The degree of ocular inflammation was assessed by "the Standardization of Uveitis Nomenclature (SUN) Working Group" (Am J Ophthalmol 2005; 140: 509–516), and macular thickness by optical coherence tomography (OCT). A comparison was made between the first visit before initializing ADA at standard dose, the start of the optimization of the drug, and the final visit.
The results are expressed as mean ± 1 SD for variables with a normal distribution, and as median [IQR 25–75] (range) when it is not normal. Comparison of continuous variables was performed using the Wilcoxon test.
**Results:** 23 patients/42 affected eyes (15 men/8 women) who had a dose optimization were studied, the median age was 37.2 ± 13.4 years (range 10–62). HLA-B51 was positive in 60.8%. Prior to ADA, and as systemic treatment besides oral steroids, they had received intravenous methylprednisolone bolus (n=7), cyclosporin A (CyA) (n=20), methotrexate (MTX) (n=11) and azathioprine (AZA) (n=11).
ADA monotherapy was used in 5 cases and also in combination with immunosuppressants: CyA (n=12), MTX (n=4) and AZA (n=2). The average remission before

optimization of the dose was 15.3 ± 9 months. In 23 patients the interval dose of adalimumab was progressively increased to 3 weeks (n=6), 4 weeks (n=13), 5 weeks (n=1), 6 weeks (n=1) and 8 weeks (n=2).
Only 2 patients had to return to the standard dose of ADA due to serious outbreak after optimizing the drug, reaching again remission of uveitis. It was also posible to suspend ADA in 4 patients after 35.2 ± 9.3 months in remission, not presenting a new outbreak after a mean of 20 ± 6.9 months following the suspension. There were not serious side effects during a mean follow-up of 34.7 ± 13.3 months after starting ADA.

TABLE 1.

| | At onset of ADA | At on set of ADA Optimization | Last Visit |
|---|---|---|---|
| VA (median [IQR]) | 0,8 [0,3-1] | 1 [0,8-1] * | 1 [0,9-1] * |
| anterior chamber cell (median [IQR]) | 0 [0-2] | 0 [0-0] * | 0 [0-0] * |
| Vitritis (median [IQR]) | 1 [0-2] | 0 [0-0] * | 0 [0-0] * |
| Retinal vasculitis (% affected eyes) | 41,8% | 10,8% * | 0% * |
| OCT (µ) (mean±SD) | 308,7±122,9 | 253±20 * | 250,5±17,9 * |

* p< 0,05 Between At onset of ADA, At onset of ADA optimization and last visit (Wilcoxon test)
Abreviatures: VA= Visual Acuicity, ADA= adalimumab

**Conclusions:** Optimizing ADA therapy, once remission is achieved, seems feasible in Behcet's síndrome uveítis refractory to systemic treatment.

## THU0567 COMPARATIVE PERFORMANCE OF FAUTREL AND YAMAGUCHI CRITERIA FOR THE CLASSIFICATION OF PATIENTS WITH ADULT ONSET STILL DISEASE: PRELIMINARY RESULTS

D. Lebrun [1], S. Mestrallet [2], M. Dehoux [3], J.-L. Golmard [4], S. Georgin-Lavialle [5], L. Arnaud [6], G. Grateau [5], J. Pouchot [7], B. Fautrel [8]. *[1] Department of Internal Medicine, Clinical Immunology and Infectious Diseases, Robert Debré Hospital, University Hospital, Reims, Reims; [2] Department of Internal Medicine and Infectious Diseases, Manchester Hospital, Charleville-Mézières; [3] Metabolic and Cellular Biochemistry Laboratory, Bichat-Claude Bernard Hospital; [4] Department of Biostatistics, Pitié-Salpêtrière Hospital; [5] APHP, Department of Internal Medicine, Reference Center for Amyloidosis and Familial Mediterranean Fever, Tenon Hospital; [6] UPMC, GRC 08, Pierre Louis Institute of Epidemiology and Public Health; [7] Department of Internal Medicine, Georges Pompidou European Hospital; [8] UPMC, GRC 08, Pierre Louis Institute of Epidemiology and Public Health – APHP, Department of Rheumatology, Pitié-Salpêtrière Hospital, Paris, France*

**Objectives:** To validate Fautrel criteria set for classification of adult onset Still's disease (AOSD), and to establish its discriminative performance to that of the Yamaguchi's set.
**Methods:** We retrospectively reviewed the medical charts of 344 patients who had ferritin and glycosylated ferritin measured at the biochemistry laboratory of Bichat Hospital. Medical informations were extracted via a standardized form. All clinical, biological, imaging features were collected, as well as elements in favor of an alternative diagnosis, specifically symptoms suggestive of other immune-mediated inflammatory diseases (IMID) or active infections. Patients were classified as AOSD or control group, according to a predefined procedure including a review by a group of experts for difficult cases. Algorithms corresponding to Fautrel's and Yamaguchi's classification criteria sets were applied for each patient.
**Results:** 49 AOSD and 229 control patients were included. Fautrel's set displayed a sensitivity of 89.8%, a specificity of 97.8%, and positive and negative predictive values of 89.8% and 97.8% respectively. 5 AOSD diagnoses were missed, and accurately classified as AOSD by standard Yamaguchi's set. The standard Yamaguchi's set – without strict application of exclusion criteria – produced a sensitivity of 95.9%, a specificity of 99.6%, and positive and negative predictive values of 97.9% and 99.1% respectively. 2 AOSD diagnoses were missed and correctly classified with the Fautrel's set. If we applied a stricter definition of exclusion criteria, the sensitivity of Yamaguchi's set decreased to 30.6% ($p<0.0001$). 34 AOSD diagnoses were also missed. These different sets showed excellent performance, although the differences did not reach statistical significance.

| Criteria sets | AOSD (n=49) | Control (n=229) | Sensitivity (%) | Specificity (%) | PPV (%) | NPV (%) | Accuracy (%) |
|---|---|---|---|---|---|---|---|
| Fautrel | 44 | 5 | 89.8[a] | 97.8[b] | 89.8 | 97.8 | 96.4 |
| Standard Yamaguchi | 47 | 1 | 95.9 | 99.6 | 97.9 | 99.1 | 98.9 |
| Strict Yamaguchi | 15 | 0 | 30.6[c] | 100.0 | 100.0 | 87.1 | 87.8 |

PPV = positive predictive value; NPV = negative predictive value; exclusion criteria defined on the referring physician's word in the classification called "standard", and defined more on a performance of predefined diagnostic investigations in the classification called "strict". [a]p=0.26, [b]p=0.10, [c]p<0.0001.

**Conclusions:** Both criteria display high discrimination power in a new cohort of cases and controls. The Fautrel criteria set includes glycosylated ferritin and does not require exclusion criteria. The Yamaguchi criteria set is highly impacted by the way the satisfaction of exclusion criteria were performed.

## THU0568 ULTRASONOGRAPHY OF SALIVARY GLANDS FOR DIAGNOSE OF IGG4-RELATED MIKULICZ'S DISEASE

D.F. Lin [1], W.Q. Yang [2], M.J. Zhao [1], J.Y. Cao [3], Z.T. Liao [1]. *[1] Rheumatology department, the 3rd Affiliated Hospital of Sun Yet-sen University, Guangzhou; [2] ENT Department, Peking University Shenzhen Hospital, Shenzhen; [3] US Department, the 3rd Affiliated Hospital of Sun Yet-sen University, Guangzhou, China*

**Background:** Immunoglobulin 4-related Mikulicz'sdisease (IgG4-MD) is a subtype of IgG4-related diseases with the future of swollen bilateral salivary glands and highly responsive to gluccocorticoids (GCs) therapy. It has the similar ultrasonography (US) features as primary sjogren's syndrome (pSS) including multiply hypoechoic zone, hyperechogenic reflections, inhomogeity and echogeneity appearance of the parotid and submandibular glands. Our study tried to distinct IgG4-MD from pSS by US.
**Objectives:** Our study tried to distinct IgG4-MD from pSS by US.
**Methods:** 7 cases of IgG4-MD with parotid involvement and 28 cases of pSS first diagnosed without treatment before were observed by ultrasonography (US) of bilateral parotid and submandibular glands. Parameters includes parotid gland depth, submandibular size were recorded, and the extent of nodal hypoechoic areas, hyperchogenic reflections, inhomogeity, echogeneity, border clearness were scored according to the pSS US scoring system designed by Hocevar. Afterward, 7 IgG4-MD and 28 pSS patients were given 16mg Methylprednisolone and then tapered 4mg per month and followed up by US after 3 months.
**Results:** 1) The parotid gland depth of IgG4-MD were significantly larger than of pSS (38±7mm: 11±5mm, $p<0.01$).
2) The scores of hypoechoic areas, hyperchogenic reflections, inhomogeity of IgG4-MD cases by Hocevar's method were significantly higher than of pSS cases repectively (mean scores=9.1: 6.3, 11.1: 3.6, 11.8: 5.9, $p<0.01$), border clearness and echogeneity were not significantly difference.
3) It is shown depth of bilateral parotid glands (38±7mm: 14±3mm) and the score of hypoechoic areas (9.1: 3.7, $p<0.01$) in IgG4-MD cases remarkably decreased after 3 month follow-up, however, no too much difference of the depth of bilateral parotid glands (11±5mm: 10±6mm) and the score of hypoechoic areas (6.3: 5.3) in pSS cases.
**Conclusions:** Ultrasound could be used for distinguish IgG4-MD salivary involvement from pSS for monitoring the depth of parotid and scoring hypoechoic areas especially during the GCs therapy.
**Disclosure of Interest:** None declared

## THU0569 PHARMACOKINETICS AND PHARMACODYNAMICS OF CANAKINUMAB IN PATIENTS WITH AUTOINFLAMMATORY PERIODIC FEVER SYNDROMES (COLCHICINE RESISTANT FMF, HIDS/MKD AND TRAPS)

F. De Benedetti [1], J. Anton [2], M. Gattorno [3], H. Lachmann [4], I. Kone-Paut [5], S. Ozen [6], J. Frenkel [7], A. Simon [8], A. Zeft [9], E. Ben-Chetrit [10], H. Hoffman [11], Y. Joubert [12], K. Lheritier [12], A. Speziale [12], G. Junge [12], X. Xu [13]. *[1] IRCCS Ospedale Pediatrico Bambino Gesú, Rome, Italy; [2] Hospital Sant Joan de Déu, Barcelona, Spain; [3] Pediatric Rheumatology, G. Gaslini Institute, Genoa, Italy; [4] UK National Amyloidosis Centre, University College London Medical School, London, United Kingdom; [5] Hôpital Kremlin Bicetre, University of Paris SUD, Paris, France; [6] Hacettepe University Children's Hospital, Ankara, Turkey; [7] University Medical Center Utrecht, Utrecht; [8] Radboud University Medical Centre, Nijmegen, Netherlands; [9] Pediatrics Rheumatology, Cleveland Clinic, Cleveland, United States; [10] Rheumatology Unit, Hadassah–Hebrew University Medical Center, Jerusalem, Israel; [11] University of California, La Jolla, United States; [12] Novartis Pharma AG, Basel, Switzerland; [13] Novartis Pharmaceuticals Corporation, East Hanover, United States*

**Background:** Periodic fever syndromes are a group of rare autoinflammatory conditions that includes, among others, cryopyrin-associated periodic syndromes (CAPS), familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and TNF receptor-associated periodic syndrome

(TRAPS). The pharmacokinetics (PK) of canakinumab (CAN) and total interleukin (IL)-1β kinetics have been well characterised in CAPS patients (pts).[1] Here we present the PK and pharmacodynamics (PD) of CAN in colchicine resistant/intolerant (crFMF), HIDS/MKD and TRAPS pts.

**Objectives:** To evaluate the PK and PD of CAN (solution for injection-liquid in vial [LIVI]) from the phase III study in crFMF, HIDS/MKD and TRAPS pts at Week 16.

**Methods:** The study (NCT02059291) comprised of 3 disease cohorts (crFMF, HIDS/MKD and TRAPS). Each cohort followed the same study design across 4 epochs (screening epoch [up to 12 weeks], randomised treatment epoch [16 weeks], randomised withdrawal epoch [24 weeks] and open-label treatment epoch [72 weeks]). Pts (age, ≥2 years) with crFMF, HIDS/MKD or TRAPS who had a flare during Epoch 1 were randomised (1:1) in Epoch 2 to receive subcutaneous (sc) CAN 150 mg (or 2 mg/kg for pts weighing ≤40 kg) every 4 weeks (q4w) or placebo. Blinded uptitration (up to 300 mg) was allowed for pts not resolving the index flare by day15. Samples for CAN concentrations and total IL-1β were collected at baseline (Day 1), and trough samples at weeks 2, 4, 8, 12 and 16.

**Results:** In crFMF, HIDS/MKD and TRAPS pts, the serum clearance and steady-state volume of distribution of CAN varied according to body weight and were estimated to be 0.14±0.04 L/day and 4.96±1.35 L, respectively. The estimated half-life of CAN was 25.6±6.4 days. CAN minimal concentration at Week 16 following 150 mg sc q4w dosing was estimated to be 15.3±6.6 μg/mL. The estimated steady state area under the serum concentration-time curve from time zero to the end of the dosing interval tau ($AUC_{tau}$) was 648±202 μg.day/mL. Similar results were obtained in 3 diseases. CAN binding to circulating IL-1β was demonstrated by increase in total IL-1β following CAN dosing in all 3 diseases. In pts requiring up titration to 300 mg, levels of total IL-1β were higher suggesting higher production of IL-1β.

**Conclusions:** This was first study to evaluate the PK characteristics of canakinumab given in the LIVI form. The results observed in crFMF, HIDS/MKD and TRAPS patients were similar to those observed in other indications (CAPS and SJIA) using the lyophilisate form. These data suggested that new formulation did not affect PK/PD of the drug and similarly to CAPS, patients with higher levels of IL-1β may require canakinumab up-titration to have an optimal disease control.

## THU0570 USE OF DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN A COHORT OF PATIENTS WITH IGG4-RELATED DISEASE

A. Fernández-Codina, I. Pinal-Fernández, O. Orozco-Gálvez, R. Solans-Laqué, S. Bujan-Rivas, V. Fonollosa-Plà, M. Vilardell-Tarrés, F. Martínez-Valle. *Systemic Autoimmune Diseases Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

**Background:** The use of non-biologic disease-modifying anti-rheumatic drugs (DMARDs) has been scarcely explored in patients with IgG4-related disease (IgG4-RD). There is only one small series reporting the use of methotrexate.

**Objectives:** This paper aims to describe the use of DMARDs in a monocentric cohort, the characteristics of the patients and the outcomes.

**Methods:** This is an observational study. Diagnoses were made according to the international 2012 criteria. Patients were divided into histologically highly suggestive and histologically probable IgG4-RD. Subjects with insufficient IgG4-RD pathological features were excluded. Medical records including baseline characteristics, treatments and outcomes were reviewed.

**Results:** Twenty-five patients were included, 8 of which (32%) were women. The median age at diagnosis was 50.5 years (IQR 14). Thirteen patients (52%) were assigned to the group of highly suggestive histological IgG4-RD and 12 (48%) in the probable group. Nine patients (36%) had systemic IgG4-RD (>1 organ affected). The most frequently involved organs were: retroperitoneum 8 (32%), orbitary pseudotumor 5 (20%) and aorta 3 (12%). Regarding treatments, 3 patients did not receive treatment (because of reluctance to treatment, minimal extension and new diagnosis, respectively). The reported use of DMARDs was: azathioprine 4 patients (16%, 50–200mg/day), mycophenolate mofetil 2 (8%, 2g/day), methotrexate 1 (4%, 15mg/day) and cyclosporin A 1 (4%, 200mg/day). The first time patients were treated, nineteen patients (76%) received corticosteroids, in 3 cases (12%) together with DMARDs. Seven patients (28%) underwent resective surgery. The response to the first treatment scheme was complete (no symptoms, >50% fibrotic mass reduction) in 12 patients (48%) and partial (no symptoms, <50% fibrotic mass reduction) in 10 (40%). Nine patients (36%) had treatment failure or relapses, always in the same organ involved at diagnosis. One of them had been treated with corticosteroids plus DMARDs. Within patients that required to be treated for a second time (treatment failure or relapses), 7 patients (77.7%) received corticosteroids. Of those, 2 individuals were given corticosteroids alone (25%) and five (62.5%) were given corticosteroids plus DMARDs. One patient received directly rituximab and another underwent surgery. Six patients (66.7%) had a complete response, 2 (22.2%) had a partial response and one was lost during follow-up. Among the five patients who received DMARDs, two had a partial response and three had a complete response. One patient was still refractory to treatment and was rescued successfully adding rituximab to the scheme. After a median follow-up of 2.5years (IQR 5.25), while no patients died.

**Conclusions:** This is the second largest single-center cohort reported in Europe. Corticosteroids seem the basis of any treatment done so far, although flares are common. The combined use of corticosteroids with DMARDs seemed effective in our series. DMARDs were more frequently used when treating flares. Although rituximab is a promising treatment, non-biological DMARDs could have a role in IgG4-RD treatment. Larger cohorts and randomized studies are required to make advances in this field.

## THU0571 PRELIMINARY RESPONSE TO JANUS KINASE INHIBITION WITH BARICITINIB IN CHRONIC ATYPICAL NEUTROPHILIC DERMATOSIS WITH LIPODYSTROPHY AND ELEVATED TEMPERATURES (CANDLE)

G.A. Montealegre[1], A. Reinhardt[2], P. Brogan[3], Y. Berkun[4], A. Zlotogorski[4], D. Brown[5], L. Gao[6], J.A. Dare[6], S. Schalm[7], T.L. Klausmeier[8], S. Murias[9], D. Chapelle[1], H. Kim[1], S. Judd[1], M. O'Brien[1], A.A. de Jesus[1], B. Kost[1], S.M. Paul[10], R.A. Colbert[1], A. Brofferio[11], C. Lee[12], C. Hadigan[13], T. Heller[14], M. Waldman[14], K.I. Rother[14], R. Goldbach-Mansky[1]. *[1]NIH/NIAMS, Bethesda; [2]Children's Hospital of Omaha, Omaha, United States; [3]Great Ormond Street Hospital, London, United Kingdom; [4]Hadassah-Hebrew University Medical Center, Jerusalem, Israel; [5]Children's Hospital Los Angeles, Los Angeles; [6]University of Arkansas for Medical Sciences, Little Rock, United States; [7]LMU Munich, Munich, Germany; [8]Riley Hospital for Children, Indianapolis, United States; [9]Hospital Infantil La Paz, Madrid, Spain; [10]NIH/CC; [11]NIH/NHLBI; [12]NIH/NCI; [13]NIH/NIAID; [14]NIH/NIDDK, Bethesda, United States*

**Background:** Elevated serum IP-10 (CXCL10) levels and gene expression studies showing a prominent "interferon (IFN) signature" suggested modulation of IFN signaling might be a therapeutic option in CANDLE patients.

**Objectives:** The objective of this compassionate use program is to provide baricitinib (JAK1/JAK2 inhibitor) to CANDLE patients who have no other comparable or satisfactory treatment options. Potential efficacy of treatment was assessed by a reduction in mean Autoinflammatory Diary Scores (ADS) to <0.5 and reduction of steroid doses by at least 50% in patients receiving steroids at baseline.

**Methods:** Paired t-test was used to compare mean ADS and prednisone doses at the last NIH clinic visit to baseline data.

**Results:** Between October 2011 and January 1st, 2016, 11 CANDLE patients have been treated (mean duration 2.5 years (SD±1)). 9 of 11 patients achieved an ADS of <0.5 at the time of their last visit (mean ADS decreased from 1.3 ± 0.8 at baseline to 0.2 ± 0.3) ($p<0.005$), 8 of 10 patients achieved a reduction in steroids doses > than 50% from baseline (mean total prednisone dose decreased from 0.8 mg/kg/day (0.2–1.8) to 0.2 mg/kg/day (0–1.1)) ($p<0.005$), 4 patients discontinued prednisone completely. The mean dose of baricitinib at the last patient visit was 6.9 ± 2.8 mg/day. 7 patients reported at least 1 serious adverse event (SAE), infection being the most common. 2 patients have been discontinued due to SAEs (avascular necrosis; BK viremia and azotemia). 1 patient required temporary interruption of baricitinib due to neutropenia, and 3 other patients had their dose electively reduced after testing positive for BK viremia: patients were asymptomatic. The most common adverse events were upper respiratory infections, cough, and BK viruria (baseline BK virus screening was not performed).1 patient died due to worsening interstitial lung disease with development of respiratory failure 4 months after discontinuation of baricitinib and initiation of another JAK inhibitor.

**Conclusions:** Preliminary efficacy data in 11 CANDLE patients treated with baricitinib are encouraging and suggest that targeting IFN signaling with a JAK1/JAK2 inhibitor may be a successful therapeutic strategy. Monitoring BK viral titers in blood and urine, in addition to other measures of safety and efficacy, may be important in dose selection and the benefit-risk assessment of baricitinib for CANDLE patients.

