline; 6.30±7.0 at 24 weeks,$p=0.0008$; 3.20±2.86 at 48 weeks, $p<0.0001$). The serum levels of matrix metalloproteinase (MMP)-3 were significantly decreased at 48 weeks (250.5±311.0 ng/mL at baseline; 85.1±81.8 ng/mL at 24 weeks, $p=0.07$; 54.9±27.2 ng/mL at 48 weeks, $p=0.04$). The proportion of CD4+ cells was significantly increased at 24 and 48 weeks compared with those at baseline (29.7±18.2% at baseline; 37.3±12.9% at 24 weeks, $p=0.0094$; 37.7±14.1% at 48 weeks, $p=0.025$). The proportions of CD25+CD4+ cells in CD4+ cells were not significantly different (5.7±4.2% at baseline; 6.1±3.4% at 24 weeks, $p=0.795$; 7.1±2.1% at 48 weeks, *$p=0.247$*). Also, the proportions of regulatory T (Treg) cells (FoxP3+CD25+CD4+ in CD4+ cells) were not significantly different (0.68±0.67% at baseline; 0.58±0.52% at 24 weeks *$p=0.752$*; 0.61±0.53% at 48 weeks, $p=0.794$).
**Conclusions:** IL-6 blockade has therapeutic effects on RA patients. However, the blockade does not change proportions of CD4+CD25+ in CD4+ T cells as well as those of Treg cells. Some other mechanisms, besides a decrease in CD4+ activation or an increase in Treg cell proportion, contribute the therapeutic effect of IL-6 blockade.
**Disclosure of Interest:** M. Murakami Grant/research support from: Chugai Pharmaceutical Co., Ltd., T. Kuritani: None declared, N. Nishimoto Grant/research support from: Chugai Pharmaceutical Co., Ltd., Consultant for: Chugai Pharmaceutical Co., Ltd.

## SAT0177 BARICITINIB FOR RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

N.V. Zamora[1], J. Tayar[1], M.A. Lopez-Olivo[1], R. Christensen[2], M.E. Suarez-Almazor[1]. [1]*General Internal Medicine, MD Anderson Cancer Center, Houston, United States;* [2]*Musculoeskeletal Statistics Unit, The Parker Institute, University Hospital Bispebjerg og Frederiksberg, Copenhagen, Denmark*

**Background:** Baricitinib is a small molecule inhibitor of the Janus kinase (JAK) pathways that reduce and modulate the production of inflammatory mediators and cytokines.
**Objectives:** We conducted a systematic review to evaluate the efficacy and safety of baricitinib for the treatment of patients with rheumatoid arthritis.
**Methods:** A comprehensive search of the literature was conducted in the following electronic databases: Cochrane Library, MEDLINE, EMBASE and Web of Science. Also, we searched clinicaltrials.gov and hand searched conference proceedings through December 2015. Any randomized controlled trial (RCT) comparing baricitinib alone or in combination with any DMARD versus placebo or other traditional or biologic DMARDs for the treatment of patients with rheumatoid arthritis were included. Two independent reviewers performed study selection, data collection and risk of bias assessment using Covidence.org. Our primary outcome was the percent of patients achieving an American College of Rheumatology (ACR) 50% response. Secondary outcomes included: clinical remission (Disease Activity Score (DAS $<2.6$)), minimum clinical important difference (MCID) $\geq0.22$ in the Health Assessment Questionnaire (HAQ), total withdrawals and serious adverse events (SAEs).
**Results:** Out of 146 citations, 7 RCTs met our inclusion criteria. Most studies were published in abstract format and risk of bias assessment was judged unclear in most domains. Five studies compared more than two doses of baricitinib, however, we only report here results for the dose of 4 mg once daily. Four comparisons were included: i) baricitinib plus methotrexate (MTX) vs MTX, ii) baricitinib alone vs MTX, iii) baricitinib plus MTX vs adalimumab (ADA) plus MTX, and iv) baricitinib plus MTX vs baricitinib alone. For the combination of baricitinib plus MTX, more patients in the baricitinib group achieved an ACR 50 response and clinical remission compared to patients in the MTX group at 12 and 24 weeks

(at 12 weeks patients in the control group were re-assigned to baricitinib). The combination group reported lower withdrawal rates at 24 weeks (RR 0.61, (95% CI 0.47–0.81) and similar SAEs at 24 weeks compared to control. For baricitinib alone vs MTX, improvement rates were higher in the baricitinib group at 12 weeks (RR 1.7, 95% CI 1.3–2.1; 1.8, 95% CI 1.2–2.6; 1.3, 95% CI 1.2–1.4; for ACR50, clinical remission, and MCID HAQ rates, respectively). No differences were found in total withdrawals or SAEs. When baricitinib was compared to ADA, greater rates of ACR50 response were observed in the baricitinib group at 12 weeks (RR 1.3; 95% CI 1.1, 1.5); but also higher rates of SAEs compared to the ADA group at 24 weeks were reported (RR 2.5; 95% CI 1.0, 6.1). No significant differences were observed between baricitinib plus MTX compared with baricitinib alone.

**Conclusions:** Baricitinib alone or combined with MTX had better efficacy responses compared to MTX alone at 12–24 weeks. Total withdrawal rates were lower in the baricitinib combined group when compared to MTX. Baricitinib had similar effects compared to adalimumab, but higher rates of SAEs. Baricitinib can be considered an additional therapeutic option to treat patients with moderate to severe disease who have an inadequate response to other treatment agents.

## SAT0178 CLINICAL RESPONSES OF SARILUMAB BASED ON RHEUMATOID FACTOR AND ANTI–CYCLIC CITRULLINATED PEPTIDE ANTIBODY STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Emery[1], H. van Hoogstraten[2], E.K. Mangan[3], J. van Adelsberg[3], C. Fan[2], A. Kivitz[4], G.da R.C. Pinheiro[5], T. Huizinga[6]. *[1]University of Leeds, Leeds, United Kingdom; [2]Sanofi, Bridgewater; [3]Regeneron Pharmaceuticals, Inc, Tarrytown; [4]Altoona Center for Clinical Research, Duncansville, United States; [5]Discipline of Rheumatology, Rio de Janeiro State University, Rio de Janeiro, Brazil; [6]Leiden University Medical Centre, Leiden, Netherlands*

**Background:** Sarilumab is a human investigational anti–IL-6 receptor mAb that has been studied in 2 randomized, double-blind, placebo-controlled, multicenter, phase 3 studies in patients with RA. Subcutaneous (SC) sarilumab q2w + MTX demonstrated efficacy in patients with inadequate response to MTX in the MOBILITY study (NCT01061736).[1] Sarilumab SC q2w + conventional synthetic DMARDs demonstrated efficacy in patients who were inadequate responders to or intolerant of TNFi in the TARGET study (NCT01709578).[2] The most common TEAEs in both studies were infections, neutropenia, injection site reactions, and increased transaminases.

**Objectives:** Negative autoantibody status has been associated with attenuated clinical response to biologic disease-modifying agents in RA.[3,4] This study assessed the clinical efficacy of sarilumab in subgroups of patients based on rheumatoid factor (RF) and anti-CCP antibody status in MOBILITY and TARGET.

**Methods:** Incidence of ACR20/50/70 response at wk 24, mean change from baseline in HAQ-DI at wk 12 (TARGET) or 16 (MOBILITY), and DAS28-CRP at wk 24 were evaluated by RF and CCP status.

**Results:** The majority of MOBILITY (78%) and TARGET (70%) patients were RF+/CCP+. Treatment-by-subgroup interaction ($P<0.05$) was observed for ACR20 response (CCP status in MOBILITY; RF and CCP in TARGET) and HAQ-DI (RF and CCP status in MOBILITY; RF in TARGET). Clinical and functional responses in RF/CCP single- and double-positive patients were generally similar to overall study results (Table). However, certain clinical measures, including HAQ-DI, showed a trend toward smaller effect sizes, particularly in double-negative patients, that was somewhat more pronounced with sarilumab 150 mg q2w (Table), though sample sizes were small. Comparable findings were observed for DAS28-CRP: mean change from baseline for placebo + MTX, sarilumab 150 mg q2w + MTX, and sarilumab 200 mg q2w + MTX was -1.56 (n=191), -2.75 (n=257), and -3.09 (n=246), respectively, for RF+/CCP+ patients and -1.97 (n=22), -2.10 (n=13), and -2.51 (n=20), respectively, for RF-/CCP- patients in MOBILITY. TARGET results were similar. Trends toward lower clinical and functional responses with RF or CCP negative autoantibody were not observed in radiographic measurements of structural progression; change from baseline in mTSS appeared to be similar regardless of autoantibody status (data on file).

**Conclusions:** Overall, within MOBILITY and TARGET, clinical responses with sarilumab were generally consistent among patients who were RF+ and/or CCP+. Regardless of autoantibody status, there was a more robust response with regard to clinical signs and symptoms with sarilumab 200 mg q2w.

Table. ACR20[a] Incidence and HAQ-DI Mean Change From Baseline in RF and CCP Subgroups in MOBILITY and TARGET Studies

| | MOBILITY | | | TARGET | | |
|---|---|---|---|---|---|---|
| | Placebo + MTX (N=398) | Sarilumab 150 mg q2w + MTX (N=400) | Sarilumab 200 mg q2w + MTX (N=399) | Placebo + csDMARD (N=181) | Sarilumab 150 mg q2w + csDMARD (N=181) | Sarilumab 200 mg q2w + csDMARD (N=184) |
| **ACR20 incidence at week 24** | | | | | | |
| RF+/CCP+ n/N (% responders) | 97/310 (31%) | 195/325 (60%) | 209/299 (70%) | 45/135 (33%) | 77/125 (62%) | 71/121 (59%) |
| RF+/CCP- n/N (% responders) | 14/26 (54%) | 16/20 (80%) | 19/28 (68%) | 1/6 (17%) | 7/9 (78%) | 9/10 (90%) |
| RF-/CCP+ n/N (% responders) | 8/30 (27%) | 18/32 (56%) | 21/37 (57%) | 8/14 (57%) | 5/10 (50%) | 10/16 (63%) |
| RF-/CCP- n/N (% responders) | 14/32 (44%) | 7/19 (37%) | 14/32 (44%) | 11/24 (46%) | 12/36 (33%) | 21/33 (64%) |
| **HAQ-DI mean change from baseline at week 16 (MOBILITY) and week 12 (TARGET)[b]** | | | | | | |

## SAT0179 EXPERIENCES OF RITUXIMAB TREATMENT IN RF+ RHEUMATOID ARTHRITIS

P. Matt, U. Lindqvist. *Department of Medical Sciences, Rheumatology, Inst. Med. Sci., Uppsala University, Uppsala, Sweden*

**Background:** Immunoglobulins (Ig) and immune complexes generate and fine-tune inflammation in rheumatoid arthritis (RA) by interacting with receptors on immune cells. After successful antirheumatic treatments, reductions of Igs are observed in many patients. Rituximab (RTX), a second line biologic anti-rheumatic drug, has proven efficacy in RA; by interacting with CD20, it causes lysis/apoptosis of B-cells. However, this may increase the patients' infection sensitivity and reduce their immune response to vaccines. Consequently, there is lack of information on the optimum level of B-cell depletion (and biomarkers thereof), and on rheumatics' exposure to infections in everyday clinical practice.

**Objectives:** To evaluate if the degree of RTX-mediated B-cell depletion in seropositive RA is correlated to joint disease activity and Ig serum levels. To review the extent, the nature, and risk factors of infectious diseases during RTX treatment in a non-selected RA cohort.

**Methods:** Sixty-nine patients (57 female/12 men, mean age 58.7 years) treated with at least one course of RTX at the Department of Rheumatology, University Hospital in Uppsala were included. A high proportion (71%) had erosive disease, 72% were on DMARD and 60% on steroid treatment. On average 1.2 other biologics had been tested prior to RTX. Analyses of Ig isotypes, IgG subclasses and IgM RF, and joint disease activity were evaluated just before the next RTX course was administered. Data were collected from medical records regarding occasions with leuco-/neutropenia, medications for concurrent diseases, admissions due to various infections, and the number of systemic or topical antibiotics prescribed.

**Results:** RA patients who were RF- at evaluation had acquired a higher total dose of RTX, had lower disease activity and lower serum IgA than RF+ patients. No difference in the number of infections or prescribed antibiotics was observed comparing RF+ with RF- patients. The total IgM levels correlated positively with the SJC and the IgG3 serum levels and negatively with the RTX total dosis. The HAQ score was negatively related to the IgG1 serum levels. In 4 patients

transient leuco-/neutropenia was observed; one of these was administered to hospital and was successfully treated for pneumonia. In the medical records, 244 systemic (1.21 per patient year) and 33 topical (0.20 per patient year) antibiotic prescriptions were observed; the most common infections were of airways (n=147), urinary tract (n=87), and skin (n=49). One case of hepatitis B reactivation was observed in a patient who voluntarily had paused prophylactic antiviral treatment. A total of 10 in-patient admissions was observed, and one death occurred due to tick borne virus encephalitis (TBE). At encephalitis onset this patient had no detectable levels of anti-TBE antibodies although she had been immunized according to guidelines. RA patients with concurrent treatments for diseases with increased risk of developing infections had more infections and antibiotic therapies than non-risk patients.

**Conclusions:** A good response to RTX-treatment is followed by conversion to seronegativity in initially RF+ individuals. During RTX treatment, an increased risk of infections is seen especially in RA patients with concomitant diseases. These patients should be recommended to review their vaccination-status, to optimize their non-RA treatments, and to seek medical care in case of infection symptoms. In endemic areas TBE vaccination before RTX start should be mandatory.

## SAT0180 ONSET OF ACTION OF SARILUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS IN 2 PHASE 3 STUDIES

R. Fleischmann[1], E.K. Mangan[2], J. van Adelsberg[2], J. Fay[2], H. van Hoogstraten[3], D. Bauer[3], D. Thompson[2], A. Kivitz[4], G.R. Burmester[5].
*[1]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas; [2]Regeneron Pharmaceuticals, Inc., Tarrytown; [3]Sanofi, Bridgewater; [4]Altoona Center for Clinical Research, Duncansville, United States; [5]Charité - University Hospital, Free University and Humboldt University of Berlin, Berlin, Germany*

**Background:** The investigational human anti–interleukin 6 receptor monoclonal antibody sarilumab plus methotrexate (MTX) has demonstrated efficacy in patients with rheumatoid arthritis (RA) and inadequate response to MTX (MOBILITY; NCT01061736),[1] while sarilumab plus conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) demonstrated efficacy in patients with RA and inadequate response or intolerance to tumor necrosis factor (TNF) inhibitors (TARGET; NCT01709578).[2] Among the most common treatment-emergent adverse events in both studies were infections, neutropenia, injection site reactions, and increased transaminases.

**Objectives:** This analysis of MOBILITY and TARGET study data assessed the time to onset of clinical efficacy of sarilumab and the durability of response over 24 weeks.

**Methods:** Adults with active, moderate-to-severe RA were randomized to 1 of 3 groups receiving subcutaneous sarilumab 150 or 200 mg or placebo every 2 weeks (q2w) plus background MTX (MOBILITY) or csDMARDs (TARGET). Clinical efficacy was evaluated in these patients at weeks 2, 4, 8, 12, and 24 in a post hoc analysis. ACR20/50/70 response rates were analyzed using the 2-sided Cochran-Mantel-Haenszel test stratified by prior biologic use and region (MOBILITY) or by region and number of prior TNF inhibitors (TARGET); nonresponder imputation was applied for patients who started rescue medication or discontinued the study. Changes from baseline in Health Assessment Questionnaire–Disability Index (HAQ-DI), 28-joint disease activity score by C-reactive protein (DAS28-CRP), and clinical disease activity index (CDAI) were analyzed with a mixed model for repeated measures; no data were imputed.

**Results:** Baseline demographic and disease characteristics were similar between treatment groups in both studies.[1,2] Improvements in ACR20 responses were observed as early as week 2 in both studies, with nominal $P<0.05$ observed at week 8 for all sarilumab-treated groups in both studies. Similar trends were observed for ACR50 and ACR70 responses. Greater reductions in DAS28-CRP mean change from baseline vs placebo were observed with both doses of sarilumab by week 2 in both studies (nominal $P<0.05$). Similarly, numerical improvements in HAQ-DI and CDAI were observed with both doses of sarilumab vs placebo by week 4 in both studies (nominal $P<0.05$; Table). Improvements in all efficacy parameters were sustained through the end of each study (ie, week 52 for MOBILITY and week 24 for TARGET). The most common treatment-emergent adverse events at week 12 were infection and neutropenia, consistent with the safety profile previously reported for the entire study periods.

Table. Effect of Sarilumab at Weeks 2, 4, 8, 12, and 24 After Treatment Initiation in the ITT Population

| | MOBILITY | | | TARGET | | |
|---|---|---|---|---|---|---|
| | | Sarilumab | | | Sarilumab | |
| | Placebo + MTX (N=398) | 150 mg q2w + MTX (N=400) | 200 mg q2w + MTX (N=399) | Placebo + csDMARD (N=181) | 150 mg q2w + csDMARD (N=181) | 200 mg q2w + csDMARD (N=184) |

## SAT0181 CXCL4 IS NOT A BIOMARKER IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT AND TOCILIZUMAB

V. D'abrosca, S. Vettori, G. Cuomo, D. Iacono, G. Valentini. *Rheumatology Section Departement of Clinical and Experimental Medicine, Second University of Naples, Naples, Italy*

**Background:** CXCL4 (platelet factor4, PF4) is a pleiotropic α-granules chemokine, produced by platelets, dendritic cells, macrophages and neutrophils. Recently, CXCL4 levels have been found to increase under treatment with infliximab, in unresponsive Rheumatoid Arthritis (RA) patients [1]. At present, the influence of non TNFalfa blockers biological DMARDs (Abatacept and Tocilizumab) on CXCL4 serum levels not have been investigated in RA.

**Objectives:** To investigate CXCL4 serum levels in RA patients naïve for biological disease-modifying anti-rheumatic drugs (bDMARDs) at baseline and after 1-year treatment and look for associations with disease features at baseline and distinct biological therapy overtime.

**Methods:** Fifty-six RA were enrolled in the study at the time of initiating a treatment with a biological DMARD. CXCL4 serum levels were investigated by a multiplex suspension immunoassay at baseline and after 1 year and compared with those detected in 30 healthy controls. Epidemiological, clinical and serological features of RA patients at baseline are showed in table 1.

**Results:** Out 56 RA patients, 39 (70%) were assigned to an anti-TNF-α treatment (3 patients to Infliximab, 12 to Etanercept, 24 to Adalimumab); 10 to Abatacept and 7 to Tocilizumab.

At baseline, CXCL4 serum levels were found to be increased in RA patients as compared to controls but the difference was not significant (1,538 ng/ml vs 1.26 ng/ml, p=0.082). Moreover, CXCL4 levels were not found to be related to any disease feature. At baseline, 6 (10%) RA patients presented serum CXCL4 levels exceeding the 95th percentile of the values detected in controls (4.569 ng/ml). These patients did not differed from the remaining RA patients in any feature. After 1 year of treatment, CXCL4 levels increased with respect to basal values in the whole series (3.280 ng/ml vs 1.538 ng/ml, $p<0.0001$). However, a different trend was detected in patients undergoing distinct treatments: CXCL4 serum levels were found to increase after 1 year in patients treated with anti-TNF agents (3.595 ng/ml, vs 1,241 ng/ml, $p<0.0001$); on the contrary, CXCL4 levels

at 1-year remained unchanged in patients treated with Abatacept (4.160 ng/ml vs 2.030 ng/ml, p=0.21) and with Tocilizumab (3.310 ng/ml, vs 3.290 ng/ml, p=0.6). At 1-year follow-up, 32 patients could be considered responsive to the treatment (R); 24 (43%) were non-responder (NR). No difference was detected in the change of CXCL4 over time, comparing the 32 responsive to treatment with the 24 unresponsive patients.

**TABLE 1.** *Epidemiological, clinical and serological features at entrance of the investigated 56 RA patients.*

| Features | Whole cohort (n = 56) | Anti-TNF-α (n = 39) | Non Anti-TNF-α (n = 17) | p |
|---|---|---|---|---|
| Sex F:M ratio | 48:8 | 35:4 | 13:4 | ns |
| Age in years (median, range) | 54 (28-71) | 47 (34-71) | 54 (40-70) | ns |
| Disease duration (median, range) | 7.5 (1-32) | 7 (1-32) | 8 (2-26) | ns |
| RF+ | 42 | 30 | 12 | ns |
| ACPA+ | 29 | 22 | 7 | ns |
| ANA+ | 8 | 4 | 4 | ns |
| ESR (mm/h) (median, range) | 25 (4-88) | 26 (4-88) | 22 (4-70) | ns |
| CRP (mg/dl) (median, range) | 0.8 (0.03-8.68) | 0.7 (0.03-8.68) | 0.8 (0.2-6.9) | ns |
| HAQ (median, range) | 1.5 (0.125-3.0) | 1.25 (0.125-3.0) | 1.625 (0.25-2.625) | ns |
| DAS28 (median, range) | 4.73 (3.38-7.2) | 4.650 (3.38-7.2) | 4.790 (3.55-6.62) | ns |
| SDAI (median, range) | 23.5 (3.42-44.18) | 22.4 (11.7-44.18) | 24.2 (3.42-34.2) | ns |
| Tender Joints (median,range) | 8 (2-28) | 7 (2-28) | 10 (2-26) | ns |
| Swollen Joints (median,range) | 2 (0-11) | 2 (0-11) | 1 (0-6) | ns |

**Conclusions:** Similarly to previous studies (1) we found an increase in CXCL4 serum levels in patients undergoing an antiTNFa agent, but we failed to find differences between responsive and unresponsive patients. Moreover, we found that treatment with Abatacept and Tocilizumab did not modify CXCL4 serum level. Finally, we failed to detect any correlation between CXCL4 levels and any disease feature both at baseline and during follow-up.

## SAT0182 CORRELATION BETWEEN POSITIVE BLOOD FLOW SIGNAL ON JOINT ULTRASONOGRAPHY AND PROGRESSION OF JOINT DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOCILIZUMAB FOR 4 YEARS

Y. Sugimura[1], S. Miyamoto[2], T. Kashiwagura[3], M. Kobayashi[4], N. Miyakoshi[1], Y. Shimada[1]. *[1]Orthopedic Surgery, Akita University Graduate School of Medicine; [2]Orthopedic Surgery, Nakadori General Hospital; [3]Rehabilitation Medicine, Akita City Hospital; [4]Orthopedic Surgery, Hiraka General Hospital, Akita, Japan*

**Background:** The goal of rheumatoid arthritis (RA) treatment is to achieve clinical, functional, and structural remission. Tocilizumab (TCZ), an anti-interleukin-6 receptor monoclonal antibody agent, has a high compliance rate and can maintain clinical and functional remissions. Imaging examination for structural remission is advanced; however, the accuracy of evaluation results is inconsistent. Joint ultrasonography is an important measurement tool to comprehensively evaluate synovitis according to the presence or absence of blood flow signal. However, only a few reports have evaluated the efficacy of TCZ by using joint ultrasonography.

**Objectives:** The objective of this study was to evaluate the correlation between positive blood flow signal on joint ultrasonography and progression of joint destruction in patients with RA treated with TCZ for 4 years.

**Methods:** Among 111 patients who were treated with TCZ in the Akita Orthopedic Group on Rheumatoid Arthritis (AORA), 16 patients were receiving TCZ for 4 years or longer and enrolled this study. We examined age, sex, disease duration, C-reactive protein (CRP) level, MMP3 level, DAS28-ESR score, and clinical disease activity index (CDAI) at the start of TCZ administration and once a year. Moreover, we examined for blood flow signal (power Doppler signal) on joint ultrasonography at 4 years and modified total Sharp score (mTSS) on radiography at the baseline and once a year. Joint ultrasonography was performed in 34 joints, including bilateral proximal interphalangeal and metacarpophalangeal joints of the five fingers, wrists, knees, and metatarsophalangeal joints of the five toes in all of the patients, as well as other joints with symptoms. The subjects were divided into the P(+) and P(–) groups according to the presence or absence of blood flow signal on joint ultrasonography at 4 years. Eight patients were classified into the P(+) group and 8 were the P(–) group. Furthermore, progression of joint destruction by using mTSS were compared among both groups.

**Results:** The mean patient age was 52 (range, 38–63) years, and the mean disease duration was 92 (range, 30–159) months. Women accounted for 69% of the patients. At the start of TCZ administration, no significant differences in age, proportion of women, disease period, CRP, CMMP3, and CDAI were observed between both groups. However, the DAS28-ESR score was significantly higher in the P(+) group than in the P(–) group (p=0.0279). Before the start of TCZ therapy, the scores of mTSS/year were 3.9 in the P(+) group and 2.7 in the P(–) group, showing no significant difference. After the start of TCZ therapy, the scores of mTSS/4 years were 3.4 in the P(+) group and 0.2 in the P(–) group, showing a significant difference (p=0.0347).

**Conclusions:** The presence of positive blood flow signal on joint ultrasonography at 4 years was significantly correlated with progression of joint destruction in patients with RA treated with TCZ.

## SAT0183 LONG-TERM EFFICACY, SAFETY, AND TOLERABILITY OF TOCILIZUMAB IN RITUXIMAB-REFRACTORY RHEUMATOID ARTHRITIS

Z. Farah[1], V. Reddy[2], S. Ali[1], F. Price-Kuehne[1], S. Moore[2], C. Mackworth-Young[1], M. Ehrenstein[2]. *[1]Rheumatology, Charing Cross Hospital; [2]Rheumatology, University College London Hospital, London, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is an inflammatory autoimmune process, and the dysregulated overproduction of interleukin-6 (IL-6) plays an important role in its pathogenesis. Tocilizumab (TCZ) is a humanized monoclonal antibody targeting the IL-6 receptor, and is recommended for use in RA. (1)

There is evidence demonstrating good outcomes with TCZ in patients who have disease refractory to B-cell depletion with rituximab (RTX), a chimeric monoclonal antibody targeting CD20 B-cells, with up to 18 months' follow-up. (2) Long-term data, however, on the efficacy, safety and tolerability of TCZ in RA that is refractory to sDMARDs, anti-TNF and RTX are lacking.

**Objectives:** To evaluate the long-term efficacy and safety of TCZ in real patients with RA refractory to synthetic DMARDs, anti-TNF agents and B cell depletion therapy with RTX, beyond 2 years.

**Methods:** We retrospectively studied 45 patients from two centres who received TCZ for median 48-months (range, 9–72) duration. All patients received anti-TNF and RTX previously. Efficacy and safety was evaluated according to the EULAR response criteria and EMEA guidance, respectively. Wilcoxon matched ranks test was used to assess changes in outcomes.

**Results:** Of 45 patients, 36 (80%) had previously discontinued RTX due to inefficacy and 9 (20%) due to intolerance. At most recent follow-up, median 48 months, 30 of 45 (67%) patients were continuing TCZ and 15 (33%) had discontinued, 7 due to inefficacy and 8 others due to intolerance.

Of 36 patients with RTX-refractory RA, 25 (69%) were continuing TCZ and 11 had discontinued due to, inefficacy in 6 (17%) and intolerance in 5 (14%): 2 patients due to diverticulitis, 2 due to upper respiratory tract infections and 1 due to discitis.

Of the 9 patients with RTX-intolerance, 5 (56%) were continuing TCZ and 4 (44%) had discontinued: 1 patient due to inefficacy and 3 due to intolerance, who had a prior history of hypogammaglobulinemia and infections associated with RTX.

There were no significant differences in lipid profile in 25 of 36 of patients continuing TCZ therapy whereas 11 required statin therapy.

**Conclusions:** A majority of patients with RA refractory to synthetic DMARDs, anti-TNF and RTX responded to TCZ. Lipid profile in a majority of patients was stable in the long-term.

Key messages:

1. The efficacy of TCZ is sustained in the long-term in patients with RTX-refractory RA.
2. TCZ appears to be safe in patients previously treated with RTX.

TCZ does not alter lipid profile in a majority of the patients with RTX-refractory RA.

## Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models

### SAT0184 SIGNAL TRANSDUCER AND ACTIVATOR OF TRANSCRIPTION 3 (STAT3) INTEGRATES SEVERAL PROFIBROTIC PATHWAYS IN SYSTEMIC SCLEROSIS

D. Chakraborty[1], B. Šumová[1,2], T. Mallano[1], C.-W. Chen[1], A. Ramming[1], O. Distler[3], G. Schett[1], J.H. Distler[1]. *[1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Germany, Erlangen, Germany; [2]Institute of Rheumatology, Department of Rheumatology of the First Faculty of Medicine, Charles University, Prague, Czech Republic; [3]Center of Experimental Rheumatology and Zurich Center of Integrative Human Physiology, University Hospital Zurich, Zurich, Switzerland*

**Background:** Signal transducer and activator of transcription 3 (STAT3) is a transcription factor that is regulated by phosphorylation of key tyrosine residues. Phosphorylation of STAT3 triggers dimerization, nuclear translocation and transcriptional activation. STAT3 can be phosphorylated by JAK2, SRC, c-ABL and JNK kinases, all of which have been implicated in aberrant fibroblast activation in systemic sclerosis (SSc). We therefore hypothesized that profibrotic signals transmitted through those kinases may converge on STAT3 and that STAT3 may be an important molecular checkpoint for tissue fibrosis in SSc.
**Objectives:** The aim of this study was to investigate the role of STAT3 in fibroblast activation and to evaluate it as a potential molecular target for antifibrotic intervention.
**Methods:** Activation of STAT3, JAK2, SRC, c-ABL and JNK was analyzed in SSc patients and in experimental models of SSc by Western Blot and immunochemistry. Selective inhibitors in conjunction with knockdown and knockout strategies were used to target STAT3 signaling and its upstream kinases in cultured fibroblasts. The anti-fibrotic potential of STAT3 genetic and pharmaceutical inhibition was evaluated in two mouse models of SSc: bleomycin-induced fibrosis and fibrosis induced by overexpression of a constitutively active TGFβ receptor type I (TBRact).
**Results:** Accumulation of phosphorylated and thus active STAT3 (P-STAT3) was detected in fibroblasts in the skin of SSc patients as compared to healthy volunteers. Enhanced STAT3 signaling was also found in murine models of SSc. The accumulation of P-STAT3 was mediated by increased TGF-β signaling and inhibition of TGF-β normalized the levels of P-STAT3 in SSc fibroblasts and in experimental fibrosis. JAK2, SRC, JNK and to a lesser degree also c-ABL were activated in SSc patients and in experimental fibrosis. Functional in vitro studies identified SRC and JAK2 as major kinases phosphorylating STAT3 in response to TGF-β in fibroblasts. To further evaluate the role of STAT3, we analyzed the effects of STAT3 inactivation on collagen release and tissue fibrosis. STAT3-deficient fibroblasts were less sensitive to the pro-fibrotic effects of TGF-β with impaired collagen release and myofibroblast differentiation. Fibroblast-specific knockout of STAT3 also ameliorated experimental fibrosis in the models of bleomycin-induced fibrosis and TBRact-induced fibrosis. Pharmacological inhibition of STAT3 also exerted potent anti-fibrotic effects and inhibited TGF-β-induced fibroblast activation and bleomycin- as well as TBRact-induced experimental fibrosis.
**Conclusions:** We demonstrate that STAT3 integrates several profibrotic signals and might thus be a novel core mediator of fibrosis. Inhibition of STAT3 prevented fibroblast activation and demonstrated potent anti-fibrotic effect in different preclinical models of SSc. Considering these potent anti-fibrotic effects and the fact that several STAT3 inhibitors are currently tested in clinical trials, STAT3 might be an interesting candidate for molecular targeted therapies of SSc.

### SAT0185 WNT5A PROMOTES FIBROBLAST ACTIVATION AND TISSUE FIBROSIS BY ROR2/ RYK DEPENDENT ACTIVATION OF PCP-SIGNALING

C.-W. Chen[1], N.-Y. Lin[1], Y. Zhang[1], J. Huang[1], K. Palumbo-Zerr[1], A. Schambony[2], C. Beyer[1], G. Schett[1], J.H. Distler[1]. *[1]Department of Rheumatology and Internal Medicine 3; [2]Department of Biology, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany*

**Background:** Canonical Wnt/beta-catenin signaling has been identified as a core pathway of fibrosis in SSc. However, the role of non-canonical Wnt signaling has not yet been investigated. A subset of Wnt proteins such as Wnt5a can bind to different cell surface receptors and activate non-canonical Wnt pathways which are independent of beta-catenin pathway.
**Objectives:** In this study we aimed to characterize the role of non-canonical Wnt signaling in fibrotic diseases and find out the major target receptor for further therapeutic antibody generation.
**Methods:** The expression of non-canonical Wnt ligands was analyzed by qPCR, IF and Western blot in patients with SSc, IPF and healthy controls as well as in experimental fibrosis. The effect of fibroblast-specific (col1a2; CreER) as ubiquitous (ubiquitin; CreER) knockout of Wnt5a was evaluated in bleomycin-induced fibrosis and in experimental cGvHD. Wnt5a was overexpressed in 3D human skin culture systems and in the skin and lungs of mice using adeno-associated vectors. Wnt5a-induced signaling pathways were analyzed in vitro and in vivo using small molecule inhibitors, siRNA mediated knockdown, Western blots and reporter assays.
**Results:** The mRNA and protein levels of Wnt5a, but not other non-canonical Wnt ligands, were increased in skin and lungs of patients with SSc and IPF as compared to healthy volunteers. Wnt5a was also upregulated in murine models of fibrosis. Co-staining with cell-type specific markers identified fibroblasts as a major cellular source of Wnt5a in fibrotic diseases. Wnt5a induced myofibroblast differentiation and collagen release *in vitro* and induced pulmonary and dermal fibrosis *in vivo*. In contrast, inducible fibroblast-specific knockout of Wnt5a ameliorated bleomycin-induced fibrosis and experimental cGvHD. The effects of fibroblast-specific knockout were comparable to those in mice with inducible ubiquitous knockout. The pro-fibrotic effects of Wnt5a were independent of Wnt/beta-catenin and Wnt/Calcium signaling, but were mediated by Wnt/PCP signaling via binding with Ror2 and Ryk receptors and subsequent phosphorylated JNK and cJun. Consistently, pharmacologic or genetic inactivation of JNK or cJun abrogated the pro-fibrotic effects of Wnt5a *in vitro* and *in vivo*. Co-incubation with neutralizing antibodies against TGFbeta and inhibitors of TGFbeta receptors demonstrated that the profibrotic effects of Wnt5a were partially mediated by rapid activation of latent TGFbeta with subsequent activation of classical downstream pathways such as Smad3.
**Conclusions:** We characterize Wnt5a as a novel mediator of fibroblast activation in fibrotic diseases. Wnt5a is upregulated in SSc and IPF and induces fibroblast activation and tissue fibrosis. The pro-fibrotic effects of Wnt5a are independent of canonical Wnt signaling and Wnt/Calcium signaling, but are mediated by PCP signaling via binding with Ror2 and Ryk receptor and JNK/cJun activation and by activation of latent TGFbeta.

### SAT0186 THE HOMEOPROTEIN ENGRAILED-1 REGULATES CANONICAL TGF-β SIGNALING VIA FIBROBLAST DIFFERENTIATION AND TISSUE FIBROSIS

T. Mallano[1], K. Palumbo-Zerr[1], C. Beyer[1], C. Dees[1], J. Huang[1], T. Wohlfahrt[1], O. Distler[2], G. Schett[1], J.H. Distler[1]. *[1]Department of Internal Medicine 3, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany; [2]Department of Rheumatology, University Hospital Zurich, Zürich, Switzerland*

**Background:** Systemic sclerosis (SSc) is a chronic fibrotic connective disease of unknown etiology that affects the skin and internal organs. Transforming growth factor-β (TGFβ) has been characterized as a key-mediator of fibroblast activation in SSc. However, the intracellular signaling cascades that control TGFβ signaling and the TGFβ-induced activation of fibroblasts are still incompletely understood. Homeobox containing transcription factor, Engrailed-1 plays a key role in embryonic development and has also been linked to disease, including cancer. EN-1 is induced by proinflammary cytokines and oxidative stress which play an important role in Systemic Sclerosis (SSc).
**Objectives:** The aim of this study was to determine the role of the embryonic homeoprotein EN-1 in fibroblast activation and tissue fibrosis in systemic sclerosis (SSc).
**Methods:** The expression of EN-1 in skin tissue and in human dermal fibroblasts was determined by real-time PCR, Western blot and immunofluorescence. Knock-down and overexpression strategies were used to evaluate the effect of EN-1 on fibroblast activation. The outcome of mice with fibroblast-specific knockout of EN-1 (EN1 fibKO) was evaluated in bleomycin-induced skin fibrosis; fibrosis induced by overexpression of a constitutively active TGF-β receptor I (TBRIact) and in the Tsk model which resembled the later stages of SSc. Co-IP and CAGA Reporter assay were performed to study the physical and functional interaction between EN-1 and Smad3.
**Results:** A five-fold increased expression of EN-1 was detected in the upper layer of the dermis of SSc patients on fibroblasts double stained for EN-1 and anti-prolyl-4-hydroxylase. EN-1 expression was induced by TGF-β in cultured fibroblasts and treatment with the TBR inhibitor SD-208 prevented the induction of EN-1 by two-fold decrease in experimental fibrosis. Fibroblasts lacking EN-1 were less sensitive to the pro-fibrotic effects of TGF-β with impaired induction of target genes mRNA and protein. Additionally, overexpression of EN-1 enhanced the profibrotic effect of TGF-β with myofibroblast differentiation and increased collagene release as well as mRNA and protein levels of target genes. Function studies demonstrated that EN-1 interacts with Smad3 to regulate the pro-fibrotic effects of TGF-β. Co-IP demonstrated that TGF-β induces binding of EN-1 to Smad3. Reporter study and analyses of the expression of classical Smad target genes such as PAI-1 demonstrated that the binding of EN-1 to Smad3 stimulates the transcriptional activity of Smad3. In the model of bleomycin-induced fibrosis dermal thickening, hydroxyproline content and myofibroblast counts were significantly decreased in EN1 fibKO mice as compared to wildtype littermates. EN1 fibKO also protected from TBRIact-induced fibrosis and ameliorated fibrosis in the Tsk1 model.
**Conclusions:** We demonstrate for the first time a role of EN-1 in fibroblast

activation and tissue fibrosis. Deficiency in EN-1 reduced the stimulatory effect of TGF-β on fibroblasts by interfering with canonical Smad and protected from experimental fibrosis in different mouse models. Considering the potent anti-fibrotic effects observed in this study, EN-1 might be a candidate for molecular targeted therapies of SSc.

## SAT0187 THE ANTIMICROBIAL PEPTIDE LL-37 AND TYPE I INTERFERON IN IDIOPATHIC INFLAMMATORY MYOPATHIES

X. Lu[1], Q. Tang[2], E. Lindroos[2], M. Lindh[3], B. Agerberth[3], I. Lundberg[2], C. Wick[2]. *[1]Department of Rheumatology, China-Japan Friendship Hospital, Beijing, China; [2]Rheumatology Unit, Department of Medicine, Solna, Karolinska Institutet, Karolinska University Hospital; [3]Department of Laboratory Medicine, Clinical Microbiology, Karolinska Institutet, Karolinska University Hospital, Huddinge, Stockholm, Sweden*

**Background:** The human antimicrobial peptide LL-37, exhibits a variety of biological functions such as activation of plasmacytoid dendritic cells (pDC) to produce type I interferon and mediate tissue damage. In autoimmune diseases such as systemic lupus erythematosus, rheumatic arthritis, and psoriasis LL-37 released by neutrophils is overexpressed at inflammatory sites and may have a role in pathogenesis by induction of type I interferon pathway. Type I interferon pathway is activated in subgroups of patients with idiopathic inflammatory myopathies (IIM). The mechanisms that drive type I interferon in IIM is unclear. We hypothesized that LL-37 in muscle and/or skin may be a factor that can activate type I interferon in these conditions.
**Objectives:** The aim of our study was to investigate the expression of LL-37 and type I interferon related proteins (MxA) in the affected organs of patients with polymyositis (PM) and dermatomyositis (DM).
**Methods:** Twelve muscle and 5 skin biopsies were obtained from 6 PM and 6 DM patients. Additional 3 skin biopsies taken from non-affected skin in 3 of DM patients. Five muscle and 7 skin biopsies from healthy subjects were selected as controls (HC). Immunohistochemistry staining of LL-37, CD66b (neutrophil), MxA (type I interferon), BDCA-2 (pDC), CD68 and CD163 (both macrophage markers) were performed in all muscle and skin specimens. Western blot (WB) was utilized to confirm the expression of LL-37 in muscle and skin tissues. Co-localization of LL-37 and neutrophils in muscle and skin tissue was confirmed by double-staining. The relationship of the markers were analyzed and compared with the clinical features of PM/DM patients.
**Results:** The expression of LL-37, CD66b, BDCA-2, and MxA in muscle as well as in skin tissue was significantly higher in PM/DM patients when compared to HC ($P<0.05$). In addition, LL-37 expression in skin lesions of DM patients was higher than in non-affected skin from the same patient ($P<0.05$). WB confirmed LL-37 expression in muscle and skin tissues of PM/DM patients but was negative in HC. A positive correlation was found between expression of LL-37 and CD66b in muscle and skin tissues of PM/DM patients (R=0.89 and 0.69 respectively, $P<0.05$). Double-staining revealed co-localization of LL-37 and neutrophils in both muscle and skin tissues. The expression of CD66b correlated to MxA expression in muscle tissue in PM/DM patients (R=0.58, $P<0.05$). Expression of LL-37 and CD66b in muscle tissue correlated to serum CK levels (R=0.85 and 0.88 respectively, $P<0.05$). LL-37 and CD66b expression in skin tissue correlated with disease activity (physician global assessment score) in DM patients.
**Conclusions:** The presence of the antimicrobial peptide LL-37 in affected muscle and skin tissues of patients with PM and DM together with the correlation of expression of LL-37 to the type I inducible protein MxA might indicate a role of LL-37 as an inducer of interferon production in patients with PM and DM. Thus, LL-37 may be involved in the pathogenesis of these diseases.

## SAT0188 SKELETAL MUSCLE FIBERS IN MYOSITIS ACTIVELY UPREGULATE IMMUNOPROTEASOME SUBUNITS

S. Bhattarai[1], K. Ghannam[1], S. Krause[2], L. Martinez-Gamboa[1], A. Marg[3], S. Spuler[3], O. Benveniste[4], W. Stenzel[5], E. Feist[1]. *[1]Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin, Berlin; [2]Friedrich Baur Institute, Ludwig Maximilians University, Munich; [3]Muscle Research Unit, Experimental and Clinical Research Center, Charité – Universitätsmedizin Berlin, Berlin, Germany; [4]La Pitié-Salpêtrière Hospital, Internal Medicine Department, AP-HP, INSERM U974, UPMC, Paris, France; [5]Department of Neuropathology, Charité – Universitätsmedizin Berlin, Berlin, Germany*

**Background:** Idiopathic inflammatory myopathies (IIMs) are characterized by enhanced sarcolemmal expression of MHC class I molecules and infiltration of immune cells including $CD8^+$ T cells into skeletal muscle tissue. Immunoproteasome is a proteolytic complex that can efficiently produce peptides for antigen presentation via major histocompatability complex class I (MHC class I) molecules and is highly expressed in immune cells. Previously, we described upregulated expression of immunoproteasome subunits (β1i and β5i) within myositis muscle biopsies at the mRNA level suggesting its possible involvement in diseases pathogenesis [1].
**Objectives:** The aim of this study was to clarify, whether immunoproteasomes are expressed within the muscle fibers of patients with IIMs and therefore, could be associated with the increased MHC class I surface expression.
**Methods:** Cryosections of muscle biopsies from sporadic Inclusion body myositis (sIBM), Immune-mediate necrotizing myopathy (IMNM), Dermatomyositis (DM) patients and healthy controls were examined for expression of proteasome subunits and cellular infiltrates by western blot and double-immunofluorescence. Proteasome activity was measured and compared between the different groups using a proteolytic assay *in vitro*.
**Results:** Western blot analyses of muscle biopsies from IBM (n=9), IMNM (n=9), DM (n=9) patients showed a strong upregulation of β1i and β5i subunits. Of note, double immunofluorescence provided clear evidence for an expression of immunosubunits β1i and β5i especially in the infiltrated muscle fibers in all studied disease conditions, whereas healthy muscle (n=4) fibers showed no staining for β1i and β5i. Interestingly, expression of proteasome immunosubunits was accompanied by increased MHC class I expression on the same muscle fibers. Both $CD68^+$ and $CD14^+$ macrophages showed strong staining of β1i and β5i in all disease group. In IBM, among the infiltrating cells about 50% of CD8+ T cells stained positive for β1i and β5i. In agreement with these results, significant increase in proteasomal chymotrypsin-like (CTL) activity was observed.
**Conclusions:** These results suggest direct involvement of immunoproteasome subunits β1i and β5i in the pathogenesis of myositis through enhanced upregulation of MHC class I.

## SAT0189 CHARACTERIZATION OF EXTRACELLULAR HISTIDYL-TRNA SYNTHETASE IN MYOSITIS

C. Fernandes Cerqueira[1], A. Sohrabian[2], I. Albrecht[1], A. Notarnicola[1], E. Ossipova[1], J. Lengqvist[1], M. Fati[3], G.J. Pruijn[4], J. Grunewald[3], J. Rönnelid[2], I.E. Lundberg[1], P.-J. Jakobsson[1]. *[1]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm; [2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala; [3]Respiratory Medicine Unit, Department of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [4]Department of Biomolecular Chemistry, Radboud Institute for Molecular Life Sciences and Institute for Molecules and Materials, Radboud University, Nijmegen, Netherlands*

**Background:** Histidyl-transfer RNA synthetase (HisRS) is a major autoantigen in myositis with lung involvement[1–4]. Simultaneous presence of anti-HisRS and anti-Ro52 antibodies has been demonstrated in patients with myositis[5–7].
**Objectives:** We investigated the presence of HisRS in the extracellular compartments plasma, sera and bronchoalveolar lavage fluid (BAL). In addition, the occurrence of anti-HisRS antibody isotypes as well as other auto-reactivities was evaluated in BAL and sera from patients with myositis.
**Methods:** HisRS was measured in sera, plasma and BAL from myositis (anti-HisRS antibody positive, anti-Jo1+ and negative, anti-Jo1-), sarcoidosis, rheumatoid arthritis (RA) patients and healthy controls (HC) by dot-blot, western-blot, immunoprecipitation and mass spectrometry. The presence in BAL and sera of anti-Jo1 isotypes and other ANA-associated autoantibodies was analysed by ELISA and addressable laser bead immunoassay.
**Results:** HisRS was detected in sera, plasma and BAL of patients with myositis, sarcoidosis and RA and in HC. HisRS systemic levels were elevated in anti-Jo1+ myositis (14 out of 20 sera) compared to anti-Jo1- myositis (10/18), sarcoidosis (0/8) and RA (3/15) patients, and HC (5/23). In BAL, significant levels of HisRS were detected in 6/8 HC and 5/8 sarcoidosis, compared to 4/8 myositis (2 anti-Jo1+ and 2 anti-Jo1-). Our results demonstrated the presence of a factor in BAL with high binding capacity for HisRS and HisRS complexed with anti-HisRS-N-terminal antibody. C1q-binding immune complexes (IC) containing HisRS were not the binding factor. However, anti-Jo1 isotypes as well as anti-Ro52 IgG were identified in both BAL (5/8 patients were positive for anti-Jo1 IgG, 3/8 for anti-Jo1 IgA, 3/8 for anti-Jo1 IgM and 4/8 for anti-Ro52 IgG) and sera (5/8 for anti-Jo1 IgG, 3/8 for anti-Jo1 IgA, 4/8 for anti-Jo1 IgM and 3/8 for anti-Ro52 IgG) from patients with myositis. Furthermore, a positive correlation between the presence of anti-Jo1 IgG and anti-Ro52 IgG in BAL was identified ($r^2$=0,881; p=0,007).
**Conclusions:** HisRS was detected both in blood and BAL fluid. The identification of extracellular HisRS, anti-Jo1 isotypes and anti-Ro52 in myositis BAL may provide additional clues for the development of autoimmunity in the lungs.

## SAT0190 HISTOLOGICAL STUDY ON THE EXPRESSION OF TRANSCRIPTIONAL INTERMEDIARY FACTOR 1 (TIF 1) IN THE PATIENTS WITH INFLAMMATORY MYOPATHIES

Y. Kim, J. Kim, S.W. Kang, S.-C. Shim, I.S. Yoo, S.-J. Yoo. *Chungnam National University Hospital, Daejeon, Korea, Republic Of*

**Background:** Myositis-specific antibodies in patients with inflammatory myopathies are known to be associated with various clinical manifestations, classifications and diagnosis. Among them, recently found anti-transcriptional intermediary factor 1 (TIF1) α, β, or γ antibodies, has been reported to be associated with dermatomyositis (DM) accompanied by cancer.
**Objectives:** Although previous studies have evaluated the association of the antibodies in serum and clinical subtypes, the information about the target antigen is insufficient. The purpose of this study was to confirm the overexpression of TIF1s in the muscle and skin tissues of patients with inflammatory myopathies.
**Methods:** From February 2004 to November 2014, skin and muscle biopsies were performed on 45 patients diagnosed with dermatomyositis and polymyositis. We stained skin and muscle tissue by immunohistochemistry using anti-TIF1α, β, or γ and compared with the results of healthy control. We analyzed the association between the clinical manifestations and protein expression in each tissue.
**Results:** When compared with the control group, any antigens showed no significant overexpression in the muscle. However, TIF1α showed higher positive rate in the skin of DM (12/15 [80%]) than in the skin of healthy control (0/7 [0%]) (p=0.001). TIF1γ expression was higher in the muscle of patients with DM while there was no expression in the muscle of healthy controls (DM, 8/19 [80%] vs. healthy control 0/7 [0%], p=0.039).
In the tissues of inflammatory myopathies, TIF1α and TIF1γ demonstrated higher positive rates in the skin than in the muscle (TIF1α, muscle, 4/35 [11%] vs. skin, 12/15 [80%], p<0.001; TIF1γ, muscle, 10/35 [29%] vs. skin, 13/15 [87%], p<0.001). When analyzing DM patients only, the result was similar (TIF1α, muscle, 1/19 [5%] vs. skin, 12/15 [80%], p<0.001; TIF1γ, muscle, 8/19 [42%] vs. skin, 13/15 [87%], p=0.013). TIF1β showed strong positivity in all tissues of myositis or healthy control.
Analyzing the association with TIF1s expression and cancer, there was no significant difference in the positive rate of TIF1α or γ in the muscle or skin between the myositis patient with or without cancer.
**Conclusions:** TIF1α was expressed more in the skin of DM patients than that in that of control group and TIF1γ in the muscle of DM patients than in that of control. The expression of TIF1α in the skin and TIF1γ in the muscle of cancer associated DM was not higher than those of DM without cancer. Thus the expression levels of TIF1α in the skin and TIF1γ in the muscle may be associated with myositis rather than with cancer.

**Background:** Systemic sclerosis (SSc) is a complex systemic autoimmune disease characterized by microvascular dysfunction, immune activation and fibrosis affecting the skin and internal organs (1). Improved characterization of the fibrotic mechanisms involved in SSc is a keystone to developing biomarkers and effective disease-modifying therapies. The activation of endothelial cells (ECs) appears very early in the course of the disease, suggesting that chronic fibroblast activation may be at least partly the result of endothelial dysfunction (1,2). However, the ability of the platelet/EC interaction to induce the secretion of factors directly involved in fibroblast activation and subsequent fibrosis in SSc remains uncertain.
**Objectives:** The objective was to provide evidence of a new pathogenic loop implicating activated platelets, microvascular ECs and ECM production in SSc.
**Methods:** A total of 203 SSc patients and 30 healthy donors (HDs) were prospectively enrolled between March 2012 and January 2015 at the University Hospital of Bordeaux. Immunohistochemistry and immunofluorescence analysis were performed on skin biopsy specimens from 18 SSc patients and 5 HDs. Serum TSLP levels were measured (ELISA) in the entire cohort. Human dermal microvascular ECs and fibroblasts were purified from normal and SSc patients skin biopsies. Extracellular matrix production by cultured fibroblasts was assessed by RT-qPCR.
**Results:** Serum TSLP levels were significantly increased in SSc patients compared to HDs (p=0.0005) and were associated with a higher frequency of vascular damage (p=0.02). The proportion of dermal TSLP-positive cells was increased in the skin biopsies of SSc patients compared to HDs (p=0.0008) and was correlated with skin fibrosis (modified Rodnan skin score) (R=0.059, p=0.01). In SSc dermis, TSLP was mainly expressed by CD31-positive ECs. In vitro, activated platelets induced TSLP production by dermal microvascular ECs in an IL1β-dependent manner. Recombinant TSLP in normal fibroblasts reproducibly induced a pro-fibrotic profile as indicated by a significant increase in the collagen/collagenase ratio (p=0.03). Interestingly, this property was shared by fibroblasts purified from non-fibrotic TSLP-negative SSc skin, but lost with fibroblasts purified from TSLP-positive fibrotic skin.
**Conclusions:** Taken together, these results identify dermal microvascular ECs as new contributors to TSLP production in SSc and suggest a potential mechanism by which platelets may profoundly affect the fibrotic process in SSc.

## SAT0192 DECREASED INTERLEUKIN-6/STAT3, BUT INCREASED INTERFERON/STAT1 SIGNALLING IN LYMPHOCYTES OF PATIENTS WITH SYSTEMIC SCLEROSIS (SSC)

C. Kittel, M. Skwarek, B. Heschel, J. Fantana, M. Aringer. *Medicine III, University Medical Center TU Dresden, Dresden, Germany*

**Background:** Increased interleukin-6 (IL-6) was found in SSc skin, and early studies suggest therapeutic efficacy of IL-6 receptor blockade in SSc. Similarly, an increased interferon (IFN) signature was found in SSc patients. Accordingly, both IL-6 and interferons may be upregulated in SSc, and both act via Stat (signal transducer and activator of transcription) molecules, namely Stat3, and Stat1, respectively.
**Objectives:** To analyze the interleukin-6 (IL-6) receptor-Stat3 axis, as well as Stat1 and phosphorylated Stat1, in lymphocytes of patients with SSc.
**Methods:** PBMC of 30 patients with SSc and 42 healthy individuals (HC) were prepared. CRP, ESR, modified Rodnan skin score (mRSS) and the EULAR activity score were recorded. For determining the percentages of CD126 and CD130 positive cells, PBMC were directly stained with PE-labelled or control antibodies. Ex vivo and after 15 minutes of incubation with or without recombinant human interferon-γ (IFNγ) or interleukin-6 (IL-6), PBMC were fixed with formaldehyde (2%), permeabilized with methanol (80%), and stained with PE-labelled control antibodies or antibodies to Stat1 or phosphorylated Stat1 (pStat1) or pStat3, respectively. Stained cells were immediately analyzed on a Becton Dickinson FACSCalibur fluorocytometer, gating for lymphocytes. As a semiquantitative measure of Stat and pStat contents, mean fluorescence intensity (mfi) was used. Data were expressed as mean±SD.
**Results:** Both chains of the IL-6 receptor, CD126 and CD130, were expressed on decreased percentages of SSc lymphocytes (50.2±18.1% vs. 60.0±7.9%, p=0.0086, and 52.6±15.1% vs. 59.6±9.5%, p=0.0212, respectively). This translated into a diminished increase of pStat3 in SSc lymphocytes upon IL-6 stimulation (Δmfi 17.2±12.1 vs. 20.5±9.3, p=0.03). In contrast, the IFNγ-induced increase in pStat1was more pronounced in SSc lymphocytes (Δmfi 10.5±11.2 vs. 4.8±3.7, p=0.0035), despite their increased Stat1 contents (mfi 51.2±27.4 vs. 16.7±9.1, p<0.0001), thus suggesting activity of the IFN system in SSc. Somewhat unexpectedly, no differences were found between diffuse cutaneous (or anti-topoisomerase positive) and limited cutaneous (or anti-centromere-positive) SSc.
**Conclusions:** In combination of increased Stat1 and Stat1 phosphorylation and decreased IL-6 receptors, our results suggest activity of both the IFN/Stat1 and the IL-6/Stat3 axis in SSc, with a shift towards phosphorylated Stat1.

SAT0193 **MACROPHAGES RESPONDING TO MECHANICAL STRESS IN SCLERODERMA**

A. Tam[1], X. Shiwen[1], H. Lopez[1], K. Khan[1], B. Ahmed-Abdi[1], H. Rosario[1], N. Arumalla[1], M. GIbson[1], C. Denton[1], D. Abraham[1], B. Smith[2], R. Stratton[1]. *[1]Centre for Rheumatology and Connective Tissue Disease, University college london, London, United Kingdom; [2]School of Medicine, Boston University, Boston, United States*

**Background:** Inflammation, vasculopathy and tissue fibrosis are key features of scleroderma (SSc). While healthy forearm skin which has a Young's modulus of 4–12kPa, SSc fibrotic skin measures 50–80kPa with its increased mechanical stiffness[1]. We have shown that mechano-sensing properties of fibroblasts in SSc are mediated by myocardin-related transcription factor A (MRTF-A)[3]. Monocytes/macrophages are likely to be involved in SSc pathogenesis but the effect of mechanical stress on these cells remain to be elucidated[3,4].
**Objectives:** To investigate if a mechanically-stressed microenvironment like that in SSc tissue, promotes macrophages towards a pathogenic phenotype, and whether MRTF-A is involved in this process.
**Methods:** Control and scleroderma skin sections were immunostained with anti-CD68 and anti-MRTF-A antibodies (n=3). Human PBMC-derived macrophages were cultured in RPMI/M-CSF on 4kPa and 50kPa collagen-fibronectin-coated plates to mimic "soft"/healthy and "stiff"/fibrotic skin, and activated with LPS (10ng/ml) or IL-10 (10ng/ml) for macrophages designated M(LPS) and M(IL-10) (n=4). MRTF-A expression was assessed by qPCR and conditioned media profiled by Luminex array for inflammatory cytokines. Mouse bone marrow-derived macrophages (BMDMs) of wildtype and MRTF-A-null mice were maintained in RPMI/M-CSF on soft and stiff substrates. The data were analysed by two-way ANOVA and Tukey test ($p<0.05$, CI 95%).
**Results:** We observed a greater number of $CD68^+$ macrophages in diffuse SSc skin compared to control skin, mainly around perivascular regions. These macrophages also expressed MRTF-A. Human macrophages expressed MRTF-A mRNA and showed differential cytokine expression when cultured on soft and stiff substrates. M(LPS) on soft matrix expressed IFN-$\gamma$, which was undetectable with M(LPS) on stiff substrate (mean difference 0.2075±0.1576pg/ml, $p<0.01$). LPS- and IL-10 activation on soft substrate increased MCP-3 expression compared to controls (mean difference 68.51±49.19pg/ml, $p<0.01$, 92.88±49.22pg/ml, $p<0.0001$, respectively). M(LPS) on stiff compared to soft substrate showed lower MCP-3 expression (mean difference 57.01±49.22pg/ml, $p<0.05$). M(IL-10) on soft substrate showed higher MCP-1 expression compared to controls (mean difference 2448±2232pg/ml, $p<0.05$). M(IL-10) on stiff substrate decreased expression of MCP-1 (mean difference 2590±2233pg/ml, $p<0.05$) and increased fractalkine levels compared to soft substrate (mean difference 51.22±36.28pg/ml, $p<0.01$). Wildtype BMDMs on stiff compared to soft substrate displayed a more elongated morphology. MRTF-A-null BMDMs remained rounded on stiff substrate.
**Conclusions:** MRTF-A is a mechanical stress-responsive factor which co-activates transcription of cytoskeletal and extracellular matrix-modifying genes. MRTF-A may couple mechanical stress to macrophage activation in SSc, where stiff matrix promotes macrophage secretion of cytokines and growth factors that exacerbate fibrosis.

SAT0194 **IL-6 SERUM LEVELS AND CORONARY MICROVASCULAR DYSFUNCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS**

E. Pigatto[1], G. Famoso[2], A. Scanu[1], P. Polito[1], P. Galozzi[1], E. Zanatta[1], L. Punzi[1], F. Cozzi[1], F. Tona[2]. *[1]Medicine, Rheumatology Unit; [2]Cardiology Unit, University of Padova, Padova, Italy*

**Background:** Functional impairment of coronary microcirculation is thought to be a pathway in the development of cardiac involvement in systemic sclerosis (SSc). The underlying mechanism is not fully understood. A reduction of coronary flow reserve (CFR) suggests a coronary microvascular dysfunction (CMD) and predicts adverse outcomes in several cardiovascular diseases. Interleukin-6 (IL-6) is involved in the pathogenesis of SSc and it is a marker of immune activation. High serum levels of IL-6 are correlated with the severity of skin lesions, pulmonary fibrosis and pulmonary hypertension, but the role of IL-6 in the development of cardiomyopathy in SSc is yet not clear.
**Objectives:** To assess the relationship between CFR values and IL-6 serum levels in SSc.
**Methods:** Forty SSc patients (32 female and 8 male, aged 55±11 years), classified according to the 2013 ACR/EULAR criteria, were enrolled. Disease activity was evaluated by EUSTAR score. Twenty-three patients were affected by diffuse cutaneous form and 17 by limited form. All patients had no clinical evidence of heart disease. Coronary flow velocity in the left anterior descending coronary artery was detected by transthoracic Doppler echocardiography at rest and during adenosine infusion. CFR was the ratio of hyperaemic diastolic flow velocity (DFV) to resting DFV. A CFR $\leq$2.5 was considered abnormal and marker of CMD. Serum levels of IL-6 and of cardiac biomarkers (pro-BNP and troponin I) were evaluated in all patients.
**Results:** CFR was reduced in 21 patients (52.5%). The average value was 2.08±0.29. Serum levels of IL-6 (n.v. <2.5 pg/mL), pro-BNP (n.v. <125 ng/L) and troponin I (n.v. <0.0017 $\mu$g/L) were increased respectively in 50%, 45% and 27.5% of cases. No significant correlation between CFR and subsets of SSc was found. Higher EUSTAR score were correlated with reduced CFR (*p=0.037*) and high values of IL-6 (*p=0.002*).
A significant correlation between the increase levels of IL-6 and the reduction of CFR (*p=0.039*) was found.
**Conclusions:** Our results showed that high serum levels of IL-6 are associated with CMD independently from the severity of SSc. A positive correlation between IL-6, EUSTAR score and the impairment of CFR in SSc patients may be suggest an implication of IL-6 in the cardiac pathogenesis of SSc. The evaluation of serum IL-6 might represent a tool for the prediction of CMD, suggesting a role in the increased cardiovascular risk in patients with SSc. Moreover they could open new possibilities for the treatment of SSc cardiomyopathy.

## Scleroderma, myositis and related syndromes

SAT0195 **EARLY NAILFOLD CAPILLAROSCOPIC PATTERN PREDOMINATES IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE**

A. Felis-Giemza[1], E. Kontny[2], E. Haładyj[1], J. Nałęcz-Janik[1], K. Walkiewicz-Pielaszek[1], Z. Czuszyńska[3], Z. Zdrojewski[3], A. Paradowska-Gorycka[4], M. Olesińska[1]. *[1]Connective Tissue Disease Department; [2]Department of Pathopphysiology and Immunology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw Poland, Warsaw; [3]Clinic of Internal Medicine, Connective Tissue Diseases&Geriatrics, Medical University of Gdańsk, Gdańsk; [4]Biochemistry and Molecular Biology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw Poland, Warsaw, Poland*

**Background:** Mixed connective tissue disease (MCTD) is a rare connective tissue disease with clinical picture consisted of multiple organ manifestations, including skin changes resembling systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and/or dermatomyositis (DM). On the background of these manifestations are microvascular changes - alteration of endothelial function and impairment of endothelial progenitor cells. The most prevalent clinical manifestation is Raynaud's phenomenon, which is only partly caused by functional narrowing of small vessels. Nailfold capillaroscopy (NFC) is widely used as a simple, non-invasive technique for investigating microvascular involvement in rheumatic diseases[1].
**Objectives:** To describe the course of skin changes in MCTD and its relation to nailfold capillaroscopy patterns.
**Methods:** We analyzed clinical picture and nailfold capillaroscopy patterns (NFC) in 79 patients (pts) with MCTD recognized according to Kasukawa criteria. Clinical data achieved on the day of examination were compared with the data from beginning of the disease collected retrospectively. NFC was performed on the day of examination and analysed by one investigator. NFC changes were classified according to phases of NFC changes by Cutolo[2] as early, active or late pattern.
**Results:** Median of MCTD pts age was 44 (18–67) years, median of disease duration - 117,6 months (min-max: 10–420). A Raynaud's phenomenon was observed in 75 (94,9%) pts with similar frequency at disease onset and in follow-up. Skin changes were present in 64 (81%) pts, involving 22% SLE-like, 27% SSc-like, 32% SLE and SSc-like, and 1% DM-like phenotype. Totally NFC changes were observed in 55 (69,6%) pts. Majority of changes were in the spectrum of early pattern - 41 (51,9%) pts, active and late pattern were observed in 8 (10,1%) and 6 (7,6%) pts, respectively. No abnormalities were observed in 24 (30,4%) pts. According to skin changes phenotype, NFC changes were observed in 37, (86%) pts with SLE-like and in 32 (66,6%) pts with SSc-like. In pts with both main types of skin changes early pattern of NFC picture predominated. SLE-like early pattern was seen in 21 (48,8%) pts, active in 5 (11,6%) and late in 5 (11,6%) pts; SSc-like early pattern was present in 21 (43,8%) pts, active in 6 pts (12,5%) and late in 5 (10,4%) pts. We did not find any correlation between NFC pattern and any clinical and serological features.
**Conclusions:** Capillaroscopy abnormalities are independent feature from the skin manifestations in MCTD. In all patients changes of early pattern predominate, even if the phenotype is SSc-like. Meanwhile, opposite to systemic sclerosis, they did not correlate with severity of organ involvement or type of skin changes.

## SAT0196 IMPRESS 2 (INTERNATIONAL MULTICENTRIC PROSPECTIVE STUDY ON PREGNANCY IN SYSTEMIC SCLEROSIS). PROSPECTIVE, CASE-CONTROL STUDY OF PREGNANCY IN SYSTEMIC SCLEROSIS

M. Betelli[1], V. Ramoni[2], M. Meroni[1], Y. Allanore[3], M. Baresic[4], F. Beneventi[2], P. Caramaschi[5], M. Cutolo[6], M. Favaro[7], M. Govoni[8], E. Hachulla[9], M. Limonta[1], M. Matucci Cerinic[10], V. Riccieri[11], E. Rosato[11], F. Salsano[11], M. Scolack[12], V. Smith[13], M. Taraborelli[14], A. Tincani[14], G. Valentini[15], M. Vonk[16], A. Brucato[1]. *[1]AO Papa Giovanni XXIII, Bergamo; [2]Policlinico San Matteo, Pavia, Italy; [3]Cochin Institute, Paris, France; [4]University Hospital, Zagreb, Croatia; [5]AOUI Verona, Verona; [6]Università di Genova, Genova; [7]Università degli Studi, Padova; [8]AOU, Ferrara, Italy; [9]Hopital Huriez, Lille, France; [10]Università degli Studi, Firenze; [11]Università Sapienza, Roma, Italy; [12]Jewish General Hospital, Montreal, Canada; [13]Gent University Hospital, Gent, Belgium; [14]Università degli Studi, Brescia; [15]Seconda Università, Napoli, Italy; [16]UMC, Nijmegen, Netherlands*

**Background:** Data on pregnancy in Systemic Sclerosis (SSc) are limited;we recently published IMPRESS,a retrospective multicenter study that compared 109 pregnancies from 99 SSc women with a general obstetric population (GOP).In SSc women preterm deliveries (PD, < W37: 25% vs.12%) and severe preterm deliveries (SPD,< W34: 10% vs. 5%),intrauterine growth restriction (IUGR, 6% vs. 1%) and very-low-birth-weight babies (VLBW, 5% vs. 1%) were significantly more frequent than GOP.Multivariable analysis found that corticosteroid use was associated with PD,while folic acid and anti-Scl70+ was protective.The disease remained stable in most SSc patients,but there were 4 cases of progression within 1 year from delivery

**Methods:** This is a fully prospective,multicenter case-control study of 3 groups of people: 1) 100 pregnant SSc patients, 2) 200 not-pregnant SSc women (matched for age, auto-antibody pattern, limited/diffuse/sine scleroderma – L/D/S – form and obstetric history), 3) 200 healthy pregnant women (matched for age and obstetric history).We will prospectively investigate disease activity during pregnancy and further year,pregnancy outcome and children health status at birth and at 1 year

**Results:** 39 pregnancies are currently ongoing,22 patients have already delivered:8 ACA+ (6 L,1 D,1 S),13 Scl70+ (7 L,4 D, 2 S),1 RNA-P3+ D, 2 L form without SSc-specific autoantibodies.We observed 4 miscarriages (1 ACA+, 2 Scl70+,1 RNA-P3+), 1 therapeutic abortion at W22 (ACA+ D in treatment with prednisone 15mg/d and cyclophosphamide),1 early voluntary termination,2 SPD in Scl70+ L (1 cesarean section at W30, due to IUGR and fetal heart rate alteration;1 spontaneous in twin pregnancy: one twin with VLBW and both of them with respiratory distress at birth), 2 PD (both of them in SCl70+ L disease at W 36), 1 pre-eclampsia at W 37 in Scl70+ limited disease, with pulmonary embolism during post-partum.