## THU0572 RELATIONSHIP BETWEEN MENSTRUATION AND SYMPTOMS OF BEHÇET'S SYNDROME

G. Guzelant, Y. Ozguler, S.N. Esatoglu, G. Karatemiz, H. Ozdogan, S. Yurdakul, H. Yazici, E. Seyahi. *Rheumatology Department, Cerrahpasa Medical Faculty, Istanbul, Turkey*

**Background:** It is well known that menstruation triggers several conditions such as migraine, recurrent aphtous stomatitis and acne vulgaris in otherwise healthy individuals (1). It may exacerbate chronic autoimmune diseases and familial Mediterranean fever (FMF) (2–4). There is also one study that briefly mentions menstruation causes activation in Behçet's syndrome (BS) (4).
**Objectives:** We investigated the relationship between menstruation and specifically the skin-mucosa lesions of BS. As controls, we studied FMF patients.
**Methods:** Premenopausal women with BS and FMF seen consecutively at the outpatient clinic of Cerrahpasa Medical Faculty at Istanbul, were interviewed. BS patients were asked whether they experienced increased skin-mucosa lesions during the menstrual period. A similar questionnaire assessing this time the frequency of serositis and fever attacks was given to the patients with FMF. As a control the participants were also asked whether they experienced headaches during the same period as well.
**Results:** A total of 140 BS patients with a mean age of 36±8 and mean disease duration of 9±6 years were studied. While 21 (15%) were off treatment, 103 (74%) were using colchicine and the remaining were using other immunosuppressive agents. As shown in the Table, among BS patients, 78 (56%) associated at least one symptom with menstruation. The most commonly reported symptom related with menstruation was the papulopustular involvement (50%), followed by oral (30%) and genital ulcers (21%) and nodular lesions (21%).
We also studied 185 patients with FMF. Their mean age was 32±8 and mean disease duration was 12±8 years. All patients were using colchicine for a mean duration of 8±7 years. A total of 138 patients (75%) reported that their attacks overlapped with menstruation. These attacks included mostly peritonitis in 126 patients (68%), pleuritis in 102 (55%), and fever in 73 (40%).
Among both BS and FMF patients, similar number of patients (41% and 41%, respectively) reported that menstruation triggered headaches.

| | Yes | No | do not remember |
|---|---|---|---|
| Behçet syndrome (n=140) | | | |
| Oral ulcer, n (%) | 42 (30) | 45 (32) | 53 (38) |
| Genital ulcer, n (%) | 30 (21) | 94 (67) | 16 (11) |
| Papulopustular lesions, n (%) | 70 (50) | 56 (40) | 14 (10) |
| Nodular lesions, n (%) | 30 (21) | 90 (64) | 20 (14) |
| At least one BS symptom, n (%) | 78 (55) | – | – |
| Headache, n (%) | 58 (41) | 45 (33) | 37 (26) |
| Familial Mediterranean fever (n=185) | | | |
| Peritonitis, n (%) | 126 (68) | 51 (28) | 8 (4) |
| Pleuritis, n (%) | 102 (55) | 74 (40) | 9 (5) |
| Fever, n (%) | 73 (39) | 100 (54) | 12 (6) |
| At least one FMF symptom, n (%) | 138 (75) | – | – |
| Headache, n (%) | 76 (41) | 77 (42) | 32 (17) |

**Conclusions:** This survey showed that, in about half of the patients with BS at least one skin mucosa lesion is exacerbated with menstruation. Most commonly reported were the papulopustular lesions. Menstruation had a stronger effect on FMF, triggering at least one symptom in about ¾ patients. The main limitation of the study was the self-reported assessment methodology, rather than a prospective diary assessment. Our findings provide further evidence that papulopustular lesions of BS and acne vulgaris are pathologically related (5).

## THU0573 SEMEN ANALYSIS IN ADOLESCENT WITH FAMILIAL MEDITERRANIAN FEVER

G.K. Aksoy[1], M.F. Usta[2], M. Koyun[1], E. Comak[1], A. Gemici[1], S. Akman[1]. *[1]Pediatric Nephrology-Rheumatology; [2]Urology, Akdeniz University Medical Faculty, Antalya, Turkey*

**Background:** Familial Mediterranean Fever (FMF) is a genetic disease that has characteristics like fever, sterile peritonitis, pleurisy, joint pain and rashes that are similar to erysipelas. In male patients, scrotal involvement is seen especially in children and adolescents with the frequency being below 5%.[1] Colchicine is an agent which regulates microtubules in cell's structure, pauses metaphase stage in cell division and stops microtubule dependent cell movement[2]. Colchicine is principal for treatment of FMF. Colchicine has a negative effect on sperm count and motility as it effects microtubules.
**Objectives:** We aimed to observe the relationship between sperm count and function with disease activity and colchicine usage in adolescent male patients with FMF.
**Methods:** Male patients between the age of 14–19 years old with FMF investigated retrospectively. Tel Hashomer and Turkish FMF Pediatric Criteria were used for diagnosis of FMF. Genetic screening was performed in all patients at the time of diagnosis. Sperm analysis was performed in 19 patients on treatment with colchicine. Demographic and clinical parameters of patients were analyzed.
**Results:** Mean age at the diagnosis was 11.13±3.82 years old, mean age at the study was 14.50±0.70 and mean follow-up period was 4.68±3.94 years. Homozygote, compound heterozygote and heterozygote mutations were found in eight, seven and one patients, respectively; no mutations in 3 patients. Mean colchicine dose was 1.16 mg/day at the start of treatment and 1.47 mg/day when sperm samples were collected. Mean sperm concentration was found as 66.26±41.02 million/ml (N>15), sperm count 113.42±132.39 million (N>35) and motility %51.78±23.70 (N>50%). Only 8 patients out of 19 had normal sperm parameters. Sperm concentration was reduced in two cases; sperm count was reduced in four patients whereas motility was reduced in nine cases. No relation was determined between sperm volume, count, concentration and motility results with age at diagnosis, follow-up period, symptoms on admission and inflammatory markers (CRP and erythrocyte sedimentation rate). Patients that had sedimentation values above 30 mm/hour during follow-up had sperm count below <35 million, with a specificity of 100% and sensitivity of 73.3% (AUC=0.858, p=0.032). It was found that patients who had FMF attacks during treatment had low sperm count and motility than patients without attacks (p: 0.034 and p: 0.02, respectively). There was an inverse relationship between the dose of colchicine with sperm motility (p: 0.025).
**Conclusions:** A high number of adolescents with FMF had abnormal sperm parameters, mostly sperm motility. It seems that both colchicine and uncontrollable attacks of FMF may be the reason of abnormal sperm parameters. We suggest that all adolescents with FMF should be screened for semen analysis.
**Disclosure of Interest:** None declared

## THU0574 CHARACTERIZATION OF EYE SARCOIDOSIS WITH OR WITHOUT SYSTEMIC INVOLVEMENT:APPLICATION OF IWOS CRITERIA IN AN UVEITIS UNIT

H. Sánchez Pérez[1], D. Ángel Pereira[2], M. García González[1], I. Ferraz Amaro[1], E. Trujillo[1], P. Rocha Cabrera[2], M. Losada Castilla[2], E. Delgado Frías[1], B. Rodriguez Lozano[1]. *[1]Rheumatology; [2]Ophthalmology, Hospital Universitario de Canarias, Tenerife, Spain*

**Background:** Sarcoidosis (Sa) eye involvement is the most common extrapulmonary manifestation and is the initial presentation in 5–20% of cases. The definitive diagnosis is histopathological.The sensitivity (S) of the conjunctival biopsy is low,so Ocular Sa (OSa) diagnostic criteria (C) were proposed: IWOS (First International Workshop on Ocular Sarcoidosis), with high S and specificity (1/0.95). However, they have been poorly validated
**Objectives:** To apply the IWOS C. and to analyze their consistency with the suspected diagnosis of OSa.To discuss differential features between patients with OSa and those with systemic involvement
**Methods:** Observational cross-sectional study.Clinical records from patients with (presumed) Sa diagnosis who had been followed during the last 10 years in a multidisciplinar Uveitis Unit of a 3rd level hospital (Ophthalmology/Rheumatology) were reviewed.Clinical variables and complementary tests results were analyzed.IWOS C. were applied if OSa was suspected.For statistical analysis we use:Chi-square test and Kappa coefficient
**Results:** 71 patients were included:47 OSa,13 with ocular-systemic involvement (OS-Sa) and 11 with systemic involvement (SSa). Women/Men 57%/43%, mean follow-up time 9.42 years (±8.55), with no intergroup differences.Significant differences between patients with OSa vs. OS-Sa/SSa were observed:mean age at diagnosis (40.23±18.18 vs. 57.54±17.65/48.27 ±17 years, p=0.01); mean ESR (16.74±12.73 vs. 26.38±15./19.4±31.55 mm/h, p=0.01); mean CRP (3.58±4.29 vs. 8.12±8.11/10.24±14.37 mg/L, p=0.03); CT abnormalities (16.6% vs. 90%/92%, p=0.001); positive biopsy (0% vs. 88/100%, p=0.002); general, joint, respiratory and skin symptoms (OSa 6–12% vs SSa 15–50%, p=0.002). ACE was increased in 74.6%, with a mean value of 71.98±33.59 U/L, with no intergroup differences. Altered lacrimal scintigraphy was more often found in the OSa subset (26.7%) vs. OS-Sa/SSa (23.1%/0%), without statistical significance. Comparing OSa vs. OS-Sa patients, ocular involvement was as follows: anterior segment involvement 48% vs 61.5%, intermediate segment 21.3% vs. 15.4%, posterior segment 8.5% vs 0%, panuveitis 10.6% vs. 7.7%, mixed involvement 10.6% vs. 15.4% (p=0.001). If OSa, bilateral involvement was present in 60% of patients, unilateral involvement was more frecuent in OS-Sa (76%), p=0.06.There were no significant differences regarding uveitis's presentation, course and number of crisis and specific intraocular findings. Applying IWOS Criteria and comparing OSa vs OS-Sa we can classify: Definite OSa 0% vs. 69.2%, Presumed OSa 23.4% vs. 7.7%, Probable OSa 14.9% vs. 15.4% and Possible OSa 2.1% vs. 0%; not fulfilling criteria: 59.6% vs. 7.7% (p=0.001). The kappa coefficient between suspicion of OSa/OS-Sa and not fulfilling/fulfilling criteria was 0.30 (p=0.003).

**Conclusions:** We could classify as Presumed OSa in 25% and as Probable OSa in 15% of patients with suspected OSa but who hadn't undergo a biopsy. We excluded the diagnosis in 60%. There wasn't a good consistency between the suspected diagnosis/IWOS C. fulfillment,nevertheless they are a useful tool in clinical practice.OSa patients were younger and had lower ESR/CRP levels. Involvement of the anterior ocular segment was the most frequent one, bilateral in OSa and unilateral in OS-Sa
**Disclosure of Interest:** None declared

## THU0575 TOCILIZUMAB IS SIGNIFICANTLY STEROID-SPARING COMPARED WITH METHOTREXATE IN POLYMYALGIA RHEUMATICA: A MULTICENTER RETROSPECTIVE STUDY (NTMC-KEIO PMR STUDY)

K. Izumi[1,2], O. Murata[1], M. Ushikubo[2], H. Ito[2,3], K. Akiya[2], Y. Kaneko[1], H. Oshima[2], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; [2]Division of Connective Tissue Diseases, National Tokyo Medical Center; [3]Division of Rheumatology, Department of Internal Medicine, Toho University Ohashi Medical Center, Tokyo, Japan*

**Background:** We have recently reported the effectiveness of tocilizumab (TCZ) against polymyalgia rheumatica (PMR) in a case series.
**Objectives:** Here, we aimed to investigate the efficacy of TCZ on the steroid-sparing effect in the treatment of PMR as compared with methotrexate (MTX).
**Methods:** We retrospectively studied all consecutive patients with PMR, diagnosed according to Bird's criteria and/or the 2012 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) provisional classification criteria, who had been treated at Keio University Hospital or National Tokyo Medical Center for at least 6 months between November 2005 and November 2015. The patients were divided into 3 groups based on the treatment at the last follow-up: prednisolone (PSL) monotherapy (PSL group), MTX+PSL (MTX group) and TCZ+PSL combination therapies (TCZ group). We evaluated the PSL dose in each therapy group at the last follow-up. TCZ was infused at 8 mg/kg every 4 weeks. 3 patients treated with both MTX and TCZ were excluded.
**Results:** Of 220 patients, 173 were in the PSL group, 32 in the MTX group, and 15 in the TCZ group. No difference was found in the proportion of women, mean age and the initial PSL dose among the PSL, MTX, and TCZ group (female, 72.8%, 78.1%, 73.3%; mean age, 73.1, 72.5, 74.1 years; initial PSL dose, 14.2, 16.2, 16.1 mg/day, respectively). The disease duration at the last follow-up in the PSL, MTX, and TCZ groups was 80.5, 60.4, and 43.3 months, respectively. The duration of MTX/TCZ use in combination with PSL was not different between the MTX and TCZ groups (30.2 vs 22.3 months, P=0.56). The PSL dose at the last follow-up in the TCZ group was much lower than the PSL and MTX groups (0.3, 3.2, 4.0 mg/day, $P<0.0001$). The patients in the TCZ group could discontinued PSL more frequently than the PSL and MTX groups (80.0%, 28.3%, 18.8%, $P<0.0001$ between the PSL and TCZ groups; $P<0.0001$ between the MTX and TCZ groups). The reduction in daily PSL dose at 6 months from the initiation of MTX/TCZ was much higher in the TCZ group than in the MTX group (-74.7% vs -29.6%, $P<0.0001$). Two patients discontinued MTX treatment because of adverse events (pneumonia and nausea) while none discontinued TCZ treatment.
**Conclusions:** TCZ is significantly steroid-sparing compared with MTX in the treatment of PMR. TCZ but not MTX may serve as an effective therapeutic option for patients who require quick reduction or discontinuation of PSL.

## THU0576 TOCILIZUMAB MONO-THERAPY FOR POLYMYALGIA RHEUMATICA ~ A SINGLE-CENTER, OPEN, SINGLE-ARM TRIAL

K. Chino, A. Shibata, A. Okuyama, T. Kondo, J. Kikuchi, R. Sakai, H. Takei, K. Amano. *Rheumatology and clinical immunology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan*

**Background:** Polymyalgia rheumatica (PMR) is a chronic inflammatory rheumatic disease that mainly affects the elderly. Corticosteroids (CSs) are a definite mainstay for the treatment of PMR; however, their use is associated with severe, serious clinical complications, such as osteoporotic fractures, diabetes, hyperlipidemia, cardio-cerebral vascular events, and glaucoma. Therefore, CS-free treatment strategies may be necessary for some patients with PMR. Interleukin-6 (IL-6) may be involved in the pathogenesis of PMR; furthermore, some case reports have already shown the efficacy of tocilizumab (TCZ), an anti-IL-6 receptor antibody, in the treatment of patients with PMR who had been intolerant or refractory to glucocorticoids [1, 2, 3].
**Objectives:** To assess the efficacy and safety of TCZ monotherapy for PMR
**Methods:** Thirteen PMR patients (3 males, 10 females) diagnosed by the 2012 ACR/EULAR classification criteria between Jan 2013 and Feb 2015 were enrolled after obtaining a written informed consent. TCZ (8 mg/kg) was administered biweekly for the first 2 months (5 infusions) and every 4 weeks for subsequent 24 weeks. ESR, CRP, visual analog scale (VAS) assessment of the patient's global health, and PMR activity score were prospectively measured every 4 weeks and were evaluated at week 24 and 52. Remission was defined as a PMR activity score less than 1.5 as proposed by Leeb [4].
**Results:** Baseline patient characteristics revealed various comorbidities in 11 of the patients; hypertension in seven, hyperlipidemia in five, diabetes mellitus in three, osteoporotic vertebral fractures in two, history of angina pectoris in one, history of brain infarction in one, history of hematemesis due to NSAID ulcer in one, and glaucoma in one patient. At week 24, nine patients achieved low disease activity as per the PMR activity score criteria, including three in remission. Two patients discontinued TCZ because of no response: one at week 6 and the other at week 16. Two patients discontinued TCZ due to adverse events [Editor 1]; pulmonary infiltrate at week 8, pemphigoid at week 50. The nine remaining patients achieved remission at week 52. There were no serious adverse events [Editor 2] except for pemphigoid during the 52-week treatment period.
**Conclusions:** TCZ monotherapy was effective in most (nine out of 13 [Editor 1]) PMR patients, although the response was not as rapid as that to CSs. TCZ monotherapy may be a good alternative therapy to CSs for the elderly with various comorbidities.

## THU0577 MUSCULOSKELETAL SARCOIDOSIS- DEMOGRAPHICS, CLINICAL CHARACTERISTICS, AND TREATMENT EXPERIENCE FROM A TERTIARY CARE CENTER IN THE UNITED STATES

M. Arakane, S. Vogelgesang, Z. Ballas, N. Singh. *Internal Medicine, University of Iowa Hospitals and Clinics, Iowa city, United States*

**Background:** Sarcoidosis, a systemic disease characterized by non-caseating granulomas within affected organs, typically targets the lungs. However, approximately 10–25% of cases manifest musculoskeletal (MSK) involvement of joints, muscles and bone tissue. Literature on the efficacy and safety of TNF-alpha inhibitors (TNFi) for treatment of MSK sarcoidosis is limited.
**Objectives:** Thus, we examined our experience with treatment of MSK sarcoidosis with TNFi.
**Methods:** We conducted an IRB-approved, retrospective EMR search using ICD-9 codes followed by EMR review of individual records to identify patients with MSK sarcoid seen in the Rheumatology clinic at the University of Iowa Hospitals and Clinics and the Iowa City Veterans Affairs Medical Center between January 1, 2000 and December 31, 2014. The diagnosis of MSK sarcoidosis was confirmed based on the presence of Löfgren's syndrome triad or positive pathology on biopsy of MSK tissue. We extracted from cases of MSK sarcoidosis variables on demographics, clinical manifestations, type and length of treatment, treatment response, relapse and adverse events.
**Results:** Retrospective chart review of 340 patients with sarcoidosis yielded 26 cases with MSK involvement, 7 fulfilling Löfgren's syndrome triad (27%) and 19 with biopsy-proven MSK sarcoid (73%). The mean age was 50 yrs and majority were females. 19 patients presented with arthritis (7 Lofgren's and 13 chronic, oligoarticular), 2 with sarcoid myopathy, and 4 with osseous sarcoid. MSK sarcoid symptoms were controlled in 69% of patients with maintenance methotrexate and/or hydroxychloroquine. 8 patients received TNFi due to failure of DMARDs. Long-term efficacy of TNFi was low (Table 1).

Table 1. Clinical outcomes of TNFi treatment of MSK sarcoidosis

| Age/Sex | Condition | Drug | Total therapy | Outcome | Side effect |
|---|---|---|---|---|---|
| 54/M | Osseous sarcoidosis | Infliximab | 8 yrs | Intolerance | Serum sickness |
| 65/F | Osseous sarcoidosis | Infliximab | 6 mo | Ineffective | None |
| 69/M | Myopathy | Infliximab | 8 yrs | Ineffective | None |
| 54/F | Chronic arthritis | Infliximab | 9 yrs | Relapsed | None |
| 57/F | Chronic arthritis | Adalimumab | 7 yrs | Ineffective | None |
| 50/F | Chronic arthritis | Adalimumab | 10 yrs | Effective | None |
| 54/M | Osseous sarcoidosis | Adalimumab | 2 yrs | Relapse | None |
| 54/M | Osseous sarcoidosis | Etanercept | 1 yr | Effective | Oral ulcers |

**Conclusions:** To our best knowledge, this study represents the largest case series of MSK sarcoidosis in North America since 1985. We also present data on outcomes of TNFi use in different forms of MSK sarcoid. In most patients standard DMARD therapy controlled symptoms of MSK sarcoid. TNFi benefited a few patients long term who failed oral DMARDs. Our case series underscores the need for identifying novel targets of treatment for the nearly one-third of patients with MSK sarcoid who fail standard DMARD treatment.

## THU0578 FACTORS ASSOCIATED WITH EARLY DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER

M.E. Tezcan[1], M. Avcı[2], N.B. Kalkan[2], A. Giousouf[2], N. Dasdemir Vardi[2], N. Akbal[2], E. Sevinc[2], S. Celik[2], M. Sargin[2]. *[1]Rheumatology; [2]Family Medicine & Diabetes, Kartal Dr. Lutfi Kirdar Training and Research Hosp., Istanbul, Turkey*

**Background:** Familial Mediterranean fever (FMF) is characterized by recurrent attacks of polyserositis. Delay in treatment may lead to recurrent attacks and amyloidosis.
**Objectives:** In this study, we aimed to evaluate clinical features of patients diagnosed early and compared to those diagnosed late
**Methods:** We enrolled 143 FMF patients over the age of 18 who met Tel-Hashomer Criterias into the study. Demographic features of the patients, duration of education, smoking habits, family history of FMF disease and amyloidosis,; features, duration and frequency of FMF attacks; age at first FMF attack; age at first admittance to a specialist, time between first FMF attack to first admittance to a specialist and which medical specialities patients admitted for their symptoms were recorded with face to face survey method. Else, MEFV gene mutations of the patients, time between first admittance to a specialist to diagnosis, clinical decision and judgement of the specialists at the time of diagnosis were obtained from hospital's medical recording system. Early diagnosis was defined as within three years after the first symptom.
**Results:** Mean diagnostic delay was 12.03±10.43 years. Age at first FMF attack (p=0.020), time between first FMF attack to first admittance to a specialist (p=0.003) and first admittance to a specialist after year 2000 (p=0.001) were found statistically important related with early diagnosis in a regression model. MEFV mutation was the only method that had an influence on the decision making of doctors in the diagnosis of FMF especially after year 2000.
**Conclusions:** Instead of demographic, clinical and genetic differences, early diagnosis may related with increased patient awareness about the disease. Furthermore, availability of MEFV mutation may influence doctors' decision making positively for facilitating early diagnosis of FMF and may replace clinical features. But, this may lead to failures in diagnosis in gene-negative FMF cases.

## THU0579 TREATING TO TARGET WITH CANAKINUMAB IN PATIENTS WITH ACTIVE SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS: RESULTS FROM THE LONG-TERM EXTENSION THE PHASE III PIVOTAL TRIAL

N. Ruperto[1], H.I. Brunner[2], P. Quartier[3], T. Constantin[1], E. Alexeeva[1], I. Kone-Paut[4], K. Marzan[1], N. Wulffraat[1], R. Schneider[2], S. Padeh[1], V. Chasnyk[1], C. Wouters[1], J.B. Kuemmerle-Deschner[1], T. Kallinich[1], B. Lauwerys[5], E. Haddad[2], E. Nasonov[1], M. Trachana[1], O. Vougiouka[1], K. Leon[6], A. Speziale[7], K. Lheritier[7], A. Martini[1], D. Lovell[2]. *[1]PRINTO-Istituto Gaslini, Genoa, Italy; [2]PRCSG, Cincinnati, United States; [3]Necker-Enfants Malades Hospital, Paris; [4]Bicêtre hospital, Paris Sud, France; [5]Cliniques Universitaires Saint-Luc and Université Catholique de Louvain, Brussels, Belgium; [6]Novartis Pharmaceuticals Corporation, East Hanover, United States; [7]Novartis Pharma AG, Basel, Switzerland*

**Background:** The main therapeutic goals that can determine success of biologic treatment in systemic juvenile idiopathic arthritis (SJIA) include achieving and maintaining clinical remission, controlling disease activity and tapering corticosteroids (CS). Canakinumab (CAN) has been shown to improve several of these parameters in previous studies[1]. However, little is known about SJIA patients (pts) using CAN long-term.
**Objectives:** To evaluate the efficacy, safety and long-term treatment response of CAN treatment-naïve pts with active SJIA.
**Methods:** This was an open-label, non-comparative study (NCT00891046) of CAN-naïve SJIA pts (age ≥2 - <20 yrs) receiving CAN 4 mg/kg by s.c. q4w. Efficacy was assessed by the adapted pediatric ACR (aACR 30/50/70/90/100) responses compared to baseline (BL); inactive disease (ID) or clinical remission (ID for >6 Mo) and changes in JADAS-CRP (Juvenile Arthritis Disease Activity Score- C-reactive protein) scores over time. Safety was assessed by adverse events (AEs) and serious AEs (SAEs) reports.
**Results:** A total of 123 pts with active SJIA were enrolled of whom 70 (57%) pts had fever and 71 (57.7%) pts used CS at BL. Mean CRP was 117.8 mg/L (normal: 0–10mg/L) and, on average, pts had, 9.9 active joints and 8.9 joints with limited motion. A rapid response was observed at Day 15, 59 (51%) with aACR ≥70 responses and 27 (26%) having aACR 100 responses. These responses increased and were maintained at subsequent time points (Table). Overall, 73.0% of pts had ID on at least 1 visit. At 6th month, clinical remission was achieved in 52 (42.3%) pts and 33 (26.8%) pts had clinical remission for at least 12 consecutive months. At BL, the median JADAS10-CRP score was 22.3 (indicating high disease activity), with median changes from BL of -12.0 at Day 15 and -16.8 at last assessment indicating moderate and low disease activity, respectively. At the last assessment, 59 (48.4%) pts were rated as ID (JADAS <1); 14 (11.5%) with low active disease activity (JADAS >1 and <3.8); while 14 (11.5%) had moderate and 35 (28.7%) with high disease activity. 24 (33.8%) pts were steroid-free at last assessment. A total of 53 (43.4%) pts had at least 1 AE. Overall rate of AEs was 2.25 events/ 100 patient-days and SAEs was 0.15/ 100 patient-days. 40 (32.5%) pts had SAEs and the most commonly reported were disease flares or worsening of SJIA in 13 (10.6%) pts, macrophage activation syndrome in 6 (4.9%) pts, and pyrexia in 4 (3.3%) pts. No deaths were reported in this study.

**Table. ACR responses achieved in the cohort : Summary statistics, by time point**

| Time point | CAN N=123 | | |
|---|---|---|---|
| | Minimum adapted ACR pediatric response | n (n/m%) | Patients with inactive disease (n/m)% |
| Month 12 | m | 85 | (1/1) 100 |
| | Non-Responders | 4 (4.7) | |
| | aACR ≥30 | 81 (95.3) | |
| | aACR ≥50 | 77 (90.6) | |
| | aACR ≥70 | 73 (85.9) | |
| | aACR ≥90 | 58 (68.2) | |
| | aACR 100 | 49 (57.6) | |
| Month 30 | m | 29 | (1/1) 100 |
| | Non-Responders | 1 (3.4) | |
| | aACR ≥30 | 28 (96.6) | |
| | aACR ≥50 | 28 (96.6) | |
| | aACR ≥70 | 26 (89.7) | |
| | aACR ≥90 | 23 (79.3) | |
| | aACR 100 | 19 (65.5) | |
| Last Assessment | m | 121 | (62/122) 50.8 |
| | Non-Responders | 28 (23.1) | |
| | aACR ≥30 | 93 (76.9) | |
| | aACR ≥50 | 89 (73.6) | |
| | aACR ≥70 | 81 (66.9) | |
| | aACR ≥90 | 74 (61.2) | |
| | aACR 100 | 62 (51.2) | |

n = number of patients who satisfy the criteria, m = number of patients with an assessment in the time period.

**Conclusions:** In this long-term study, CAN treatment was associated with rapid response and sustained therapeutic effect over the long-term in the naïve pts with active SJIA. The safety profile is consistent with other CAN studies.

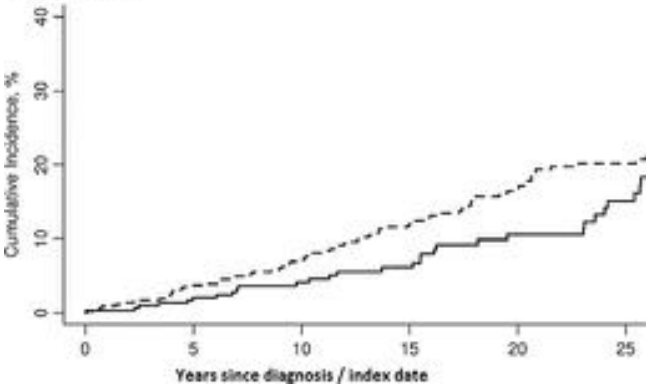
## THU0580 PANNICULITIS IN RHEUMATOLOGY PRACTICE: RESULTS OF LONG-TERM FOLLOW UP

N.M. Savushkina, O.N. Egorova, B.S. Belov, S.G. Radenska-Lopovok. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*



**Background:** Panniculitis (Pn) is a group of heterogeneous inflammatory diseases characterized by involvement of the subcutaneous fat (SF), musculoskeletal system and internal organs.
**Objectives:** to evaluate the clinical course and outcomes of Pn in a prospective study.
**Methods:** 73 pts (F-64, M-9) aged 19 - 77 y., referred for examination and treatment to V.A. Nasonova Research Institute of Rheumatology with referral diagnoses of "erythema nodosum" (EN) and "panniculitis", disease duration from 1 week to 13 years, were followed up. Patient evaluation included physical examination, lab tests (serum levels of $\alpha$1-antitrypsin, amylase, lipase, ferritin, creatine phosphokinase (CPK), rheumatoid factor) (RF), ANF, anti-DNA, ANCA), bacteriological and serological tests, radiological examination (chest CT scan), ultrasound examinations of skin and SF around the nodules, tuberculin skin test and histopathology of nodular skin samples. Patients were re-tested during the follow up (FUP) when necessary. The FUP period lasted from 3 to 5 years.
**Results:** based on clinical, lab and instrumental findings the following diagnoses were verified: EN, associated with infection (22 pts – Group1), lipodermatosclerosis (LDS) (15 pts – Group 2), Weber-Christian's Pn (11 pts – Group 3), Lőfgren syndrome (25 pts – Group 4). In Group 1 EN recurrences were documented in 10 (45%) pts during the FUP, presumably caused by: common cold (4), exacerbation of chronic tonsillitis (1), acute respiratory viral infection (ARVI) (1), stress (1), rapid down of dose of GCs (1), unknown cause (2). In Group 2 recurrences occurred in 9 (60%) pts due to stress (4), failure to observe anti-inflammatory therapy (hydroxychloroquine) (2), trauma (2), weight lifting (1). There were no recurrences in 3 pts from Group 2, nevertheless they failed to reach complete regression of the nodi, most probably due to poor compliance with treatment. 10 relapses (90,9%) registered in Group 3 were associated with absence/discontinuation of anti-inflammatory therapy (6), insufficient efficacy of administered anti-inflammatory therapy (2), and common cold (2). Relapse of nodules in 6 (24%) pts from Group 4 had the following plausible explanation: common cold /ARVI (5), GCs discontinuation (1). Two (2/7%) death were documented during the FUP: in 1 patient with LDS due to acute heart failure, and in 1 patient with Weber- Christian disease due to chronic cardio-pulmonary failure.
**Conclusions:** common cold and viral infections were the leading causes of relapses in pts with EN associated with infection and with Lőfgren syndrome, while stress and absence/insufficient efficacy of anti-inflammatory therapy were the major causes of recurrence in pts with Weber-Christian Pn and LDS. In this Pn case series mortality was 2,7% during the FUP.

## THU0581 RISK OF MALIGNANCY AMONG PATIENTS WITH SARCOIDOSIS: A POPULATION-BASED COHORT STUDY

P. Ungprasert, C.S. Crowson, E.L. Matteson. *Rheumatology, Mayo Clinic, Rochester, United States*

**Background:** Previous studies on the association between sarcoidosis and malignancy yielded conflicting results.
**Objectives:** This study was aimed to investigate the risk of malignancy in patients with sarcoidosis in a population-based cohort.
**Methods:** An inception cohort of patients with incident sarcoidosis in 1976–2013 in a geographically well-defined population was identified based on comprehensive individual medical record review. Inclusion required physician diagnosis supported by histopathologic evidence of non-caseating granuloma, radiographic evidence of intrathoracic sarcoidosis, compatible clinical presentation, and exclusion of other granulomatous diseases. For each sarcoidosis subject, two sex and aged-matched comparator subjects without sarcoidosis were randomly selected. Cases and comparators were then cross-indexed with the Cancer Registry of the institution, which collected data on every type of malignancy except for non-melanoma skin cancer, for malignancy ascertainment.
**Results:** 345 incident cases of sarcoidosis and 690 comparators were identified. The median duration of follow-up was 12 years. There was no difference in the prevalence of malignancy at sarcoidosis incidence/index date between the 2 groups (14 cases, 3.8% among cases and 30 cases, 4.3% among comparators, *P*=0.87) compared to non-sarcoidosis subjects. During follow-up, 37 patients with sarcoidosis and 91 subjects without sarcoidosis developed malignancy with a cumulative incidence at 10 years of 4.1% and 7.1%, respectively. The difference corresponded to a hazard ratio of 0.74 (95% confidence interval (CI), 0.50 -1.09). The cumulative incidences at 10 years for individual types of malignancy were also similar between patients with sarcoidosis and non –sarcoidosis comparators, with non-significant hazard ratios. However, subgroup analysis found that cases with extra-thoracic involvement were at higher risk of incident hematologic malignancy compared with cases without extra-thoracic involvement (HR 1.87; 95% CI 1.09–3.22)

Figure. Cumulative Incidence of Any Cancer excluding non-melanoma skin cancers (Sarcoidosis solid line; Non-Sarcoidosis dashed line)

**Conclusions:** Risk of malignancy was similar among patients with sarcoidosis compared to non-sarcoidosis subjects. However, the risk of incident hematologic malignancy was significantly higher among patients with sarcoidosis with extra-thoracic involvement compared to patients without extra-thoracic disease.
**Disclosure of Interest:** None declared

## THU0582 PROGNOSTIC FACTORS OF MACROPHAGE ACTIVATION SYNDROME IN ADULTS: ANALYSIS OF 40 CASES IN 2 TERTIARY REFERRAL CENTERS

P. Ruscitti[1], F. Ciccia[2], P. Cipriani[1], G. Guggino[2], V. Liakouli[1], F. Carubbi[1], O. Berardicurti[1], P. Di Benedetto[1], G. Triolo[2], R. Giacomelli[1]. *[1]Division of Rheumatology, University of L'Aquila, L'Aquila; [2]Division of Rheumatology, University of Palermo, Palermo, Italy*

**Background:** Macrophage activation syndrome (MAS) is a rare, life-threatening disease in which early diagnosis and aggressive therapeutic strategy may improve the outcome [1]. Due to its rarity, epidemiologic data are still lacking. Hyperferritinemia is frequently associated with MAS and might modulate the cytokines storm the latter contributing to the development of multi-organ failure [2].
**Objectives:** In the current study, we aimed to investigate clinical data, treatments, and outcome of adult MAS patients secondary to autoimmune rheumatic disease.
**Methods:** We retrospectively investigated clinical data, treatments, and outcome of 40 adult MAS patients secondary to autoimmune rheumatic disease. For all the MAS patients, the following clinical characteristics were recorded: age, gender, values of serum ferritin, erythsedimentation rate (ESR) and C-reactive protein (CRP), treatments, concomitant comorbidities, time of observation and outcome. Furthermore, we evaluated the correlations among these clinical features and MAS-associated death.
**Results:** Forty consecutive MAS patients, 15 men (37.5%) and 25 women (62.5%), whose mean age at diagnosis was 48.20±14.10 (mean±SD) were enrolled. Thirty out of 40 enrolled patients reported an history of adult onset Still's disease (AOSD) (75%), 8 patients an history of systemic lupus erythematosus (20%), 1 patient an history of systemic sclerosis (2.5%), and 1 an history of ankilosing spondylitis (2.5%). Twenty-four out of enrolled patients (60%) did not show any comorbidity, and MAS was diagnosed during an AOSD flare. A severe

infections was associated with MAS in the other patients. The laboratory data (mean±SD) reported a strong increase of inflammatory markers: i. serum ferritin 6842.70±7569.70 ng/mL; ii. ESR 63.87±30.19 mm/hr; iii. CRP 51.59±46.92. All the patients were treated with pulsed high dosage of methylprednisolone (1000 mg/daily for a maximum of 6 cycles) and 16 patients (16, 40%) received a combination therapy with: cyclosporin (13, 32.5%); methotrexate (6, 15%); intravenous immunoglobulin therapy (3, 7.5%); anakinra (3, 7.5%); tocilizumab (1, 2.5%). MAS-associated death occurred in 17 patients (42.5%). By using Cox regression proportional hazard model of survival of enrolled MAS patients, we observed that: older age [p=0.017, EXP(B): 1.305, 95%CI: 1.006–1.365], increased serum ferritin levels [p=0.001, EXP(B): 1.776, 95%CI: 1.030–2.728], increased CRP levels [p=0.029, EXP(B): 1.511, 95CI%: 1.021–1.651], higher number of comorbidities [p=0.01, EXP(B): 1.751, 95%CI: 1.142–2.2686], and the use biologics [p=0.015, EXP(B): 2.915, 95%CI: 1.233–6892] were significantly associated with MAS-associated death.

**Conclusions:** Adult MAS is still associated with higher mortality rate. Some clinical features at diagnosis, such as older age, increased serum ferritin and CRP levels and higher number of comorbiditis, may be associated with MAS-associated death.

## THU0583 QUIESCENCE IN ACTIVE AND INACTIVE NON-INFECTIOUS, INTERMEDIATE, POSTERIOR, OR PANUVEITIS IN PATIENTS TREATED WITH ADALIMUMAB: VISUAL I AND VISUAL II TRIALS

R. Landewe[1], I. van der Horst-Bruinsma[2], S. Tari[3], S. Florentinus[3], A. Song[3], M. Kron[4], S. Pathai[5], J. Rosenbaum[6]. *[1]University of Amsterdam; [2]VU University Medical Center, Amsterdam, Netherlands; [3]AbbVie Inc, North Chicago, United States; [4]AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany; [5]AbbVie Ltd, Maidenhead, United Kingdom; [6]Oregon Health & Science University, Portland, United States*

**Background:** There is an unmet need for effective therapies for patients (pts) with non-infectious intermediate, posterior, or panuveitis who are at risk for long-term side effects from chronic corticosteroid use. The therapeutic goal in uveitis is to achieve quiescence and adalimumab (ADA) has been shown to lower uveitic flare or vision loss in pts with active (VISUAL I) and inactive (VISUAL II) uveitis[1,2]. As 40–50% of uveitis pts have accompanying extra-ocular rheumatic associations such as Behcet's disease, sarcoidosis, understanding ocular quiescence will not only aid ophthalmologists but also rheumatologists in the overall management of the pt[3].

**Objectives:** To assess the control of inflammation over time in pts treated with ADA in the VISUAL I and II trials.

**Methods:** Adults with non-infectious intermediate, posterior, or panuveitis were enrolled in 2 global phase 3, double-masked trials: VISUAL I (pts with active uveitis despite ≥2 weeks [wk] of prednisone [PS] 10–60 mg/d) and VISUAL II (pts with inactive disease dependent on 10–35 mg/d of PS to maintain inactivity). Pts were randomized 1:1 to receive placebo (PBO) or ADA (80mg wk0, followed by 40mg every other wk from wk1 up to 80wks). In VISUAL I, all pts received a PS burst followed by taper to 0mg by wk15. In VISUAL II, PS taper to 0mg was mandatory by wk19. Quiescence as a pre-specified endpoint was defined as no new active inflammatory lesions and anterior chamber cell grade and vitreous haze grade ≤0.5+. Steroid free quiescence at each visit was additionally reported from wks16–52 for VISUAL I and from wk20- 52 for VISUAL II. Non-responder imputation was used for missing data. Statistical comparison between PBO and ADA was based on Chi-square test. Adverse events (AEs) were monitored.

**Results:** A greater proportion of pts in the ADA group than the PBO group achieved quiescence at each visit in both VISUAL I and VISUAL II. Statistically significance between ADA and PBO groups were observed at each visit from wks6–52 for VISUAL I, excluding wks6 and 12 and from wks8–52, excluding wks12 and 32 for VISUAL II (Fig. A,B).Similar results were observed for pts in steroid-free quiescence. Statistically significant differences between ADA and PBO groups occurred at each visit from wks20–52 for VISUAL I and from wks20–52, except wk32 for VISUAL II (Fig. C,D).Safety data from the VISUAL I and II trials have previously been reported[1,2]. Rates of AEs were similar between ADA and PBO groups.

**Conclusions:** Pts with non-infectious, intermediate, posterior, or panuveitis achieved significantly higher rates of quiescence and steroid-free quiescence with ADA treatment than PBO in the VISUAL I and II trials. The safety profile of ADA was consistent with the known safety profile across the approved ADA indications.

## THU0584 CLINICAL CHARACTERISTICS OF SARCOID ARTHROPATHY

S. Kobak[1], F. Sever[2], O. Usluer[3], T. Goksel[4], M. Orman[5]. *[1]Rheumatology; [2]Chest Diseases, Sifa University Faculty of Medicine; [3]Chest Surgery, Suat Seren Chest Diseases Hospital; [4]Chest Diseases; [5]Statistics, Ege University Faculty of Medicine, Izmir, Turkey*

**Background:** Sarcoidosis is known as a Th1-mediated disease which can mimic many primary rheumatologic diseases or can sometimes co-exist with them. Clinical characteristics of sarcoid arthropathy are not well described as only referral-based studies have been reported.

**Objectives:** The aim of this study were to evaluate the incidence and clinical characteristics of sarcoid arthropathy.

**Methods:** We used an inception cohort of sarcoidosis patients seen between July 2011 and August 2015. A total of 114 (32 male) sarcoidosis patients, who admitted to our clinic were included in the study. Clinical, demographical, laboratory, radiological and histological data of these patients obtained during 4-year follow-up and treatment period were compiled and analyzed.

**Results:** The mean patient age was 48.1 years (20–82 years), and the mean disease duration was 40.5 months (1–300 months). Sarcoid arthritis was observed in 71 (62.3%), and arthralgia in 106 (92.9%) patients. Out of the 71 patients with arthritis, 61 (85.9%) had involvement of ankle, 7 (9.8%) knee, two (2.8%) wrist, MCP and PIP joints, and one (1.4%) had shoulder periarthritis. Oligoarthritis (two to four joints) was the most common pattern followed by monoarthritis and polyarthritis. When the correlation between clinical findings were considered, erythema nodosum and arthritis and female gender were found to be correlated (p=0.03, p=0.001, respectively). Again in patients with arthritis, even higher levels of CRP/ESR as well as ANA and RF positivity were observed (p=0.03, p=0.01, p=0.01 and p=0.02, respectively). Eleven patients had another rheumatic pathology concurrent with sarcoidosis (1SjS, 3RA, 1Still disease, 1 Scleroderma, 4AS, 1FMF).