Till now,16 mothers and 28 SSc controls had completed one year surveillance after delivery.We observed disease progression in two cases: the ACA+D patient treated with prednisone and cyclophosphamide who underwent therapeutic abortion showed a kidney function worsening till hemodyalisis;the Scl70+L patient who underwent twin pregnancy showed significant worsening in pulmonary function testing,without specific findings at chest CT.

One child,born at W36 from Scl70+L mother, died at 3 months due to cardiac malformation and aesopaghus atresia;all other children showed a regular growth at 12 months pediatric evaluation

**Conclusions:** IMPRESS 2 is still going on,and we hope to answer to important questions: 1) are complications of SSc more frequent during pregnancy? 2) Are some autoantibodies protective for prematurity? 3) Which is the impact of prematurity on children development?

**Disclosure of Interest:** None declared

## SAT0197 CAPILLAROSCOPY AND MACROVASCULAR DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS

J.J. Alegre Sancho[1], M. Robustillo Villarino[1], G. Albert Espí[1], C. Vergara Dangond[1], E. Vicens Bernabeu[1], È. Valls Pascual[1], À. Martínez-Ferrer[1], D. Ybáñez García[1], J.A. Román Ivorra[2]. *[1]Rheumatology Department, Hospital Universitari Dr. Peset; [2]Rheumatology Department, Hospital Universitari i Politècnic la Fe, Valencia, Spain*

**Background:** Different studies and meta-analysis have shown that subclinical atherosclerosis (AS) and vascular complications (VC) are higher in patients with Systemic Sclerosis (SSc) than in healthy population. However, the relationship between macrovascular damage and microvascular affection has not been adequately studied by specific techniques such as capillaroscopy.

**Objectives:** To explore the possible relation between several macrovascular disease variables (carotid doppler ultrasound, ankle-brachial index [ABI]) and capillaroscopy findings in patients with SSc.

**Methods:** Transverse descriptive study with analytical components. Study population: a cohort of 115 patients with SSc controlled in the Rheumatology Department of a tertiary hospital. Variables: 1) *clinical variables*; 2) *capillaroscopy study:* findings of scleroderma pattern (megacapillaries, haemorrhages and avascular areas) and classification of evolving patterns according to Cutolo et. Al.; 3) *vascular study:* ankle-brachial index (ABI) and carotid doppler ultrasound (ESAOTE MyLab XV70, 7–12 MHz linear transducer, software $^{RF}$QIMT) measuring intima-media thickness (IMT) and presence of atheroma plaques (Mannheim Consensus). A vascular surgeon measured ABI and the capillaroscopy and carotid doppler ultrasound were done by a highly experienced rheumatologist, blind to the rest of findings, in a term of 3 months after the initial evaluation. Statistical analysis: IBM-SPSS Statistics v22.0 package.

**Results:** 115 patients where included consecutively, of which 108 were studied; with a mean age of 60,16 years (SD ±15.16); 99 women (91.7%) and 9 men (8.3%). Mean SSc evolution was 11.45 years (S*D* ±8.84). LSSc was most frequently diagnosed (50%), followed by SSc without scleroderma (18.5%) and, decreasingly, DSSc (16.7%), overlap syndrome (9.3%) and pre-SSc (5.6%). The mean right side IMT was 0,579 mm (S*D* ± 0,126), and the left side 0,657 mm (SD ± 0,158); 33,3% had atheroma plaques. In total, 37% had a pathological carotid ultrasound, and 39,8% had macrovascular damage (atheroma plaque and/or IMT >0,9 mm and/or ABI<0,9). In the capillaroscopy study, megacapillaries, haemorrhages and avascular areas were found in a 82,4%, 74,1% and 56,5% of patients, respectively. When re-classifying the findings according to Cutolo et al, 31,5% of patients showed an early pattern, 37% an active pattern and a 22,2% a late SSc pattern.

In the bivariate analysis, the existence of macrovascular affection showed an association with a capillary pattern with more avascular areas and fewer megacapillaries. Statistically, this association was significant between the presence of avascular areas and the macrovascular damage ($\chi^2$=4,412; *p*-value = 0,036) and the pathological carotid ultrasound ($\chi^2$=4,107; *p*-value = 0,043) variables. A tendency towards an association between these last two macrovascular variables and capillaroscopy patterns of major microvascular damage was seen.

**Conclusions:** Nailfold capillaroscopy might be a useful tool to predict the presence of AS and macro vascular damage in patients with SSc.

**Disclosure of Interest:** None declared

Lóránd[4], B. Maurer[6], U. Müller-Ladner[10], S. Nihtyanova[5], G. Riemekasten[11], E. Siegert[8], S. Vettori[12], U.A. Walker[9], F. Del Galdo[2], M. Matucci-Cerinic[1]. *[1]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]Department of Rheumatology, University of Paris Descartes, Paris, France; [4]Department of Rheumatology and Immunology, University of Pécs, Pécs, Hungary; [5]Department of Rheumatology, University College London, Royal Free Hospital, London, United Kingdom; [6]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [7]Department of Rheumatology and Clinical Immunology, Justus-Liebig University Giessen, Kerckhoff Clinic Bad Nauheim, Giessen/Bad Nauheim; [8]Department of Rheumatology and Immunology, Charité University Hospital, Berlin, Germany; [9]Department of Rheumatology, University of Basel, Basel, Switzerland; [10]Department of Rheumatology and Clinical Immunology, Justus-Liebig University Giessen, Kerckhoff Clinic Bad Nauheim, Giessen/Bad Nauheim; [11]University Schleswig-Holstein Lübeck, Lübeck, Germany; [12]Department of Rheumatology, Second University of Naples, Naples, Italy*

**Background:** In SSc, the management of DU is a problem in clinical practice, therefore their prevention is highly warranted. Sildenafil, iloprost, calcium channel blockers (CCB), ACE inhibitors (ACEi) and bosentan, alone or in combination, are used for DU prevention without unanimous agreement.

**Objectives:** DeSScipher ("to decipher the optimal management of SSc") is an EC-funded FP7 research project that consists of five observational trials (OT) addressing different aspects of SSc. The aim of OT1 was to evaluate the efficacy of vasoactive and vasodilating drugs or a combination therapy for the management of DU in SSc.

**Methods:** Longitudinal data were collected for up to 24 months by 28 DeSScipher centres. In SSc patients, the efficacy of sildenafil, bosentan, sildenafil+bosentan, iloprost or CCB /ACEi for the prevention of new DU was evaluated. Clinical features, ulcer type and other drugs were also recorded. Time without new DU, proportion of patients without new DU, risk of developing new DU and the mean number of new DU per patient were evaluated at 6 months follow-up.

**Results:** In OT1, 1394 patients were enrolled. The history of DU was a significant risk factor for developing new DU (OR=3.146; (95%CI:1.19–8.31), p=0.021), therefore analysis was focused on secondary prevention (prevention of new DU in patients with DU history). 473/1394 (33.9%) had a history of DU and 268/473 (56.7%) had follow up data (58.2% limited and 41.8% diffuse SSc subset). 47/268 (17.5%) were on Bosentan, 33/268 (12.3%) on Sildenafil, 40/268 (14.9%) on Iloprost, 31/268 (11.6%) on Sildenafil and Bosentan combination and 117/268 (43.7%) on CCB/ACEi alone. In patients with history of DU in the last 24 weeks, the treatment with CCB/ACEi alone was associated with 7 fold increased risk of developing new DU compared to all other treatment arms (OR =7.313; 95%CI:1.248–42.85, p=0.027). Patients on concomitant immunosuppressive treatment had a trend towards faster DU recurrence.

**Conclusions:** History of DU in the past 24 weeks should prompt a more

aggressive preventive strategy other than therapy with CCB/ACEi alone due to its lower efficacy to prevent DU recurrence compared to the other treatment options.

## SAT0199 NMR-BASED METABOLOMIC ANALYSIS FOR THE DIAGNOSIS OF SYSTEMIC SCLEROSIS

K.H. Jung[1], S. Oh[2], W. Park[1], M.J. Lim[1], S. Kwon[1], S. Park[2]. *[1]Division of Rheumatology, Department of Internal Medicine, Inha University, Incheon; [2]College of pharmacy, Seoul national university, Seoul, Korea, Republic Of*

**Background:** Systemic sclerosis (SSc) is a complex multi-organ autoimmune disease that is caused by inflammation, vasculopathy and fibrosis. Clinical heterogeneity, unpredictable course, high mortality and resistance to treatment make physicians still frustrated. Recently, there are unmet needs of useful biomarkers for diagnosis, disease activity and severity of SSc. Metabolomics is expected to be a useful tool for the identification of biomarkers and new therapeutic targets. Several researchers have applied metabolomics to autoimmune diseases such as systemic lupus erythematosus, and rheumatoid arthritis.
**Objectives:** To identify the biomarker candidates for the diagnosis of SSc using metabolomic analysis.
**Methods:** Fifty-five patients (48 females (87%); mean age 59.30 ± 11.44 years; disease duration 6.92 ± 4.36 years; 11 diffuse cutaneous SSc, 44 limited cutaneous SSc) and thirty age, gender matched healthy controls (HCs) were enrolled. Serum samples after 8 h of fasting were stored at -80° and analysed using nuclear magnetic resonance (NMR)-based metabolomics.
**Results:** Multivariate analysis showed metabolic differences between SSc and HCs using partial least squares discrimination analysis (PLS-DA: $R^2Y$=0.654, $Q^2$=0.482) and orthogonal partial least squares discrimination analysis (OPLS-DA: $R^2Y$=0.83, $Q^2$=0.674) (Figure 1). We identified nine discriminatory metabolites ($p$<0.05): isopropanol, lactate, 2-oxoisocaproate, glucose, and formate were increased and pyruvate, glutamate, methylguanidine, and methanol were decreased in SSc compared with those in the HCs. Using these metabolites for diagnosis of SSc, sensitivity was 96.36% and specificity was 80% by Leave-one-out analysis.

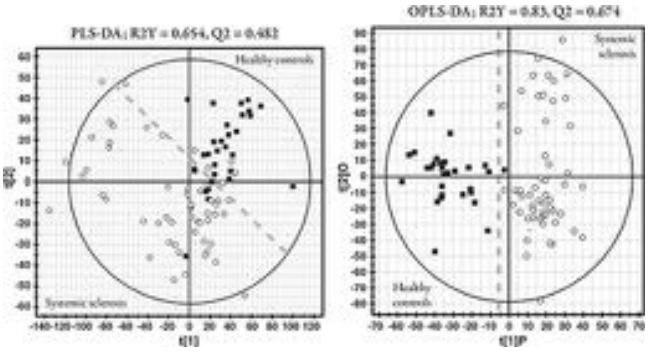

Figure 1. PLS-DA and OPLS-DA plots based on NMR analysis of systemic sclerosis (white dots) and healthy controls (black square). PLS-DA: partial least squares discrimination analysis, OPLS-DA: orthogonal partial least squares discrimination analysis.

**Conclusions:** There are considerable differences in the serum metabolomic characteristics between SSc and HCs. We expect that metabolomic analysis can be a useful tool for identification of potential diagnostic biomarkers of SSc.
**Disclosure of Interest:** None declared

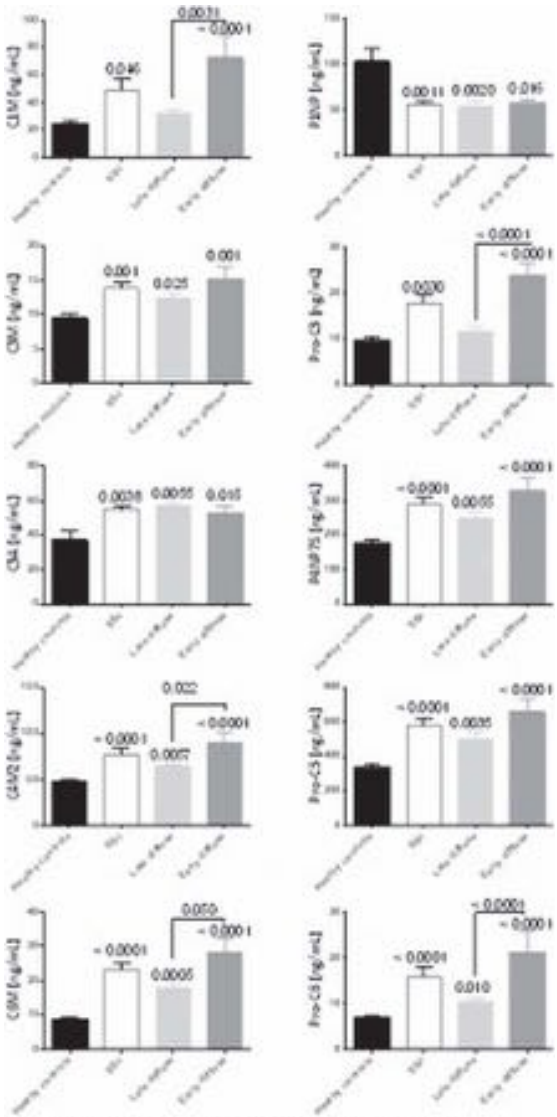
## SAT0200 SERUM BIOMARKERS OF COLLAGEN TURNOVER IN EARLY AND LATE DIFFUSE SYSTEMIC SCLEROSIS

P. Juhl[1], R.T. Domsic[2], A.-C. Bay-Jensen[1], M. Karsdal[1], A.S. Siebuhr[1], N. Franchimont[3], J. Chavez[3]. *[1]Nordic Bioscience, Herlev, Denmark; [2]Scleroderma Center, University of Pittsburgh, Pittsburgh PA; [3]Clinical Development, Biogen, Cambridge, MA, United States*

**Background:** Systemic sclerosis (SSc) is characterized by vascular damage and excessive collagen deposition in the skin and internal organs. The excessive collagen deposition results from accelerated turnover, both formation and degradation, contributing to release of extracellular matrix (ECM) fragments to the circulation, where they may be quantified as biomarkers. Skin is rich in type I and III collagen, while type IV, V and VI collagen are present in a lesser amount. Thus, the turnover of these collagens is potentially altered in SSc.
**Objectives:** The objective was to investigate the level of collagen (type, I, III, IV, V and VI) turnover in early and late stage diffuse SSc patients compared to healthy controls (HC).
**Methods:** Diffuse SSc patients (n=40) were included together with HC (n=20). Twenty patients were early diffuse (<2 years of SSc symptoms) and twenty were late diffuse (>10 years of disease with stable skin for at least six months), all without progressive lung disease. Biomarkers of type I, III, IV, V and VI collagen formation (P1NP, Pro-C3, P4NP7S, Pro-C5 and Pro-C6, respectively) and type I, III, IV and VI collagen degradation (C1M, C3M, C3A, C4M2 and C6M, respectively) were assessed in serum. Statistical differences between the groups were tested by Kruskal-Wallis test with Dunn's multiple comparisons test. The potential discrimination capacity of these biomarkers were analysed by receiver operating characteristics (ROC) area under the curve (AUC) on HC, SSc, early and late diffuse SSc versus each other.
**Results:** In early diffuse SSc Pro-C3, P4NP7S, Pro-C5 and Pro-C6 ($p$<0.0001) levels were significantly increased compared to HC (figure). In late diffuse SSc compared to HC a significant increase in P4NP7S (p=0.005) and Pro-6 (p=0.006) levels were observed. Contrary, P1NP was significantly decreased in both early (p=0.016) and late (p=0.002) diffuse SSc compared to HC. Moreover, a significant increase in Pro-C3 (p=0.0006), Pro-C5 (p=0.003) and Pro-C6 (p=0.0043) levels were detected in early diffuse SSc compared to late diffuse SSc.
The degradation biomarkers were significantly increased in early SSc compared to HC (C1M, C4M2 and C6M: $p$<0.0001, C3M: p=0.001 and C3A: p=0.02). Increased levels were found in late diffuse SSc compared to HC in C3M (p=0.02), C3A (p=0.006), C4M2 (p=0.005) and C6M (p=0.003). A significant difference



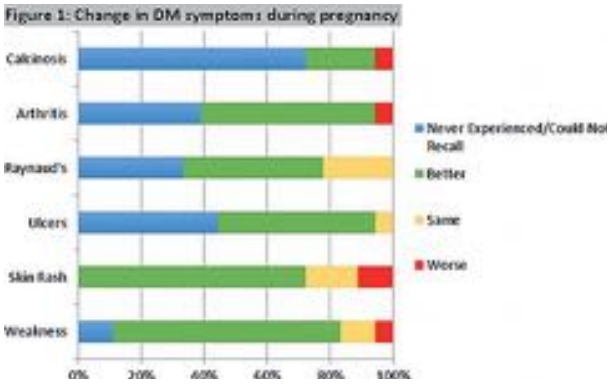


**Figure: Mean level of collagen turnover biomarker in healthy controls, diffuse SSc patients.** Kruskal-Wallis test with Dunn's multiple comparisons test was used to test differences between groups. Statistical significance was considered when p<0.05.

between early and late diffuse SSc was also observed for C1M (p=0.02), C4M (p=0.022) and C6M (p=0.05).
The best predictive value was found for Pro-C6 and C6M with AUC values of 0.92 and 0.93 for HC vs. SSc, 0.94 and 0.99 for HC vs. early diffuse, and 0.91 and 0.87 for HC vs. late diffuse, respectively. Pro-C6 had an AUC of 0.88 for early vs. late diffuse. In addition, C4M2, Pro-C3, P4NP7S and Pro C5 all had AUC values of more than 0.90 when assessing HC vs. early diffuse.
**Conclusions:** This pilot study showed that collagen turnover appears to be significantly different between HC and SSc, as well as between early and late stage diffuse patients. The discriminatory power of these biomarkers was high, especially C6M and Pro-C6. These data suggest that serological assessment of ECM turnover could be relevant in SSc, and offers an area of investigation of the pathogenesis.

## SAT0201 DERMATOMYOSITIS AND PREGNANCY: ASSESSMENT OF DISEASE ACTIVITY AND PREGNANCY OUTCOMES COMPLICATED BY MATERNAL DERMATOMYOSITIS

G.D. Miller[1], E. Moore[2], A. Valenzuela[3], L. Chung[3], V. Werth[2]. *[1]Department of Medicine, Division of Rheumatology, Harbor-UCLA Medical Center, Torrance; [2]Dermatology, University of Pennsylvania, Philadelphia; [3]Medicine, Division of Rheumatology, Stanford University, Stanford, United States*

**Background:** The effect of pregnancy on Dermatomyositis (DM) disease activity and on maternal and fetal outcomes in patients with DM is unclear[1,2].
**Objectives:** Evaluate disease activity and pregnancy outcomes complicated by maternal dermatomyositis.
**Methods:** A total of 10 patients with 21 pregnancies from a cohort of 438 DM patients of child-bearing potential, diagnosed between 2006 and 2015 from two centers, were eligible for interview with a specific questionnaire regarding pregnancy and fetal outcomes.
**Results:** Weakness, rash and arthritis were the most common clinical symptoms that improved during pregnancy in affected patients (Figure 1). In 16 out of 18 pregnancies, patients experienced weakness. Weakness improved during 13 pregnancies (81.3%), stayed the same during 2 pregnancies (12.5%), and worsened during one (6.3%). All 10 patients experienced cutaneous rash during all 18 pregnancies carried to live birth. Cutaneous rash improved during 13 pregnancies (72.2%), remain unchanged during 3 (16.7%), and worsened during 2 (11.1%). Five patients experienced arthralgias or arthritis in a total of 11 pregnancies. Symptoms improved during 10 of these pregnancies (91%) and worsened during one (9%).There were no cases of interstitial lung disease, cancer or antiphospholipid antibody syndrome among the 10 patients studied. One patient suffered from pre-eclampsia while diagnosed with DM. 3 total pregnancy losses: two early miscarriages (<10 weeks gestation) one therapeutic abortion for an ectopic pregnancy. 3 neonates out of 18 live births went to the NICU after delivery – reasons for transfer: meconium aspiration; apnea and pre-term birth.

**Conclusions:** Pregnancy does not appear to carry a worse prognosis for DM patients and all but one of our patients experienced improvement in clinical symptoms during pregnancy.

## SAT0202 NAILFOLD MICROANGIOPATHY EXTENT AND CHOROIDAL VASCULAR THICKNESS EVALUATED BY NAILFOLD VIDEOCAPILLAROSCOPY AND OPTICAL COHERENCE TOMOGRAPHY IN SYSTEMIC SCLEROSIS PATIENTS

E. Bernero[1], A. Sulli[1], C. Pizzorni[1], S. Paolino[1], E. Alessandri[1], M. Nicolò[2], C.E. Traverso[2], C.A. Cutolo[2]. *[1]Department of Internal Medicine, University of Genova, Research Laboratory and Academic Division of Clinical Rheumatology; [2]DINOGMI, University of Genova, Ophtalmology Clinic, Genova, Italy*

**Background:** Systemic sclerosis (SSc) is a connective tissue disease characterized by progressive microvascular involvement (1). Nailfold videocapillaroscopy (NVC) represents the best and safest method to detect and to follow the progression of morphological microvascular SSc abnormalities (2). Microvascular alterations in SSc are observed in several organs, including the choroidal plexus of the eye (3). Modern optical coherence tomography (OCT) imaging and analysis have allowed the choroid to become observable and measurable (4). An overall thinning of choroidal layer has been observed in SSc patients consistent with an impairment of choroidal perfusion; the process becomes progressively more severe and extensive in overt SSc (5).
**Objectives:** To compare severity of nailfold microvascular damage with the choroidal thickness, as assessed by NVC and OCT. To evaluate OCT plausibility in SSc staging.
**Methods:** Twelve SSc patients according to recent ACR/EULAR classification criteria (6) (disease duration 4.8 ± 2.8 years, age 58±13 years) underwent NVC (4 "early", 3 "active", 5 "late" scleroderma NVC pattern) and ophthalmologic examination by OCT. NVC patterns were scored by quantitative rating scale and the "microangiopathy evolution score (MES)" was calculated (7). OCT images were recorded by 3D-2000 OCT using protocol "line" that averages 50 B-scans and generates a horizontal 6 mm line. Choroidal thickness area measurements were performed manually using image J software. Statistical analysis was performed by non parametric tests.
**Results:** Despite the limited number of enrolled SSc patients, a statistically significant negative correlation was observed between the progressive severity of the microvascular damage score (MES) and the choroidal thickness values (OCT) (r=-0.39, p=0.05).
**Conclusions:** Nailfold microangiopathy evolution, as evaluated by NVC in SSc patients, seems to correlate with the choroid thickness, as assessed by OCT. Microangiopathy progression seems to involve the choroidal plexus by showing a thinner layer thickness in SSc patients. Therefore, OCT may be useful in the evaluation of possible retinal microvascularization damage in SSc patients.

## SAT0203 RITUXIMAB IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES ASSOCIATED WITH INTERSTITIAL LUNG DISEASE

A.N. Khelkovskaya-Sergeeva[1], O.A. Antelava[2], Y.A. Olyunin[1], G.M. Tarasova[3], N.E. Lopatina[3], S.E. Palshina[3], E.G. Sazhina[3], N.O. Nikonorova[3], O.A. Koneva[3], E.N. Alexandrovna[3], E.L. Nasonov[3]. *[1]Laboratory of rheumatic diseases therapy standartization, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; [2]Sechenov First Moscow State Medical University; [3]V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Moscow, Russian Federation*

**Background:** Interstitial lung disease (ILD) is the most common internal organ manifestation of idiopathic inflammatory myopathies (IIM) that can severely affect the course of the disease. IIM patients with ILD often show resistance to conventional treatment with glucocorticoids (GC) and cytotoxic drugs so addition of biologic agents is an interesting possibility.
**Objectives:** To assess efficacy and tolerability of rituximab (RTM) in IIM patients with ILD.
**Methods:** IIM patients fulfilling Bohan and Peter criteria and having ILD were followed up in the Nasonova Research Institute of Rheumatology from 2009 to 2015. RTM was administered in case of intolerance or inadequate response to GC and other immunosuppressive drugs. Manual muscle testing (MMT), dyspnea assessment according to NYHA, creatinkinase (CK) and anti-Jo-1 antibodies (anti-Jo-1) assay; forced vital capacity (FVC) and carbon monoxide diffusion capacity (DLCO) evaluation as well as high-resolution computed tomography (HRCT) scanning of the chest were performed at baseline, 6–12 and 18–24 months after inclusion.
**Results:** 41 patients (34 females, 7 males) with median age 50 [44;56], median disease duration 24 months [7;108] were included. 28 from them had decreased MMT value and class 1–2 NYHA dyspnea was present in 19. 18 patients were positive for anti-Jo-1 and 15 had elevated CK level. HRCT showed ILD signs

including ground glass opacities (GGO) in all cases. FVC<80% was revealed in 16 and DLCO<80% - in 32 cases. All patients received GC 10–90 mg/day equivalent to prednisolone, 28 were treated with immunosuppressive agents (cyclophosphamide or mycophenolate mofetil). Patients received RTM courses consisted from 2 infusions of RTM 1000 or 500 mg at days 0 and 14. 1 RTM course was provided in 13, 2 – in 10, 3 – in 11, 4 – in 2, 5 – in 2, and 8 – in 3 patients. The follow up lasted for at least 12 months in 33, and for at least 24 months – in 15 patients. Dyspnea subsided and CK level decreased to normal values in all patients within 6–12 months after the first RTM infusion. 16 patients improved FVC by >10%, and 7 demonstrated DLCO increase by >10%. Worsening of pulmonary function tests was documented in 2 cases, while in the rest they were stable. After 18–24 months of follow up FVC remained +10% better vs baseline value in 10, DLCO – in 8 patients. In the rest patients these parameters remained stable. ILD was not progressing in 27 patients based on HRCT images in 6–12 months, moreover GGO lesions count was reduced in 10 patients, but there were cases of ILD worsening documented in 6 patients. Although, HRCT monitoring in 18–24 months showed ILD improvement in 7 patients and worsening – in 2, in remaining patients ILD was stable. Comorbid infections were documented in 18 patients, commonly manifesting in 2–3 months after the first RTM infusion.

**Conclusions:** RTM treatment allows to achieve stable disease without typical for this condition further progression of pulmonary lesions in the majority of IIM patients with ILD.

**Disclosure of Interest:** None declared

## SAT0204 THE EULAR SYSTEMIC SCLEROSIS IMPACT OF DISEASE (SCLEROID) SCORE – A NEW PATIENT-REPORTED OUTCOME MEASURE FOR PATIENTS WITH SYSTEMIC SCLEROSIS UNDER DEVELOPMENT

R. Dobrota[1], M. Becker[2], K. Fligelstone[3], J. Fransen[4], A. Kennedy[5], Y. Allanore[6], P. Carreira[7], L. Czirijak[8], C. Denton[9], R. Hesselstrand[10], G. Sandqvist[10], O. Kowal-Bielecka[11], M. Matucci-Cerinic[12], C. Mihai[13], A. Gheorghiu[13], U. Müller-Ladner[14], M. Frerix[14], T. Heiberg[15], O. Distler[1].
*[1]Division of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Department of Rheumatology and Clinical Immunology, Charitè University Hospital, Berlin, Germany; [3]FESCA, Portsmouth, United Kingdom; [4]Division of Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands; [5]FESCA, Dublin, Ireland; [6]Rheumatology A Department, Cochin Hospital, Paris, France; [7]Division of Rheumatology, Hospital 12 de Octubre, Madrid, Spain; [8]Department of Immunology and Rheumatology, Faculty of Medicine, University of Pécs, Pécs, Hungary; [9]Centre for Rheumatology, Royal Free and University College London Medical School, Royal Free Campus, London, United Kingdom; [10]Department of Rheumatology, Lund University, Lund, Sweden; [11]Department of Rheumatology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; [12]Division of Rheumatology, University of Florence, Florence, Italy; [13]Department of Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [14]Department of Rheumatology and Clinical Immunology, Justus-Liebig University Giessen, Kerckhoff-Klinik, Bad Nauheim, Germany; [15]Department of Health and Social Sciences, Oestfold University College, Oslo, Norway*

**Background:** Patient reported outcome measures (PROM) are required as key outcomes in disease modifying therapeutic trials in systemic sclerosis (SSc) and could also improve the clinical care of patients with SSc. A PROM tool for clinical trials and practice in SSc, covering the different features of this multi-organ autoimmune disease, is lacking.

**Objectives:** To develop and validate a brief, disease-specific, patient-derived, composite disease impact score for scientific and clinical use in SSc.

**Methods:** This multi-center project involves SSc patients and experts from 11 European countries. Firstly, using the nominal group technique, patients with SSc selected the health dimensions where the disease has the most significant impact. The dimensions were subsequently given numeric priority by an international group of SSc patients. The dimensions with the top 10 median ranks, as ranked by the patients, were used to construct the ScleroID questionnaire using numeric rating scales. Further, the dimensions are currently weighted by distributing 100 points among the dimensions by a larger cohort of patients from all participating countries. The calculation of the score will be based on the ranking of the weights.

**Results:** 24 SSc patients selected 17 health dimensions in the nominal group exercise. The prioritization cohort included 108 SSc patients from 11 centers (female:male 82:25, limited:diffuse SSc subset 53:54). The top 10 health dimensions which were ranked most relevant by the patients were Raynaud's phenomenon, hand function, upper and lower gastrointestinal tract symptoms, pain, fatigue, limitation of life choices and activities, body mobility, breathlessness and digital ulcers (Figure 1).

**Conclusions:** The EULAR ScleroID score is a novel tool under development designed for use in clinical practice and clinical trials to display the disease impact of SSc. Further validation of this new instrument will be performed as soon as the weighting procedure is completed.

**Acknowledgement:** Contributing patients: Yanne Perriault, Susanne Tuppeck, Helene Kambourakis, Elisabeth Scheel, Stephan Houbertz, Anna Vegh, Beata Garay Toth, Barbara Zappitello, Grazia Tassini, Silvia Sandulescu, Ana Marcela Badea, Stefana Dumitru, Rachida Amrouch, Alicia García Oliva, Begoña María Gorricho Corta, Heleen Lever, Johanna Berglind, Mervat Gaafar, Natalie Perruchoud, Alice Martins Correia, Richard Dodds, Nicola Whitehill.

Figure 1. Results of the prioritization of the health dimensions' (N=108).

| No. | Health dimensions | Mean rank | Median rank | Order by median rank | %Patients giving rank 1 to the dimension | %Patients giving rank 1-3 to the dimension | %Patients giving rank 1-10 to the dimension |
|---|---|---|---|---|---|---|---|
| 1 | Raynaud | 5,78 | 5 | 1 | 19,4 | 36,1 | 84,3 |
| 2 | Hand function | 6,65 | 5 | 1 | 8,3 | 25 | 78,7 |
| 3 | Upper GI | 7,16 | 6 | 2 | 7,4 | 24,1 | 73,1 |
| 4 | Pain | 6,94 | 6 | 2 | 10,2 | 25,9 | 75,9 |
| 5 | Fatigue | 6,67 | 6 | 2 | 9,3 | 26,9 | 78,7 |
| 6 | Lower GI | 7,82 | 7 | 3 | 10,2 | 24,1 | 69,4 |
| 7 | Limitation of life choices and activities | 8,34 | 8 | 4 | 4,6 | 20,4 | 66,7 |
| 8 | Body mobility | 8,71 | 8,5 | 5 | 2,8 | 11 | 65,7 |
| 9 | Breathlessness | 8,57 | 9 | 6 | 12 | 27,8 | 52,8 |
| 10 | Digital ulcers | 9,45 | 10 | 7 | 1,9 | 17,6 | 54,6 |
| 11 | Anxiety | 10,18 | 10 | 7 | 2,8 | 9,3 | 50,9 |
| 12 | Dryness | 10,13 | 10 | 7 | 1,9 | 9,3 | 54,6 |
| 13 | Appearance | 10,31 | 11 | 8 | 3,7 | 9,3 | 49,1 |
| 14 | Concentration difficulties | 10,87 | 12 | 9 | 1,9 | 9,3 | 39,8 |
| 15 | Cough | 11,26 | 13 | 10 | 1,9 | 10,2 | 38,9 |
| 16 | Depression | 11,63 | 13 | 10 | 0,9 | 7,4 | 35,2 |
| 17 | Calcinosis | 12,52 | 14 | 11 | 0,9 | 6,5 | 31,5 |

'Patients were asked to rank the dimensions in order of their importance by giving a rank from 1(most important) to 17 (least important). Each rank could only be used once. The top 10 dimensions with the lowest median rank (highest importance) were selected for the questionnaire. The 10th dimension had an equal median rank but clearly higher role for more patients (% giving top rank, last 2 columns) and was consequently chosen in favor of dimensions 11,12.

## SAT0205 ULTRASONOGRAPHIC FEATURES OF THE HANDS IN PATIENTS WITH SYSTEMIC SCLEROSIS REFLECT VISCERAL MANIFESTATIONS OF THE DISEASE

G. Coiffier[1], A. Lescoat[2,3], C. Droitcourt[4], C. Cazalets[2], J.D. Albert[1], P. Jégo[2,3], A. Perdriger[1]. *[1]Rheumatology; [2]Internal Medicine, University Hospital of Rennes; [3]Team 1, Research Institute in Health, Environment and Occupation/IRSET; [4]Dermatology, University Hospital of Rennes, Rennes, France*

**Background:** In a recent EUSTAR study, joint synovitis and tendon friction rubs reflecting fibrotic tenosynovitis (fTS) have proven to be independent predictive factors for disease progression in patients with early systemic sclerosis (SSc). Power Doppler Ultrasonography (PDUS) of the hand can detect early asymptomatic joint synovitis or fTS and is a reliable tool to perform a vascular evaluation of the hand, especially to assess ulnar artery involvement.

**Objectives:** The objective of this study is to determine whether joint synovitis, fTS and ulnar artery occlusion (UAO) assessed by PDUS of the hand are associated with visceral manifestations of SSc and can thus be considered as severity markers of the disease.

**Methods:** 47 systemic sclerosis patients matching the 2013 EULAR/ACR classification criteria of SSc were consecutively included in this observational transversal study. Patients were also classified using 2008 LeRoy classification subsets. A bilateral US evaluation of both hands of every patients was performed assessing the presence of active synovitis, fTS or UAO. PDUS features were confronted to the visceral manifestations of the disease assessed by the annual standard investigations: pulmonary function tests (PFTs), thoracic CT-scan, echocardiographic evaluation. A right heart catheterization (RHC) was conducted if pulmonary arterial hypertension (PAH) was suspected based on the results of the previous tests. PDUS of the hand was performed blinded for the results of visceral investigations.

**Results:** A fibrotic TS was present in 17% of the patients. fTS was associated with an interstitial lung disease on CT-scan and a diffuse cutaneous involvement (respectively p=0,023; Odds ratio (OR)=10,06; 95% confidence interval (1,13–89,94) and p=0,018; OR=11,2; 95%CI (1,125–100,31). An active synovitis was present in 14,9% of the patients and was associated with pericarditis on the echocardiographic evaluation (p=0,05; OR=15,6; 95%CI (1,19–204,78)). There was a significant association between PAH on RHC and bilateral UAO on PDUS (p=0,008, OR non available because every patient with PAH had a bilateral UAO).

*Table 1.* Associations between PDUS features and visceral manifestations in 47 SSc patients

| Association between Tenosynovitis and fibrotic visceral manifestations | OR (95%CI) | p |
|---|---|---|
| ILD | 10,06 (1,128-89,94) | 0,023 |
| Diffuse cutaneous SSc | 11,20 (1,125-100,31) | 0,018 |
| **Association between active synovitis and inflammatory manifestations** | | |
| Pericarditis | 15,6 (1,189-204,78) | 0,05 |
| **Association between bilateral UAO and PAH** | | |
| PAH suspected on Echocardiography | 1,64 (0,403-6,705) | NS |
| PAH Confirmed on RHC* | NA | 0,008 |
| PAH Confirmed on RHC** | 1,27 (1,004-1,598) | 0,022 |

PDU=Power doppler ultrasonography; DU =Digital Ulcers; UAO=Ulnar Artery Occlusion; FPBF=Finger Pulp Blood Flow; dSSc=Diffuse Systemic Sclerosis; Pulmonary Fibrosis =PF ACA=anticentromere antibodies; NS=not significant; NA=not available Level of significance : p<0,05 . * among patients who had a RHC(n=9) ** among all patients (n=47)

**Conclusions:** The evaluation of the hand by Power Doppler Ultrasonography in SSc provides new evidence that vascular, joint and tendon involvements reflect visceral manifestations of SSc and therefore constitute severity markers of the disease. These results should be completed by prospective studies to determine whether these PDUS features are also independent predictive factors for disease progression, especially in patients with early SSc.

## SAT0206 VASCULAR EVALUATION OF THE HAND BY POWER DOPPLER ULTRASONOGRAPHY PROVIDES NEW PREDICTIVE MARKERS OF ISCHAEMIC DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

A. Lescoat[1,2], G. Coiffier[3], A. Rouil[3], C. Droitcourt[4], C. Cazalets[1], M. De Carlan[1], A. Perdriger[3], P. Jégo[1,2]. *[1]Internal Medicine, University Hospital of Rennes; [2]Team 1, Research Institute in Health, Environment and Occupation/IRSET; [3]Rheumatology; [4]Dermatology, University Hospital of Rennes, Rennes, France*

**Background:** The consequences of the macrovascular disease on ischaemic digital ulcers (DUs) onccurence are still to be determined in systemic sclerosis (SSc) patients and power doppler ultrasonography (PDUS) is a simple and non-invasive efficient tool to evaluate ulnar artery and fingers pulp blood-flow (FPBF).
**Objectives:** Our aim was to evaluate in a longitudinal study the relevance of PDUS as a predictive tool of new ischaemic DUs in a cohort of unselected SSc patients.
**Methods:** 55 SSc unselected patients fulfilling the 2013 EULAR classification criteria of SSc underwent PDUS of both hands to evaluate the prevalence of ulnar artery occlusion (UAO) at baseline. Finger pulp blood flow (FPBF) of the third and fourth fingers were also assessed and considered as pathological if a defect of doppler signal on a finger pulp was observed. All patients were clinically re-evaluated 6 and 12 months later and new ischaemic DUs occurrence in the meantime was then retrospectively recorded. Patients were also asked to phone if new DUs occurred between the consultations. The main outcome measure was the first new ischaemic DU occurring after PDUS evaluation, defined as a new loss of epidermis with dermis exposure appearing on a finger pulp during follow-up and unoticed at the time of PDUS evaluation. We did not take into account traumatic and calcinosis related DUs.
**Results:** The mean age was 57,6 years, 76.4% of the patients were women, 64.6% had a limited cutaneous SSc, 34.2% had a history of multiple episodes of DUs.
The prevalence of UAO was 36.3% and was bilateral in 70% of the SSc cases. 56.4% of SSc patients had a pathological FPBF.
UAO and pathological FPBF were both associated with a history of multiple DU episodes (OR=8.98; 95%CI (2.52–32.01); p<0.001 and OR=4.69; 95%CI (1.30–16.93); p=0.014) and with the occurrence of new ischaemic DUs during the follow-up (OR=8.73; 95%CI (2.00–38.16); p=0.005 and OR=12.65; 95%CI (1.50–106.77); p=0.005).
Multivariate analysis revealed an independent association between PDUS parameters and a history of multiple DU episodes at baseline (p<0.05).
Kappa coefficients of inter-rater agreement were 0.94 for the presence of pathological FPBF and 0.97 for the presence of UAO on PDUS images. Kappa coefficients of intra-rater agreement were 0.90 for the presence of pathological FPBF and 0.93 for the presence of UAO.
**Conclusions:** UAO and pathological FPBF are associated with a history of multiple DU episodes and are predictors of new ischaemic DUs in SSc patients. These parameters could therefore be used as prognostic factors and considered in further studies evaluating DUs treatment strategies.

## SAT0207 ULNAR ARTERY OCCLUSION EVALUATED BY POWER DOPPLER ULTRASONOGRAPHY IS ASSOCIATED WITH ACRO-OSTEOLYSIS IN SYSTEMIC SCLEROSIS

A. Lescoat[1,2], G. Coiffier[3], C. Droitcourt[4], C. Cazalets[1], J.-D. Albert[3], A. Perdriger[3], P. Jégo[1,2]. *[1]Internal Medicine, University Hospital of Rennes; [2]Team 1, Research Institute in Health, Environment and Occupation/IRSET; [3]Rheumatology; [4]Dermatology, University Hospital of Rennes, Rennes, France*

**Background:** Acro-osteolysis and calcinosis are frequent clinical features in Systemic sclerosis (SSc). These manifestations are thought to have a vascular origin but there is still a lack of evidence to objectively support this hypothesis. Ulnar artery occlusion (UAO) is also a specific and frequent vascular feature in systemic sclerosis and Power Doppler Ultrasonography (PDUS) has proven to be a reliable tool to assess the permeability of the ulnar artery.
**Objectives:** The objective of this study is to determine whether calcinosis and acro-osteolysis (AO) are related to vascular features evaluated by PDUS.
**Methods:** A vascular Power Doppler Ultrasonographic evaluation of both hands and bilateral hand X-rays were systematically performed in 43 patients matching the ACR 2013 classification criteria of SSc. PDUS of both hands was performed to evaluate the prevalence of UAO. Finger pulp blood flow (FPBF) of the third and fourth fingers were also assessed and considered pathological if a defect of the doppler signal on a finger pulp was observed. Radiological assessment of calcinosis and acro-osteolysis was performed blinded for the results on PDUS features.
**Results:** 43 patients were consecutively recruited during a 6-month period. The mean age was 56,6 years, 70% of the patients were women, 44,2% had a limited cutaneous SSc, 37,2% had a history of multiple digital ulcers (DUs).
23 patients had a pathological FPBF (53,5%), 22 had a UAO (51,2). Patients with AO on X-rays were more likely to have a pathological FPBF or UAO (respectively p=0,029, Odds Ratio (OR) =4,36; 95% confidence interval (1,112–17,128) and p=0,002; OR=8,67; 95%CI (1,97–38,41)). There was no association between calcinosis on X-rays and pathological FPBF or UAO (p=0,362 and 0,076 respectively). UAO and FPBF were both associated with classical ischemic manifestations of the disease such as multiple DUs history (p=0,002 and p=0,029). Multivariate logistic regression analysis revealed an independent association between UAO and AO (p=0,003, OR=2,08; 95%CI (1,79–35,74)).
**Conclusions:** A study has recently shown that acro-osteolysis was independently

associated with the late nailfold videocapillaroscopic pattern (Morardet et al. Arthirtis Care Research, jul 2015). These results strengthened the link between this radiographic lesion and digital destructive vasculopathy. Our study reveals an association between UAO or FPBF assessed by PDUS and acro-osteolysis. These results suggest once again a vascular etiology to AO and provides new evidence of the link between micro and macro-vascular damages in SSc.

## SAT0208 INFLAMMATORY MYOPATHIES ASSOCIATED WITH SJÖGREN'S SYNDROME DO NOT DIFFER FROM THOSE WITHOUT SJÖGREN'S SYNDROME ASIDE FROM OLDER AGE AT DIAGNOSIS AND LESS FREQUENT NORMAL MUSCLE BIOPSY

A. Meyer[1], F. Maurier[2], C. Larroche[3], A. Tournadre[4], P. Dieudé[5], E. Dernis[6], O. Vittecoq[7], J.-J. Dubost[4], A.-L. Fauchais[8], X. Mariette[9], J. Sibilia[1], J.-E. Gottenberg[1]. *[1]CHU, Strasbourg; [2]HP, Metz; [3]CHU Avicenne, Paris; [4]CHU, Clermont-Ferrand; [5]CHU Bichat, Paris; [6]CHU, le Mans; [7]CHU, Rouen; [8]CHU, Limoges; [9]CHU Bicêtre, Paris, France*

**Background:** Prevalence of Sjogren's syndrome (SS) in inflammatory myopathies (IM) and whether IM patients with SS represent a distinct disease subset are currently unknown.
**Objectives:** To assess the signification of SS in IM with regard to phenotype and prognosis.
**Methods:** IM patients with SS (IM-SS group) were identified among a cohort of 270 patients with IM using European-American Consensus Group (EACG) classification criteria. Clinical, serological, muscle pathological features, management and outcomes of IM-SS patients were retrospectively studied and compared to the IM patients who had been assessed for SS but did not fulfill these criteria (IM-noSS group).
**Results:** EACG criteria were available in 63 IM patients of the total cohort and 29 (46%) were diagnosed as having SS. These IM-SS patients were older at IM diagnosis than the 34 IM-noSS patients (56±3.1 vs 47.7±2.8 years, p=0.05), sex ratio wasn't different.
SS was mostly diagnosed at the time of IM diagnosis (n=23, 79%) and less frequently preceded (n=3: 1, 3 and 4 years) or followed (n=3, 3, 6 and 30 years) IM diagnosis. IM-SS patients had subjective sicca syndrome (29/29, 100%) with objective dryness (10/12, 92%), anti-SSA/SSB antibodies (14/29, 48%) and/or focus score $\geq$3 in minor salivary glands biopsy (n=21/24, 88%).
Creatine kinase level was not different between IM-SS and IM-noSS (1400±320 vs 2538±214 UI/L, p=0.5). A normal muscle biopsy was less frequently found in IM-SS than in IM-noSS patient (7/28 vs 1/24 p=0.05). According to the ENMC criteria, DM was the more frequent muscle histological finding in IM-SS patients (n=10, 42%) but all histological patterns were represented (including nonspecific IM: 6 (25%), inclusion body myositis: 4 (17%), polymyositis: 2 (8%), necrotizing myopathy: 1 (4%). This distribution was not different from the IM-noSS group.
IM-SS patients also suffered from interstitial lung disease (n=10, 34%), arthralgia and/or arthrithis (n=17, 59%), skin involvement (n=14 48%) and Raynaud syndrome (n=14, 48%) which occurrence characteristics were not different from IM-noSS group.
Anti-SSA (n=13, 45% vs n=1, 3%, p=0.0001) and anti-SSB (n=6, 21% vs n=0, 0% p<0.01) were more frequent in IM-SS groups. Other auto-antibodies were found in 14 IM-SS patients (48%) and in 19 IM-noSS patients (56%, p=0.62) which specificities were not significantly different between the two groups. Cryoglobulin was also found with a similar frequency in both groups (n=3, 10% vs n=3, 9%; p=1.0). Six IM-SS patients (21%) were diagnosed with cancer versus 4 IM-noSS patients (12%) (p=0.49). Mean number of treatment was not different between the two groups (1.9±0.2951 vs 1.6±0.2616; p=0.41) and after a follow-up >7 years, 6 patients died in both groups, whithout any significant difference in survival (p=0.23).
**Conclusions:** SS is frequently observed in IM. No difference was found between IM-SS and IM-noSS with regards to phenotype, serotype and survival aside from older age at diagnosis and less frequent normal muscle biopsy.

## SAT0209 IDIOPATHIC INFLAMMATORY MYOPATHIES: EVALUATION OF SKELETAL MUSCLE GLUCOSE METABOLISM BY PET-CT 18F-FDG

J. Matuszak, A. Meyer, I.-J. Namer, B. Geny, J. Sibilia, C. Blondet. *Hôpitaux Universitaires, Strasbourg, France*

**Background:** There is a need for tools to measure muscle disease activity in inflammatory myopathies (IM).
**Objectives:** To assess the contribution of metabolic imaging with positron emission tomography combined with computed tomography (PET-CT) 18F fluorodeoxyglucose-(18F-FDG) for muscle disease activity assessment in patients with IM.
**Methods:** The SMGM was higher in IM than in the control group in visual analysis ($p<0.001$) and quantitative analysis ($p<0.001$). No correlation was found between the SMGM and the muscle histological findings. In addition, the quantitative measurement of SMGM was significantly correlated with serum CK levels (Spearman $\rho$=0.47, $p<0.01$) and with the MITAX (Spearman $\rho$=0.72; p=0.001). Finally, in 9 patients who underwent two consecutive 18F-FDG PET-CT, the evolution of the SMGM was concordant with the clinical course according to the MITAX in 8.
**Results:** The SMGM was higher in IM than in the control group in visual analysis ($p<0.001$) and quantitative analysis ($p<0.001$). No correlation was found between the SMGM and the muscle histological findings. In addition, the quantitative measurement of SMGM was significantly correlated with serum CK levels (Spearman $\rho$=0.47, $p<0.01$) and with the MITAX (Spearman $\rho$=0.72; p=0.001). Finally, in 9 patients who underwent two consecutive 18F-FDG PET-CT, the evolution of the SMGM was concordant with the clinical course according to the MITAX in 8.
**Conclusions:** These data suggested that 18F-FDG PET-CT, which is useful for the screening of cancer associated IM, is also helpful for the measurement of IM muscle disease activity.

**Disclosure of Interest:** None declared

## SAT0210 HIERARCHICAL CLUSTER STUDY OF PATIENTS WITH ANTI-KU ANTIBODIES IDENTIFIES TWO PHENOTYPICAL SUBGROUPS WITH DISTINCT PROGNOSIS RECOGNIZED BY ANTI-DNA STATUS

L. Spielman[1], M. Schaeffer[2], J. Goetz[2], T. Martin[2], J. Sibilia[2], A. Meyer[2]. *[1]Hôpitaux Universitaires de Strasbourg; [2]Hôpitaux Universitaires, Strasbourg, France*

**Background:** The presence of anti-Ku antibody is associated with a wide variety of clinical manifestations and various outcomes.
**Objectives:** We attended to refine anti-Ku associated disease by identifying subgroups of Ku-positive patients with similar clinico-biological features and prognosis.
**Methods:** We reviewed clinical, biological characteristics, diagnosis and management of 24 patients with anti-Ku antibody. A multidimensional analyze was performed to highlight homogeneous groups of patients. We search for features that most strongly match with each group.
**Results:** Anti-Ku positive patients had joint (n=19), muscle (n=10), lung (n=9), skin (n=9), renal (n=9), hematological (n=8), thrombotic (n=6), serous (n=6) and gastrointestinal (n=4) involvements. Associated antibodies were anti-DNA (n=7), -SSA (n=6), -RNP (n=4), -SSB (n=1), -Sm (n=1), rheumatoid factor (n=9) and ACPA (n=4). Diagnosis were overlap myositis (n=9), lupus erythematosus (n=8), Sjögren's syndrome (n=7), rheumatoid arthritis (n=3), undifferentiated connective (n=2), and systemic sclerosis (n=2). Many patients had criteria for several connectivite tissue diseases. Managements were heterogeneous.
Multidimensional analyze identified to groups that were mutually exclusive: (i) Patients characterized by scleroderma-like skin disease,myositis and ILD,frequently treated with high dose of corticosteroids, (ii) Patients with lupus like skin disease, haematological and renal involvements frequently receiving cyclophosphamide and mycophenolate mofetil.
Anti-DNA antibody, absent in the first group and present in the second was the most powerful criteria to distinguish these two subsets of the anti-ku associated disease (sensibility 93% and a sensitivity of 86%).
**Conclusions:** Anti-DNA status distinguishes patients at risk of muscle and lung involvement (anti-DNA negative) from patients at risk of renal involvement (anti-DNA positive). These data significantly refine anti-Ku associated disease and help to personalize monitoring and care of the patients.

**Disclosure of Interest:** None declared

## SAT0211 RELIABILITY, VALIDITY, AND SENSITIVITY TO CHANGE OF THE DURUOZ HAND INDEX IN SYSTEMIC SCLEROSIS*

A.M. Gherghe[1,2], H. Gyorfi[2,3], R. Capota[3], A. Matei[2,3], R. Oneata[2,3], M. Milicescu[2,3], L. Macovei[2,3], M. Sasu[3], M. Bojinca[1,2], V. Stoica[1,2], C. Mihai[1,2]. *[1]Internal Medicine and Rheumatology, Cantacuzino Hospital; [2]Carol Davila University of Medicine and Pharmacy; [3]Cantacuzino Hospital, Bucharest, Romania*

**Background:** Hand involvement is observed in almost all patients with Systemic Sclerosis (SSc), and is due to skin and tendon fibrosis, arthritis and microvascular impairment, sometimes complicated with digital ulcers (DUs).
**Objectives:** The Duruoz's Hand Index (DHI) (or Cochin hand functional disability scale), is a reliable tool for hand function assessment and can be used in diseases like rheumatoid arthritis and SSc. The purpose of this study was to assess the reliability, validity and sensitivity to change of the DHI in SSc patients.
**Methods:** 66 patients with SSc according to the 2013 ACR/EULAR criteria, examined in our EUSTAR center from 1.10.2014 to 31.12.2015 were included. Patients completed the DHI, the Scleroderma Health Assessment Questionnaire (SHAQ) questionnaires and the Hand Mobility in Scleroderma (HAMIS) test. Three anthropometric measures to assess finger range of motion were also measured: the finger extension (FE), finger-to-palm distance (FTP) and $\Delta$ FTP (FE - FTP).
*Step 1:* In 38 patients the test-retest reliability, using intra-class correlation coefficients (ICC), and the internal consistency (Cronbach's alpha test) were examined. *Step 2:* In all 66 patients, the criterion validity by correlation coefficients with SHAQ, HAMIS and the anthropometric measures, and the discriminative capacity between different subsets of patients were examined. *Step 3:* 27 consecutive patients had a second evaluation at an interval of (mean±SD) 9.3±2.3 months; among them, only 4 patients had progressive early diffuse SSc. Sensitivity to change was assessed in these patients using the effect size (ES) (Cohen's d) and the standardized response mean (SRM).
**Results:** The study included 59 females/7 males with SSc, age 50.8±13.0 years, disease duration 6.2±6.0 years; 24 with diffuse cutaneous SSc (dcSSc) and 38 with limited cutaneous SSc (lSSc).
The DHI had a mean±SD score of 22.8±19.5, range 0–71 (with possible range 0–90) at baseline, and 24.3±21.1, range 0–73 at follow-up. The DHI presented an excellent test-retest reliability (ICC 0.98), a good internal consistency (Cronbach's alpha 0.960). Criterion validity of the DHI was proved by moderate to strong correlations with HAMIS, FE, FTP, $\Delta$ FTP and the SHAQ disability index (Spearman rho 0.57–0.85, $p<0.001$). The discriminative capacity of the DHI was proven by statistically significant differences between patients with and without: synovitis, flexion contractures of the fingers, and history of DUs. The sensitivity to change (ES of 0.27 and SRM of 0.52) was acceptable for detecting the minimally important difference.
**Conclusions:** The DHI is a reliable, valid and easy to apply tool for hand involvement assessment in patients with SSc. The preliminary results on sensitivity to change suggest DHI could be a sensitive measure to detect change in clinical status, however more early diffuse SSc patients are needed to confirm these findings.

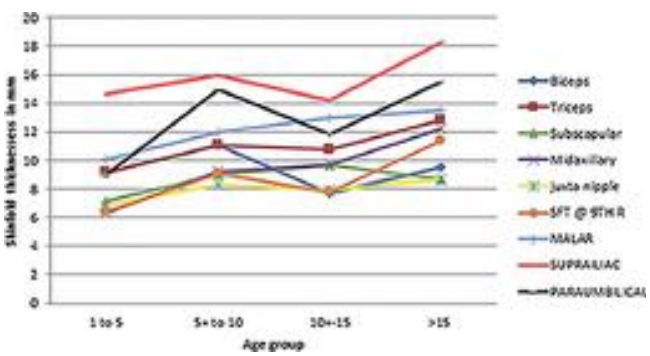
## SAT0212 PERICARDIAL EFFUSION RELATED TO SYSTEMIC SCLEROSIS: A POSSIBLE CONTRIBUTION OF THE SERUM LEVELS OF ADIPOKINES AND INTERLEUKINES



A. Chialà, C. Rotondo, M.G. Anelli, C. Scioscia, E. Praino, S. Perniola, M. Nivuori, D. Natuzzi, C. Fiorentini, G. Lopalco, G. Lapadula, F. Iannone. *Rheumatology Unit, Bari University - Policlinico, Bari, Italy*

**Background:** Pericardial effusion (PE) is a common clinical manifestation in systemic sclerosis (SSc). Few data are available about its pathogenesis. The role of adipokines and interleukins produced by the adipose tissue and the immune system in PE related to SSc had never been investigated.
**Objectives:** This study aimed at evaluating the differences in serum levels of adipokines and interleukins (IL) in systemic sclerosis (SSc) patients with and without PE.
**Methods:** A total of 87 outpatients (84 female, mean age of 52,6±14,2 ys, and disease duration of 8,2±6,7 ys), who fulfilled the ACR/EULAR 2013 SSc classification criteria, were recruited in this study. The anthropometric measures, as body mass index (BMI), demographic, clinical and laboratoristic characteristics and SSc related manifestations were assessed in each patient. The presence of PE was evaluated by means of echocardiographic techniques (the presence of fluid $\geq$5 cc was considered pathologic). Sera levels of adiponectin, leptin, resistin, visfatin, tumor necrosis factor $\alpha$ (TNF-$\alpha$), interferon g (INF-g), IL-2, IL-10 and IL-17 were measured in SSc patients, using Multiplex Immunoassay (Bioplex 200 System), by means of two kits (Bioplex ProTM Cytokine/Chemokine and Growth Factor Assay e Bioplex Pro Diabetes Assay). The data normality was verified using Kolmogorov-Smirnov Test; the comparisons between SSc patients groups were evaluated by Mann-Whitney U test and t-student test, where appropiate. Statistic significance was set at $p\leq0,05$. The results are expressed as median and interquartile range (IQR) or means±1standard deviation. The data analysis were assessed using IBM SPSS statistic 20.
**Results:** 11 SSc patients had PE. The SSc patients groups (with and without PE) did not differ in age, sex and BMI. 11 SSc patients were obese (BMI$\geq$30) (2 with PE and 9 without PE). We found significant differences between SSc patients with PE and without PE in sera levels of visfatin (1546,9 (8590,9) vs 388,8 (103); p=0,036), adiponectin (2845000 (4132900,0) vs 5272100,0 (8243600,0); p=0,027) and IL-17 (1,33 (3,5) vs 0,05 (0,56); p=0,45). Moreover higher adiponectin/leptin ratio was found in patients with PE than SSc patients without PE (569,2 (1415,3) vs 166,9 (504,9) p=0,032). The presence of interstitial lung disease, pulmonary arterial hypertension, limited or diffuse skin subset, the different nail fold videocapillaroscopy pattern and the modified Rodnan skin score did not influenced the serum levels of adipokines and IL. In the SSc patients with PE there is no differences in visfatin and adiponectin serum level and adiponectine/leptin ratio between patients that are in menopause and those who are not.
**Conclusions:** The visfatin and adiponectin could play an important role in pathogetic mechanism in pericardial effusion related to SSc. Further study are necessary to unravel a role of visfatin and adiponectin as biomarkers of SSc and a role of the adipose tissue and innate immune system in PE related to SSc pathology.

## SAT0213 STUDY OF MUSCLE & SUBCUTANEOUS FAT MASS IN CHILDREN WITH JUVENILE DERMATOMYOSITIS

A. Kallesh, A.K. Bhalla, S. Singh, S.V. Attri. *Pediatrics, PGIMER Chandigarh, chandigarh, India*

**Background:** Juvenile dermatomyositis (JDMS) is a rare but serious inflammatory myositis of childhood with proximal muscle and skin involvement with lipodystrophy (LD) being an important complication. Most studies on JDMS are either on diagnostic or treatment aspects with a paucity of information on the pattern of muscle mass and subcutaneous fat depletion amongst these patients.
**Objectives:** To study the pattern of muscle mass assessed in terms of MUAMC (mid upper arm muscle circumference) & sub-cutaneous fat mass in terms of different skinfold thicknesses (SFT), and to see the correlation between selected anthropometric parameters and different components of lipid profile amongst children with JDMS.
**Methods:** Thirty-five patients (14 male, 21 female) aged between 1 to 22 years diagnosed as cases of JDMS were enrolled in a tertiary care institute in north India. Controls (35) were age and sex matched. All the study subjects underwent standardized anthropometric measurements and 9 different i.e. (biceps, triceps, subscapular, mid-axillary, juxta nipple, 9th rib SFT, malar, suprailiac and paraumbilical) skinfold thicknesses were measured using Harpenden skinfold calipers (Holtain, Dyfed, UK). All absolute skinfold thicknesses were transformed in to their logarithms by formula given Edwards et al. MUAMC was derived using the modified Jelliffe & Jelliffe formula. Lipid profile was measured only in patients
**Results:** Statistically significant ($p<0.05$) difference was obtained for mid axillary SFT in 1–5 years age group, biceps, triceps and juxta nipple SFT in 10–15 years age, triceps and 9th rib SFT in >15years of age, while none was noted in 5–10 years of age group. In pooled age group biceps, juxta nipple and paraumbilical SFT became statistically significant. Maximum (26.3%) fat loss was recorded for Juxtanipple SFT, while minimum was in suprailiac region (13.6%).The remaining skinfolds enjoyed an intermediate percentage fat loss. 63–71% reduction in c.v was observed for different SFT after log transformation. Overall 97% patients had muscle mass significantly lesser ($p<0.01$) with mean difference of 2.8±1.9 cm (10%) than controls. No significant correlation was noted between SFT and triglycerides or total cholesterol. Only moderate level significant associations between juxta nipple, malar SFT and LDL as well as between HDL and triceps and malar SFT, shows persistence of interdependence of these two biochemical parameters with only few selected anthropometric measurements of sub cutaneous fat despite influence of the disease.

**Conclusions:** The subcutaneous fat mass and muscle content was substantially

reduced in patients as compared to control subjects in our cohort which were site specific and of variable magnitude. Log transformed skinfold thickness to be preferred than absolute values to arrive at logical conclusions on dynamics of subcutaneous fat mass. Further studies are warranted with a larger sample size to arrive at scientifically more meaningful conclusions.

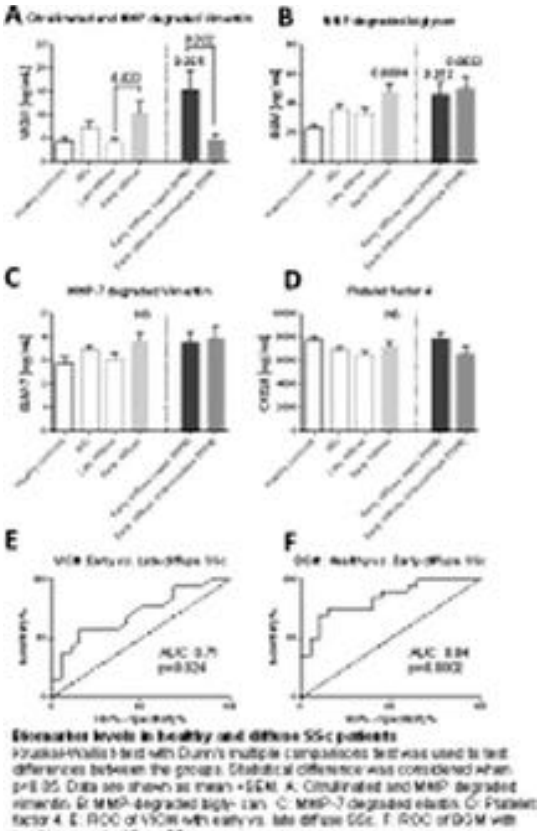
## SAT0214 MACROPHAGE ACTIVATION AND BIGLYCAN AS DISEASE ACTIVITY AND DIAGNOSTIC BIOMARKERS IN SYSTEMIC SCLEROSIS



A.S. Siebuhr[1], R.T. Domsic[2], P. Juhl[1], A.-C. Bay-Jensen[1], M.A. Karsdal[1], N. Franchimont[3], J. Chavez[3]. *[1]Biomarkers and Research, Nordic Bioscience, Herlev, Denmark; [2]Scleroderma Center, University of Pittsburgh, Pittsburgh; [3]Clinical Development, Biogen, Cambridge, United States*

**Background:** Systemic sclerosis (SSc) is a chronic disease characterized by vascular damage, immunologic activation and excessive extracellular matrix (ECM) deposition in the skin and internal organs. The excessive ECM deposition leads to the release of ECM fragments into circulation, where they may be quantified as biomarkers. Activation of macrophages is a hallmark of the immunologic activation in autoimmune diseases and the activation lead to uncontrolled ECM destruction. In addition, activated macrophages has been shown to secrete the intermediate filament vimentin, making it an ideal protein biomarker of activated macrophages.

**Objectives:** The objectives were to investigate 1) if biomarkers of ECM turnover and macrophage activation could seperate diffuse SSc patients and healthy and 2) the diagnostic power of these biomarkers.

**Methods:** Diffuse SSc patients (n=40) fulfilling the American College of Rheumatology criteria were included. Patients were divided into early and late diffuse based on disease duration (n=20 per group). Furthermore, early SSc patients were divided into intermediate and rapid skin thickness progression rate (STPR; n=10 in each). Twenty healthy controls were included. The macrophage activation biomarker citrullinated and MMP-degraded vimentin (VICM), the ECM biomarkers matrix metalloproteinase (MMP) degraded biglycan (BGM) and MMP-7 degraded elastin (ELM-7) were assessed in serum. The currently best diagnostic and prognostic biomarker (platelet factor 4; CXCL4) was furthermore investigated in serum. Statistical differences between the groups were tested by Kruskal-Wallis test with Dunn's multiple comparisons test. Diagnostic capacity was analysed by receiver operating characteristics (ROC) area under the curve (AUC) on healthy vs. diseased, healthy vs. early or late diffuse and between early and late diffuse.

**Results:** VICM level was significantly increased in early SSc compared to late SSc (p=0.023). The VICM level in the rapid STPR was significantly increased compared to healthy (p=0.025) and intermediate STPR (p=0.022). Of notice, the VICM level of intermediate STPR was at the level of healthy. BGM level was significantly increased in early diffuse SSc compared to healthy (p=0.0003). Both early SSc groups (rapid and intermediate STPR) was increased compared to healthy (p=0.012 and p=0.0022, respectively). There were no difference in the ELM-7 and CXCL4 levels between any groups.

The diagnostic capacity of the biomarkers were assessed. VICM did not reach significance, but reached an AUC of 0.71 for diagnosing early vs. late SSc. BGM had an AUC of 0.79 for healthy vs. SSc. The diagnostic power increased when only testing early SSc (AUC=0.84) and decreased when only testing late SSc (AUC=0.74).

**Conclusions:** VICM could identify the group with rapid STPR, whereas BGM was a possible diagnostic biomarker of early SSc. CXCL4 was in this study not a diagnostic tool of SSc as previously shown[A]. The current study illustrates that serological biomarkers of BGM could be a diagnostic tools in SSc and that macrophage activation (VICM) could be potential biomarkers of SSc disease activity (VICM).

## SAT0215 TWELVE YEAR FOLLOW-UP ON PROGRESSION OF NAILFOLD MICROANGIOPATHY DETECTED THROUGH TRANSITION BETWEEN DIFFERENT CAPILLAROSCOPIC PATTERNS OF MICROVASCULAR DAMAGE IN SYSTEMIC SCLEROSIS

C. Pizzorni, B. Ruaro, S. Paolino, D. Camellino, M.A. Cimmino, M. Cutolo, A. Sulli. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

**Background:** Microangiopathy, which features may be detected by nailfold videocapillaroscopy (NVC), is an early aspect of systemic sclerosis (SSc). It is not a static event, but dynamic and may progress through different patterns of microvascular damage (named "early", "active" and "late") during follow-up (1,2). The time of transition is variable, and it was little investigated (2). Furthermore, only a few studies demonstrated correlations between microvascular damage extent and organ involvement over long time (2–4).

**Objectives:** Longitudinal study to investigate the transition of nailfold microangiopathy through different NVC patterns of microangiopathy in SSc, looking for associations with organ involvement and progression over long time.

**Methods:** Thirty-four SSc patients according to LeRoy criteria (mean age 57±11 years, mean disease duration from Raynaud's phenomenon onset 9±11 years) with the "early" pattern of nailfold microangiopathy at first capillaroscopic visit were enrolled and followed by both NVC and clinical assessment for a mean time of 12±3 years. Only SSc patients with fully complete documentation were included into the study. The proper pattern of microangiopathy was recorded by NVC at each visit as previously reported (1,2), as well as organ involvement and antinuclear antibody (ANA) profile.

**Results:** At the end of the twelve-year follow-up, 12 (35%) of patients were still showing the "early" scleroderma-pattern, while the NVC pattern of microangiopathy was changed in 65% of the patients. The NVC pattern was found "active" in 10 patients (30%) and "late" in 12 patients (35%). The median time of progression from the "early" to the "active" pattern was 31 months, from "active" to "late" 38 months, and from "early" to "late" 66 months. Interestingly, in the subgroup of patients whose microangiopathy progressed from the "early" to the "late" NVC pattern through the "active" pattern, the median time of progression from the "early" to the "active" pattern was only 14 months, while in the subgroup of patients whose microangiopathy progressed only from the "early" to the "active" NVC pattern it was 42 months. The median time of progression from "early" to "late" pattern was shorter in SSc patients with either nucleolar IIF ANA pattern or Scl70 autoantibodies. Organ involvement was found progressively larger in SSc patients with "early", "active" and "late" NVC pattern of microangiopathy, respectively.