**Conclusions:** Inflammatory arthritis occurs in a majority of patients with sarcoidosis. Acute arthritis with bilateral ankles involvement was the most common pattern of sarcoid arthropathy. Sarcoidosis can mimic many primary rheumatic disease and/or may coexist. Sarcoidosis should be considered not only as a mimicker but also as a Th1-mediated primary rheumatologic pathology.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.1650

## THU0585 DISTINCT CLINICAL FEATURES DISTINGUISHING IGG4-RELATED DISEASE AND MULTICENTRIC CASTLESMAN'S DISEASE

T. Sasaki[1], Y. Kaneko[1], M. Akiyama[1], T. Mori[2], H. Yasuoka[1], K. Suzuki[1], K. Yamaoka[1], S. Okamoto[2], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine; [2]Division of Hematology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** IgG4-related disease (IgG4-RD) is a fibro-inflammatory disease with multiple-organ involvement characterized by infiltration of $IgG4^+$plasma cells and elevated serum IgG4 concentrations. However, similar findings are observed in multicentric Castleman's disease (MCD)[1], thereby making it difficult to differentiate one disease from the other.
**Objectives:** The aim of this study was to clarify the differences of clinical characteristics and laboratory findings in IgG4-RD and MCD for differential diagnosis.
**Methods:** All consecutive patients with IgG4-RD and MCD who visited the Rheumatology or Hematology department in our institutes from January 2000 to November 2015 were retrospectively reviewed. Patient characteristics and laboratory data at the time of diagnosis were compared.
**Results:** Forty-nine patients with IgG4-RD and 48 patients with MCD were included. Patients with IgG4-RD were older compared to MCD (57.4 vs 47.3 years, $p<0.0001$) and there was no difference in gender distribution. While lymph nodes were affected less frequently in IgG4-RD compared to MCD (49% vs 100%, $p<0.0001$), lacrimal glands, salivary glands and pancreas were affected only in IgG4-RD. The levels of serum IgG, IgA and IgM were significantly lower in patients with IgG4-RD compared to MCD (IgG: 1945.6 mg/dl vs 4317.5 mg/dl, $p<0.0001$, IgA: 172 mg/dl vs 669 mg/dl, $p<0.0001$, IgM: 83 mg/dl vs 279 mg/dl, $p<0.0001$), whereas no difference was observed in serum IgE levels. Although level of serum IgG4 was also equivalent between IgG4-RD and MCD (607 mg/dl vs 353 mg/dl, $p=0.211$), IgG4/IgG ratio was significantly higher in IgG4-RD compared to MCD (0.30 vs 0.09, $p<0.0001$). In addition, atopic history was more frequent (71.4% vs 16.7%, $p<0.0001$), and the proportion of eosinophils (6.4% vs 2.7%, $p<0.0001$) was significantly higher in IgG4-RD compared to MCD. The level of serum C-reactive protein (0.3 mg/dl vs 5.4 mg/dl, $p<0.0001$) and erythrocyte sedimentation rate (35.9 mm/hr vs 110.7 mm/hr, $p<0.0001$), the prevalence of anemia (10.2% vs 50.0%, $p<0.0001$) and thrombocytosis (2.0% vs 31.3%, $p<0.0001$) were significantly higher in MCD compared to IgG4-RD.
**Conclusions:** The involvement of lacrimal gland, salivary gland and pancreas was unique for IgG4-RD. While allergic reaction such as hypereosinophilia and atopic history was more frequently observed in IgG4-RD, intense inflammation was the distinct characteristics for MCD. The distribution of organ involvement and marked inflammatory reaction represented by elevated serum CRP, anemia and thrombocytosis were important features to distinguish between IgG4-RD and MCD.

## THU0586 AGREEMENT OF PATIENT AND PHYSICIAN GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN ADULT ONSET STILL'S DISEASE

U. Kalyoncu[1], T. Kasifoglu[2], B. Kisacik[3], M.F. Oksuz[4], A. Omma[5], C. Bes[6], M. Cinar[7], O.N. Pamuk[8], O. Kucuksahin[9], S. Akar[10], K. Aksu[11], F. Yildiz[12], A.M. Onat[3], N.A. Kanitez[6], A. Erden[1], E. Dalkilic[4], S. Ermurat[4], M. Hayran[13]. *[1]Department of Internal Medicine, Division of Rheumatology, Hacettepe University, Ankara; [2]Rheumatology, Osmangazi University, Eskisehir; [3]Rheumatology, Gaaziantep University, Gaziantep; [4]Rheumatology, Uludag University, Bursa; [5]Rheumatology, Ankara Numune Training and Research Hospital, Ankara; [6]Rheumatology, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul; [7]Rheumatology, Gulhane Military Medical Academy, School of Medicine, Ankara; [8]Rheumatology, Trakya University, Edirne; [9]Rheumatology, 11. Yıldırım Beyazit University, Faculty of Medicine, Atatürk Education and Research Hospital, Ankara; [10]Rheumatology, Izmir Katip Celebi University School of Medicine; [11]Rheumatology, Ege University, Izmir; [12]Rheumatology, Van Education and Research Hospital, Van; [13]Preventive Oncology, Hacettepe University, Ankara, Turkey*

**Background:** There is not valid outcome measures for assessment Adult onset Still's disease (AOSD) activity. The patients or physicians global view is relevant way to assess this kind of complex diseases. However, it is well known that there is discordance between patient and physician perspective for disease activity in different inflammatory diseases.
**Objectives:** Objective of this study was to evaluate agreement of patient and physician perspective in AOSD patients.
**Methods:** We conducted a cross-sectional, multicenter study for assessment of disease activity in AOSD patients. All AOSD patients were fulfilled Yamaguchi criteria. For every center, at least 20% of AOSD patients had to be an active state according to physician assessment. Age, sex, disease duration, current disease symptoms was recorded. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), leucocyte, and ferritin level also recorded. Visual analog scale (VAS) (0–10 cm) used for physician and patient global assessment of disease activity. Disease activity status were also assessed by likert scale (as remission, low, moderate, severe, and more severe disease activity) for both patients and physician perspective. Patient global assessment VAS and physician global assessment were correlated by correlation coefficient (r). Agreement of disease activity level for patient and physician perspective were calculated with kappa. Kappa $>0.6$ was accepted as significant.
**Results:** One hundred thirty (83, 63.4% female) AOSD patients were enrolled. Mean age was 38 (14) years old and median disease duration was 3 years (0–29). Currently AOSD symptoms followed; fever 34 (26.2%), rash 28 (21.5%), arthritis 31 (23.8%), arthralgia 60 (46.2%), sore throat 28 (21.5), myalgia 42 (32.3), lympadenopathy 12 (9.2%), splenomegaly 17 (13.1%), hepatomegaly 7 (5.4%), pleuritic 3 (2.3%), hemophagocytic syndrome 2 (1.5%). ESR 47.7%, CRP 43.8%, ferritin 27.0%, and leucocyte 43.1% were higher than upper limit. Mean patient global assessment VAS was 3.53 (3.25), and mean physician global assessment VAS was 2.71 (2.95). Correlation coefficient (r) of patient and physican global VAS was 0.89. There was excellent agreement according to severe/more severe disease activity at patient and physician level (kappa 0.88 (CI 95% 0.79–0.98). There was also good to excellent agreement according to low disease activity/remission at patient and physician level (kappa 0.74 (CI 95% 0.62–0.86).
**Conclusions:** Although, features of AOSD seems more complex with constitutional symptoms, joint or reticuloendothelial system involvement, patients and physicians assess level of disease activity similarly. We thought, this results will be helpful for procedure of new composite index in AOSD.

## THU0587 CLINICAL CHARACTERIZATION OF CASTLEMAN'S DISEASE IN A GROUP OF PEDIATRIC PATIENTS

V.I. Burlakov, A.L. Kozlova, A.J. Shcherbina, A. Kozlova, D. Abramov, N. Miakova, A. Maschan, A. Shcherbina. *Immunology, Federal Research and Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation*

**Background:** Castleman's disease (CD) is a rare lymphoprolipherative mostly benign disorder presenting in two major forms: localized (unicentric) and systemic (multicentric). Based on pathomorphological finding it is classified as hyaline-vascular, plasma cell or mixed type. The age of onset can differ greatly from infancy to adulthood. Except for lymph node hyperplasia, patients with CD can also develop such symptoms as anemia, fatigue, hepatosplenomegaly, low-grade fevers and other systemic symptoms.
**Objectives:** Analysis of clinical manifestations, pathomorphology and treatment efficiency in a group of pediatric patients.
**Methods:** We conducted a retrospective analysis of 12 patients (11 boys and 1 girl) with histologically confirmed cases of Castleman's disease.
**Results:** Age of onset varied from the moment of birth to 16 years (median 8,5 years) 8 patients had unicentric form of disease, 3 had multicentric form and one patient had two groups of lymph nodes affected, thus could not be precisely classified. The majority of the patients (9 patients) had hyaline-vascular variant of CD, one patient had plasma-cell type and two patients had the mixed pathomorphological type. The reason for seeking medical attention in three patients was visible unilateral enlargement of neck lymph nodes, four patients initially presented with anemia, fatigue, fever and laboratory signs of inflammation, and in 4 patients enlarged lymph nodes were incidentally visualized during control X-ray, and no other symptoms of CD were present. Interestingly, of 3 patients with multicentric form of CD, two had underlying primary immunodeficiency – Wiskott-Aldrich syndrome (WAS). They presented with plasma cell type and mixed type of CD, respectively. No immunodeficiency has been proven in other patients. We have conducted tests to indicate HHV VIII in affected lymph node biopsies and blood samples via PCR in half of the patients and none occurred to be positive.
*Treatment:* The affected lymph nodes were completely excised surgically in 7 patients with unicentric form, with no relapse of the disease on follow-up. Both patients with WAS received rituximab treatment followed by bone marrow transplantation, which was originally planned as a treatment of WAS, with remission on follow-up at 3 month and 2 years, respectively. Third patient with multicentric form received several courses of anti-cytokine and immunosuppressive treatment including tocilizumab, cyclophosphamide, vincristine and prednisolone (total of 5 blocks), rituximab (6 infusions) with partial effect, then surgical excision of large conglomerates of lymph nodes followed by bortezomib and bendamustine (total of 6 blocks) with positive effect. However at the one year follow-up patients demonstrated enlarged lymph nodes again, so she was started on JAK tyrosine kinase inhibitor ruxolitinib. Follow-up results are pending.
**Conclusions:** Our analysis of a group of pediatric patients demonstrates great variability in symptoms and severity of the disease. Castleman's disease is a disorder with poorly studied pathogenesis. Based on our experience, the role of primary defects of immune system in development of CD requires further investigation.

## THU0588 IGG4-RELATED DISEASE: FEATURES AND TREATMENT RESPONSE IN AN ASIAN COHORT

W. Fong [1,2,3], I. Liew [4], D. Tan [1,3,5], K.H. Lim [6], A. Low [7], Y.Y. Leung [1,2,3]. *[1] Duke-NUS Medical School; [2] Rheumatology and Immunology, Singapore General Hospital; [3] Yong Loo Lin School of Medicine, National University of Singapore; [4] Singapore General Hospital, Singapore, Singapore; [5] Department of Gastroenterology and Hepatology; [6] Department of Pathology; [7] Department of Diagnostic Radiology, Singapore General Hospital, Singapore, Singapore*

**Background:** Most descriptions of IgG4-related disease (IgG4-RD) have been from Japanese and Caucasian populations.
**Objectives:** To describe the clinical, laboratory, histological features and treatment outcomes of IgG4-RD in multi-ethnic Asian patients in Singapore.
**Methods:** Patients diagnosed with IgG4-RD were identified from a Rheumatology and Gastroenterology patient database in a tertiary hospital. Demographics, clinical manifestations, laboratory results, disease activity, clinical outcomes and therapeutics used were derived from medical records. Disease activity was assessed by the IgG4-RD Responder Index.
**Results:** 42 patients (76% male) were included; all had a diagnosis of IgG4-RD made by a rheumatologist or gastroenterologist experienced in IgG4-RD. 79% and 17% fulfilled the 2011 comprehensive diagnostic criteria for IgG4-RD[1] for definite and probable IgG4-RD respectively. 81% were Chinese and 19% were Malays. Mean age of the cohort was 62.7 ± 13.1 years. Mean age of diagnosis was 57.5 ± 12.8 years. Mean duration of disease was 4.5 ± 3.5 years. Common initial manifestations included jaundice (52%), abdominal pain (36%), swollen salivary glands (26%) and constitutional symptoms (21%). Only 36% had a history of allergy. 83% had $\geq$1 organ involvement, including autoimmune pancreatitis (67%), lymphadenopathy (45%), sclerosing cholangitis (43%), sialadenitis (31%) and dacryoadenitis (21%). 86% (6/7) of patients with isolated lesions involved only the pancreas. There was no gender difference in type of organ involvement. Erythrocyte sedimentation rate (ESR), IgG1, IgG2, IgG3, IgG4 levels were elevated in 83%, 22%, 74%, 37%, 41% of patients respectively. IgG4 levels did not correlate with ESR, age, disease duration, IgE levels and number of organs involved. The most common histopathological feature was that of $>$10 IgG4+ cells per high power field (66%), followed by lymphocytic infiltration (51%) and storiform fibrosis (51%). Only 7% had obliterative phlebitis. 94% (34/36) of patients were treated with moderate to high doses of glucocorticoids, including 17 patients with combination immunosuppressants. Of these, all patients responded to therapy by 3 months. With a mean follow-up of 4.8 ± 3.1 years, 69% (25/36) needed low dose of glucocorticoids to maintain disease remission. 26% had relapse of disease, of which 82% had disease recurrence in the same organs.
**Conclusions:** Pancreatitis, lymphadenopathy and cholangitis were the commonest manifestations in Asians with IgG4-RD. All patients responded to glucocorticoid therapy by 3 months, two-thirds required maintenance therapy with glucocorticoids, and one-quarter developed relapse of disease.

## THU0589 INFLIXIMAB THERAPY FOR NEURO-, VASCULAR, AND INTESTINAL BEHÇET'S DISEASE: EFFICACY, SAFETY, AND PHARMACOKINETICS IN A MULTICENTER PROSPECTIVE STUDY

Y. Ishigatsubo [1], S. Hirohata [2], H. Kikuchi [3], U. Tateishi [4], N. Sato [5], K. Ozaki [5], K. Kondou [5], T. Hibi [6]. *[1] Yokohama City University; [2] Department of Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Yokohama; [3] Department of Internal Medicine, Teikyo University School of Medicine; [4] Department of Diagnostic Radiology and Nuclear Medicine, Tokyo Medical and Dental University Graduate School of Medicine, Tokyo; [5] Mitsubishi Tanabe Pharma Corporation, Osaka; [6] Center for Advanced IBD Research and Treatment, Kitasato University Kitasato Institute Hospital, Tokyo, Japan*

**Background:** Behçet's disease (BD) is a multisystem disease characterized by mucocutaneous, ocular, neurologic, vascular, or gastrointestinal manifestations. Involvement of the neuronal (NBD) and vascular (VBD) systems and intestinal tract (intestinal BD) is rare, although such cases tend to have a poor prognosis.
**Objectives:** We conducted a prospective multicenter clinical trial to determine the efficacy, safety, and pharmacokinetics of infliximab (IFX) in BD patients with these serious complications who had displayed poor response or intolerance to conventional therapy (ClinicalTrials.gov, NCT01532570).
**Methods:** IFX at 5 mg/kg was administered to 18 patients (3 NBD [2 acute and 1 chronic progressive], 4 VBD, and 11 intestinal BD) at Weeks 0, 2, and 6 and every 8 weeks thereafter until Week 46. In patients who showed inadequate responses to IFX after Week 30, the dose was increased to 10 mg/kg. We then calculated the percentage of complete responders according to the predefined criteria depending on the symptoms and results of examinations (ileocolonoscopy, brain MRI, CT angiography, positron emission tomography, cerebrospinal fluid, CRP, or ESR), exploring the percentage of complete responders at Week 30 as the primary endpoint.
**Results:** The percentage of complete responders was 61% (11/18) at both Weeks 14 and 30 and remained the same until Week 54. By BD type, the percentage of complete responders at Week 30 was 33% (1/3) among NBD patients, 100% (4/4) among VBD patients, and 55% (6/11) among intestinal BD patients. In acute NBD patients, IFX lowered the cell count and IL-6 concentrations in the cerebrospinal fluid and inhibited the onset of attacks. In a chronic progressive NBD patient, IFX lowered cerebrospinal fluid IL-6 concentrations along with inhibition of progression of clinical symptoms and brainstem atrophy. VBD patients showed improvement in clinical symptoms at an early stage (Week 2) with reductions in serum CRP levels and ESR. Accordingly, positron emission tomography/CT imaging studies showed reversal of inflammatory changes in three of the four VBD patients. Intestinal BD patients also showed improvements in clinical symptoms along with decrease in serum CRP levels after Week 2. Consistently, scarring or healing of the principal intestinal ulcer in each patient was found in more than 80% of these patients after Week 14. Irrespective of the type of BD, all patients achieved improvements in visual analogue scale and Short Form 36 scores, leading to the dose reduction or complete withdrawal of steroids. IFX dose was increased to 10 mg/kg in three intestinal BD patients, resulting in improvement of clinical symptoms, CRP level, and visual analogue scale score. Safety and pharmacokinetics profiles were comparable to those in patients with rheumatoid arthritis or Crohn's disease.

Table: Proportion of complete responders

| | Complete responders | | | | | |
|---|---|---|---|---|---|---|
| | | NBD | | | | |
| | All three types | All NBD | Acute NBD | Chronic progressive NBD | VBD | Intestinal BD |
| Week 14 | 61% (11/18) | 33% (1/3) | 0% (0/2) | 100% (1/1) | 100% (4/4) | 55% (6/11) |
| Week 30 (Primary endpoint) | 61% (11/18) | 33% (1/3) | 0% (0/2) | 100% (1/1) | 100% (4/4) | 55% (6/11) |
| Week 54 | 69% (11/16) | 50% (1/2) | 0% (0/1) | 100% (1/1) | 100% (4/4) | 60% (6/10) |
| Final point of 5 mg/kg therapy | 67% (12/18) | 33% (1/3) | 0% (0/2) | 100% (1/1) | 100% (4/4) | 64% (7/11) |

NBD, neuro-Behçet's disease; VBD, vascular Behçet's disease; intestinal BD, intestinal Behçet's disease

**Conclusions:** The results demonstrate that IFX is effective and well tolerated in the treatment of recalcitrant NBD, VBD, and intestinal BD with poor response or intolerance to conventional therapy. IFX may therefore represent a promising new therapeutic option for use in BD patients with these serious complications.

## THU0590 RISK FACTORS FOR CYTOMEGALOVIRUS REACTIVATION IN PATIENTS WITH CONNECTIVE-TISSUE DISEASES

Y. Ota, Y. Kaneko, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Intensive immunosuppressive treatment for remission induction in connective tissue diseases (CTDs) sometimes causes serious infection. Cytomegalovirus (CMV) is a herpesvirus remaining latent after primary mild or asymptomatic infection, and the reactivation of CMV is one of the problematic opportunistic infections in immunocompromised patients. However, little is known

about risk factors for CMV reactivation, therefore, identifying patients at risk for CMV reactivation is of importance.
**Objectives:** To investigate risk factors relevant with CMV reactivation in patients with CTD during remission induction therapy.
**Methods:** All hospitalized patients with CTD who started immunosuppressive agents as induction therapy from 2012 until 2015 were retrospectively reviewed. Clinical information were collected from their medical charts. CMV reactivation was defined by the detection of CMV PP65 antigen in polymorphonuclear leukocytes from peripheral blood. Risk factors for CMV reactivation were statistically analyzed.
**Results:** A total of 170 CTD cases with CMV pp65 measured during the induction therapy were enrolled in the analysis. Mean age was 56.9±16.9 years old and the female ratio was 68.8%. The CTDs were 43 systemic lupus erythematosus (25.3%), 35 antineutrophil cytoplasmic antibody -associated vasculitis (20.6%), 21 polymyositis/dermatomyositis (12.4%), 20 rheumatoid arthritis (11.8%), 10 adult-onset Still's disease 10 (5.9%), and 41 others 41 (24.1%). 112 cases (65.9%) were new-onset. All cases were treated with moderate to high dose of glucocorticoid (mean prednisolone (PSL) dose, 50.1±10.8 mg/day). Methylprednisolone (mPSL) pulse therapy was conducted in 56 (33.9%), and concomitant immunosuppressants were used in 113 (68.5%).
CMV was reactivated in 64 (37.6%) including 16 CMV infection (bone marrow suppression 12, pericarditis 2, liver injury 1, retinitis 1). Multivariate logistic analysis identified initial PSL dose (p=0.003, OR 1.066) and lower baseline serum albumin level (p=0.023, OR 1.946) as an independent risk factor for CMV reactivation. Among 34 patients who were observed without antiviral treatment, 11 required ganciclovir during the course owing to the exacerbation of CMV disease. The lymphocyte count at 2 week after the initiation of immunosuppressive therapy in those 11 cases was significantly less than the 23 cases in whom CMV disappeared spontaneously (710±709/μl vs 1116±766/μl, p=0.016).
**Conclusions:** The study demonstrates the risk factors for CMV reactivation in CTD patients treated with intensive immunosuppressive therapy. The results lead us to improve the management of opportunistic infection in immunosuppressed patients with CTD.

### THU0591 CLINICAL FEATURES OF ERYTHEMA NODOSUM IN SARCOIDOSIS

Y. Karpova, B. Belov, O. Egorova, S. Radenska-Lopovok. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Erythema nodosum (EN) is a type of septal panniculitis with multiple underlying etiological trigger factors. Combination of EN with involvement of ankle joints, fever and intra-thoracic lymphatic nodes (ITLN) is known as the Lőfgren syndrome. This syndrome is associated with acute clinical course of sarcoidosis, which usually does not require a morphological confirmation.
**Objectives:** To analyze specific clinical features of EN in sarcoidosis patients.
**Methods:** 125 EN patients (M-21,F-104), aged 18 - 69 years associated with sarcoidosis were examined. All patients were subjected to standard diagnostic clinical examination and lab procedures, including chest computed tomography (CT).
**Results:** Mean age of patients was 42±12 years. Disease duration up to 1 month was documented in 35% patients, 1- 3 months – in 41%, >3 months – in 20%. Range of complaints included cough – in 24% patients, and fatigue – in 10%. Dyspnea, sweating, myalgia, and sore throat were found in 5% of patients each, respectively. Skin lesions typically occurred on the lower leg (96%), but also on the thighs (35%), the upper limbs (24%), and on the trunk (3%). Average number of nodules was 15±13. More than 10 nodules in number were documented in 64% of cases. Dense aggregation of nodules was found in 46% patients. The VAS score was 45±28 mm. Acute EN course was documented in 20% of cases, subacute - in 62%, and chronic – in 18% of patients. Distribution of joints involved looks as follows: ankles – 92%, shoulder – 11%, small joints in the hand and feet– 3%. CT findings included enlarged ITLN in 65% of cases, ground glass opacity (GGO) pulmonary lesions- in 35%. GGO pulmonary lesions predominated in male patients (30%), ($p$=0,004 R=0,25), demonstrating nodule-aggregation pattern in the majority of cases ($p$=0,0009 R=0,29). In patients with isolated ITLN involvement, cough ($p$=0,0048 R=0,25), and subacute course ($p$=0,016 R=0,22) were the special clinical features of the disease.
**Conclusions:** combination of ankle joints involvement, fever, and EN necessitates thoracic CT, as in 1/3 of such patients lungs would inevitably be involved. Male gender and EN aggregation pattern are most likely indicative of the emergence of GGO-symptom.
**Disclosure of Interest:** None declared

## Epidemiology, health services and outcome research

### THU0593 VALIDITY OF THE BRISTOL RA FATIGUE MULTI-DIMENSIONAL QUESTIONNAIRE (BRAF-MDQ) AND RHEUMATOID ARTHRITIS IMPACT OF DISEASE (RAID) SCALE ACROSS 6 EUROPEAN COUNTRIES

S. Hewlett[1], J. Nicklin[1], C. Bode[2], F. Cramp[1], L. Carmona[3], B. Davis[4], E. Dures[1], M. Engelbrecht[5], J. Fransen[6], R. Greenwood[4], S. Hagel[7], J. Kirwan[8], M. van de Laar[2], A. Molto[9], I. Petersson[7], M. Redondo[10], G. Schett[5], L. Gossec[9]. *[1]University of the West of England, Bristol, Bristol, United Kingdom; [2]University of Twente, Twente, Netherlands; [3]3Instituto de Salud Musculoesquelética, Madrid, Spain; [4]Bristol Royal Infirmary, Bristol, United Kingdom; [5]University of Erlangen, Nuremburg, Germany; [6]Radboud University, Nijmegan, Netherlands; [7]Lund University, Lund, Sweden; [8]Bristol Universiot, Bristol, United Kingdom; [9]University of Paris, Paris, France; [10]Universidad Camilo, Madrid, Spain*

**Background:** The BRAF-MDQ[1,2] and RAID[3] are patient-reported outcome measures derived from the patient perspective. The 20 item BRAF-MDQ has 4 factors (physical, cognitive, emotional fatigue, living with fatigue) and the 7 item RAID is uni-dimensional. The BRAF-MDQ properties have not been tested outside the UK, nor the validity of the new Swedish RAID examined.
**Objectives:** To test the structure, construct and criterion validity of the BRAF-MDQ and the RAID in 6 EU countries.
**Methods:** Survey of RA clinic patients in clinics in France, Germany, Netherlands, Spain, Sweden and UK (F, G, N, Sp, Sw, UK), using BRAF-MDQ, RAID and SF-36. Factor structure examined by Confirmatory Factor Analysis and internal consistency by Cronbach's Alpha. Criterion validity for the BRAF-MDQ evaluated by internal Spearman's correlations, and for BRAF-MDQ and RAID fatigue item by correlation with each other and SF-36 Vitality subscale. Construct validity of BRAF-MDQ and RAID evaluated by Spearman's Correlation with each other, HAQ, and SF-36 domains. Analysis conducted overall and by individual country and for BRAF-MDQ by total and subscales.
**Results:** 1276 patients participated: F 206, G 216, N 317, Sp 157, Sw 170, UK 210. Disease duration <5 yrs for 25%, 76% female, median HAQ 1.0 (IQR 0.375–1.5). Mean total BRAF-MDQ was 26/70 (SD 26) with subscales physical fatigue 11.38/22 (SD 5.77), living with fatigue 6.46/21 (SD 5.4), cognitive 4.28/15 (SD 8.7) and emotional fatigue 3.41/12 (SD 3.22). Mean RAID was 4.15/10 (SD 2.31).
Confirmatory factor analysis: BRAF-MDQ original UK 4 factor structure was confirmed in each country, demonstrating one factor for each set of variables, with high factor loadings (0.71–0.96). Bootstrapping (4 sets of analyses on 20 random samples of 50% of patients/country), found the structure held true in at least 19/20 sets per country. RAID single factor structure was confirmed in all countries (0.75–0.95). Internal consistency ranged from 0.75–0.96 for the BRAF-MDQ (total and subscales) and the RAID ranged from 0.93–0.96 (overall and by country).
Criterion validity overall and by country: The BRAF-MDQ correlated internally and with the SF-36 Vitality and RAID fatigue items (0.6–0.93). Construct validity: BRAF-MDQ and RAID correlatied with each other, the HAQ, and remaining 8 SF36 domains (0.46–0.86).
**Conclusions:** The BRAF-MDQ and RAID demonstrate strong, consistent factor structure and internal consistency, with moderate-good criterion and construct validity across 6 EU countries, reflecting their robust methods of development. This indicates no specific country scoring is necessary, and strengthens the case for measuring both fatigue and impact in multi-country studies.

### THU0594 TOWARDS DEVELOPMENT OF A MINIMUM CORE DATASET AND STANDARDS OF DATA COLLECTION FOR OBSERVATIONAL RHEUMATOID ARTHRITIS RESEARCH – A EULAR INITIATIVE

H. Radner, E. Nikiphorou, K. Chatzidionysiou, L. Gossec, K. Hyrich, C. Filip, Y. van Eijk-Hustings, P. Williamson, W. Dixon, J. Askling on behalf of EULAR Task Force for Standardising Minimum Data Collection in Rheumatoid Arthritis Observational Research. *EULAR, Zurich, Switzerland*

**Background:** Collaborative research is compromised by heterogeneity of data collection in observational rheumatoid arthritis (RA) databases. Therefore a EULAR taskforce has been convened to develop a minimum core dataset (MCD) to 1) harmonize future data collection 2) act as a common data model existing databases can be mapped to 3) serve as a template for standardized data collection for RA research in clinical practice.
**Objectives:** To identify data items (i.e. "what to collect") and instruments (i.e. "how to collect") for inclusion in a MCD using an online survey.

**Abstract THU0594** – Table 1. Frequency of rating importance of items/instruments to include in a MCD from 1 (not important) to 9 (very important)

| ITEM | Rate 1–3 | Rate 7–9 | ITEM | Rate 1–3 | Rate 7–9 | ITEM | Rate 1–3 | Rate 7–9 |
|---|---|---|---|---|---|---|---|---|
| Diagnosis of RA | 0% | 100% | Quality of life | 3% | 95% | MSK ultrasound | 22% | 66% |
| Composite Score | 0% | 100% | selected comorbidities | 4% | 93% | BMI | 5% | 65% |
| Tender joint count | 0% | 100% | x-ray hand /feet | 4% | 92% | Occupational therapy | 21% | 64% |
| Swollen joint count | 0% | 100% | NSAIDs | 8% | 90% | Chest-xray | 26% | 63% |
| Patient global | 0% | 99% | Smoking | 0% | 89% | Treatment not related to RA | 22% | 63% |
| Physical function | 1% | 99% | Symptom duration | 7% | 86% | Physiotherapy | 21% | 63% |
| Acute phase reactants | 0% | 99% | Extra-articular manifestation | 6% | 86% | Psychological /Emotional therapy | 19% | 61% |
| Current DMARD | 0% | 99% | Work productivity | 4% | 82% | Physical exercise | 12% | 57% |
| Steroids | 0% | 99% | Joint surgery | 13% | 82% | Grip strength | 21% | 57% |
| Disease duration | 0% | 97% | Fatigue | 3% | 81% | Charlson comorbidity index | 18% | 54% |
| Evaluator global | 0% | 97% | Morning stiffness | 3% | 81% | Podiatry | 29% | 51% |
| Serology | 0% | 97% | Adverse events | 13% | 81% | MRI of joints | 28% | 49% |
| DMARD history | 1% | 97% | Family history | 14% | 79% | Alcohol intake | 7% | 47% |
| Gender | 2% | 96% | Ethnicity | 12% | 69% | Sexual life | 18% | 46% |
| Pain | 1% | 96% | Vaccination | 14% | 68% | Martial status | 41% | 31% |
| Age | 0% | 95% | Socio-economic status | 9% | 67% | Diet | 35% | 27% |

**Methods:** First we performed a hierarchical literature review to identify data items and instruments of existing RA cohorts/registers. Extracted data presented in a separate abstract were used to develop an online survey to gather information from an expert panel involving Presidents of National Societies and selected representatives from each European country, patients, rheumatologists, other health professionals, and researchers. Experts were asked to rate importance of 48 different items and their instruments for possible inclusion in a MCD on a scale from 1 (not important) to 9 (very important). For analyses ratings of 1–3 (NO inclusion) and of 7–9 (INCLUSION) were combined and percentages of responses calculated.
**Results:** 90 experts from 28 different European countries (patients 18%, health professionals 18%, physicians 55%, researchers 10%) participated in the survey. 27/48 items were regarded to be important for inclusion in a MCD by >80% of responders. Highest level of agreement to INCLUDE an item was found for: diagnosis of RA, composite scores, tender and swollen joint count (100%; table). Discrepancies of rating were observed for instruments: 24/126 instruments were rated as important for inclusion by >80% of responders.
**Conclusions:** Based on expert ratings the majority of items were considered appropriate for inclusion into a MCD, leading to an extensive template. For most instruments no consensus was achieved. Results of the survey were moved forward onto the next phase of the project.

## THU0595 IMPACT OF PHYSICIAN-PATIENT INTERACTIONS ON DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Drenkard[1], G. Bao[1], H. Kan[2], B. Pobiner[3], P. Julie[3], W. Eastman[3], S.S. Lim[1]. *[1]Rheumatology, Emory University, Atlanta; [2]Health Policy and Management, Johns Hopkins Bloomberg School of Public Health, Baltimore; [3]US Medical Affairs, GSK, North Carolina, United States*

**Background:** Physician-patient interactions can influence both quality of care and patient self-management decisions, which in turn can impact patients' health outcomes.
**Objectives:** Examine the influence of physician-patient interactions on disease activity in a sample of SLE patients at high risk for poor outcomes.
**Methods:** The Georgians Organized Against Lupus (GOAL) is a predominantly African-American (AA) cohort largely drawn from a population-based registry of patients with SLE in Atlanta, GA, US. A subset of 125 GOAL participants from the most recent survey collection were provided two validated patient-reported multidimensional surveys to complete. The Interpersonal Processes of Care (IPC) was used to assess patient perceptions of their interactions with physicians within 3 domains: Communication, Shared Decision Making and Interpersonal Style. The Systemic Lupus Activity Questionnaire (SLAQ) was used to measure disease activity and SLAQ scores were adjusted for age, disease duration, sex, race, education, and insurance.
**Results:** 97 (78.2%) participants were AA, 19 (15.3%) Caucasian, and 8 (6.5%) of other races. The IPC survey results indicate that patient perceptions were associated with the extent of their SLE disease activity (see table below; p-values <0.05 are starred).
**Conclusions:** Higher IPC scores indicating hurried communication were associated with higher disease activity, while higher IPC scores indicating effective and compassionate patient-centered interactions were associated with lower disease activity. Our findings highlight the potential impact of physician-patient interaction on SLE outcomes as perceived by the patient.

## THU0596 PHYSICIAN'S GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS, REFLECTS SOLELY OBJECTIVE MEASURES AND DISREGARDS PATIENT REPORTED OUTCOMES

G. Eugenio[1], R. Ferreira[1,2], C. Silva[3], C. Duarte[1,3], J.A.P. Silva[1,3]. *[1]Department of Rheumatology; [2]Health Sciences Research Unit: Nursing (UICiSA:E); [3]Clínica Universitária de Reumatologia, Faculty of Medicine, University of Coimbra, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

**Background:** Physician's global assessment of disease activity (PhGA) has been shown to be a determinant factor for therapeutic decisions in Rheumatoid Arthritis (RA). The adequacy of this assessment is, therefore crucial, to assure that the best options are taken in the perspective of the patient's interest.
**Objectives:** To evaluate the determinants of PhGA, including clinical variables and patient reported outcomes.
**Methods:** Consecutive RA patients followed in a Tertiary Rheumatology Department were included in this cross-sectional study. Patient demographics and clinical assessments were collected through a standardized protocol which included age, gender, disease duration, DAS(28)4v-CRP (and its individual measures), DAS(28)4v, pain (VAS 0–100mm), Patient Global Assessment (PGA) of disease activity (VAS 0–100mm) and function (Health Assessment Questionnaire (HAQ)). From physicians were collected PhGA (VAS 0–100 mm), summary score of the patient's mobility and deformity (VAS 0–100mm).
To identify independent predictors of PhGA, Pearson's Correlation Coefficient was used to select variables ($p<0.05$) to subsequent inclusion in multivariable linear regression (stepwise model).
**Results:** 311 patients were included: 81.7% females, 60±12 years, 11±9 years of disease duration, 8±5 years of formal education and a mean DAS(28)4v-CRP=2.9±1.2. PhGA was statistically and strongly associated only with swollen joint count (SJC28) (r=0.71). Moderate correlations were observed with tender joint count (TJC28) (r=0.41), DAS(28)3v–CRP (r=0.655) and DAS(28)3v (r=0.550). Weak correlations ($r<0.4$) were observed with pain, PGA, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and HAQ, as well as with mobility and deformity in the physician's perspective. In multivariable analysis, SJC28 ($\beta$=5.02, 95%CI: 4.29;5.73, $p<0.001$) and CRP ($\beta$=3.0, 95%CI: 1.56;4.46,

Table 1. Multivariable linear regression (stepwise model) to explain PhGA in RA patients

| Variable | Adjusted R-Squared | p-value | β | p-value | 95% CI for β | |
|---|---|---|---|---|---|---|
| | | | | | Lower bound | Upper bound |
| SJC28 | 0.747 | <0.001 | 5.02 | <0.001 | 4.29 | 5.73 |
| CRP (mg/dl) | | | 3.0 | <0.001 | 1.56 | 4.46 |
| PhGA mobility | | | 0.085 | 0.04 | 0.027 | 0.14 |

p<0.001) were the most significant predictors of PhGA, with a small contribution of the physicians assessment of patient mobility.
**Conclusions:** Physicians consider objective measures when assessing disease activity, apparently disregarding pain and the PGA. This may lead to suboptimal management approaches from the patient's perspective, especially regarding disease dimensions that are not directly affected by immunosuppressive therapy.

## THU0597 COMPARAISON OF SELF ASSESSMENT OF DISEASE ACTIVITY TO DAS28 IN RHEUMATOID ARTHRITIS: DATA FROM THE RANDOMIZED "ROC" TRIAL

C. Sordet[1], E. Chatelus[1], P. Ravaud[2], J. Sibilia[1], J.-E. Gottenberg[1] on behalf of the ROC Trial Investigators. *[1]University Hospital, Strasbourg; [2]Hotel Dieu, Paris, France*

**Background:** In rheumatoid arthritis (RA), self assessment of disease activity by patients could be useful in clinical practice. Data in literature regarding the relevance of self-assessment remain limited. We therefore addressed this issue in the Rotation Or Change of biologics (ROC) trial.
**Objectives:** To compare self-assessment of disease activity by patients to assessment of disease activity by physicians in RA.
**Methods:** The ROC trial randomized patients with an insufficient response to a 1st anti-TNF to receive either a second anti-TNF or a non-TNF targeted biologic. At enrollment in the trial, a very brief oral information on self assessment of disease activity, along with a short written reminder, was provided to patients. Within 2 weeks of enrollment and at 6 months, patients received a phone call by a clinical research technician to collect the self-DAS28 (patient-derived DAS28). The clinical research technician was unaware of the arm of randomization and of the result of the DAS28. The concordance between self-DAS28 and DAS-28-ESR assessed by the physician was analyzed using the Bland and Altmann method.
**Results:** At enrollment, self-DAS28 was collected in 97 patients treated with a non TNF-targeted biologic and in 94 patients treated with a second anti-TNF. Mean (SD) self-DAS28 was 4.97 (1.46) and mean DAS28-ESR assessed by the physician was 5.06 (1.10). The systematic difference between self DAS-28 and DAS28 (statistically significant if the confidence interval does not include 0) was -0.11 [-0.29; 0.07]. Thus, self-DAS28 at enrollment sligthly but not significantly underestimated DAS28 assessed by the physician.
At 6 months, self-DAS28 was collected in 91 patients treated with a non TNF-targeted biologic and in 84 patients treated with a second anti-TNF. Mean (SD) self-DAS28 was 3.82 (1.56) and mean DAS28-ESR assessed by the physician was 3.53 (1.40). The systematic difference between self DAS-28 and DAS28 was 0.29 [0.09; 0.46]. Thus, self-DAS28 sligthly but not significantly overestimated DAS28 at 6 months.
**Conclusions:** Self-assessment of disease activity by patients, even without a long period of training, provides a correct appreciation of genuine disease activity in RA. Self-assessment of disease activity could be helpful for patients to have a better perception of disease activity between times of referrals to their rheumatologist, and might therefore contribute to optimize disease control in RA.

## THU0598 VARIATIONS IN POLICIES AND SOCIAL SECURITY REGULATIONS FOR PATIENTS WITH RHEUMATOID ARTHRITIS THAT EXPERIENCE RESTRICTIONS IN WORK PARTICIPATION: RESULTS FROM A SURVEY ACROSS 44 COUNTRIES OF THE EUROPEAN REGION

P. Putrik[1], S. Ramiro[2], F. Guillemin[3], M. Péntek[4], F. Sivera[5], M. de Wit[6], A. Woolf[7], A. Zink[8], T. Sokka[9], A. Boonen[1] on behalf of Working Group Access to Social Security for patients with RA across Europe. *[1]MUMC, Maastricht; [2]Leiden University Medical Center, Leiden, Netherlands; [3]University of Lorraine, Nancy, France; [4]Corvinus University, Budapest, Hungary; [5]Hospital General Universitario de Elda, Alicante, Spain; [6]Patient Association Reumazorg Nederland, Nijmegen, Netherlands; [7]Royal Cornwall Hospital, Truro, United Kingdom; [8]DRFZ, Berln, Germany; [9]Jyväskylä Central Hospital, Jyväskylä, Finland*

**Background:** Despite important influence of country of residence on labour force participation among patients with RA, no attempt has been made to understand the role of national policies and social security (SS) systems. We hypothesized that: 1) access to SS depends on the type of SS system; 2) wealthier countries offer more facilities to maintain work but also easier access to income compensation; 3) work retention and SS policies have an impact on sick leave (SL) and long-term work disability (WD).
**Objectives:** To explore regulations in SS including availability of work support facilities to maintain paid employment and income substitution in relation to SL and WD.
**Methods:** A survey was conducted among countries of the European WHO Region (n=50). One rheumatologist per country completed a questionnaire about regulations related to SS for RA patients, including efforts to support employment, criteria for eligibility as well as level and duration of income compensation. To investigate whether the regulations differed by the type of SS system (Anglo-Saxon, Bismarckian, Mediterranean, Post-Communist, and Scandinavian), country's wealth (Gross Domestic Product (GDP)) or national disability/employment rates, correlations or subgroup comparisons were done with t-test/Mann-Whitney and chi-square/Fisher's test, as appropriate.
**Results:** Forty-four (28 EU and 16 non-EU member states) countries (88%) provided data. While all countries had arrangements to support patients with restrictions to work, large heterogeneity was observed in all specific regulations (Table). Twenty-nine (66%) and 26 (59%) countries had a requirement for employment history or social insurance contributions to be eligible for SL or WD compensation, respectively. Maximum SL length before transition to WD varied from 3 to 36 months (mean (SD) 13 (9)). Compensation for SL and WD varied from 25 to 100% and 18% to 100% of previous income, respectively. Although the majority of countries had facilities to support patients with RA in paid employment (n=33, 75%), only in a quarter of countries rehabilitation efforts were obligatory to qualify for WD. No relationship was found between any of these regulations and the type of SS system, GDP or rates of disability and employment.
The table shows the regulations related to sick leave in 44 countries of the European region.

| Regulation | N (%) |
|---|---|
| Rheumatologist authorized to certify sick leave | 33 (75%) |
| Minimal income compensation for sick leave, <70% | 15 (34%) |
| First 1-3 days of sick leave unpaid | 11 (25%) |
| Obligatory rehabilitation before work disability assessment | 11 (25%) |
| Minimum duration SL before work disability assessment | 22 (50%) |
| Factors accounted for in work disability assessment: | |
| Profession | 25 (57%) |
| Diagnosis | 31 (70%) |
| Physical disability | 33 (75%) |
| Physical ability | 18 (41%) |
| Earning capacity | 12 (27%) |
| Age and/or Sex | 19 (43%) |
| Income compensation | |
| In case of moderate (50%) work disability, <70% | 23 (74%) |
| In case of severe (75%) work disability, <70% | 16 (52%) |

**Conclusions:** Three quarters of countries had facilities to support employment while all countries had income compensation schemes. Large heterogeneity was observed in most regulations including income compensation. Differences in SL and WD in RA patients seem not to be explained by differences in work retention facilities nor social by security system. Inequalities in support and income compensation call for a platform to harmonize policies for patients with RA who experience restrictions in work participation.