**Conclusions:** The results confirm the progression of the SSc microvascular damage, quantified through the transition of different NVC patterns, in 65% of SSc patients. Patients showing either a fast progression from the "early" to the "active" NVC pattern of microangiopathy or positive ANA with a nucleolar IIF pattern should be strictly monitored as at risk of rapid progression to the "late" NVC pattern of microangiopathy which is associated to a larger risk of organ involvement.

## SAT0216 CHEST ULTRASOUND SIGNS OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS PATIENTS: A COMPARISON BETWEEN HIGH RESOLUTION CHEST COMPUTED TOMOGRAPHY FINDINGS

C. Rotondo, A. Chialà, M. Nivuori, L. Coladonato, M. Giannini, M.G. Anelli, G. Righetti, C. Scioscia, C. Fiorentini, G. Lopalco, G. Lapadula, F. Iannone. *Rheumatology Unit, Bari University, Bari, Italy*

**Background:** Interstitial lung disease (ILD) is a typical clinical manifestation in Systemic Sclerosis (SSc). The high resolution chest computed tomography (HRCT) is the gold standard to evaluate and grade ILD. The presence of fibrotic tissue in the lung, or other structures beside the air, allows obtaining specific sonography images (such as ultrasound lung comet, higher pleural line thickness, irregular pleural margins and subpleural cysts) by chest ultrasound. In previous studies it was demonstrated that the ultrasound comets number increases in SSc patients.
**Objectives:** We aimed at correlating the specific lung sonography signs with ground glass and honeycombing pattern detected by chest HRCT.
**Methods:** A total of 60 SSc outpatients (54 female, mean age 56,2 ± 13,8 ys and disease duration of 9,57±8,7 ys), who fulfilled ACR/EULAR 2013 SSc classification criteria, were recruited. All patients underwent chest HRCT and US examination. The US examination was performed with 7,5 Mhz probe and conducted with patients in sitting position from paraspinal line to anterior axillary line, for each intercostals space. The presence of typical ultrasound signs as lung comets (pathological if >35), higher pleural line thickness (pathological if >2mm), irregular pleural margins, subpleural cysts and pleural effusion was detected. The sensitivity, specificity and accuracy of US patterns (compared to chest HRTC) were evaluated by ROC analysis. Statistic significance was set at $p<0.05$. All results are expressed as mean ± 1 standard deviation.
**Results:** 23 patients had the CT honeycombing pattern, of which 92% had the US irregular pleural margins, 70% had US higher pleural line thickness and sub-pleural cysts, just 54% had US lung comets. 16 patients had the CT ground glass pattern, of these in 94% the US irregular pleural margins, in 87% US lung comets, in 60% US higher pleural line thickness were found. As regard the CT ground glass pattern the US sign with the highest specificity (91%), sensibility (85,7%) and accuracy (88%) was the lung comets; while regarding the CT honeycombing pattern the US sign with the highest specificity (92%), sensibility (69,6%) and accuracy (82%).
**Conclusions:** The lung US is a good diagnostic technique for its repeatability, low cost and risklessness. Although HRCT remains the best imaging technique to assess the ILD, in SSC the lung US could be a useful tool to detect the presence or the evolution of ILD and to improve the timing of HRTC without exposing the patients to high radiation doses over time.

## SAT0217 AXON REFLEX VASODILATATION OF DIGITAL ARTERIES IN SYSTEMIC SCLEROSIS PATIENTS, EVALUATED BY LASER-DOPPLER FLUXMETRY

C. Rotondo, M. Nivuori, A. Chialà, E. Praino, L. Coladonato, M.G. Anelli, M. Giannini, N. Lascaro, R. Fanizzi, G. Laselva, F. Cacciapaglia, G. Lapadula, F. Iannone. *Rheumatology Unit, Bari University, Bari, Italy*

**Background:** Systemic sclerosis (SSc) is a connective disease characterized by severe microvessels vasculopathy. The important role of endothelial dysfunction in SSc pathogenesis is widely demonstrated, but the SSc related autonomic nervous system impairment is controversial and rarely described. The dysregulation of axon reflex vasodilatation of fingertip microvessels in SSc has been reported in some studies, but the functional involvement of digital arteries in SSc patients had never been investigated.
**Objectives:** We aimed at evaluating the blood flux changes mediated by axon reflex response upon heating stimulus in SSc patients.
**Methods:** 87 SSc patients (SSc pt) and 22 healthy controls (HC) were recruited in this study. The SSc patients were aged 52,7±16,2 yrs, with disease duration of 8,23±7,8 yrs. The LD Flowmetry (Periflux System 5000, Perimed) with 4 LD heating probes was used to measure the skin blood flux of the middle phalanx of the 2nd, 3rd, 4th and 5th fingers of the left hand. The skin fingers flux was recorded at pre-heating period with probes temperature fixed at 34 °C (PHF) and after 5 min heating at 44 °C (IHF). Therefore, the heating test assesses the variation of digital artery flux in response to local heating stress at 44 °C. The ratio IHF/PHF evaluates the axon reflex mediated vasodilatation (ARMV). The results are expressed as average across 4 fingers at each time. The flux was expressed in perfusion unit (PU) and HC and SSc patients responses were compared by the t-student test. Statistic significance was set at $p\leq0,05$. The data analysis was performed using IBM SPSS statistic 20.
**Results:** The ARMV was significantly reduced in SSc patients (2,2±1,4) in comparison with HC (4,8±2,7, p=0,0001). IHF was lower in SSc patients (118,6±54,3) than HC (168±78, p=0,001). Dividing the SSc pts group by the presence of pitting scars (PS), digital ulcers (DU) and digital necrosis (DN), we observed a lower IHF in SSc pts with PS (103,2±48,6) than in SSc pts without (138,1±56, p=0,003), and in SSc pts with DU (97,8±47,6) than in SSc pts without (160,27±120,1, p=0,002). Moreover, SSc pts with ND showed a lower ARMV (1,8±1) than SSc pts without (2,6±1,5, p=0,006), and a lower IHF (98,3±49,1 vs 133,2±54,5, p=0,004). The age, sex, concomitant therapy with Ca-antagonist or Bosentan or cardioaspirin did not influence the digital artery flux.
**Conclusions:** This study provided evidence that a functional impairment of DA occurs in SSc, and it worsens with increasing severity of vascular clinical manifestations.
**Disclosure of Interest:** None declared

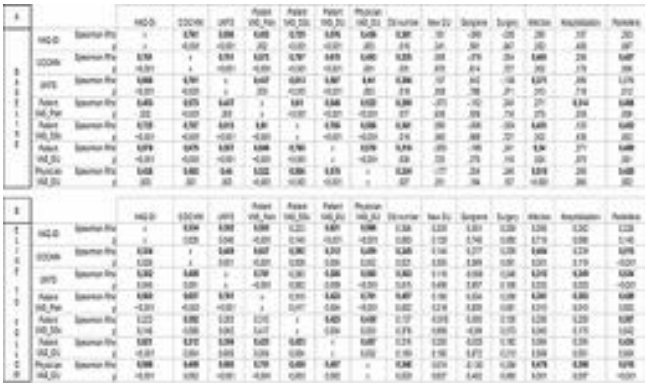
## SAT0218 EFFICACY OF BOSENTAN FOR THE TREATMENT OF DIGITAL ULCERS IN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES

C. Moriano Morales[1], A. López Robles[1], M. Retuerto Guerrero[1], J.L. Andreu Sánchez[2], A. García Valle[1], M. Garijo Bufort[1], C. Iñiguez Ubiaga[1], E. Díez Álvarez[1], C. Álvarez Castro[1], M. Martín Martínez[1], T. Pérez Sandoval[1]. *[1]Rheumatology Unit, Hospital León, León; [2]Rheumatology Unit, Hospital Puerta Hierro-Majadahonda, Madrid, Spain*



**Background:** Patients with Systemic Autoimmune Diseases (SADs), in particular, systemic sclerosis, are prone to suffer from severe Raynaud's phenomenon (RP), accompanied with digital ulcers secondary to ischemia and associated with a high rate of morbidity and mortality. Bosentan, a dual endothelin receptor antagonist, is a therapeutic option for refractory cases with an inadequate response to conventional management.
**Objectives:** The objectives of our study were: i) to assess safety and efficacy of bosentan in patients suffering from different kinds of SADs and active digital ulcers secondary to RP, ii) to determine predictive factors of response, and iii) to identify predictive factors for survival.
**Methods:** This is a retrospective observational study of patients suffering from SADs and digital ulcers secondary to RP, treated with bosentan in our department between January 1st, 2005 and December 31st, 2014. Patients with ischemic ulcers caused by other factors were excluded. The following baseline independent variables were considered: type of SAD, exposition to cold or to toxic substances, clinical and epidemiological characteristics, concomitant treatments, the coexistence of pulmonary hypertension, and number and location of digital ulcers. Therapeutic response, adverse effects, the need for amputation and death were considered as dependent outcome variables. Chi-square, Student t test, and Mann-Whitney U test were used to establish statistical significance in the univariate analysis between independent baseline variables and outcomes. A $p<0.05$ was considered significant.
**Results:** We included 31 patients (26 women, mean age 57 years). Twenty patients had systemic sclerosis (10 cases the limited form, and 10 cases the diffuse form). Eight patients had concomitant pulmonary hypertension. Mean follow-up after starting bosentan was 1470 days. Six patients had, at least, an adverse effect, being the most frequent alterations of liver function tests. In 87% of the cases, ulcers improved significantly, with a clinical response within the first 12 weeks of treatment in 77% of the cases. Ninety percent of the patients received concomitant treatment with calcium channel blockers and 45% had received previous treatment with prostaglandins. Despite bosentan therapy, amputation was done in 4 patients. Type of SAD, gender, or exposition to cold did not show any significant correlation with morbidity and mortality. Nine patients died. Smoking habit showed a correlation with death (p=0.05). There was a significant correlation between the duration of the disease and death (p=0.0235), as well as with the age of the patient (p=0.0013). Pulmonary hypertension was predictive of a poor therapeutic response (p=0.043) and mortality (p=0.015).
**Conclusions:** This open study suggests that bosentan is an effective agent for ischemic digital ulcers in patients with SADs, with a favorable safety profile. Age and associated pulmonary hypertension are predictors of mortality and poor outcome.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5814

## SAT0219 CORRELATION BETWEEN PATIENT-REPORTED OUTCOMES AND CHANGES IN DIGITAL ULCER STATUS IN SYSTEMIC SCLEROSIS PATIENTS

C. Bruni[1], T. Ngcozana[2], F. Braschi[1], S. Guiducci[1], S. Bellando-Randone[1], L. Tofani[3], C.P. Denton[2], D.E. Furst[4], M. Matucci-Cerinic[1]. *[1]Department of experimental and clinical medicine, division of Rheumatology, University of Firenze, Firenze, Italy; [2]Centre for Rheumatology and Connective Tissue Diseases, UCL Division of Medicine, London, United Kingdom; [3]Department of Neurosciences, Psychology, Drug Research and Child Health, University of Firenze, Firenze, Italy; [4]Department of Medicine, Division of Rheumatology, University of California at Los Angeles, Los Angeles, United States*

**Background:** Among various measures used to evaluate patients with systemic sclerosis (SSc), the Health Assessment Questionnaire (HAQ-DI) for disability, the UK scleroderma Functional Score (UKFS) and the Cochin Scale for hand functionality, the Visual Analogic Scale (VAS) to estimate pain, general disease activity and digital ulcers status are among the more frequently used [1]. Digital Ulcers (DU) are a major clinical complication in patients with Systemic Sclerosis (SSc), leading to a severe impairment of the quality of life and possibly determining important complication (from infections to amputation).

**Objectives:** this study aimed at evaluating the correlation between Clinician-Reported outcomes (CROs) and patient-reported outcome (PROs) and how changes in different parameters related to DU status in SSc patients may reflect changes in the above mentioned outcome measures.
**Methods:** SSc patients presenting at least one DU and attending the Rheumatology Wound Care Clinic of the Florence University Hospital or the London Royal Free Hospital were eligible for the study. Patients were assessed with HAD-DI, UKFS, Cochin scale, VAS for pain, DU status and general disease status (as PROs) and VAS for DU status (as CROs) at baseline and then every 4 weeks for a total of 16 weeks (or until DU healing, if occurred before). Number of DU, appearance of new DU, presence of gangrene, infection, need for hospitalization or surgery procedures, painkillers use were recorded at each visit. Correlations were tested through Spearman test.
**Results:** forty-four SSc patients were enrolled in the study. At baseline, all the PROs and CROs were positively correlated to each other, with most of the scales being also correlated with baseline DU number, presence of infection, need for hospitalization and painkillers use. When investigating baseline to mean follow-up changes, significant correlations were confirmed between CROs and PROs (except for VAS for general disease status), as well as between changes in PROs/CROs and changes of DU parameters being already significant at baseline.

**Conclusions:** PROs are useful outcome measures paralleling changes in clinical evaluation of DU status, which is influenced by changes in DU number, presence of infection, need for hospitalization and painkillers use.

## SAT0220 RETROSPECTIVE AUDIT COMPARING BSR STANDARDS WITH DETECT CRITERIA FOR PAH-SCREENING IN SYSTEMIC SCLEROSIS PATIENTS AT A DGH

D. Hall [1], L. Williamson [2]. [1]*Health Sciences, University of Bristol, Bristol;* [2]*Rheumatology, Great Western Hospital, Swindon, United Kingdom*

**Background:** Pulmonary arterial hypertension (PAH) is a complication of Systemic Sclerosis (SSc). It is the lead cause of mortality and can affect up to 20% of SSc patients. The DETECT study developed an evidence-based screening algorithm to aid early detection and diagnosis; as well as guide management of those with SSc-PAH. Many studies, including DETECT have shown earlier detection, higher survival rates and improved outcomes in those enrolled to a screening programme. PAH is often diagnosed late, when symptoms are advanced and prognosis is poor. Therefore, screening is crucial to enhance patient safety and improve outcomes. In light of this; a retrospective audit of 29 SSc patients at a DGH in July 2015 was performed to compare adherence rates to the national BSR standards of annual pulmonary function testing (PFT) echocardiogram and DETECT criteria for PAH-screening.
**Objectives:** 1. Evaluation of current practice against the BSR standards.
2. Evaluation of current practice against DETECT criteria
**Methods:** Data was retrospectively collated from written medical notes, Medway and CVIS in accordance with a Microsoft Excel proforma of 30 variables, including annual echocardiography and PFT; and eight PAH-predictive variables identified by the DETECT study (FVC %predicted/DCLO %predicted, Telangiectasias, ECG Right Axis Deviation (RAD), Serum Urate, Serum Anti-Centromere Antibody (ACA) and Serum NTproBNP).
**Results:** Adherence to the BSR standard was 75.9% over the last 18 months. Stratification showed higher rates of adherence in those with more recent diagnoses; 70%, 83.3% and 100% for 0–4years, 5–8 years and 9–12 years disease duration respectively, compared to 50% and 0% for 17–20 years and 21–24 years respectively.
DETECT scores were calculable for 2/29 patients. Serum NTproBNP, serum urate and ECG RAD are not routinely tested for or documented in SSc patients. Furthermore, in this audit, less than 50% of patients had a documented serum ACA in their notes. As a result, DETECT scores were not calculable for most patients.
**Conclusions:** Adherence rates in the last 18 months are 75.9%. Adherence is highest in those with more recent diagnoses. Seven patients (24%) did not receive annual screening in the past 18 months. Adherence to BSR standards and patient safety could therefore be improved. As a result of this audit, a centralised patient list was uploaded to CVIS for automatic annual screening appointments.
The use of DETECT criteria is not currently applicable. However small, inexpensive changes in routine management of SSc patients would make this possibile.

## SAT0221 DETERMINANTS ASSOCIATED WITH INTERSTITIAL PULMONAR INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS – A CROSS-SECTIONAL STUDY

D.R. Gonçalves, R. Fonseca, F. Aguiar, T. Martins-Rocha, M. Bernardes, L. Costa. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** Interstitial lung disease (ILD) is one of the major types of lung involvement in systemic sclerosis (SSc). Affected patients have a worse prognosis than patients with SSc who are free of pulmonary involvement. Therefore, it is important to explore determinants of this organ complication.
**Objectives:** To found possible determinants of ILD in SSc patients.
**Methods:** A cross-sectional study was conducted in 104 SSc patients (2013 ACR/EULAR criteria) from a university hospital of Portugal. The analyzed variables were: age, sex, age at disease onset, disease duration, antinuclear antibodies (ANA), topoisomerase I DNA (Scl70) and anticentromere antibodies (ACAs) status, Raynaud phenomenon, areas of skin sclerosis (limited was divided into sclerodactyly or proximal to the metacarpophalangeal (MCP) joints), digital ulcers (DU), digital pitting scar and telangiectasia status, diffusion capacity of carbon monoxide transfer/alveolar volume (DLCO/VA, % of the predicted value) at diagnosis and esophagus involvement. Descriptive statistics were calculated for several demographic and clinical characteristics. Pearson or Spearman correlation and chi-square or Fisher's exact test was used for the assessment of the correlation between ILD and the different continuous and categorical variables. Subsequently, binary logistic regression analysis (method enter) was carried out using the ILD as the dependent variable. As independent variables, were included variables that had clinical or statistical significance.
**Results:** Most (89.4%) of patients were women; mean (SD) age was 59 (±13) years. Mean age at diagnosis was 51 (±13) years with disease duration median (min;max) of 6 (0;38) years. Ninety-three (89.4%) patients had limited (lcSSc) scleroderma. Most (98.1%) patients had ANA positive (mainly centromere (n=61) followed by nucleolar pattern (n=15)), 61 (58.7%) patients were ACAs positive and 21 (20.2%) positive for Scl70 antibodies. DLCO/VA mean at SSc diagnosis was 74.8% (±13.6). Twenty-three (22.1%) patients had ILD (most NSIP pattern) and 64 (61.5%) had esophagus involvement. Correlation coefficients with statistical significance were noted for disease duration and age however, these were weak (rô=0.22, p=0.03 and r=0.29, p=0.004; respectively). For categorical variables we observed statistical significance for SSc subgroups (ILD prevalence of 15.1% in lcSSc vs 72.7% in diffuse SSc; $p<0.001$), ACAs and Scl70 serology (6.6% in ACAs vs 57.1% in Scl70 positive patients; $p<0.001$) and DU (33.3% if history vs 15.5% if without history of DU, p=0.02). Correlation of ILD with DLCO/VA at SSc diagnosis and sex had not statistical significance (p=0.064). In logistic regression the following variables were introduced: age, disease duration, SSc subgroups, ACAs and Scl70 serology, skin sclerosis proximal to the MCP joints, DU status and DLCO/VA at SSc diagnosis. The analysis showed that the age (OR=1.13,p=0.003), SSc subgroups (OR=22.95,$p<0.001$) and ACAs status (OR=0.08,p=0.001) influence the ILD in the model.
**Conclusions:** Our results suggest that higher age and diffuse sclerosis increased ILD risk and ACAs decreases. A prospective longitudinal study with a larger sample is desirable to confirm these results.
**Disclosure of Interest:** None declared

## SAT0222 B CELL DEPLETION THERAPY IN SYSTEMIC SCLEROSIS ASSOCIATED INTERSTITIAL LUNG DISEASE. A MULTICENTER, OPEN LABEL, COMPARATIVE STUDY WITH A FOLLOW UP OF 94 PATIENT-YEARS

K. Melissaropoulos[1], D. Daoussis[1], G. Sakellaropoulos[2], I. Antonopoulos[1], T.E. Markatseli[3], T. Simopoulou[4], P. Georgiou[5], A.P. Andonopoulos[1], A.A. Drosos[3], L. Sakkas[4], S.-N. Liossis[1]. *[1]Rheumatology, University Hospital of Patras; [2]Medical Physics, University of Patras, Patras; [3]Rheumatology, University Hospital of Ioannina, Ioannina; [4]Rheumatology, University Hospital of Larissa, Larissa; [5]Rheumatology, Agios Andreas General Hospital, Patras, Greece*

**Background:** We have previously shown that rituximab (RTX) may favorably affect lung function and skin fibrosis in patients with systemic sclerosis (SSc).
**Objectives:** To assess long term efficacy and safety of RTX in SSc compared to standard treatment.
**Methods:** Fifty one patients with SSc associated interstitial lung disease were recruited and treated with RTX (n=33) or standard treatment (n=18). RTX cycles were repeated every 6 months throughout follow up apart from 6 patients where RTX was discontinued following 2 years of continuous treatment. Mean follow up was 2.9 years (range 1–7). Standard treatment consisted of azathioprine (n=2), methotrexate (n=6) and mycophenolate (n=10).
**Results:** Patients in the RTX group showed an increase in FVC during the first year of treatment (mean ± SEM of FVC: 80.60 ± 3.69 vs 83.02 ± 3.37 at baseline vs 1-year, respectively, p=0.13); this beneficial effect was further augmented at 2 years (86.90 ± 4.72, p=0.04 compared to baseline). In sharp contrast, patients in the control group had no change in FVC during the first 2 years of follow up. At 2 years, the RTX group was numerically better than the control group; however, differences tended but did not reach statistical significance (p=0.063). At the 7 year time point patients in the RTX group had higher FVC compared to baseline (mean ± SEM of FVC: 91.60 ± 6.62, p=0.15 compared to baseline) in contrast to patients in the control group where FVC deteriorated ($p<0.01$, compared to baseline). Direct comparison between the 2 groups showed a significant benefit for the RTX group (p=0.013). DLCO also improved following 2 years of RTX treatment (mean ± SEM of DLCO: 59.22 ± 3.16 vs 61.51 ± 4.02 at baseline vs 2-years, respectively, p=0.05). In the standard treatment group DLCO constantly deteriorated throughout follow up. In 6 patients where RTX was stopped following 2 years of continuous treatment a decline in PFTs was evident. Improvement of skin thickening was found in both the RTX and the standard treatment group, however, direct comparison between groups strongly favored RTX at all time points (p=0.002, 0.015, 0.002, 0.053 0.029 for the 1, 2, 3, 4 and 5-year time point, respectively). In the RTX group, six cases of respiratory infection requiring hospitalization, one case of hepatitis B reactivation and one case of herpes zoster were recorded. Two patients were diagnosed with cancer (lung and prostate). Five deaths were recorded: end stage respiratory failure (n=2), lung cancer (n=1), sudden death (n=1), unknown (n=1). In the control group, five patients with respiratory and four patients with urinary infection were hospitalized. In four cases, infections were recurrent. Two deaths were reported due to respiratory infection.
**Conclusions:** Our data indicate that continuous treatment with RTX has a beneficial effect on lung function and skin fibrosis in patients with SSc. Treatment was well-tolerated. Randomized controlled studies are highly needed.
**Disclosure of Interest:** None declared

## SAT0223 SOLUBLE SEMAPHORIN 3A AND NEUROPILIN-1: NEW MARKERS FOR DYSREGULATION OF ANGIOGENESIS IN SYSTEMIC SCLEROSIS?

A. Olewicz-Gawlik[1], D. Sikorska[2], W. Samborski[2]. *[1]Department of Rheumatology and Clinical Immunology; [2]Department of Rheumatology and Rehabilitation, Poznan University of Medical Sciences, Poznan, Poland*

**Background:** Semaphorins, through interactions with their receptors- neuropilins, play critical roles in many biological processes such as the regulation of immunity, apoptosis, cell migration and angiogenesis. Systemic sclerosis (SSc) is an autoimmune disease, characterised by dysregulation of angiogenesis, leading to severe ischemia and loss of capillaries.
**Objectives:** The aim of the study was to investigate if soluble semaphorin 3A and neuropilin-1 could be involved in the dysregulation of angiogenesis in systemic sclerosis.
**Methods:** This was an investigator-initiated cross-sectional study. Serum samples obtained from 37 patients with systemic sclerosis (age 53 ± 9 years) and control serum samples obtained from 24 healthy individuals (age 51 ± 15 years) and 20 patients with Sjögren's syndrome (age 46 ± 9 years). Samples were analyzed for the presence of soluble semaphorin 3A and neuropilin-1 using enzyme-linked immunosorbent assays. The results were expressed as median and range and compared by Mann-Whitney U test. $P \leq 0.05$ were considered statistically significant.
**Results:** Serum semaphorin 3A levels were significantly higher in patients with systemic sclerosis (median 1.81 ng/mL; range 0.43–4.72 ng/mL) versus healthy controls (median 0.21 ng/mL; range 0.16–0.28 ng/mL) ($p<0.001$). Neuropilin-1 levels were significantly increased (median 844.26 pg/mL; range 556.80–1271.54 pg/mL) in comparison to those detected in healthy controls (median 58.60 pg/mL; range 33.75–80.00 pg/mL) ($p<0.001$) and patients with Sjögren's syndrome (median 278 pg/mL; range 137.50–443.70 pg/mL) ($p<0.001$). There was tendency to higher values of neuropilin-1 in patients with long lasting illness (Spearman's; r=0.29, p=0.075).
**Conclusions:** Our data show that semaphorin 3A and neuropilin-1 levels are significantly increased in patients with systemic scleroderma. Semaphorin 3A and neuropilin-1 may be involved in the modifications of neuro-vascular mechanisms leading to dysregulation of angiogenesis in systemic scleroderma.

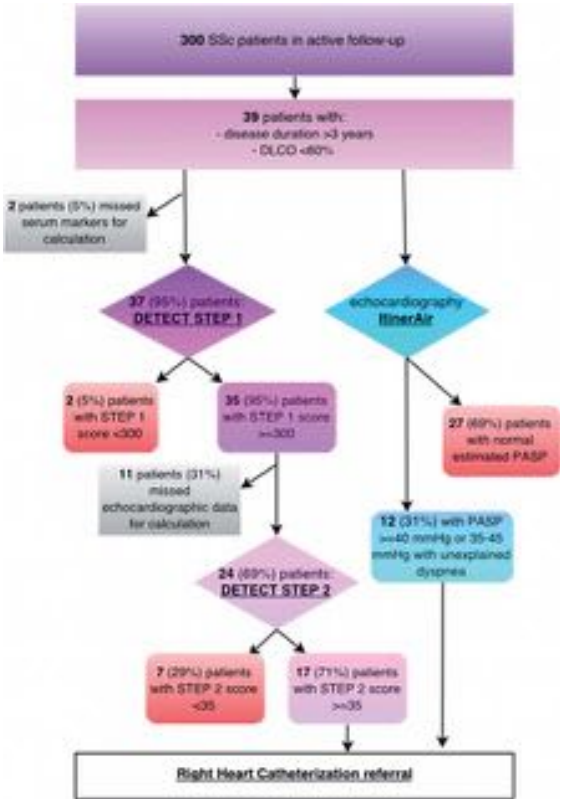
## SAT0224 NAILFOLD VIDEOCAPILLAROSCOPIC FINDINGS IN UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE (UCTD) AND THEIR RELATIONSHIP WITH RAYNAUD'S PHENOMENON (RP)

R. De Angelis, E. Di Donato, W. Grassi. *Clinica Reumatologica, Università Politecnica delle Marche, Ancona, Italy*



**Background:** The term undifferentiated connective tissue disease (UCTD) is used to describe a group of patients that lack definitive characteristics of any specific, well-defined connective tissue disease. The microcirculation may be affected and nailfold capillary abnormalities were sometimes described.
**Objectives:** The aim of the study was to evaluate and depict the capillaroscopic features in these patients, especially in combination with Raynaud's phenomenon (RP).
**Methods:** A consecutive cohort of 78 patients with UCTD and disease duration of at least one year was included in the study. Diagnosis of RP was based on a detailed history and/or observation of bilateral, cold-induced blanching and/or cyanosis of the fingers. Nailfold videcapillaroscopy (NVC) was performed blinded to disease group by the same investigator using a computerized videomicroscope at 200x magnification. The capillaroscopic findings were classified as normal, non-specific (tortuous, crossed, bizarre capillaries, haemorrhages, thrombotic capillaries), scleroderma pattern (SP) findings (definitely enlarged capillaries, giant loops/megacapillaries, bushy capillaries and angiogenesis, no, moderate or extensive loss of capillaries, architectural disruption of the nailfold capillary bed). Different data of continuous variables were described and compared using the Mann-Whitney U test. Comparison of categorical variables was performed using the $\chi^2$ test with continuity correction. Statistical significance was defined as $p<0.05$.
**Results:** The 78 patients consisted of 87% women (68/78) and we diagnosed RP in 41 (52.5%). The mean age was 45.1±14.7 (yrs±SD) and the mean disease duration 48.6±50.0 (months±SD). NVC abnormalities were present in 18/41 (43.9%) patients with UCTD+RP and in 1/37 (2.7%) without RP ($p<0.0001$). A considerable percentage of patients with RP (15%) had a normal NVC, compared to patients without RP (36.6%) (p=0.0004). Homogeneously enlarged loops were identified in 30/41 (73.1%) of UCTD+RP, in a higher percentage respect to patients without RP (27.0%) (p=0.0001). Irregularly enlarged loops and megacapillaries were found in 55% and 35% of UCTD+RP patients, respectively, in a significant high frequency respect to patients without RP. Bushy or angiogenetic capillaries and/or avascular areas were not found in both group. The combination of features suggestive for a SP without reduction in capillary density were present in 18/41 patients with UCTD+RP, and in 1/37 without RP (p=0.0003).
**Conclusions:** In our UCTD+RP patients, irregularly enlarged and giant loops were predominant. We found neither moderate capillary loss, nor avascular areas in any of our patients. Only the SP without capillary loss distinguishes patients with RP from those without. This fact would also be supported by other results, which failed to show any of the findings typical of a severe or "active' disease involving nailfold microcirculation, such as features suggesting capillary re-growth ("bushy" capillaries), and "destruction" of capillaries (capillary loss/avascular areas) The typology of microvascular damage found in our patients is consistent with the general profile of UCTD, commonly considered as a condition characterised by a mild clinical picture.

## SAT0225 SCREENING FOR PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS PATIENTS: SINGLE CENTER REAL-LIFE PERFORMANCE OF THE DETECT ALGORITHM

F. De Nard[1], V. Codullo[1], V. Grosso[1], A. Gallarati[1], S. Ghio[2], L. Scelsi[2], C. Raineri[2], R. Caporali[1], C. Montecucco[1]. *[1]Rheumatology Unit; [2]Cardiology Unit, IRCCS Policlinico San Matteo Foundation, Pavia, Italy*

**Background:** A new algorithm for early detection of PAH in Systemic Sclerosis (SSc) patients has been recently developed (1). However, the cost-effectiveness of this strategy has not yet been defined in a real-life setting.
**Objectives:** The aim of this study was to compare two methods of PAH screening among SSc patients for the referral to invasive tests (right heart catheterization (RHC)) in a single PH referral center.

**Methods:** Patients with SSc according to the ACR/EULAR 2013 classification criteria were enrolled in the study and prospectively followed in a Scleroderma Unit of a University Hospital which is also a PH referral center between Jan 2015 and Jan 2016 with at least 6-monthly visits. According to the ESC/ERS 2015 guidelines (2), annual screening with echocardiography, DLCO, ECG and serum biomarkers (including urate and NT-proBNP) was performed. Patients satisfying the two-steps DETECT score and/or with echocardiographically estimated Pulmonary Arterial Systolic Pressure (PASP) ≥45 mmHg or between 35–45 mmHg with unexplained dyspnea (3) were referred to an expert cardiologist to undergo RHC.
**Results:** Three-hundred patients with a diagnosis of SSc were screened and 39 patients (13%) met the criteria for the application of the DETECT algorithm (disease duration >3 years, DLCO <60%). The male:female ratio was 1:12; 16 patients (41%) were positive for anticentromere antibodies; 14 patients showed cutaneous teleangectasias (26%); 33 patients (85%) were classified as limited SSc, 4 (10%) as diffuse SSc and 2 as SSc without skin involvement (5%). For 2 of them (5%), STEP 1 score was not calculated due to missing serum biomarkers. Among the remaining 37 patients, 2 (5%) had a STEP 1 score <300; and 35 (95%) showed a STEP 1 score ≥300. Among the latter, for 11 (31%) echocardiographic measures for the calculation of the STEP 2 score could not be derived. In 7/24 (29%) the STEP 2 score was <35 while in 17/24 (71%) ≥35, thus needing referral to RHC according to the DETECT algorithm. In the same 39-patients group, 12 (31%) satisfied the ItinerAir criteria for RHC (p=0,0019, chi-squared).

**Conclusions:** Our results indicate that the feasibility in clinical practice of both PAH screening methods strongly depends on the performance of a correct echocardiographic screening, with a complete assessment and quantification of right heart parameters, which often lacks in outpatient practice. In addition, applying the DETECT algorithm, a larger number of patients should be sent to RHC than those identified by solely echocardiographic parameters. Further observational studies are needed to define the real-life sensivity and cost-effectiveness of this new algorithm.

## SAT0226 CIRCULATING SERUM LEVELS OF CORTISOL ARE ASSOCIATED WITH THE PAIN THRESHOLD IN SYSTEMIC SCLEROSIS: CORRELATIONS WITH DEPRESSION

G. Bagnato[1], F. Cordova[2], D. Sciortino[1], A. Fiorenza[1], A. Ferrera[1], G. Coppolino[1], D. Sangari[1], W.N. Roberts[3], S. Gangemi[1], A. Bruno[2], M.R.A. Muscatello[2], G. Pandolfo[2], R.A. Zoccali[2], G. Bagnato[1]. *[1]Department of Clinical and Experimental Medicine; [2]Department of Neurosciences, University of Messina, Messina, Italy; [3]Department of Medicine, University of Louisville, Louisville, United States*

**Background:** Previous studies on pain prevalence among systemic sclerosis (SSc) patients confirms its prominent role in disease outcomes[1]. Although pain perception is receiving more importance among patient-reported outcomes in SSc research, still its interface with mood disorders and immune system need to be further elucidated. The prevalence of clinically significant symptoms of depression or anxiety in SSc varies between 36% and 65% according to the evaluation used, and are rather associated with increased disability and altered HRQoL, than with disease-specific organ manifestations. An endocrine influence on pain perception and threshold is supported by robust evidences, more specifically related to sex, adrenal and thyroid hormones.
**Objectives:** To analyze the association between pain threshold, depression and cortisol serum levels in systemic sclerosis patients, major depression disorder patients and healthy controls.
**Methods:** Thirty SSc patients, 30 major depressive disorder (MDD) patients and 30 healthy controls completed the study. All participants underwent pressure pain threshold (PPT) assessment through an algometer in three anatomical surfaces, the ungula bed (UPPT) and the metacarpophalangeal joint (MPPT) of the second finger of the right hand and the anterior portion of the quadriceps muscle (QPPT), and depression evaluation, assessed by patient health questionnaire 9 (PHQ-9). Serum cortisol was measured in SSc and MDD patients for further analysis. Patients under treatment with corticosteroids were excluded.
**Results:** PHQ-9 values showed that 15% of SSc patients had no signs of depression, while 30% had mild and another 30% moderate signs of depression, 18% moderate/severe and 9% severe signs. Among MDD patients, PHQ-9 12% had mild depression, 45% moderate, 15 moderate to severe and 28% severe depression. PHQ-9 scores were significantly higher in SSc and MDD compared to controls ($p<0.0001$) and furthermore MDD patients had significantly higher than those reported by SSc patients ($p<0.005$). Pain threshold scores were significantly lower in SSc and MDD patients compared to healthy subjects in all sites ($p<0.0001$). In addition, SSc patients showed significant lower pain thresholds when compared to MDD, regardless the site of measurement (UPPT: p=0.0053; MPPT: p=0.0121; QPPT: p=0.0086). In addition, cortisol serum levels were significantly higher in MDD patients compared to SSc (17.1±5.7 vs 8.5±3.7 μg/dl; $p<0.0001$). Both in SSc and MDD a significant direct correlation was observed between cortisol serum levels and PPT in all sites.
**Conclusions:** The interface between pain, depression and cortisol could represent an additional complex aspect of care of patients with either SSc or MDD.

Maurer[6], U. Müller–Ladner[7], S. Nihtyanova[5], G. Riemekasten[10], E. Siegert[11], G. Valentini[12], S. Vettori[12], U. Walker[9], M. Matucci-Cerinic[3], F. Del Galdo[1] on behalf of DeSScipher Consortium and contributing EUSTAR centres. *[1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [2]Department of Rheumatology, University of Paris Descartes, Paris, France; [3]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy; [4]Department of Rheumatology and Immunology, University of Pécs, Pécs, Hungary; [5]Department of Rheumatology, University College London, Royal Free Hospital, London, United Kingdom; [6]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [7]Department of Rheumatology and Clinical Immunology, Justus–Liebig University Giessen, Kerckhoff Clinic Bad Nauheim, Giessen/Bad Nauheim; [8]Department of Rheumatology and Immunology, Charité University Hospital and German Rheumatism Research Centre, Berlin, Germany; [9]Department of Rheumatology, University of Basel, Basel, Switzerland; [10]University Schleswig-Holstein Lübeck, Lübeck; [11]Department of Rheumatology and Immunology, Charité University Hospital, Berlin, Germany; [12]Department of Rheumatology, Second University of Naples, Naples, Italy*

**Background:** Digital ulcers (DU) are an important driver of poor quality of life

in Systemic Sclerosis (SSc). Real life clinical management of DU includes the use of vasoactive (Bosentan) and vasodilating (Sildenafil, Iloprost, CCB and ACE inhibitors) drugs in different combinations, without strong evidence for efficacy.
**Objectives:** One of the aims of the EC-funded FP7 research project DeSScipher (acronym for "to decipher the optimal management of SSc") was to determine the relative effectiveness of the above treatments for the healing of DU in SSc patients.
**Methods:** Twenty eight centres in Europe participated to the study. Longitudinal data were collected over 24 months in a specific web based EUSTAR database. The DU distal to PIP joints at the inclusion visit or developed over the follow-up were included. End-points included: mean number of healed ulcers/patient; proportion of patients with healed DU; and time to healing of at least one DU.
**Results:** Out of 1394 enrolled patients, 265 met inclusion criteria. Follow-up data were available for 156 patients. 57% of patients were on vasodilators (Sildenafil, Iloprost, CCB, alone or in combination), 5.8% were on single vasoactive drug (Bosentan) and 37.2% patients were on combination therapy. The mean number of DU/patient at the inclusion visit was comparable among the 3 treatment arms. At 12 and 24 months, the mean number of healed DU/patient was higher in the vasodilator group compared to the vasoactive and combination groups (1.8 vs 1 vs 1.2, p=0.013 and 2.4 vs 1.3 vs 1.3, p=0.018 respectively). No significant difference was observed at 6 months. The proportion of patients with all or at least one DU healed was not significantly different between treatment arms. Initial exploratory analysis also suggested that the estimated mean time to healing of at least one DU was 9.71±2.2 months in vasoactive arm, 8.7±0.5 in vasodilator arm and 7.9±0.6 in combination therapy arm. Further, when considered separately, patients on Sildenafil (±CCB) showed the highest healing rate at 6months follow-up, compared to other drug combinations. However, correction for concurrent treatment and confounding factors is still on going.
**Conclusions:** Vasodilating treatment achieved a major number of healed DU at 12 and 24 months. The combination treatment seems to be of help in obtaining a shorter time to healing and limiting observation at 6 months may bias overall interpretation of data. Further analysis is ongoing for different drug combination at different time-points.

## SAT0228 EFFICACY OF RITUXIMAB FOR THE TREATMENT OF INTERSTITIAL LUNG DISEASE ASSOCIATED WITH CONNECTIVE TISSUE DISEASES – A RETROSPECTIVE ANALYSIS

H. Jethwa[1], I. Patel[1], A. Steuer[1], F. Demetriadi[1], S. Power[1], M. Adler[2], M. Lloyd[3], E. Pretsell[3]. *[1]Rheumatology Dept., Wexham Park Hospital; [2]Respiratory Dept., Wexham Park Hospital; [3]Rheumatology Dept., Frimley Health NHS Trust, Wexham, United Kingdom*

**Background:** Interstitial lung disease (ILD) is a notable complication of Connective Tissue Diseases (CTDs) characterised by lung inflammation and scarring, leading to a reduced functional capacity, shortness of breath and exercise-induced hypoxia. To date, the mainstay of treatment for this condition is Cyclophosphamide (CYC); some patients, however, fail to respond and recent reports have shown that Rituximab may be beneficial as a second-line option. Currently, no guidelines are available to direct the management of CYC-resistant patients and, at present, these individuals remain to be treated on a case-by-case basis.
**Objectives:** To retrospectively evaluate the efficacy of Rituximab treatment in patients with ILD associated with CTDs.
**Methods:** We retrospectively reviewed patients in our trust with CTD associated ILD, refractory to cyclophosphamide, in whom Rituximab has been used. Parameters assessed were lung function (forced vital capacity (FVC) and carbon monoxide transfer factor (TLCO)), radiographic changes and creatine kinase (CK) response (for myositis) both pre- and post-treatment.
**Results:** Our cohort included 7 patients (4 females, 3 males) – average age 42 years. 6 patients had underlying diagnosis of polymyositis (3 anti-Jo, 2 anti-Jo/Ro, 1 anti-Zo) and 1 had an undifferentiated CTD. Average disease duration of 70 months. On high resolution CT scan, 3 patients had non-specific interstitial pneumonia (NSIP) pattern, 2 had usual interstitial pneumonia (UIP), 1 organising pneumonia, and one had features of both cryptogenic pneumonia and NSIP. Of note, one patient had mild co-existant pulmonary arterial hypertension. Previous treatments included CYC, azathioprine and steroids.
Lung function results were available for 6 of 7 patients – 5 of these patients showed improvement in post-treatment FVC and TLCO (average improvement 11.2% predicted; 0.14L and 4.06% predicted, respectively). Two patients had CT scans following treatment – one showed no change from baseline scan, and one (who later died of disease progression) showed worsened fibrosis.
Regarding muscle involvement, 5 of 7 patients had pre-treatment CK values available – two of these patients had a normal CK prior to Rituximab treatment. Interestingly, in the 3 patients with elevated CK levels, an average 45.3% improvement in CK was noted following Rituximab therapy.
**Conclusions:** This study reports improvement in both lung function tests and CK response in the majority of a small cohort of patients with CTD associated ILD following Rituximab treatment. Similar results have been shown in other small cohort studies. Larger, randomised studies are needed to further assess the response to Rituximab therapy and determine whether these findings have statistical significance. Consideration of a formal treatment pathway for patients resistant to CYC treatment would be helpful on both a local and national level to determine which patients are likely to have poor response to CYC, when to trial Rituximab and to determine markers of response to Rituximab treatment, including patient reported outcomes.

## SAT0229 A NOVEL SERUM TEST BASED ALGORITHM TO AID IN VERY EARLY DIAGNOSIS OF SYSTEMIC SCLEROSIS (VEDOSS)

J. Blagojevic[1,2], G. Abignano[1], E.M. Hensor[1], S. Guiducci[2], S. Bellando Randone[2], C. Bruni[2], G. Lepri[2], E. Romano[2], C. Mazzotta[2], N. Calder[3], M.P. Messenger[3], M.H. Buch[1], P. Emery[1], M. Matucci-Cerinic[2], F. Del Galdo[1]. *[1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [2]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy; [3]NIHR Diagnostic Evidence Co-operative, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** VEDOSS project relied on a specific set of inclusion criteria identifying patients in very early stage of systemic sclerosis (SSc) to be submitted to a tight follow up and unravel factors linked to the progression of the disease. The components of the ELF score (PIIINP, TIMP-1 and HA) have been shown to correlate with severity of skin and lung fibrosis in SSc.
**Objectives:** Our aim was to analyze the concentrations of ELF components in a subset of patients enrolled in the VEDOSS study and determine their potential diagnostic value.
**Methods:** Sera from 114 patients enrolled into the VEDOSS data base and 67 SSc controls fulfilling ACR/EULAR 2013 criteria (subsets: 33 diffuse; 34 limited) were obtained from 2 centres. Serum concentrations of ELF components were determined on Siemens Advia Centaur platform. Logistic regression analysis of the results was performed employing classification of SSc as state variable.
**Results:** Among the 114 patients enrolled from VEDOSS, 30 subjects had primary Raynaud's phenomenon (PRP); 54 had Raynaud's phenomenon (RP) and at least one of the following "red flags" (risk factors) for SSc: (Puffy fingers, ANA, SSc specific autoantibodies or SSc-specific capillaroscopic pattern) without fulfilling 2013 ACR/EULAR criteria (score $<9$). 30 VEDOSS patients fulfilled new ACR/EULAR criteria (score $>9$) despite having no evidence of skin involvement nor interstitial lung disease at lung high resolution CT or pulmonary arterial hypertension, left ventricular systolic impairment or renal involvement.
All serum biomarkers concentrations correlated with age ($p<0.05$ for all). Logistic regression analysis using the three biomarkers as variables identified a specific model (SSc score) ranging from -3.92 to 5.77. The new score showed good ability to discriminate between patients with SSc (VEDOSS patients already classified as SSc and SSc controls) versus VEDOSS patients not yet classified as SSc (AOUC under ROC curve: 0.853, 95%CI 0.797–0.910). Within the VEDOSS database, SSc score showed a fair ability to discriminate between VEDOSS patients fulfilling SSc classification criteria, despite lack of skin internal organ involvement (lung, heart and kidneys), and those not fulfilling the criteria (AOUC =0.756, 95%CI 0.646–0.865). Indeed, patients fulfilling SSc classification criteria, had average score of 0.44 vs -0.86 of patients not fulfilling the criteria and the score remained significant even after correcting for age (p=0.026). Furthermore, SSc controls had significantly higher SSc score compared to VEDOSS patients already classified as SSc, confirmed after age correction ($p<0.000$). No difference in SSc score has been observed between PRP and VEDOSS patients not yet classified as SSc.
**Conclusions:** Our data indicate that the SSc score is a simple serum test based model that can be used in patients with RP to aid in the very early diagnosis of SSc. Furthermore, the identification of VEDOSS patients with a high SSc score test and already classified as SSc even in the absence of internal organ involvement can be used in intervention trials aimed to prevent further disease progression.

## SAT0230 PROGRESSION OF LEFT VENTRICULAR MYOCARDIAL DYSFUNCTION IN SYSTEMIC SCLEROSIS: USING SPECKLE TRACKING STRAIN ECHOCARDIOGRAPHY TO IDENTIFY PATIENTS AT RISK

J.K. De Vries-Bouwstra[1], S.E. van Wijngaarden[2], S. Ben Said-Bouyeri[1], M.K. Ninaber[2], J.J. Bax[2], V. Delgado[2], N. Ajmone Marsan[2]. *[1]Rheumatology; [2]Heart and Lung Centre, LUMC, Leiden, Netherlands*

**Background:** Cardiac involvement is a main cause of mortality in systemic sclerosis (SSc)[1]. Its detection remains challenging using conventional echocar-

diographic parameters and little is known about which patients are at risk for deterioration of cardiac function. Speckle-tracking strain analysis of echocardiographic images can detect subtle myocardial dysfunction in patients with SSc, and decreased strain has been shown to associate with lower functional capacity and rhythm disturbances[2]

**Objectives:** This study evaluated: 1. changes in cardiac performance over time in SSc patients including echocardiographic myocardial speckle tracking strain analysis, and 2. baseline characteristics associated with deterioration of cardiac function.

**Methods:** 205 SSc patients (171 female, 52±14 years) were evaluated at baseline and follow-up (2.25years IQR1.3–3.8), including complete physical examination and screening for organ involvement with at least HRCT-thorax, pulmonary function test, cardiopulmonary exercise test, electrocardiography and echocardiography.

**Results:** Left ventricular (LV) ejection fraction did not change significantly (61%±7 vs 61%±8,p=0.148) while global longitudinal strain (LS) decreased significantly (-21%±2 vs -19%±3, p<0.001). 39 patients showed progression of LV dysfunction as defined by ≥15% decline in LS. These patients showed significant worsening of LV diastolic function (figure) and TAPSE (22mm±4 vs 19mm±4, p=0.003) and 8% developed pulmonary hypertension. Baseline parameters associated with progression of LV dysfunction were proximal muscle weakness (OR: 4.264 IQR: 1.473–12.342, p=0.007), diffusing capacity of carbon monoxide (DLCO, OR: 0.972 IQR: 0.948–0.995, p=0.020) and LV diastolic dysfunction (OR: 2.245 IQR: 1.019–4.946, p=0.045).

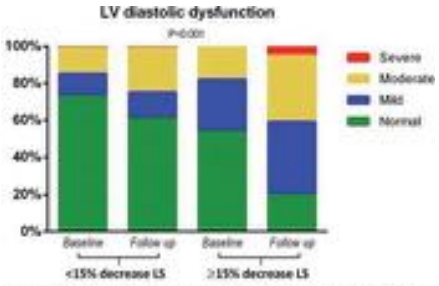

Figure 1: association of decrease in global longitudinal strain (LS) with degree of left ventricular (LV) diastolic dysfunction at baseline and follow-up; ≥ 15% decrease in LS is associated with worsening of LV diastolic function

**Conclusions:** In SSc patients, progression of LV systolic dysfunction was detected by speckle tracking strain analysis but not by LV ejection fraction. Proximal muscle weakness, DLCO and LV diastolic function may identify patients at higher risk and in need of closer cardiac monitoring.

## SAT0231 PHYSICAL ACTIVITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

S.I. Liem[1], J.M. Meessen[2], R. Wolterbeek[3], A.A. Schouffoer[1], M.K. Ninaber[4], N. Ajmone Marsan[4], T.P. Vliet Vlieland[2], J.K. De Vries-Bouwstra[1].
*[1]Rheumatology; [2]Orthopaedics; [3]Medical Statistics; [4]Heart and Lung Centre, LUMC, Leiden, Netherlands*

**Background:** Due to involvement of the skin and vital organs systemic sclerosis (SSc) can affect physical activity (PA). For SSc, positive effects of exercise therapy have been reported.[1] To support SSc patients to improve the exercise capacity it is important to be informed about the overall level of PA of patients with SSc, and disease specific manifestations that might interfere with exercise.

**Objectives:** To gain more insight in the level of PA of Dutch SSc patients, this study assessed the self-reported levels of PA in SSc patients and compared these levels to data of the general Dutch population. In addition, factors associated with PA levels in SSc patients and needs and preferences of SSC patients regarding exercise were examined.

**Methods:** Fifty-nine SSc patients referred to a multidisciplinary health care program and fulfilling the ACR 1980[2] or LeRoy[3] criteria for systemic sclerosis filled in the Short QUestionnaire to ASess Health-Enhancing PA (SQUASH) comprising 10 questions about PA[4]. The proportion of patients meeting the Dutch public health recommendation for PA (i.e., moderate PA for 30 minutes on > or =5 days/wk) and the total number of minutes of PA per week were calculated. These data were compared with similar data from a representative sample of the general Dutch population. Characteristics of patients with high level of PA (defined as > mean PA in minutes/week for the Dutch population) were compared with patients with low level of PA (≤ mean PA in minutes/week for the Dutch population). The needs and preferences of patients with SSc regarding exercise were assessed.

**Results:** The proportion of SSc patients meeting the Dutch Recommendation for Health Enhancing PA was higher than the proportion of the general Dutch population (68% vs 59% for the total group; P not significant). The average number of minutes of PA per week was significantly lower in the SSc population compared with the general population (1729 vs. 2614, respectively, P<0.001). No significant association was found between specific disease characteristics and lower level of PA. SSc patients who did not meet the Dutch Recommendation for Health-Enhancing PA more often reported pain during exercise and a lack of energy interfering with exercise. Thirty percent of patients stated to need more information about exercising and depended on advices of the rheumatologist concerning exercise.

**Conclusions:** The proportion of SSc patients meeting the Dutch Recommendation for Health-Enhancing PA is not significantly different from the Dutch population. However, with respect to the average number of minutes of PA per week, SSc patients were less physically active. In patients not meeting the Dutch recommendation for Health Enhancing PA pain and lack of energy might interfere with proper exercising.

## SAT0232 ANTI-CENTROMERE ANTIBODY POSITIVE DIFFUSE SCLERODERMA IS UNCOMMON BUT HAS A DISTINCT CLINICAL PHENOTYPE

J. Caetano[1], S. Nihtyanova[2], J. Harvey[3], V. Ong[2], C. Denton[2]. *[1]Medicine IV, Fernando Fonseca Hospital, Amadora, Portugal; [2]Centre for Rheumatology and Connective Tissue Diseases, University College London Medical School, Royal Free Hospital; [3]Department of Immunology, Royal Free Hospital, London, United Kingdom*

**Background:** Anti-centromere antibodies (ACA) typically associate with limited cutaneous disease subset (lcSSc) in scleroderma, and are protective for renal crisis (RC) and interstitial lung disease (ILD). Only 5–7% of ACA positive patients have the diffuse subset (dcSSc). Both antibody specificity and disease subset may influence disease phenotypic expression and organ manifestations.

**Objectives:** To describe demographic and clinical manifestations of ACA positive patients with dcSSc (ACA+diffuse), comparing with two other subsets: ACA positive with lcSSc (ACA+limited) and ACA negative with dcSSc (non-ACA diffuse).

**Methods:** Retrospective study of consecutive patients ACA+diffuse from a single large referral center between 2001–2015. Comparative analysis was made with 160 consecutive patients ACA+limited and 260 consecutive patients non-ACA diffuse. Data were obtained by medical records review.

**Results:** 1313 patients ACA+ were identified, 36 (2.7%) had dcSSc. The peak modified Rodnan skin score was lower in ACA+diffuse compared with non-ACA diffuse (24.0±9.9 vs 27.4±10.4, p=0.031), but occurred later in disease course (88.8±77.2 vs 30.7±33.1 months, p<0.001).

Survival in ACA+ was similar for both subsets with 5, 10 and 15 years survival rates of 96%, 84% and 73% in ACA+limited and 94%, 80% and 72% in ACA+diffuse. Non-ACA diffuse had lower survival of 85%, 72% and 55% at 5, 10 and 15 years respectively, although the difference from ACA+diffuse was not significant.

ACA+diffuse had higher incidence of ILD than ACA+limited (p=0.018), but significantly lower than non-ACA diffuse (p=0.003). During follow-up at 5 years, 15% of ACA+diffuse developed ILD (3% - ACA+limited; 36% - non-ACA diffuse). At 15 years, cumulative incidence of ILD was 26% in ACA+diffuse (5% - ACA+limited; 49% - non-ACA diffuse).

More patients developed pulmonary hypertension (PH) in ACA+diffuse group (27.8%), than in the other groups (12.5% - ACA+limited; 11.9% - non-ACA diffuse), though this was mainly due to longer follow-up of ACA+diffuse. Cumulative incidence of PH in ACA+diffuse was not different from the other groups. At 5 years, 8% of ACA+diffuse had PH (6% - ACA+limited, 6% - non-ACA diffuse), while at 15 years cumulative incidence was 24%, 20% and 18% respectively.

Similarly, cardiac involvement was more frequent in ACA+diffuse (8.3%) vs 1.9% in ACA+limited and 6.5% in non-ACA diffuse, but differences were not significant adjusting for time of follow-up. In contrast, incidence of RC was higher in non-ACA diffuse (13.9%), affecting only 2 patients in ACA+diffuse (5.6%) and none in ACA+limited.

**Conclusions:** This study confirms that ACA diffuse subset is infrequent, but has a distinct clinical phenotype. Despite the dcSSc, these patients have a more insidious onset of skin and major organ involvement, which may represent a therapeutic window for early intervention. We confirm that ACA+ has a protective role and is associated with lower incidence of ILD and RC and better survival than expected in dcSSc. The role of ACA in patients with dcSSc as a possible phenotype modifier needs to be explored further in larger prospective studies.

## SAT0233 DESCRIPTIVE STUDY OF CARDIOVASCULAR RISK FACTORS AND ENDOTHELIAL DISFUNCTION IN PATIENTS DIAGNOSED WITH SCLERODERMA AND MIXED CONECTIVE TISSUE DISEASE

J.J. Gonzalez Martin[1], O. Carrion[2], A. Abdelkader[2], E. Calvo[1], M. Valero[1], S. Rodriguez[1], I. Amil[1], C. Marin[1], C. Sangüesa[1], L. Ruiz[1], F. Aramburu[1], F. Sainz[2], P. Garcia de la Peña[1]. *[1]Rheumatology; [2]Vascular Surgery, Hospital Madrid Norte Sanchinarro, Madrid, Spain*

**Background:** Cardiovascular complications are a common cause of morbidity in inflammatory arthritis and connective tissue diseases like several studies have shown.
**Objectives:** Detection of cardiovascular risk factors and endothelial dysfunction in patients diagnosed with Systemic Sclerosis (SSc) and Mixed Connective Tissue Disease (MCTD). Creation of a longitudinal cohort of patients.
**Methods:** Studies have been collected from April 2012 to December 2015. The data collection protocol included BMI, dyslipidemias, DM, HTN, previous or active smoking, thrombotic episodes, strokes and ischemic cardiopathy. ESR, CPR, cholesterol level, LDL, HDL, triglycerides, 25OH-D and homocysteine levels were requested to all patients. Vascular surgery's ultrasound protocol was: 1. Carotid study, intima-media thickness (IMT) and presence of plaques; 2. Ankel branquialindex (ABI), being pathological when ABI $\leq$0.9; 3. Endothelial dysfunction was assessed measuring abnormal brachial artery flow-mediated dilatation (FMD) after a four minutes transient ischemia period, being patologic if FMV $<$10% and severe if $<$5%.
**Results:** A total of 61 patients (95.1% women) were included: 28 SSc limited, 21 SSc diffuse, 2 SSc Sine Scleroderma, 4 MCTD, 3 overlap SSc-polymyositis and 3 Prescleroderma. The mean age at the time of the study and diagnosis were 49 (19–76) and 46 years (17–75). The average time of the disease was 5 years (0–37). 7 patients had HTN, 2 had DM, 18 hyperlipidemia (10 HCL, 2 HTG, 6 mixed hyperlipidemia), 9 active smokers, 18 ex-smokers, 2 patients with stroke, 2 have had thrombotic episodes and 1 had ischemic heart disease. The mean BMI was 24 (18–50) and 37.3% had a BMI$>$25.
The mean value of the different analytic parameters was: ESR: 15 mm/h (1–55), PCR: 2.7 mg/L (0,1–22), COL: 198 mg/dL (143–298), 25OH D Vitamin:23,6 ng/mL (12–118), homocystein 10.8 micromol/l (5,9–19,5) and 21.4% had pathological levels $\geq$15 micromol/l. The mean modified Rodnan skin score was 9 (0–42), 20% of patients had ILD and 3 patients had PAH. 64% patients were treated with steroids, 65% DMARDs and 13.1% biologic therapies.
The echographic findings were the following:
1. The mean right and left common carotid IMT were 0.6 (0.47–1.2) and 0.7 mm (0.44–1.3) respectively. 66% and 61.2% of the cases had an increase of right and the left IMT respectively and 43% of both when it was compared with age group of reference population.
2. 26% had unilateral plaques and 7% bilateral plaques.
3. Three patients had a pathologic ABI.
4. The average FMV was 4%, 80% cases had endothelial dysfunction, being severe in 51% of these.

**Conclusions:**
1. Nearly 40% of patients have overweight (BMI$>$25).
2. A high percentage of patients (16%) have hyperhomocyisteinemia.
3. The percentage of subjects with increased IMT is high, around 65%. The presence of plaques is less frequent (30%).
4. Endothelial dysfunction was found in 80% of the cases, and it was severe in almost 50%.

## SAT0234 STUDY OF THE ROLE OF IL-6 IN THE DEVELOPMENT OF ATHEROSCLEROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

J.J. Alegre Sancho[1], M. Robustillo Villarino[1], G. Albert Espí[1], C. Vergara Dangond[1], E. Vicens Bernabeu[1], D. Ybáñez García[1], È. Valls Pascual[1], À. Martínez-Ferrer[1], J.A. Román Ivorra[2]. *[1]Rheumatology Department, Hospital Universitari Dr. Peset; [2]Rheumatology Department, Hospital Universitari i Politècnic la Fe, Valencia, Spain*

**Background:** IL-6 is one of the cytokines with greater presence in Systemic Sclerosis (SSc) and also one of the key cytokines in the development of atherosclerosis (AS). A recent study (Schiopu E, et al. Rheumatology 2014;53:704–713) has shown a relationship between IL-6 and carotid AS. However, the number of patients was scarce, the results were not confirmed in a multivariate analysis and whether these results are replicable in different populations in different geographical areas has not been tested.
**Objectives:** To assess the relation between plasma IL-6 and AS findings (carotid ultrasound, ankle-brachial index [ABI] and arterial pressure difference between arms) in patients with SSc.
**Methods:** Transverse descriptive study with analytical components. Study population: a cohort of 115 patients with SSc controlled in the Rheumatology Department of a tertiary hospital. Variables: 1) clinical variables; 2) determination of serum IL-6 (IMMULITE 2000; Siemens Healthcare Diagnostics, UK); 4) vascular study: ABI and carotid doppler ultrasound (ESAOTE MyLab XV70, 7–12 MHz linear transducer, software $^{RF}$QIMT) measuring intima-media thickness (IMT) and presence of atheroma plaques (Mannheim Consensus). A vascular surgeon measured ABI, and the doppler ultrasound was done by a highly experienced rheumatologist, blind to the rest of findings, in a term of 3 months. Statistical analysis: IBM-SPSS Statistics v22.0 package.
**Results:** 115 patients where included consecutively, of which finally 108 were studied; with a mean age of 60,16 years (SD ±15.16); 99 women (91.7%) and 9 men (8.3%). Mean SSc evolution time was 11.45 years (SD ±8.84). LSSc was most frequently diagnosed (50%), followed by SSc without scleroderma (18.5%) and, decreasingly, DSSc (16.7%), overlap syndrome (9.3%) and pre-SSc (5.6%). 38.9% of patients were hypertensive, 46.3% suffered a DL and 6.3% were diabetic. Mean concentrations of serum IL-6 were 4.34 pg/mL (SD ± 5). Mean right IMT was 0.579 mm (SD ± 0.126), and left 0.657 mm (SD ±0.158); 33.3% had atheroma plaque. In total, 37% had a pathological carotid ultrasound and 39.8% macrovascular damage (atheroma plaque and/or IMT$>$0.9 mm and/or ABI$<$0.9). In the bivariate analysis, serum IL-6 was associated to the IMT as well as the presence of atheroma plaque ($p$-value = 0.002).This association was maintained when jointly considering an ABI$<$0.9 ($p$-value = 0.003). Serum IL-6 was also related to the difference in systolic arterial pressure between both arms (r-Pearson =0.236; $p$-value = 0.022). In the multivariate analysis, the number of atheroma plaques and the macrovascular damage variable maintained statistical significance in the different models.
**Conclusions:** Serum IL-6 concentrations are independently related to the presence of AS and macrovascular disease in patients with SSc. Blocking the action of IL-6 by means of specific therapies could be a therapeutic option which could reduce macrovascular damage in patients with SSc.

## SAT0235 SURVIVAL IN SYSTEMIC SCLEROSIS RELATED PULMONARY ARTERIAL HYPERTENSION IN THE MODERN TREATMENT ERA: RESULTS FROM A MULTICENTRE AUSTRALIAN COHORT STUDY

K. Morrisroe[1], M. Huq[2], W. Stevens[3], C. Rabusa[2], S. Proudman[4], M. Nikpour[3] on behalf of Australian Scleroderma Interest Group (ASIG). *[1]Rheumatology and Medicine, St Vincent's Hospital, Melbourne; [2]Rheumatology, St VIncents Hospital; [3]Rheumatology, St Vincent's Hospital, Melbourne; [4]Rheumatology, Royal Adelaide Hospital, Adelaide, Australia*

**Background:** Pulmonary arterial hypertension (PAH) is the leading cause of mortality in patients with systemic sclerosis (SSc).
**Objectives:** To determine the cumulative survival rates and predictors of mortality in SSc- PAH
**Methods:** Patients enrolled in a SSc longitudinal cohort between 2007 and 2015 were included. PAH was diagnosed on right heart catheterization (RHC) (mPAP $>$25 and PAWP $<$15 mmHg). Patients with pulmonary hypertension secondary to interstitial lung disease (ILD) and co-existent PAH and severe interstitial lung disease (ILD) (defined as a HRCT scan demonstrating ILD with a FVC$<$60%) were excluded. Summary statistics, chi-square tests and survival methods including Kaplan-Meier survival curves and cox proportional hazards regression were used to determine survival rates and identify predictors of mortality.
**Results:** Among 132 SSc PAH, 84.9% were female, 68.9% had limited disease subtype (lcSSc), the mean age at diagnosis of PAH was 62.3 years and disease duration at PAH diagnosis was 14.1 years. Over a median follow-up of 3.7 years, 60 (45.5%) patients died with a median survival time from PAH diagnosis of 3.7 years. The standardized mortality ratio for patients with SSc-PAH compared with mortality in the general population is 5.8 (95%CI 4.3–7.8). The years of life lost overall for both males and females due to SSc-PAH was 15.22 years (95%CI 12.3–18.1). Kaplan-Meier survival curves showed a survival advantage with

Table 1. Independent predictors of mortality in SSc-PAH

| Characteristic | Hazard Ratio (95% CI) | p-value |
|---|---|---|
| Age at diagnosis of PAH, years | 1.05 (1.0–1.1) | 0.03 |
| ILD (FVC $>$60%) | 2.83 (1.4–5.6) | 0.01 |
| WHO functional class | 2.01 (1.1–3.9) | 0.03 |
| Pulmonary arterial pressure, mmHg | 1.06 (1.0–1.1) | 0.001 |
| Digital ulcers present | 3.12 (1.4–7.2) | 0.01 |
| Specific PAH therapies and anticoagulation | | |
| Vasodilator monotherapy only | reference | reference |
| Vasodilator monotherapy and anticoagulation | 0.39 (0.1–1.2) | 0.09 |
| Vasodilator combination therapy only | 0.49 (0.2–1.2) | 0.10 |
| Vasodilator combination therapy and anticoagulation | 0.28 (0.1–0.7) | 0.007 |

Abbreviations: PAH, pulmonary arterial hypertension; WHO, World Health Organization; ILD, interstitial lung disease; 6MWD, six minute walk distance; mRAP, mean right atrial pressure; mPAP, mean pulmonary arterial pressure; HCQ, Hydroxychloroquine.

combination therapy and anticoagulation. In cox proportional hazards regression analysis (table1), older age at PAH diagnosis, presence of mild ILD, worse WHO functional class, higher mean pulmonary arterial pressure at PAH diagnosis and presence of digital ulcers were predictive of PAH mortality. Combination PAH therapy together with anticoagulation, provided the most significant survival advantage with a 72% reduction in mortality compared with pulmonary vasodilator therapy alone.

**Conclusions:** Despite advanced therapy, the median survival in SSc PAH is only 4 years. In our study, the addition of anticoagulation to standard combination therapy was associated with a significant survival advantage, pointing to mechanisms involving endothelial abnormalities and small vessel thrombosis in the pathogenesis of PAH.

## SAT0236 THE TRADITIONAL CARDIOVASCULAR RISK FACTORS AND THEIR RELATIONS TO HEART STRUCTURE IN PATIENTS WITH SYSTEMIC SCLEROSIS

L. Ananyeva, E. Cheremukchina, D. Novikova, R. Alekperov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Cardiac involvement is one of the important factors of a poor prognosis in Systemic Sclerosis (SSc). Different pathogenetic mechanisms are involved in heart pathology in SSc, including microvascular disease and the atherosclerotic process. The relationship between primary cardiac involvement and atherosclerosis (AS) is under investigation.

**Objectives:** To evaluate frequency of the traditional cardiovascular disease risk factors (TRF) and their relations with the heart structure abnormalities in SSc

**Methods:** 125 pts with SSc (113 women, mean age 51±12 years, mean duration of the disease 8, 9±8) who met to ACR/EULAR criteria (2013). The limited type of the disease had 73% of pts. There were no cases of nephropathy, 18 pts (15%) had systolic pulmonary arterial pressure (PAP) >40 mmHg and 63 (50%) had interstitial lung disease. The assessed TRF were age, sex, overweight (a body mass index [BMI] >25 kg/m$^2$, arterial hypertension [AH] (>140/90 mmHg), DM, smoking, total cholesterol (TC). The ten-year risk of fatal cardiovascular disease (CVD) was evaluated by SCORE. 50 age- and sex matched volunteers were used as a control. Echocardiography (ECHO) was performed in 121 pts

**Results:** The increased BMI was detected in 60 (48%) of pts and 15 (30%) of controls (p=0, 03). The TC level was >5, 2 mmol/l in 69 (55%) of pts and 38 (76%) of controls (p=0, 01). Arterial blood pressure (ABP) was elevated in 33 (25%) of pts and in 16 (32%) of controls (p>0, 05), the frequency of others TRF was not significantly different from controls. The high/very high SCORE >5% had 36 (28, 8%) of pts and 4 (8%) of controls (p=0,003). Among them the very high risk (SCORE >10% or coronary heart disease and experienced a cardiovascular event) had 20% of pts and 6% of controls (p=0, 02). The low/moderate values of SCORE <5% had 89 (71%) of pts and 46 (92%) of controls (p=0,003). When compared pts >50 and ≤50 yrs. the higher prevalence of AH (36% and 12%, p=0,003) and hypercholesterolemia (62, 7% and 44%, p=0, 04) were demonstrated in older pts. The ECHO revealed abnormalities in 100 (83%) of pts. The prevalence of ECHO changes was significantly higher in pts with AH when compared to pts with normal level of ABP. The following changes had higher rate in pts with AH: the diastolic dysfunction of left ventricle (LV) (60,6% and 36,4%, p=0,016), thickened aortic (88% and 52%, p=0,0003) and/or mitral leaflets (69,7% and 36%, p=0,001); calcinosis of aortic (36% and 16%, p=0,015) and/or mitral leaflets (33% and 4,5%, p=0,000), dilatation of the left atrium (30% and 8%,p=0,0016). The rate of ECHO valvular abnormalities was higher in pts who were older 50 yrs compared with those <50 yrs. The LV hypertrophy was revealed in 10/58 of pts with overweight and in 3/63 of pts with normal weigh (p=0, 03). The prevalence of thicked aortic leaflets was higher in pts with elevated level of TC comparing with those who had normal values of TC in sera (p=0, 02).

**Conclusions:** Our study displayed the higher cumulative 10-year risk for CVD according to SCORE and indicated a higher prevalence of clinical AS (CHD) ischemic arterial events) in SSc comparing with controls. Presence of the TRF in patients was assosiated with more severe heart structure abnormalities. Appropriate management should be carried for high CVD risk categories of patients, especially in older ones in presence of systemic AH.

## SAT0237 NAILFOLD CAPILLAROSCOPY FINDINGS IN SCLERODERMA PATIENTS – PROGNOSTIC IMPLICATIONS

L.C. Teixeira, I. Cordeiro, S. Sousa, A.C. Duarte, J. Canas da Silva, A. Cordeiro, M.J. Santos. *Rheumatology, Hospital Garcia de Orta, Almada, Portugal*

**Background:** Nailfold *capillaroscopy* (NCP) is a useful tool for the diagnosis and follow-up of systemic rheumatic diseases and represents one of the best methods to evaluate microvascular abnormalities.

**Objectives:** To characterize NCP findings of patients with Systemic Sclerosis (SSc), and understand how NCP associates with the presence of digital ulcers, gastrointestinal involvement, pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD).

**Methods:** NCP findings of adult patients with SSc followed-up in our center were reviewed. Demographic and clinical features were collected. Nonparametric tests were used to determine potential associations between capillaroscopy findings/patterns and the presence of digital ulcers, gastrointestinal involvement, PAH and ILD.

**Results:** In total, 52 out of 103 patients with SSc had at least one NCP result available. Forty five were female (86.5%) and seven male (13.5%), the age was 56.6 ±13.2 years and disease duration 10.9 ±10.5 years. Thirty one (59.6%) had limited cutaneous SSc, seven (13.5%) diffuse cutaneous SSc, ten (19,2%) VEDOSS, three (5.8%) overlap syndromes and one (1.9%) SSc sine scleroderma. (table 1). The most frequent NCP findings were hemorrhages (54.7%) megacapillaries (54.7%), and capillary dilatations (52.8%).

We found that digital ulcers were significantly associated with the existence of avascular areas (p=0.02), and with neoangiogenesis (p=0.03) in univariate analysis, but were not associated with any capillaroscopy pattern. Looking to interstitial lung disease, there is a trend for association with the presence of avascular areas (p=0.056). Only one patient had PAH confirmed by right heart catheterization. In this case NCP showed giant capillaries, neoangiogenesis and avascular areas. There was also a trend for association between avascular areas and higher values of NT pro BNP (p=0.078). Gastrointestinal involvement was not significantly associated with NCP findings (table 2).

Table 1. Distribution of patients according to NCP and disease subtypes

| | Diffuse cutaneous (n=7) | Limited cutaneous (n=31) | Overlap syndrome (n=3) | VEDOSS (n=10) | Sine scleroderma (n=1) |
|---|---|---|---|---|---|
| Early pattern n (%) | 0 (0) | 9 (29) | 1 (33) | 6 (60) | 0 (0) |
| Active pattern n (%) | 1 (14.2) | 5 (16.1) | 1 (33) | 2 (20) | 0 (0) |
| Late pattern n (%) | 3 (42.9) | 7 (22.6) | 0 (0) | 0 (0) | 0 (0) |
| Nonspecific n (%) | 3 (42.9) | 8 (25.8) | 1 (33) | 1 (10) | 1 (100) |

| **Dilatations** (%) (p value) | 64.3 (0.451) | 42.9 (0.693) | 0 | 45.5 (0.647) |
| **Haemorrhages** (%) (p value) | 71.4 (0.233) | 42.9 (0.360) | 0 | 45.5 (1) |
| **Megacapillaries** (%) (p value) | 71.4 (0.124) | 57.1 (0.693) | 100 | 45.5 (0.647) |
| **Neoangiogenesis** (%) (p value) | 57.1 **(0.03)** | 42.9 (0.282) | 100 | 45.5 (0.390) |
| **Avascular areas** (%) (p value) | 0.5 **(0.02)** | 42.9 **(0.056)** | 100 | 36.4 (0.673) |

Table 2 – NCP findings and clinical manifestations of SSc (*Patients submitted to right heart catheterization).

**Conclusions:** In our study the presence of avascular areas and neoangiogenesis in NCP was significantly associated with the existence of digital ulcers. Also, ILD and higher values of NT-proBNP were more common in patients who present avascular areas. These results suggest that abnormalities detected in the NCP might help predict organ involvement, although long term follow up and greater numbers of patients are needed in order to confirm the prognostic value of NCP findings.

## SAT0238 SUBCLINICAL ATHEROSCLEROSIS IS LOWER IN PATIENTS WITH SYSTEMIC SCLEROSIS THAN IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Robustillo Villarino[1], E. Rodilla Sala[2], C. Vergara Dangond[1], G. Albert Espi[1], D. Ybáñez García[1], È. Valls Pascual[1], À. Martínez-Ferrer[1], E. Vicens Bernabeu[1], M. Aguilar Zamora[1], J.J. Alegre Sancho[1]. *[1]Rheumatology, Hospital Universitario Dr. Peset; [2]Internal Medicine, Hospital General de Sagunto, Valencia, Spain*

**Background:** Different studies and meta-analysis have shown that subclinical atherosclerosis (AS) and vascular complications (VC) are higher in patients with Systemic Sclerosis (SSc) than in healthy population. A major intrahospital mortality because of VC in patients with SSc as to those with Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) has also been described (Dave AJ, et al. Arthritis Care Res 2014; 66: 323–7).

**Objectives:** To compare the presence of subclinical AS among patients with SSc, RA and a population of healthy people.

**Methods:** Transverse study including patients diagnosed with SSc and RA, controlled in a Rheumatology Department of a tertiary hospital. Patients with previous VC, renal failure and/or diabetes were excluded. The control group (healthy individuals) were volunteers from the same geographical area. We gathered demographic variables (age,gender,BMI), smoking status, clinical (blood pressure), and analytical variables (cholesterol fractions, atherogenic index [AI]). The extracranial branches of carotid artery were explored by ultrasonography

(US) using an ESAOTE MyLab XV70 with a 7–12 MHz linear transducer and an automated program measuring intima-media thickness (IMT) through radiofrequency ($^{RF}$QIMT). The presence of atheroma plaques as per the Mannheim consensus was registered. Statistical analysis was done using the IBM-SPSS Statistics v22.0 package.
**Results:** 266 patients were included, 23,7% (85) with SSc and 50,4% (181) with RA. The control group was conformed by 93 healthy individuals. Women proportion, arterial hypertension and age were greater in RA and SSc patients than in healthy subjects ($p<0,001$); but smoking status was higher in healthy subjects ($p<0,001$). BMI showed lower values in patients with SSc than RA (p=0,046) and the healthy group (p=0,008). No differences were found between groups in the rest of analyzed variables. Results of the vascular study, grouped by diagnosis, is shown in the table below.

| | AS plaques % (n) | IMT μ mean (SD) | Pathologic IMT % (n) | Pathologic US % (n) |
|---|---|---|---|---|
| SSc | 22,6 (19) | 643,1 (149,7) | 8,2 (7) | 27,1 (23) |
| RA | 42 (76) | 718,2 (158,0) | 12,7 (23) | 44,2 (80) |
| Healthy | 24,7 (23) | 590,3 (123,0) | 0 (0) | 23,7 (22) |

A major prevalence of atheroma plaque and pathologic US was seen in RA patients than in SSc patients (p=0,002 and p=0,007, respectively) and healthy subjects (p=0,005 and p=0,001, respectively), whereas no differences between SSc and healthy subjects were seen within these results. Patients with SSc, however, showed higher mean IMT values than healthy subjects (p=0,047) but less than patients with RA ($p<0,001$), with a higher percentage of patients with IMT>0,9 than healthy subjects (p=0,005) in the bivariate analysis. However, this association was lost in the multivariate analysis, and these differences might be due to age and arterial hypertension differences between groups.
**Conclusions:** RA is a more atherogenic disease than SSc, probably because of its higher inflammatory load. Higher mortality by VC in SSc could be attributed to a major multiorganic affection of the disease. In our serie we didn't find a higher prevalence of subclinical AS in patients with SSc than in healthy subjects.

## SAT0239 THE CUMULATIVE NUMBER OF MICRO-HAEMORRHAGES AND MICRO-THROMBOSIS IN NAILFOLD VIDEOCAPILLAROSCOPY IS A GOOD PREDICTOR OF DISEASE ACTIVITY IN SYSTEMIC SCLEROSIS: A VALIDATION STUDY OF NEMO SCORE

N. Del Papa [1], R. Irace [2], R. Andracco [1], D. Sambataro [1], S. Vettori [2], F. Pignataro [1], R. Ferrara [2], E. Zaccara [1], W. Maglione [1], C. Vitali [3], G. Valentini [2]. *[1] U.O.C. Day Hospital Reumatologia, Osp. G. Pini, Milano; [2] Rheumatology Unit, Dept Internal Experimental Medicine, II University Naples, Napoli; [3] Sez. Reumatologia, Villa S. Giuseppe, Anzano del Parco, Como, Italy*

**Background:** In a previous study it has been shown shown that, in patients with systemic sclerosis (SSc), the cumulative number of micro-haemorrhages (MH) and micro-thrombosis (MT), computed in eight finger nailfold videocapillaroscopy (NVC), and called NEMO score, was strongly predictive of disease activity (DA) measured by means of European Scleroderma Study Group (ESSG) score. Even the number of giant capillaries (GC) was correlated to a lesser extent with the ESSG score, and then a modified (m) NEMO score was proposed in which the combined presence of a MH/MT and GC was considered [1].
**Objectives:** The present study was aimed at validating NEMO score in different cohorts of patients.
**Methods:** NEMO score and the total number of GC were assessed by eight finger NVC in 122 patients with SSc referring to the Rheumatic Disease Unit of the "Istituto G.Pini" of Milan, where the preliminary study had been carried out (internal validation). The same procedure was performed in 99 patients collected in a different centre, i.e., the Rheumatic Dept. of the II University of Naples (external validation). In all of the patients DA, measured by ESSG score, was assessed at the same time of NVC performance.

Table 1

| | Number of patients | Male/ female | Patients with lcSSc/dcSSc | Age (years), mean (range) | Years from diagnosis, mean (range) | Patients with a ESSG score ≥3 |
|---|---|---|---|---|---|---|
| Milan Cohort | 122 | 8/114 | 60/62 | 53 (17–82) | 6 (0–28) | 54 |
| Naples Cohort | 99 | 10/89 | 58/41 | 53 (20–80) | 8 (1–30) | 77 |
| All patients | 221 | 18/203 | 118/103 | 53 (17–82) | 7 (0–30) | 121 |

lcSSc = limited cutaneous SSc; dcSSc = diffuse cutaneous SSc.

Table 2

| | Correlation* of NEMO vs. ESSG score | Correlation* of GC vs. ESSG score | NEMO ROC curve for ESSG score ≥3 | Sens./spec. of NEMO >7 for ESSG score ≥3 |
|---|---|---|---|---|
| Milan Cohort | R=0.54; p<0.0001 | R=0.22; p<0.02 | AUC=0.81 | 75.9/79.7 |
| Naples Cohort | R=0.59; p<0.0001 | R=0.50; p<0.0001 | AUC=0.88 | 89.5/71.9 |
| All patients | R=0.58; p<0.0001 | R=0.31; p<0.0001 | AUC=0.83 | 83.2/77.1 |

*By Spearman Rank correlation; Sens./spec. = sensitivity/specificity.

**Results:** Demographic and clinical characteristics of the patients were summarised in Table 1. Table 2 shows the main statistical results obtained by the analysis of the two cohorts.
The mNEMO score does not add anything in terms of sensitivity and specificity to the performance of the simple NEMO score in predicting DA.
**Conclusions:** This validation study confirms that the presence of a certain number of MH plus that of MT in eight finger NVC may represent a simple screening method to predict the presence of DA in patients with SSc.

## SAT0240 SNPS IN THE BAFF GENE ARE ASSOCIATED WITH INCREASED RISK OF ANTI-JO-1-POSITIVITY AND HIGH SERUM BAFF LEVELS IN PATIENTS WITH MYOSITIS

O. Krystufkova [1,2], T. Svitalkova [1,2], H. Hulejova [1], M. Svetla [1], L. Plestilova [1], M. Pavlíková [1], M. Misunova [1], M. Klein [1,2], H. Mann [1], P. Novota [1], J. Vencovsky [1]. *[1] Institute of Rheumatology; [2] Department of Rheumatology, 1st Faculty of Medicine of Charles University, Prague, Czech Republic*

**Background:** B-cell activating factor of the TNF family (BAFF) plays a role in (auto)antibody production. Elevated serum levels (sBAFF) were found in patients with myositis. Associations of elevated sBAFF with a SNP in the 5'regulatory region of the BAFF gene were reported in patients with autoimmune diseases, together with TTTT haplotype of the four SNPs located upstream of the BAFF gene. TTTT was associated with myositis in Czech patients, independently from the HLA-DRB1*03 allele.
**Objectives:** Here we evaluate associations of sBAFF with particular SNPs, anti-Jo-1-autoantibodies, HLA-DRB1*03, ILD and disease activity in myositis.
**Methods:** The SNPs (rs9514828:871C>T, rs9514827:-2841T>C, rs3759467:-2704T>C and rs1041569:-2701T>A) were analysed by direct DNA sequencing in 311 patients with myositis (age:58.0±14.5 (years), females=74%) and 113 healthy controls (age:40.6±14.3, females=70%). Levels of sBAFF were measured by ELISA. Autoantibodies were detected by immunoprecipitation. Multivariable logistic regression model for presence of anti-Jo-1-autoantibodies and nonparametric tests for group comparisons and correlation analysis were used.
**Results:** Analysed patients cohort included 150 DM, 139 PM, 51% ILD and 24% anti-Jo-1-positive patients. HLA-DRB1*03 was present in 45% of patients and 16% of controls. Higher s-BAFF levels were detected in: patients compared to healthy controls ($p<0.0001$), patients with anti-Jo-1-autoantibodies compared to autoantibody negative (p=0.02), patients with early (duration≤6 month; n=114) compared to late disease (p=0.038) and were associated with creatine kinase (CK) levels (rho=0.36; $p<0.0001$) and disease duration (rho=-0.2; p=0.0007).
Logistic regression model explaining 49% (McFadden $R^2$=0.49) of the data variability included, besides ILD (OR=27.24; $p<0.0001$) and HLA-DRB1*03 (OR=5.26; p=0.0009), significant additive effect of the BAFF gene SNPs: -2841T allele (OR=2.55; p=0.028) and a -871TT genotype (OR=7.75; p=0.007). The alternative substitution of CK concentration (OR=1.48; p=0.175) with sBAFF (OR=0.67; p=0.037) lowered model stability ($R^2$=0.38). However, the additive effect of -871T allele to sBAFF levels in anti-Jo-1-positive patients compared to autoantibody-negative (higher in -871TT: p=0.023 and -871CT: p=0.043) and the opposite association in -2841TT genotype (higher in -2841CC: p=0.033 and -2841CT: p=0.068) were seen.
**Conclusions:** In addition to ILD and HLA-DRB1*03 allele, SNPs of the promotor region of the BAFF gene, -871C>T and -2841T>C, increase the risk of having anti-Jo-1-autoantibodies and high sBAFF levels in patients with myositis.

## SAT0241 OBSERVATIONAL STUDY OF SEASONAL MONTHLY INFUSIONS OF ILOPROST –EXPERIENCE FROM A REGIONAL CENTRE IN UK

P. Joshi [1], S. Venkatachalam [2], T. Sheeran [2]. *[1] Rheumatology, Hospital, Ahmedabad, India; [2] Rheumatology, Cannock Chase Hospital, Cannock, United Kingdom*

**Background:** Iloprost (Prostacyclin) is effective for resistant Raynaud's phenomenon. We describe our practice of seasonal once monthly infusion which is more cost-effective and flexible than the usual practice of giving iloprost for 3 to 5 days.
**Objectives:** To identify the characteristics, response and tolerance of patients on seasonal monthly infusions of Iloprost from a regional centre in Cannock, United Kingdom.
**Methods:** Retrospective data analysis of patients having monthly iloprost infusions before and during winter for 3–4 months a year (November to February) for resistant Raynaud's phenomenon in 2013 and 2014.
**Results:** There were 72 patients; 57 females and 15 males (F/M =3.8/1), with a mean age of 50.2 (±15.1) years at the start of the iloprost infusion.

Underlying diagnosis:

| | |
|---|---|
| Scleroderma – limited | 26 (36.1%) |
| Scleroderma – diffuse | 6 (8.3%) |
| Mixed connective tissue disease | 10 (13.8%) |
| Primary Raynaud's | 10 (13.8%) |
| Systemic lupus erythematosus | 7 (9.7%) |
| Rheumatoid arthritis | 5 (6.9%) |
| Undifferentiated connective tissue disease | 3 (4.1%) |
| Dermatomyositis | 2 (2.8%) |
| Others | 3 (4.1%) |

Sixty-four patients (88.9%) received calcium channel blockers like nifedipine prior to iloprost and 2 of them also had sildenafil. Thirteen (18.1%) patients had iloprost for 3 to 5 days before switching to seasonal monthly treatment; 8 of them had a digital ulcer or gangrene at presentation. Average follow up was 3.4 (± 2.3) years and mean number of infusions/patient/year was 3.28 ± 0.98.Iloprost improved Raynaud's symptoms in winter in all the patients and was well tolerated by most. Dose adjustment of the iloprost was necessary in 6 (8.3%) patients while 5 (6.9%) of them discontinued due to intolerance.
**Conclusions:** Monthly seasonal iloprost during winter is effective and well tolerated in patients with resistant Raynaud's phenomenon. It is also less expensive than longer courses of iloprost.

## SAT0242 LUNG INVOLVEMENT IN UNDIFFERENTIATED CONNECTIVE TISSUE DISEASES (UCTD): RELATIONSHIP WITH CLINICAL AND CAPILLAROSCOPIC FEATURES

R. Irace, A. Riccardi, S. Vettori, M. Iudici, G. Valentini. *Department of Internal and Experimental Medicine, rheumatology unit, naples, Italy*

**Background:** Patients with UCTD (1) have been reported to present lung involvement most frequently characterized by nonspecific interstitial pneumonia (NSIP) at High Resolution Computerized Assial Tomography (HR-CAT), FVC and DLCO values lower than predicted (2).
**Objectives:** To investigate UCTD patients for the presence of lung involvement and search for demographic, serological, capillaroscopic and organ involvement features associated with it.
**Methods:** Eighty-six patients consecutively admitted to the Rheumatology Unit of the Second University of Naples and satisfying criteria for the classification of UCTD (1) were enrolled into the study. Patients presenting with any major CTD marker autoantibody other than anti-Ro (SSA) and/or scleroderma capillaroscopic specific pattern were excluded. Each patient underwent a careful history, a complete physical examination, evaluation of serum Antinuclear (ANA) and anti Extraible Nuclear Antigens antibody (anti-ENA), videocapillaroscopy, echo-Doppler-cardiography with evaluation of Left ventricular E/A ratio. Those who consented also underwent HR-CAT and esophagotonometry. Interstitial lung disease (ILD) was defined by HR-CAT or, if unavailable, by FVC<80% plus DLCO<80%.
**Results:** The table lists the features detected in the patients subdivided according to the presence of lung involvement. DLCO <80% was found in 30/86 (34.8%) patients; FVC <80% in 3/86 (1.2%); HR-CAT was carried in 36/86 (41.8%) patients. It pointed a lung involvement NSIP pattern in 5/36 patients (13%).
An isolated reduction of DLCO resulted the be the most frequent finding and might depend on pulmonary vascular disease. Anti-SSA positivity and Capillaroscopic alterations were detected more frequently in patients with lung involvement (either isolated reduction of DLCO or ILD).

| FEATURE | Normal Findings (n=56) | Isolated DLCO < 80% (n=25) | ILD (n=5) | P |
|---|---|---|---|---|
| Sex (M/F) | 6/50 | 1/24 | 3/2 | 0.0004 |
| Age at admission (median;IQ range) | 38 (30- 46) | 42 (37.7- 48) | 52 (44-60) | >0.05 |
| ANA positivity (>1:160) | 56/56 | 25/25 | 5/5 | >0.05 |
| Anti SSA positivity | 9/56 | 6/25 | 2/5 | 0.01 |
| Capillaroscopic alterations | 22/56 | 15/25 | 5/5 | 0.03 |

**Conclusions:** We detected a prevalence of ILD in UCTD lower than previously reported (2) (80%). Nevertheless, we found an isolated reduction of DLCO in about 35% of the UCTD patients. Lung involvement resulted to be significantly associated with capillaroscopic alterations and anti-SSA positivity.

## SAT0243 REDUCTION OF PULMONARY ARTERY PRESSURE IN SCLERODERMA PATIENTS: THE ROLE OF LONG-TERM, INTENSIVE IV ILOPROST TREATMENT

R. Foti[1], E. Visalli[1], G. Amato[1], A. Benenati[1], G. Converso[1], S. Bellofiore[2], M. Mulè[3], M. Di Gangi[1]. *[1]Rheumatology Unit; [2]Division of General Thoracic Surgery; [3]Division of Cardiology, AOU Policlinico Vittorio Emanuele, Catania, Italy*

**Background:** Cardiopulmonary involvement is recognized as a poor prognostic factor in systemic sclerosis (SSc). So, stabilizing the cardiopulmonary parameters as long as possible may represent an important therapeutic goal. Intravenous iloprost is a first-line option for the treatment of SSc-related digital vasculopathy to reduce the frequency and severity of SSc-Raynaud's phenomenon (RP) attacks and to heal active digital ulcers in patients with SSc.[1] Some studies have suggested its role in preventing the incidence of most severe vascular complications in long term treated patients.[2–3]
**Objectives:** The aim of our study is to evaluate the evolution of the disease, with particular focus on cardiopulmonary function, in a group of consecutive patients chronically treated with iloprost at the Rheumatology Unit of AOU Policlinico Vittorio Emanuele, Catania Italy, from 2006 to 2015.
**Methods:** 59 SSc patients (59F, 51.8±12.1 years). At baseline, 71.2%, 20.3% and 6.8% had a limited, diffuse and early SSc, respectively, and 23% had interstitial lung disease.Iloprost was administered for a mean duration of 31.1±18.9 months, with a regimen of 6 infusions per month (6 hours/day, 0.5–2.0 ng/kg/min) to treat secondary RP, diagnosed at an average age of 45.9±14.8 years.We evaluated: skin score (SS), systolic pulmonary arterial pressure (PAPs), plane tricuspid annular systolic excursion (TAPSE), lung diffusing capacity of carbon monoxide (DLCO), forced vital capacity (FVC), alveolar volume (VA), DLCO/VA, pro-brain natriuretic peptide (pBNP), and NYHA class.We analyzed the patients as whole group and in groups divided according to the length of treatment: <1 year (n=10), 1–2 years (n=9), 2–3 years (n=21), >3 years (n=19).
**Results:** In the whole group of patients, SS showed statistically significant improvement from baseline (4.6±6.2 vs 3.9±6.0, p=0.034) while the other parameters showed no significant changes: TAPSE (21.5±2.3 vs 23.1±8.1 mm), PAPs (31.3±6.4 vs 30.1±9.0 mmHg), DLCO (83.5±14.4 vs 81.1±14.2 mmol/kPa.min), FVC (108.2±15.1 vs 107.9±18.2 liters), VA (93.4±11.7 vs 92.2±13.1 liters), DLCO/VA (88.1±13.7 vs 87.6±15.8), pBNP (105.2±75.1 vs 90.8±64.0 pg/ml), and NYHA class (1.0±0.0 vs 1.1±0.4).Subgroup analysis indicates a significant improvement in the SS from >1 year follow-up on, and a significant reduction of the PAPs in the subgroup of patients treated for more than 3 years. We observed an inverse correlation (R=-0.97) between the duration of treatment and the reduction of the PAPs from baseline.
**Conclusions:** An intensive (6 inf/month) and chronic regimen of iv iloprost administration seems to stabilize and potentially improve the long term evolution of disease in SSc patients, as suggested by the stabilization of cardiopulmonary parameters and the significant improvement of SS and PAPs in patients treated for more than 3 years.Our results suggest a potential effect of iv iloprost on the evolution of the disease, with a role that goes beyond the mere treatment of SSc vasculopathy.

## SAT0244 ACTIVE SKIN DISEASE AT BASELINE DOES NOT PREDICT PROGRESSION OF SKIN FIBROSIS AT ONE YEAR FOLLOW UP – A EUSTAR ANALYSIS

R.C. Dobrota[1], B. Maurer[1], N. Graf[2], O. Kowal-Bielecka[3], M. Matucci-Cerinic[4], P. Airò[5], P. Caramaschi[6], P. Carreira[7], G. Riemekasten[8], E. Rosato[9], Y. Allanore[10], O. Distler[1] on behalf of EUSTAR. *[1]Division of Rheumatology, University Hospital Zurich, Zurich; [2]Graf Biostatistics, Winterthur, Switzerland; [3]Department of Rheumatology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; [4]Division of Rheumatology, University of Florence, Florence; [5]Servizio di Reumatologia Allergologia e Immunologia Clinica, Spedali Civili di Brescia, Brescia; [6]Unità di Reumatologia, AOUI, Verona, Italy; [7]Division of Rheumatology, Hospital 12 de Octubre, Madrid, Spain; [8]Department of Rheumatology, Charitè University Hospital, Berlin, Germany; [9]Dipartimento di Medicina Clinica, Università la Sapienza, Policlinico Umberto I, Roma, Italy; [10]Rheumatology A Department, Cochin Hospital, Paris, France*

**Background:** In clinical trials of systemic sclerosis (SSc), there is an unmet need for better inclusion criteria to enrich for patients with progressive skin fibrosis [1,2]. Recent trials on skin fibrosis frequently used active skin disease at baseline as an enrichment parameter. However, there is little data available supporting such an approach.

**Objectives:** To investigate the relationship between active skin disease at baseline and progression of skin fibrosis after one year in patients with diffuse cutaneous SSc (dcSSc).
**Methods:** A longitudinal analysis of the EUSTAR registry was performed. The inclusion criteria were: dcSSc, fulfillment of ACR criteria, baseline mRSS≥7, available data for mRSS at 12±2 months. Skin progression was defined as increase in mRSS of >5 points AND ≥25% within 1 year [1]. Activity of skin fibrosis was assessed by patient-reported parameters (worsening of skin within the past month), by using a modified skin thickness progression rate (defined as MRSS at baseline visit/disease duration (years)) and by following patients with progression of mRSS in the recent 12 months for another 12 months. Additionally, non skin specific activity parameters such as the Valentini index, elevated serum inflammatory markers, and other patient reported activity parameters were also analyzed. The Mann-Whitney and the Chi-square tests were used.
**Results:** From the 637 patients included, 9.7% had progressive skin fibrosis after 1 year. The patient-reported worsening of skin fibrosis within the past month prior to baseline was not significantly associated with progressive skin disease after 1 year (p=0.774). Similarly, the modified skin progression rate at baseline did not differ between progressive and non-progressive patients at 1 year follow up (p=0.323). Most interestingly, patients with progression of skin fibrosis in the previous year were not significantly more likely to show progression of skin fibrosis in the following year (p=0.385, none of the initially progressive patients at one year showed further progression). In addition, other more general activity parameters at baseline including the Valentini activity index (p=0.673) and inflammatory markers (Erythrocyte sedimentation rate, p=0.287; C-reactive protein p=0.358) were also not associated with progression of skin fibrosis after one year (Figure 1).

Figure 1. Association of baseline parameters of active skin fibrosis and other activity parameters with skin progression at one year

| Parameter of disease activity* | Association with skin progression after one year (P-value**) |
|---|---|
| Worsening of skin in the last month (185/637) | 0.774 |
| Modified skin progression rate (590/637) | 0.323 |
| Progression of mRSS in the recent 12 months*** (377/637) | 0.385 |
| Erythrocyte sedimentation rate (175/637) | 0.287 |
| CRP elevation (177/637) | 0.358 |
| Worsening of finger vascularisation in the last month (185/637) | 0.100 |
| Worsening of cardiopulmonary symptoms in the last month (184/637) | 0.100 |
| Valentini activity index (139/637) | 0.673 |

Abbreviations: mRSS: modified Rodnan skin score
* (available cases/whole cohort)
** as by Mann-Whitney or Chi-square tests, as appropriate by variable type
*** Progression of the mRSS between the 2nd (1-year follow-up) and 3rd visit was computed only if the 3rd visit took place 12 ± 2 months after the 2nd visit.

**Conclusions:** dcSSc patients with recently active skin disease have a similar or even lower likelihood to show further progression of skin fibrosis in a 12 months trial – most likely because they have reached their peak skin score already. Recently active skin disease should not be used as an enrichment criterion in clinical trials targeting skin fibrosis.

## SAT0245 COMPARISON OF PAIN CHARACTERISTICS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY

G. Cengiz, K. Erol, K. Gok, S. Ozgocmen. *Erciyes Univ. Sch. Med. Div. Rheum. Kayseri, Kayseri, Turkey*

**Background:** Rheumatoid arthritis (RA) is a systemic inflammatory disease characterized by progressive destruction of inflamed joints leading to severe disability and functional loss. Systemic sclerosis is a multisystem autoimmune disease characterized by vasculopathy, diffuse fibrosis of skin and various internal organs. Pain is usually an overlooked entity in patients with SSc compared to RA.
**Objectives:** To compare pain characteristics particularly in terms of neuropathic pain (NeP) and to assess the possible impact of neuropathic component on functioning, physical and mental components of health related quality of life (HRQoL) in patients with RA and SSc.
**Methods:** Patients who met ACR/EULAR criteria for SSc and RA were recruited. Patients with prior diagnosis or taking medications for NeP, mood disorders, uncontrolled diabetes or neurological disorders or taking any biologic agents for their treatments were excluded. Patients were examined and evaluated for disease specific and generic outcome measures including disease activity parameters, physical functions, psychological status and health related quality of life measures (SF-36; HAQ; Hospital Anxiety and Depresson Scale, HADS). The DN4 interview and PainDetect questionnaire were applied by the same experienced physician who was blind to patients clinical and outcome data. Patients with a score ≥4 in DN4 were considered as "probable NeP"; between 13–18 or ≥19 in PainDetect were considered as "possible" or "likely NeP", respectively.
**Results:** Fifty patients (44 F, 6 M) with SSc and fifty-one (45 F, 6 M) with RA were included. Patients had similar age and similar gender, educational and smoking status, as well as functioning and HRQoL. However, patients with RA declared more severe pain on VAS-pain (p=0.012), and higher body mass index than patients with SSc (p<0.0001). NeP component was similar in patients with SSc vs RA. NeP component was detected 42.0% in SSc, and 47.1% in RA (p>0.05) according to DN4 scores. According to PainDetect questionnaire, possible NeP was detected in 12.0% vs 15.7%, whereas 16.0% vs 17.6% had likely NeP in SSc and RA, respectively (p>0.05). Neuropathic characteristics of pain were similar in SSc and RA defined as burning, electric shock, tingling, pins and needles, and itching except for numbness and painful cold which were significantly more prevalent in patients with SSc (%50.0 vs %25.5, p=0.011 and %50.0 vs %19.6, p=0.001; respectively). In SSc patients with or without NeP component had similar functioning and HRQoL measures. However, having NeP component revealed a heavier burden of disease regarding functioning, HRQoL and psychometric components patients with RA.

| | NeP +ve | NeP –ve | P |
|---|---|---|---|
| SSc | (n=21) | (n=29) | |
| Age | 53.43±9.58 | 43.55±13.82 | 0.004 |
| HAQ | 0.55±0.62 | 0.53±0.60 | 0.758 |
| SF-36 – PCS | 53.90±21.62 | 48.58±20.41 | 0.350 |
| SF-36 – MCS | 64.33±21.36 | 53.87±20.85 | 0.087 |
| HADS – depression | 7.76±3.45 | 7.10±3.63 | 0.636 |
| HADS – anxiety | 7.38±3.75 | 6.10±4.17 | 0.252 |
| 6-min walk, m | 408.95±67.16 | 433.21±82.46 | 0.336 |
| RA | (n=24) | (n=27) | |
| Age | 50.21±9.17 | 51.30±11.02 | 0.850 |
| HAQ | 0.48±0.62 | 0.57±0.64 | 0.727 |
| SF-36 – PCS | 40.55±17.63 | 59.77±20.37 | 0.0001 |
| SF-36 – MCS | 42.83±15.06 | 68.99±21.14 | 0.0001 |
| HAD – depression | 9.29±4.30 | 5.56±4.33 | 0.004 |
| HAD – anxiety | 10.08±3.78 | 5.67±4.37 | 0.0001 |
| 6-min walk, m | 378.33±77.27 | 368.15±69.74 | 0.690 |

**Conclusions:** The NeP component was similar in patients with RA and SSc. However NeP was associated a heavier burden of disease in patients with RA.
**Disclosure of Interest:** None declared

## SAT0246 COMPARISON OF LEVEL OF FATIGUE AND DISEASE CORRELATES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC SCLEROSIS

K. Gok, K. Erol, G. Cengiz, S. Ozgocmen. *Erciyes Univ. Sch. Med. Div. Rheum. Kayseri, Kayseri, Turkey*

**Background:** Rheumatoid arthritis (RA) and systemic sclerosis (SScl) are two different forms of connective tissue diseases associated with significant morbidity. While fatigue is not required for a diagnosis of RA or SScl persistent fatigue is an important clinical problem which may interfere with loss of functioning and health related quality of life (HRQoL) and contribute to the increased disease burden. Several studies compared these two diseases in terms of clinical, laboratory and imaging aspects, however level of fatigue has not been evaluated comparatively.
**Objectives:** The aim of this study was to compare levels of fatigue in RA and SSc and to assess potential influence of fatigue on clinical variables.
**Methods:** Patients meeting the ACR/EULAR criteria for SSc and RA with an age more than 18 were consecutively recruited. Patients with a prior diagnosis of psychiatric disorders or fibromyalgia or taking medications for these disorders,

or with uncontrolled diabetes, neurological disorders or taking any kind of biologic agents were excluded. Patients were examined and evaluated for disease specific and generic outcome measures including disease activity parameters, physical functions, psychological status and health related quality of life (HRQoL) measures. Level of fatigue was assessed by Fatigue Severity Scale (FSS) and Multidimensional Assessment of Fatigue (MAF) scale. These were interviewed by the same experienced physician who was blind to clinical data.
**Results:** Fifty patients (44 F, 6 M) with SSc and fifty-one (45 F, 6 M) with RA were included. Patients had similar age and similar gender, educational and smoking status, as well as functioning and HRQoL. However, patients with RA declared higher levels on VAS-pain (p=0.012), and higher body mass index than patients with SSc (p<0.0001) and lower distances in 6-minute walking test (p=0.002). Levels of fatigue which were assessed by VAS, FSS and MAF were quite similar between patients with RA and SSc. Levels of fatigue, measured by different scales, were significantly correlated with physical functions and HRQoL measures and psychometric variables in both groups, however the correlation coefficients were relatively higher in patients with RA.

| | SSc, n=50 | RA, n=51 | P |
|---|---|---|---|
| Age | 47.70±13.07 | 50.78±10.11 | 0.189 |
| BMI, kg/m$^2$ | 26.26±5.95 | 30.96±6.17 | 0.0001 |
| Symptom duration, years | 10.10±7.04 | 11.06±8.01 | 0.525 |
| VAS – pain | 3.95±2.94 | 5.25±2.08 | 0.012 |
| HAQ | 0.54±0.60 | 0.53±0.63 | 0.946 |
| SF-36 – vitality | 48.40±20.26 | 51.76±21.54 | 0.421 |
| SF-36 – PCS | 50.81±20.88 | 50.72±21.27 | 0.983 |
| SF-36 – MCS | 58.27±21.49 | 56.68±22.60 | 0.719 |
| FSS | 4.67±1.77 | 4.39±1.94 | 0.439 |
| MAF – severity | 6.37±2.07 | 5.50±2.37 | 0.064 |
| MAF – distress | 5.80±2.74 | 5.56±2.56 | 0.656 |
| MAF – interference ADL | 4.78±2.25 | 5.07±2.17 | 0.534 |
| MAF – timing | 6.39±2.05 | 6.56±2.08 | 0.696 |
| MAF – global fatigue index | 27.77±12.22 | 25.27±12.77 | 0.317 |
| 6-min walk, m | 423.40±76.82 | 372.94±83.43 | 0.002 |
| VAS – F | 5.96±2.67 | 5.14±2.84 | 0.148 |

**Conclusions:** Fatigue is a major problem in patients with RA and SSc. This is the first report comparing these two diseases in terms of fatigue and its correlates. Patients with RA and SSc should be carefully evaluated for fatigue by using valid scales and the impact of fatigue on clinical measures should not be overlooked.

## SAT0247 HIGHER FIBRINOGEN PLASMA LEVELS AT BASELINE ARE ASSOCIATED WITH A FASTER DEVELOPMENT OF NEW DIGITAL PITTING SCARS/ULCERS AT FOLLOW-UP IN SYSTEMIC SCLEROSIS PATIENTS

S. Vettori, V. Giacco, D. Capocotta, B. Russo, G. Valentini. *Internal and Experimental Medicine, Second University of Naples, Naples, Italy*

**Background:** The -455 G>A polymorphism in the proximal promoter region of β-fibrinogen gene is known to increase fibrinogen plasma levels and to promote arterial and venous thrombosis in the general population (1). We previously showed that systemic sclerosis (SSc) patients with pitting scars and/or ulcers have a higher frequency of the β-fibrinogen -455 A allele and higher plasma levels of fibrinogen (2).
**Objectives:** We aimed to investigate fibrinogen plasma levels in a prospective cohort of SSc patients and to search for associations with features of vascular involvement at follow-up (FU).
**Methods:** SSc patients meeting the 2013 ACR/EULAR criteria for disease classification with measurement of fibrinogen plasma levels and at least one FU visit with complete clinical evaluation were enrolled. The comparison of fibrinogen levels in different patient groups was performed using the Mann-Whitney U test; differences between patients with fibrinogen levels higher or equal/lower than the median value were analyzed by Kaplan-Maier curves applying the log-rank test.
**Results:** One-hundred and thirty-three SSc patients, aged 51±13 years, were investigated (91% females; median disease duration 8 years, range 1–49). Seventy-six % of patients had a limited SSc subset (lcSSc); 24% had a diffuse subset (dcSSc). All patients were ANA positive (40% had anti-centromere antibodies, 35% anti-Scl70+; 3% anti-RNApolymerase III; 2.3% anti-PmScl; 1.5% anti-U1RNP). All patients were under low-dose aspirin and oral vasodilators. Forty-one % of patients had already pitting scars and/or ulcers at baseline; 13% developed new digital ischemic injury during observation (median FU 3 years; range 0.7–22). Baseline fibrinogen levels were higher in patients who developed digital ischemic lesions during FU (385 mg/dl, range 180–688 versus 344 mg/dl, range 81–765; p<0.05). SSc patients with levels higher than the median value developed new ischemic lesions in the digits faster than patients with values lower or equal to the median ($\chi^2$=4.3; p<0.05).
**Conclusions:** Consistently with our previous findings, here we first show that higher fibrinogen levels at baseline in SSc patients are associated with a faster development of new digital ischemic lesions over time. Of note, all our patients were taking aspirin, which, however, does not affect platelet-fibrinogen interaction. In addition, all of them were taking an oral vasodilator, that is recommended for the treatment of peripheral vasculopathy in SSc (3). Randomized controlled clinical trials in larger SSc cohorts to explore the potential benefit of gpIIb/IIIa inhibitors± low-dose aspirin in these patients are needed.

## SAT0248 B CELL CHARACTERIZATION IN SYSTEMIC SCLEROSIS: CD19 CORRELATES INVERSELY WITH DISEASE ACTIVITY AND PLASMABLASTS DIRECTLY WITH DIFFUSE DISEASE AND LUNG INVOLVEMENT

S.L. Bosello, B. Tolusso, G. Berardi, S. Canestri, F. Parisi, C. Di Mario, G. Canestrari, M. Rucco, G. Ferraccioli. *Institute of Rheumatology, Catholic University, Rome, Italy*

**Background:** B cells play an important role in Systemic Sclerosis (SSc).
**Objectives:** To determine the phenotypic characteristics of blood B cell subsets in patients with SSc and their possible association with organ involvement and disease activity.
**Methods:** 100 SSc patients (83.0% females; mean age 56.5±13.9 years; 49 (49.0%) with diffuse skin involvement-dcSSc) and 50 age and sex matched healthy controls (HC) were studied. Clinical, immunological and inflammatory characteristics were assessed for all the SSc patients. Peripheral blood samples were analyzed by flow cytometry for the distribution of circulating B cell subpopulations by staining with surface markers CD45, CD19, CD38, CD27 and IgD (1). For each patient at study entry, disease activity and severity were evaluated (2,3). Patients with an activity score ≥3.0 were considered to have an active disease.
**Results:** The distribution of circulating CD19+ cells of SSc patients and healthy controls was comparable. Considering the two main phenotypes of the disease, the percentage of CD19+ cells was lower in patients with dSSc versus HC (8.0±4.8%vsHC 10.6±3.3%, p=0.01), as well as versus patients with limited skin disease (lSSc) (11.3±5.3%, p=0.01). The percentage of CD19 cells inversely correlated with activity index (R=-0.36, p=0.001) and patients with active disease showed lower percentage of CD19 (8.1±4.2%) compared with patients with inactive disease (11.6±5.9%, p=0.001). ROC curve analysis showed a CD19 cut off of 5.5% as the one that identified patients with active disease (AUC=0.31, p=0.006). Patients with CD19 higher than 5.5% more frequently presented a diffuse disease (p=0.02) and a restrictive lung involvement (p=0.001). The analysis of B cell subsets showed a lower percentage of pre-switched memory B cells (IgD+CD27+: 7.9±8.3p<0.001) and an higher percentage of naïve B cells (IgD+CD27-: 70.7±16.9, p=0.001) in SSc patients with respect to HC (IgD+CD27+:13.3±8.3,p<0.001;IgD+CD27-:64.4±11.1,p=0.001). An higher percentage of naïve B cells and a lower percentage of pre-switched memory B cells were confirmed either for diffuse (IgD+CD27-:8.4±9.3%; IgD+CD27+: 69.5±18.9%) or the limited subset of the disease (IgD+CD27-: 7.4±7.5%; IgD+CD27+: 71.4±19.0%) with respect to HC (p<0.02 for all comparisons).Furthermore an higher percentage of plasmablasts (CD38+CD27+: 4.0±4.5%) was observed in dSSc patients compared to HC (2.0±2.6%, p=0.004) and compared with the limited disease (2.2±2.8%, p=0.003). Considering organ involvement, an higher percentage of plasmablast (3.9±3.4) characterized patients with restrictive lung disease (FVC<79%) with respect to patients with FVC>79% (2.9±3.9%, p=0.01).
**Conclusions:** Systemic sclerosis patients show an immune deregulation of B cell subset phenotypes in the peripheral blood. The difference in the percentage of CD19 population in the different subsets of the disease and when the disease is active suggests that the CD19 count may be a potential simple biomarker of the activity. Plasmablasts represent crucial biomarkers of dSSc with lung involvement.

## SAT0249 PREDICTORS OF RESPONSE TO METHOTREXATE IN PATIENTS WITH EOSINOPHILIC FASCIITIS

W.A. Sifuentes Giraldo[1], D. Grados Canovas[2], M. de los Riscos Álvarez[3], M. Pascual Pastor[4], P. Moreno Fresneda[5], E. Loza[6], M.J. García de Yébenes y Prous[6], A. Olivé Marques[2], P. Carreira Delgado[3], J. Narvaez García[4], R. García-Vicuña[5], A. Zea Mendoza[1]. *[1]Rheumatology, University Hospital Ramon y Cajal, Madrid; [2]Rheumatology, Hospital Universitario Germans Trias i Pujol, Barcelona; [3]Rheumatology, Hospital Universitario 12 de Octubre, Madrid; [4]Rheumatology, Hospital Universitario de Bellvitge, Barcelona; [5]Rheumatology, Hospital Universitario la Princesa; [6]Instituto de Salud Musculoesquelética (InMusc), Madrid, Spain*

**Background:** Eosinophilic fasciitis (EF) is a rare scleroderma-like disorder

described in 1974 by Shulman. It is characterized by the acute onset of edema and induration of the skin and the subcutaneous tissue associated with peripheral blood eosinophilia. Deep skin biopsy shows characteristic alterations in the muscle fascia. There is no consensus regarding the treatment of the FE. Oral or intravenous glucocorticoids (GC) are usually the initial treatment with significant improvement in most cases. Immunosuppressive drugs may be associated when the response is insufficient and the most used is methotrexate (MTX). The response to MTX is usually favorable, especially in cases with concomitant morphea lesions. However, there are no studies that specifically analyze which factors predict response to treatment with this drug in EF.

**Objectives:** To determine which demographic, clinical and laboratory baseline features are associated with remission during treatment with MTX in patients with EF.

**Methods:** We performed an observational, retrospective (1983–2014) and multicentric study of patients with EF from 5 Spanish university hospitals. Inclusion criteria: 1) characteristic cutaneous manifestations; 2) deep biopsy with consistent changes in muscle fascia, and 3) treatment with MTX. Response to treatment with this drug is divided into: 1) complete remission (absence of symptoms and disappearance of lesions); 2) partial response (patients who develop limitation despite treatment); and 3) lack of response (persistence of symptoms and findings on examination). Statistical nonparametric tests were used for the data analysis, Kruskal Wallis for continuous variables and x2 for categorical variables.

**Results:** 33 patients were included, 18 women (54.5%), with a mean age of 54.6 years (range 22–81) and a median duration of disease until diagnosis of 4 months (range: 1–25). Most of these patients had previously been treated with GC (97%) with insufficient response, 8 (24.2%) had previously received other Immunomodulatory drugs (hydroxychloroquine, azathioprine, cyclosporine) and 5 (15.2%) with photochemotherapy (PUVA). The median MTX dose used was 15 mg/week (range: 10–25), 16 (48.5%) cases achieved complete remission with this drug, 15 (45.5%) partial response and 2 (6%) lack of response. Patients who achieved complete remission had a mean age at diagnosis slightly higher (64), presented more frequently induration $\geq$50% of body surface, myalgia and associated malignancies but C-reactive protein (CRP) levels were lower. Of all the variables analyzed, only low CRP level was significantly associated with complete remission (p=0.004). Two patients in remission relapsed after discontinuation of MTX, with a favourable response to re-treatment with GC.

**Conclusions:** The only variable that seems to be associated with remission during treatment with MTX in our series is the absence of elevated CRP. All other variables showed no significant differences, although the statistical power may be small due to the limited sample size.

## SAT0250 SCREENING FOR SUBCLINICAL PULMONARY VASCULAR DISEASE OF SYSTEMIC SCLEROSIS: THE BEST NON-INVASIVE TEST AND WHAT WE FOUND BY GENE EXPRESSION ANALYSIS OF PERIPHERAL BLOOD

Y. Koyama[1], S. Fuke[2], Y. Sato[3], T. Higuchi[1]. *[1]Center for Autoimmune Diseases, Division of Rheumatology; [2]Department of Cardiology, Japanese Red Cross Okayama Hospital, Okayama; [3]DNA Chip Research Inc, Tokyo, Japan*

**Background:** Pulmonary arterial hypertension (PAH) remains a leading cause of death in systemic sclerosis (SSc) in spite of current best treatments. As the better treatment effects is expected in the earlier PAH, current studies focus on early diagnosis. On the other hand, it is known that pulmonary vascular disease (PVD) can be well compensated for. Therefore, more than a half of the pulmonary circulation is considered to be obstructed by PVD before early PAH is detected. Recently, it has been reported that stress testing with exercise or infusion of dobutamine can reveal abnormal mean pulmonary artery pressure-cardiac output (mPpa-Q) responses, which may facilitate early diagnosis of PVD.

**Objectives:** We tried to detect changes at the stage of subclinical PVD in SSc with using non-invasive or invasive examinations including pulmonary function test, cold stress thermography, stress Doppler echocardiography (DE) or stress right heart catheterization (RHC). And then, gene expression profiles, including subclinical PVD of SSc, in peripheral blood were explored

**Methods:** Total of 58 cases categorized NYHA I with Raynaud symptoms (78.0%), puffy fingers (49.2%), or serological abnormality related to SSc including anti-centromere (44.8%), anti-topoisomerase I (1.7%), or anti-U1-RNP antibody positive (10.3%) were investigated. To find the best non-invasive index to screen for early PVD, correlation between mPpa-Q by dobutamine stress RHC and the result of clinical tests were evaluated (n=15). The tests includes serum BNP, %DLCO and %VC/%DLCO by pulmonary function test, thermography of hand with cold stress, resting tricuspid regurgitation pressure gradient (rest TRPG), maximum TRPG and mPpa-Q estimated by DE with Master's two-step stress. Then, the expressed genes in peripheral blood, which correlated with the best non-invasive index, were explored with using next-generation sequencing (n=58).

**Results:** The mPpa-Q by dobutamine stress RHC was found to correlate most strongly with maximum TRPG estimated by exercise DE (R=0.65, p<0.01, FDR<0.05). The analysis of gene expression profile revealed that expressions of 94 genes were highly correlated with maximum TRPG by exercise DE (p<0.0001, FDR<0.05). It includes fibroblast growth factor (FGF) 12 (R=0.59, P<0.000001, FDR<0.05) and FGF 23 (R=0.50, P<0.0001, FDR<0.05). It also contained the genes of bone morphogenetic protein (BMP) 10 (R=0.47, P<0.001, FDR<0.05) and endothelin 2 (R=0.47, P<0.001, FDR<0.05), that are reported to be directly implicated in the development of PAH[1)].

**Conclusions:** Although detection of early PVD in SSc patients remains a major challenge, maximum TRPG by stress DE seems to be an encouraging candidate for non-invasive screening. The results of gene expression analysis shed on changes in circulating blood cells at the early stage of SSc-associated PVD. By the analysis of gene expression, we found a very strong correlation between FGF12/23 and maximum TRPG by exercise DE. It is of particular interest that BMP-10 and endothelin-2 were also correlated significantly. As these factors were reported to be involved in the development of PAH, it is possible that theses factors could be candidates for therapeutic target to prevent the progression of SSc-associated PVD.

**Background:** Vascular involvement is an early feature of Systemic sclerosis (SSc) and has a major role in the phenotypic presentation of the disease. Recent data showed overlapping pathways between bone and vascular biology. OPG was shown to enhance neovascularization and protects micro-vascular endothelial cells (ECs) from apoptosis; Signaling studies on human umbilical vein endothelial cells (HUVECs) showed that OPG is a positive regulator of micro-vessel formation acting as a pro-angiogenic molecule, OPG is also increased in idiopathic pulmonary artery hypertension (iPAH). RANKL, has shown anti-angiogenic properties with subsequent inhibition of EC proliferation. Vinculin: in turn was shown to be over expressed in ECs and may have a role in the impaired angiogenic process seen in SSc. we hypothesize that overexpression of Vinculin in SSc may trigger anti-vinculin antibodies (abs) which may contribute to vasculopathic features in SSc.

**Objectives:** We wanted to investigate the role of OPG/RANKL, anti-Vinculin antibodies as biomarkers of vascular dysfunction such as PAH and ulcers in SSc.

**Methods:** Serum levels of OPG/RANKL and Anti-Vinculin abs were measured by ELISA in serum obtained from 70 SSc patients. Correlations between serum levels and clinical aspects of SSc patients (skin ulcers, PAH) were done by linear regression analysis. Clinical assessments, procedures, questionnaires and lab results were obtained from medical charts for clinical correlations.

**Results:** 70 SSc pts, mean age 56 yrs, 58females, 23 (32%) pts with PAH, active ulcer in 19 (28%) (table 1). Higher OPG was associated with older age (p=0.003), lower Ulcer visual analogue scale (VAS) (p=0.036), lower FEV1 (p=0.042). No association was found with PAH (p=0.50). Higher RANKL levels were associated with presence of skin ulcers (p=0.039). There was no evidence of differential prediction of OPG and RANKL for any of the clinical variables, given PAH status, using linear regression. In contrast, Linear regression analysis for anti-vinculin identified PAH (p value<0.052) as significant predictors of higher anti-vinculin in SSc patients. Further regression analysis for predictors of PAH with higher vinculin levels revealed smoking (current or former) as a significant (p value <0.01) predictor.

**Conclusions:** Higher RANKL correlated with the presence of skin ulcers while Higher OPG correlated Lower ulcer VAS regardless of the PAH status. Anti-vinculin antibodies correlated with PAH regardless the skin ulcer status of our SSc patients.

Although vascular dysfunction has a major role in driving the various morbidities in SSc (ulcer and PAH), Our Study Suggests that Different pathogenic pathways are involved in skin ulcer and Pulmonary artery hypertension.

**Disclosure of Interest:** None declared

SAT0252 **LONG-TERM SURVIVAL ANALYSIS AND PROGNOSTIC OUTCOME FACTORS IN IDIOPATHIC INFLAMMATORY MYOPATHY**

Y. Zuo[1], Y. An[2], C. Li[2], Z. Guo[3], Z. Li[2]. *[1]Rheumatology and Immunology, China-Japan Friendship Hospital; [2]Rheumatology and Immunology, Beijing University People's Hospital, Beijing; [3]Rheumatology and Immunology, Xinxiang Central Hospital, Henan, China*

**Background:** Idiopathic inflammatory myopathy is a group of systemic connective tissue diseases, including dermatomyositis (DM), polymyositis (PM) and inclusion body myositis (IBM). PM/DM are characterized by chronic muscle inflammation and can affect other internal organs. Survival rate and prognostic factors of PM/DM vary widely. The 5-year survival rates for PM/DM range from 60% to 95%. Additionally, the long-term outcome of a large group of Chinese patients with PM/DM is absent. Although Interstitial lung disease (ILD) and coexistent cancer were indicated to be predictors of mortality, few studies conducted multivariate regression analysis to provide independent prognostic factors, as well as the calculation of Standardized Mortality Ratio for PM/DM patients.
**Objectives:** To analyze the survival rate, cause of death and the prognostic outcome factors in idiopathic inflammatory myopathy (IIM).
**Methods:** A total of 201 IIM patients treated in Peking University People's Hospital from January 1996 to September 2013 were included. Medical records were abstracted for clinical, laboratory and therapeutic data.
**Results:** The follow-up time of 201 IIM patients, including 121 with DM, 33 with PM and 47 with CADM, ranged from one to 492 months, and 56 cases were lost to follow up. Overall cumulative survival rate was 93.0%, 87.0%, 86.0% and 84.0% at 1, 3, 5 and 10 years respectively from the disease onset. The rates were similar in DM, PM and CADM. During the follow-up period, 26 (19.3%) patients died, among which 21 cases died within 3 years from the onset. Respiratory failure associated with ILD was the main cause of death, followed by cardiac involvement and coexistent malignancy. Rapidly progressive ILD, myalgia, fever, abnormal ECG, normal CKMB, lymphopenia and hypoalbuminemia, elevated LDH and CEA were associated with mortality ($P<0.05$). In multivariate Cox regression analysis, elevated CEA was the significant predictor of poor outcome. Therapy with glucocorticoids combined with immunosuppressants for more than one year was negatively correlated with mortality, as well as methylprednisolone pulse therapy for patients with rapidly progressive ILD. Intravenous cyclophosphamide therapy was associated with a better survival than MTX.
**Conclusions:** The ten-year survival rate shows no statistically significant difference among DM, PM and CADM. The survival rate of patients with rapidly progressive ILD is significantly lower than patients with chronic or without ILD. Elevated CEA acts as the independent risk factor for poor prognosis. Glucocorticoids combined with immunosuppressants for more than one year is associated with high survival rate. Intravenous cyclophosphamide therapy is associated with a better survival than MTX.

## Paediatric rheumatology

SAT0253 **EVANS SYNDROME AT CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS DIAGNOSIS: A LARGE MULTICENTER STUDY**

G.E. Lube[1], M.P.L. Ferriani[1], L.M. Campos[1], M.T. Terreri[2], E. Bonfá[3], C.S. Magalhães[4], N.E. Aikawa[3], D.P. Piotto[2], O.A. Peracchi[2], M.C. Santos[5], S. Appenzeller[6], V.P. Ferriani[7], R.M. Pereira[3], C.A. Silva[1]. *[1]Pediatric Rheumatology Div., Faculdade de Medicina da Universidade de São Paulo; [2]Pediatric Rheumatology Div., UNIFESP; [3]Rheumatology Div., Faculdade de Medicina da Universidade de São Paulo, São Paulo; [4]Pediatric Rheumatology Div., UNESP, Botucatu; [5]Pediatric Rheumatology Div., Santa Casa de São Paulo, São Paulo; [6]Pediatric Rheumatology Div., UNICAMP, Campinas; [7]Pediatric Rheumatology Div., FMUSP - Ribeirão Preto, Ribeirão Preto, Brazil*

**Background:** Evans syndrome (ES) is an uncommon manifestation characterized by autoimmune destruction of red cells and platelets and concomitant or sequential appearance of immune thrombocytopenia (ITP) and autoimmune hemolytic anemia (AIHA). This involvement has been associated to severe disease activity in adult patients with systemic lupus erythematosus (SLE), particularly at disease onset. However, ES studies in childhood-onset SLE (cSLE) patients have been rarely reported and limited to small populations.
**Objectives:** The objective of the present multicenter study was to assess ES in a large cSLE cohort at diagnosis evaluating prevalence, clinical features, laboratory findings and outcomes.
**Methods:** A retrospective multicenter cohort study (Brazilian cSLE group) was performed in 10 Pediatric Rheumatology services including 850 patients with cSLE (ACR criteria). None of them had secondary etiologies of autoimmune cytopenias, such as infections, primary immunodeficiencies and malignancies. Patients were divided in two groups for the assessment of lupus manifestations, laboratory exams and treatment at cSLE diagnosis: patients with ES and patients without ES.
**Results:** ES was observed in 11/850 (1.3%) cSLE patients at diagnosis. The majority of them had hemorrhagic manifestations (58%) and active disease (82%). All patients with ES were hospitalized and none of them died. Comparisons of cSLE patients with and without ES at diagnosis revealed similar frequencies of female gender, multi-organ involvement, autoantibody profile and low complement levels ($p>0.05$). Patients with ES had a lower frequency of malar rash (9% vs. 53%, p=0.003) and musculoskeletal involvement (18% vs. 69%, p=0.001) than those without this complication. The median of hemoglobin [7.4 (5.4–9.4) vs. 10.3 (3.5–16.4)g/dL, $p<0.001$] and platelets [27 (15–54) vs. 231 (2–761)x$10^3$/mm$^3$, p=0.005] were significantly lower in ES compared to non-ES patients, whereas lymphocytes were significantly higher in ES patients [1.8 (1–2.38) vs. 1.16 (0.07–7)x$10^3$/mm$^3$, $p<0.001$]. The frequencies of intravenous methylprednisolone (82% vs. 43%, p=0.013) and intravenous immunoglobulin use (64% vs. 3%, $p<0.0001$) were significantly higher in the former group. Current prednisone dose between the two groups was similar [1.1 (0.76–1.5) vs. 1.0 mg/kg/day (0–30), 0.195].
**Conclusions:** Our large multicenter study identified that ES was a rare and severe cSLE manifestation with a difficult diagnosis due to the absence of typical lupus manifestations, often requiring hospitalization and intravenous treatment.

SAT0254 **THE ICEBERG IN JUVENILE ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: SUBCLINICAL DETERIORATION OF CARDIAC FUNCTIONS ASSESSED WITH TWO-DIMENSIONAL SPECKLE TRACKING ECHOCARDIOGRAPHY AND CONTRIBUTING FACTORS OF SYSTOLIC DYSFUNCTION**

S. Sahin[1], R. Dedeoglu[2], A. Adrovic[1], F. Oztunc[2], K. Barut[1], A. Koka[2], D. Cengiz[3], O. Kasapcopur[1]. *[1]Department of Pediatric Rheumatology; [2]Department of Pediatric Cardiology, Istanbul University, Cerrahpasa Medical School; [3]Department of Statistics, Istanbul Commerce University, Arts and Science Faculty, Istanbul, Turkey*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by vasculitis and inflammation in various organs. Cardiovascular involvement, although not frequent in juvenile-onset SLE (j-SLE), if present, is a significant cause of morbidity and mortality (1). Particularly, involvement of the myocardium layer may lead to ventricular dysfunction since its progression is insidious (1,2). Speckle tracking echocardiography (STE) could demonstrate subclinical myocardial deformations (strain) that globally seems normal in conventional echocardiography (2).
**Objectives:** The aim of this study is early detection of subclinical systolic dysfunctions in j-SLE with STE and if present, then to investigate whether this is disease-related or it is a result of other predisposing conditions.
**Methods:** 35 patients with j-SLE and 30 healthy children as a control group were evaluated between January and August 2015 at outpatient clinics of Cerrahpasa Medical Faculty. STE was performed on all patients and controls. Medical records that are including age at diagnosis, duration of the disease, diagnostic criteria, laboratory tests and cumulative clinical manifestations were evaluated. SLE disease activity was assessed using the SLE Disease Activity Index (SLEDAI). A SLEDAI score >4 was arbitrarily designated as a sign of moderate/severe disease activity.
**Results:** j-SLE patients had lower EF values than control subjects. Left ventricular end diastolic dimension (LVEDD) and left ventricular end systolic dimension (LVESD) were significantly greater in j-SLE patients (42,278±4,530 vs. 37,314±5,535; 28,108±3,344 vs. 24,055±3,290 p=0.001, respectively) than in the control group. There was a significant reduction in systolic parameters of longitudinal strain in the j-SLE group ($p<0.05$) at all segments compared to control patients.
SLE patients were divided into two subgroups. Group 1 included patients having SLEDAI scores >8 at the beginning of the disease but who improved with therapy during follow up, with resulting SLEDAI scores less than or equal to 4 points. Group 2 included j-SLE patients with SLEDAI scores >8 at diagnosis but with SLEDAI scores still greater than 4 at the end of follow up.
In comparisons of two groups, mid inferior and mid inferolateral LV segment STE

strain measurements of Group 2 were significantly lower than those in Group 1, (15.9000±6.47130 vs. 20.0714±4.49725 mid inferior; 17.9000±7.23341 vs. 23.2308±3.87629 mid inferolateral, p=0.075, 0.055, respectively).
**Conclusions:** We can say that prevention of long-term cardiovascular complications in j-SLE begins with noticing the iceberg early, before irreversible changes take place. In this regard, STE is an accurate method for detecting subclinical systolic dysfunction.

## SAT0255 PROSPECTIVE STUDY: THE ROLE OF URINARY HER2 AS A LUPUS NEPHRITIS BIOMARKER

P. Costa Reis[1,2,3,4], K. Dietzmann-Maurer[1], E. Von Scheven[5], J.M. Burnham[6], K.E. Sullivan[1,2]. *[1]Division of Allergy and Immunology, The Children's Hospital of Philadelphia; [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, United States; [3]Department of Pediatrics, Hospital de Santa Maria; [4]Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal; [5]Division of Pediatric Rheumatology, University of California – San Francisco, San Francisco; [6]Division of Pediatric Rheumatology, The Children's Hospital of Philadelphia, Philadelphia, United States*

**Background:** Recently, a dramatic increase in HER2 expression in the glomeruli and in the tubular compartment of patients with lupus nephritis was observed. A similar pattern was not seen in patients with IgA nephropathy, post-streptococcal glomerulonephritis or granulomatosis with polyangiitis. HER2 overexpression was also found in NZM2410 mice and it correlated with disease activity. *In vitro*, IRF1 and α-interferon increased HER2 expression in human mesangial cells and HER2 regulated the levels of miR-26a and miR-30b. These miRNAs control mesangial cell proliferation, by regulating the expression of several genes, including those controlling cell cycle. It was also found that urinary HER2 levels were increased in patients with active lupus nephritis in an adult cohort and correlated with the urine protein:creatinine ratio and with the levels of MCP-1 and VCAM-1.
**Objectives:** Determine the role of HER2 as a urinary biomarker for lupus nephritis activity.
**Methods:** This is an interim analysis of a prospective, multicentric study, of patients with juvenile-onset systemic lupus erythematosus with biopsy-proven lupus nephritis. Urine samples were collected from patients at every clinical visit and also from age-sex matched controls. The samples were centrifuged and the supernatants were analyzed by enzyme-linked immunosorbent assays for HER2. Clinical data were also collected. The activity of lupus nephritis was measured using renal SLEDAI. Unpaired and paired t tests were used for the comparisons between samples. The relationship between HER2 and disease activity was defined by Pearson's correlation and linear regression.
**Results:** Urinary HER2 is significantly increased in children with lupus nephritis (N=15) when compared to controls (N=24) (p=0.003). Furthermore, our preliminary data from patients analyzed at different visits showed that HER2 levels tend to reflect disease activity.
**Conclusions:** HER2 was significantly increased in the urine of children with lupus nephritis and its levels changed between visits, reflecting disease activity. Further studies are necessary to determine if HER2 levels can be clinically useful, namely if they can predict the occurrence of a flare. These findings also support the study of anti-HER2 drugs for cell proliferation control in lupus nephritis.

## SAT0256 JUVENILE SYSTEMIC SCLEROSIS COHORT WITHIN THE CHILDHOOD ARTHRITIS AND RHEUMATOLOGY RESEARCH ALLIANCE (CARRA) LEGACY REGISTRY: BASELINE AND FOLLOW UP CHARACTERISTICS

B. Stevens[1], K.S. Torok[1], S. Li[2], N. Hershey[1], M. Curran[3], G. Higgins[4], K. Moore[5], E. Rabinovich[6], A.M. Stevens[7] on behalf of CARRA Registry Investigators; Childhood Arthritis and Rheumatology Research Alliance, Stanford, CA. *[1]Children's Hosp of Pittsburgh of UPMC, Pittsburgh; [2]Hackensack Univ Medical Center, Hackensack; [3]Northwestern Univ Feinberg School of Medicine, Chicago; [4]Nationwide Children's Hosp, Columbus; [5]Children's Hosp Denver, Denver; [6]Duke Univ Medical Center, Durham; [7]Seattle Children's Research Institute, Seattle, United States*

**Background:** Systemic sclerosis (SSc) is a rare multisystem autoimmune disease characterized by vasculopathy and organ fibrosis. From 2010–2013, the North American CARRA Legacy Registry enrolled and prospectively followed children with rheumatologic conditions including juvenile systemic sclerosis (jSSc).
**Objectives:** Describe disease manifestations, physician metrics, and patient quality of life (QOL) at enrollment and follow up of jSSc subjects.
**Methods:** Descriptive statistics were used for demographic and clinical features. We used McNemar's test for paired data and Fisher's exact for group comparisons.
**Results:** For the 64 children with SSc in the database, the majority were female (84%) and Caucasian (78%); 86% identified as non-Hispanic. Median age of onset was 10.3 yr while age at first pediatric rheumatology (PRH) evaluation was 11.8 yr, with 23% having a ≥2 yr delay to PRH. Baseline visit occurred a median of 3.6 yrs after disease onset and data obtained 1–2 yr from enrollment was analyzed for follow up (n=25, median 1.4 yrs).
For those with complete clinical data, 81% met ACR/EULAR 2013 adult criteria for SSc at baseline. Overlap with juvenile dermatomyositis was reported in 3 individuals, with mixed connective tissue disease in 1. Of those with documented testing for specific antibodies, 80% were ANA positive, 46% anti-Scl70 and 15% ACA. Three of 15 patients tested for anti-PM-Scl antibodies were positive.
At baseline, the most prevalent organ manifestations were dermatologic (93%) and vascular (92%), with Raynaud phenomenon as the most common feature. Multiple organs were affected in 93%, and 38% had ≥4 organ systems involved. Disease manifestations remained stable at follow up with the exception of decreased frequency of arthritis (4 to 1) and increased joint contractures (7 to 11). At conclusion of the study, no interval development of renal, cardiac, or pulmonary manifestations or mortalities occurred.
Frequency of disability, measured by ACR functional class, decreased from 44% at baseline to 25% at follow up. Median Physician Global Disease Activity scores improved from 3 (IQR 1–4) to 2 (1–3), with trending significance for those with <2 years of disease at enrollment (n=7, $p$=0.059). While there were no statistically significant differences in QOL measures over time, trends of improvement in pain scale (3.5 to 2) and global well-being scale (5 to 3) were appreciated in this early disease group.
**Conclusions:** Even with inclusion of overlap patients, baseline clinical data from this cohort are similar to the jSSc cohort described by Martini et al in 2006 and most met current ACR/EULAR adult SSc criteria. Most organ manifestations were stable with time and for the duration of the study observation period, there was no interval development of major organ involvement or mortality. While limited by the cross sectional nature of enrollment, trends of improvement in disability and disease activity were appreciated after 1–2 years of follow up.