## THU0599 KEY DRIVERS IN BIOSIMILAR PRESCRIPTION IN INFLAMMATORY AUTOIMMUNE DISEASES INDICATIONS IN GERMANY

E. Sullivan[1], J. Piercy[1], J. Waller[1], C. Black[2], S. Kachroo[2]. *[1]Adelphi Real World, Adelphi Real World, Macclesfield, United Kingdom; [2]Merck, Kenilworth, NJ, United States*

**Background:** There is currently limited evidence relating to, and thus understanding of, physician views on prescribing biosimilars in the real world.
**Objectives:** Our aim is to address this lack of understanding, specifically by describing rheumatologists' motivations to prescribe, and perceptions of, biosimilars for Rheumatoid Arthritis (RA), Axial Spondyloarthritis (AxSpA) and Psoriatic Arthritis (PsA).
**Methods:** The Adelphi Biosimilars Therapy Insight Programme uses a well-established methodology, similar to that used in over 100 separate projects, and contains real-world, cross-sectional survey data from 50 German rheumatologists who currently prescribe biosimilars, collected in Q4 2015 - Q1 2016 in RA, AxSpA and PsA. Rheumatologists report their use of current therapies, therapy preferences, as well as experiences with prescribing biosimilars, including their reasons for prescribing them.
**Results:** Rheumatologists reported that in the absence of restrictions or guidelines for 1st and 2nd line biologics their preference would be to prescribe bio-originator; only 8%, 18% and 20% stated a biosimilar would be their preferred 3rd line option for Ra, AxSpA and PsA respectively. However, despite these data on rheumatologist preference it was shown that when biosimilars were prescribed, it was in place of a 1st and 2nd line biologic in 88% and 69% of cases respectively. Key reasons for biosimilars prescribing were non-clinical with 77% of rheumatologists indicating cost related issues and 73% reported a desire to gain experience with biosimilars. Only 60% stated they prescribed biosimilars because they were convinced of equivalent efficacy with bio-originators. Respondents indicated that with increased discounts they would be more likely to prescribe biosimilars in stable patients. However, in patients where the bio-originator has failed, 18%

of rheumatologists would be motivated to prescribe the biosimilar if it was 10% cheaper than bio-originator. Rheumatologists (86%) said that they would consider using a biosimilar once they had decided to prescribe that therapy, but the availability of a biosimilar was unlikely to affect the choice of therapy prescribed.
**Conclusions:** The results clearly indicate that the main drivers for biosimilar use are cost and desire for experience. It is possible that the desire to gain experience in prescribing biosimilars is a consequence of physicians anticipating payer pressure to prescribe biosimilars in future, even in well controlled bio-originator patients. Physician preference is to prescribe bio-originators but cost savings are leading to their use, mainly in place of the bio-originator of the same therapy. We observed that the majority of rheumatologists are not convinced of the interchangeability of biosimilars as they preferred not to switch (and were unlikely to switch) well managed patients from bio-originators to biosimilars. Given the economic pressures towards prescribing biosimilars, it is critical that the impact of non-clinical switches be fully understood to ensure patients are not put at undue risk for economic reasons. Given that German physicians are responsible for drug prescribing budgets these data may help provide insights into modeling in other markets where clinicians have to work with other budget holders to decide on appropriate use of drugs.

## THU0600 PATIENTS' PERCEPTION AND SATISFACTION OF WAITING TIME AT MEDICAL OUTPATIENTS

R. Magro[1], J. Aquilina[2]. *[1]Rheumatology, Mater Dei Hospital; [2]Faculty of Economics, Management and Accountancy, University of Malta, Msida, Malta*

**Background:** Patient satisfaction is an important determinant of health care quality. Decreasing waiting time is imperative in achieving patient satisfaction.
**Objectives:** The aim of this study was to determine the mean waiting time at medical outpatients and to assess waiting time satisfaction. A further aim was to identify factors that affect the patients' perceived waiting time.
**Methods:** Data was collected through questionnaire responses from 190 patients attending medical outpatients between 20th March and 9th April 2013. This included demographic data, waiting time and service satisfaction, expected and perceived waiting time, level of boredom and comfort while waiting. Moreover the actual waiting time was noted by the observer. The relationship between expected and perceived waiting time; and between actual and perceived waiting time were in turn analyzed using scatter plots and correlation coefficients. Approval to carry out this study was obtained from the University Research and Ethics Committee.
**Results:** The participants had a mean age of 53 (range 19 to 86), of which 59% were females. On a 10-point Likert scale, the mean waiting time satisfaction was 7.1, while the mean service satisfaction was 9.3. The mean expected waiting time was 65 minutes and the mean perceived waiting time was 55 minutes. The mean actual waiting time was 51 minutes.This study revealed that as perceived waiting time increased, patient satisfaction tended to decrease consistently and significantly ($p<0.001$). On the other hand, regression analysis revealed that perceived waiting time has a positive and significant linear relationship with the actual waiting time ($p<0.001$) and the boredom levels of patients ($p<0.001$). Patients seated comfortably had a significantly lower perceived waiting time that those who were not ($p<0.001$). Perceived waiting time was not influenced by whether the patient was accompanied ($p=0.313$) or being seen for the first time ($p=0.712$). The patients reported that the provision of free tea or coffee, magazines or television, could help reduce boredom and divert their attention, thus reducing perceived waiting time and in turn enhancing satisfaction. 11% (21 patients) suggested that the operation of free wireless internet in the waiting areas would also reduce the level of their boredom during their wait.
**Conclusions:** Overall service satisfaction was extremely positive, while waiting time satisfaction was moderate. Although reducing the actual waiting time may be difficult, altering patients' perceived waiting time may be beneficial to increase their satisfaction. This could be done by increasing their comfort and decreasing their boredom while waiting.

## THU0601 WORK PARTICIPATION AFTER TWO YEARS IS EXCELLENT IN EARLY RA PATIENTS TREATED ACCORDING TO A TIGHT CONTROL STRATEGY, AND IMPROVED COMPARED TO PREVIOUS CLINICAL PRACTICE

S. Lillegraven[1], M.D. Mjaavatten[1], N. Sundlisæter[1], A.-B. Aga[1], I.C. Olsen[1], T. Uhlig[1], D.H. Solomon[2], T.K. Kvien[1], E.A. Haavardsholm[1] on behalf of the ARCTIC Study Group. *[1]Diakonhjemmet Hospital, Oslo, Norway; [2]Brigham and Women's Hospital, Boston, United States*

**Background:** Rheumatoid arthritis (RA) is a known cause of work productivity loss. Participation in work-related activities is defined as part of the primary goal of RA treatment in the 2015 treat to target recommendations (1).
**Objectives:** The objectives of the current study were to assess changes between baseline and 24 months in work participation in early RA treated according to a tight control treat to target strategy, and to compare sick leave rates to a cohort of early RA patients followed without treat to target.
**Methods:** We used data from two studies: the ARCTIC study (inclusion Oct 2010 – April 2013, RA patients fulfilling the 2010 ACR/EULAR classification criteria, symptom duration<2 years, DMARD-naïve with indication for DMARD) and the NOR-VEAC study (inclusion Oct 2004 – Aug 2010, patients included in the analyses fulfilled 2010 criteria for RA, had symptom duration <16 weeks and were DMARD-naïve). Data collection included patient reported outcomes with identical questions on work participation in both studies, clinical examination and laboratory assessment. In addition, the Work Productivity and Activity Impairment Questionnaire (WPAI) was recorded in ARCTIC. Absenteeism (work time missed) and presenteeism (impairment while at work) were calculated in ARCTIC at baseline and study completion, 24 months. We compared the proportion of patients reporting sick leave (among patients not reporting retirement or disability pension) across studies at baseline, 8 and 16 months, the time points with most data available in both cohorts, by chi-square test.
**Results:** The mean (SD) age for the 229 patients in ARCTIC was 51.4 (13.7) years, disease duration 7.1 (5.4) months, DAS28 4.4 (1.2), 61.1% were female and 86.2% seropositive. The 259 NOR-VEAC patients had shorter mean (SD) disease duration (2.0 (1.0) months, p-value <0.001), higher DAS28 (5.3 (1.3), p-value<0.001) and lower seropositivity rate (74.0, p-value <0.001). NOR-VEAC patients had comparable age (52.7 (14.1) years) and gender distribution (63.9% females) to ARCTIC. In ARCTIC, levels of presenteeism and absenteeism at 2 years were overall very low, with substantial improvement from baseline (figure). While 30.9% of employed patients reported 100% absenteeism at baseline, the corresponding number at 24 months was 3.7%. When comparing the cohorts after 16 months 14.5% of patients in ARCTIC and 26.1% of patients in NOR-VEAC reported sick leave (p-value 0.01). No difference in sick-leave was found between ARCTIC and NOR-VEAC at baseline (34% vs. 40%, p-value 0.24) but a trend was observed at 8 months (19.0 vs. 28.4%, p-value 0.06).

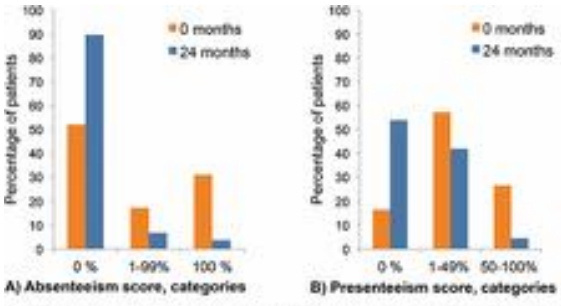

**Figure:** Absenteeism and presenteeism in ARCTIC patients at baseline and after 24 months. **A)** Absenteeism, results in employed patients. **B)** Presenteeism, results in patients with work attendance.

**Conclusions:** Patients with early RA participating in a tight control treat-to-target study reported very little work productivity loss after two years. After treatment, sick-leave rates with treat to target were significantly lower than in a previous cohort of early RA patients followed without implementation of such principles. The results support that patient care based on modern treatment strategies improves participation in work-related activities, a defined goal for RA treatment.

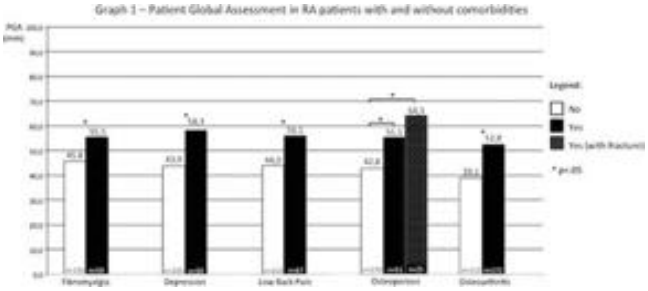
## THU0602 PATIENT GLOBAL ASSESSMENT IN RHEUMATOID ARTHRITIS CONVEYS A VARIABLE BLEND OF DISEASE ACTIVITY AND DISEASE IMPACT: A CROSS-SECTIONAL STUDY WITH 311 PATIENTS

R. Ferreira[1,2], C. Duarte[1,3], C. Silva[3], G. Eugénio[1], M. Ndosi[4], L. Gossec[5], J.A.P. da Silva[1,3]. *[1]Rheumatology, Centro Hospitalar e Universitário de Coimbra, EPE; [2]Health Sciences Research Unit: Nursing (UICiSA:E); [3]Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal; [4]School of Healthcare, University of Leeds, Leeds, United Kingdom; [5]Paris 06 University, Paris, France*

**Background:** Patient global assessment (PGA) is a key outcome measure in rheumatoid arthritis (RA) and the sole patient-reported outcome included in measures currently used to guide treat-to-target (T2T) strategies. However, it is still not clear which concepts it conveys and how appropriate they are to guide therapy.
**Objectives:** to explore the meaning of PGA in RA patients, namely the influence of disease activity, disease impact, comorbidities, and psychological aspects.
**Methods:** This was an observational, cross-sectional study including consecutive RA patients (ACR/EULAR 2010 or ACR 1987 criteria) followed in a tertiary rheumatology outpatient department. Data collection included PGA (100mm VAS), pain and fatigue (0–10 NRS), Health Assessment Questionnaire (HAQ),

Functional Assessment of Chronic Illness Therapy (FACIT), Hospital Anxiety and Depression Scale (HADS), Happiness Subjective Scale (HSS), and Ten Item Personality Inventory (TIPI). Demographic data, comorbidities, and disease activity [tender joint (TJC28) and swollen joint counts (SJC28), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP)] were also collected. Disease activity categories were defined as: 1) remission (ACR/EULAR 2011 boolean-based definition), 2) near-remission (only PGA>1), and 3) non-remission. Univariate (Pearson correlation, student's *t* test and One Way ANOVA) and multivariable analysis (linear regression, with stepwise methods and assessment of multicolinearity) were performed to explain PGA.



**Results:** 311 patients were included (82% females, 60±12 years, 11±9 years of disease duration, 8±5 years of formal education and a mean DAS(28)CRP4v = 2.9±1.2). All comorbidities assessed were associated with statistically ($p<0.05$) higher PGA than RA alone (Graph 1).

PGA was statistically correlated with all predictor variables, except for the personality domain "agreeableness". In multivariable analysis, PGA was explained ($R^2_{adj.}=0.58$) by pain ($\beta=0.33$), fatigue ($\beta=0.23$), function ($\beta=0.21$), anxiety ($\beta=0.13$), and SJC28 ($\beta=0.09$). The predictors of PGA were different between disease activity categories (Table 1).

Table 1. Multivariable linear regression models (stepwise-backward method) to explain PGA in RA patients

| Variable | Patients (β adjusted*) | | | |
|---|---|---|---|---|
| | All (n=281) | Remission (n=120) | Near-misses (n=19) | Non-remission (n=152) |
| Pain | 0.33 | 0.35 | | 0.28 |
| Fatigue | 0.23 | 0.44 | 0.72 | |
| HAQ | 0.21 | | | 0.30 |
| HADS-Anxiety | 0.13 | | | 0.19 |
| SJC28 | 0.09 | | | 0.12 |
| TJC28 | | 0.20 | 0.45 | |
| CRP | | | –0.31 | |
| $R^2$ adj. | 0.58 | 0.57 | 0.78 | 0.55 |

*All with $p<0.05$.

**Conclusions:** PGA does not only convey the inflammatory activity of the disease but also pain (of whatever musculoskeletal origin), fatigue, functional capacity, and psychological variables. These predictors present different relative impacts in different disease activity categories. In near-misses, the group where PGA is decisive for T2T, PGA is determined by fatigue, TJC28 and negatively associated with CRP.

Including PGA in composite indices drifts these measures away from strict disease activity representation. This may negatively affect the adequacy of target-driven decisions regarding immunosuppressive therapy, inherently designed to control inflammation.

## THU0603 PERFORMANCE OF THE 2013 AMERICAN COLLEGE OF RHEUMATOLOGY/EUROPEAN LEAGUE AGAINST RHEUMATISM SYSTEMIC SCLEROSIS CLASSIFICATION CRITERIA

A.M. Gheorghiu[1,2], R. Dobrota[1,2], T. Predescu[1,2], L. Grigorescu[1,2], A. Soare[1,2], M. Gorga[2], R. Ionitescu[1,2], R. Jurcut[2,3], S. Magda[2,4], T. Constantinescu[2,5], R. Sfrenţ-Cornăţeanu[6], M. Bojinca[1,2], V. Stoica[1,2], C. Mihai[1,2]. *[1]Internal Medicine and Rheumatology, Cantacuzino Hospital; [2]Carol Davila University of Medicine and Pharmacy; [3]C.C. Iliescu Institute for Cardiovascular diseases; [4]Emergency University Hospital; [5]Marius Nasta Institute of Pneumology; [6]Phisiopathology and Immunology Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

**Background:** Systemic sclerosis (ScS) is a polymorphic autoimmune disease, with increased morbidity and mortality, often diagnosed in advanced stages. The recently published 2013 American College Of Rheumatology/European League Against Rheumatism (ACR/EULAR) classification criteria for SSc were developed to increase the identification of early/mild SSc patients.

**Objectives:** To compare the sensitivity and specificity of the 2013 ACR/EULAR criteria with 1980 ACR criteria in a single-centre cohort of patients with SSc, diagnosed according to expert oppinion.

**Methods:** Data of SSc patients evaluated in our EUSTAR centre between 2004–2015 have been retrospectively analyzed. The control cohort included patients with Raynaud's phenomenon of other ethiology than SSc, evaluated between 2009–2015. The sensitivity and specificity of the 2013 ACR/EULAR and 1980 ACR criteria were tested using the McNemar test for correlated proportions.

**Results:** One hundred and fifty one patients with SSc (90.1% women, mean±SD age 58.4±13.2 years) and 65 controls (87.7% women, mean±SD age 43.7±14.6 years) were included. The sensitivity of the 2013 ACR/EULAR and 1980 ACR criteria were 94.7% and 84.4%, respectively ($p<0.001$). The specificity of the 2013 ACR/EULAR and 1980 ACR criteria were 86.2% and 96.9%, respectively ($p=0.01$). Patients missclassified according to the new 2013 ACR/EULAR criteria were 17, whereas according to the old 1980 ACR criteria were 32. The sensitivity of the 2013ACR/EULAR was significantly better than the 1980 ACR criteria in the limited cutaneous SSc patients (93.1 vs. 82.2%, $p<0.001$).

**Conclusions:** The 2013 ACR/EULAR criteria have a better sensitivity and missclassify fewer patients than the 1980 ACR criteria. Their excelent performance is close to the gold standard of diagnosis in SSc (expert opinion).

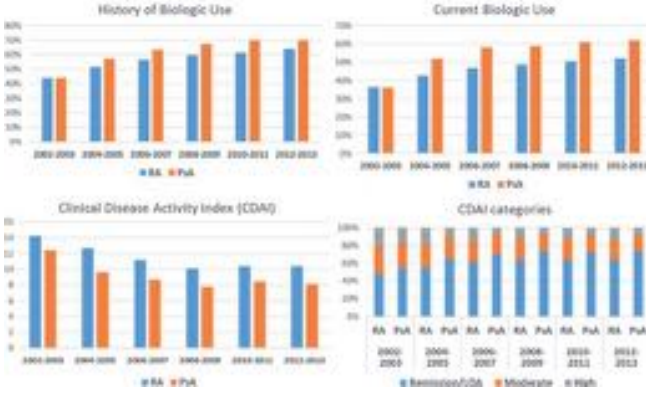
## THU0604 DISEASE ACTIVITY AND BIOLOGIC USE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS IN THE PAST 10 YEARS: RESULTS FROM THE CORRONA REGISTRY

A. Kavanaugh[1], J. Griffith[2], C. Karki[3], C.J. Etzel[3,4], J.M. Kremer[5], J.D. Greenberg[3,6], A. Ganguli[2]. *[1]University of California, San Diego, La Jolla, CA; [2]AbbVie, Inc., North Chicago, IL; [3]Corrona, LLC, Southborough, MA; [4]UT MD Anderson, Houston, TX; [5]Albany Medical College and The Center for Rheumatology, Albany, NY; [6]NYU School of Medicine, New York, NY, United States*



**Background:** While some treatment options for psoriatic arthritis (PsA) are similar to those initially developed for rheumatoid arthritis (RA), their introduction to the clinic has generally increased in the recent years. Also, there has been a perception among some that RA is perhaps associated with greater disease burden compared to PsA.

**Objectives:** The objective of this study was to determine and compare the disease activity related to peripheral arthritis and biologic use in patients with RA and PsA over the past 10 years in Corrona registry.

**Methods:** All patients between 01/2002 – 03/2013 were included and patients were grouped in 2 year intervals 2002–2003, 2004–2005, 2006–2007, 2008–2009, 2010–2011, 2012–2013. Within each time period, standardized differences were used to identify patient characteristics that were different between PsA and RA patients. Logistic regression models evaluated the likelihood of being in moderate/high clinical disease activity index (CDAI) and use of biologics in PsA patients compared to patients with RA, adjusting for covariates within each time period. Random effects logistic regression models were also considered to account for site random effects.