**Background:** Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. Currently just retrospective data exist regarding evolvement of organ involvement. In the retrospective studies assessment of the organ involvement is not standardized. Our project is the first one, where prospectively and with a standardized assessment data of jSSc patients are collected.
**Objectives:** to learn about the characteristics and evolvement of jSSc
**Methods:** Patients with jSSc were recruited worldwide and were prospectively assessed, using the proposed standardized patient assessment protocol.

**Results:** 26 centers from 17 countries applied to participate on the project. The assent and consent forms were translated into the local native languages. Up till now 74 patients were enrolled. Sixty (81%) of the 74 patients were female. The mean age of the onset of Raynaud symptomatic was 9.2 years (0.2 – 15.9). The mean age at the onset of the non-Raynaud symptomatic were 9,7 years (0.3 -15.9). 56 (76%) of the 74 have diffuse subtype, 10 (14%) of them have an overlap symptomatic. At the time of the inclusion the mean modified Rodnan Skin Score was 16.0. ANA positive were 55/71 (77%), 24/70 (34%) of them were anti-Scl 70 positive and 3/42 (7%) was anticentromere positive. 43/74 (58%) had already capillary changes and 36/72 (50%) inactive ulcerations, 13/72 (18%) had active ulceration at the time of the inclusion. 38/74 (51%) had cardiopulmonary involvement, 19/38 (50%) of had signs of interstitial lung disease on imaging, 18/42 (43%) had FVC <80% and 12/21 (57%) had DLCO <80%. 6/38 (16%) patients had pulmonary hypertension. 5/74 (7%) had renal involvement. 26/74 (35%) had gastrointestinal involvement, and 23/26 (88%) of them esophageal involvement. 46/73 (63%) had musculoskeletal involvement. 2/74 (3%) showed neurologic involvement. The mean CHAQ score was 0.4 (0–2.5). Patient global disease activity on VAS (0–100) was 44.9 and disease damage 41.6. Physician global of disease activity on VAS (0–100) was 39.7 and physician global of disease damage was 34.6.
**Conclusions:** The current recruitment data confirms that pediatric patients are different from the adult patients, there is a significantly higher proportion of diffuse subset patients with 81%. 14% of the patients have overlap features.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2636

## SAT0258 ASSESSING MYOCARDIAL DEFORMATION OF KAWASAKI PATIENTS WITH SPECKLE-TRACKING ECHOCARDIOGRAPHY ON LONG TERM FOLLOW UP

S. Sahin[1], R. Dedeoglu[2], F. Oztunc[2], K. Barut[1], A. Adrovic[1], S.U. Atik[2], D. Cengiz[3], O. Kasapcopur[1]. *[1]Department of Pediatric Rheumatology; [2]Department of Pediatric Cardiology, Istanbul University, Cerrahpasa Medical School; [3]Department of Statistics, Istanbul Commerce University, Arts and Science Faculty, Istanbul, Turkey*

**Background:** Myocardial dysfunction due to coronary arterial lesions is an important complication after Kawasaki disease in childhood (1,2). Speckle-tracking echocardiography (STE) is a recently developed technique for evaluation of myocardial deformation (3).
**Objectives:** Our objective was to examine myocardial deformation at long term follow-up of Kawasaki patients.
**Methods:** We assessed regional myocardial function in 32 asymptomatic Kawasaki patients and 30 age matched healthy child as control group. STE examination were recorded and the acquired raw data were saved for offline analysis The inferoseptal, anterolateral, inferior, anterior, and inferolateral (posterior) walls were investigated for longitudinal systolic peak values for strain (LV-SR) imaging.
**Results:** Mean age was 21±12 months, mean follow up time 61 months, Left ventricular ejection fraction was 57,373±8,338 in patients and 61,100±3,804 in control group. LV-SR of Kawasaki patients at basal-inferoseptal (20,000±6,046 vs 25,200±5,074), basal-anterolateral (19,595±5,713 vs 22,733±3,494), apical-septal (23,378±5,609 vs 26,267±4,334), apical-inferior (24,054±3,696 vs 25,200±2,396) segments had lower values than control group.
**Conclusions:** We demonstrated subclinical systolic impairment of function especially at left ascending artery territories with STE. STE has the potential to detect these subtle abnormalities, and help management during long term follow up.

## SAT0259 DERMATOLOGICAL FEATURES OF KAWASAKI DISEASE: DATA EXTRACTED FROM THE FRENCH KAWASAKI DISEASE COHORT (KAWANET)

C. Specht[1], M. Darce[2], K. Brochard[3], P. Lechevalier[4], E. Launay[5], I. Kone Paut[6], M. Piram[6] on behalf of the Kawanet study group. *[1]Department of Pediatric Rheumatology, National referral centre for auto-inflammatory diseases (CEREMAI); [2]CEREMAI, CHU de Bicêtre, AP-HP, le Kremlin Bicêtre; [3]Paediatric Nephrology and Internist Medicine, Hôpital des Enfants, Toulouse; [4]Paediatric Department, CHU Robert Debré, APHP, Paris; [5]Paediatric Department, CHU de Nantes, Nantes; [6]Department of Pediatric Rheumatology, CEREMAI, CHU de Bicêtre, AP-HP, le Kremlin Bicêtre, France*

**Background:** Kawasaki disease (KD) is a systemic vasculitis of unknown origin affecting mainly young children. The diagnosis criteria for KD described by the American Heart Association (AHA) include fever accompanied by five criteria, which are mainly mucocutaneous.
**Objectives:** Given the importance of dermatological manifestations in KD we aimed to describe their types and frequencies in a large French cohort of patients, and to analyze their possible association with coronary arteries abnormalities (CAAs).
**Methods:** Patients with complete and incomplete KD according to the AHA criteria and included between May 2011 and March 2013 in the French national database for KD (Kawanet), were analyzed. Consents were obtained for all included patients. Mucocutaneous signs of the disease were described (modification of the extremities detailed on erythema, edema and/or desquamation, diffuse exanthema, seat erythema and perineal desquamation, erythema or induration at BCG inoculation site, bilateral non purulent conjunctivitis, cheilitis (dry lips), raspberry tongue, erythema of oral mucosa) and their association with coronary artery abnormalities studied by multivariate analysis
**Results:** We analyzed 142 KD patients classified according to the AHA criteria. Their mean age was 2.9 years. One hundred and twenty four (87.3%) were complete KD and 18 (12.7%) were incomplete KD. Changes in lips and oral cavity were found in 132 children (93%), bilateral conjunctiva injection in 129 (92%), changes in extremities in 117 (82%), diffuse exanthema in 107 (79%), perinea involvement in 53 (41%), and erythema or induration at the site of previous BCG immunization in 10 vaccinated children (13%). This latest sign was significantly more frequent in patients less than 1 years than in older ones (36% vs 9% p=0.01). CAAs were detected in 25 patients with complete KD (22%) and in all patients with incomplete Kawasaki disease by definition. No significant associations were found between any type of mucocutaneous lesion and CAAs in this study.
**Conclusions:** Our study has underlined the importance of mucocutaneous symptoms for the definition of KD, and as expected, using the AHA criteria, they were associated with the phenotype of complete KD. In patients <1 year, modification on the site of previous TB immunization was significantly more reported than in older patients and so could be considered a diagnostic criterion. In addition, modification on the site of previous TB immunization and seat involvement were major and frequent dermatological clues for the diagnosis. Even frequent, none of the cutaneous symptoms were related to KD prognosis. Two limitations were present in this study: (i) some data were entered retrospectively; (ii) some groups of comparison were small and could explain the absence of association between mucocutaneous lesions and CAAs.
This study was supported by a grant from the APHP: PHRC2009

## SAT0260 A NOVEL MRI-BASED ANALYSIS WORKFLOW FOR CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS (CRMO)

Y. Chu[1], D. Roettger[1], C. Trentin[1], M. Hinton[1], O. Kubassova[1], R. Hargunani[2], M. Boesen[3], P. O'Donnell[2]. *[1]Image Analysis Limited, London; [2]Royal National Orthopaedic Hospital, Stanmore, United Kingdom; [3]Department of Radiology, Copenhagen University Hospital Bispebjerg and Frederiksberg, Copenhagen, Denmark*

**Background:** Chronic recurrent multifocal osteomyelitis (CRMO) is an auto-inflammatory bone disorder affecting children and adolescents, characterised by sterile bone inflammation. There is a clinical spectrum, ranging from presentation with a single, non-recurrent bone lesion to a chronic relapsing course affecting multiple, often symmetrical bone sites. Whole body MR imaging may reveal multiple lesions and therefore is promising for assessing progression of CRMO and effectiveness of treatment. Nevertheless, no tool has been available for quantitative measurement of multiple lesions in whole body MRI scans, and a fast, reproducible scoring system for CRMO patient assessment is warranted.
**Objectives:** To test a novel postprocessing scoring method for the quantification of multiple lesions in CRMO patients from static whole body STIR MRI scans, using the normalized intensity ("NormI") parametric map function, in combination with the region of interest (ROI) tools built into the software Dynamika, a platform for quantitative MRI analysis (www.imageanalysis.org.uk).
**Methods:** Whole-body static MRI STIR images from 4 patients were analysed by 2 different readers. The workflow for each reading was: 1) Define reference/baselines in fat, bone and muscle region in both left and right side of the body, respectively. 2) Draw regions of interests (ROIs) around lesions defined as areas of marrow hyper intensity. 3) Compute, NormI parametric maps by comparison with corresponding baseline. NormI have previously shown to be useful in semi-automatic quantification of inflammatory lesions in the spine on STIR or DWI-MRI sequences [1]. 4) Group the selected 2D ROIs across slices into volume of interests (VOIs). 5) Generate and save report - automated generation of lesion ROI parameters, including the sum, maximum and mean of all positive pixel values in the VOIs (SumNormI,MaxNormI and MeanNormI). Inter-reader agreement for SumNormI and MeanNormI was calculated using the intraclass correlation coefficient for each VOI.
**Results:** Single or multiple lesions seen in whole body MRI scans of CRMO patients were identified and quantified using NormI parametric maps. As shown in figure, quantification parameters for the lesions identified in right femur and right clavicle have been computed by normalising to the baseline in muscle. Reproducibility assessed by ICC is shown in table.

| | Intraclass Correlation Coefficient (ICC) | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | Patient 1 | | Patient 2 | | Patient 3 | | Patient 4 | |
| | Single | Average | Single | Average | Single | Average | Single | Average |
| SumNormI | 0.95 | 0.98 | 0.98 | 0.99 | 0.63 | 0.79 | 0.34 | 0.51 |
| Mean NormI | 0.76 | 0.86 | 0.95 | 0.98 | 0.50 | 0.67 | 0.60 | 0.73 |

Single measure: reliability of raters is computed from a single measure. Average measure: reliability of raters is computed taking average of rater's measures.

**Conclusions:** The suggested workflow and postprocessing technique provides a relatively fast and reproducible scoring method for both single and multiple lesions in CRMO from wholebody STIR MRI scans. Larger trials to test day-to-day variation and sensitivity to change following treatment response are warranted and currently ongoing.

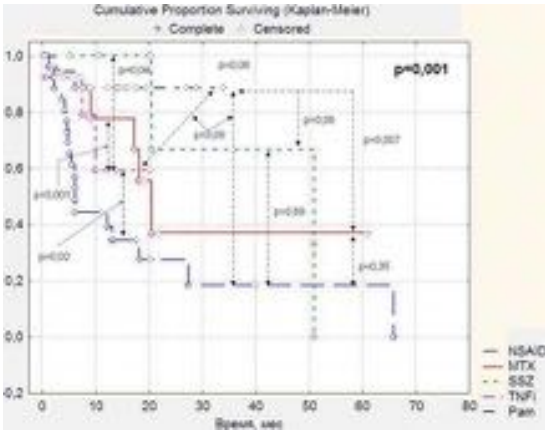
## SAT0261 DIFFERENT TREATMENT STRATEGIES FOR CHRONIC NON-BACTERIAL OSTEOMYELITIS: THE EXPERINCE OF 52 PATIENTS



M.M. Kostik[1], O. Kopchak[1,2], I. Chikova[1], V. Masalova[1], M. Dubko[1], L. Snegireva[1], E. Isupova[1], O. Kalashnikova[1], A. Mushkin[3], V. Chasnyk[1]. *[1]Saint-Petersburg State Pediatric Medical University, Saint-Petersburg; [2]Kirov's regional children's hospital, Kirov; [3]Science research Institute of Phthisiopulmonology, Saint-Petersburg, Russian Federation*

**Background:** Chronic non-bacterial osteomyelitis (CNO) is a heterogenous group of immune-mediated inflammatory bone diseases, often co-exist with other rheumatic diseases. There are no approved treatments for CNO except non-steroid anti-inflammatory drugs (NSAID). The efficacies of methotrexate (MTX), sulfasalazine, pamidronate (PAM), anti-IL1 and TNFα-inhibitors (TNFα-inh) were shown in different reports.

**Objectives:** The aim of study: to compare the efficacy of non-randomized different treatment approaches in pediatric patient CNO cohort.

**Methods:** 52 children (25 M and 27 F) with CNO has average age at the onset of disease 8.4 years (5.4÷11.0), the number of foci - 3.0 (2.0÷6.0, incl. multifocal cases in 80.8%), fever at the onset – 38.5%, spine involvement - 34.6%, positive family autoimmune diseases (AID) history - 7.7%, concomitant AID - 67.3%. NSAID was the first-line treatment for non-vertebral cases, as well as PAM for vertebral involvement. Second-line treatment includes MTX, PAM and TNFα-inh. Dynamics of pain, patient's (PVAS) and physician's (MDVAS) assessment and ability to each medication to achieve remission of CNO activity we evaluated.

**Results:** According to the NSAID, MTX, SSZ, PAM and TNFα-inh groups next data were registered: PVAS: -14.2% (p=0.05), -50.0% (p=0.04), -23.1 (p=0.89), -83.3% (p=0.0001), -73.6% (p=0.0007); pain: -21.9% (p=0.01), -18.6% (p=0.13), +36,4 (p=0.89), -79.7% (p=0.00016), -74.1%, (p=0.0015);
MDVAS: -13.8% (p=0.13); -56.4% (p=0.09), +30.8% (p=0.89), -74.7%, (p=0.0001), -82.1 (p=0.0015) respectively.
The ability of each treatment strategy to achieve the CNO remission was 52.6%, 44.4%, 57,1%, 88.8% and 73.3% respectively (log-rank test, p=0,001, figure). TNFα-inh usually used as second-third line treatment in cases where other options, especially PAM were fall.

**Conclusions:** The most effective treatment approaches for CNO were PAM and TNFα-inh. The randomized controlled trials for assessment efficacy and safety of these medications is mandatory to confirm these results.

**Disclosure of Interest:** None declared

## SAT0262 7 CASES OF CHINESE JUVENILE RELAPSING POLYCHONDRITIS AND SYSTEMIC REVIEW

D.F. Lin[1], W.Q. Yang[2], P.P. Zhang[3], Q. Lv[1], O. Jin[1]. *[1]Rheumatology department, the 3rd Affiliated Hospital of Sun Yet-sen University, Guangzhou; [2]ENT department, Peking University Shenzhen Hospital, Shenzhen; [3]Paediatrics department, the 3rd Affiliated Hospital of Sun Yet-sen University, Guangzhou, China*

**Background:** Relapsing polychondritis (RP) is a rare systemic autoimmune disease characterized by recurrent episodes of inflammation and progressive destruction of cartilaginous tissues. Juvenile RP (<18 years) mentioned more severe than adult as previous reports.

**Objectives:** Our work is to study the clinical and prognostic features of Juvenile Relapsing polychondritis (RP).

**Methods:** 7 RP cases from 1994–2013 in our hospital were reviewed and compared with 51 international juvenile cases and 158 Chinese adult case series reported from 1985–2013 including clinical features, systemic involvement, differential diagnosis and prognosis.

**Results:** 1)Average age at the onset was 15.1 years old, the mean age at first symptoms was 15.1 months and female-male ratio was 0.4:1, 6 of 7 had been misdiagnosed. 2)The incidences of arthritis (100%: 53%), nasal chondritis (1%: 53%), laryngotracheal syndromes (86%: 68%), auricular chondritis (86%: 67%), cardiovascular involvement (14%: 10%) and autoimmune diseases (14%: 5%) were higher than in Chinese adult except skin (20%: 46%). 3) Our juvenile RP patients had more severe in respect toocular inflammation (57%: 40–47%), arthritis (100%, 71–90%), cardiovascular (14%: 3–10%) and skin involvement (20%:10–11%) than Caucasian juvenile RP.

**Conclusions:** Our juvenile RP series were more severe than Chinese adult RP as the same as in Caucasians and has its unique characteristics in spite of sharing most clinical features with case series in literature.

## SAT0263 COHORT STUDY OF 80 PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS DURING TRANSITION FROM PEDIATRIC TO ADULT CARE

A. Beaumel, A. Belot, A. Duquesne, J.P. Larbre, F. Coury. *Hospices civils de lyon, Lyon, France*

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic inflammatory rheumatism in children. The International League of Associations for Rheumatology 2001 (ILAR) classification includes 7 subgroups: systemic JIA, polyarticular JIA, oligoarticular JIA, enthesitis related arthritis (ERA), psoriatic arthritis and undifferenciated arthritis. Most pediatric inflammatory rheumatism persist into adulthood. Therefore, a transition from pediatric to adult rheumatology is a necessary step. Transition is defined as an active process by which a young patient with a chronic disease develops skills and resources to gradually assume his pathology. The transition phase should be anticipated and structured because of the risk of failure in monitoring. However difference in classification criteria in pediatric and adult rheumatism represents a major difficulty for adult rheumatologist.

**Objectives:** The aim of this study was to determine the characteristics of juvenile-onset rheumatism seen during transition period and to compare pediatric classification criteria to adult criteria.
**Methods:** A retrospective single-center study was performed. Patients with JIA according to ILAR classification were included and had transition visit. JIA classification criteria were compared to ACR/EULAR 2010 criteria for rheumatoid arthritis (RA), Yamaguchi criteria for adult Still's disease and ASAS criteria for spondyloarthritis.
**Results:** 80 patients were included: 12 systemic JIA, 17 polyarticular JIA, 13 oligoarticular JIA, 29 ERA and 9 psoriatic arthritis. The median duration of disease was 7 years and the median age of transition was 19 years old. Six uveitis in oligoarticular JIA and 4 uveitis in ERA were observed as extra-articular manifestations. Radiographic structural damages were assessed and showed 12.5% of erosions and 7.6% of carpitis, mainly in polyarticular and systemic JIA patients. 39.3% of patients with ERA displayed sacroiliitis. In comparison with adult rheumatism 42% of patients with systemic JIA fulfilled Yamaguchi criteria and 29% of patients with polyarticular JIA fulfilled ACR/EULAR criteria for RA. 54% of patients with oligoarticular JIA, 76% with ERA and 100% with psoriatic arthritis fulfilled ASAS criteria for spondyloarthritis. In addition 78.75% of patients were in remission and 70% of patients were treated with biotherapy.
**Conclusions:** Our study confirmed an articular destructive potential of polyarticular and systemic JIA and an ocular risk of oligoarticular JIA. Comparison of JIA criteria to adult rheumatism criteria showed that polyarticular JIA with positive rheumatoid factor fulfilled ACR/EULAR criteria for RA. However, oligoarticular JIA and polyarticular JIA without rheumatoid factor did not fulfill any adult rheumatism criteria and seem to be pediatric entities. Finally, most of patients with ERA and psoriatic arthritis fulfilled ASAS criteria for spondyloarthritis.

## SAT0264 A SINGLE CENTRE EXPERIENCE OF CHILDHOOD POLYARTERITIS NODOSA FROM NORTH INDIA

A. Kumar[1], A. Gupta[1], M. Singhal[2], A. Gupta[1], R. Nada[3], R.W. Minz[4], D. Suri[1], S. Singh[1]. *[1]Pediatrics; [2]Radiodiagnosis; [3]Histopathology; [4]Immunopathology, PGIMER, Chandigarh, India*

**Background:** Polyarteritis nodosa (PAN) is a necrotizing vasculitis involving medium or small sized vessels. It is characterized by a variable clinical presentation, ranging from a benign cutaneous involvement to a more severe systemic disease with multisystem involvement
**Objectives:** We describe clinical and laboratory features, treatment and outcome of pediatric PAN patients
**Methods:** A retrospective case review of all children diagnosed as PAN at a single tertiary care hospital in north India between 1990 to 2014 was done. Diagnosis of PAN was based on European League against Rheumatism (EULAR)/Paediatric Rheumatology European Society (PRES)/Paediatric Rheumatology International Trials Organisation (PRINTO) classification criteria. (1)
**Results:** A total of 16 children (12 boys and 4 girls) with PAN were identified. Median age of symptom onset and diagnosis was 8 years (range 1–11 years) and 9 years, respectively. The presenting symptoms were fever (68%), CNS complaints [headache, seizures, altered sensorium, stroke or vision loss] (50%), fatigue (44%), myalgia (44%), gangrene (31%), weight loss (31%), gastrointestinal complaints [pain abdomen, bleed] (31%) and bluish black patches over body (19%). Hypertension was present in 88% patients at admission. Various neurological manifestations were seen in 62.5% patients. Skin involvement (digital gangrene, livedo reticularis, bluish black patches, erythema nodosum or necrotic ulcer) was seen in 50% patients. Renal and gastrointestinal involvements were seen in 38% patients each.
CT angiography was done in 13 patients. Aneurysmal dilatation of vessels was seen in 6 patients, while 3 patients showed features of renal infarcts. CT angiography was normal in 4 patients. In 2 such patients, digital subtraction angiography (DSA) showed aneurysmal dilatation of vessels. ANCA was positive in 4 patients (c-ANCA in 3 and p-ANCA in 1). HBsAg was positive in 3 patients (not treated as liver function remained normal). ASO was positive in 4 patients (2 patients were given penicillin; one patient had a relapse with high ASO titres on stopping penicillin).
Two patients had only a single visit to the clinic; hence their treatment details were not available. Treatment regimen included cyclophosphamide (78%), methylprednisolone pulses (43%), oral prednisolone (93%), maintenance azathioprine (36%), and IVIg and methotrexate (14% each). Mean follow up was for 4.8 years (range 0–25 years).
Five patients experienced relapses with more than 1 relapses seen in 2 patients. Relapses were noted as early as 6 months and as late as 22 years after diagnosis
**Conclusions:** We found a significant male preponderance in our cohort. Streptococcal infection can have a pathogenic role in the disease progression and relapse, and penicillin prophylaxis can prevent disease relapse in susceptible patients

## SAT0265 EVALUATION OF BIOLOGICAL AGENTS IN JUVENILE IDIOPATHIC ARTHRITIS, SINGLE CENTER RESULTS

B. Sozeri[1], Z. Gunduz[1], A. Pac Kisarslan[2], H. Poyrazoglu[2], I. Dursun[2], R. Dusunsel[2]. *[1]Pediatric Rheumatology; [2]Erciyes Universitesi Tip Fakultesi Hastanesi, Kayseri, Turkey*

**Background:** JIA is a chronic inflammatory joint disease with onset in children <16 years of age. Several biological agents (BAs) have become available for the treatment of JIA.
**Objectives:** To analyze trends in prescription patterns of biological agents and drug efficacy, achievement of inactive disease and reason for switching in JIA.
**Methods:** This was a retrospective study of children with JIA treated with biologic agent (BA) between 2006 and 2015. Efficacy was determined using the Juvenile Arthritis Disease Activity Score (JADAS)-27.
**Results:** We enrolled total 111 patients (61female, 50 male). The JIA type differentiated was systemic JIA (sJIA) (n=16), Extended Oligo (n=21); Poly JIA (n=33);Entezitis related arthritis (ERA) (n=32); psoriatic arthritis (n=4) and undifferentiated JIA (n=5). The median age of the patients at diagnosis of JIA was 94 months [interquartile range (IQR) 60–138), while the median age at the time of treatment with first BA was 141 months (IQR 83–177). The median disease duration prior to treatment with BA was 20 months (IQR 7–48). 94 patients (84.7%) received their BA in combination with mtx (alone or with another DMARD) while 15.3% had BA alone. Pretreatment steroids was higher in sJIA with 15 (94%), than in Poly (n=20,60%) and ERA (n=14,45%) patients (p=0.00).The JADAS 27 was available for 94% of patients at baseline, with a median score of 18.5 and no significant variation with the subtypes (p=0.68). The median JADAS27 after prior BA was 4 (IQR 2–8). No statistically significant differences was seen in baseline CHAQ across the subtypes (p=0.32). In ERA, the median JsPD score was 4,5 at baseline. The BAs were etanercept (ETA) (62%), adalimumab (ADA) (36%), tocilizumab (19%), infliximab (9%), canakinumab (7%), abatacept (7%) and anakinra (2.7%). ADA and ETA were preferred with equal in ERA while ETA was the first BA in other subtypes (p=0.00). 26% of patients (n=29) received more than one biologic during follow-up (2 agents, n=18; ≥3agents, n=11). Most of the switchers were in SJIA (38%, p=0.00), less often were in Poly (31%) and ERA (14%). In the switchers, median follow-up duration on BA was 13 months (range 1–69) under the first BA, 6.8 months (range 1–26) under the second and 6.5 months (range 1–19) under the third BA, (p>0.05). The reasons of switching was loss of response (58.6%, n=15), lack of effectiveness (27.5%,n=8), adverse event (13.7%, n=4), and convenience of use and patient's choice in 2 patients each (2%). At last follow up, 97 patients (87.4%) achieved inactive disease, in 78 (80%) of these patients with a first BA, 12 (12.3%) with a second BA, 4 (4%) with a third and 2 (2%) under a fourth BA. Minimal disease activity was seen in 11 patients while 3 patients were still in the active.A persisting limitation or loss of normal range of articular motion of ≥1 joint was recorded in 26 of patients (23.4%) at last follow-up. No case of cancer or death was recorded. 8 patients had developed short stature, 6 had osteoporosis, 2 had amyloidosis,2 had neuropathic pain and 2 had glaucoma at last examination. Two patients underwent surgical intervention (hip arthroplasty and wrist arthrodesis).
**Conclusions:** Biologic agents appear to be highly effective in children and adolescents with JIA who were resistant DMARDs. Reumatologists take into patient factors andnewly data in choosing the optimal BA
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3605

## SAT0266 SAFETY ASSESSMENT OF BIOLOGICAL AGENTS USED IN PEDIATRIC RHEUMATIC DISEASES, SINGLE CENTER RESULTS

B. Sozeri[1], Z. Gunduz[1], R. Dusunsel[2], A. Pac Kisarslan[2], I. Dursun[2], H. Poyrazoglu[2]. *[1]Pediatric Rheumatology; [2]Erciyes Universitesi Tip Fakultesi Hastanesi, Kayseri, Turkey*

**Background:** In recent years, the biologic drugs has led to a dramatic change in the management of rheumatic diseases in children. Currently available biologics include TNF-α blockers, agents that target IL-1 and IL-6, T-cell costimulation inhibitors and antibodies against the CD20 molecule present on B cells. The studies about the long term safety of biologic agents (BA) in pediatric patients with rheumatic diseases are still limited.

**Objectives:** The aim of this study was carry out a safety evaluation of biologic agents in patients with rheumatic disease
**Methods:** This was retrospective study in Erciyes University Faculty Medicine, the tertiary center for pediatric rheumatology in Turkey. We recruited the patients who were diagnosed a rheumatic disease and treated with a biologic agent (BA) between 2009 and 2015. Adverse events (AEs) were categorized and graded based on the Common Terminology criteria for AEs (CTCAE). Grades 3–5 were considered SAEs. The time until discontinuation of BA was counted as patient-years (PY).
**Results:** We included 127 consecutive patients: Juvenile idiopathic arthritis (n=102, 80.3%), Familial Mediterranean fever (n=9, 7.8%), Uveitis (n=7, 5.5%), sarcoidosis (n=3, 2.4%), Systemic lupus erythematosus (n=2, 1.6%), Hyperimmunglobulin D syndrome (HIDS) (n=2, 1.6%), Takayasu arteritis (n=1, 0.8%), Tumor necrosis factor receptor associated periodic syndrome (TRAPS) (n=1,0.8%). The median age of the patients at diagnosis was 91 months [interquartile range (IQR) 60–138), while the median age at the time of treatment with biologic therapy was 144 (IQR 90–184) months. The median disease duration prior to treatment with biologics was 22 months (IQR 8–49).
A total of 241.3 patient years (PY) were included: 132 py (72 patients) for etanercept, 44.5 (41) for adalimumab, 23 (20) for tocilizumab, 22 (13) for canakinumab, 7.7 (9) for infliximab, 4.2 (15) for anakinra, 6 (7) for abatacept and 1.9 (2) for rituximab.
A total of 113 patients (89%) were on methotrexate prior to biologics and 90 (71%) during biologics. A total of 38 patients (30%) had been on two or more biologics, 7 (5.5%) on three, 5 on four (3.9%) and 1 on five.
A total of 35 patients (27.6%) had at least one AE. Those with AEs 45 months (IQR 57) had a significantly longer median follow-up of 31 months (IQR 41) than those without an AE (p=0.01). Forty-five patients experienced 93 AEs (38.5/100 py). Of those AEs, 20 were reported as serious AEs (8.3 /100 py). The SAEs were lower with anti TNF alpha agents than others (6.8 for ETN, 21.7 for TOS, 4.5 for ADA, 25.9 for INF, 4.5 for CAN, 23.8 for ANK, 33.3 for ABT) (p=0.00).
Eight of the SAEs (40%) were classified as noninfectious (infusion reaction, anaphylaxis, vasculitis, macrophage activation syndrome, seizure and glomerulonephritis) were documented. Three patients on ETN developed reactivation of latent tuberculosis. No deaths, malignancies, opportunistic infections, demyelinating diseases, or lupus-like reactions were observed during biologic agents exposure.
**Conclusions:** Here in, we presented safety data comparing biologic drugs in pediatric patients retrospectively. The frequency of mild infections and latent tuberculosis was higher on Anti TNF alpha drugs, but sAEs were lower than others. To better define the safety profile of biologic drugs need for prospective studies and large cohorts.

## SAT0267 ROLE OF MUSCULOSKELETAL ULTRASONOGRAPHY IN THE EVALUATION OF HEMOPHILIC ARTHROPATHY IN CHILDREN

D. Al-Zifzaf[1], N. Nassar[1], I. Ghanima[1], E. Khalil[1], H. Saqr[2], M. Alfy[3].
*[1]Rheumatology & Rehabilitation; [2]Radiodiagnosis; [3]Paediatrics, Ain Shams University, Cairo, Egypt*

**Background:** Recurrent clinical and subclinical joint bleeding almost inevitably causes arthropathy with affected function up to severe loss of motion of elbows, knees and ankles. Diagnosis of hemophilia is essentially clinical and laboratory based, however, imaging is an important tool for evaluation of complications and therapeutic follow-up. Musculoskeletal Ultrasound (MSUS) is a useful method for frequent follow-up in pediatric patients being non-invasive, easy repeatable, painless, without ionizing radiation, relatively inexpensive, with no need for sedation.
**Objectives:** To investigate the role of MSUS as a tool for evaluation of joint affection in hemophilic arthropathy compared to clinical and functional assessment as well as conventional x-ray.
**Methods:** This study included 20 male children (a total of 120 joints) with severe hemophilia type A (6–15ys). Twenty age and sex matched non-hemophilic children served as controls. Patients underwent clinical examination, assessment of the Hemophilic Joint Health Score, functional assessment according to Functional Independence Score for Hemophilia, radiological evaluation using conventional X-ray according to Pettersson classification as well as qualitative ultrasongraphic scoring according to Klukowska et al., 2001, and Muca-perja et al., 2012. For more accurate quantitative values, we designed an MSUS index based on measurements of the cartilage thickness and joint space dimensions. All above was done at the knees, ankles and elbow joints.
**Results:** The knee joint was the principal joint affected among hemophilic patients. Cartilage thinning was the predominant pathological disorder with subsequent joint space narrowing especially at the medial condylar side of the knee. Using the designed quantitative score the cartilage thickness among patients, as well as the joint space, showed a highly significant negative correlation with age, clinical scores and the radiological score while no statistically significant relation was detected with the functional scoring. The ultrasonography qualitative scores failed to show statistically significant relation on correlating with clinical, functional and radiological scores. The prevalence of cartilage damage among patients according to Klukowska et al., score was 75% of the total 40 knee joints, 47.5% with synovial hypertrophy, 30% with synovial effusion and 20% with increased synovial vascularity. The prevalence of cartilage damage among patients according to Muca-perja et al., 2012 was 90% of the total 40 knee joints, 47.5% with synovial hypertrophy, 27.5% with bone erosions and 20% with synovial hyperemia.
**Conclusions:** MSUS successfully detected changes in the hemophilic joints even before functional affection started. MSUS provides accurate assessment, allowing early detection of hemophilic arthropathy as well as precise follow up of progression of damage by standardizing and simplifying the planes and landmarks for acquisition of the sonographic images using quantitative measurements in haemophilic joints

## SAT0268 TOCILIZUMAB THERAPY IN CHILDREN WITH POLYARTHICULAR COURSE JUVENILE IDIOPATHIC ARTHRITIS

E. Alexeeva[1,2], R. Denisova[1], S. Valieva[1], T. Bzarova[1], K. Isayeva[1], T. Sleptsova[1], E. Chistyakova[1], A. Chomahidze[1], O. Lomakina[1], M. Soloshenko[1], A. Fetisova[1], E. Kashchenko[1]. *[1]Rheumatology, Scientific center of children's health; [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** Patients with polyarticular-course Juvenile idiopathic arthritis (pcJIA) have risk for profound disability.Although these patients may respond to methotrexate (MTX) or biological agents approved for pcJIA, up to 30% continue to have active disease.Interleukin-6 (IL-6) is concentrations are positively correlated with the severity of joint involvement and with C-reactive protein (CRP) levels. Tocilizumab is effective drug for the treatment of JIA refractory to immunosuppressive drugs.
**Objectives:** To evaluate safety and efficacy of tocilizumab treatment in children with pcJIA
**Methods:** Analysis of efficacy and safety tocilizumab therapy was performed in 46 patients (4 - RF+, 3-enthesitis related arthritis, 1-psoriatic JIA) and in 24 patients, whom follow up period was 6 and 12 m. Median age was 9,8 y (range; 1,9 to 17,2 y) and median disease duration was 5,1y (range; 0.4 to 13,7 y). Tocilizumab was administrated intravenously at a dose of 8or 10 mg/kg every 4 weeks. 29 patients were treated by biologics previously. The majority of patients received concomitantDMARDs, 31 patients received methotrexate, 1-leflunomid, 1-sulfasalazin,5-cyclosporin and 8- prednisolone at dose 0.4 (0.2; 1) mg/kg/day. 14 patients had uveitis: 6-not active,1-subactive and 7-active. Efficacy end points included the American College of Rheumatology (ACR)for improvement 30 (ACR30), ACR50, ACR70, ACR90 and criteria of inactive disease andindex JADAS10. During the follow-up period, significant side-effects were sought.
**Results:** The ACR Pedi 30, 50, 70, 90 and 100 improvement were achieved by 92% (n=36), 82% (n=32), 56% (n=22), 23% (n=9),and 12% (n=5) of patients at Week 24 (n=39), by 100% (n=24), 87% (n=21), 83% (n=20), 54% (n=13), and 20% (n=5) of patients at Week 48 (n=24)respectively. Inactive disease was achieved by 14/39 (36%) of patients at week 24 and by 12/24 (50%) of patients at week 48. The JADAS10 decreased from 23,4 (14,8; 27,8) to 6,2 (1,6; 11,8) at week 24 ($p<0.001$) and to 2,0 (0,5; 4,9) at week 48 ($p<0.001$). The number of platelets decreased from 383 x109/l (302; 488) to 250 (220; 282) at week 24 ($p<0.001$) and to 258 (216; 284) at week 48 ($p<0.001$), number of leucocytes – from 8,8 x109/l (7,6; 9,9) to 6,5 (5,3; 7,3) at week 24 ($p<0.001$) and to 6,4 (4,7; 6,8)) at week 48 ($p<0.001$); level of hemoglobin increased from 112 (100; 123) g/l to 126 (118; 132) at week 24 ($p<0.01$) and to 129 (122; 136)) at week 48 ($p<0.001$).The frequently observed non-severe adverse events were nasopharyngitis, upper respiratory tract infections and gastroenteritis. No cases of opportunistic infections, malignancies or death were reported. 12 patients had incidences of neutropenia, 2 – thrombocytopenia,7-increased level of ALT and AST. Tocilizumab treatment was discontinued in 7 patients during the follow-up 48 weeks period. The causes for cancellation were lack of efficacy (n=6), infusion reaction (n=1), flare (n=1). 5patients were switched to antiTNF blockers and 2 – to abatacept.
**Conclusions:** Tocilizumab treatment provided clinically meaningful improvement for patients with pcJIA. Tocilizumab induced remission of the disease The safety profile of tocilizumab was consistent that seen in other studies

## SAT0269 SURVIVAL OF THE SECOND TNF INHIBITOR IN PATIENTS WITH POLY-JIA

T. Bzarova[1], E. Alexeeva[1,2], S. Valieva[1], R. Denisova[1], K. Isayeva[1], T. Sleptsova[1], E. Chistyakova[1], A. Chomahidze[1], O. Lomakina[1], M. Soloshenko[1], A. Fetisova[1], E. Kashchenko[1]. [1]*Rheumatology, Scientific center of children's health;* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** TNFα is one of the most important cytokine in the pathogeneses of poly-JIA. There are several TNF inhibitors for the treatment poly-JIA. Switching TNF-blockers is often strategy in the treatment of poly-JIA.
**Methods:** An open observational study in patients with poly-JIA taking the second TNFinhibitor. A total of 119 patients (46 boys and 73 girls) were included in this study. The mean age was 11 (7;14), disease duration was 5 (3;8) years. By the switching time 54/119 had active polyarthritis, 58/119 – olygoarthritis, 7/119 – active uveitis without arthritis. Infliximab was the first TNF inhibitor in 105/119, adalimumab – in 3/119, etanercept – 11/119. 81/119 were switched to adalimumab, 38/119 – to etanercept. Analysis of survival the second TNF blocker treatment was performed in all patients by Kaplan–Meier curve.
**Results:** The causes for cancellation of the first and second TNF blockers were second inefficacy (3,7% and 8%), adverse events (5,6% and 2,5%) and administration causes (7% and 8%). Infliximab was cancelled because of primary inefficacy (7/105, 6.7%), second inefficacy (57/105, 54.3%), adverse events (12/105, 11.4%), relapse of uveitis (7/105, 6.7%), disease remission (19/105, 18.1%), administration causes (3/105, 2.8%). Etanercept was discontinued because of primary inefficacy (1/11, 9%), second inefficacy (2/11, 18%), adverse events (2/11, 18%), relapse of uveitis (6/11, 55%). Adalimumab was cancelled because of primary inefficacy (1/3), adverse events (1/3), administration causes (1/3). The second TNF inhibitor treatment survival in patients with the primary inefficacy of the first TNF inhibitor at 1,2 year was 73%, at 1,8 year was 73%, at 2,4 year was 53%. The second TNF inhibitor treatment survival in patients with the second inefficacy of the first TNF inhibitor at 1,2 year was 82%, at 1,8 year was 82%, at 2,4 year was 69%. The second TNF inhibitor treatment survival in patients with the remission of the first TNF inhibitor and relapse of disease at 1,2 year was 82%, at 1,8 year was 82%, at 2,4 year was 72%. The number of AE was 32.2 and 24.5 per 100 p.y. on the 1st and 2nd TNF blocker treatment, accordingly ($p<0,0001$).
**Conclusions:** The highest percent of survival of the second TNF inhibitor treatment was registered in patients with poly-JIA whom the first TNF inhibitor was cancelled because of disease remission and the lowest percent – in patients with poly-JIA whom the first TNF inhibitor was cancelled because of the primary inefficacy of the first TNF inhibitor.

## SAT0270 SUBCLINICAL INFLAMMATION IN CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER: MEASUREMENT OF SERUM AMYLOID A LEVELS

E. Comak[1], E. Isıyel[2], F. Kılıcbay[3], G. Kaya Aksoy[1], A. Gemici[1], M. Koyun[1], S. Akman[1]. [1]*Pediatric Nephrology - Rheumatology, Akdeniz University, Antalya;* [2]*Pediatric Nephrology - Rheumatology;* [3]*Pediatrics, Kocaeli Derince Training and Research Hospital, Kocaeli, Turkey*

**Background:** Familial Mediterranean Fever (FMF) is an autosomal recessive, inherited, autoinflammatory disease characterized by recurrent, self-limited febrile episodes of inflammation of serous membranes and marked elevation of acute phase proteins. In some patients with FMF, the laboratory markers of inflammation do not return to normal levels during attack-free periods, and complications related with persistent subclinical inflammation may occur.
**Objectives:** The aim of this study was to evaluate the clinical role of serum amyloid A (SAA) and other acute-phase proteins during the treatment and follow-up of children with FMF.
**Methods:** The children with the diagnosis of FMF were enrolled in the study. Information including clinical and laboratory findings, erythrocyte sedimentation rate (ESR), SAA and C-reactive protein (CRP) levels, type of MEFV mutation were collected from the hospital's records following approval by the local ethics committee. Children were divided into four groups according to the time of SAA determination: group I during diagnostic evaluation (before colchicine treatment), group II asymptomatic children treated with low-dose colchicine, group III asymptomatic compliant children treated with adequate dose colchicine according to the their body weight, group IV non-compliant children with colchicine treatment.
**Results:** A total of 141 children, 73 (51.8%) girls with a median age of 11 years (1.5–18) and a median follow-up period of 12 months (3–135) were included in the study. Thirty two children, (22.7%) had parental consanguinity and 79 children (56.0%) had family history of FMF. Thirty three children (23.4%) were homozygous, 66 children (46.8%) were compound heterozygous and 42 children (29.8%) were heterozygous for MEFV gene. Colchicine treatment was started in all patients. The main clinical characteristics of the children were: abdominal pain in 87.2%, fever in 61.7%, arthralgia/myalgia in 52.5%, arthritis in 15.6%, chest pain in 10.6%, erysipelas-like erythema in 4.3%, history of appendectomy in 6.2%, microalbuminuria in 15.6% and proteinuria 6.4%. There were 21 children in group I, 9 in group II, 84 in group III and 27 in group IV. Elevated SAA levels (>10 mg/L) found in 55 children (39.0%), elevated CRP levels (>0.5 mg/dl) in 45 children (31.9%) and elevated ESR (>20 mm/hour) in 42 children (29.8%). Comparison of the acute-phase proteins revealed significant differences between four groups as expected (Table 1). In group II, number of children who had elevated SAA levels was higher than the number of children with elevated CRP levels (88.9% vs 44.4%) and none of these children had elevated ESR.

Table 1. Number of patients with elevated acute phase protein levels on groups

| | Group I (n=21) | Group II (n=9) | Group III (n=84) | Group IV (n=27) | p |
|---|---|---|---|---|---|
| SAA levels (>10 mg/L), n (%) | 18 (85.7) | 8 (88.9) | 5 (6.0) | 24 (88.9) | 0.001 |
| CRP levels (>0.5 mg/dl), n (%) | 14 (66.7) | 4 (44.4) | 4 (4.8) | 23 (85.2) | 0.001 |
| ESR (>20mm/hour), n (%) | 15 (71.4) | 0 | 3 (3.6) | 24 (88.9) | 0.001 |

**Conclusions:** Our findings suggest that SAA level is important laboratory parameter for determination of subclinical inflammation especially in asymptomatic children treated with low-dose colchicine. Monitoring of SAA levels should be part of routine follow-up of children with FMF for the prevention of the development of FMF-related complications.
**Disclosure of Interest:** None declared

## SAT0271 HEPATOSPLENOMEGALY: A COMPLICATION OF PERSISTENT SUBCLINICAL INFLAMMATION IN CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER?

E. Comak[1], G. Duygulu[2], E. Isıyel[3], F. Kılıçbay[4], M. Koyun[1], S. Akman[1]. [1]*Pediatric Nephrology - Rheumatology, Akdeniz university, Antalya;* [2]*Radiology;* [3]*Pediatric Nephrology - Rheumatology;* [4]*Pediatrics, Kocaeli Derince Training and Research Hospital, Kocaeli, Turkey*

**Background:** Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disorder characterized by attacks of painful inflammation. Some patients with FMF have subclinical inflammation persisting between the attacks. This subclinical inflammation may leads to many important clinical complications such as anemia, splenomegaly, decreased bone density, and amyloidosis.
**Objectives:** The aims of this study were to evaluate sonographic findings in patients with familial Mediterranean fever (FMF) during attack-free periods and examine whether there is an association between hepatosplenomegaly and *inflammatory* markers in FMF.
**Methods:** Medical records of children with FMF were reviewed during attack-free periods. Demographic features, clinical and laboratory findings, hematological data (leukocyte, hemoglobin and platelet counts),er*ythrocyte* sedimentation rate (ESR), SAA and C-reactive protein (CRP) levels, type of MEFV mutation, family history of FMF were collected from the hospital's computerized database following approval by the local ethics committee.
**Results:** A total of 136 patients, 74 (54.4%) girls were included in this cross sectional study during non-attack period. Median age of 11.25 years (2–18 years) and median follow-up period were 18 months (3–129 months) at time of sonographic evaluation. Thirty one patients (22.8%) had parental consanguinity and 472 (52.9%) patients had family history of FMF. Thirty three patients (24.3%) patients were homozygous, 61 (44.9%) patients were compound heterozygous and 42 (30.9%) patients were heterozygous for MEFV gene. Hepatomegaly and splenomegaly were found in 22 (16.2%) and 32 patients (23.5%), respectively. Ten patients had both hepatomegaly and splenomegaly. Spleen size had a negative correlation with platelet count and a positive correlation with ESR, CRP and SAA (all $p<0.05$). Also, there was significant positive correlation between liver size and CRP levels ($p<0.05$). White blood cell count, hemoglobin, urinary protein-creatinine ratio were not associated with spleen and liver size. And also, patients with splenomegaly had significantly higher SAA, CRP and ESR levels than the patients with normal spleen size (Table 1).

Table 1. Laboratory findings of patients

| | SAA (mg/L) | CRP levels (mg/dl) | ESR (mm/hour) |
|---|---|---|---|
| Patients with splenomegaly | 11.02±9.10 | 2.3±3.4 | 19.06±12.32 |
| Patients without splenomegaly | 8.8±15.25 | 1.01±1.79 | 14.89±12.28 |
| P value | 0.03 | 0.03 | 0.01 |

**Conclusions:** Hepatomegaly and splenomegaly are not uncommon in FMF, which might be due to the chronic inflammatory characteristics of the disease. We speculate that FMF is a chronic inflammatory disease rather than episodic illness.
**Disclosure of Interest:** None declared

## SAT0272 SURVIVAL OF BIOLOGICAL TREATMENT IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS NON-SYSTEMIC

H. Moruno-Cruz[1,2], A. Pérez Gómez[2], D. Clemente Garulo[1], J.C. López Robledillo[1]. *[1]Pediatric Rheumatology Service, "Niño Jesús" Universitary Children's Hospital, Madrid; [2]Immune System Diseases - Rheumatology Service, "Principe de Asturias" Universitary Hospital, Alcalá de Henares, Spain*

**Background:** Currently we have biological treatments for control juvenile idiopathic arthritis (JIA), we have specific protocols that help us to handle, and do not know the exact time they keep these treatment, which conducted this study survival the biological agent.
**Objectives:** The purpose this work is describe the survival time of biological drugs used in patients diagnosed with JIA, excluding the form systemic, in a pediatric unit of a children's hospital in the last 5 years.
**Methods:** Descriptive analytic study of patients diagnosed with JIA (non-systemic) (as proposed by ILAR nomenclature, Edmonton 2001), who received biological treatment from 1 January 2010 to 30 June 2015. It considered as an event end the suspension of treatment by state remission or change to regimen decrease. Statistical analysis performed using the Kaplan-Meier and log rank test with SPSS.19.0 program.
**Results:** Total 90 patients diagnosed with JIA with biological treatment in the last 5 years, 2/3 female (60 girls, 66.7%), 1/3 male (30 boys, 33.3%), mean age 5 years 2 months (minimum: 1 year 11 months, maximum: 15 years 6 months). The distribution of JIA: Oligoarticular arthritis 40% (42 patients). Polyarticular RF negative arthritis 22.9% (24 patients). Enthesitis-Related arthritis 15.2% (16 patients). Polyarticular RF positive arthritis 3.8% (4 patients). Psoriatic arthritis 3.8% (4 patients).
Total 100 treatments: 49% adalimumab, 46% etanercept, 5% Tocilizumab. Median time of 36 months overall monitoring (SD ± 21.8). Continue with the drug 45 patients, 45 achieved remission or regimen decrease (23 adalimumab, 20 etanercept, 2 tocilizumab), replaced by inefficiency 7, suspended for toxicity 3. Namely 45 and 55 censored events cases.
Medians for survival time: 56 months adalimumab (95% CI 46.5–65.5), 48 months etanercept (95% CI 38.8–57.2), Tocilizumab 46 months.
The comparison between the survival curves of etanercept and adalimumab (Logrank) was 0.092 (p=0.762).
**Conclusions:** The time when "survive" (remain) biological treatment are significantly prolonged, over 4 years, with little difference between the two treatments used (etanercept and adalimumab). In addition, it can be deduced that serious side effects are rare, since in this cohort were replaced only in three cases by significant adverse effects.
No significant differences in the comparison of the survival curves of the main biological treatments used were found.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4438

## SAT0273 CORTICOSTEROIDS AS RESCUE THERAPY FOR RESISTANT KAWASAKI DISEASE

L. Das[1], K.L. Teh[2], M. Tanya[1], S. Yoo[1], J.H.T. Tan[1], J.T.L. Choo[3], T.H. Tan[3], T. Arkachaisri[1,4]. *[1]Rheumatology and Immunology Service, Department of Paediatric Subspecialties; [2]Dept of Paediatrics; [3]Cardiology, Dept of Paediatrics, KK Women's and Children's Hospital; [4]Duke-NUS Medical School, Singapore, Singapore*

**Background:** Kawasaki Disease (KD) is one of the most common systemic vasculitidies in children today. IVIG is the mainstay of treatment, however, about 1/5 of patients do not respond (Teraguchi) resulting in an increased risk of Coronary Artery Abnormalities (CAA). Based on the current literature and from experience it is our preference to use Intravenous Methylprednisolone (IVMP) in the treatment of IVIG resistant Kawasaki Disease (rKD) patients.
**Objectives:** To examine the differences in CAA seen in patients who were treated with IVMP versus retreatment with IVIG
**Methods:** Demographic, clinical manifestations and echocardiogram data were collected and analyzed. Descriptive statistics were used to describe the data. Chi square/Fisher Exact Test were used to test association, student t test or Mann Whitney U were used to compare the data where appropriate. Kaplan Maier analysis was used to assess the time to CAA resolution. Significance was set at 0.05.
**Results:** Of the 78 rKD patients included (type of KD: complete 55, incomplete 23), 33 received 2nd IVIG and 45 received IVMP. 13 rKD patients who failed the 2nd IVIG treatment were excluded from the analysis (2nd IVIG failure 27.7%). Median age at onset was 1.5 years (IQR 0.76, 2.58) and 45 patients were male. There was no significant difference in regards to gender (p=0.63), age at onset (p=0.14), type of KD (p=0.89) or KD clinical manifestations between treatment groups (p=0.25–0.56). 88.9% of IVMP and 57.6% of 2nd IVIG patients had CAA prior to therapy (p=003). The median duration to completing CAA resolution was 1.19 years; 2nd IVIG group (IQR 0.62, 2.43) and IVMP (IQR 0.84, 3.27). Time to achieve CAA resolution was not different between treatment groups (p=0.11, Figure 1).
**Conclusions:** Between 2nd IVIG and IVMP as rKD rescue therapy, there was no difference in duration of achieving CAA resolution. Our group has described higher number of rKD with CAA prior to IVMP treatment. A larger, prospective randomized controlled trial is needed to confirm our preliminary observations for which this is underway in our region.

## SAT0274 INDIRECT COMPARISON OF BIOLOGICAL AGENTS IN JUVENILE IDIOPATHIC ARTHRITIS: META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

M. Fan[1], J. Liu[2], B. Zhao[2], P. Zhang[1], Y. Mou[1], J. Gu[1]. *[1]The Third Affiliated Hospital of Sun Yat-Sen University; [2]The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in childhood. Recent advances in biologics have greatly changed the prognosis of JIA.
**Objectives:** To evaluate the efficacy and safety of biological agents in patients with JIA.
**Methods:** We included all randomized controlled trials (RCTs) that compared biologics with placebo in JIA patients. According to the American College of Rheumatology Pediatric (ACR Pedi) criteria, the proportions of patients reaching 30%, 50% or 70% improvement (ACR Pedi 30/50/70) or suffering disease flare were used as the efficacy outcomes. Adverse events (AEs), infections and severe AEs were applied to evaluate the safety. The biological agents were pooled to perform comparison with placebo and among themselves, calculating odds ratios, probability of being best ($P_{best}$) and numbers needed to treat (NNT).
**Results:** Sixteen RCTs totaling 18 reports (1689 patients) were included in the analysis focusing on 4 different types of biologics, i.e. tumor necrosis factor (TNF) inhibitors (etanercept, infliximab, adalimumab and golimumab), anti-interleukin-1 agents (anakinra, rilonacept, canakinumab), anti-interleukin-6 agent (tocilizumab) and cytotoxic lymphocyte-associated antigen-4 agent (abatacept). All biological agents were efficacious in achieving ACR Pedi 30/50/70 responses and preventing disease flare compared with placebo but with a higher risk of infections. No significant differences in efficacy were found among biologics, except that tocilizumab had a higher rate of ACR Pedi 30 response than TNF inhibitors. And for ACR Pedi 30/50/70 responses, tocilizumab was ranked the most effective option with NNT of 2 ($P_{best}$ 89.9%, 82.3% and 48.4%, respectively).
**Conclusions:** Compared to placebo, biologics are all effective in the treatment of JIA but with a higher risk of infections. Tocilizumab is more likely to achieve ACR Pedi 30/50/70 responses.

## SAT0275 KAWASAKI DISEASE – AN EASTERN INDIAN COHORT OF 7YEARS

P.P. Giri, P. Pal. *Pediatric Medicine, Institute of Child Health, Kolkata, India*

**Background:** Kawasaki disease (KD), an acute febrile childhood vasculitis can present with varying clinical features and the main complication is involvement of coronary arteries (1). The epidemiological pattern may be different in different geographical regions, even it can vary within a country. KD is not unusual in India but published series are infrequent (2). Here we present a series of 185 cases of KD diagnosed in our hospital in last 7 years to have a look in to the varied clinical manifestations, epidemiology, atypical features and complications.
**Objectives:** 1. To analyse the record of Kawasaki disease diagnosed in the study period.
2. Compare the epidemiology and clinical features of KD in our part of the country with that of the published series from northern India.
3. To note the atypical features and estimate the incidence of coronary involvement.
**Methods:** Clinical records of 185 children fulfilling the diagnostic criteria of Kawasaki Disease and admitted at the Institute of Child Health, Kolkata during the time period October 2008 to January 2016 were reviewed. The data collected included details of clinical and laboratory features, treatment and outcome.
**Results:** A total of 185 patients were diagnosed as KD (4.8 per 1000 hospital admission). Among these 185 patients,171 presented with typical features of KD, rest 14 were atypical including KD with erythroderma, KD with bilateral ptosis,

neonatal KD, KD with facial Palsy,KD with nephrotic syndrome etc. Average age of presentation was 22 months. Most patients presented with fever of an average duration of 9 days. Besides the typical features, we want to stress upon some special features of KD, like orange-brown chromonychia (orange brown discolouration of nails) in 65% of cases, BCG scar reactivation in 14%, extreme irritability in 86% and greenish loose stools in about 68%. Echocardiographic abnormalities (ectasia or aneurysm) were detected in 29% of cases. All patients received Intravenous Immunoglobulin of which 7 did not respond to a single dose of 2gram/kg.

**Conclusions:** 1. A bimodal seasonality has been seen with clustering of cases during March- April and September-October.
2. Mean age of onset (22 months) is lower than the north India series.
3. Most (94%) presented with typical form with a response rate of 96% with first dose ivIg.
4. Orange brown Chromonychia is a novel finding that has been seen in a significant number of patients.
5. Coronary abnormalities is on the higher side than the reported series from north India as well as other parts of the world.

## SAT0276 CYCLOSPORINE IN RESISTANT SYSTEMIC JIA - A CHEAPER ALTERNATIVE TO BIOLOGICS FOR DEVELOPING COUNTRIES

P.P. Giri[1], P. Pal[2]. *[1]Pediatric Medicine; [2]Pediatric Rheumatology, Institute of Child Health, Kolkata, India*

**Background:** Systemic juvenile idiopathic arthritis (sJIA), though well responsive to corticosteroids (1), but toxicity limit their prolonged usage. Other disease modifying anti rheumatic drugs (DMARDs) have been tried to limited effect (1). Only the newer biologic agents (Anakinra, Tocilizumab) are promising (1,2), but in a developing country like India, accessibility and prohibitive costs limit their use. We started trying Cyclosporine, a potent immunosuprressive agent for the cost benefit in steroid dependent or refractory sJIA specially in those who relapsed with predominant systemic symptoms. Here, we present a series of 15 cases refractory sJIA most of whom were successfully treated with oral Cyclosporine in conjunction with methotrexate ± low dose steroids.
**Objectives:** 1. To assess the efficacy of Cyclosporine in patients of steroid unresponsive or steroid dependent Systemic JIA. 2. To evaluate the optimum dosing and blood level to achieve and maintain remission.
**Methods:** Clinical records of children fulfilling the diagnostic criteria of sJIA admitted at the Institute of Child Health, Kolkata during the time period July 2009 to November 2015 were reviewed. The data collected included details of clinical and laboratory features, treatment and outcome. In this prospective study a total of 82 sJIA was diagnosed. 15 were refractory and included as a candidate for cyclosporine therapy.
*Criteria for initiating Cyclosporine:* sJIA relapsing frequently (at least 3 times) on withdrawing or attempting to taper off steroids, in spite of being on Methotrexate +/– Hydroxychloroquine.
**Results:** Among the 15 patients of frequently relapsing, steroid dependent sJIA, 13 responded to cyclosporine and Steroid could be withdrawn completely after a mean duration of 6.15 months of starting Cyclosporine.
Among this 13, 11 never relapsed after initiation of Cyclosporine and 2 relapsed but managed with a short course of steroid. So we achieved a permanent remission rate of 73% (P value0.02) with a mean follow up of 15 months after starting cyclosporine.
At present:
1. Off Steroid, off Cyclosporine -11 (9 never relapsed, 2 relapsed but responded to short course steroids)
2. Off Steroid, on Cyclosporine-2 (never relapsed)
3. Did not respond to Cyclosporine -2
The mean dose of Cyclosporine to achieve the remission was 3.9 mg/kg/day.
The mean blood level in which remission was induced was 138.4ng/ml.
There was no significant side effect noted except hirsuitism in one and another one developed transient hypertension.
**Conclusions:** 1. Cyclosporine was found to be effective in almost 75% of frequently relapsing steroid dependent sJIA to achieve and maintain remission.
2. Cyclosporine was found to be a cheaper alternative to Tocilizumab as the average cost of therapy for a 20kg patient on Cyclosporine was found to be 10,000 INR (143 EURO)/patient over a 6 months period; which would amount to 100,000 INR (1430 EURO)/patient with Tocilizumab for the same duration (Anakinra not available in India).

## SAT0277 NEUROPSYCHIATRIC INVOLVEMENT IN JUVENILE-ONSET SYSTEMIC LUPUS

R. Fonseca, F. Aguiar, M. Rodrigues, I. Brito. *Pediatric Rheumatology Unit, São João Hopital Centre, Oporto, Portugal*

**Background:** Neuropsychiatric involvement in systemic lupus erythematosus (NPSLE) includes the neurological syndromes of the central, peripheral or autonomic nervous systems and psychiatric disorders. Some studies suggests that juvenile systemic lupus erythematosus (jSLE) has a more serious course and a more frequent neuropsychiatric involvement than adult onset, coursing with significant morbidity and mortality. Its prevalence ranges from 22 to 50.9%.
**Objectives:** To assess neuropsychiatric manifestations in juvenile-onset SLE patients and study the predictors and association to disease characteristics.
**Methods:** Retrospective observational study was performed including consecutive patients with jSLE (disease onset before 16 years of age,) that fulfilled American College of Rheumatology (ACR) criteria followed in our Paediatric Rheumatology Unit. Clinical, demographic and laboratory characteristics were retrospectively collected by consulting the medical records. The neuropsychiatric manifestations were defined according to the nomenclature and classification of ACR. Patients with NPSLE were compared with others using Student t-test, Mann-Whitney test, Chi-square or Fisher test (SPSS 23.0). Significance level was set as $<0.05$.
**Results:** 38 patients were included, 92.1% (35) were female, with a mean age at diagnosis of 12.9 ± 3 years. Median period between onset of symptoms and diagnosis of SLE was 0.3 [0–1.2] years and median duration of follow-up was 14 [0.75–26]. Neuropsychiatric manifestations of the SLE were observed in 8 (21%) patients: chorea (n=1), psychosis (n=2), seizures (n=1), transverse myelitis (1), stroke and weakness (n=1), headache (n=2).
Among the 8 patients with NPSLE, 7 were female and 1 was male. The median time between diagnosis and NPSLE manifestation was 1.75 [0–3] years. The two patients with headaches were treated with oral glucocorticoid. The remaining patients were treated methylprednisole pulses, 3 were treated with cyclophosphamide and 1 with rituximab.
Full recovery was observed in almost patients, except for those with headaches that had many recurrences of symptoms during follow up.
Comparing patients that had NPSLE with the remaining, we found a statistically significant higher SLEDAI and SLICC scores in those with NPSLE (4 vs 2, p=00.04 and 1.5 vs 0, p=0.003, respectively).The age, sex and disease duration were comparable between the groups.
NPSLE was associated with more frequent lupus nephritis (75% vs 43.3%, p=0.03) and presence of antiphospholipide syndrome (APS) (20% vs 11.2%, p=0.04).
NPSLE patients also had higher lupus anti-coagulant prevalence (25% vs 10.7%) and anticardiolipine antibodies (23.3% vs 12.5%) %), yet none of the above reached statistical significance.
**Conclusions:** The neuropsychiatric manifestations are frequently observed in patients with jSLE and central nervous system manifestations were more frequently observed than manifestations affecting the peripheral nervous system. Our study suggests an association between NPSLE and lupus nephritis, higher disease activity and the presence of APS. We observed a good outcome with complete resolution in the majority of the cases.

## SAT0278 ASSOCIATION BETWEEN MUCOCUTANEOUS MANIFESTATIONS AND CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS IN JUVENILE-ONSET SYSTEMIC LUPUS

R. Fonseca[1], F. Aguiar[1], M. Rodrigues[1], I. Brito[1,2]. *[1]Pediatric Rheumatology Unit, São João Hopital Centre; [2]Medical School of University of Oporto, Oporto, Portugal*

**Background:** Patients diagnosed with juvenile-onset systemic lupus erythematosus (jSLE) often have skin and oral lesions as part of their presentation. It is suggested, in literature, that mucocutaneous involvement in jSLE may be associated with some antibodies and systemic disease and often require treatment with systemic immunosuppressive drugs in order to achieve adequate disease control.
**Objectives:** To assess mucocutaneous manifestations in jSLE and to study it's associations with clinical and immunological characteristics.
**Methods:** Retrospective observational study was performed including consecutive patients with jSLE (disease onset before 16 years of age) followed in our Paediatric Rheumatology Unit. Clinical, demographic and laboratory characteristics were retrospectively collected by consulting the medical records. All patients fulfilled the clinical and laboratory criteria of the American College of Rheumatology (ACR). Patients with mucocutaneous manifestations were compared with others using Student t-test, Mann-Whitney test, Chi-square or Fisher test. (SPSS 23.0). Significance level was set as $<0.05$.

**Results:** 38 patients were included, 92.1% (35) were female, with a mean age at diagnosis of 12.9 ± 3 years. Median period between onset of symptoms and diagnosis of SLE was 0.3 [0–1.2] years and median duration of follow-up was 14 [0.75–26].
84.3% had mucocutaneous manifestations, (78.9% malar rash, 5.2% discoid rash, 70.3% photossensibility and 39.5% ulcers). 78.9% of the patients also had musculoskeletal symptoms, 63.2% haematological manifestations, 50% had renal involvement, 21% serositis and 13.2% neuropsychiatric involvement.
Patients with mucocutaneous involvement had more frequently renal involvement (58% vs 14.2%, p=0.001), haematological manifestations (70.9% vs 28.5%, p=0.02), positive lupus anticoagulant (13.8% vs 4.3%, p=0.012), positive coombs test (59% vs 14.2%, p=0.04) and positive anti-SSa (35.4% vs 3.3%, p=0.04). SLEDAI and SLICC scores were comparable between the two groups.
Analysing by type of skin involvement, patients with malar rash had also more frequently haematological involvement (76.7% vs 12.5%, p=0.002) and it was associated with the presence of anti-SSa (33.3% vs 12.5%, p=0.04).
Patients with photossensibility had more frequently positive anti-SSa (34.5% vs 11.1%, p=0.029).
Two patients (5.2%) had discoid lupus and 15 (39.5%) had ulcers but it was not associated with any other clinical or immunological manifestation.
**Conclusions:** Mucocutaneous are frequent manifestations in jSLE, and they are associated with active disease occurring frequently in patients with also haematological and renal manifestations. Anti-Ssa antibody is important in these patients as we have demonstrated it's association with some particularly skin manifestations.

## SAT0279 CYTOKINE GENE POLYMORPHISMS (IL10, IL6, TNFα) IN CHILDREN WITH RHEUMATIC FEVER IN LATVIA

V. Staņēviča[1], L. Ņikitina-Zaķe[2], L. Zepa[2], Z. Dāvidsone[1], R. Šantere[3], A. Ščegolevs[3]. *[1]Pediatrics, Riga Stradiņš University; [2]Latvian Biomedical Research and Study Centre; [3]Pediatrics, Children's Clinical University Hospital of Latvia, Riga, Latvia*

**Background:** Rheumatic fever (RF) is an autoimmune disease which pathogenesis is based on the response of cellular and humoral immune system, that develops after Group A beta hemolytic Streptococci infection with following 45% obtained heart disease (Guilherme L, 2011). One of the most typical clinical manifestations is polyarthritis. So far it is found that genetic polymorphisms may affect the immune system functions and phenotype of RF clinical manifestations. Since cytokines are central immune system molecules, and cytokine gene promoter polymorphisms can affect cytokine production *in vitro*, the following polymorphisms are among the candidates to be studied in pathogenesis of rheumatic fever. The most frequently studied polymorphisms - TNFa-308G/A is associated with mitral valve (MV) damage and TNFa-238G/A - with myocarditis and aortal valve (AV) damage (Rajendranath R, 2007). Data are different and Hernandez-Pacheeco (2003) proved TNFa-238 as unrelated.
**Objectives:** To investigate the following cytokine gene promoter polymorphisms – TNFa-238G/A (ra361525), -308G/A (rs1800795), IL 1-592C/A (rs1800872)-819T/C (rs1800871), -1082G/A (rs1800896) and IL6-174G/C (rs1800795) in patients with rheumatic fever in Latvia.
**Methods:** Clinical and DNA material were analyzed of 70 rheumatic fever patients (born 1984–2002) and 254 healthy. Data and DNA from controls were obtained from the State Population Genome Database. To determine rs1800795 and rs1800896 polymorphisms, was used real time TaqMAn SNP genotyping. Other polymorphisms were analyzed performing polymorphism-containing region Sanger sequencing. Statistical analysis were done with Plink 1.06. All genotyped polymorphisms corresponded to Hardy-Weinberg equation and initial SNP genotyping efficiency was over 98.8%.
**Results:** 48 out of 70 RF patients (68.5%) were boys, 22 (33.4%) were girls. Up to 7 years of age were 23 (32.8%) and after - 47 (67.1%) patients. Acquired rheumatic heart disease developed in 47 (67.1%) patients, MV insufficiency in 24 (34.3%) patients, AV insufficiency in 3 (4.3%) patients and combined MV and AV damage in 20 (28.6%) patients. Polyarthritis were diagnosed in 34 (48.6%) patients. 8 (11.4%) patients suffered from *chorea minor* and 3 (4.3%) patients had *erythema annulare*. Analyzing TNFa and IL-10 genes SNP of promoters in different clinical patients groups and comparing them with controls, statistically significant differences in the frequency of alleles were not observed, but in patients with polyarthritis IL-6 genes rs1800795 alleles showed statistically significant differences comparing with other clinical groups p=0.04737, OR=0.4621.
**Conclusions:** 1. Inflammatory cytokine IL-6 gene promoter's-174G/C position (rs1800795) polymorphism is polyarthritis development affecting SNP in patients with rheumatic fever in Latvia. 2. There was no proven link between TNFa-238G/A and-308G/A SNP and acquired heart disease development.

## SAT0280 RAYNAUD'S PHENOMENON AS AN EARLY SYMPTOM OF RHEUMATIC DISEASE IN CHILDHOOD

M. Chęć, A. Szabat, V. Opoka-Winiarska. *Department of Pediatric Pulmonology and Rheumatology, Medical University of Lublin, Lublin, Poland*

**Background:** Raynaud's phenomenon (RP) can be an initial manifestation of rheumatic disease [1]. In 2013 PReS Congressnewe consensus standards for clinical practice for children with RP was presented [2]. In 2014 a panel of experts established new diagnostic criteria for RP [3]. Nailfold capillaroscopy is an easy test with a well defined diagnostic role in the management of rheumatic diseases [4].
**Objectives:** The aim of the study was the assessment of RP in children and adolescents with the evaluation of nailfold capillaroscopy and the relation of the clinical features to the capillaroscopic pattern.
**Methods:** 77 children aged 7 to 18 years with symptoms of RP diagnosed according to the new diagnostic criteria [3] in Department of Pediatric Pulmonology and Rheumatology Medical University of Lublin were included in the study. RP was differentiated into primary (PRP) and secondary (SRP) RP in accordance with the new criteria [3]. Patients were reviewed for Raynaud's and other clinical symptoms, antinuclear antibodies (ANA) titer and other features. Capillaroscopic patterns were assessed by qualitative and semiquantitative methods and defined as normal, nonspecific changes or scleroderma pattern. Images of the study were archived.
**Results:** 77 patients were included in the study (66 female and 11 male), average age of RP onset was 14,2 years. ANA and capillaroscopy were examined in all patients. Positive ANA (titer≥1/160) were found in 36 (46,75%) patients. Capillaroscopy results were normal in 33 (42,85%) cases, nonspecific changes in 25 (32,46%). The scleroderma patterns were recognized in 19 (24,7%) patients. According to diagnostic criteria for RP, 49 (63,6%) patients had secondary RP, among them systemic sclerosis was diagnosed in 1, juvenile dermatomyositis - 1, juvenile lupus erythematosus - 1, mixed connective tissue disease - 1, juvenile idiopathic arthritis in 3 patients and undifferentiated connective tissue disease in 16. Moreover, we recognized autoimmune thyroiditis in 7 patients, who had SRP. In patients with SRP: 19 (38,8%) had scleroderma pattern in capillaroscopy, 15 (30,6%) - nonspecific changes, 15 - 30,6% results were normal. In children with PRP: the results of capillaroscopy were normal in 18 cases (64,3%), nonspecific changes were observed in 10 (35,7%).
**Conclusions:** In the present group of patients, more than half had secondary RP recognized.
Typically, RP had a beginning in teenage years with marked female predominance.
Almost half of the patients with SRP was diagnosed with a rheumatic disease.
The new criteria and consensus standards for clinical practice in children with RP defined and the objective criteria for the assessment of the capillaroscopic exam significantly clarify the procedure of management of children or adolescents with RP.
A high percentage of secondary RP in our experience confirms the need for further follow up, even after the transition to adult age.

# SLE, Sjögren's and APS - clinical aspects (other than treatment)

## SAT0281 COMPENSATORY BRAIN MECHANISMS TO MAINTAIN COGNITIVE FUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Barraclough[1,2], I.N. Bruce[1,2], S. McKie[2,3], B. Parker[1,2], R. Elliott[2,3]. *[1]ARUK Centre for Epidemiology, CfMR, Institute of Inflammation and Repair, MAHSC, the University of Manchester; [2]NIHR Manchester Musculoskeletal BRU, CMFT; [3]Neuroscience and Psychiatry Unit, Institute of Brain and Behaviour and Mental Health, MAHSC, the University of Manchester, Manchester, United Kingdom*

**Background:** Cognitive dysfunction (CD) has been reported to affect up to 80% of systemic lupus erythematosus (SLE) patients. The cause of CD in SLE is unclear and studies examining structural brain abnormalities have been inconclusive. Functional magnetic resonance imaging (fMRI) is well used in other diseases and is now starting to be used in SLE. Preliminary studies have suggested that patients employ compensatory brain mechanisms to maintain adequate cognitive function but many questions remain unanswered.
**Objectives:** Our study aims to examine the effects of disease activity in SLE on

CD using fMRI, also considering potential confounding factors such as depression and medication.
**Methods:** 32 SLE participants (11 with active disease, SLE-F, and 21 stable, SLE-S) and 30 healthy controls (HC) undertook a working memory task (n-back) and a facial emotional recognition task (FERT) during fMRI. The n-back task had three levels (0-, 1- and 2-back) with the 2-back level being the most difficult. The FERT displayed faces expressing different emotions: happiness, sadness, fear and neutral. fMRI responses to both tasks were analysed using SPM12, the n-back using a cluster significance threshold of $p<0.05$ familywise error corrected and the FERT using a region of interest approach focusing on the amygdala. Demographic, mood and disease variables were analysed using SPSS 22.
**Results:** The three groups were matched on age, sex and handedness but varied on IQ and mood scores. The two SLE groups were well-matched on disease characteristics except, as expected, on the measure of current disease activity (SLEDAI) ($p<0.001$). During the n-back task, the SLE patients had an increased BOLD signal in lateral frontal areas compared to the HC group for the 2-back condition ($p<0.05$). This was more pronounced in the SLE-F group. Also, in the ventral anterior cingulate cortex (vACC), the SLE-S and HC groups had attenuated BOLD signals compared to the SLE-F group ($p<0.05$). For the FERT, there was a strong trend towards the SLE groups having a greater BOLD signal in the left amygdala compared to the HC group ($p=0.07$) (fig. 1).

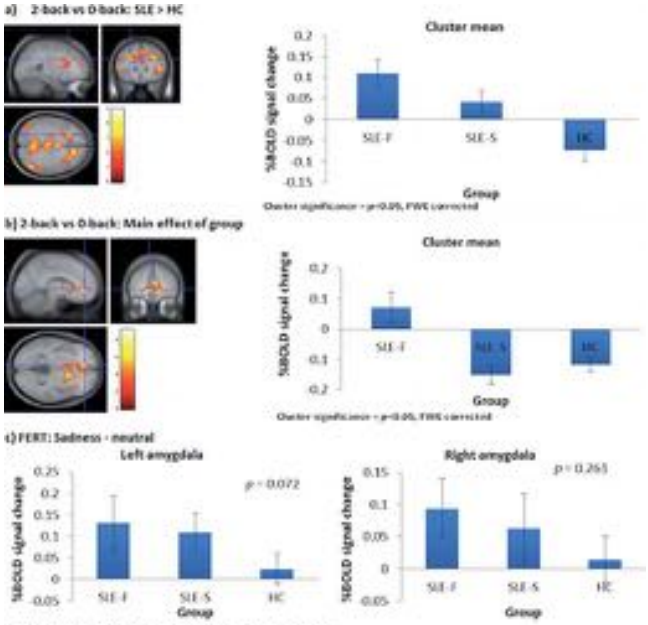

**Figure 1: Results from the n-back and FERT tasks**
N-back task, 2-0back condition:
a) Increased BOLD signal for SLE groups in lateral frontal areas (cluster co-ordinates: -24 23 30, 15 35 30).
b) Attenuated BOLD signal in the vACC for the SLE-S and HC groups (cluster co-ordinates: -9 44 0, 18 11 10, -21 38 -10).
FERT task:
c) BOLD response in the amygdala for the sadness minus neutral condition.

**Conclusions:** Our results in lateral frontal areas supported findings from previous studies that suggested SLE patients employ compensatory prefrontal mechanisms to maintain adequate cognitive function on effortful tasks. The vACC is part of a "default mode network", putatively involved in reflective self-focused processing and typically suppressed during cognitive tasks. The inability of the SLE-F to suppress signal in this region may negatively impact their cognitive function by allowing self-reflective processes to interfere with performance. The trend towards an increased BOLD signal in the left amygdala for the SLE groups is similar to that seen in depressed patients, which suggests that low mood in SLE has detectable neuronal effects. Overall, these results indicate that regardless of current disease activity, SLE affects cognitive and emotional function at a neuronal level. Some effects are more pronounced in SLE-F patients, in particular inability to suppress self-reflective "default mode" processing while undertaking cognitive tasks.

## SAT0282 FREQUENCY AND PREDICTORS OF ATTAINMENT OF THE LUPUS LOW DISEASE ACTIVITY STATE (LLDAS) IN A CROSS SECTIONAL STUDY OF SLE PATIENTS IN THE ASIA PACIFIC

V. Golder[1], R. Kandane-Rathnayake[1], A. Hoi[1], W. Louthrenoo[2], Y. An[3], Z.G. Li[4], S.F. Luo[5], S. Sockalingam[6], C.S. Lau[7], A.L. Lee[7], M.Y.T. Mok[7], A. Lateef[8], K. Franklyn[1], S.V. Navarra[9], L. Zamora[9], Y.-J. Wu[10], L. Hamijoyo[11], M. Chan[12], S. O'Neill[13], F. Goldblatt[14], M. Huq[15], M. Nikpour[15], E.F. Morand[1] on behalf of Asia-Pacific Lupus Collaboration. *[1]Rheumatology, Monash University, Melbourne, Australia; [2]Chang Mai University, Chang Mai, Thailand; [3]Rheumatology, Peking University Health Science Center; [4]Rheumatology, Peking University Health Science Centre, Beijing, China; [5]Rheumatology, Chan Gung University, Taipei, Taiwan, Province of China; [6]Medicine, University of Malaya, Kuala Lumpur, Malaysia; [7]Hong Kong University, Hong Kong, Hong Kong; [8]National University Hospital, Singapore, Singapore; [9]University of Santo Tomas Hospital, Manila, Philippines; [10]Chang Gung University, Taipei, Taiwan, Province of China; [11]Hasan Sadikin Hospital, Bandung, Indonesia; [12]Tan Tock Seng Hospital, Singapore, Singapore; [13]University of New South Wales, Sydney; [14]Repatriation General Hospital, Adelaide; [15]University of Melbourne, Melbourne, Australia*

**Background:** Systemic lupus erythematosus (SLE) is a heterogeneous disease characterised by fluctuating disease activity. A low disease activity endpoint, the Lupus Low Disease Activity State (LLDAS), was recently reported and retrospective validation showed that time spent in LLDAS translated into reduced damage accrual (Franklyn, Ann Rheum Dis, 2015). A large prospective study to validate LLDAS in a multiethnic cohort of lupus patients from the Asia Pacific Region is underway.
**Objectives:** To describe the frequency and identify the predictors of fulfilling criteria for LLDAS in baseline visit data from a large multinational multiethnic cohort of patients with SLE in nine Asia Pacific countries.
**Methods:** Prospectively collected baseline visit data from 1846 SLE patients enrolled in a longitudinal study were analysed cross sectionally against the recently published definition of LLDAS, and patient characteristics associated with LLDAS attainment determined.
**Results:** LLDAS criteria were met by 44% of patients at a single baseline visit. Stepwise multivariable logistic regression revealed that patients with shorter disease duration were less likely to be in LLDAS (OR 0.31, 95% CI 0.19–0.49, $p<0.001$). Likewise, discoid rash (OR 0.66, 95% CI 0.49–0.89, p=0.006), renal disease (OR 0.60, 95% CI 0.48–0.75, $p<0.001$), elevated double stranded DNA (OR 0.65, 95% CI 0.53–0.81, $p<0.001$) or hypocomplementaemia (OR 0.52, 95% CI 0.40–0.67, $p<0.001$) were negatively associated with LLDAS attainment. Significant differences in LLDAS attainment between countries were observed, and higher national social wealth as measured by the Gross Domestic Product per capita was positively associated with LLDAS (OR 1.57, 95% CI 1.25–1.98, $p<0.001$).
**Conclusions:** Low disease activity was observed in less than half of SLE patients at a single point in time. Disease duration and phenotype, as well as national social wealth, were predictive of LLDAS attainment.

## SAT0283 RELAPSES OF LUPUS NEPHRITIS - RISK FACTORS, INCIDENCE AND IMPACT ON OUTCOME

D.V. Monova[1], S. Monov[2]. *[1]Department of Internal Diseases; [2]Department of Rheumatology, Medical Institute, Sofia, Bulgaria*

**Background:** Lupus nephritis (LN) is one of the most severe complications of systemic lupus erythematosus (SLE). In recent years, the morbidity and mortality of LN have improved considerably owing to more appropriate use of traditional drugs, such as corticosteroids and cyclophosphamide, and the incorporation of new ones, such as mycophenolate mofetil and biologic agents. Renal relapses are part of the natural history of LN and represent a significant challenge not only because they are associated with an increased risk of decline in renal function, but also there is a cumulative toxicity of immunosuppressive treatments.
**Objectives:** The aim of this study was to review renal flare frequency, to identify potential risk factors for relapses, to assess the value of serological tests during flares and to analyse their impact on global outcome in LN patients.
**Methods:** Patients with biopsy proven LN diagnosed between 1985 and 2015 were identified from our database. All patients (pts) met the ACR criteria for SLE. LN classes based on glomerular pathology were defined according to the ISN/RPS classification. Clinical and laboratory data were obtained from the records of patients. According to the response to treatment, LN pts were divided into 3 groups of complete remission (CR), partial remission (PR) and no response (NR). Those in remission were divided into 2 groups of relapsing and non-relapsing during maintenance period. Associated factors for remission and relapse were analyzed. CR was defined as proteinuria less than 0.5 g/24 h and stable or improved serum creatinine, whilst PR was defined as more than 50% reduction in baseline proteinuria achieving less than 1,0 g/24 h with stable or improved creatinine. We defined proteinuric flares as proteinuria above 1 g/24 h in pts with CR, and doubling of proteinuria in cases of PR.
**Results:** 218 (70,64%) of 276 SLE pts (250 females and 26 males) with biopsy proven LN (class I ISN/RPS LN – 18 pts, class II – 45 pts, class III – 56 pts, class

IV – 75 pts, class V – 54 pts, class VI – 2 pts, mixed forms – 26 pts) achieved either CR (n=154; 55,8%) or PR (n=64; 23,2%). 47 pts (38 had preceding CR and 9 had PR) with LN had one flare, 36 (26 had preceding CR and 10 - PR) – two flares, 27 (14 had preceding CR and 13 - PR) – three flares, 17 (7 had preceding CR and 10 - PR) ≥4 flares. The median time between remission and relapse was 23,5 ± 21,9 months in pts with CR, and 11,4 ± 9,3 months in pts with PR. The maintenance immunomodulating drugs at the time of flare was low dose (<10 mg/24 h) corticosteroids and/or azathioprine. 123 LN pts (48%) had angiotensin blockers in therapy. Non-adherence to treatment at time of relapse was documented in 26 pts. At the time of first flare, the median proteinuria was 1,84 ± 0,97 g/24 h in pts with CR, and 2,78 ± 1,25 g/24 h in pts with PR. 42 LN pts had raised serum creatinine, 65 had raised anti-double stranded deoxyribonucleic acid, 94 had low complements at flare.

**Conclusions:** Renal flares in patients with LN are common, have a negative impact on outcome, but cannot be readily predicted. Our study shows that 58,83% of LN patients develop at least one relapse after reaching remission, usually within 2 years. The length of time to flare tends to be shorter in cases of preceding PR than in CR. Lack of adherence to long term immunosuppression was identified as a significant factor in LN flare (20,47%). Patients with LN in remission require close follow-up.

**Disclosure of Interest:** None declared

## SAT0284 BOTH PROLONGED REMISSION AND LUPUS LOW DISEASE ACTIVITY STATE ARE ASSOCIATED WITH REDUCED DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS

M.W.P. Tsang-A-Sjoe, I.E.M. Bultink, M. Heslinga, A.E. Voskuyl. *Department of Rheumatology, Amsterdam Rheumatology and immunology Center, Amsterdam, Netherlands*

**Background:** Treat-to-target strategies in systemic lupus erythematosus (SLE) are thought to be the next step in improving outcome for SLE patients. Composing and validating treatment targets are therefore important. Recently, criteria for remission [1] and for Lupus Low Disease Activity State (LLDAS)[2] have been proposed.

**Objectives:** To identify predictors of organ damage and specifically the relationship between prolonged disease remission or LLDAS and damage accrual in a longitudinal cohort of SLE patients.

**Methods:** Patients from the Amsterdam SLE cohort were prospectively assessed including the occurrence of minor/major flares, and once a year: remission and LLDAS. To determine which variables were predictive of damage accrual (dependent variable), variables with p<0.10 in univariable analysis were entered into the respective multivariate logistic regression model in a backward stepwise elimination manner. Secondly, odds ratios (ORs) for damage accrual during follow-up were calculated for patients with or without prolonged remission during 5 years, and with or without LLDAS in ≥50% of observations.

**Results:** Data from 183 patients (90.2% female, 68.3% Caucasian) with a median follow-up duration of 5.0 years were analyzed. In univariable analysis, patients with damage accrual had higher SDI scores, number of fulfilled ACR criteria, frequency of nephrological manifestations and hypertension at baseline, higher mean SLEDAI-2K, mean daily doses of prednisone, and frequency of ≥1 major flare during follow-up, and lower frequency of remission at all visits and ≥50% of observations in LLDAS. The most important predictors for damage accrual were: occurrence of ≥1 major flare (OR 5.2, 95% CI 1.8 – 14.5, p=0.002), mean daily prednisone dose during follow-up (OR 1.1, 95% CI 1.0 – 1.2, p=0.03 per increase of 1 mg), and nephrological manifestations at baseline (OR 2.2, 95% CI 1.1 – 4.5, p=0.03). Prolonged remission was present in 32.5% (38/117) and LLDAS in ≥50% of observations in 64.5% (118/183) of patients. Both the presence of prolonged remission during 5 years and LLDAS in ≥50% of observations were associated with a reduced risk of damage accrual (OR 0.20, 95% CI 0.07 – 0.53, p=0.001 and OR 0.52, 95% CI 0.28 – 0.99, p=0.046, respectively).

**Conclusions:** In this observational study, we present for the first time longitudinal data regarding disease activity and damage accrual in our cohort. Prolonged remission and LLDAS were associated with an improved outcome, as determined by yearly assessments. Remission and LLDAS are therefore realistic targets as the respective criteria were fulfilled frequently in our cohort. In order to improve the outcome in SLE patients, future studies should investigate whether these targets can be reached actively with therapeutic strategies.

## SAT0285 VACCINATIONS IN SLE: COVERAGE AND REASONS FOR NON-VACCINATION - RESULTS FROM THE LULA-STUDY

G. Chehab[1], J.G. Richter[1], R. Brinks[1], R. Fischer-Betz[1], B. Winkler-Rohlfing[2], M. Schneider[1]. *[1]Policlinic of Rheumatology and Hiller Research Unit Rheumatology, Heinrich-Heine-University Medical Faculty, Duesseldorf; [2]German Lupus Self-Help Community, Wuppertal, Germany*

**Background:** Infections are an important factor for morbidity and mortality in patients with systemic lupus erythematosus (SLE). Vaccinations may prevent certain infections. In Germany vaccination recommendations have been released by the German Society for Rheumatology based on the recommendations of the German Standing Committee on Vaccination. Similar suggestions have been published by the European League against Rheumatism. Vaccination coverage in the general population often falls short of reaching its goal.

**Objectives:** Our objective was to assess vaccination rates and reasons for non-vaccination in a representative sample of German SLE patients.

**Methods:** The LuLa-Study is a longitudinal patient-reported cross-sectional survey of the German LE self-help community on a multitude of LE associated factors. It is being conducted annually by means of a self-reported questionnaire since 2001. Amongst others medication, health-related quality of life, damage and disease activity are surveyed. In 2012 we additionally inquired about vaccinations as a main topic using a compilation of questions regarding usage, monitoring, execution and physician' respectively patients' reservations against vaccinations.

**Results:** 579 patients (94.0% female) aged 52.3 ± 13.4 years (mean ± standard deviation) and disease duration of 16.8 ± 9.1 years completed the questionnaire. Their vaccination status is primarily checked by the general practitioner (GP) (57.3%) and only occasionally by an internal specialist (7.9%), their rheumatologist (7.6%) or others (8.5%). A quarter of patients (24.9%) reported that their vaccinations status is not checked by any of their attending physicians. Ninety-three participants (16.1%) stated that at least one of their attending physicians had generally advised against the use of vaccinations. Characteristics (clinical and demographic) did not differ significantly compared to participants that had never been advised against the use of vaccinations.

37.5% of the participants stated that they rejected vaccinations before. The two main reasons expressed for rejecting a vaccination were the fear of developing a lupus flare (21.8%) or developing adverse events after vaccination (13.5%). Only accrued damage was significantly different in univariable analysis between participants that rejected vaccinations before and participants who did not with more damage being reported by the latter ('Brief Index of Lupus Damage' 2.2 ± 2.0 vs. 1.9 ± 2.1; p=0.009). There was no evidence for differences in other demographic or clinical characteristics between the two groups. We observed vaccinations rates of 65.8% for tetanus (past 10 years), 45.2% for influenza (past year), 32.2% for pneumococcal (past 5 years) and 6.1% for meningococcal (past 5 years) vaccinations.

**Conclusions:** Standard vaccination (tetanus) as well as medically indicated vaccination (influenza, penumococcal, meningococcal) coverage in SLE patients is still low in Germany. Reasons for non-vaccination are physician-based, patient-based but also due to organizational deficits because of competing responsibilities (GP vs. rheumatologist). Patients' and physicians' education is of major importance to increase vaccination rates. The rheumatologist bears the responsibility for this process optimization.

## SAT0286 RISK OF SEVERE HERPES SIMPLEX VIRUS INFECTION IN PATIENTS SLE: A NATIONWIDE POPULATION COHORT STUDY

T.-H. Li[1], C.-C. Lai[1], Y.-S. Chang[2]. *[1]Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei Veterans General Hospital, Taipei City; [2]Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Shuang Ho Hospital, Taipei Medical University, New Taipei City, Taiwan, Province of China*

**Background:** Severe herpes simplex virus (HSV) infections, especially encephalitis and keratitis, often affect immunocompromised patients and result in severe sequela. However, only few attempts have been made at the association between systemic lupus erythematosus (SLE) and HSV.

**Objectives:** To identify the risk of severe HSV infection in SLE patients by means of a nationwide population-based cohort study.

**Methods:** We identified SLE patients from the National Health Insurance research database between 1997 and 2012. We compared the incidence rate (IR) of severe HSV infection, including viral septicaemia, CNS infection, ocular infection, visceral infection and those with complications after infection, with that of non-SLE cohort. A Cox multivariable proportional hazards model was applied to evaluate the risk of severe HSV infection in the SLE cohort.

**Results:** A total of 122,520 subjects (24,504 SLE patients and 98,016 age- and gender-matched subjects as control group) were analyzed and revealed a significantly higher IR of severe HSV infection in SLE (Incidence rate ratio =3.52, $p < 0.001$). Previous skin infection (HR=2.17, $p$=0.047), intravenous steroid pulse therapy (HR=4.48, $p<0.001$), oral daily steroid dose over 7.5mg prednisolone or equivalent (HR=1,60, $p$=0.010) were independent risk factors for severe HSV infection in SLE patients, while Age ≤18 (Hazard ratio [HR]=0.47, $p$=0.021) was a protective factor.

Table 1. Risk factors of severe HSV infection in patients with SLE[a]

| Variable | Univariate analysis | | Multivariable analysis[a] | |
|---|---|---|---|---|
| | HR (95% CI) | *P*-value | HR (95% CI) | *P*-value |
| Age | 1.01 (1.00–1.03) | 0.017 | | |
| ≤18-year-old | | | 0.47 (0.24 – 0.89) | 0.021 |
| >18-year-old | | | 1.23 (0.54–2.82) | 0.612 |
| Male | 0.986 (0.57–1.71) | 0.974 | | |
| Diabetes mellitus | 0.56 (0.31–1.02) | 0.057 | | |
| End-stage renal disease | 0.96 (0.62–1.49) | 0.844 | | |
| Malignancy | 1.12 (0.28–4.54) | 0.871 | | |
| CHF | 0.79 (0.46–1.36) | 0.399 | | |
| Previous skin infection | 2.21 (1.03–4.73) | 0.042 | 2.17 (1.01–4.65) | 0.047 |
| Hydroxychloroquine | 1.05 (0.75–1.46) | 0.108 | | |
| Azathioprine | 1.60 (1.10–2.3.2) | 0.015 | – | – |
| Mycofenolate mofetil | 0.40 (0.06–2.89) | 0.367 | | |
| Cyclosporine | 1.58 (0.58–4.26) | 0.371 | | |
| Cyclophosphamide | 1.67 (0.87–3.18) | 0.122 | | |
| MTX | 1.32 (0.58–2.99) | 0.507 | | |
| Intravenous | 5.24 (3.52–7.79) | <0.001 | 4.48 (2.95–6.80) | <0.001 |
| Oral daily dose over 7.5mg[†] | 2.03 (1.44–2.86) | <0.001 | 1.60 (1.12–2.30) | 0.010 |

**Conclusions:** A higher risk of severe HSV infection was observed in SLE patients Risk factors for severe HSV infection were age over 18, previous skin infection, intravenous steroid pulse therapy and an oral daily steroid dose over 7.5mg.

Sacco Univ, Milan, Italy; [38]Privado Hosp, Córdoba, Argentina; [39]Sao Paulo Federal Univ, Sao Paulo, Brazil*

**Objectives:** To analyse the influence of ethnicity on the clinical presentation at diagnosis in an international cohort of patients with primary Sjögren syndrome (pSS).

**Methods:** The Big Data Sjögren Project is a multicentre registry formed by international experts from the EULAR-SS Task Force. By January 2016, the database included 8315 consecutive patients fulfilling the 2002 AE criteria (20 countries, 5 continents). Ethnicity was classified according to FDA (White=W, Black/African American=B, Asian=A, Hispanic=H, Others=O).

**Results:** Ethnicity data was available in 7887 (95%) patients: 6177 W (78%), 1066 A (13%), 393 H (5%), 104 B (1%) and 147 O (2%). European patients were overwhelmingly white compared with Americans (96% vs 52%, $p<0.001$). The greatest differences between ethnicities ($p<0.001$) were observed for mean age at diagnosis (47yrs in B vs 54yrs in W), and the frequency of males (12% in B vs 4% in A), dry eyes (76% in A vs 98% in O), dry mouth (83% in A vs 99% in O), abnormal ocular tests (79% in O vs 90% in H), abnormal oral tests (65% in O vs 91% in H), positive minor salivary biopsy (75% in O vs 95% in H), positive anti-Ro (54% in O vs 84% in A) and positive anti-La (28% in O vs 50% in A).

**Conclusions:** White patients had the oldest age at diagnosis, Black/African Americans the highest frequency of men and the lowest mean age, Asians the highest frequency of women, the lowest frequency of sicca symptoms and the highest frequency of Ro/La and Hispanics the highest frequency of abnormal diagnostic tests. Ethnicity plays a capital role in the phenotypic expression at diagnosis of primary SS.

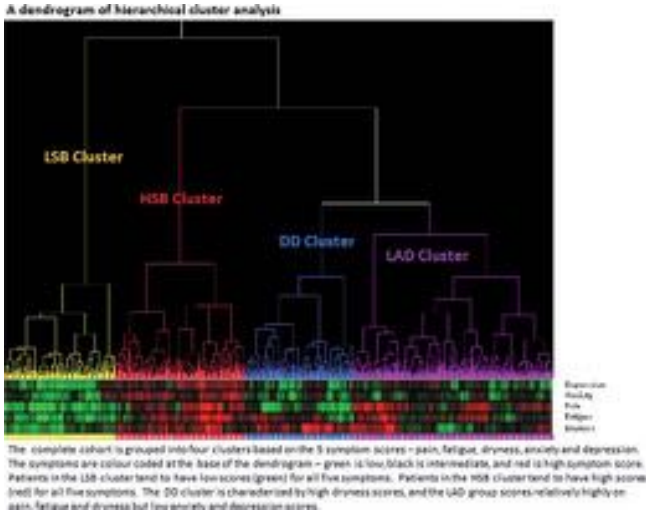
## SAT0288 CLINICAL PHENOTYPING IN 608 PATIENTS FROM THE UNITED KINGDOM PRIMARY SJÖGREN'S SYNDROME REGISTRY



N. Howard Tripp, D. Lendrem, J. Tarn, K. Hackett, W.-F. Ng. *Institute of Cellular Medicine, University of Newcastle, Newcastle upon Tyne, United Kingdom*

**Background:** Primary Sjögren's Syndrome (pSS) is a chronic multi-system disease causing a wide-range of symptoms including dryness, pain and fatigue.[1,2] Individual experiences of pSS differ considerably resulting in a heterogeneous patient population.[3] These differences in disease-manifestation have not yet been characterised and the biological basis of varied patient-reported outcomes remains unclear.

**Objectives:** We aim to identify distinct clinical phenotypes within pSS, using patient-reported symptoms and to determine whether such clinical subgroups display differences in healthy utility values, and biological measures of disease activity.

**Methods:** Symptoms of 608 patients on the United Kingdom Primary Sjögren's Syndrome Registry (UKPSSR) were reviewed.[4] Phenotypes were identified using hierarchical cluster analysis of patient reported rating scales for pain, fatigue, dryness, anxiety and depression symptoms. Non-parametric analysis of variance was used to evaluate differences between clusters.

**Results:** Four phenotypic clusters were identified: High symptom burden (HSB), Low symptom burden (LSB), dryness dominant (DD) and Low Anxiety and Depression (LAD). Not surprisingly, there were significant differences between these groups in measures of health status and quality of life (EQ-5D $p<0.0001$, TTO $<0.0001$). More interestingly, objective measures of disease activity (ESSDAI $p=0.039$), objective dryness (salivary flow $p=0.007$, Schirmer's $p=0.014$), and biological parameters (IgG $p<0.0001$, lymphocytes $p=0.0005$, ESR $p=0.003$) suggest these subgroups may reflect different underlying endotypes.

**Conclusions:** Distinct biological differences may underlie pSS clinical phenotypes. The identification of these different clinical subsets of pSS could impact on the future study and management of the condition using a stratified approach.

## SAT0289 SONOGRAPHIC ALTERATIONS DURING THE COURSE OF SJÖGREN'S SYNDROME – A FIVE-YEAR FOLLOW UP

B. Hofauer[1], M. Bas[1], N. Mansour[1], D. Loeffelbein[2], A. Knopf[1].
*[1]Otorhinolaryngology/Head and Neck Surgery; [2]Oral and Maxillofacial Surgery, Klinikum Rechts Der Isar, Technical Universitiy Munich, Munich, Germany*

**Background:** Sonography in the evaluation of salivary gland alterations in suspected Sjögren's Syndrome (SS) and its benefit with regard to the diagnosis is part of continuing investigation. With most studies concentrating on the contribution to the diagnosis, few reports exist on longitudinal changes in the sonomorphology of salivary glands in SS. An improvement of salivary gland echostructure six months after rituximab infusion [1] and a decline of salivary gland stiffness evaluated with shear wave elastography after a two months period of a liposomal local therapy could be observed [2]. Despite intense research, many questions in ultrasound of salivary glands remain unanswered. Amongst other things it is unclear why not all patients with SS manifest sonographic abnormalities, when during the course of SS sonographic changes occur or if theses sonographic observations proceed the clinical symptomatic.
**Objectives:** Which variation of sonographic salivary gland alterations can be observed during the five-year follow up of patients with primary Sjögren's Syndrome (pSS)?
**Methods:** Patients with pSS diagnosed according to the AECG classification criteria were included in this study. The EULAR SS Patient Reported Index (ESSPRI) was applied for the evaluation of patient's symptoms and the EULAR SS Disease Activity Index (ESSDAI) for systemic features. During 2011 and 2016 the sonographic evaluation of salivary gland alterations in patients with primary Sjögren's Syndrome were evaluated. The echostructure of the parotid (PG) and submandibular glands (SMG) was graded on a scale of 0 to 4 (grade 0=normal, homogeneous gland; grade 1=mild parenchymal inhomogeneity (PIH), hypoechoic areas $<$2mm; grade 2=evident PIH, hypoechoic areas of 2–6mm; grade 3=gross PIH, hypoechoic areas $>$6mm; grade 4=adipose degeneration of the gland and parenchymal atrophy).
**Results:** Fifty patients diagnosed with pSS were included (45 female, age: 56y). In 2011 the mean ESSPRI score was 8.3 (SD=4.6) and the mean ESSDAI score was 5.6 (SD=7.5). The sonographic evaluation of the PG resulted in a mean score of 1.6 (SD=0.6) and in the SMG of 1.7 (SD=1.0). The sonographic score did not correlate with the time since onset of symptoms. Clinical examination and ultrasonographic evaluation was repeated after five years in 2016, revealing a mean ESSPRI score of 6.1 (SD=3.2, p=0.002) and a mean ESSDAI score of 4.6 (SD=7.0, p$<$0.001). The mean sonographic score of the PG was 1.4 (SD=0.7, p$<$0.001) and of the SMG was 1.9 (SD=1.0, p=0.034). There was a decline in the sonographic score of the PG of 0.27 (SD=0.5) and increase of the SMG of 0.1 (SD=1.1) on average. The mean time interval between onset of first symptoms and first sonographic examination in 2011 was 57.3 months (SD=60.8).
**Conclusions:** The five-year sonographic follow up of salivary gland alterations in patients with pSS revealed only minor alterations, even in patient with short illness duration. The relation to systemic or local therapeutic interventions is part of on-going analysis.

## SAT0290 A HIGHER DISEASE ACTIVITY IN ANTI-SSA/SSB POSITIVE SJÖGREN'S SYNDROME IS EXPLAINED BY A HIGHER CLINICAL AND BIOLOGICAL B-CELL ACTIVATION

L. Quartuccio[1], C. Baldini[2], E. Bartoloni[3], F. Carubbi[4], A. Alunno[3], R. Priori[5], R. Gerli[3], G. Valesini[5], R. Giacomelli[4], S. Bombardieri[2], S. De Vita[6] on behalf of GRISS group. *[1]Department of Biological and Medical Sciences, Rheumatology Clinic, University Hospital of Udine, Udine; [2]University of Pisa, Rheumatology Unit, Pisa; [3]University of Perugia, Rheumatology Unit, Perugia; [4]University of L'Aquila, Rheumatology Unit, L'Aquila; [5]University of Rome la Sapienza, Rheumatology Clinic, Rome; [6]University of Udine, Rheumatology Clinic, Udine, Italy*

**Background:** Anti-SSA/SSB positive Sjögren's syndrome is characterized by a higher risk for developing lymphoma (1), but no data already exist on systemic disease activity in subgroups of SS, as measured by validated scores for primary SS, such as the ESSDAI or ClinESSDAI.
**Objectives:** Primary objective of the study was to demonstrate the differences between anti-SSA/SSB positive and anti-SSA/SSB negative SS patients as regards systemic disease activity.
**Methods:** 955 patients affected by primary SS were included. All patients fulfilled the American-European Consensus Group Criteria for primary SS. Patients showing isolated anti-SSB positivity were excluded from these analyses. Patients were 911 female (95,4%), with a mean age of 52±14 years. ESSDAI and ClinESSDAI scores were measured (2, 3). Mann-Whitney U test was used to compare the ESSDAI and ClinESSDAI scores between anti-SSA/SSB positive and negative patients.
**Results:** Patients with anti-SSA with or without anti-SSB antibodies were 684 (71.6%), while anti-SSA and anti-SSB antibody negative patients were 271 (28.4%). Median (range) ESSDAI and median (range) ClinESSDAI were 5 (0–54) and 6 (0–53) in anti-SSA/SSB positive patients, and 4 (0–63) and 4 (0–60) in anti-SSA/SSB negative patients, respectively. Both the ESSDAI and the ClinESSDAI scores were significantly higher in anti-SSA/SSB positive patients (p$<$0.001 and p=0.021, respectively). Importantly, these differences were determined by a significant difference in the frequency of some domains, i.e., "lymphadenopathy" (p=0.034, Chi-square test), "glandular" (p=0.0004, Chi-square test), "cutaneous" (p=0.017, Chi-square test), "hematological" (p$<$0.0001, Chi-square test) and "biological" (p$<$0.0001, Chi-square test) (table 1). Notably, anti-SSA/SSB positive patients were younger than anti-SSA/SSB negative patients (50±14 vs. 57±11 years, p$<$0.0001 by t-test). Rheumatoid factor positivity (p$<$0.0001, Chi-square test), low C3 (p$<$0.0001, Chi-square test), low C4 (p=0.045, Chi-square test) and the presence of serum cryoglobulins (p=0.022, Chi-square test) were also significantly linked to the presence of anti-SSA/SSB positivity.

Table 1

| | Anti-SSA/SSB+ (%) | Anti-SSA/SSB– (%) | P value |
|---|---|---|---|
| Constitutional | 92 (13.5) | 30 (11.1) | 0.376 |
| Lymphadenopathy | 183 (26.8) | 54 (19.9) | 0.034 |
| Glandular | 196 (28.7) | 47 (17.3) | 0.0004 |
| Articular | 390 (57) | 150 (55.4) | 0.692 |
| Cutaneous | 102 (15.9) | 24 (8.9) | 0.017 |
| Pulmonary | 37 (5.4) | 24 (8.9) | 0.069 |
| Renal | 22 (3.2) | 6 (2.2) | 0.544 |
| Muscular | 6 (0.9) | 4 (1.5) | 0.482 |
| PNS | 39 (5.7) | 15 (5.5) | 0.920 |
| CNS | 8 (1.2) | 6 (2.2) | 0.239 |
| Hematological | 206 (30.1) | 43 (15.9) | $<$0.0001 |
| Biological | 434 (63.5) | 78 (28.8) | $<$0.0001 |

**Conclusions:** Clinical and biological signs of B-cell lymphoproliferation more specifically characterized anti-SSA/SSB positive patients, glandular, hematological and biological domains showing the most significant differences. This feature appears to clearly differentiate Sjögren's disease from Sjögren's syndrome.

## SAT0291 INTIMA MEDIA THICKNESS AND ATHEROSCLEROTIC PLAQUES AS MARKERS OF SUBCLINICAL ATHEROSCLEROSIS AND CARDIOVASCULAR MANIFESTATION IN SLE PATIENTS

A. Smržová[1], M. Schubertová[1], J. Vymětal[1], M. Skácelová[1], A. Petráčková[2], E. Kriegova[2], Z. Heřmanová[2], F. Mrázek[2], P. Horák[1]. *[1]3Rd Department of Internal Medicine – Nephrology, Rheumatology and Endocrinology; [2]Department of Immunology, Faculty of Medicine and Dentistry, Palacký University Olomouc, Olomouc, Czech Republic*

**Background:** Cardiovascular diseases are the main cause of morbidity and mortality in SLE patients. Detection of risk factors can increase survival and improve quality of life.
**Objectives:** The aim of study was the detection of subclinical atherosclerosis

measured by ultrasound evaluation of intima media thickness and its correlatation to PVW (pulse velocity wave), traditional risk factor, and clinical profile of the disease, autoantibodies and selected laboratory markers.
**Methods:** From March 2015 to January 2016 we examined 42 patients with SLE (5 men, 37 women) by ultrasound of carotic arteries. Traditional risk factors, clinical manifestation, immunological profile and disease activity scores (SELENA-SLEDAI 2K, SLICC) were collected. Cumulative dose of glucocorticosteroids and duration of disease was calculated. History of cardiovascular events was recorded. Statistical tests (descriptive statistic, Student t-test, Spearman test, ANOVA) were performed, p-value $\leq$0.05 was considered as significant.
**Results:** Pathological IMT was detected in 10 patients (23.8%). IMT correlated with cumulative dose of glucocorticoids, levels of anti ds DNA (p=0.05), low levels of C3 (p=0.03), positivity of LA and high LSR (p=0.007,p=0.05), low levels of GF and serum creatinine (p=0.03, p=0.04), anti La antibodies (p=0.009), leucopenia (p=0.007), haematological manifestation (p=0.04), dyslipidemia (p=0.03) and PVW (p=0.01). The presence of plaques correlated with BMI (p=0.05), cardiac failure (p=0.03), anti ds DNA (p=0.03), LA (p=0.003), low levels of HDL (p=0.005), hsCRP (p=0.05), PWV (p=0.04). If groups with or without pathological IMT were compared, there was difference in age ($p\leq0.001$), smoking - packet-years (p=0.01), cardial failure (p=0.02), stroke and lupus CNS (p=0.02, resp. 0.003), cardiac manifestation (p=0.003) and hrCRP (p=0.02). There was no correlation in lipid profile. In this group 5 strokes, 5 cardiac failure, 2 myocardial infarction, 4 ischemic heart disease and 6 cardiac manifestation were present.
**Conclusions:** IMT and detection of plaques are very important markers of subclinical atherosclerosis. They correlated with traditional risk factors and are good prognostic factor of cardiovascular and ischemic CNS manifestation. It is important to evaluated both IMT and plaques. The result of the study highlights the necessity of active screening of cardiac involvement in SLE patients.

## SAT0292 SERUM AND SALIVARY CYTOKINES AND CHEMOKINES LEVELS AS DISEASE ACTIVITY BIOMARKERS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

A.A. Tzec Pérez [1], R.E. Barbosa Cobos [1], G.E. Lugo Zamudio [1], L.T. Becerril Mendoza [1], M.A. Moreno Eutimio [2], N.G. Nieto Velázquez [2], C. Liceaga Escalera [3], M.E. Vélez Cruz [3], L.A. Montoya Pérez [3], A.A. Castillo Ortiz [1]. *[1]Rheumatology; [2]Investigation; [3]Maxillofacial Surgery, Hospital Juárez de México, Mexico, Mexico*

**Background:** Evidence suggests that levels of different cytokines in primary Sjögren's syndrome (pSS) are associated with cell infiltration degree within salivary and lacrimal glands and severity of the disease. Chemokines appear to contribute to the pathogenesis of pSS.
**Objectives:** To evaluate the association between serum and salivary Th1/Th2/Th17 cytokines and chemokines leves and disease activity in patients with pSS.
**Methods:** Case-control study, 18 patients with pSS and 13 healthy controls were included. Disease activity was assessed by EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI); serum and salivary IFN-$\gamma$, TNF, IL-2, IL-4, IL-6, IL-10, IL-17, IP10, MCP-1, MIG, RANTES and IL-8 levels were measured by bead-based assays following the sandwich immunoassay principle (BD Cytometric Bead Array; BD Biosciences). Differences between groups were analyzed using the Mann-Whitney U test, correlation was estimated by Spearman's correlation coefficient.
**Results:** IL-17, IL-2, IL-4, IFN$\gamma$, MIG and RANTES salivary levels were statistically different between controls and patients with pSS ($p<0.005$). Significant correlation ($p<0.005$) was showed in patients between serum IL-6 and serum IL-12 (r=0.004), IL-10 (r=0.006); serum IL-12 and serum RANTES (r=0.008); serum IP-10 and serum MIG (r=0.000), RANTES (r=0.003); serum MIG and serum RANTES (r=0.014); salivary IL-17 and salivary IL-2 (r=0.004), IL-4 (r=0.001), INF$\gamma$ (r=0.000), TNF (r=0.002), IL-10 (r=0.000); salivary IL-6 and salivary IL-2 (r=0.000), IL-4 (r=0.000), TNF (r=0.000), IL-10 (r=0.000), IL-8 (r=0.0003), MCP-1 (r=0.007); salivary IL2 and salivary IL4 (r=0.000), INF$\gamma$ (r=0.006), TNF (r=0.001), IL10 (r=0.000); salivary IL4 and sallivary TNF (r=0.001), IL10 (r=0.000), MCP-1 (r=0.009); salivary TNF and salivary INF$\gamma$ (r=0.002), IL-10 (r=0.000), IP-10 (r=0.006); salivary MCP-1 and salivary TNF (r=0.000), IL-10 (r=0.001), IL-8 (r=0.003).
**Conclusions:** Increased salivary Th1/Th2/Th17 cytokines and chemokines levels were found in pSS. No correlation was found between serum or salivary cytokines and chemokines levels and pSS disease activity.

## SAT0293 SERUM AND TEAR CYTOKINES AND CHEMOKINES LEVELS AS DISEASE ACTIVITY BIOMARKERS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

A.A. Castillo Ortiz [1], R.E. Barbosa Cobos [1], L.T. Becerril Mendoza [1], G. Lugo Zamudio [1], V. Lima Gómez [2], M.A. Moreno Eutimio [3], N.G. Nieto Velázquez [3], A.A. Tzec Pérez [1]. *[1]Rheumatology; [2]Ofthalmology; [3]Inmunology, Hospital Juárez de México, Mexico, Mexico*

**Background:** Evidence suggests that levels of different cytokines in primary Sjögren's syndrome (pSS) are associated with cell infiltration degree within lacrimal and salivary glands and severity of the disease. Chemokines appear to contribute to the pathogenesis of pSS.
**Objectives:** To evaluate the association between serum and tear Th1/Th2/Th17 cytokines and chemokines leves and disease activity in patients with pSS.
**Methods:** Case-control study, 19 patients with pSS and 13 healthy controls were included. Disease activity was assessed by EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI); serum and tear IFN-$\gamma$, TNF, IL-2, IL-4, IL-6, IL-10, IL-17, IP10, MCP-1, MIG, RANTES and IL-8 levels were measured by bead-based assays following the sandwich immunoassay principle (BD Cytometric Bead Array; BD Biosciences). Differences between groups were analyzed using the Mann-Whitney U test, correlation was estimated by Spearman's correlation coefficient.
**Results:** TNF, IL-2, IL-4, IL-6, IL-10, IP-10, MCP-1, RANTES and IL-8 tear levels were statistically different between controls and patients with pSS ($p<0.005$). Significant correlation ($p<0.005$) was showed in patients between serum IL-6 and serum IL-2 (r=0.652), IL-4 (r=0.731); serum IL-2 and serum IP-10 (r=0.640); serum IL-2 and tear IL-2 (r=0.614), IL-8 (r=0.723), IP-10 (r=0.795), MIG (r=0.755); serum IL-4 and tear IL-8 (r=0.696), MIG (r=0.707); serum IP-10 and serum MIG (r=0.847), RANTES (r=0.626); serum IP-10 and tear IP-10 (r=0.619); serum MIG and serum RANTES (r=0.719); serum MIG and tear IL-17 (r=0.619); serum RANTES and tear IL-2 (r=0.628), IL-4 (r=0.619), IL-6 (r=0.736), IL-8 (r=0.770), IP-10 (r=0.687), MCP-1 (r=0.566), MIG (r=0.740).
**Conclusions:** Increased tear Th1/Th2 cytokines and chemokines levels were found in pSS. No correlation was found between serum or tear cytokines and chemokines levels and pSS disease activity.

## SAT0294 CIRCULATING LIN1-DABP-CD34+CD133+CD309+ ENDOTHELIAL PROGENITOR CELLS (EPC) ARE REDUCED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) BUT NOT ASSOCIATED WITH BIOPHYSICAL MARKERS OF CARDIOVASCULAR DISEASE (CVD)

A. Mak [1], L. Ling [1], N. Kow [1], A.M. Fairhurst [2]. *[1]Medicine, National University of Singapore; [2]Singapore Immunology Network, Singapore, Singapore*

**Background:** Dysfunctional EPC have been proposed to contribute to CVD in SLE patients. Due to various methodological flaws in identifying the rare EPC population in previous studies, how the true circulating EPC count is altered in SLE patients remains unclear. Furthermore, how the EPC population correlates with the biophysical markers of CVD in SLE patients has not been adequately addressed.
**Objectives:** To quantify and compare circulating EPC count between SLE patients and healthy controls (HC) based on a stringently modified EPC identification method proposed by the European League Against Rheumatism Scleroderma Trials and Research (EUSTAR) group that involves lineage-positive and dead-cell exclusion and fluorosphere calibration (1). To address the functional relevance of EPC by evaluating the relationship between EPC count and biophysical markers of CVD in SLE patients.
**Methods:** Peripheral blood (32ml) were obtained from SLE patients and HC

naïve of CVD, cerebrovascular disease, diabetes mellitus and antiphospholipid syndrome. Clinical and serological parameters of SLE patients were collected. The peripheral blood mononuclear cell (PBMC) fraction was prepared for flow cytometry. Singlets were gated from the PBMC population, followed by exclusion of the lineage-positive (Lin-1 FITC+) and dead cells (DAPI+). To mitigate the issue of autofluoresence, 3 fluorescence-minus-one (FMO) panels (panels stained all but one respective fluorochrome) were designed. From the Lin1-DAPI- population, CD309-APC, CD133-PE and CD34-PerCP-Cy5.5 were gated from the corresponding FMO panels. All the FMO gates were then applied on the all-stained samples to identify the true EPC population (Lin1-DAPI-CD34+CD133+CD309+). The absolute EPC counts were calculated by fluorosphere calibration. Endothelial reactivity, arterial stiffness and carotid atherosclerosis were assessed by brachial artery flow-mediated dilation (FMD), pulse-wave velocity (PWV) and carotid intima-media thickness (cIMT) respectively. Relationships between EPC count and disease-related factors, FMD, PWV and cIMT were studied by Spearman correlations.

**Results:** Thirty SLE patients and 22 HC (5 and 3 men in SLE and HC groups respectively, p=1.0) were studied. Mean±SD age of SLE patients and HC was 34.63±11.5 and 31.87±8.4 years respectively (p=0.34). The mean±SD disease duration, daily prednisolone dose, atherogenic index (AI) (total cholesterol/HDLc), SLEDAI and SLICC/DI were 60.17± 69.4 months, 14.77±16.5 mg, 3.49±0.9, 5.53± 5.4 and 0.10±0.3 respectively in SLE patients. Mean±SD EPC count in SLE patients was significantly lower than that of HC (3.93±4.4 vs. 9.24±8.5 cells/ml, p=0.014), despite ANCOVA adjustment for PBMC count (p=0.018). No significant relationships were found between EPC count and disease duration, daily prednisolone dose, AI, SLEDAI, SLICC/DI, FMD, PWV and cIMT in SLE patients.

**Conclusions:** Incorporating the FMO gating strategy into the EUSTAR recommendation of EPC identification confirmed significantly lower circulating EPC count in SLE patients as compared to HC, but the reduced EPC level was not associated with biophysical CVD markers in SLE patients. Prospective studies are needed to address the impact of reduced EPC on CVD in SLE patients.

## SAT0295 AUTOIMMUNE HEMOLYTIC ANEMIA AND THROMBOCYTOPENIA IN A SINGLE CENTRE COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS FROM TURKEY: CLINICAL ASSOCIATIONS AND EFFECT ON DISEASE DAMAGE AND SURVIVAL

B. Artim-Esen, M. Erdugan, E. Oguz, B. Toz, B. Erer, S. Kamali, A. Gül, L. Ocal, M. İnanç. *Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey*

**Background:** Hematologic involvement is common in patients with SLE. Thrombocytopenia and AIHA, prevalences of which have been reported as 10–40% and 5–10% respectively, have considerable impact on prognosis.

**Objectives:** Herein, we aimed to investigate the frequencies of these hemocytopenias, their clinical and serological associations and effect on disease outcome in a large single centre cohort of patients.

**Methods:** We analysed our cohort of 852 patients who fulfilled at least 4 of the ACR criteria for SLE. The data presented was the cumulative clinical and serological manifestations throughout the follow-up period. Hemolytic anemia was defined as a drop in hemoglobin accompanied by increased reticulocyte count, high serum lactate dehydrogenase and reduced haptoglobin levels in the presence of a positive Coombs' test. Thrombocytopenia was defined as a platelet count of $<100x10^9/mm^3$. Demographic characteristics, clinical features, autoantibody profiles, damage and mortality data retrieved from the database were compared between patients with and without each hematological abnormality. The $\chi^2$ test, logistic regression and Kaplan-Meier survival analyses were used.

**Results:** There were 93 (10.9%) patients with AIHA and 215 (25.3%) with thrombocytopenia. Patients with AIHA were significantly younger at diagnosis (27±13 vs 31±12, $p<0.05$) and had a significantly shorter disease duration (95±84 vs 118±85 mo, $p<0.05$). AIHA and thrombocytopenia were both associated with neuropsychiatric (NP) involvement ($p<0.05$) and associated with each other ($p<0.05$) and leukopenia ($p<0.05$). Comparison of patients with AIHA or thrombocytopenia to the rest of the cohort displayed significant associations with antiphospholipid syndrome (APS), anticardiolipin (aCL) antibodies and lupus anticoagulant (LA). In patients with thrombocytopenia the relationship with APS features, namely thrombosis and pregnancy morbidity, was stronger ($p<0.001$).

Compared to the rest of the cohort, more patients in both groups had organ damage and their mean SLICC damage score was significantly higher. Association to NP damage was discernible in both groups ($p<0.05$). In addition, damage in renal and cardiovascular domains and diabetes were more pronounced in patients with thrombocytopenia ($p<0.001$)

Kaplan Meier survival analysis showed that patients with AIHA had significantly reduced survival rates at 10 (94 vs 77%) and 20 (88 vs 77%) years ($p<0.001$). In the thrombocytopenia group, despite the lack of significant differences, there was a tendency for lower survival rates.

**Conclusions:** We demonstrated that both AIHA and thrombocytopenia were associated with aCL antibodies, coexisting APS and NP involvement and damage in our cohort. There was a strong link between AIHA and thrombocytopenia. Patients with AIHA had a younger age at disease onset with reduced survival. No significant reduction in survival rates was observed in patients with thrombocytopenia. However, besides NP involvement, thrombocytopenia delineated a subgroup of patients with a higher renal and cardiovascular damage which perceivably can affect prognosis. Overall, AIHA and thrombocytopenia may predict a poorer outcome in patients with SLE.

## SAT0296 IS HYPERURICEMIA AN INDEPENDENT RISK FACTOR FOR ARTERIAL THROMBOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS?

C.C. Mok, K.L. Chan, L.Y. Ho, C.H. To. *Medicine, Tuen Mun Hospital, HK, Hong Kong*

**Objectives:** To evaluate whether hyperuricemia is independently associated with cardiovascular events in a cross-sectional study of Chinese patients with SLE.

**Methods:** Consecutive patients who fulfilled ≥4 ACR criteria for SLE were recruited. Fasting blood was taken for serum urate level, along with other atherosclerosis risk factors that included glucose, total, LDL, HDL cholesterol and triglyceride. Patients were assessed for body mass index (BMI), waist circumference and the presence of the metabolic syndrome (MetS) as defined by the updated joint consensus criteria, using the Asian criteria for central obesity. The 4-variable estimated glomerular filtration rate (eGFR) was also calculated. Patients were stratified according to different serum urate levels: <0.35mmol/L, 0.35–0.48mmol/L, 0.48–0.60mmol/L and >0.60mmol/L. Comparison of the prevalence of vascular risk factors, the MetS and arterial thrombotic events (acute coronary syndrome, stroke, peripheral vascular event) was made among patients with different levels of urate. Cox regression models were established to study whether hyperuricemia was independently associated with arterial events with adjustment of demographic variables, eGFR, vascular risk factors and the antiphospholipid (aPL) antibodies.

**Results:** 485 SLE patients were studied (93% women; mean age 46.2±14 years); 259 (53%) had renal involvement and 73 (15%) had chronic kidney disease (stage ≥3). Hyperuricemia (urate >0.35mmol/L) was present in 185 (38%) patients. The number of patients who had serum urate levels of 0.35–0.48, 0.48–0.60 and >0.60mmmol/L was 131 (27%), 40 (8.7%) and 14 (2.9%), respectively. Patients with hyperuricemia, compared with those without, were more likely to be men (14% vs 3%; $p<0.001$), have renal disease (72% vs 42%; $p<0.001$), hypertension (34% vs 15%; $p<0.001$), lower eGFR (73.4±34 vs 101±27; $p<0.001$) but longer SLE duration (14.3±8.7 vs 12.2±7.4 years; p=0.006). The LDL-cholesterol level (3.34±1.37 vs 2.89±1.51mmol/L; p=0.001), triglyceride level (1.62±0.77 vs 1.29±0.78mmol/L; $p<0.001$), BMI (23.2±4.5 vs 22.3±3.8kg/$m^2$; p=0.04) and occurrence of the MetS (22% vs 12%; p=0.007) were significantly higher in patients with hyperuricemia. Over an observation of 12.9±8.0 years, 50 acute arterial events (17 acute coronary syndrome; 24 stroke, 7 peripheral vascular event and 2 retinal artery thrombosis) developed in 47 patients. Acute coronary events were significantly more common in patients with hyperuricemia than those without (7.6% vs 1.0%; p=0.001). Cox regression analysis revealed that HDL<1.0mmol/L (HR 3.44 [1.62–7.27]; p=0.001], lupus anticoagulant (HR 3.84 [1.92–7.65]; $p<0.001$) and age of SLE onset (1.03 [1.004–1.05] per year; p=0.02) were independently associated with arterial thrombosis. In separate regression models, elevated urate levels (>0.35, >0.48 or >0.60mmol/L) were not significantly associated with arterial events after adjustment for age, sex, eGFR, smoking, LDL-cholesterol, HDL-cholesterol, triglyceride, BMI, diabetes mellitus, hypertension and the apL antibodies.

**Conclusions:** In patients with SLE, hyperuricemia was associated with atherosclerotic risk factors, the MetS and acute coronary events. However, in multivariate regression models, hyperuricemia was not an independent risk factor for any arterial events after adjustment for confounding factors.

## SAT0297 PRIMARY SJOGREN SYNDROME: CLINICAL AND BIOLOGICAL FEATURES ACCORDING TO THE PRESENCE OF ANTI-SSA ANTIBODIES FROM A COHORT OF 176 PATIENTS

S. Ismael[1], S. Lechtman[1], K. Champion[1], P. Cacoub[2], P. Cacoub[2], D. Sene[1]. *[1]Internal Medicine, Lariboisière Hospital; [2]Internal Medicine, Pitié-Salpetriere Hospital, Paris, France*

**Background:** Since 2002, the European American Consensus Group criteria required the presence of 4 criteria among whom the presence either anti-SSA/anti-SSB antibodies or a focus score upper or equal to 1 at the labial salivary gland biopsy for the diagnosis of pSS. The direct consequence of such classification criteria is the constitution of two different immunological patterns in pSS: one with positive anti-SSA or anti-SSB antibodies, representing 60 to 70% of patients (called seropositive pSS) and the second with negative anti-SSA and anti-SSB antibodies (seronegative pSS).

**Objectives:** To analyze the clinical and biological differences between anti-SSA

seropositive patients and seronegative patients from a cohort of 176 pSS patients.
**Methods:** We included 176 patients fulfilling 2002-AECG criteria for pSS and retrospectively analyzed their clinical and biological features according to the presence or absence of anti-SSA antibodies.
**Results:** The median age at pSS diagnosis was 54 years; 79% were female; 68% Caucasian and 13% Black. The median follow-up time was 41 months.
pSS criteria included xerostomia for 89% of patients, xerophtalmia 96%; a positive minor salivary glands biopsy 83% of 151 patients and anti-SSA antibodies 62% (109 patients) and anti-SSB antibodies 32%. Cumulative extraglandular manifestations included arthralgia in 66%, purpura 13%, lung involvement 10%, peripheral neuropathy 36%, central nervous system involvement 6% and B-NHL 6%. Peripheral neuropathy was small fiber neuropathy (24%), large fiber sensory neuropathy (6%) and sensorimotor neuropathy (4.5%).
Seropositive patients (109 patients, 62%), when compared to seronegative patients (67 patients, 38%), were younger at pSS diagnosis (49 vs 58 years; P=0.00015), more frequently Black (18% vs 4.5%; P=0.010) and had less frequently xerostomia (84% vs 97%; P=0.006), peripheral neuropathy (28% vs 51%; P=0.002), mainly small fiber neuropathy (16% vs 39%; P=0.001) but more often purpura (20% vs 3%; P=0.01). There was no significant difference regarding, articular or lung involvement or B-NHL. Biologically, they were hallmarked by a higher prevalence of 1) B-cell chronic activation markers which included hypergammaglobulinemia (61% vs 25%; $P<10^{-5}$), rheumatoid factor (65% vs 32%; $P<10^{-5}$), and abnormal FLC ratio (31% vs 0%; $P<10^{-5}$), 2) peripheral cytopenia including anemia (27% vs 8%; P=0.003), leucopenia (17% vs 5%; P=0.03) and lymphopenia (50% vs 29%; P=0.01). There was no difference regarding mixed cryoglobulin (11% vs 6%) and monoclonal gammopathy (16%vs 16%).
**Conclusions:** Our results showed that the presence or the absence of anti-SSA antibodies are associated with two distinct clinical and biological faces of the "same disease". Anti-SSA positive patients are younger at diagnosis with a higher prevalence of purpura and B cell activation markers and cytopenia; inversely, anti-SSA negative patients are older at diagnosis with a lower prevalence of B cell activation and are more prompt to develop sensory neuropathies mainly small fiber neuropathies. These findings question the pSS clinical and biological homogeneity and the selection of patients for B cell targeting therapies.

## SAT0298 RETROSPECTIVE EVALUATION OF BASAL LEPTIN LEVELS IN SLE PATIENTS WHO DEVELOPED DISEASE FLARES AND DAMAGE ACCRUAL

D.P.E. Margiotta, M. Vadacca, L. Navarini, F. Basta, M. Lo Vullo, A. Afeltra. *Unit of Allergology, Immunology and Rheumatology, Università Campus Bio-Medico di Roma, Rome, Italy*

**Background:** Adipokines are citkokines mainly secreted by adipose tissue and involved in a wide spectrum of processes including metabolism, insulin sensitivity, atherogenesis and immunity. Leptin is the first adipokine discovered and plays important immunological functions. Crescent scientific data confirm the leptin involvement in many human autoimmune diseases. We described leptin hyperexpression in sera of female SLE patients, especially in fertile age, in relation with metabolic parameters and disease activity
**Objectives:** To evaluate the basal leptin levels in SLE patients who develop disease flares and damage accrual in 3 years follow-up.
**Methods:** We performed a retrospective evaluation of basal serum leptin levels, metabolic parameters and SLE disease features in 20 female SLE patients. For all subjects, complete data concerning disease activity and damage were available over a period of almost 3 years after the baseline assessment. Metabolic parameters included basal insulin, glycaemia, HOMA-IR, plasma lipid profile, BMI, waist-hip ratio. SLE disease features were expressed as anti-dsDNA positivity, complement fraction C3 and/or C4 depletion, disease activity measured by SELENA SLEDAI and disease damage evaluated by SDI. SLE disease flares were assessed by revised SFI index. Number of disease flares was evaluated during the fist year of follow-up and at the end of a 3 years follow-up. SDI was measured at baseline and at the end of year 3.
**Results:** We found hyperexpression of basal leptin levels in SLE patients who developed almost 1 flare at year 1 compared to patients without flares (p 0.002). Basal leptin in subject with almost 1 flare at the end of the 3 years of follow-up was higher in comparison with patients who didn't develop disease flares (p 0.0003). Basal leptin was increased in patients who presented almost 1 new point of SDI at the end of the 3 years follow-up versus patients without SDI increase (p 0.0003). The survival curve of the time without a lupus flare in subjects with leptin above 50 percentile significantly differed compared to subjects with leptin levels below 50 percentile (p 0.003). Patients with almost 1 flare at year 1 and year 3 and subject with almost 1 new SDI point at year 3 presented increased basal HOMA-IR, BMI and basal SELENA-SLEDAI. At baseline, leptin levels positively correlated with HOMA-IR (r 0.8, $p<0.0001$), BMI (r 0.8, $p<0.0001$) and SELENA SLEDAI (r 0.8, $p<0.0001$).
**Conclusions:** We found basal leptin hyperexpression in SLE patients who developed disease flares and damage accrual in a 3 years follow-up period. These patients presented increased insulin-resistance and disease activity at baseline and leptin was tightly related to both these aspects. Further studies are required to evaluate the possible role of leptin as predictor of SLE prognosis

## SAT0299 ANGIOGENESIS BIOMARKERS AND DOPPLER ULTRASOUND OF UTERINE ARTERIES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND/OR ANTIPHOSPHOLIPID SYNDROME CAN BE HELPFUL IN DIFFERENTIAL DIAGNOSIS BETWEEN PREECLAMPISA AND DISEASE ACTIVITY

E. Rodriguez[1], M. Galindo[1,2], E. Gonzalo-Gil[2], A. Usategui[2], I. Herráiz[2,3], P. Gómez-Arriaga[2,3], P. Vallejo[2], A. López-Jiménez[2], A. Galindo[2].
*[1]Rheumatology; [2]Hospital Doce de Octubre, Madrid, Spain; [3]Obstetrics and Gynaecology, Hospital Doce de Octubre, Madrid, Spain*

**Background:** Preeclampsia (PE) is a specific pregnancy syndrome that affects 2–5% of healthy women. This risk increases up to 10–30% in patients with autoimmune diseases such as Systemic Lupus Erythematosus (SLE) and/or Antiphospholipid Syndrome (APS). Differential diagnosis between PE and disease flare during pregnancy is often difficult. Pulsatility index of uterine arteries (mPI-UtA), serum levels of endoglin and the ratio tyrosine kinase-like soluble receptor/placental growth factor (sFlt-1/PlGF) are useful markers for early diagnosis of PE, even in asymptomatic women.
**Objectives:** To analyse the utility of these markers among pregnant patients with SLE/APS.
**Methods:** We included patients consecutively followed in our high-risk pregnancy clinic from 2008 to the present. These patients had diagnosis of SLE (ACR criteria 1987), LES-like (<4 ACR-SLE 1987 criteria), APS (Sydney criteria) or antiphospholipid antibodies without fulfilling criteria APS (aPL). PE and its severity were diagnosed according to the International Society for the Study of Hypertension in Pregnancy criteria (ISSHP). Lupus activity was assessed with moderate considering SLEPDAI index $\geq$6 and APS according to the clinical activity. Follow-up visits were performed at 11–13, 22, 28 and 32 weeks and postpartum. We collected clinical data about autoimmune disease and pregnancy, treatments, toxic and cardiovascular risk factors, analytical data including endoglin and ratio and Doppler ultrasound (mPI-UtA). We performed a descriptive analysis, Chi-square or t-Student tests according to the type of variable. Odds ratio and confidence intervals were calculated by using simple logistic regression.
**Results:** We analysed 58 pregnancies. Lupus activity during pregnancy was detected in 6 patients (10.3%), 5 with SLE and one with LES-like diagnosis. Two patients developed moderate to severe activity (SLEPDAI 25 and 12, respectively) with worsening since 24th week (33.3%). Two patients with SLE +/– APS developed PE (3.4%). We found statistically significant association between PlGF and ratio values in week 32 and development of PE [(mean 151.76±118.85 with p=0.023) and (89.62±114.70 with p=0.020), respectively)]. In addition, the values of endoglin, ratio and mPI-UtA were higher in PE than in normal pregnancy or flares since 24 week (see Table). On the other hand, there not seems to be differences in scores between patients with lupus activity and normal development of pregnancy.
**Conclusions:** Despite the limited number of patients who develop complications in our cohort, it seems that the mPI-UtA, endoglin and ratio in patients with SLE and/or APS behaves as in the general population and may help in the differential diagnosis of preeclampsia and disease activity.