**Results:** A total of 20982 and 2552 RA and PsA patients respectively were studied over the six time intervals. The mean age was 59 yrs and 53 yrs for RA and PsA patients respectively. Mean CDAI and percentage of patients in moderate/severe disease activity were significantly higher in RA and PsA over the years; disease activity generally decreased over time for both (Figure). History of biologic use was similar between the two groups in 2002–03 (44% in RA vs 42.5% in PsA), however there was an upward trend in biologic use in both groups with higher use among PsA patients over the past years (figure). Similarly current biologic use also increased from 36.3% vs 36.1% in RA vs PsA in 2002–03 to 52.1% vs 62% in 2012–2013 respectively. Adjusted models showed that PsA patients were significantly less likely to be in moderate/severe disease activity defined by CDAI (OR (95% CI): 0.79 (0.72, 0.88)) over the past years and more

**Figure 1: Disease activity and biologic use in RA and PsA patients at different time intervals**

likely to be on a biologic compared to RA patients in 2012–13 (Odds ratio (95% CI): 1.37 (1.25, 1.49)).
**Conclusions:** Although disease activity has generally decreased while biologic therapy use has increased over recent years, there continues to be a significant proportion of PsA and RA patients with moderate/severe disease. Joint burden among PsA patients is slightly lower in comparison to RA, although biologic use was higher in the PsA population. Future research should evaluate the correlation in disease activity and biologic use over time.

## THU0605 OMEGA-3 FATTY ACIDS ASSOCIATES WITH DECREASED PAIN, INDEPENDENT OF INFLAMMATION, IN MTX TREATED EARLY RA PATIENTS

C. Lourdudoss[1], A. Wolk[2], D. Di Giuseppe[3], H. Westerlind[4], L. Klareskog[5], L. Alfredsson[4], R. van Vollenhoven[1], J. Lampa[5]. *[1]Dept of Medicine, Unit for Clinical Therapy Research, Inflammatory Diseases; [2]Dept of Environmental Medicine, Unit of Nutritional Epidemiology; [3]Dept of Medicine, Clinical Epidemiology Unit; [4]Dept of Environmental Medicine, Unit of Cardiovascular Epidemiology; [5]Dept of Medicine, Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden*

**Background:** Dietary intake of omega-3 fatty acids (FA) may play a role in etiology of RA [1] and has also been shown to be anti-inflammatory in RA [2]. Increased intake of omega-6 FA as well as omega-6:3 FA ratio are associated with inflammation in RA [3]. However, little is known about how omega-3 FA may affect pain in RA.
**Objectives:** To study the association between omega-3, omega-6, omega-6:3 FA ratio and pain, despite inflammatory control, after three months of MTX treatment in early RA patients.
**Methods:** We included newly diagnosed RA patients with MTX monotherapy from Epidemiological Investigation of Rheumatoid Arthritis (EIRA) study linked to clinical data from Swedish Rheumatology Quality register (SRQ). Data on omega-3, omega-6, and omega-6:3 FA ratio (dietary questionnaires) were linked with data on self-assessed pain after three months of MTX treatment. Pain despite inflammatory control (Remaining Pain) was defined based on the Patient Acceptance Symptom Scale (PASS)[4] together with low systemic inflammation (VAS pain >40mm and CRP<10mg/L). Statistical analysis: logistic regression adjusted for age, sex, smoking, education, BMI, energy intake and omega-3 FA supplementation.
**Results:** We included 591 patients (median age: 55 years; females: 70.6%; ACPA+: 67.9%). Mean values for clinical measures at baseline were: DAS28 5.2±1.3, VAS pain 53.9±24.7 and HAQ 1.1±0.6. Mean BMI was 25.8±4.7 kg/m$^2$. Omega-3 FA supplements were used by 19.5% of the patients. After three months, 92 patients (15.6%) had Remaining Pain. These patients had lower intake of omega-3 FA compared to those without Remaining Pain (0.6±0.4 vs. 0.7±0.3 g/day, p=0.004). Omega-3 FA intake was inversely associated with Remaining Pain (OR=0.5 [95% CI 0.3–0.9]), after adjustment. Omega-6:3 FA ratio but not omega-6 FA alone was directly associated with remaining pain (OR=2.3 [95% CI 1.3–4.2]). Similar ORs were found after adjustment for ACPA and physical activity. Omega-3 FA was not associated with CRP or EULAR response at the follow-up.
**Conclusions:** Omega-3 FA was inversely associated with Remaining Pain and omega-6:3 FA ratio was directly associated with Remaining Pain. These associations were independent of inflammation. Our data suggest that dietary omega-3 FA may dampen the development of chronic pain in early RA.

## THU0606 INCIDENCE AND PREVALENCE OF CARDIOVASCULAR RISK FACTORS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIASIS, OR PSORIATIC ARTHRITIS

D.H. Solomon[1], T. Lesperance[2], H. Radner[3], N. Accortt[2]. *[1]Brigham and Women's Hospital, Harvard Medical School, Boston; [2]Amgen, Inc, Thousand Oaks, United States; [3]Medical University of Vienna, Vienna, Austria*

**Background:** Studies have suggested that the chronic inflammatory nature of rheumatic conditions (rheumatoid arthritis (RA) and psoriatic arthritis (PsA)) as well as psoriasis (PsO) may predispose patients to cardiovascular (CV) disease and metabolic disorders. However, the individual impact of RA, PsA, and PsO on traditional CV risk factors is not well understood.
**Objectives:** We estimated the incidence and prevalence of traditional CV risk factors - hypertension, diabetes mellitus (DM), hyperlipidemia, and obesity - among three separate cohorts of patients with RA, PsA, or PsO.
**Methods:** Patients with RA, PsA, and PsO between January 1, 2002 and June 30, 2014 were identified (and included in three separate cohorts) in the Truven Health MarketScan Commercial and Medicare Supplemental databases. Index date was defined as the date of RA, PsA or PsO diagnosis. Patients were required to be continuously enrolled for 12 months prior to the index date. Follow-up time for the identification of the CV risk factors began on the day after index date and continued until disenrollment from MarketScan, or the end of the study. The primary outcome was the first occurrence of the CV risk factors during the follow-up period. Incidence rates (IR) per 1,000 patient-years (PY) with 95% confidence intervals (CI) were calculated. The prevalence (number of cases/total population) of CV risk factors prior to the index date was also calculated.
**Results:** We identified 266,167 patients with RA, 35,050 with PsA, and 301,593 with PsO. Mean age at index date was similar for both PsO and PsA patients (51 yrs), but RA patients were older (58 yrs). Mean follow-up time ranged from 2.3 years to 2.5 years. Prevalence of the CV risk factors ranged as follows: hypertension 24.7% in PsO to 34.6% in RA; DM 8.2% in PsO to 10.4% in RA; Hyperlipidemia 16.5% in PsO to 18.2% in RA; and Obesity 5.1% in PsO to 6.7% in PsA. The pattern of CV risk factors development after RA, PsA, and PsO diagnosis was similar as prior to diagnosis. The RA cohort demonstrated the highest incidence of hypertension and hyperlipidemia whereas PsA cohort demonstrated the highest incidence of DM and obesity. All risk factors were lowest in the PsO cohort (Table 1).

Table 1. Incidence rate (per 1,000 person-years) of CV risk Factors among RA, PsA, and PsO patients

| CV risk factors | Events | Person-years | IR [95% CI] | IR ratio |
|---|---|---|---|---|
| Hypertension | | | | |
| RA | 39,887 | 340,946 | 117.0 [115.8, 118.1] | 1.52 |
| PsA | 4,432 | 48,167 | 92.0 [89.3, 94.8] | 1.20 |
| PsO | 35,447 | 461,152 | 76.9 [76.1, 77.7] | Ref |
| Diabetes mellitus | | | | |
| RA | 9,768 | 585,435 | 16.7 [16.4, 17.0] | 1.08 |
| PsA | 1,312 | 70,031 | 18.7 [17.7, 19.8] | 1.22 |
| PsO | 10,052 | 652,719 | 15.4 [15.1, 15.7] | Ref |
| Hyperlipidemia | | | | |
| RA | 33,543 | 476,658 | 70.4 [69.6, 71.1] | 1.13 |
| PsA | 4,025 | 58,231 | 69.1 [67.0, 71.3] | 1.11 |
| PsO | 33,023 | 532,193 | 62.1 [61.4, 62.7] | Ref |
| Obesity | | | | |
| RA | 18,522 | 619,621 | 29.9 [29.5, 30.3] | 1.03 |
| PsA | 2,602 | 73,138 | 35.6 [34.2, 37.0] | 1.23 |
| PsO | 19,665 | 678,401 | 29.0 [28.6, 29.4] | Ref |

**Conclusions:** The incidence rates of hypertension, hyperlipidemia, DM, and obesity are higher among patients with RA and PsA compared to patients with PsO. Differences in levels of systemic inflammation may underpin differences in rates of risk factors. Different treatment strategies may be useful in preventing these comorbidities. The results highlight the importance of close monitoring and managing CV risk factors in patients with RA, PsA and PsO.

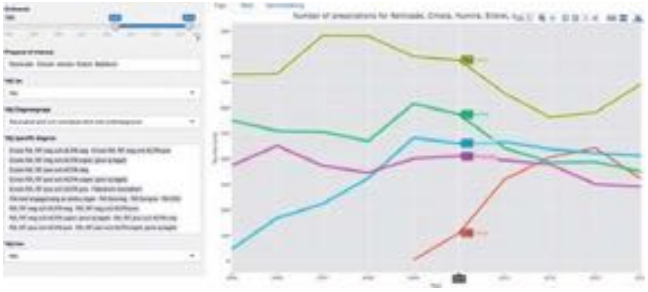
## THU0607 EFFECTIVENESS AND PERSISTENCE OF GOLIMUMAB ACROSS RHEUMATIC DISEASE INDICATIONS IN CLINICAL PRACTICE: RESULTS FROM THE NATIONAL SWEDISH REGISTER

D. Di Giuseppe, T. Frisell, J. Askling. *Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden*

**Background:** Real life evidence regarding the effectiveness and discontinuation of golimumab across indications is limited.

**Abstract THU0607** – Table 1. Baseline characteristics of the golimumab treated population, stratified by indication. Reported numbers are median and interquartile range in parenthesis



| | All (n=2984) | RA (n=1366) | PsA (n=655) | AS (n=499) | SpA (n=464) |
|---|---|---|---|---|---|
| Symptom duration (years) | 6 (1–15) | 3 (1–13) | 6 (2–14) | 12 (5–23) | 7 (2–13) |
| Concurrent therapy | | | | | |
| NSAID | 989 (38.98%) | 441 (36.78%) | 182 (45.16%) | 209 (37.06%) | 157 (42.32%) |
| MTX | 1252 (49.35%) | 793 (66.14%) | 71 (17.62%) | 271 (48.05%) | 117 (31.54%) |
| Non-MTX DMARD | 310 (12.22%) | 184 (15.35%) | 21 (5.21%) | 64 (11.35%) | 41 (11.05%) |
| Percentage bionaïve | 47% | 48% | 47% | 46% | 48% |
| Among patients switching from previous biological therapy: | | | | | |
| Time from start of first biologic (months) | 41 (15–80) | 48 (16–93) | 35 (14–69) | 42 (19–72) | 30 (13–67) |
| Number of biologics before golimumab | 1 (1–2) | 1 (1–2) | 2 (1–2) | 1 (1–2) | 2 (1–2) |
| Difference between start of treatment and the 6 months visits: | | | | | |
| ΔDAS28 | | −1.41 (−2.33; −0.48) | −1.38 (−2.41; −0.53) | NA | NA |
| ΔHAQ | | −0.13 (−0.50; 0) | −0.13 (−0.50; −0) | NA | NA |
| ΔTJC | | −3 (−6; −1) | −3 (−6; 0) | NA | NA |
| ΔSJC | | −3 (−6; 0) | −1 (−4; 0) | NA | NA |
| ΔPatient global assessment (VAS) | | −16 (−39; 0) | −20 (−40; 2) | −22 (−43; −3) | −23 (−47; −8) |
| ΔPain in general (VAS) | | −18 (−37; 0) | −18 (−40; 3) | −28 (−48; −2) | −26 (−49; −7) |
| ΔEQ-5D | | 0.04 (0; 0.26) | 0.07 (0; 0.23) | 0.09 (0; 0.38) | 0.17 (0; 0.5) |
| ΔCRP | | −2 (−10; 0) | −1.40 (−8.60; 0) | −6 (−14.1; 0) | −1.40 (−10.40; 0) |
| ΔSR | | −4 (−12; 1) | −3 (−13; 0) | −7 (−19; −1) | −4 (−15; 0) |

**Objectives:** To describe the effectiveness and persistence of golimumab in a real-life setting, in rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA), and other spondyloarthropathies (SpA), in relation to disease activity at treatment initiation.
**Methods:** The national Swedish Rheumatology Quality Register (SRQ) was used to identify patients starting treatment with golimumab between 2009 and 2014. Effectiveness was assessed using the difference between start of treatment and at the 6 months visits (defined as 110–240 days from start of treatment) of different measures of disease activity. Persistence was evaluated using Kaplan Meier curves and Cox proportional hazard model.
**Results:** A total of 2984 patients (1366 RA (69% were RF positive), 655 PsA, 499 AS and 464 SpA) started treatment with golimumab. The percentage of bionaïve patients was similar across indications (from 46% in AS to 48% in RA). There was positive response at 6 months across all indications, according to DAS28, HAQ, tender and swollen joint counts (TJC and SJC), patient global health, pain, EQ-5D, CRP and SR (Table 1). Proportion of persistence was highest in AS (69% at 1 year, 56% at 2, and 50% at 3), and was lowest in PsA (60%, 49%, and 42%). Across all indications, the hazard ratio of discontinuation was higher among women, lower among bionaïve compared to non-bionaïve patients, and 34% higher among RA patients >65 years old compared to RA patients 56–65 years old. There was no association between age and discontinuation among patients with other indications, and between DAS28 and HAQ and discontinuation in RA and SpA.
**Conclusions:** In this real-life national cohort, patients on golimumab experienced clinical improvement. Persistence is dependent on contextual factors rather than disease activity at start, and is better in AS than in RA.
**Disclosure of Interest:** None declared

## THU0608 VISUALIZATION AND ANALYSIS PLATFORM IN THE SWEDISH RHEUMATOLOGY REGISTER FOR REAL-TIME DATA FEEDBACK

D. Di Giuseppe[1], H. Eriksson[2], A.-C. Elkan[3], S. Ernestam[3,4]. *[1]Department of Medicine Solna, Karolinska Institutet; [2]Carmona AB; [3]Medical Management Centre, Inst LIME; [4]Dept of Rheumatology, Inst of medicine, Solna, Karolinska Institutet, Stockholm, Sweden*

**Background:** The Swedish Rheumatology Quality register (SRQ) started in 1995 and is one of the largest register collecting data on rheumatoid arthritis and other rheumatic diseases in the world. The aim of the register has always been to support health care along with collect data for research. The national coverage is 82.7% in rheumatoid arthritis. However, the extraction of useful real-time data in every day practice have been so far only limited.
**Objectives:** To design and implement a tool connected to the SRQ that allows users to monitoring their local data and results of care in comparison to national data.
**Methods:** We designed a Visualization and Analysis Platform (VAP) based on R language, using the web framework of Shiny (© RStudio, Inc.). The platform is based on predefined types of analyses such as flexible tabular presentations, cross-sectional and longitudinal comparisons. A user interface with reactive programming was implemented to control the appearance of interactive graphs and tables, and to explore the changes in outcome measures.
**Results:** A web-based platform for live visualization of data was developed and linked to the SRQ, a register containing ca. 75,000 patients and 500,000 registered visits, as long as 60,000 prescriptions of biological treatments. The users is able to control the specifics of the data analysis using a flexible interface, and it can visualize the results in a graph as long as in a table, that can easily be download. An explanation of the graph is included, to support the user in the understanding of what is represented. The VAP tool has been used to visualize data on the so called Open Comparison diagrams, 5 quality indicators that have been discussed at national level and that have been used to evaluate performances of care across counties in Sweden. We also applied this tool to the analysis of use of biological treatments in Stockholm (Fig.1). The user is therefore able to visualize how many times a specific biological treatment has been prescribed in his unit and compare it to the national value, as long as select different periods of time of interest and different diagnosis.

**Conclusions:** The VAP offers a flexible tool for visualization and analysis of real-time SRQ's data and it is aimed to satisfy the growing request of data by clinicians, patients, researchers, care providers and pharma companies. Moreover, the VAP tool by its nature allows the possibility of fast changes in this structure, following the changes in everyday rheumatology care in real-time.

## THU0609 PATIENT-REPORTED OUTCOMES FROM A PHASE 3 STUDY OF BARICITINIB VERSUS PLACEBO OR ADALIMUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO BACKGROUND METHOTREXATE THERAPY

E. Keystone[1], P. Taylor[2], Y. Tanaka[3], C. Gaich[4], A.M. DeLozier[4], A. Dudek[5], J. Velasco Zamora[6], J. Covarrubias Cobos[7], S. de Bono[4], V. Arora[4], L. Yang[4], B. Linetzky[4], M.E. Weinblatt[8]. *[1]The Rebecca MacDonald Centre for Arthritis, Mt. Sinai Hospital, Toronto, Canada; [2]Kennedy Institute of Rheumatology, University of Oxford, Oxford, United Kingdom; [3]University of Occupational and Environmental Health, Fukuoka, Japan; [4]Eli Lilly and Company, Indianapolis, United States; [5]Medica Pro Familia, Warsaw, Poland; [6]Instituto Médico CER, Buenos Aires, Argentina; [7]Unidad Reumatologica Las Americas S.C.P., Mérida, Mexico; [8]Brigham and Women's Hospital, Boston, United States*

**Background:** Baricitinib (bari), an oral JAK1 and JAK2 inhibitor, was efficacious in a Ph 3 study (RA-BEAM) in RA patients (pts) with active disease and an inadequate response (IR) to MTX.[1]
**Objectives:** To evaluate patient-reported outcomes (PROs) from RA-BEAM.
**Methods:** Pts on stable background MTX were randomized to placebo (PBO), bari 4 mg QD, or adalimumab (ADA) 40 mg Q2W. PROs listed in the table and the Work Productivity and Activity Impairment-Rheumatoid Arthritis (WPAI-RA) were collected on electronic tablets during study visits. Bari vs. PBO and bari vs. ADA were assessed with ANCOVA and logistic regression models.
**Results:** 1305 pts were randomized. Functional disability at baseline (mean HAQ-DI) was: 1.55, 1.57, 1.59 for PBO, bari, and ADA, respectively. Compared to PBO, bari was superior in physical function, Pt's Global Assessment of Disease Activity (PtGDA), pain, fatigue and quality of life (physical component score [PCS]), at Wk 12 and 24. Compared to ADA, bari was superior in physical function, PtGDA, and pain at Wks 12, 24 and 52. Compared to PBO, a similar proportion of bari and ADA pts were employed throughout the study. Statistically significant improvements in all components of the WPAI-RA (absenteeism, presenteeism, work productivity loss and activity impairment) were seen in the bari pts compared

to PBO at Wk 12; statistically significant improvements were seen for work loss and activity impairment for bari pts compared to ADA at Wk 12.

**Conclusions:** In this Ph 3 study of RA patients with an IR to MTX, treatment with bari resulted in significant improvement in most PROs compared with PBO or ADA, including functional disability, pain, and fatigue.

## THU0610 THE SPONDYLOARTHRITIS IN SUB-SAHARAN AFRICA IN THE ERA OF ASAS CLASSIFICATION CRITERIA FOR AXIAL AND PERIPHERAL SPONDYLOARTHRITIS

F. Kemta Lekpa[1], M.S. Doualla[1], M. Singwe-Ngandeu[2], H. Namme Luma[1].
*[1]Rheumatology, Douala General Hospital, Douala; [2]Rheumatology, Central Hospital, Yaoundé, Cameroon*

**Background:** The ASAS classification criteria for axial and peripheral spondyloarthritis have revolutionized the management of patients with suspicion of spondyloarthritis (1,2). These criteria have not been validated in sub-Saharan Africans. Moreover, the application of these new criteria on a population of sub-Saharan Africa with spondyloarthritis has not yet been published.

**Objectives:** To classify sub-Saharan Africans followed for spondyloarthritis according to the new ASAS classification criteria for axial spondyloarthritis and peripheral spondyloarthritis (1,2).

**Methods:** We performed a cross-sectional study among 6804 patients seen in the Rheumatology Unit of the Douala General Hospital, a tertiary healthcare centre in Cameroon, between January 2004 and December 2013. All patients followed for spondyloarthritis according to the Amor and/or ESSG criteria were collected to classify them according to the ASAS classification criteria for axial spondyloarthritis and peripheral spondyloarthritis.

**Results:** Seventy two (27 men and 45 women) patients fulfilled Amor and/or ESSG criteria. The mean age of these patients was 34 ± 13.9 years. The diagnosis was made primarily on the basis of clinical examination and X-rays of the spine and pelvis. No patient achieved a magnetic resonance imaging (MRI). The HLA B27 was negative in all patients tested. Ankylosing spondylitis was the most common spondyloarthritis, followed by reactive arthritis. The distribution of patients according to nosological entities and the predominant topography, axial and/or peripheral are respectively shown in Table 1 and Table 2. Two patients were not classified according to the ASAS criteria.