## SAT0300 THE RELATIONSHIP BETWEEN GENETIC VARIATIONS OF ADAPTIVE IMMUNE SYSTEM INTRACELLULAR SIGNAL TRANSDUCTION PATHWAYS AND CLINICAL FINDINGS IN SYSTEMIC LUPUS ERYTHEMATOUS

F. Saritas[1], G.E. Pamuk[2], H. Gurkan[3], H. Tozkir[3], D. Julide[4], O.N. Pamuk[1].
*[1]Rheumatology; [2]Hematology; [3]Genetics; [4]Health Services Vocational College, Trakya university, Edirne, Turkey*

**Background:** In T-cells of the systemic lupus erythematosus (SLE), the gene expression of two variants of CD44; CD44v3 and CD44v6 are increased and their expression correlates with disease activity. Moreover, the existence of these two variants is related with kidney involvement and anti-DNA positivity. Increased CD44v3 and CD44v6 expressions were shown in cells that infiltrated the kidney in SLE. It was also revealed that the hyperactivity of the B-cells in the SLE were related to increased plasmablasts and naive B-cells, increased stimulation through

TLR9, activation and longer survival through BAFF, and decreased suppressor signals.
**Objectives:** Genetic variations related to signal cell transduction in the adaptive immune system were seen to be active in SLE in different studies, and their association with clinical findings in different populations should be known.
**Methods:** Eighty three SLE patients and 116 healthy control subjects were included into the study. The clinical features, organ involvements, laboratory values and outcome of SLE patients were obtained from hospital records. SLE patients' treatment modalities since diagnosis, their response to therapy and relapses were recorded. Polymorphisms of BANK1 gene (rs10516487 and rs10516483) –involved in B-lymphocyte intracellular signal transduction pathway-, and polymorphisms of CD44 gene (rs507230 and rs2732552) –playing a role in T-cell signal transduction- were studied from blood samples of patients by PCR method.
**Results:** In the SLE group, rs570230 (CD44) polymorphism CT genotype was significantly more frequent than in the control group (39.8% vs. 22.4%, p=0.014). SLE group had significantly less frequent rs10516487 (BANK1) polymorphism AA genotype (1.2% vs. 8.6%); and significantly more frequent GG genotype (59% vs. 44%) and A allele than controls (p values, 0.027, 0.036 and 0.013). No significant differences were found in terms of rs10516483 (BANK1) and rs2732552 (CD44) polymorphisms. In SLE patients with nephritis, rs570230 polymorphism TT genotype was significantly more frequent (50% vs. 20.7%, p=0.009), whereas the CT genotype was less frequent in the active disease group (31% vs. 61.4%, p=0.01). rs10516487 polymorphism GG genotype was significantly more frequent in SLE patients with arthritis (62.5% vs. 40%, p=0.045).
While SLE patients with neurologic involvement had more frequent rs2732552 polymorphism AA genotype (35.3% vs. 11.5%, p=0.038), GG genotype was more frequent in patients with lupus nephritis (57.7% vs. 29.6%) and anti-nucleosome positivity (78.6% vs. 31.3%) (p values, 0.023 and 0.004). rs10516483 polymorphism CC genotype was higher in patients with alopecia in contrast to others (77.8% vs. 34.8%, p=0.042).
**Conclusions:** In our SLE group, there is a significant association between BANK 1 (rs10516487) and rs570230 polymorphisms.
**Disclosure of Interest:** None declared

## SAT0301 PREVALENCE OF ABORTIONS AND FETAL ATRIOVENTRICULAR BLOCK IN PATIENTS WITH POSITIVE ANTI-RO AND ANTI-LA ANTIBODIES

F.M. Ortiz Sanjuan[1,2], J. Ivorra Cortés[1], L. González Puig[1], I. Chalmeta Verdejo[1], E. Grau Garcia[1], C. Feced Olmos[1], E. Labrador Sánchez[1], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Fragio Gil[1], I. Martínez Cordellat[1], J. Valero Sanz[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], G. Poveda Marín[1], J. Román Ivorra[1]. *[1]Rheumatology Department, HUP la Fe; [2]Rheumatology Research Group, IIS la Fe, Valencia, Spain*

**Background:** Anti-SSA/Ro and anti-SSB/La antibodies are present in inflammatory autoimmune disease patient sera, and there are related to different clinical manifestations. It is well known the association between the presence of these antibodies in maternal blood and fetal atrioventricular block. However, there are no much studies about infertility or repeated abortions and anti-SSA/Ro and anti-SSB/La antibodies in broad series.
**Objectives:** To characterise a cohort of patients with positive anti-SSA/Ro and/or anti-SSB/La antibodies and to evaluate the prevalence of abortions and neonatal mortality.
**Methods:** Observational descriptive study with 162 patients older than 15 years old with pregnancies history and positive anti-SSA/Ro and/or anti-SSB/La antibodies from February 2011 to July 2015. We consider healthy women with pregnancies history and with comparable characteristics as negative control group.
**Results:** We included 162 patients with positive anti-SSA/Ro and/or anti-SSB/La antibodies with a mean age of 50.5±14.2 years old. Main diagnosis were systemic lupus erythematosus (n=85), Sjögren syndrome (n=40), rheumatoid arthritis (n=16), systemic sclerosis (n=6), mixed connective tissue disease (n=3) and other diagnosis (n=12). Lupus anticoagulant was positive in 8 cases and 57 patients showed low complement values. 37% of patients had at least one pregnancy, and the 36.7% aborted during pregnancy.
There were no significant differences in the abortion incidence between our cohort of patients and the healthy control group considered.
We observed 4 cases of fetal atrioventricular block, all of them with positive anti-SSA/Ro and/or anti-SSB/La antibodies and only in one case also with positive lupus anticoagulant.
**Conclusions:** In our series, pregnant women with positive anti-SSA/Ro and/or anti-SSB/La antibodies did not show high prevalence of abortion. However, the positivity of these antibodies was statistically correlated with the presence of fetal atrioventricular block.
**Disclosure of Interest:** None declared

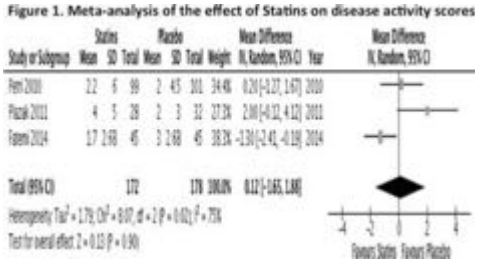
## SAT0302 ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS ASSOCIATES WITH CAROTID INTIMA-MEDIA THICKNESS PROGRESSION

A. Berti[1], A. Baragetti[2,3], M. Magnoni[4], K. Garlaschelli[3], L. Grigore[3,5], M. Berteotti[4], I. Scotti[4], E. Bozzolo[1], G.A. Ramirez[1], A.A. Manfredi[1], E. Ammirati[6], A.L. Catapano[2,5], G.D. Norata[2,3]. *[1]Unit of Internal Medicine and Immunology, IRCCS Ospedale San Raffaele; [2]Dept of Pharmacological and Biomolecular Sciences, University of Milan; [3]Center of Atherosclerosis, Bassini Hospital; [4]Unit of Cardiology, IRCCS Ospedale San Raffaele; [5]IRCCS Multimedica Hospital; [6]Unit of Cardiology, Niguarda Ca' Granda Hospital, Milano, Italy*



**Background:** A relationship between systemic inflammation and increased cardiovascular risk is often postulated. Simple and affordable clinical predictors of increased cardiovascular risk in patients with autoimmune disease, however, are not yet available in the clinical practice.
**Objectives:** To address the role of clinical, serological markers of disease activity, and of classical cardiovascular risk factors (CVRF) in predicting the carotid intima-media thickness (c-IMT) progression at 5 years (∆c-IMT) in patients with the prototypic autoimmune disease systemic lupus erythematosus (SLE).
**Methods:** Clinical and biochemical data including SLEDAI were collected at baseline and at five years of follow up from 50 patients with SLE and 50 age- and gender-matched healthy controls. C-IMT was also measured at baseline and at 5 years to evaluate progression.
**Results:** A higher SLEDAI score at baseline correlated with a faster ∆c-IMT (0.007 (0.006) mm/year vs 0.003 (0.001) mm/year when compared to controls, P=0.026), irrespectively of the presence of CVRF and of the serological profile. Patients with higher SLEDAI score at baseline also experienced disease flares more frequently (p=0.037) than those with milder disease at baseline. Patients with a higher disease activity during follow up had also a faster ∆c-IMT when compared to those with a persistently low disease activity (0.008 (0.004) mm/year vs -0.006 (0.004) mm/year, P=0.021). Elevated LDL-C levels were the only CVRF associated with disease flare-up; this might a consequence of the aggressive immunosuppressant therapy in those patients.
**Conclusions:** Patient with SLE show an increased cardiovascular risk as estimated by the c-IMT. Disease activity and in particular disease flares accelerate the progression of the vascular damage.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5698

## SAT0303 EFFECT OF HMG-COA REDUCTASE INHIBITOR DRUGS (STATINS) ON SYSTEMIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY: A SYSTEMATIC REVIEW AND META-ANALYSIS

G.M. Garcia, A. Urbano, E. Salido. *Section of Rheumatology, University of the Philippines-Philippine General Hospital, Manila, Philippines*

**Background:** Statins have a known effect in reducing the morbidity and mortality due to atherosclerosis. Recently, statins have been proposed to have anti-inflammatory and immunomodulatory effects. In in-vitro studies these drugs inhibit inflammatory cells like monocytes, macrophages, and lymphocytes, decrease the expression of major histocompatibility complex (MHC) and decrease adhesion molecules and inflammatory cytokines such as IL6 and IL10, that are also implicated in SLE pathogenesis. In terms of immunomodulary effects, animal studies demonstrated that statins exacerbate or trigger cellular apoptosis and induce a shift in the Th1/Th2 balance leading to B-cell reactivity and production of pathogenic autoantibodies. Also it has been found that Treg cells can be unstable in the periphery and may promote autoimmunity. These may promote preexisting autoimmune conditions to progress toward clinical disease, such as SLE.
Statins have not been widely studied in SLE. The existing studies mostly have primary endpoints on the evaluation of atherosclerosis, and in terms of disease activity, these studies showed contradicting results. Thus, we sought to determine the effect of statins on the disease activity of SLE based on the best available evidence.
**Methods:** To identify relevant publications on statins and SLE disease activity, a systematic literature search of PubMed, Scopus, and Cochrane databases was done with no date and language restrictions. Included studies were on adult SLE patients. Only randomized controlled trials that used statins as intervention and reported SLE disease activity as an outcome measure were included. Two reviewers did quality appraisal, risk bias assessment, and data extraction.
**Results:** Three studies have met the eligibility criteria and were included in this review. Quantitative synthesis was then done. The pooled analysis of these

**Figure 1. Meta-analysis of the effect of Statins on disease activity scores**

studies suggests that statins have no significant effect on disease activity on random effects model with an overall effect of 0.13 (P=0.90, 95% CI -1.65, 1.88).
**Conclusions:** Statins neither increased nor decreased SLE disease activity; therefore possibly it can be safely given to SLE patients without the risk of triggering or exacerbating a flare.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5612

## SAT0304 COAGULATION FACTOR XIII MIGHT BE A PROMISING MARKER FOR PREDICTING ATHEROSCLEROSIS IN SLE

I. Matsuura[1,2], E. Lourenco[1], J. Grossman[1], B. Skaggs[1], M. McMahon[1].
*[1]Rheumatology, UCLA David Geffen School of Medicine, Los Angeles, United States; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

**Background:** Several traditional and non-traditional risk have been implicated in the development of atherosclerosis in systemic lupus erythematosus (SLE). However, while growing evidence demonstrates that blood coagulation factor XIII (FXIII) may play an essential role in atherothrombotic disease in patients with primary antiphospholipid syndrome, the role of this coagulation factor in atherothrombotic disease and overall disease activity in patients with SLE is still poorly understood. Plasma FXIII cross-links fibrin with itself and with the endothelium, making clots resistant to fibrinolysis. Intracellular FXIII in monocytes also cross-links Type I angiotensin receptor dimer, which increases monocyte adhesion to endothelial cells and accelerates atherosclerosis. We investigated whether FXIII was associated with intima media thickness (IMT) of carotid arteries or disease activity in patients with SLE.
**Objectives:** to evaluate clinical significance of FXIII in SLE.
**Methods:** the study involved 50 consecutive patients with SLE enrolled in a longitudinal study on atherosclerosis biomarker from 2008 through 2015 at UCLA. Plasma FXIII activity (FXIIIa) was measured in the blood samples by ELISA. B-mode and Doppler Scanning was performed to measure IMT at baseline and 24–36 month.
**Results:** Table1 shows the correlation with plasma level of FXIIIa and variables that were independently associated with SLE activity and atherosclerosis. There was a strong inverse correlation with the SLE Disease Activity Index (SLEDAI), physician global assessment (PGA), and dsDNA antibody, whereas there was a significant positive correlation between FXIIIa and C3 and IMT at the follow-up ultrasound (Figure1). In patients with high plasma FXIIIa (>143%), the mean SLEDAI was significantly lower, (2.17± 3.7 vs. 4.1 ± 3.2, p=0.009) and IMT at follow-up was significantly higher (0.61 ± 0.17 vs. 0.51 ± 0.14, p=0.009).

Table 1. Correlations between FXIII and variables in SLE

| Variable | Plasma level of XIII activity | |
|---|---|---|
| | Correlation | P-value (Spearman's) |
| SLEDAI | –0.378 | 0.007** |
| PGA | –0.311 | 0.028* |
| ds DNA antibody | –0.361 | 0.014* |
| C3 | 0.440 | 0.002** |
| C4 | 0.294 | 0.050 |
| Diagnosis of APS | –0.021 | 0.914 |
| Positive aCL | –0.118 | 0.463 |
| Hypertension | 0.110 | 0.466 |
| Diabetes | 0.255 | 0.090 |
| Dyslipidemia | 0.142 | 0.354 |
| Tobacco | 0.286 | 0.046* |
| IMT at follow up | 0.400 | 0.010* |

**p<0.01 (2-tailed), *p<0.05 (2-tailed).

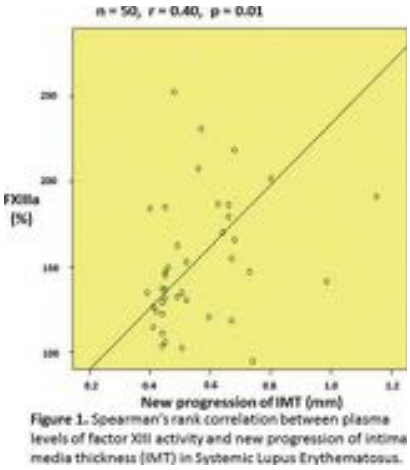


Figure 1. Spearman's rank correlation between plasma levels of factor XIII activity and new progression of intima media thickness (IMT) in Systemic Lupus Erythematosus.

**Conclusions:** Although further confirmatory testing is underway, FXIII might be a novel marker for increased IMT in SLE.

## SAT0305 NEUTROPHIL EXTRACELLULAR TRAPS MARKERS ARE ELEVATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Jeremic[1], B. Bonaci Nikolic[2]. *[1]Institute of Rheumatology, Belgrade; [2]Institute of Allergy and Clinical Immunology, Belgrade, Serbia*

**Background:** Impaired removal of apoptotic waste in patients with systemic lupus erythematosus-SLE has been long known as important factor that trigger autoimmune response. Neutrophil extracellular traps could be another source of autoantigens in patients with SLE.
**Methods:** We analysed sera from 84 SEL patients (60 patients had one sample and 24 patients were followed 2 or 3 times) and 50 healthy blood donors. Serum levels of myeloperoxidase, B-cell activating factor-BAFF, cell free DNA, complement components C3 and C3, antibody to dsDNA by CLIFT end ELISA assays, netolitic activity and DNAse I were measured.
**Results:** Patients with SLE had higher cfDNA (1.69±0.23 vs. 1.42±031 ng/mL, p=0.0003), MPO activity (p<0.05) and BAFF levels (160735±2353.23 vs. 891.16±184.31, p<0.05). DNAse concentration was also lower in healthy controls (5.84±5.72 vs. 9.38±6.97 pg/mL, p<0.05). BAFF showed strong correlation with anti-dsDNA antibodies determined by ELISA method (ρ=0.564, p=0.000), MPO activity (ρ=0.256, p=0.021), DNAse I concentration (ρ=0.27, p=0.012) and cfDNA concentration (ρ=0.262, p=0.014). MPO activity showed correlations with cfDNA levels (ρ=0.386, p=0.001), DNAse concentration (ρ=0.501, p=0.000), and anti-MPO antibodies (ρ=0.293, p=0.006). Cell free DNA levels additionally correlated with DNAse activity (ρ=0.288, p=0.007) as well with netolytic activity (ρ=0.244, p=0.026).
**Conclusions:** Increased NETs' footprints (myeloperoxidase and cfDNA) are present in lupus sera. As probably compensatory mechanism increased DNAse I concentrations also were found in lupus sera. NET burden is followed by production of various antibodies recognizing different NET structures.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5946

## SAT0306 HOW DOES CIGARETTE SMOKING AFFECT SJÖGREN'S SYNDROME?

J.C. Sarmiento-Monroy, N. Molano-González1, M. Rodríguez-Jiménez, R.D. Mantilla, A. Rojas-Villarraga, J.-M. Anaya. *Center for Autoimmune Diseases Research (CREA), School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia*

**Background:** Cigarette smoking has been found to play a pathogenic role in several autoimmune diseases. However, data about its influence on Sjögren's syndrome (SS) is scarce [1,2].
**Objectives:** To assess the impact of cigarette smoking on patients with SS.
**Methods:** This was a cross-sectional study in which consecutive patients with SS (2002 AECG) followed at a single center were included. Smoking status (ever) together with additional environmental factors and clinical and laboratory characteristics were assessed. Bivariate analysis and the mixed-cluster methodology based on multivariate descriptive methods were employed to analyze data.
**Results:** Out of a total of 277 patients, 94% were women. The mean age of patients was 51.2 ± 12.5 years, and the mean duration of the disease was 7.1 ± 7.1 years. By Chisholm and Mason classification, 93% of patients were positive for a minor salivary gland biopsy. Anti-Ro and anti-La antibodies were present in 65% and 40% respectively (by ELISA). Polyautoimmunity was registered in 43% of patients. Smokers showed a longer duration of the disease and were mostly men. Cigarette smoking was associated with parotidomegaly (OR: 1.9; 95%CI 1.05–4.3; p=0.03), polyautoimmunity (OR: 1.9; 95%CI 1.2–3.3; p=0.009), acid peptic disease (OR: 2.3; 95%CI 1.4–4.0; p=0,0008), and coffee consumption (OR: 1.7; 95%CI 0.98–3.6; p=0.04). In order to clarify whether the observed associations were influenced by gender or coffee consumption, 4 clusters were built: 1) men with a high frequency of smoking and coffee consumption (5.6%), 2) women who exclusively reported coffee consumption (42%), 3) women who all drank coffee and smoked cigarettes (30%) and 4) women with no coffee consumption but a third had been exposed to tobacco (22.4%). Cluster 2 patients were statistically less prone to present factors found in the bivariate analysis suggesting that coffee consumption may counteract the harmful effects of smoking.

**Conclusions:** Our results indicate that cigarette smoking has significant effects on SS expression, which could be modified by coffee consumption.

## SAT0307 JACCOUD ARTHROPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS: ASSOCIATION BETWEEN ANTI-CITRULLINATED PROTEIN ANTIBODIES AND EROSIVE DAMAGE

L. Massaro, F. Ceccarelli, M. Pendolino, C. Perricone, E. Cipriano, S. Truglia, F. Miranda, F.R. Spinelli, C. Alessandri, G. Valesini, F. Conti. *Medicina Interna e Specilità Mediche, Reumatologia, Sapienza Università di Roma, Roma, Italy*

**Background:** Jaccoud arthropathy (JA) is a deforming, non-erosive arthritis, occurringin 2–35% of Systemic Lupus Erythematosus (SLE) patients. The deformities could be easily misdiagnosed as those identified in rheumatoid arthritis (RA), even though, unlike in RA, they are reducible. To date no specific markers for JA are available. The evaluation of Rheumatoid Factor (RF) and anti-citrullinated protein antibodies (ACPA) in JA patients demonstrated a higher frequency of RF in comparison with SLE patient without JA. No differences in ACPA positivity were found. Imaging techniques could be helpful in the assessment of JA: the traditional radiographic definition of non-erosive arthropathy has been modified in the last years thanks to the use of new imaging techniques such as ultrasonography (US). So far, small JA populations have been evaluated by US, identifying the presence of mild articular and peri-articular involvement.
**Objectives:** The aim of the present study was to evaluate the prevalence of JA in a wide monocentric cohort of SLE patients and to describe clinical, serological and ultrasonographic features in this subset of patients.
**Methods:** Consecutive SLE patients (ACR criteria 1997) were evaluated. JA index was applied for patients with reducible deformities. Patients with JA index $\geq$5 underwent physical examination, blood draws and US assessment. ACPA and RF was detected by using the commercial ELISA kit. We compared JA patients with a subgroup of 62 SLE patients, age and sex matched, with joint involvement without JA. A single rheumatologist performed the US assessment of bilateral wrist and hands. All abnormalities were evaluated according to the OMERACT definitions.
**Results:** Four hundred eighty SLE patients were evaluated: 17 (3.5%) showed a JA index $\geq$5 (M:F 1:16; mean age±SD 50.7±11.1 years; mean disease duration±SD 247.8±116.2 months). The most frequent deformity was *ulnar drift* of MCP joints (88.2%).RF resulted significantly more frequent in JA patients compared with ACPA (41.2% versus 23.5%, P=0.009). We compared the frequency of RF and ACPA in JA patients with a subgroup of 62 SLE patients, age and sex matched, with joint involvement without JA. JA patients showed a significantly higher frequency of RF than SLE patients without JA (41.2% *vs* 17.7%, respectively; P=0.0006). Conversely, no significant difference in ACPA frequency was found between these two groups of patients. No differences were found in the titre of ACPA and RF. Bone erosions, in at least one joint, have been found in 10 JA patients (58.8%) and the most frequent joints involved were I and II MCP (17.6% of the patients for both joints). Subgrouping JA patients according with ACPA status, ACPA+ patients showed significantly more frequent erosive damage compared with ACPA- (75% versus 53.8%, P=0.002).
**Conclusions:** The present study identified an association between ACPA positivity and erosive damage in JA patients. These results suggest the possibility to use ACPA as a marker of severity in this subgroup of SLE patients, driving therapeutical approach in order to prevent chronic damage accrual.

## SAT0308 THROMBOCYTOPENIA IS A THROMBOTIC RISK FACTOR IN PATIENTS WITH POSITIVE ANTIPHOSPHOLIPID ANTIBODIES WITHOUT CLINICAL CRITERIA OF THE DISEASE?

R. Demetrio Pablo[1], P. Muñoz[2], V. Calvo-Río[3], L. Riancho-Zarrabeitia[3], M. López-Hoyos[4], V.M. Martínez-Taboada[3]. *[1]Ophtalmology; [2]Primary Care Management; [3]Rheumatlogy; [4]Immunology, Hospital Universitario Marqués de Valdecilla. IDIVAL. Facultad Medicina. UC, Santander, Spain*

**Background:** Antiphospholipid Syndrome (APS) is an acquired immune disorder defined by the presence of thrombosis and/or pregnancy morbidity together with the presence of positive antiphospholipid antibodies (aPL) (anticardiolipin antibodies (aCL), anti -beta2 glycoprotein I (AB2GPI) and/or lupus anticoagulant (LA). There is a clear relationship between aPL and some events not included in the clinical criteria such us the hematologic manifestations. Among these, thrombocytopenia has been described in 20–50% of patients with APS. Although thrombocytopenia in APS is usually not serious, its impact on the clinical curse of the diseasesis unknown.
**Objectives:** a) To study the probability of developing clinical APS in patients with positive aPL and thrombocytopenia b) To identify potential risk factors for the development of APS. c) To study the association of thrombocytopenia with aPL autoantibodies.
**Methods:** Retrospective study of patients with positive aPL on at least 2 times, separated by a minimum of 12 weeks in medium or high titers without fulfilling clinical criteria for APS. The patients were selected from the database of the Department of Immunology of a tertiary hospital (1999–2004). Thrombocytopenia was defined as a platelet count $\leq$100000 platelets/L. We excluded patients with other causes of thrombocytopenia.
**Results:** 17 of 138 (12%) patients in the study had thrombocytopenia (mean platelet count 60,000/mm$^3$). Ten patients received oral glucocorticoids. Only 2 patients with <5.000 platelets/mm$^3$ were treated with intravenous gammaglobulins. Smoking was more common in patients with thrombocytopenia (47.1% vs 24%; p=0.044). The risk for thrombocytopenia was almost 3 times higher in smokers (OR 2.8; 95%CI 1.0–8.0; p=0.044).
We found no statistically significant relationship with the distribution of the different antibodies, except for AL (OR 13.5, 95%CI 3.8–47.6; p<0.001). Patients with 2 and 3 positive antibodies were more likely to develop thrombocytopenia than those with a single antibody (OR 12.4 and 50.8 respectively; p=0.002 and p<0.001).
After a mean follow-up of 146±60.3 months, 5 patients with thrombocytopenia (29.4%) developed thrombosis (4 arterial: 1 anterior ischemic optic neuropathy, 1 transient ischemic attack, 1 stroke and 1 acute myocardial infarction, and 1 deep venous thrombosis of the lower limbs with secondary pulmonary embolism), fulfilling clinical criteria for APS. The mean time from the confirmation of the presence of aPL to the diagnosis of APS was 73±61.5 months. Patients with thrombocytopenia had higher number of thrombosis compared with patients with normal platelet count (29.4% vs 6.6%, OR 5.9; 95%CI 1.7–20.9; p=0.003).
**Conclusions:** a) In our series, the incidence of thrombocytopenia in patients with positive antiphospholipid antibodies that do not meet clinical criteria for APS is 12%. APL-positive patients who develop thrombocytopenia have a potential risk of developing APS in the future. b) Tobacco use could be a risk factor for the development of thrombocytopenia in this population. c) Autoantibodies load is a risk factor for the development of thrombocytopenia.

## SAT0309 PRIMARY SJÖGREN'S SYNDROME AND LYMPHOMA – A POPULATION-BASED STUDY FOCUSED ON LYMPHOMA AS EXCLUSION CRITERION FOR PRIMARY SJÖGREN'S SYNDROME DIAGNOSIS

L. Vasaitis[1], G. Nordmark[1], E. Theander[2], C. Backlin[1], K.E. Smedby[3], J. Askling[3], C. Sundström[4], E. Baecklund[1]. *[1]Dept. of Medical Sciences, Section of Rheumatology, Uppsala University, Uppsala; [2]Dept. of Rheumatology, Skåne University Hospital, Lund University, Malmö; [3]Clinical Epidemiology Unit, Dept. of Medical Sciences, Karolinska Institutet, Stockholm; [4]Dept. of Immunology, Genetics and Pathology, Rudbeck laboratory, Uppsala University, Uppsala, Sweden*

**Background:** In the widely used American-European Consensus Group (AECG) classification criteria for primary Sjögren's syndrome (pSS), pre-existing lymphoma is one of the exclusion criteria for pSS diagnosis (1). This is in contrast to the American College of Rheumatology (ACR)/Sjögren's International Collaborative Clinical Alliance (SICCA) 2012 classification criteria (2). The rationale and consequences of excluding or not excluding pSS in patients with pre-existing lymphoma have not specifically been described.
**Objectives:** To compare patients with pre-existing lymphoma and a later pSS diagnosis, and patients with pSS and a subsequent lymphoma, derived from a large-population-based cohort of individuals with pSS and lymphoma.
**Methods:** Patients with an International Classification of Diseases (ICD) diagnosis code for "Sjögren's syndrome/sicca syndrome" (SS) and prior or subsequent lymphoma diagnosis were identified by linking the Swedish Patient Register 1964–2007 with the Cancer Register 1990–2007 (n=205). Clinical data and lymphoma tissues were reviewed and the diagnoses evaluated. All 71 patients fulfilling the AECG and/or the proposed ACR-EULAR criteria for pSS (3) with a confirmed lymphoma were included in the study.
**Results:** We identified 11 patients with pre-existing lymphoma, defined as lymphoma diagnosed before (n=4, median time four years to pSS diagnosis) or within six months after pSS diagnosis (n=7, median time three months to lymphoma diagnosis), and 60 pSS patients with subsequent lymphoma.
The pSS characteristics were similar in patients with pre-existing lymphoma and pSS patients with subsequent lymphoma. There were no differences in reported duration of sicca symptoms (median time from sicca onset until pSS diagnosis 5 years in pre-existing lymphoma group vs. 4 years in pSS patients with subsequent lymphoma, p=0.1), sex distribution, median ages at sicca onset, pSS and lymphoma diagnoses, presence of autoantibodies, laboratory findings, overall survival after lymphoma diagnosis, and extraglandular pSS manifestations. However, lymphadenopathy at pSS diagnosis was more common in patients with pre-existing lymphoma (p<0.0001).
There were some differences in lymphoma characteristics. Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT) (72% vs. 22%, p<0.002), and lymphoma involvement of the salivary glands (82% vs. 32%, p<0.005) were more common in patients with pre-existing lymphoma than in pSS patients with subsequent lymphoma.
**Conclusions:** This study suggests that pre-existing lymphoma should not be used as a general exclusion criterion for pSS, which may erroneously remain

undiagnosed. On the contrary, the combination of sicca symptoms and MALT lymphoma in the salivary glands could instead be a reason for adequate pSS investigation.

## SAT0310 THE RELATIONSHIPS BETWEEN THE OCCURRENCE OF ANTIBODIES USED IN CLINICAL PRACTICE FOR DIAGNOSIS OF LUPUS AND CLINICAL CRITERIA USED IN THE SLICC CLASSIFICATION SYSTEM

M. Dryglewska[1], M. Majdan[1], D. Suszek[1], A. Majdan[1], Z. Kiełbik[1], M. Grzywnowicz[2]. *[1]Department of Rheumatology and Connective Tissue Diseases; [2]Department of Experimental Hematooncology, Medical University of Lublin, Lublin, Poland*

**Background:** The relationships between the occurrence of antibodies used in clinical practice for diagnosis and monitoring of the disease activity of systemic lupus erythematosus (SLE) and clinical criteria used in the SLICC classification system are a matter of discussion.
**Objectives:** The aim of the study was to investigate whether there are any relationships between the presence of clinical criteria used in the SLICC classification system and the presence of antibodies characteristic for SLE detected by multiparametric assay.
**Methods:** The study involved 81 (72-female and 9-male) consecutive SLE patients treated in the Department of Rheumatology and Connective Tissue Diseases. All patients fulfilled the SLICC classification criteria of SLE and 21 SLE pts - criteria of secondary Antiphospholipid Syndrome (SAPS). The mean age in the study group was: 37.6±11.1 years (from 19 to 71), the duration of the disease was 9.6±8.5 (from 0 to 33) years and mean SLE activity (SLEDAI scale) 4.1±4.9 (from 0 to 22).
The presence of antibodies (Ab) was determined by multiparametric enzyme-linked immunosorbent assay Polycheck Rheuma (Biocheck, GmbH, Münster, Germany). Statistical data analysis was performed using Statistica v10.0.
**Results:** In the studied group the following symptoms of SLE were found: malar rash – 46 pts, discoid rash -3 pts, photosensitivity – 34 pts, vasculitis – 21pts, oral ulcers – 22 pts, alopecia – 36 pts, musculoskeletal – 58 pts, arthritis – 36 pts, serositis – 14 pts, renal disorder – 7 pts, lupus nephritis – 33 pts, neurological disorders – 20 pts, hematologic disorders – 56 pts.
In the examined group of 81 patients the following antibodies were detected: anti-dsDNA – 10 pts (12.3%), anti-Sm-9 pts (11.1%), anti-Rib P – 4 pts (4.9%), anti-Histons – 15 pts (18.5%), anti-Ro/SS-A 52 – 2pts (2.5%), anti-Ro/SS-A 60 – 22 pts (27.2%), anti-La/SS-B – 7 pts (8.6%), anti-Scl-70 – 3 pts (3.7%), anti-CENP-B – 1 pts (6.2%), anti-PM/Scl-100 – 3 pts (3.7%), anty-U1-snRNP – 9pts (11.1%), anti Ku – 5 pts (6.2%), anty-Jo-1 and anty-Mi-2 – 0 pts.
In the data group of SLE patients, a statistically significant correlation was found only between vasculitis and presence of antibodies: anti-dsDNA (p=0.021, Φ Yule'a=0.27), anti-Ro SS-A 60 (p=0.027, Φ Yule'a=0.26), anti-Sm (p=0.028, Φ Yule'a=0.26).
**Conclusions:** In the SLE pts no significant association was found between the presence of clinical criteria used in the SLICC classification system and the antibodies used in clinical practice for diagnosis and monitoring of disease activity. Only vasculitis is significantly associated with the presence of anti-dsDNA, anti-Ro SS-A 60, and anti-Sm antibodies.

## SAT0311 THE COMPARABILITY OF PATIENT AND PHYSICIAN GLOBAL ASSESSMENT IN EARLY AND NON-EARLY SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. Pasali[1], V. Sadovici-Bobeica[1], M. Cebanu[1], V. Salaru[2], L. Mazur-Nicorici[1], M. Mazur[1]. *[1]Rheumatology; [2]Family Medicine, State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

**Objectives:** To compare patient and physician global assessment of disease activity in patients with systemic lupus erythematosus (SLE) depending on disease duration.
**Methods:** In performed case-control study were included patients that fulfilled SLICC classification criteria, 2012. The research included two groups: patients with early SLE – first group (disease duration less than 24 months) and non-early SLE – second group (disease duration more than 24 months). Patient and physician global assessments (PGA and PhGA) were rated by 0 -100 numeric scale. We evaluated the concordance of PGA and PhGA in each group and compared the results between groups.
**Results:** A total of 72 SLE patients were analyzed. First group included 36 patients with a mean age 37.2±13.2 (range 18–67) years, 83.3% female and mean disease duration was 12±9.4 months. Mean PGA value were lower compared to PhGA values in this group (47.5±22.0 versus 49.1±21.0), but the difference wasn't statistically significant (p>0,05). The second group included also 36 patients, mean age was 43±10.6 (range 24–73) years, 91.7% female and mean disease duration was 120±50 months. Mean PGA value was also lower than mean PhGA in this group, but with a smaller discrepancy (50.0±19.7 versus 50.2±20.9, p>0,01). The comparison of groups showed that in patients with early SLE the discordance between PGA and PhGA, is more important than in patients with longer disease duration.
**Conclusions:** The comparison of PGA and PhGA in patients with early SLE patients and ones with longer disease duration showed that patients early in disease duration tend to diminish PGA underestimating their general estate, but without statistically significant difference. In longer disease duration PGA and PhGA variables become similar, that suggest the patient's better understanding of their disease and general estate.

## SAT0312 WORK DISABILITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN MOLDAVIAN LUPUS STUDY GROUP

M. Cebanu[1], V. Salaru[2], V. Sadovici[1], L. Mazur-Nicorici[3], M. Pasali[1], N. Loghin-Oprea[1], M. Mazur[1]. *[1]Rheumatology; [2]Family Medicine; [3]Cardiology, State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

**Background:** As systemic lupus erythematosus (SLE) is a chronic disease, it can lead in time to important functional limitations that impair not only their quality of life but also their ability to work. Prior studies on work disability in patients with SLE have shown that about one third of the patients become disabled within 3–12 years of diagnosis [1,2].
**Objectives:** To assess the work disability in patients with systemic lupus erythematosus in Moldavian lupus study group.
**Methods:** Using a cross-sectional design, patients who fulfilled the SLICC (2012) classification criteria for SLE, were recruited from rheumatology departement. Data collection included demographics, disease duration, physician-rated indices of disease activity (SLAM) and damage index (SLICC DI). Work disability was defined by patients self-report.
**Results:** The study included 106 patients (97 females, 9 males) with a mean age (±SD) of 41,1±12,6 years, mean disease duration of 90,0±87,2 months. The disease activity by SLAM was 11±5,17 points and mean SLICC/ACR DI 1,9±2,4 points. The rate of self-reported work disability among the 106 patients studied was 35,8% (38 patients). Disability rate in the first year of disease was reported by 39,5% (15) patients; after 2 to 5 years of disease the estimated rate was of 47,4% (18 patients); after 6 to 10 years of disease the estimated rate was of 10,5% (4 patients) and after 10 years of disease the self-reported work disability was 2,6% (1 patient).
**Conclusions:** The rate of work disability was 35,8% with the highest rate in the first five years of disease, affecting younger persons, which make crucial to identify strategies aimed to reduce work disability is in those patients.

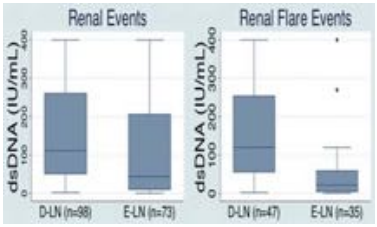
## SAT0313 DIFFERENT SEROLOGICAL PROFILES AND ACTIVITIES IN TWO ONSET CATEGORIES OF LUPUS NEPHRITIS



M. Nakano, Y. Takahashi, H. Yamashita, H. Kaneko, A. Mimori. *Division of Rheumatic Diseases, National Center for Global Health and Medicine, Tokyo, Japan*

**Background:** Previously, we reported a different renal prognosis between two onset categories of lupus nephritis (LN): LN that developed as a flare of systemic lupus erythematosus (SLE) after treating the prior non-renal SLE conditions successfully (delayed, D-LN) and LN manifesting at the time of SLE onset (early, E-LN).[1)] D-LN had a poorer renal prognosis than E-LN independent of the renal histology based on the chart review, but we had not analyzed the serological data in those LN patients.
**Objectives:** This study investigated possible differences in the serological profiles and activities between E-LN and D-LN. We focused on the serum levels of complement C3 and anti-ds DNA antibodies (Ab) as serological activities, and anti-Sm Ab as a serological profile.
**Methods:** Our hospital records for 1990–2015 were reviewed, and we identified 361 SLE patients diagnosed according to the American College of Rheumatology criteria for SLE. This study had two parts.
1. *Serological activity (C3 and anti-dsDNA Ab):* Of the 361 patients, 166 with LN (83 E-LN, 83 D-LN) had serum C3 and anti-dsDNA Ab levels measured on each admission to treat a total of 347 active SLE events (204 renal and 143 non-renal events). The serum data were compared between the E-LN and D-LN groups using the Mann–Whitney U-test and two-way analysis of variance (ANOVA).

2.*Prevalence of positive serum anti-Sm Ab:* From the 361 patients, we enrolled 129 patients diagnosed with SLE between Jan. 1996 and Oct. 2010 who were observed for more than 5 years. Patients diagnosed before 1996 were excluded because comprehensive anti-Sm Ab data were not available. Anti-Sm-Ab-positive patients were defined by at least once positive result before or at an LN manifestation. The frequency of anti-Sm-Ab-positive patients was compared among three patient-groups: E-LN, D-LN, and non-LN-SLE (the patients with no LN for more than 5 years).

**Results:** 1. The treated SLE conditions in the 83 E-LN patients included 91 renal events (35 flares) and 36 non-renal events, and those in the 83 D-LN patients comprised 113 renal events (52 flares) and 107 non-renal events. Serum anti-dsDNA Ab levels were higher in D-LN than in E-LN for the renal events (169 ± 139 IU/mL (EIA), n=98 *vs.* 120 ± 143 IU/mL, n=73, $p<0.01$) and renal flare events (169 ± 130 IU/mL, n=47 *vs.* 48.8 ± 79.7 IU/mL, n=35, $p<0.01$) (Fig). In both the D-LN and E-LN groups, the serum anti-dsDNA Ab levels were higher at renal events than non-renal events. The serum C3 levels were similar in the D-LN and E-LN groups during renal events.

2. The enrolled patients comprised 39 E-LN, 23 D-LN, and 67 non-LN-SLE. The frequency of anti-Sm-Ab-positive patients was higher in D-LN than non-LN-SLE (15/23, 65.2% *vs.* 16/67, 23.9%, $p$=0.001) and higher in D-LN than E-LN (15/23, 65.2% *vs.* 12/39, 30.8%, $p$=0.016).

**Conclusions:** High serum anti-dsDNA Ab titers were characteristic of LN that developed later in the course of an SLE flare (D-LN) compared with LN manifesting at the onset of SLE (E-LN). D-LN may reflect intractable SLE conditions. Positive serum anti-Sm antibodies were prevalent in D-LN patients in our study. Therefore, anti-Sm-Ab-positive SLE patients without LN may be at risk for the subsequent development of D-LN.

## SAT0314 CLINICAL AND IMMUNOLOGICAL FEATURES OF ANTI-CENTROMERE ANTIBODY POSITIVE SJÖGREN'S SYNDROME

M. Tsukamoto, K. Suzuki, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Sjögren's syndrome (SjS) is a systemic autoimmune disease presenting dryness symptoms and various extraglandular manifestations. Anti-centromere antibody (ACA)-positive SjS is considered as a distinct clinical subgroup in SjS. [1–2] While ACA is often detected in sera from other autoimmune diseases, such as limited cutaneous systemic sclerosis (SSc) and primary biliary cirrhosis, the role of ACA in their pathogenesis still remains unclear. In addition, comprehensive and enough clinical information from the point of view of ACA positive cases have not been accumulated.

**Objectives:** To clarify clinical and immunological features of ACA-positive SjS and their association with autoantibodies.

**Methods:** Patients with discrete-speckled pattern in anti-nuclear antibody (ANA) test and/or positive ACA, who visited to our service between 2012 and 2015, were enrolled. Clinical information and immunological tests including serum autoantibodies and immunoglobulins (Ig) were collected and statistically analyzed.

**Results:** Discrete-speckled pattern in ANA test and/or positive ACA were identified in 198 patients. There were 190 female and 8 male and the average age was 59. 142 patients were classified into any autoimmune disease. In the 142 patients, 59 patients and 19 patients were diagnosed with SSc without SjS and SSc/SjS overlap cases, respectively. Another 33 patients were diagnosed with primary SjS and 17 patients were diagnosed with rheumatoid arthritis. Proportion of concomitant ANA patterns in 142 patients were speckled (15%), homogenous (11%), cytoplasmic (6%) and/or nucleolar (4%) pattern. Focusing on ACA positive two dominant diseases, SSc and SjS, no significant difference was not observed in age. All patients except one were female. Raynaud's phenomenon and sclerodactyly were less frequent in SjS patients (65% and 18%) than SSc patients and SSc/SjS overlap patients (100% and 100%, 76% and 84%) ($p<0.01$ and $p<0.01$, $p<0.01$ and $p<0.01$). Dryness symptoms were more frequent in SjS patients (96%) and SSc/SjS overlap patients (84%) than SSc patients (20%) ($p<0.01$ and $p<0.01$). Examining autoantibodies, serum anti-SS-A/Ro antibodies were positive in 39% of SjS patients and SSc/SjS overlap patients (30%), which were significantly higher than SSc patients (11%, $p<0.01$ and $p<0.01$). In laboratory parameters, peripheral leukocyte count in SjS patients was lower than in SSc patients (p=0.014). Other laboratory findings including platelets, hemoglobin, serum IgG, A, M, C3, C4 and CH50 did not significantly differ between SjS and SSc patients. Interestingly, leukocyte count and C4 in anti-SS-A/Ro antibody positive SjS patients were lower than the negative SjS and SSc patients (p=0.017). Anti-SS-A/Ro negative SjS patients and SSc/SjS overlap patients did not differ from SSc patietns without SjS in all laboratory parameters.

**Conclusions:** Our cross-sectional cohort study confirmed that ACA-positive cases were dominantly classified into SSc and/or SjS, presenting different clinical characteristics. Our data suggested that ACA-positive SjS was immunologically characterized by low peripheral leukocyte counts different from other ACA-positive diseases, and additional anti-SSA/Ro positivity critically determined serum level of C4 and leucocyte count in ACA-positive patients.

## SAT0315 DEMYELINATING SYNDROME SECONDARY TO SYSTEMIC LUPUS ERYTHEMATOSUS: SYSTEMATIC LITERATURE REVIEW AND ANALYSIS OF A MONOCENTRIC COHORT

M. Piga [1], E. Chessa [1], A. Floris [1,2], A. Cauli [1], A. Mathieu [1]. *[1]Rheumatology, University Clinic, Cagliari, Italy; [2]Rheumatology, Oxford's University, Oxford, United Kingdom*

**Background:** Demyelinating syndrome (DS) secondary to Systemic Lupus Erythematosus (SLE) is rare (<1%) but represents a challenging condition for both patients and clinicians.

**Objectives:** To describe the features of DS secondary to SLE through a systematic review and the analysis of a monocentric cohort of patients.

**Methods:** Using PubMed a systematic review was carried out according to PRISMA guidelines including the following Mesh terms: " Lupus Erythematosus, Systemic", "Lupus Vasculitis, Central Nervous System", "Demyelinating Diseases", "Leukoencephalopathies", "Vasculitis, Central Nervous System", "Cranial Nerve Diseases", "Diplopia", "Brain Stem". Last Medline was performed on the 31/01/2015.

Moreover, a retrospective analysis of 334 SLE adult patients, followed-up in a third level center of Rheumatology between 1990 and 2015, was performed to identify those patients that developed DS.

Patients were classified as affected with DS defined as acute of relapsing demyelinating encephalomyelitis with evidence of discrete neurologic lesions distributed in space and time according to the 1999 ACR nomenclature and attributed to SLE according to the algorithm proposed by the Italian Society of Rheumatology (1).

Cases identified by systematic review and cohort analysis were classified as affected by 4 different syndromes: A) neuromyelitis optica (NMO), B) neuromyelitis optica spectrum disorders (NMOS), C) DS prevalently involving the brain (DSB), D) DS prevalently involving the brainstem (DSBS).

**Results:** The literature search identified 1612 articles, of which 50 were considered relevant for the present study for a total of 74 case reports. The retrospective cohort analysis retrieved 4 cases. Presented data have been pooled. The mean age at the time of DS onset was 33.3 years and only 6 patients were male. DS was the onset manifestation in 57 (73.1%) patients. Among the 78 patients identified 40 (51.3%) were classified as suffering with NMOS, 23 (29.5%) with NMO, 8 (10.2%) with DSBS and 7 with DSB (9.0%). The clinical spectrum of the identified syndromes was heterogeneous but longitudinal extensive transverse myelitis was the most frequent manifestation being present in 23 patients with NMO and 26 (65.0%) with NMOS. Cranial nerve palsies was the less frequent being present in 9 (11.5%) patients (4 NMOS, 3 NMO, 1 DSBS and 1DSB). The most prescribed treatment was methylprednisolone pulses (60, 76.9%) associated with cyclophosphamide (36, 46.1%), but plasma-exchange (15, 19.2%) and Rituximab (7, 9.0%) were also used. Worse functional prognosis was associated with NMO (8.7% complete and 34.8% partial resolution). Demise was reported in 6 NMO cases (26%), 3 (7.5%) NMOS and 1 (14.2) DSB as a results of DS or associated complications.

**Conclusions:** Although rare DS secondary to SLE may be life-threatening. If DS occurs in SLE patients it should be promptly treated with high dose of intravenous corticosteroids and Cyclophosphamide or Rituximab as steroid sparing agents.

## SAT0316 NEUROLOGICAL INVOLVEMENT IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: A CASE SERIES WITH A LONG-TERM FOLLOW-UP

M. Estévez, A. Argibay, A. Pérez, C. Vázquez-Triñanes, B. Machado, R. Lorenzo, A. Sousa, I. Villaverde, M. Freire, A. Rivera. *Thrombosis and Vasculitis Unit, University Hospital of Vigo, Vigo, Spain*

**Background:** Antiphospholipid syndrome (APS) is a systemic autoimmune disorder characterized by autoantibody production and thrombosis or pregnancy morbidity. Central nervous system abnormalities are a common feature of APS that have been attributed to both vascular thrombosis as well as direct injury to neuronal tissue by antiphospholipid antibodies. Neurological manifestations in APS are diverse and may be confused with other neurologic syndromes.
**Objectives:** The aim of our study was to determine the prevalence and the type of neurological involvement in patients with APS.
**Methods:** A case series of patients with APS diagnosed and followed for a long period in a specific unit of Thrombosis and Vasculitis was conducted. Clinical and laboratory data were collected in a retrospective manner. Patients with neurological manifestations were compared with patients without nervous system involvement. Chi2 and t-student were used, using the statistical package SPSS22.0.
**Results:** 88 patients with APS were included, 63 (71,6%) female, mean age 56,5 ± 20 years [range 11–89], with a mean follow-up of 9,1 years (median 7 years). 23 patients (26,1%) had a secondary APS: 20 SLE, 2 systemic sclerosis and 1 Sjögren's syndrome. 4 (4,5%) were pure obstetric APS, 36 (40,9%) had an arterial thrombosis, 30 (34,1%) had a venous thrombosis and 18 (20,4%) had mixed events (arterial, venous and obstetric). 60 (68,2%) patients had a cardiovascular risk factor (hypertension, dyslipidemia, type 2 DM) and 15 (17%) had atrial fibrillation. 49 patients of 88 with APS (55,7%) had neurological involvement. 26 (53,1%) patients had ischemic stroke, 8 (16,3%) transient ischemic attack, 16 (32,6%) cognitive deficits, 14 (28,6%) epilepsy, 8 (16,3%) headache, 5 (10,2%) psychosis, 7 (14,3%) movement disorders and 3 (6,1%) had sensorineural hearing loss. 28 (31,8%) patients had ≥2 neurologic symptoms. 19 patients (38,8%) had white matter lesions on MRI but only 1 patient was diagnosed with multiple sclerosis. In 17 patients (34,7%) neurological involvement was diagnosed before APS (mean 7,2 ± 7,9 years). Only 3 patients had livedo reticularis: 2 SLE y 1 Sneddon syndrome. No significant differences in age, sex, classification, antiphospholipid antibodies, comorbidities and therapy were observed between patients with or without neurological manifestations. Hospitalization (93,9% vs 74,4%, p 0,01) and mortality (36,7% vs 7,7%, p 0,001) was higher in neurological APS.
**Conclusions:** More than half of patients with APS had neurological involvement. Cerebrovascular ischemic events and cognitive deficits were the most common manifestations. Neurological involvement was associated with higher mortality and hospitalization. Neurological symptoms may occur long before diagnosis of APS. We have not identified risk markers of central nervous system involvement.

## SAT0317 THE ASSOCIATION BETWEEN ABO BLOOD TYPES AND VENOUS THROMBOEMBOLISM IN INDIVIDUALS WITH A POSITIVE ANTIPHOSPHOLIPID PROFILE IS VARIED BY SEX

M. Shusterman[1], E. Golub[1], W.B. Mowrey[2], A. Broder[3]. [1]*Department of Medicine, Montefiore Medical Center;* [2]*Department of Epidemiology & Population Health, Albert Einstein College of Medicine;* [3]*Department of Rheumatology, Montefiore Medical Center, Bronx, New York, United States*

**Background:** Persistently positive antiphospholipid antibodies (aPLs) are associated with an increased risk of arterial and venous thrombotic events (VTE). The pathogenesis of thrombosis is multifactorial and non-aPL thrombosis risk factors including hypertension (HTN), obesity, smoking, and diabetes (DM) influence the risk of thrombosis.[1] ABO blood group, a determinant of plasma levels of von Willebrand factor (vWF), is an established thrombosis risk factor in the general population; non-type O blood type is associated with a higher risk of VTE. It is not known whether non-O blood type is associated with VTE in patients with persistent aPLs.
**Objectives:** To investigate the association of ABO blood type with VTE in patients with persistent aPLs.
**Methods:** We included patients >18 years old followed at an urban tertiary care center between 2000 and 2015 with the serologic criteria for aPL positivity by the revised Sapporo Criteria (anticardiolipin IgG or IgM >40 IU, and/or anti-beta-2-glycoprotein1 IgG or IgM >40 IU or LAC+ measured twice at least 12 weeks apart) and a type and screen.[2] VTEs were verified through chart review by radiological criteria and historical records. Data including age, sex, race, body mass index, smoking status, blood type, HTN or DM diagnoses, and ever use of aspirin or warfarin were ascertained from chart review. Odds ratios of VTE were estimated with logistic regression models for O vs. non-O blood type.
**Results:** Of the 230 patients included in the study, 48 (21%) were men, 78 (19 men, 59 women) had a VTE. Patients with and without VTE were similar with respect to age, sex, race, HTN, DM, and other clinical risk factors for VTE. The prevalence of non-O blood type was 46% in non-VTE and 56% in VTE, unadjusted OR 1.5 (95% CI 0.88, 2.62), p=0.14. However, among men, the prevalence of non-O was significantly higher in VTE than in non-VTE, 68% and 34%, respectively, p=0.021. Men with non-O blood type had higher odds of developing VTE, OR 4.0 (95% CI 1.1, 14.0), p=0.04 after adjusting for age, race, and DM and HTN. The association between ABO and VTE was not significant among women. In the overall sample, women were slightly younger at the time of aPL measurement, and were less likely to smoke, but more likely to have low density lipoprotein levels ≥100 mg/dl (Table 1). aPL positive women who developed VTE were more likely to be Hispanic compared to men with VTE, 54% and 25%, respectively, p=0.03, and were less likely to smoke compared to men.

**Table 1. Baseline characteristics of aPL+ patient by sex.**

| Patient Characteristics | APL positive women n=182 | APL positive men n=48 | p-value |
|---|---|---|---|
| Age, at APL measurement, median (IQR), years | 43 (29, 53) | 47 (38, 63) | 0.02 |
| Black race, n (%) | 57 (36) | 16 (36) | 0.92 |
| Hispanic ethnicity | 61 (33) | 11 (43) | 0.22 |
| History of diabetes, n (%) | 63 (35) | 22 (46) | 0.15 |
| History of hypertension, n (%) | 112 (62) | 36 (75) | 0.08 |
| Ever Smoked, n (%)* | 45 (30) | 19 (51) | 0.01 |
| LDL>100 mg/dL, n (%)* | 60 (53) | 9 (27) | 0.01 |
| BMI, median (IQR), kg/m$^2$ | 28 (23, 34) | 28 (25, 36) | 0.55 |
| Aspirin use | 88 (48) | 26 (54) | 0.48 |
| Anticoagulation use | 72 (40) | 27 (56) | 0.04 |
| Prednisone use | 88 (48) | 26 (54) | 0.47 |
| SLE by ACR/SLICC criteria | 61 (36) | 9 (21) | 0.06 |
| Non-type O blood type | 91 (48) | 23 (50) | 0.80 |

*Data unavailable for >30% of patients
BMI: body mass index
LDL: low density lipoprotein

**Conclusions:** In this retrospective study, we have shown that the association between ABO and VTE varies by sex in aPL+ individuals. The non-O blood type is associated with a higher risk of VTE in men, but not women. The effects of ABO blood types on vWF in aPL+ individuals may be attenuated by genetic and environmental factors that differ by sex. Understanding the relationship between sex, ABO, and aPL may elucidate thrombosis mechanisms of VTE in aPL+ individuals.

## SAT0318 THE SIGNIFICANCE OF ANTIPHOSPHOLIPID TESTING IN MULTIPLE SCLEROSIS: SYSTEMATIC REVIEW AND META ANALYSIS

M. Merashli[1], P. Ames[2]. [1]*Leeds University, Muskuloskeletal Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom;* [2]*Vascular Disease Unit, Nova University, Lisbon, Portugal, Lisbon, Portugal*

**Background:** The association between antiphospholipid antibodies (aPL) and multiple sclerosis (MS) is controversial.
**Objectives:** To evaluate whether aPL relate to MS and its severity.
**Methods:** Systematic review of EMBASE and PubMed from inception to October 2015 according to PRISMA guidelines. Peto's meta-analysis for rare events.
**Results:** The relationship between aCL (anticardiolipin) antibody of either IgG/IgM isotype and MS was addressed in 10 case control studies totalling 801 controls and 614 MS patients; the pooled prevalence for IgG was 1.9% in controls and 6.8% in MS yielding an odds ratio (OR) of 3.602 (95% CI 2.005, 6.471); the pooled prevalence for IgM aCL was 2.49% in controls and 10.7% in MS patients yielding an OR of 4.720 (95% CI 2.828, 7.877). The relationship between anti-beta$_2$glycoprotein-I (a$\beta_2$GPI) of IgG isotype and MS was addressed in 5 case control studies totalling 405 controls and 401 MS patients; the pooled prevalence was 5.18% in controls and 1.24% in MS yielding an OR of 0.230 (95% CI 0.086, 0.618); the relationship between IgM a$\beta_2$GPI and MS was addressed in 5 case control studies totalling 379 controls and 367 MS patients; the pooled prevalence for the IgM isotype was 2.49% in controls and 10.7% in MS patients yielding an OR of 3.251 (95% CI 1.805, 5.855). The relationship between anti-prothrombin antibody (aPT) of IgG isotype and MS was addressed in 3 case control studies totalling 328 controls and 260 MS patients; the pooled prevalence was 9.75% in controls and 4.61% in MS yielding an OR of 0.447 (95% CI 0.225, 0.887).
Three studies addressed the relationship between aPL and MS employing as controls patients with ischaemic stroke (IS) totalling 599 IS and 505 MS patients. The pooled prevalence of IgG aCL in IS was 8.9% and in MS was 6.34% for an OR of 1.011 (95% CI non evaluable). The pooled prevalence of IgM aCL in IS was 6.84% and in MS was 9.72% for an OR of 0.995 (95% CI non evaluable). The relationship between aCL of either isotype and stable/active MS was evaluated in 4 case control studies totalling 200 stable/remission MS patients and 84

active/relapsing MS patients. The pooled prevalence of IgG aCL in the former was 19.5% and in the latter 22.6% for an OR of 1.206 (95% CI 0.649, 2.241) and likewise the pooled prevalence of IgM aCL was 21% and 36.9% respectively for an OR of 0.150 (95% CI 0.086, 0.264). The relationship between a$\beta_2$GPI of either isotype and different disease stages of MS was evaluated in 123 stable/remission MS patients and 69 active/relapsing MS. The pooled prevalence of IgG $\beta_2$GPI was 1.62% in stable/remission MS and 20.2% in active/relapsing MS for an OR of 15.4 (95% CI 3.383, 70.095). The pooled prevalence of IgM $\beta_2$GPI was 3.2% in stable/remission MS and 40.5% in active/relapsing MS for an OR of 20.3 (95% CI 6.721, 61.411).

**Conclusions:** The calculated OR suggest that IgG/IgM aCL and IgM a$\beta_2$GPI are weakly associated with MS and that IgG/IgM $\beta_2$GPI are associated with active/relapsing MS though with very wide CIs. Most of the studies reported the percentage of positive aPL per group but not the average PL titre per group, precluding better assumptions on the relationships found.

## SAT0319 SEVERITY IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: A LATENT TRAIT ANALYSIS

N. Molano-González, J.C. Sarmiento-Monroy, M. Rodríguez-Jiménez, R.D. Mantilla, A. Rojas-Villarraga, J.-M. Anaya. *Center for Autoimmune Diseases Research (CREA), School of Medicine and Health Sciences, Universidad del Rosario, Bogotá, Colombia*

**Background:** Systemic Lupus Erythematosus (SLE) is a complex disease which can potentially involve any organ and, therefore, has a wide range of clinical manifestations (i.e., subphenotypes) [1].

**Objectives:** To propose a novel methodology for building an index of severity in patients with SLE.

**Methods:** A cross-sectional analytical study was done on 319 SLE patients (1997 ACR). A structural model for the latent trait in the 2pl item response theory model was fitted following the Ogasawara's formulation [2] in order to characterize a severity construct of 17 variables. In addition, the model analyzed possible associations of the severity latent trait with other patient covariates including cardiovascular disease, age at onset of the disease, and expositional factors.

**Results:** Baseline characteristics of patients were as follows: female gender 91%, median age 37 (IQR 21) years, median duration of the disease 5 (IQR 10) years, lupus nephritis 37.3%, and central nervous system involvement in 16%. Several symptoms were excluded from the severity construct due to inconsistency according to Cronbach-Mesbah Curve including lupus nephritis, diffuse alveolar hemorrhage, and vasculitis. A total of 11 symptoms were included in the item response theory model showing three levels of disease severity (Figure 1). The only covariate registered that reaches an association with severity was coffee consumption.

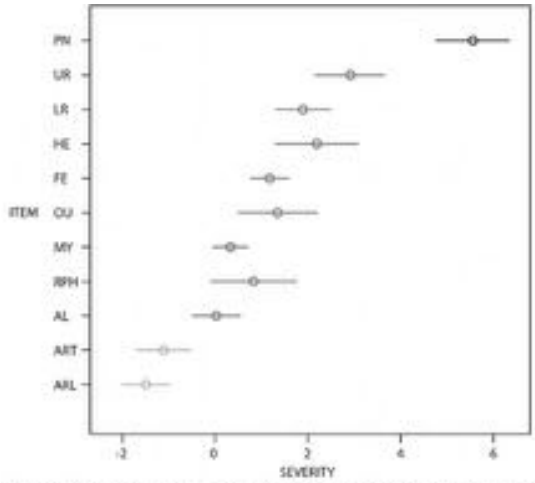

**Figure 1.** Graphic approximation to performance levels for the severity scale in the 2plScov model. *Low-severity*: Arthritis (ART), Arthralgia (ARL); *Moderate-severity*: Fever (FE), Myalgia (MY), Headache (HE), Raynaud phenomenon (RPH), Urticaria (UR), Livedo reticularis (LR), Oral ulcers (OU), Alopecia (AL); *High-severity*: Peripheral neuropathy (PN)

**Conclusions:** Symptoms excluded due to inconsistency share the same pathogenic mechanism in SLE, which corresponds to autoantibody-driven tissue damage, and are associated with high mortality risk. The remaining symptoms are related to inflammation and vasculopathy, and in most cases, require a less aggressive immunosuppressive treatment [3]. The order of symptoms on the present scale of severity coincides with clinical experience, and the three levels of performance can be associated with low, moderate, and high severity. The present index of severity is useful for SLE patients with less severe phenotype (i.e., without nephritis, diffuse alveolar hemorrhage, and vasculitis). A further replication study is necessary to validate these results.

## SAT0320 IGG3 AUTOANTIBODIES BINDING TO STATHMIN-4 AS MARKER OF POLYNEUROPATHY IN PRIMARY SJÖGREN SYNDROME

S. Ross, T. Witte, M. Stangel, R.E. Schmidt, N.T. Baerlecken. *Department of Clinical Immunology and Rheumatology, Medical University Hannover, Hannover, Germany*

**Background:** Primary Sjögren-syndrome (pSS) is considered as autoimmune phenomena affecting exocrine glands with various clinical phenotyps. PSS can appear with different extraglandular manifestations such as arthritis, myositis, vasculitis and peripheral or central neuropathies. 8.5–67% of patients with pSS complain about neurological symptoms. About 9% can be diagnosed having a destinct form of polyneuropathy (PNP).

**Objectives:** Here, we investigated autoantibodies binding to stathmin-4 (STMN-4) in pSS with PNP.

**Methods:** We screened 4 versus 4 having pSS with and without PNP for discriminating autoantibodies by using protein array technology. We identified autoantibodies binding to STMN-4 in patients with pSS and PNP. We evaluated our finding by establishing different ELISA detections for STMN-4 autoantibodies using sera of different underlying diseases (n=484).

**Results:** Using Anti-IgG3 STMN-4, we tested the following groups. In pSS with PNP 33% had anti-IgG3 STMN-4 antibodies and 6% without PNP had anti-IgG3 STMN-4 (likelihood 5.5).

| Groups | Frequency of anti-STMN |
|---|---|
| pSS | 8/62 13% |
| pSS without PNP | 3/47 6% |
| pSS with PNP | 5/15 33% |
| *pSS with sensomotoric/axonal PNP* | *5/11 45%* |
| Blood donors | 5/128 4% |
| RA | 11/62 18% |
| SLE | 3/36 8% |
| GPA | 2/21 10% |
| Plasmacytoma | 3/44 7% |
| Multiple Sclerosis | 0/37 0% |
| sSS | 3/20 15% |
| UCTD | 4/27 15% |
| PNP (metabolic, toxic origin) | 1/47 2% |

Anti-IgG3 STMN is associated with PNP in pSS patiens (Fisher exact two-tailed p-value=0.016). We could not see any significant association in other diseases with PNP and metabolic or toxic induced PNP.

**Conclusions:** Anti-IgG3 STMN is a new potential marker for PNP in patients with pSS.

## SAT0321 PREVALENCE AND MORTALITY FROM INFECTIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN A TERTIARY LEVEL HOSPITAL

O. Vera Lastra[1], C. Camacho Guerra[1], M.A. Saavedra[2], M.D.P. Cruz Dominguez[1], G. Medina[1]. *[1]Internal Medicine; [2]Reumatology Department, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico*

**Background:** Systemic lupus erythematosus (SLE) is a chronic multisystem autoimmune disease characterized by clinically heterogeneous manifestations. Infections can be the initial trigger to the development of autoimmunity. Initial presentation of SLE can mimic infections, and in turn infections can mimic disease flares in established SLE. Infections are an important cause of morbidity and mortality in SLE. Bacterial infections are most frequent, followed by viral and fungal infections. The impaired cellular and humoral immune functions seen in patients with SLE are predisposing conditions. Disease activity and high doses

of methylprednisolone or cyclophosphamide are well-recognized risk factors for infection.
**Objectives:** To determine the prevalence and mortality from infection in SLE patients as well as to identify etiology, associated factors to severity and site of infection.
**Methods:** We performed a retrospective study from 2010 to 2014 in a referral hospital. We analyzed risk factors (RF) on admission, involved organ, infectious type and etiology. Statistical analysis: We did descriptive statistical, $Chi^2$, multivariate analysis.
**Results:** There were 328 patients, 87% women and 13% men, mean age 32.4±9.9 years. Infections as cause of hospitalizations were 42.2%, prevalence of infections was 49%, and mortality from severe infections was 45%. The RF for severe infections were: renal involvement Odds Ratio (OR) 3.057, $P<0.019$; hematologic OR 1.9, $p<0.001$; increased dsAnti-DNA RM 5.1 $p<0001$, hypocomplementaemia: OR 2.673, $P<0.02$, leukolymphopenia OR 2.5, $p<0001$. Type of infecctions: bacterial 87%, viral: 3.4%, fungal: 8%, mycobacterial: 1.5%. Site of infection: lower respiratory tract 38%, urinary tract: 49% soft tissues: 6.1%, central nervous system: 1.2%, Others: 4.2%. Most frequent etiology agent were: bacterial: *S. aureus, E. coli, A. baumanii, E. faecalis. Virales: H. zoster, mycotic: candida albicans and M. tuberculosis.*
**Conclusions:** Infections are an important cause of morbidity, mortality and hospitalization in SLE patients. The lower respiratory tract infections of bacterial origen were most frequent. The renal and hematological involvement, increased dsAnti-DNA, hypocomplementaemia, and leukolymphopenia were the most important factors for severe infections. Infections in active SLE patients constitute a true challenge for the clinician

## SAT0322 PREVALENCE AND RISK FACTORS FOR COGNITIVE IMPAIRMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS

O. Vera-Lastra, M. Castrejon, J. Sepulveda-Delgado, M.D.P. Cuz-Dominguez, G. Medina, L.J. Jara. *Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico*

**Background:** Neuropsychiatric disorders have a high morbidity being cognitive impairment (CI) one of the most frequent syndromes in systemic lupus erythematosus (SLE) which lead to a poor quality of life
**Objectives:** To determine the prevalence and risk factors of CI in patients with systemic lupus erythematosus
**Methods:** Twenty seven patients were selected from a total of 150 patients with SLE. CI was evaluated in all patients by the test of Barcelona (for qualitative evaluation of cognitive state: language, reading, writing, visual recognition, memory and abstraction) and the Montreal cognitive assessment (COCA). The following risk factors were evaluated: SLEDAI, obesity/overweight, systemic arterial hypertension, dyslipidemia, pulses of methylprednisolone, SLIC/ACR, use of benzodiazepine, cyclophosphamide and chloroquine. Statistical analysis: Fisher test, T-test Student and logistical regression.
**Results:** There were 27 SLE patients (25 women and 2 men), mean age 42±14 years) mean disease evolution (10±8.6 years), length of education (11.7±4.2 years). With the test of Barcelona we found that 100% of patients had involvement in at least one item, being the most affected areas: attention in 33%, memory in 52%, analysis synthesis and abstraction in 44.4%. With respect to the MOCA a prevalence of 55.6% (15 of 27) of CI was found. Of these patients 12 of 15 had mild CI and 3 of 15 dementia. We only found that the use of chloroquine conferred protection against cognitive impairment (OR 0.236, CI 0.120–0.692, $p<0.003$). The other risk factors were not significant: dyslipidemia (OR 8.5, CI 0.508–143, p= NS), SLIC/ACR (OR 6.3, CI 0.64–109.7), obesity/overweight (OR 0.407, CI 0.02–5-2, systemic arterial hypertension (OR 0.782, CI 0.031–754), pulses of methylprednisolone (1. 85, CI 0.64- 18.119), use of cyclophosphamide (OR 0. 327, CI 0.115–7.056), among others.
**Conclusions:** We found a high prevalence of cognitive impairment being the use of chloroquine a protective factor. It is important to recognize these patients in order to offer them a medical alternative with a psychological rehabilitation.
**Disclosure of Interest:** None declared

## SAT0323 CLINICAL VARIANTS OF SYSTEMIC LUPUS ERYTHEMATOSUS IN CHILDREN

P.K. Ishuova. *Scientific Center of Pediatrics and Children's Surgery, Almaty, Kazakhstan*

**Background:** In pediatric rheumatology, features of the initial period of systemic lupus erythematosus (SLE) and clinical types, depending on which principles and tactics of therapy should be based, remain undifferentiated.
**Objectives:** To study the variants of the clinical manifestations of SLE in children at an early stage of the disease
**Methods:** The basis of this work was aimed to survey results and data of archival materials of 153 SLE patients observed in the clinic of the Scientific Center of Pediatrics and Pediatric Surgery, the Republic of Kazakhstan.
**Results:** We noted lupus carditis most commonly in the debute of the disease – 129 children (84.3%), and generalized vasculitis – 128 (83.7%) cases, followed by nephritis – 78 (51.0%), polyserositis – 72 (48.4%) and cerebrovascular – 47 (31.0%) children. Less relatively marked was a detection of secondary antiphospholipid syndrome – 40 (26.1%) children. In distribution of SLE patients over the age, main group consisted of 12 years and older aged children (60.1%) and younger than 12 years children (39.9%). While in children under the age of 12 years, the first manifestations of the disease in almost half of the cases, along with fever, dermatitis and arthritis were cardio, polyserositis and cerebrovascular (42,1% ± 3,65, 48,6% ± 3,26 and 49,1% ± 3,11, respectively), lupus nephritis (LN), generalized vasculitis (GV) and secondary APS (61,5% ± 3,25, 66,7% ± 8,55 and 70% ± 8,24, respectively, $p<0.05$). Diagnosis of carditis (78.29% ± 2,18), polyserositis (94,44% ± 1,09) in patients older than 12 years were significantly more determined in the first year of the disease. While considering the remaining forms of the disease (SLE with APS, GV and VN), diagnosis from the first signs of the disease in the first year was 35.0 ± 3,35, 50% ± 8,42 and 56,41% ± 2,41, respectively, ($p<0.01$ - 0.05), which complicates the course and outcome of the disease.
Precede factors were - ARI (42.6%), hyperinsolation (28.7%), sore throat (11.6%), other factors of 3.9%, not connection was in 17 (13.1%) cases. In SLE mainly affecting the kidneys, one of the main trigger factors were acute respiratory infections (51.2%), followed by photosensitivity (23.0%), purulent tonsillitis as a prior factor was found in 10 children less frequently representing 12.8%, other factors were important in 2.7% of cases, and not established causes composed 10.3%. In polyserositis, a prior factor in the development of the disease in half of the cases was an acute viral infection (52.8%) and purulent infection and insolation was revealed equally often (21.1% and 20.8%, respectively). The prior factor in CNS in almost half of the patients (43.9%) was acute respiratory infection, and in third of the children - hyperinsolations (19.1%).
In patients with secondary APS and generalized vasculitis (GV), viral (62.5% (APS), 62.5% (GV)) and purulent infection (25.0% (APS), 33.3% (GV)) had fundamental importance. Hypothermia, physical and emotional overloads, vaccinations were noted among the other factors.
**Conclusions:** Clinical variants of the disease were established: with primary lesions of a heart and/or kidney, with generalized vasculitis and antiphospholipid syndrome. For carditis, polyserositis and nephritis main prior factors have been infection and hyperinsolation. For generalized vasculitis (95.8%) and a secondary APS (87.5%) infection was more important in triggering the disease.

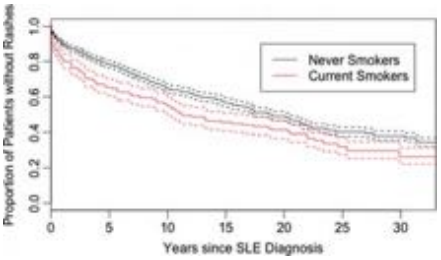
## SAT0324 HEADACHES IN PATIENTS WITH SLE – CLINICAL CHARACTERISTICS

S. Monov [1], R. Shumnalieva [1], D. Monova [2], E. Chamurliiska [3], R. Rashkov [1]. [1] *Clinic of rheumatology;* [2] *Medical Institute – MVR, Medical University - Sofia;* [3] *Privet Practice, Privet Practice, Sofia, Bulgaria*



**Background:** According to different authors central nervous system involvement in SLE called neuropsychiatric SLE (NPSLE) varies widely. One of the manifestations of NPSLE is the headache. Although the latter is not included into the diagnostic criteria, its presence is a sign of disease activity. Lupus headache could presents as: migraine, tension, headache of intracranial hypertension, atypical and relapsing pattern.
**Objectives:** The objective of our study is to identify and characterize the lupus headache in SLE patients with different clinical characteristics.
**Methods:** 225 SLE patients were included in the study. They were divided in three groups: group I - 62,28% of the patients, with clinically manifested of neuropsychiatric symptoms, group II – 37,72%, with no clinical manifestations of NPSLE and group III – 25,78%, with incomplete SLE. The presence of lupus headache was diagnosed based on the 1999 ACR classification criteria and other possible causes for it have been excluded (untreated hypertension, infections, treatment regimen, etc.).
**Results:** Lupus headache was present in 52 (23,11%) of the studied patients. It was more common in the patients with clinically active NPSLE (group I) – in 41 (39,42%) of them. In 24 (58,54%) of them the headache had a tension characteristic and a duration from 10 minutes to 4 days. In 10 (24,39%) of them it had a characteristic of migraine. In the rest of the patients with lupus headache – 7 (17,07%), is was the only symptom in the absence of neurologic abnormalities, and in 2 of them (4,88%) retinal vasculitis has been diagnosed by direct ophthalmoscopy. The use of corticosteroids had good therapeutic effect in 87,80% of cases of lupus headache. In group II there were not patients with lupus headache. Lupus headache was demonstrated in 11 patients (18,97%) patients in group III. Lupus headache was more common in the patients with longer disease duration (p=0,047) or higher levels of matrix metalloproteinase 9 in the serum ($p<0,001$).
**Conclusions:** In the majority of the SLE patients the lupus headache has a tension characteristic. The use of corticosteroids has good effect in controlling this disease manifestation.

## SAT0325 SMOKING IS ASSOCIATED WITH FUTURE LUPUS CUTANEOUS ACTIVITY IN PROSPECTIVE ANALYSES

S.G. Kwatra[1], W. Fu[2], M. Petri[2]. *[1]Dermatology; [2]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, United States*

**Background:** Smoking is associated with increased disease activity in patients with systemic lupus erythematosus[1] (SLE) and cutaneous lupus erythematosus (CLE) in cross-sectional analyses.[2]
**Objectives:** We determined the associations between smoking status, cutaneous activity, and SLE disease activity among patients enrolled in a US-based SLE Cohort featuring a large African-American population.
**Methods:** The Hopkins Lupus Cohort was queried for demographic/clinical information and laboratory parameters between current smokers and never smokers among SLE patients. SLE patients that developed rash vs. those that did not (according to the SLEDAI criteria for rash) were compared with smoking status and the following co-variables: age, ethnicity, sex, ESR, urine protein/creatinine ratio, anti-Ro, anti-La, anti-DNA, Low C3, and Low C4.
**Results:** *Current smokers vs. never smokers.* Current smokers were significantly more likely than never smokers to have an active rash (49.58% vs. 36.31%, $p<0.0001$) and ESR $>20$ (63.25% vs. 52.75%, $p<0.0006$). Non-smokers were significantly more likely to have anti-Ro antibodies as compared to current smokers (32.62% vs. 26.44%) with no significant differences found in anti-La, urine protein/creatinine ratio, anti-dsDNA antibody, low C3 or low C4.
*SLE Patients who developed new rash during the course of follow-up vs. patients without rash.* SLE patients who developed a new rash were significantly more likely than SLE patients without a rash to have a younger age of SLE diagnosis (30.69 vs. 32.79, $p<0.0015$), higher SLEDAI continuous score (5.53 vs. 2.26, $p<0.0001$) and SLEDAI score $\geq 2$ (100% vs. 57.04%, $p<0.0001$), Urine protein creatinine ratio $>0.5$ (17.14% vs. 10.67%, p 0.0256), anti-dsDNA $\geq 10$ (36.12% vs. 23.78%, $p<0.0001$), low C3 $<79$ (28.1% vs. 20.08%, 0.0001) and low C4 $<12$ (20.49% vs. 12.86%).
*Association between smoking and new rash.* Smoking was significantly associated with new rash in SLE patients after adjusting for sex, ethnicity, and hydroxychloroquine use ($p<0.0001$). In addition, duration from SLE diagnosis to new rash were compared between current smokers and never smokers. Both non-parametric Kaplan-Meier curve and a parametric Weibull curve demonstrated current smokers developed rash significantly earlier than never smokers. Based on the Weibull distribution, the hazard of developing a rash is 40% higher among current smokers than never smokers, with the effect persisting after adjusting for sex and ethnicity.

**Conclusions:** Current smokers with SLE are significantly more likely than non-smokers to have an active rash. In addition, the hazard of developing a rash is 40% higher among current smokers than never smokers. SLE patients who developed rash as compared to patients that did not develop a rash had significantly increased SLE disease activity and several laboratory abnormalities including increased urine protein creatinine ratio $>0.5$ (17.14% vs. 10.67%, p 0.0256), anti-dsDNA $\geq 10$ (36.12% vs. 23.78%, $p<0.0001$), low C3 $<79$ (28.1% vs. 20.08%, 0.0001) and low C4.

## SAT0326 EFFICACY AND SAFETY OF AUTOLOGOUS PLATELET LYSATE EYE DROPS IN SJÖGREN'S SYNDROME: A NEW APPROACH

S. Parisi[1], V. Aragno[2], V. Testa[2], M. Scarati[1], M. Priora[1], F. Machetta[2], C.L. Peroni[1], S. D'Antico[3], E. Fusaro[1], R. Caporali[4], C. Montecucco[4]. *[1]Rheumatology Unit, Azienda Ospedaliero Universitaria Città della Salute e della Scienza; [2]Ophthalmology Clinic – Surgery Department, University of Turin; [3]Blood Bank, A.O.U. Città della Salute e della Scienza, Turin; [4]Rheumatology Unit, University and Irccs Foundation Policlinico S. Matteo, Pavia, Italy*

**Background:** Sjögren's Sydrome (SS) is a chronic multisystem autoimmune disease characterized by hypofunction of salivary and lacrimal glands. The result of the immune-mediate infiltration of the lacrimal gland is a severe dry eye disease. None of the commercially available artificial tear preparations and anti-inflammatory topical treatment has the properties of the human tears as Growth factors (GFs), that are necessary for maintenance of normal corneal epithelium. Platelet alfa granules are a major source of GFs and are rich in platelet derived growth factor (PDGF), which plays an important role in the maintenance of ocular surface and tear film stability (1).
**Objectives:** To determine the efficacy and safety of autologous platelet lysate (APL) eye drops in patients with primary SS dry eye, refractory to standard therapy, in comparison to patients treated with artificial tears. We focused on the effect of APL on cornea morphology with the in vivo confocal microscopy (IVCM).
**Methods:** We included patients with a diagnosis of SS according to the classification criteria of the American-European Consensus (2), a dry eye severity level $\geq 2$ (Dry Eye Severity Grading Scheme, Workshop 2007). Patients were assigned in two groups, according to the randomization criteria 1:1
– Group A used autologous platelet lysate (BiomedDevice) QID for 90 days.
– Group B used preservative-free artificial tears QID (Ialuronic Acid 0,2%) for 90 days.
Ophthalmological assessments included: ocular surface disease index (OSDI), Schirmer test, fluoresceine score and break up time (BUT). Both Group A and Group B underwent IVCM; corneal basal epithelium, sub basal nerves, Langherans cells, anterior stroma activated keratocytes were evaluated. The study was conducted in accordance with the Declaration of Helsinki (1964) and approved by our Ethics Committee.
**Results:** 43 patients (female:male =42:43) with mean age of 59,75 years (SD±13,10) affected by primary SS from 7,48 years (SD±5,56) were enrolled. The two groups (A=22 pts; B=21 pts) did not have significant differences at baseline in terms of disease (duration, autoantibodies) and treatment (steroids, DMARDs) characteristics. In group A, the mean of improvement of OSDI, fluorescein score and BUT values ($\Delta$38.82; $\Delta$1.0; $\Delta$1.5 respectively) were higher than group B ($\Delta$7.07; $\Delta$0.0; $\Delta$0.0 respectively) with statistical significance ($p<0.05$). The IVCM showed a significant increase in basal epithelium cells density, sub basal nerve plexus density and number and a decrease in Langerhans cells density ($p<0.05$) only in group A. No adverse events were observed in all patients treated.
**Conclusions:** APL has proved to be effective and safety in the treatment of SS dry eye and IVCM seems to be a useful tool to visualize cornea morphologic modifications. Further studies are required to evaluate the long-term effects and the timing of retreatment.

## SAT0327 B CELL-BOUND COMPLEMENT ACTIVATION PRODUCTS IN THE DIAGNOSIS AND MONITORING OF SYSTEMIC LUPUS ERYTHEMATOSUS

J. Beckmann[1], N. Bartholomä[2], N. Venhoff[2], P. Henneke[1], A. Janda[1], U. Salzer[2]. *[1]Centre for Paediatrics and Adolescent Medicine; [2]Rheumatology and Clinical Immunology, University Hospital of Freiburg, Freiburg, Germany*

**Background:** Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by diverse pathogenic autoantibodies and clinical phenotype. Laboratory monitoring of complement activation products (CAP; C3a, C5a, C3d, C4d) is commonly used in diagnosis and follow up. CAP bound to cellular surfaces (CB-CAP) analysed by flow cytometry offer a relatively novel approach to study complement turnover in SLE.
**Objectives:** We evaluated the significance and usability of cell bound CAP in monitoring complement turnover in a whole blood staining approach, comparing cell bound CAPs on different leucocyte subpopulations with conventional complement and disease activity parameters.
**Methods:** CAP bound to lymphocyte subpopulations were analysed by flow cytometry, compared to serological complement and other SLE activity parameters determined by nephelometry, rocket electrophoresis and ELISA.
**Results:** We have analysed CB-CAPs bound to lymphocytes in 50 adult patients with SLE. B-cells and CD4+ T-cells of SLE patients showed significantly

higher levels of cell-surface-bound C4d compared to controls. C4d bound to B-lymphocytes was inversely correlated with serum levels of C4 (r = -0.309, p=0.013) and C3 (r= - 0.356, p=0.004) reflecting complement decay. In addition, B-cell C4d showed a significant positive correlation with anti-dsDNA antibody levels (r =0.574, p<0.001) and plasma C3d (r =0.319, p=0.009) thereby corresponding to disease activity. CB-CAPs were stable over 24 hours after blood drawing thus offering more flexibility in sample handling than conventional complement turnover assays.
**Conclusions:** Our data show that CB-CAP measurement correlates with established disease activity markers, and given its easier handling, is of possible utility in routine diagnostic and monitoring of patients with SLE. A multicentre study for evaluation of this method in a cohort of paediatric patients is planned.
**Disclosure of Interest:** None declared

### SAT0328 BIG-FIVE PERSONALITY IN SJOGREN SYNDROME – ASSOCIATION WITH ESSPRI

V. Milic[1], M. Grujic[2], J. Marinkovic-Eric[3], J. Barisic[4], D. Duisin[4], N. Damjanov[1]. *[1]Institute of Rheumatology, School of Medicine, University of Belgrade; [2]Institute of Rheumatology; [3]Institute of social medicine, School of Medicine, University of Belgrade; [4]Institute of psychopatology, Clinical Centre, Belgrade, Serbia*

**Background:** The severity of symptoms of dryness, pain and fatigue may be determined by psychological features patients with Sjogren's syndrome (SS). The Big-Five framework is a widely examined model which represent personality at the broadest level of abstraction. The NEO Personality Inventory-Revisited (NEO-PI-R) is frequently used questionnaire to assess the Big-Five domains: Neuroticism (*N*), Extraversion (*E*), Openness to Experience (*O*), Agreeablenes (*A*) and Conscientiousness (*C*).
**Objectives:** To Big-Five analyse of personality of SS patients and association with the severity of dryness, pain and fatigue measured by ESSPRI (EULAR SS Patient Reported Index).
**Methods:** One hundred and five patients with confirmed SS by AECG criteria (mean age 51,34 years, mean disease duration 5,98 years) and fifty-four healthy controls (mean age 51,35 years) participated in study. All participants were females and provided written informed consent. The diseasy activity was measured by ESSDAI (EULAR SS disease activity index) and ESSPRI. All participants filled out the sociodemographic questionnaire (age, educational level, work and marital status, residence, social support and comorbidity). The Big-Five personality traits were measured using NEO-P-R. The 240 items are answered on a 5-point Likert scale ranging from strongly disagree to strongly agree. The analysis was performed using the SPSS program (version 16.0). Data were examined by independent *t*-test, Chi-square test and Mann-Whitney test. The association of the Big Five personality traits with the ESSPRI was examined using linear regression analyses. A p-value $<0.05$ was considered significant.
**Results:** Statistical significant differences between two groups were observed in educational level (p=0.001), work status (p=0.001), residence (p=0.001) and social support (p=0.05), but they did not different in age, marital status and comorbidity (p>0.05). In SS patients, the median of ESSDAI was 6 (range 4–11), the median ESSPRI was 5.33 (range 3.66–6.66). Compared to healthy controls, SS patients showed significatly higher scores in *N* (94.76 vs. 84.63, p=0.006) and lower *E* (94.79 vs.104.20, p=0.002) and *O* (101.86 vs. 111.17, p=0.05) domens. Scores *A* and *C* were similare in groups (120.48 vs 121.04 and 122.97 vs. 125.02, p>0.05). Futher, *E* and *O* domens were significantly associated with ESSPRI (p=0.008, p=0.000), while *N* was borderline (p=0.056). After adjustment for confounding variables, only *E* domen remained significantly associated with ESSPRI (p=0.01). The analyse showed that *E* domen was negatively associated with age (B= -0.341, p=0.013), unmarital status (B= -4.317, p=0.013) and positive associated with social support (B=7.952, p=0.013).
**Conclusions:** Patients with SS had a higher levels of Neuroticism and lower levels of Extraversion and Opennes to experiences compared to healthy persons. In SS patients, Extraversion and Openness were associated with severity of symptoms of dryness, pain and fatigue. The social support is significantly associated with higher level Extraversion, in contrast to older and single individuals.

### SAT0329 LUPUS NEPHRITIS IS ASSOCIATED WITH MORE CORTICOSTEROID-ASSOCIATED ORGAN DAMAGE BUT LESS CORTICOSTEROID NON-ASSOCIATED ORGAN DAMAGE

Y.B. Joo[1], S. Won[2], H.H. Kwon[1], C.-B. Choi[1], S.-C. Bae[1]. *[1]Hanyang University Hospital for Rheumatic Diseases; [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul, Korea, Republic Of*

**Background:** Lupus nephritis (LN), one of the most serious manifestations of systemic lupus erythematosus (SLE), has been suggested to be a predictor of organ damage accrual. Also, LN is considered a strong determinant for survival. Since patients with LN are more exposed to immunosuppressive agents, such as cyclophosphamide and high-dose corticosteroid, and also have high inflammatory burdens, they might be more vulnerable to organ damage than patients without LN. Thus, proper adjustment for these potentially confounding variables needs to be performed to determine the precise effect of LN on organ damage. Also, it is important to identify the types of organ damage that are associated with LN. However, these aspects have not been previously investigated.
**Objectives:** We investigated the impact of LN on organ damage accrual and mortality after adjusting for potential confounders. In particular, we identified the types of organ damage that are more or less associated with LN.
**Methods:** Patients with SLE were propectively enrolled and followed from 198 to 2012 in the Hanyang BAE Lupus cohort. LN was defined as the disorder with the persistent proteinuria greater than 0.5 grams per day Organ damage was assessed using SLICC/ACR Damage Index (SDI). Damage presumed to be corticosteroid associated (cataract, avascular necrosis, diabetes and osteoporosis items) and non-associated (5 pulmonary, 5 gastrointestinal, erosive arthritis, 3 skin, premature gonadal failure and malignancy items) selected from 41 items were compared. Association of LN with organ damage was analyzed using multivariable logistic regression analysis, adjusting for potential confounders. Age- and sex adjusted standardized mortality ratio (SMR) was evaluated in patients with or without LN.
**Results:** Among the 1,112 SLE patients, 515 (46.3%) had LN. Patients with LN showed higher percentage of male (p=0.003), were younger at diagnosis (p<0.001), had longer disease duration (p<0.001), higher adjusted mean SLE Disease Activity Index (AMS) score (p<0.001), lower percentage of prescribed anti-malarial agents (p<0.001), and higher percentage of corticosteroids (p<0.001) and immunosuppressant use.
After mean follow-up of 7.6 years, patients with LN had higher percentage of overall organ damage than patients without LN (51.5% vs 35.7%, p<0.001) with OR of 1.40, after adjusting for age at diagnosis, gender, disease duration, anti-malarial agents, corticosteroids and immunosuppressant. However, LN was not associated with non-renal organ damage (p=0.883). In subgroup analysis, the odds of corticosteroid-associated damage was higher in patients with LN (2.06, 95% CI 1.43–2.96), but whereas odds of non-associated damage was lower in patients with LN (0.50, 95% CI 0.35–0.75), compared not having LN.
Age- and sex adjusted SMR of patients with LN was 5.17 (95% CI 3.49–7.38) and 2.32 (95% CI 1.47–3.48) in patients without LN.
**Conclusions:** LN was associated with more overall organ damage but not more non-renal organ damage. Patients with LN had more corticosteroid-associated damage, but less corticosteroid non-associated damage compared with patients without LN. Additionally, the SMR of patients with LN was significantly higher than the SMR of patients without LN

## Vasculitis

### SAT0330 EFFECTIVE AND RAPID TREATMENT OF FLARES IN PATIENTS WITH BEHÇET'S DISEASE BY THE SINGLE CHAIN ANTI-TNF ANTIBODY DLX105

T. Xenitidis[1], C. Berger[2], T. Jung[2], J. Henes[1], I. Koetter[3]. *[1]Dept. Internal Medicine II, University Hospital, Tuebingen, Germany; [2]Delenex Therapeutics AG, Zurich, Switzerland; [3]Internal Medicine 4, Asklepios Clinic Altona, Hamburg, Germany*

**Background:** Behçet's Disease is a rare, chronic variable vessel vasculitis presenting with oral and genital aphthous lesions, a variety of skin symptoms, arthritis and depending on its severity with uveitis, CNS and GI symptoms. Most often used drugs are colchicine, corticosteroids, azathioprine and cyclosporine. TNF inhibitors are used off-label (only in Japan approved) in particular for patients with uveitis to prevent blindness. Usually given TNF inhibitors are infliximab and adalimumab. These monoclonal antibodies are large molecules and as such they do not penetrate well into tissues following systemic administration.
We explored the clinical effect of a single chain anti-TNF antibody fragment (DLX105) consisting of 246 amino acids (molecular weight: 26 kDa) for flaring mucocutaneous Behçet's Disease.
**Objectives:** The primary objective of this study was the describe the pharmacokinetics of DLX105 after a single fixed dose in patients with Behçet's Disease. The exploratory objective was to explore the preliminary efficacy of a single fixed dose of DLX105 on mucocutaneous lesions in patients with Behçet's Disease.
**Methods:** A total of 6 patients with flaring Behçet's Disease received a single dose of 10 mg/kg i.v. DLX105. The main inclusion criteria were: males and females aged 18 to 65, with flaring Behçet's Disease defined by the criteria of the "International Study Group for Behçet's Disease (ISBD)" with at least two oral ulcerations for at least 3 days prior to enrollment. Patients were allowed to be on colchicine or low dose corticosteroids (≤7,5 mg/d). After a dosing visit (Day1) all patients attended two follow-up visits (Day 5 and 8) and an end-of-study-visit (Day 15).
**Results:** Each patient had oral lesions at baseline (mean 3.7 ulcers, SD 2) which rapidly and almost completely disappeared within one week (mean 1 ulcer, SD 1.3) and stayed improved even after 2 weeks (mean 1.5 ulcers, SD 1). Genital lesions in one patient also resolved. Two patients with erythema nodosum showed a prompt and complete disappearance of skin nodules after one week of treatment. The number of papulo-pustular skin lesions in 5 patients also rapidly declined (mean 14.3 at baseline, after one week 7.2). Arthralgia present in 3

patients resolved within one week of treatment. The ISBD questionnaire score (range 0–12) dropped from 4.3 to 3.3 within one week and to 3.0 within two weeks indicating a sustained response. There were no SAEs and adverse events were mild and disappeared within 2 weeks.
**Conclusions:** These data suggest that DLX105 has a rapid and strong onset of action likely due to its unique property to penetrate effectively into inflamed tissues. The duration of the response is far longer than its serum pharmacokinetics with a half-life of roughly one day suggested. Thus, DLX105 is a strong development candidate to treat flaring mucocutaneous Behçet's Disease.

## SAT0331 ITNFα AGENTS IN REFRACTORY NON-INFECTIOUS AORTITIS: STUDY ON 19 PATIENTS

C. Fernández-Díaz[1], J. Loricera[1], R. Blanco[1], J.L. Hernández[1], S. Castañeda[2], A. Humbría[2], S. Melchor[3], P. Collado[4], J. Calvo-Catalá[5], E. Rubio[6], J. Rosas[7], R. Ariza[8], Í. Rúa-Figueroa[9], E. Peiró[1], V. Calvo-Río[1], C. González-Vela[1], M.Á. González-Gay[1]. *[1]Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander; [2]Rheumatology, Hospital Universitario la Princesa; [3]Rheumatology, Hospital Universitario 12 de Octubre; [4]Rheumatology, Hospital Universitario Severo Ochoa, Madrid; [5]Rheumatology, Hospital General Universitario de Valencia, Valencia; [6]Rheumatology, Hospital Universitario Virgen del Rocío, Sevilla; [7]Rheumatology, Hospital Marina Baixa, Villajoyosa; [8]Rheumatology, Hospital Universitario Virgen Macarena, Sevilla; [9]Rheumatology, Hospital Doctor Negrín, Las Palmas de Gran Canaria, Spain*

**Background:** Non-infectious aortitis is often refractory to standard immunosuppressive therapy. In these cases, the use of inhibitors of TNF-α (iTNF-α) had been reported.
**Objectives:** Our aim was to assess the efficacy of iTNF-α in a series of patients with refractory non-infectious aortitis.
**Methods:** Retrospective multicenter study of patients diagnosed with aortitis refractory to traditional immunosuppressive agents and who received iTNFα. The diagnosis of aortitis was based on imaging techniques (MRI-angiography, computed tomography, PET scan, ultrasonography and/or arteriography).
**Results:** We studied 19 patients (15 women/4 men) with a mean age of 42±13 years. The iTNFα used were: infliximab (IFX) (n=14), adalimumab (ADA) (n=3) and etanercept (ETN) (n=2). The underlying conditions were: Takayasu arteritis (TA) (n=11), giant cell arteritis (GCA) (n=2), relapsing polychondritis (RP) (n=1), ulcerative colitis (n=1), Crohn's disease (n=1), Behçet's disease (n=1), sarcoidosis (n=1) and psoriatic arthritis (n=1). Seventeen patients were previously treated with traditional immunosuppressive agents [methotrexate (MTX) (n=15), azathioprine (AZA) (n=7), cyclophosphamide (CPM) (n=5), mycophenolate mofetil (MM) (n=3), chlorambucil (n=1), cyclosporine A (n=1), tacrolimus (n=1)]. Two patients needed a switching between biologic agents (a female with TA who switched from IFX to ETN; and a male with psoriatic arthritis who switched from ETN to ADA; in both cases switching was due to inefficacy of the first biologic drug). After a median follow-up of 16 [12–36] months, most patients experienced clinical improvement, showing a reduction of erythrocyte sedimentation rate from 37.5 [30–56] mm/1st hour at baseline, to 20.5 [10–24] mm/1st hour at the last visit. Besides, C-reactive protein decreased from 1.5 [0.1- 2.6] mg/dL to 0.3 [0.1–0.8] mg/dL. After 3 months of treatment, 55% of patients had experienced clinical improvement ($p<0.01$); and at 12 months, clinical improvement was attained by 94% of the patients ($p<0.01$). A corticosteroid sparing effect was also achieved (from 25.7±22.0 mg/day of prednisone at iTNFα onset, to 6.6±5.4 mg/day at the last visit). Improvement on imaging techniques was also observed in 10 out of 13 patients (77%) who underwent a follow-up imaging procedure. Three patients had to discontinue the iTNFα agent (IFX in the 3 cases) due to inefficacy (n=1), recurrent pneumonia (n=1) and severe infusional reaction (n=1).

**TABLE**

| | At onset | At 3 months | At 6 months | At 12 months |
|---|---|---|---|---|
| CRP, median [IQR] | 1.5 [0.1-2.6] (15) | 0.1 [0.1-0.5] (12)* | 0.3 [0.1-0.9] (12)* | 0.2 [0.1-0.6] (11)* |
| ESR, median [IQR] | 37.5 [30-56] (14) | 17.5 [9-25] (14)* | 16 [9-20] (13)* | 16 [11-18] (13)* |
| Prednisone dose, median [IQR] | 20 [5-50] (17) | 12.5 [5-20] (15)* | 10 [5-10] (16)* | 7.5 [5-10] (16)* |

In brackets, the number of patients with available data.
*p≤0.05
"p" refers to the percentage of improvement at 3, 6 and 12 months compared to baseline

**Conclusions:** iTNFα therapy appears effective and relatively safe in patients with non-infectious aortitis refractory to traditional immunosuppressive drugs.

## SAT0332 TAKAYASU ARTERITIS (TA): THE PATHOLOGICAL CHANGES IN THE CORONARY ARTERIES

O. Zimba. *the Department of Internal Medicine, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine*

**Background:** There is controversy surrounding the prevalence of abnormalities of the coronary arteries (CA) in TA. A Japanese institute (1) reported 38.3% of CA involvement in TA. Sun T. et al. (2) estimated the prevalence of CA lesions at 7, 7% in 587 patients hospitalized with TA.
**Objectives:** To investigate the variants of pathological findings in the coronary arteries in autopsy cases of TA.
**Methods:** Microscopic examinations of the coronary arteries were performed in sixty fatal cases (52 men and 8 women aged 18 to 45 years) of TA over period of 11 years. The median age at disease onset was 25, 7 years.
**Results:** The second-leading cause of death from TA was acute heart failure due to myocardial infarction (25%). Pathological changes in the coronary arteries have been found in 46 cases (76, 7%) of TA. The predominant lesions were on the coronary orifices, or more rarely, in the proximal parts of CA. The most remarkable finding was intimal hyperplasia consists of areas of musculo-fibrous proliferation or multi-layer scleral hyaline plaques. This pillow-like thickening of the intima around of the coronary orifices leads to their luminal narrowing. No morphological abnormalities were observed in the distal parts of CA. In the studied material we found the features of granulomatous arteritis with diffuse or focal infiltration of lymphocytes, plasma cells, histiocytes. Infiltrate being preferentially located in the medio-adventitial junction and also around the vasa vasorum of the adventitia. Contrary to other studies giant cell granulomatous reaction has not been detected in any specimen. Complete obliteration of the arterial lumen with recanalization of organized thrombi has been presented in 13 cases of TA complicated by fatal acute myocardial infarction. Coronary atherosclerosis of varying severity was observed in 35 cases (58, 3%). The most common location of atherosclerotic deposits was regions of the pillow-like thickening of the intima around of the coronary orifices. In two patients, a 30-year-old man and a 35-year-old man, typical for TA changes accompanied by severe atherosclerotic narrowing of the coronary arteries resulted in a fatal myocardial infarction.
**Conclusions:** Our date show high frequency (76, 7%) of pathological changes of CA in TA. It can be assumed that intimal hyperplasia, granulomatous arteritis, and coronary atherosclerosis are typical lesions of CA in TA. The coronary orifices are the site most commonly affected by TA. Luminal narrowing of CA with coronary flow reduction led to subsequent fatal myocardial infarction in 15 cases (25%). High prevalence of coronary atherosclerosis in TA (58, 3%) may be regarded as accelerating the atherosclerotic process due to chronic autoimmune inflammation in CA. In addition, it should be noted that in our series of autopsy cases of TA, males (86, 7%) were most frequently affected compared with results other investigations.

## SAT0333 HEMOSTATIC MECHANISMS MAY PLAY A ROLE IN THE DEVELOPMENT OF THROMBOSIS IN MALE PATIENTS WITH BEHCET'S DISEASE: A THROMBOELASTOGRAPHIC ANALYSIS

B. Kara Kivanc[1], E. Gonullu[2], C. Bal[3], M.O. Akay[4], A. Erturk[5], D. Uskudar Cansu[5], T. Kasifoglu[5], C. Korkmaz[5]. *[1]Internal Medicine; [2]Rheumatology Division, Eskisehir State Hospital; [3]Biostatistic; [4]Hematology Division; [5]Rheumatology Division, Osmangazi University, Eskisehir, Turkey*

**Background:** In Behcet's disease (BD), vascular involvement is seen frequently in young male BD patients. However, its reason is not well known.
**Objectives:** Our aim was to compare thrombotic tendency according to gender by using the modified Rotational Thromboelastography parameters and platelet-leucocyte complex levels.
**Methods:** 126 BD patients (71 male, 55 female; mean age:41±9 yrs) who met ISSG criteria for Behcet's disease were included into study. This group was divided into 3 subgroups as non-thrombotic (n=73), acute thrombotic (n=25) and chronic thrombotic group (n=28). As disease control and healthy control group, 23 patients with vasculitis (16 female, 7 male; mean age 49±16 yrs), 8 patients with thrombosis (3 female, 5 male; mean age:55±11 yrs) and 25 healthy individuals (11 female, 14 male; mean age:37±10 yrs) were included to study.

By using the modified rotation thromboelastogram, clotting time (CT), clot formation time (CFT) and maximum clot formation (MCF) were determined by INTEM and EXTEM analysis. Thrombocyte-leucocyte complexes and thrombocyte activation marker (p62) were investigated by flow-cytometric method.
**Results:** In terms of thrombocyte-leucocyte complexes and P62 levels, no significant difference was found in female BD patients vs male BD pts, active BD pts vs inactive BD pts and thrombotic BD pts vs non-thrombotic BD pts. Thrombocyte-leucocyte complexes levels were higher in vasculitis group than BD group ($p<0.01$) and HC group ($p<0.04$). I-MCF was significantly prolonged in male BD patients than female BD patients. E-CFT was found to be shorter in male BD patients compared to female BD patients. E-MCF was statistically prolonged in male BD patients. In inactive male BD patients, while I-CFT was shorter than HC individuals, I-MCF and E-MCF were statistically prolonged than HC ($p<0.02$, $p<0.03$), respectively. However, No significant differences were found between inactive female BD patients and HC in terms of all ROTEM parameters. In active BD patients, E-CFT was shorter ($p<0.02$) and E-MCF was significantly prolonged than those of inactive BD patients ($p<0.005$).
**Conclusions:** These results support that male BD patients have a hypercoagulable state compared to female BD patients which may be an explanation why male patients are prone to thrombotic complications.

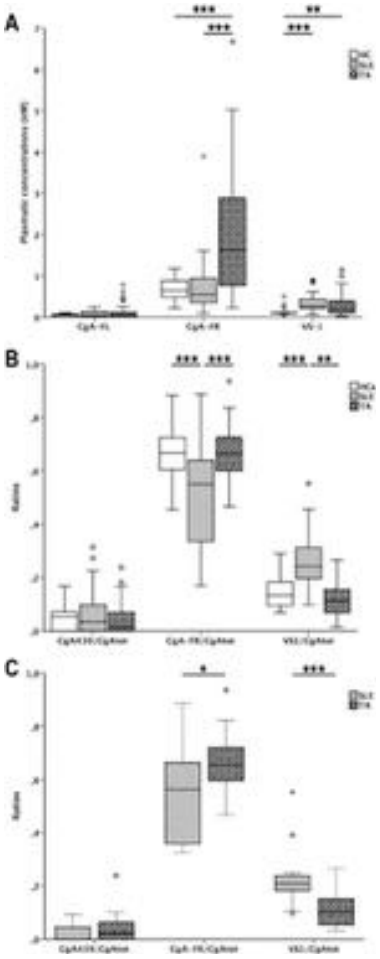
## SAT0334 NATIONWIDE TRENDS IN HOSPITALIZATION AND IN-HOSPITAL MORTALITY ASSOCIATED WITH ANCA-ASSOCIATED VASCULITIS (AAV)



Z. Wallace[1], L. Lu[1], E. Miloslavsky[1], S. Unizony[1], J. Stone[2], H. Choi[2].
*[1]Rheumatology Unit; [2]Rheumatology, Massachusetts General Hospital, Boston, United States*

**Background:** ANCA-associated vasculitis (AAV) is associated with severe end-organ damage (e.g., renal failure) and treatment-related complications (e.g., severe infection) which often lead to hospitalization. However, no data on recent hospitalization trends and associated mortality are available[1].
**Objectives:** We evaluated recent trends in nationwide hospitalization, cost, and in-hospital mortality among patients with AAV.
**Methods:** We used the National Inpatient Survey (NIS) which is the largest all-payer inpatient database in the US. We studied all hospitalizations with a discharge diagnosis of AAV (ICD 9: 446.4) between 1993 and 2011. We investigated trends in hospitalization, cost, and mortality by comparing AAV to overall inpatient hospitalization trends. Analyses were performed using hospital-level sampling weights provided by the NIS to obtain US national estimates.
**Results:** From 1993 to 2011, the rate of hospitalization for AAV increased from 1.9/100,000 persons to 4.5/100,000 persons (P-for-trend $<0.0001$). This was primarily driven by a rapid increase in the hospitalization rate among those with a secondary discharge diagnosis of AAV (1.4/100,000 persons to 3.9/100,000 persons, $P<0.0001$). Over the study period, there was a significant decline in in-hospital death from 9.9% (±1.2%) in 1993 to 3.5% (±0.4%) in 2011 (P-for-trend $<0.0001$). Overall, the annual relative change in AAV mortality was - 4.8% (95% CI: -5.6 to -4.0%). This was a significantly greater decline than overall US inpatient hospitalization mortality (-2.18%, 95% CI -2.19% to -2.17%). Infection was the most common principal diagnosis when AAV was a secondary diagnosis.
**Conclusions:** Between 1993 and 2011, there was a significant decline in in-hospital mortality among those admitted with a diagnosis of AAV. This decline was significantly greater than that of the overall US in-hospital mortality rate. The declining in-hospital mortality rate may be due to earlier recognition of GPA, shifts in treatment that emphasize less cyclophosphamide use and more tempered use of glucocorticoids, and secular trends in the management of infections and end-organ complications[2].

## SAT0335 DIFFERENTIAL MODULATION OF THE CHROMOGRANIN-A SYSTEM IN TAKAYASU ARTERITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS

E. Tombetti[1,2], B. Colombo[1], M.C. Di Chio[2], S. Sartorelli[1], E. Tombolini[1], G. Ramirez[2], M. Papa[1], E. Baldissera[1], M.G. Sabbadini[1,2], F. De Cobelli[1,2], A. Corti[1], A.A. Manfredi[1,2]. *[1]San Raffaele Scientific Institute; [2]Vita-Salute San Raffaele University, Milan, Italy*

**Background:** Chromogranin-A (CgA) is a multi-source protein proteolitically processed into a family of peptides with various paracrine and endocrine functions. CgA-derived peptides influence vascular biology and neoangiogenesis: CgA1–439 (CgA439) and vasostatin-1 (VS1, CgA1–76) have anti-angiogenic properties, while fragments lacking the C-terminal domain (CgA-FRs) are pro-angiogenic. The mechanisms regulating vascular events and systemic inflammation in Takayasu Arteritis (TA) and Systemic Lupus Erythematosus (SLE) are poorly characterized.
**Objectives:** To evaluate how the CgA system is modulated in TA and SLE
**Methods:** 42 consecutive patients (pts) with TA were enrolled and matched with 20 age- and sex- matched SLE pts and 20 healthy subjects (HCs). Exclusion criteria were moderate/severe heart failure or contraindication to MR angiography (MRA). TA pts were longitudinally studied with 2 MRAs (12 months apart). Disease activity was assessed with NIH criteria and SLEDAI in the TA and SLE group, respectively. Arterial progression was defined as the appearance of new lesions or worsening of pre-existing lesions at MRA. CgA peptides and total CgA (CgAtot) were quantified with validated ELISAs. CgA processing was studied by ratios of CgA peptides to CgAtot. The antiangiogenic CgA potential was quantified in TA by summing the ranks of CgA439 and VS1.
**Results:** Median age of TA patients (39W, 3M) was 46 (IQR 34–54) years. Median disease duration was 10 (IQR 7–14) years for TA, and 13 (7–21) years for SLE. Twelve TA and 8 SLE pts had active disease. Thirty TA and 10 SLE pts received proton pump inhibitors (PPI), which are known to increase CgA levels. Nine TA pts (8 treated with PPIs) underwent arterial progression. Serum CgA-FR were significantly higher in TA pts than in SLE pts ($p<0.001$) and HCs ($p<0.001$); VS1 was higher in SLE and TA than HCs ($p<0.001$ and $p=0.020$, Fig 1A). CgA processing was similar in TA and HCs; a distinctive processing was evident in SLE, with higher VS1/CgAtot ($p<0.001$ Vs Ta and HCs) and lower CgA-FR/CgAtot ($p=0.001$ Vs TA and 0.009 Vs HCs, Fig 1B). PPI increased serum CgA-FR, with a greater effect in TA, and quenched of the distinctive SLE-associated processing (Fig 1C). CgA peptides did not correlate with disease activity in TA nor in SLE. However, in the homogeneous group of TA pts on PPI, arterial progression was associated with reduced a reduced antiangiogenic CgA potential ($p=0.010$).

**Conclusions:** A selective processing of CgA is evident in SLE, whose molecular bases are unknown. TA associates with a greater increase in CgA-FR levels than SLE during PPI therapy. CgA peptides do not correlate with disease activity. Antiangiogenic CgA potential is reduced in TA pts on PPI undergoing progression, underlining the importance of angiogenesis in arterial remodelling and suggesting an involvement of CgA peptides in TA pathogenesis.

## SAT0336 DAMAGE-ASSOCIATED MOLECULAR PATTERNS IL-33 AND HIGH-MOBILITY GROUP BOX 1 AMPLIFY INFLAMMATORY PROCESSES IN GRANULOMATOSIS WITH POLYANGIITIS

A. Kerstein[1], A. Erschig[1], K. Holl-Ulrich[2], G. Marschner[1], S. Pitann[1], A. Mueller[1], G. Riemekasten[1], P. Lamprecht[1]. *[1]Department of Rheumatology; [2]Institute of Pathology, Universität zu Lübeck, Lübeck, Germany*

**Background:** Granulomatosis with polyangiitis (GPA) is characterized by extravascular necrotizing granulomatous inflammation and systemic anti-neutrophil cytoplasmic autoantibody (ANCA) – associated vasculitis. The pathogenic mechanisms, especially of the granulomatous inflammation, are still not fully understood. Cell death and tissue damage could be a driving force for chronic inflammation in GPA.
**Objectives:** To investigate the role of the damage-associated molecular patterns (DAMPs) IL-33 and high-mobility group box 1 (HMGB1) in the granulomatous inflammation of GPA.
**Methods:** Tissue expression of HMGB1, IL-33 and their corresponding DAMP receptors "receptor for advanced glycation end products" (RAGE) and "suppression of tumorigenicity 2" (ST2), respectively, were analyzed in nasal GPA biopsies compared to chronic rhinosinusitis (CRS) by immunostaining. Circulating soluble RAGE (sRAGE) and soluble ST2 (sST2) were measured in GPA sera compared to CRS or healthy controls (HC) using ELISA. Expression of HMGB1 and the autoantigen proteinase 3 (PR3) in nasal GPA tissues and on isolated neutrophils was determined by immunofluorescence staining. Full-length IL-33 was cleaved *in vitro* by either activated, necrotic or NETotic neutrophils. The biological activity of these IL-33-cleavage fragments was tested by subsequent stimulation of human mast cells (HMC-1). The resulting activation of mitogen-activated protein kinases (MAPK) was determined by western blot.
**Results:** Increased tissue expression of extranuclear HMGB1 ($p<0.01$) and strong upregulation of RAGE was observed in the necrotizing granulomatous inflammation compared to CRS. In addition, substantial numbers of IL-33 and ST2 expressing cells were found in close proximity to necrotic areas and lymphoid structures in the granulomatous inflammation compared to CRS. However, neither sRAGE nor sST2 were elevated in GPA sera compared to controls. In GPA tissue co-localization of HMGB1 and PR3 was detected on neutrophils. This co-localization could be induced on isolated neutrophils by apoptosis *in vitro*. Full-length IL-33 was processed by activated, necrotic or NETotic neutrophils into different cleavage products. IL-33 fragments produced by necrotic GPA neutrophils induced a significantly stronger MAPK activity in HMC-1 compared to those from HC.
**Conclusions:** In this study, we demonstrate a direct link between dying neutrophils and necrosis-derived DAMPs HMGB1 and IL-33 in the granulomatous inflammation of GPA. Differential cleavage of IL-33 by dying neutrophils, IL-33-dependent MAPK activation and high tissue expression of RAGE and ST2 suggest a considerable role of these DAMPs in sustaining chronic inflammation in GPA. Moreover, HMGB1/PR3 co-localization on apoptotic neutrophils reveals a possible adjuvant function of HMGB1 for the autoimmune response against PR3.

## SAT0337 HYPERTROPHIC PACHYMENINGITIS ASSOCIATED WITH ANCA VASCULITIS; A CASE SERIES OF 16 PATIENTS

T. Sakairi, K. Hiromura, N. Sakurai, H. Hamatani, H. Ikeuchi, Y. Kaneko, A. Maeshima, Y. Nojima. *Department of Medicine and Clinical Science, Gunma University Graduate School of Medicine, Maebashi, Gunma, Japan*

**Background:** Recent reports indicate that hypertrophic pachymeningitis (HPM) develops in association with myeloperoxidase (MPO) anti-neutrophil cytoplasmic antibody (ANCA)-positive vasculitis[1,2]. However, little is known about clinical features and outcomes of the disease.
**Objectives:** We aimed to describe clinical, laboratory and radiological features and treatment course of HPM occurred in patients with ANCA-associated vasculitis (AAV).
**Methods:** We retrospectively analyzed 16 Japanese adult patients (11 males and 5 females), who had been treated at our hospital in a study period from January 2006 through December 2015. Diagnosis of HPM was made with MRI T1 sequence with gadolinium by detecting thickening and enhancing of brain and/or spinal dura mater in patients manifesting neurological symptoms. Diagnosis and classification of AAV was performed according to a report by Watts, et.al.[3].
**Results:** The mean age at HPM onset was 60.1 years (range, 35–78 years). Out of 16 patients, HPM was detected at the onset of AAV in 9 (56.3%), at the relapsing AAV under treatment in 6 (37.5%), and before the diagnosis of AAV as idiopathic HPM in 1 (6.3%). Headache and cranial nerve palsy due to HPM were observed in 13 (81.3%) and 11 (68.8%) patients, respectively. Otitis media and sinusitis were found as complications of AAV in 7 (43.8%) and 6 (37.5%) patients. Twelve patients (75%) were classified as granulomatosis with polyangiitis (GPA). Microscopic polyangiitis, eosinophilic granulomatosis with polyangiitis and unclassifiable vasculitis were applied to 2 (12.5%), 1 (6.3%) and 1 (6.3%) patients, respectively. Serum myeloperoxidase (MPO)-ANCA and proteinase 3 (PR3)-ANCA were positive in 9 (56.3%) and 5 (31.3%), respectively, and 2 (12.5%) patients had neither of them. The mean serum C-reactive protein levels were 4.87 mg/dL (range, 0.26–17.11 mg/dL). Spinal fluids were analyzed in 6 patients, and a mild increase in spinal cell counts and protein levels were identified in 3 patients each. With MRI, thickening of dura mater in cranial fossa and tentorium cerebelli were found in 11 (68.8%) and 9 (56.3%) patients, respectively. All patients were treated with corticosteroids and 10 (62.5%) patients were concomitantly administered with other agents including cyclophosphamide, methotrexate, azathioprine and mizoribine for remission induction. All patients achieved remission of the neurological symptoms and improvement of dura mater thickening. In a mean follow-up period of 41.8 months (range, 5–89 months) after diagnosis, 4 (25%) patients experienced a relapse of HPM and received re-induction therapy.
**Conclusions:** Our results indicate that occurrence of HPM is mostly associated with GPA having either type of ANCA serology. Dura mater in cranial fossa and tentorium cerebelli was commonly involved, which could lead to cranial nerve impairment. Immunosuppressive therapy is effective, but a relapse of HPM occasionally occurs.

## SAT0338 CLINICAL CHARACTERISTICS AND TREATMENT OUTCOMES OF PATIENTS WITH CHRONIC PERIAORTITIS

H. Jeong[1], I.Y. Kim[1], J.-M. Oh[2], H. Kim[1], J. Lee[1], J.-S. Kim[3], E.-M. Koh[1], D.-K. Kim[1], H.-S. Cha[1]. *[1]Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul; [2]Medicine, Anyang SAM Hospital, Anyang; [3]Medicine, eju University School of Medicine, Jeju, Korea, Republic Of*

**Background:** Chronic periaortitis (CP) is rare disease that involves the aorta which is characterized by a fibro-inflammatory periaortic cuff in imaging studies and adventitia-predominant inflammation and fibrosis in histopathology. Associations between aortitis and idiopathic retroperitoneal fibrosis, inflammatory abdominal aortic aneurysm had been reported, and this spectrum of disorders is now categorized as CP. CP has aroused controversy on the question of incorporating it into the spectrum of primary large vessel vasculitis. Recent investigations have documented significant overlap between CP and the newly recognized systemic inflammatory disorder known as IgG4-related disease (IgG4-RD), suggesting that at least a fraction of cases of CP might be IgG4-RD.
**Objectives:** The aim of this study is to investigate clinical characteristics and treatment outcomes of patients with CP.
**Methods:** A retrospective review was performed on 2,496 patients who visited Samsung Medical Center between January 2004 and December 2014. Patients compatible with CP based on characteristic imaging findings of fibrosclerosing encasing lesions around the aorta were enrolled. The clinical, radiological, histopathological features, treatments and outcomes of patients were analyzed. Additionally, patients were further classified into two subgroups: IgG4-related and non IgG4-related CP according to the comprehensive diagnostic criteria for IgG4-RD proposed by a Japanese study, and comparison of the subgroups was performed. Patients without an initial serum IgG4 level or with a history of prior treatment were excluded from this analysis.
**Results:** A total of 61 patients with CP were identified. Patients showed a male predominance with the median age of 61 at diagnosis. The abdominal aorta was the most commonly involved site (84%), and half of the patients had aortic lesion confined to the abdominal aorta without involvement of the thoracic aorta. The thoracic aorta was involved in 46% of patients. Only 2 (3%) patients had stenotic lesions of the aorta, while 19 (31%) patients had aneurysmal changes of the aorta. Ureteral obstruction was found in 30% of patients. 49 (80%) patients received glucocorticoids with a median initial dose of 50 mg per day as prednisolone. 19 (31%) patients received additional immunosuppressant including azathioprine, methotrexate and mycophenolate. Nine patients underwent vascular surgery including seven cases of surgical abdominal aorta aneurysm repair, two cases of aortic valve replacements and four patients underwent endovascular abdominal aneurysm repair during their disease course. Overall 60% of patients achieved remission without relapse during the course. When the Japanese criteria for IgG4-RD were applied to patients, ten were classified as IgG4-related and twenty-five as non IgG4-related. The overall male predominance did not differ and there were no significant differences in clinical features, treatments and outcomes between two groups, with the exception of older age (median 69 vs. 59 years, $p=0.021$), higher serum globulin, IgG and IgG4 levels and greater pancreas involvement in IgG4-related patients (30% vs. 0%, $p=0.018$).
**Conclusions:** We identified 61 patients with CP. Further integrated investigations into pathogenesis, practical diagnostic criteria and markers for disease activity and prognosis are warranted.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2420

## SAT0339 THE EFFICACY OF THE 2015 EULAR/ACR RECOMMENDATIONS FOR THE MANAGEMENT OF POLYMYALGIA RHEUMATICA IN JAPANESE PATIENTS

A. Ueno[1], Y. Yamamura[2], K. Fujita[1], N. Shibutou[1], M. Yamamura[1]. *[1]Center for Rheumatology, Okayama Saiseikai General Hospital; [2]Center for Rheumatology, Okayama Saiseikai General Hospital, Okayama, Japan, Okayama, Japan*

**Background:** Glucocorticoids (GCs) are effective for polymyalgia rheumatica (PMR); however, some patients show inadequate responses to initial GC doses or relapses during GC tapering and develop side effects of GCs. The 2015 EULAR/ACR recommendations for the management of PMR has been proposed very recently, in which early introduction of methotrexate (MTX) in addition to GCs was recommended for such GC-resistance or -intolerance[1)]. Similarly, we have used MTX frequently for PMR patients with relapse, prolonged GC therapy and high risk of GC adverse effects.
**Objectives:** To examine the efficacy of this 2015 EULAR/ACR recommendation for managing Japanese patients with difficult-to-treat PMR.
**Methods:** Thirty-five patients were diagnosed with PMR according to the 2012 EULAR/ACR provisional classification criteria for PMR[2)], including 13 males and 22 females. The average (± SD) age was 69.2 ± 9.4 years; disease duration before therapy 1.9 ± 1.8 months; and the length of observation after starting treatment 23.8 ± 20.7 months.
**Results:** All patients had active PMR, as demonstrated by high serum CRP levels (6.43 ± 4.50 mg/dL), erythrocyte sedimentation rate (ESR; 85 ± 33 mm/hr) and matrix metalloproteinase-3 (MMP-3; 188 ± 132 ng/mL). All patients with newly-diagnosed PMR were treated first with GCs (starting with the mean dose of prednisolone (PSL) of 15 mg/day; rage 10 - 60 mg/day; 60 mg/day for giant cell arteritis). Twenty-two patients experienced disease relapses, when PSL dose was reduced to 7.1 ± 3.7 mg/day at 7.9 ± 5.8 months. MTX (8.8 ± 3.4 mg/wk) was added in 21 patients and PSL was increased in a patient. Seven patients relapsed after MTX introduction, followed by adding tocilizumab (TCZ) in 6 patients and azathioprine in a patient. One patient with tocilizumab was thereafter switched to adalimumab due to insufficient response to TCZ. At present, PMR became inactive and GC was successfully withdrawn in 8 patients after total 18.0 ± 4.7 month treatment. No significant differences in basal levels of CRP, ESR and MMP-3 was found between GC-response and –resistant patients. Adverse effects included cataract (n=2), diabetes (n=1), metabolic syndrome (n=1), and osteoporosis (n=1).
**Conclusions:** The results indicate that early addition of MTX for GC-resistance and –intolerance, as recommended by the EULAR/ACR recommendations, may be effective also for Japanese patients, but there are cases refractory to MTX addition, who will require further treatment options including TCZ.

## SAT0340 DISTINCT DISTRIBUTION PATTERNS OF LARGE VESSEL VASCULITIS ASSESSED WITH 18F-FDG PET/CT: A CLUSTER AND PRINCIPAL COMPONENT ANALYSIS STUDY

A. Soriano[1,2], G. Pazzola[2], L. Boiardi[2], F. Muratore[2], P. Macchioni[2], R. Aldigeri[3], M. Casali[4], A. Versari[4], C. Salvarani[2,5]. *[1]Campus Bio-Medico University, Rome; [2]Department of Internal Medicine, Rheumatology Unit, Arcispedale Santa Maria Nuova - IRCCS, Reggio Emilia; [3]Department of Clinical and Experimental Medicine, University of Parma, Parma; [4]Nuclear Medicine Unit, Arcispedale Santa Maria Nuova - IRCCS, Reggio Emilia; [5]Modena and Reggio Emilia University, Modena, Italy*

**Background:** The interpretation of data from 18F-FDG PET/CT studies on large vessel vasculitis (LVV) is difficult due to the scarcity of studies and to the heterogeneity of LVV populations examined. In the absence of gold standard parameters for the assessment of LVV arterial inflammation, there is a great need to develop analytical methodologies useful to properly exploit the information derived from such studies. Principal component analysis (PCA) and cluster analysis (CA) have not yet been applied to explore the LVV distribution patterns, assessed by 18F-FDG PET/CT.
**Objectives:** The aim of our study was to investigate whether PCA and CA are useful methods in identifying distinct distribution patterns of LVV, according to the specific diagnostic entity examined (giant cell arteritis, GCA; Takayasu's arteritis, TAK).
**Methods:** A total of 130 18F-FDG PET/CT studies have been retrospectively examined by a nuclear physician blinded to clinical data. Maximum standardized uptake values (SUVmax) in 14 vascular districts including aortic segments (ascending aorta, thoracic aorta, aortic arch, discending thoracic aorta and abdominal aorta) and the main tributaries (carotid, subclavian, axillary, iliac and femoral arteries) have been measured and transformed into Z-scores. Identification of distribution patterns of vascular involvement has been performed using PCA and agglomerative hierarchical CA (SPSS Statistics, version 22nd).
**Results:** Three groups of vascular districts with similar trends in terms of standardized SUVmax have been identified: epiaortic arteries; aortic arch and ascending aorta; descending and abdominal aorta, with iliac and femoral arteries. A component including the entire aortic district was identified in TAK group, but not in GCA group.
**Conclusions:** PCA and CA approach revealed a subtle skewing in terms of distribution patterns of arterial involvement between TAK and GCA, assessed by 18F-FDG PET/CT SUVmax values. The influence of atherosclerosis and immunosenescence on the different trends in the aorta districts of TAK and GCA needs to be further elucidated.

## SAT0341 ASSESSMENT OF DAMAGE IN BEHCET'S DISEASE: DO WE NEED A SPECIFIC DAMAGE INDEX?

A.U. Unal[1], H.G. Yildirim[1], C. Cikikci[1], G. Ozen[1], N. Inanc[1], P. Atagunduz[1], T. Ergun[2], H. Direskeneli[1]. *[1]Department of Rheumatology; [2]Department of Dermatology, Marmara University Faculty of Medicine, Istanbul, Turkey*

**Background:** Behcet's Disease (BD) is a systemic inflammatory disease characterized by involvement of vessels of any size and type. In the course of systemic vasculitis, it is important to distinguish disease activity from disease damage to prevent unnecessary immunosuppression. Additionally damage is an important surrogate for long-term outcome in vasculitis. Although a well-established validated damage index, "vasculitis damage index" (VDI) is available for vasculitis, its performance in determining the damage in BD has never been assessed.
**Objectives:** To assess the damage in BD by using VDI, to determine whether VDI covers all BD-associated damage and lastly to develop a preliminary BD-specific damage index with the obtained data.
**Methods:** A total of 139 consecutive patients with BD (F/M: 58/81, mean age 38.9±10.9 yrs, disease duration 9.5±7.4 yrs) from a single center were evaluated for damage in a cross-sectional study using the VDI. Considering the patients data and items of VDI with further literature search for BD-specific damages, new items (detailed cardiovascular, ocular, and vascular involvement-, particularly venous disease-related damages) were added to VDI. This modified VDI (Behcet's Disease-VDI [B-VDI]) was also scored in all patients.
**Results:** Seventy seven patients (55.4%) had major organ involvement and 105 (75.5%) patients were on immunosupressive (IS) treatment (Table 1). The mean VDI score was 0.3±0.7 and the majority of the patients had score "0" ("0" in 107 [77%], "1" in 22 [15.8%], "2" in 7 [5%], "3" in 1 [0.7%], and "4" in 2 [1.4%] patients). The mean B-VDI score was 0.6±1.1 ("0" in 92 [66.2%], "1" in 25 [18%], "2" in 13 [9.4%], "3" in 4 [2.9%] and "4" in 3 [2.2%] patients, "5" in 1 [0.7%], and "6" in 1 [0.7%] patient) and was significantly higher than VDI ($p<0.001$). The main difference between VDI and B-VDI was in vascular (0.05±0.2 vs 0.3±0.6, $p<0.001$) damage items. Both VDI and B-VDI scores were significantly higher in patients with major organ involvement compared to mucocutaneous BD. Both scores also positively correlated with the age, disease duration and total duration of IS treatment. When individual organ items were evaluated, damage in patients with major organ involvement was observed to be predominantly associated with ocular and vascular involvements. Although VDI-eye and B-VDI-eye scores were not significantly different (both 0.3±0.6, p=0.32), B-VDI-vascular scores were significantly higher than VDI-vascular scores both in the entire cohort and in patients with major organ involvement (0.6±0.8 vs 0.1±0.3, $p<0.001$).

**Table 1.** Baseline demographic and clinical characteristics of patients with Behcet's Disease (n=139)*

| | |
|---|---|
| Age, years | 38.9±10.9 |
| Male, n (%) | 81 (58.3) |
| Disease duration, years | 9.5±7.4 |
| Oral ulcer, n (%) | 139 (100) |
| Genital ulcer, n (%) | 119 (85.6) |
| Erythema nodosum/folliculitis, n (%) | 110 (79.1) |
| Arthritis, n (%) | 84 (60.4) |
| Ocular involvement, n (%) | 55 (39.6) |
| Vascular involvement, n (%) | 41 (29.5) |
| Gastrointestinal involvement, n (%) | 4 (2.9) |
| Neurologic involvement,n (%) | 4 (2.9) |
| Glucocorticoid treatment, n (%) | 86 (61.9) |
| Immunosuppressives, n (%) | 105 (75.5) |
| Cyclophosphamide | 7 (5) |
| Azathioprine | 77 (55.4) |
| Others | 21 (15.1) |
| Anticoagulant treatment, n (%) | 27 (19.4) |

*The values are presented as mean±SD, unless indicated otherwise.

**Conclusions:** Both VDI and B-VDI capture reliable data on damage among patients with BD. However, VDI does not cover all vascular involvement-related damages of BD. Therefore addition of new items, especially about vascular damage, to VDI will provide more comprehensive assessment of damage in BD. Further prospective follow-up is required to determine the prognostic value of these damage indices in BD.

## SAT0342 FEATURES OF ORBITAL INFLAMMATORY DISEASE AND RESPONSE TO IMMUNOSUPPRESSIVE THERAPY

A. Casian[1], S. Sangle (joint first author)[1], R. Malaiya[2], P. Lutalo[3], L. Nel[1], B. Menon[4], H. Verma[5], M. Stanford[6], D. D'Cruz[1]. *[1]Lupus Unit, Guy's and St. Thomas' NHS Foundation Trust; [2]Rheumatology, Guy's and St Thomas' NHS Foundation Trust; [3]Rheumatology, University Hospital Lewisham; [4]Rheumatology; [5]Radiology; [6]Ophthalmology, Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom*

**Objectives:** To characterize a single centre retrospective case series of patients with infra-orbital inflammatory masses with autoimmune disease including granulomatosis with polyangiitis (GPA) (formerly Wegener's granulomatosis), eGPA (eosinophillic granulomatosis with polyangiitis) or Immunoglobulin G4 (IgG4) related disease (IgG4-RD).
**Methods:** We identified 30 patients with infra-orbital inflammation on MRI imaging. Clinical and laboratory data was collected from electronic clinical records. Comprehensive Diagnostic Criteria were used for IgG4-RD and Chapel Hill criteria for GPA and eGPA. Statistical analysis was performed by GraphPad software; continuous variables were compared between IgG4-RD and GPA groups using non-parametric Mann-Whitney test and categorical variables were compared by Fisher's exact test.
**Results:** The study included 21 Caucasian, 6 Asian and 3 patients of African descent. There were 19 female and 11 male patients. The median age of the patients was 44 years (range 29–76).
13 patients were diagnosed with GPA, 1 with eosinophillic granulomatosis with polyangitis 9eGPA), 11 patients had IgG-RD, 1 patient with lymphoma, 2 other vasculitis, 1 IgA dacryoadenitis, 1 non-specific granuloma.
7/12 patients with IgG4-RD had isolated infra-orbital masses whereas all 14 GPA patients suffered extra-ocular manifestations (p=0.01), usually sino-nasal or pulmonary.
11/14 GPA patients had positive ANCA vs 2/12 patients with Ig4-RD (p=0.04). IgG4 level was elevated pre-treatment in IgG4 RD patients (median 2.46 g/l (range 1.2–23.7)) and dropped to 1.25 g/l (range 0.37–10.4) after therapy; immunoglobulin subclasses were not checked routinely in GPA.
All 12 patients with IgG4-RD underwent diagnostic orbital biopsy vs 3/14 GPA (p=0.0001).
All 30 patients were treated with corticosteroids (used alone in 3/12 IgG4-RD patients). The median number of DMARDs ever used to treat GPA was 3 vs 1 DMARD for IgG4-RD (p=0.001). Rituximab was effectively administered to 10/14 GPA patients vs 3/12 IgG4-RD (p=0.04), is planned for 2 further IgG4-RD patients and approval was refused for 1 case. Surgical debulking was undertaken in 6/12 IgG4-RD vs 1/14 GPA (p=0.03). All 40 patients had subsequent MRI to assess response to therapy.

| Patient Group | GPA | IgG4-RD | P value |
|---|---|---|---|
| Number of patients | 14 | 11 | |
| Median age (years) | 46 | 58 | 0.16 |
| Gender distribution | 8 female / 6 male | 7 female / 4 male | 1.0 |
| Ethnic distribution | 10 Caucasian / 3 Asian / 1 African | 6 Caucasian / 3 Asian / 2 African | 0.4 |
| ANCA status | 11 ANCA+ / 3 ANCA- | 2 ANCA+ / 9 ANCA- | 0.04 |
| Bilateral orbital inflammation | 4/14 | 2/11 | 0.7 |
| Extra-ocular manifestations | 14/14 | 4/11 | 0.01 |
| Median number of DMARDs | 3 (range 1-5) | 1 (range 0-3) | 0.001 |
| Rituximab treatment | 10/14 | 3/11 | 0.04 |
| Surgical debulking | 1/14 | 6/11 | 0.02 |
| Chronic damage (visual loss, diplopia, orbital pain /swelling) | 8/14 | 5/11 | 0.7 |
| Improvement of orbital inflammation on MRI | 9/14 | 10/11 | 0.2 |

**Conclusions:** IgG4-RD is an important differential diagnosis of infra-orbital inflammation, especially if ANCA is negative. Unlike GPA that was associated with extra-ocular manifestations in all patients, IgG4-RD was more likely to present with isolated orbital inflammation and to require biopsy or surgical debulking as the diagnosis was initially uncertain. Treatment with corticosteroids +/– DMARDs was effective. Rituximab can specifically deplete the pool of autoreactive B lymphocytes producing IgG4 and future systematic studies are required to establish the optimum therapeutic strategy.

## SAT0343 UTILITY OF VASCULAR FINDINGS BY PET/CT SCAN IN THE DIAGNOSIS AND ACTIVITY ASSESSMENT OF TAKAYASU ARTERITIS

B. Toz[1], Z.G. Ozkan[2], G. Alçın[2], S. Kamalı[1], B. Artım Esen[1], B. Erer[1], A. Gul[1], L. Ocal[1], S.N. Ünal[2], M. Inanc[1]. *[1]Division of Rheumatology Istanbul School of Medicine, Istanbul University; [2]Department of Nuclear Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey*

**Background:** Takayasu arteritis (TA) is a large-vessel vasculitis predominantly affecting the aorta and its main branches. Assessing disease activity is difficult and mainly based on the clinical findings, levels of acute phase reactants and angiography, but these items generally do not correlate well
**Objectives:** The aim of the this study was to investigate the role of PET/CT in the diagnosis of the disease and assessing disease activity in TA
**Methods:** Thirty TA patients fulfilling ACR criteria underwent FDG-PET/CT were retrospectively assessed. Disease activity was defined according to NIH criteria. A nuclear physician who was blinded to clinical and laboratory data examined all PET/CT scans. PET/CT scans were considered negative if vascular FDG uptake was lower than liver uptake, if there was moderate (equivalent to that of liver) or marked (more than liver) FDG uptake in at least one vessel area, the scan was considered positive for vasculitis. The levels of C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were measured concomitantly. The correlation between CRP and ESR with $SUV_{max}$ values of vessels was investigated. Disease activity with the NIH cirteria, CRP levels and ESRs were compared in subjects with or without positive PET/CT scans. ROC curve analyses were performed to assess the sensitivity and specificity of CRP and ESR according to PET/CT positivity
**Results:** PET/CT was performed for diagnostic purposes early in the disease course in 9 subjects and to assess disease flare in 21 subjects on follow-up. The rate of a positive PET/CT examination tended to be higher in diagnostic/early use (88.9% positive) compared with use for flare-assessment (61.9% positive), although the difference was not significant (Fisher=0.2). Median CRP and ESR tended to be higher in PET/CT positive patients compared with PET/CT negative subjects (median CRP 19 vs. 14, p=0.16; mean ESR 59.8±36.5 vs. 35.2±19.7, p=0.07). ROC curve analysis showed an ESR of 38 mm/h or higher was 68.4% sensitivity and 66.7% specificity to predict a positive PET/CT examination (positive and negative predictive values 81.6% and 50%). A CRP of 14.5 mg/L or higher was 66.7% and 55.6% specific to predict a positive PET/CT examination (positive and negative predictive values 77.8% and 41.7%). While CRP was significantly correlated with mean $SUV_{max}$ value of aorta (r=0.41, p=0.02), ESR was weakly correlated with $SUV_{max}$ value of aorta (r=0.3, p=0.13). There was moderate agreement between PET-CT and NIH criteria (kappa 0.462, p=0.01, sensitivity 81%, spesificity 67%).
**Conclusions:** These results suggested that clinical benefit of PET/CT might be higher in diagnostic use (early in the disease course) compared with use for flare assessment (after treatment) in TA. There was a moderate association between NIH activity criteria and PET/CT activity. The predictive value of increased ESR and CRP was similar for a positive PET/CT scan with lower negative predictive values. CRP levels had a better correlation with $SUV_{max}$ levels of aorta compared to ESR. PET/CT is a promising tool in the diagnosis and activity assessment of TA but discrepancies with other activity parameters do exist.

## SAT0344 TREATMENT OF NON-INFECTIOUS AORTITIS: STUDY OF 32 PATIENTS FROM A SINGLE CENTRE

C. Fernández-Díaz[1], J. Loricera[1], C. Pena[2], R. Blanco[1], J.L. Hernández[3], J.M. Carril[4], I. Martínez-Rodríguez[4], A. Canga[5], E. Peiró[1], A. Corrales[1], V. Calvo-Río[1], C. González-Vela[6], M.Á. González-Gay[1]. *[1]Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain; [2]Rheumatology, Hospital Interzonal General de Agudos, San Martín, Mar del Plata, Buenos Aires, Argentina; [3]Internal Medicine; [4]Nuclear Medicine; [5]Radiology; [6]Pathology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain*

**Background:** Non-infectious aortitis is often an underrecognised condition. Early diagnosis and treatment is crucial to prevent serious complications.
Corticosteroids represent the first-line therapy of non-infectious aortitis. However, disease-modifying antirheumatic drugs (DMARDS) and/or biologic therapy are usually required.
**Objectives:** Our aim was to assess the treatment and outcome of patients diagnosed with non-infectious aortitis from a single centre.
**Methods:** Retrospective study of 32 patients (22 women/10 men) diagnosed with non-infectious aortitis based on imaging techniques. We have considered 3 groups: *group a)* patients who only received corticosteroids; *group b)* patients