Table 1, Distribution of patients according to disease entities

| | n (%) | Mean age ± SD | Sex (M/F) |
|---|---|---|---|
| Ankylosing spondylitis | 36 (50.0) | 46±13.6 | 19/17 |
| Reactive arthritis | 29 (40.2) | 38±8.2 | 7/22 |
| Psoriatic arthritis | 3 (4.2) | 34±7.0 | 0/3 |
| Spondyloarthritis associated to inflammatory bowel diseases | 2 (2.8) | 32±3.8 | 1/1 |
| Undifferentiated spondyloarthritis | 2 (2.8) | 21±15.7 | 0/2 |

Table 2. Distribution of patients according to ASAS classification

| | n (%) | Mean age ± SD | Sex (M/F) |
|---|---|---|---|
| Spondyloarthritis (all the patients) | 72 (100) | 36±13.9 | 27/45 |
| Axial Spondyloarthritis | 40 (55.5) | 39±12.6 | 11/29 |
| Peripheral Spondyloarthritis | 29 (40.3) | 34±16.7 | 14/15 |
| "Unclassified Spondyloarthritis" according to ASAS classification | 3 (4.2) | 27±11.5 | 1/1 |

**Conclusions:** The ASAS criteria have not changed the epidemiology of spondyloarthritis in Cameroon (prevalence 1.05%), and probably in all the sub-Saharan Africa. The diagnosis is difficult because of the lack of biological markers (HLA B27 negative) and limited access to MRI (available since 2014 in our hospital). Improving the performance of the ASAS criteria for axial and peripheral spondyloarthritis will require numerous other modifications.

## THU0611 SUBJECTIVE WELL-BEING OF JAPANESE RA PATIENTS WHO REACH TREATMENT TARGET IS HIGHER THAN THE JAPANESE AVERAGE

G. Kageyama[1,2], A. Onishi[1], Y. Ueda[1], Y. Kamei[1], H. Yamada[1], Y. Ichise[1], D. Waki[1], I. Naka[1], K. Tsuda[1], T. Okano[1], S. Takahashi[1], M. Nishida[1], K. Akashi[1], K. Nishimura[1], S. Sendo[1], Y. Kogata[1], J. Saegusa[1], A. Morinobu[1].
*[1]Department of Rheumatology, Kobe University Hospital, Kobe; [2]Department of Rheumatology, Hyogo Prefectural Amagasaki General Medical Center, Amagasaki, Japan*

**Background:** Subjective Well-Being (SWB) refers to a construct which includes one's emotional responses, domain satisfactions, and global judgments of life satisfaction. Many variables such as age, sex, income, employment and marital status are related to SWB. Being healthy is also an important factor of SWB. RA is a chronic illness which is considered to influence SWB. However, little is known about the impact of RA on SWB.

**Objectives:** To evaluate the SWB of Japanese RA patients and identify factors that associate with SWB.

**Methods:** This study was done in cooperation with the Cabinet Office Government of Japan Economic and Social Research Institute. This institute had previously conducted the "Well-being studies 2014" surveying the SWB of randomly selected Japanese citizens. In this survey, SWB was determined by having the participants rate their happiness between 10 (Very happy) and 0 (very unhappy). The Well-being studies 2014 also included a questionnaire consisting of 56 questions covering topics closely associated with well-being such as socioeconomic and health status. The same survey was done for RA patients at Kobe University Hospital and clinical data including disease duration, stage, class, disease activity, HAQ, complications and the therapeutic drug was also collected at the same time.

**Results:** Multivariate analysis on data including RA patients (n=339) and Japanese controls (n=7690) revealed that RA patients with high or moderate disease activity had similar SWB scores as Japanese controls. However, the SWB of RA patients with remission or low disease activity were higher than Japanese controls. Age, sex, marital status, presence of child, household income, financial

| | Value | Std.Error | p-value | |

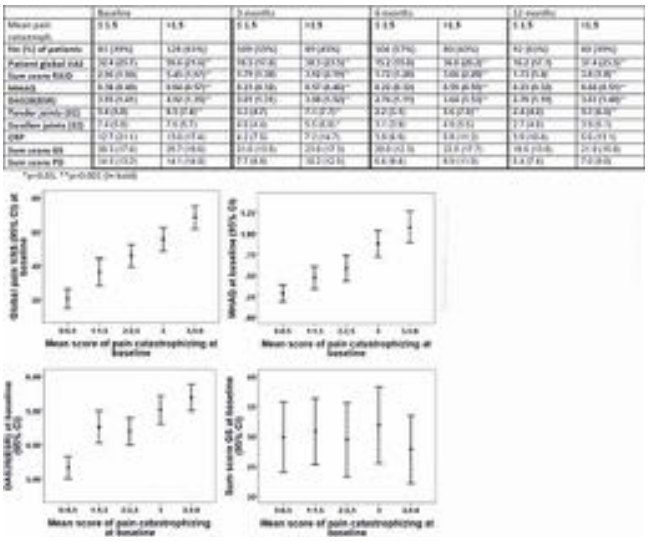
## THU0612 DEVELOPMENT AND VALIDATION OF AN ACCURATE AND PRECISE NATURAL LANGUAGE PROCESSING SYSTEM TO CAPTURE RHEUMATOID ARTHRITIS DISEASE ACTIVITY MEASURES

G.W. Cannon[1], S. Mehortra[2], B.R. South[3], J. Leng[2], C.-C. Lu[2], B.C. Sauer[2]. *[1]Rheumatology; [2]IDEAS Center; [3]Biomedical Informatics, Salt Lake City VA Medical Center and University of Utah, Salt Lake City, United States*

**Background:** Systems to electronically retrieve disease activity measures in medical records would significantly aid rheumatoid arthritis (RA) management and enhance epidemiologic research. As part of the national VA rheumatoid arthritis (VARA) registry our clinic measures 28 joint disease activity score (DAS28) by manual extraction (ManEx).
**Objectives:** 1. To develop a natural language processing (NLP) system to extract core measures from patient clinic note text and erythrocyte sedimentation rate (ESR) from the laboratory data to calculate DAS28.
2. To compare the accuracy and precision of the NLP DAS28 with ManEx DAS28.
3. To validate these findings in a second RA cohort.
**Methods:** An NLP application used clinical notes between January 1, 2015 and September 30, 2015 for RA patients in VARA (n=207) at our single site to extract tender joint count (TJC), swollen joint count (SJC), and patient global assessment (PtGA) from note text. The ESR value within 2 weeks closest to the clinic visit was combined with TJC, SJC, and PtGA to calculate DAS28. During the same observation period, ManEx of DAS28 observations were also identified. Discrepancies between ManEx and NLP were resolved by investigator review of the clinic notes. An analysis of all notes identified either by ManEx or NLP were evaluated for accuracy (% of values correctly detected in all notes) and precision (% of retrieved values by either ManEx or NLP correctly identified by that specific method). The NLP system was validated in a second cohort of RA patients in VARA (n=214) at our site between April 1, 2014 to December 31, 2014.
**Results:** The derivation set contained a total of 472 notes; 440 (93%) identified by both ManEx and NLP; 20 (4%) by ManEx alone and 12 (3%) notes by NLP alone. The accuracy and precision for TJC, SJC, PtGA, ESR and DAS28 are as noted in the table. Failure of NLP to detect core measures was because of use of incorrect note template (n=5, 1.0%) and template modification (n=18, 3.8%); however, when detected NLP precision was near 100%. Failure of ManEx was a result of missed notes (n=19, 4.0%) and data entry errors (n=13, 2.8%). Similar results were seen in the validations set of notes (n=484).

Table 1



| | | Derivation set | | | Validation set | |
|---|---|---|---|---|---|---|
| | | Accuracy | Precision | | Accuracy | Precision |
| ManEx | TJC | 459/472 (97.2%) | 459/459 (100%) | TJC | 467/484 (96.5%) | 467/468 (99,8%) |
| | SJC | 459/472 (97.2%) | 459/459 (100%) | SJC | 465/484 (96.1%) | 465/467 (99.6%) |
| | PtGA | 445/472 (94.3%) | 445/450 (98.9%) | PtGA | 462/484 (95.5%) | 463/465 (99.5%) |
| | ESR | 439/472 (93.0%) | 439/451 (97.3%) | ESR | 442/484 (91.3%) | 442/456 (94.2%) |
| | DAS28 | 433/472 (91.7%) | 433/441 (98.2%) | DAS28 | 434/484 (89.7%) | 434/452 (96.0%) |
| NLP | TJC | 437/472 (92.6%) | 437/437 (100%) | TJC | 450/484 (93.0%) | 450/450 (100%) |
| | SJC | 439/472 (93.0%) | 439/439 (100%) | SJC | 446/484 (92.1%) | 446/446 (100%) |
| | PtGA | 434/472 (91.9%) | 434/434 (100%) | PtGA | 445/484 92.1%) | 445/446 (99,8%) |
| | ESR | 435/472 (92.2%) | 435/435 (100%) | ESR | 438/484 (91.8%) | 438/443 (98.9%) |
| | DAS28 | 415/472 (87.9%) | 415/415 (100%) | DAS28 | 416/484 (87.0%) | 416/421 (98.8%) |

**Conclusions:** This accurate and precise NLP system can retrieve DAS28 from clinic notes to aid in clinical care and research activities. This method can be implemented at other VARA sites and other research networks to collect RA outcomes.
**Disclosure of Interest:** None declared

## THU0613 PAIN CATASTROPHIZING HAS A MAJOR IMPACT ON BOTH SUBJECTIVE AND COMPOSITE OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS; RESULTS FROM A LONGITUDINAL STUDY OF PATIENTS STARTING BDMARDS

H.B. Hammer[1], J. Lampa[2]. *[1]Dept of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [2]Dept. of Medicine, Rheumatology Unit, Center of Molecular Medicine (CMM), Karolinska Institute, Stockholm, Sweden*

**Background:** Patient reported outcomes (PROs) are important for the evaluation of treatment response in patients with rheumatoid arthritis (RA). The degree of pain catastrophizing (conceptualized as a negative cognitive–affective response to anticipated or actual pain) may influence the patient's scoring of disease activity. Ultrasound (US) is a sensitive method for assessing inflammation, including grey scale synovitis (GS) and vascularization (power Doppler (PD)).
**Objectives:** To explore the impact of pain catastrophizing on subjective outcomes and composite scores in comparison with objective outcomes, such as US-defined synovitis, during one-year follow-up of patients with RA starting treatment with biologic DMARDs (bDMARDs).
**Methods:** A total of 209 patients with RA (mean (SD) age 53 (13) years, disease duration 10 (9) years, 81% women, 79% anti-CCP positive) were included when starting bDMARD. The patients were assessed at baseline and after 1, 2, 3, 6 and 12 months with PROs (joint pain VAS, patient's global disease activity VAS, Rheumatoid Arthritis (RA) Impact of Disease (RAID) score, MHAQ), clinical examination (assessor's disease activity VAS, tender and swollen joint counts (SJC) of 32 joints, performed by a study nurse) and laboratory variables (ESR and CRP). DAS28(ESR) and CDAI were calculated. Pain catastrophizing was assessed by the mean of two questions (each score 0–6) from the Coping Strategies Questionnaire (CSQ); "When I have pain, it's terrible and I think it's never going to get any better" and "When I have pain, I feel I can't stand it anymore". All US examinations (semi-quantitative scoring (0–3)) of GS and PD (PIP 2–3, MCP 1–5, wrist (RC, IC, RU), elbow, knee, talo-crural, MTP 1–5 and extensor carpi ulnaris/tibialis posterior tendons bilaterally) were performed by one rheumatologist (HBH) (Siemens Acuson Antares, excellence version, 5–13 MHz probe). Correlations were explored by use of Spearman's, Wilcoxon explored changes from baseline and Mann-Whitney examined for differences between two independent groups.
**Results:** 209 patients were included and 152 patients (72.7%) continued their bDMARD for the whole 12 months study. All variables, including pain catastrophizing, decreased significantly ($p<0.001$) during follow-up. Pain catastrophizing was highly correlated with patient reported outcomes (r=0.51–0.65, $p<0.001$), moderate with DAS28/CDAI (0.43/0.32, $p<0.001$) but not with CRP (r=0.1), SJC (r=-0.01) or GS (r=–0.06)/PD (r=-0.04) scores. All the subjective and composite scores were much higher ($p<0.001$) in patients with higher levels of pain catastrophizing (cut-off 1.5) (4 time points shown below), while there were no differences for CRP, SJC or US scores. All subjective and composite scores had increasing levels with increased quintiles of pain catastrophizing ($p<0.001$), while this was not found for CRP, SJC or US (some variables illustrated).

**Conclusions:** It is generally assumed that the tendency to catastrophize plays a causal role in the pain experience which may influence the PROs. Pain catastrophizing was presently found to have a major impact on all the subjective as well as composite scores, but not on inflammatory variables like CRP, SJC or US assessments. This emphasises the importance of taking into account the degree of pain catastrophizing when evaluating disease activity in RA patients.

## THU0614 FOREWARNED IS FOREARMED? RISK COMMUNICATION DURING THE COMMENCEMENT OF METHOTREXATE; PRESENTING THE CLINICIANS' & PATIENTS' PERSPECTIVES

H.F. Hope[1], C. Cronin[2], C. Jacklin[3], L. Cordingley[4], K. Hyrich[5], S.M. Verstappen[5]. *[1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Centre for Musculoskeletal Research, Manchester; [2]Medac GmbH UK Branch, Stirling; [3]National Rheumatoid Arthritis Society, Maidenhead; [4]Centre for Musculoskeletal Research, Manchester, United Kingdom; [5]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester, United Kingdom*

**Background:** Methotrexate (MTX) is the first-line treatment for rheumatoid arthritis (RA). Previously, we have shown that patient concerns about side effects were associated with early MTX non-adherence. The first opportunity to address these concerns is during the initial clinical consultation. A crucial factor in determining

if a patient initiates and adheres to MTX could be if side effects are adequately addressed in the initial clinical consultation.
**Objectives:** The aims of this research were to evaluate from a patient's and rheumatologist's perspective i) the extent to which MTX risks are addressed during consultation and ii) possible factors constraining discussion of side effects
**Methods:** This is a mixed methods study. To evaluate the patient's perspective an online survey was co-constructed with the National Rheumatoid Arthritis Society in the UK. The survey gathered basic demographic information and included items relevant to risk communication during the initial consultation, including the extent to which side effects were discussed. The responses of patients who reported commencing methotrexate were selected for descriptive analyses.
To evaluate the rheumatologist's perspective interviews were conducted with rheumatologists. A sampling strategy ensured the views of senior and junior clinicians from different clinical settings across the UK were represented. The semi-structured topic guide contained questions about the MTX commencement consultation, including key information patients should have, how this was communicated and barriers to communication. The interviews were audio-recorded, transcribed and analysed qualitatively using Framework Analysis.
**Results:** Overall 648 people with RA completed the online survey, (83% female & 63% aged between 46 and 65 years). Eleven rheumatologists with one to 25 years experience as consultants and four trainees consented to be interviewed. The majority of respondents to the patient survey (62%) reported their initial consultation was less than 30 minutes. Of the 587 respondents who reported commencing methotrexate 16% reported they discussed side effects very little and 16% did not discuss side effects with their rheumatologist at all. Rheumatologists reported that patients should be informed about the side effects of methotrexate, however clinicians (n=9) were concerned about overloading the patient with information. Particular barriers to discussing side effects included; limited consultation time and concurrent diagnosis of RA and methotrexate commencement. These barriers were perceived as particularly acute when patients were unprepared for the diagnosis or had pre-existing negative beliefs about methotrexate.
**Conclusions:** Patients and rheumatologists separately reported side effects were not always discussed when commencing methotrexate, and barriers to communication were identified. Given that suspected side effects are a reason for non-adherence to methotrexate these need to be addressed. The development of new tools acceptable to patients and clinicians that facilitate the discussion of side effects, without extending the clinical consultation, may improve patient understanding and adherence.

## THU0615 COST PER RESPONSE FOR ABATACEPT COMPARED WITH ADALIMUMAB IN THE TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON ANTI-CITRULLINATED PROTEIN ANTIBODY TITRES IN ITALY, SPAIN AND CANADA

J. Foo[1], F. Mennini[2], J.M. Rodriguez Heredia[3], D. Choquette[4], G. Attina[5], S. Jiménez Merino[6], M. Mtibaa[7], E. Alemao[8], J. Gaultney[1]. *[1]Mapi Group, Houten, Netherlands; [2]University of Rome Tor Vergata, Rome, Italy; [3]Hospital Universitario de Getafe, Madrid, Spain; [4]University of Montreal, Quebec, Canada; [5]Bristol-Myers Squibb, Rome, Italy; [6]Bristol-Myers Squibb, Madrid, Spain; [7]Bristol-Myers Squibb, Quebec, Canada; [8]Bristol-Myers Squibb, Princeton, United States*

**Background:** RA is a chronic inflammatory disorder leading to disability and reduced quality of life. Effective treatment with biologic DMARDs poses a significant economic burden. The Abatacept versus Adalimumab Comparison in Biologic-Naive RA Subjects with Background Methotrexate (AMPLE) trial was a head-to-head, randomized study comparing SC abatacept with SC adalimumab.[1] Recent subgroup analyses showed improved efficacy for abatacept in serum anti-citrullinated protein antibody (ACPA)-positive patients, with increasing efficacy across ACPA quartile levels.[2]
**Objectives:** To evaluate the cost per response of abatacept relative to adalimumab in ACPA-positive patients with RA from the Italian, Spanish and Canadian societal perspectives.
**Methods:** A decision tree was designed to compare the cost per response of abatacept with adalimumab in a cohort of 1000 ACPA-positive patients (Q1: 28–235 AU/mL, Q2: 236–609 AU/mL, Q3: 613–1046 AU/mL, Q4: 1060–4894 AU/mL) over 2 years. Clinical inputs were based on the AMPLE trial, and response was based on ACR20/50/70/90 and HAQ-DI. Unit costs for direct medical costs of AEs were based on local tariffs for disease-related groups and the ex-manufacturer's price, including mandatory reductions, payback and transparent discounts for drugs. Societal costs included patient costs, indirect costs of work absence and early retirement, according to HAQ functional capacity categories.
**Results:** The cost per response in ACPA-positive patients favoured SC abatacept compared with SC adalimumab for ACR20, ACR70, ACR90 and HAQ-DI across all countries (Table 1). When evaluating across ACPA quartiles, cost per ACR20, ACR50 and ACR70 favoured SC abatacept with increasing stringency of response criteria and serum ACPA levels. Cost per ACR90 and HAQ-DI response consistently favoured SC abatacept across all ACPA subgroups and countries. In terms of cost per remission across all countries, cost per DAS28 favoured SC abatacept in ACPA-negative patients, while cost per CDAI and SDAI favoured SC abatacept in ACPA-positive patients.SC abatacept was consistently favoured in ACPA-Q4 patients across all outcomes and countries.

**Table.** Differences in costs per outcome (abatacept versus adalimumab) according to ACPA status across Italy, Spain and Canada

| | | Italy | Spain | Canada | | | Italy | Spain | Canada |
|---|---|---|---|---|---|---|---|---|---|
| | | Difference in costs per outcome (abatacept minus adalimumab) | | | | | Difference in costs per outcome (abatacept minus adalimumab) | | |
| Monthly cost per responding patient – ACPA-negative | ACR20 | -€244 | €266 | $35 | Monthly cost per responding patient – ACPA-positive | ACR20 | -€154 | -€76 | -$83 |
| | ACR50 | -€534 | -€81 | -$200 | | ACR50 | -€33 | €340 | $111 |
| | ACR70 | €1301 | €4.794 | $2430 | | ACR70 | -€644 | -€1072 | -$899 |
| | ACR90 | -€7052 | -€11.675 | -$7243 | | ACR90 | -€6426 | -€15.399 | -$8083 |
| | HAQ-DI | -€1976 | -€3552 | -$2109 | | HAQ-DI | -€281 | -€366 | -$254 |

| | SDAI | €942 | €2149 | $1188 | | SDAI | -€1333 | -€2573 | -$1495 |

**Conclusions:** The costs per responder were lower for SC abatacept than SC adalimumab in ACPA-Q4 patients across all countries. Cost savings were greater when more stringent response criteria were applied and also with increasing ACPA levels, which could lead to a lower overall healthcare budget impact with abatacept compared with adalimumab in Italy, Spain and Canada.

## THU0616 TREATMENT ADHERENCE AND ATTITUDES TOWARDS SYSTEMIC MEDICATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN DIFFERENT GEOGRAPHICAL REGIONS

J.S. Smolen[1], D.D. Gladman[2], H.P. McNeil[3], J. Weinman[4], S.H. Park[5], J. Sommer[6], P. Nurwakagari[7]. *[1]Medical Univ. of Vienna, Vienna, Austria; [2]Univ. of Toronto, Toronto, Canada; [3]Macquarie Univ., Sydney, Australia; [4]Inst. of Pharm. Sciences & Inst. of Psychiatry, King's College, London, United Kingdom; [5]Catholic Univ. of Korea, Seoul, Korea, Republic Of; [6]GKM Gesellschaft für Therapieforschung, Munich; [7]AbbVie, Wiesbaden, Germany*

**Background:** Adherence to systemic medication may vary between patients (pts) from different geographic areas.
**Objectives:** To explore differences in self-reported adherence and attitudes to systemic medications in different geographical regions, and identify factors associated with high adherence in pts with rheumatoid arthritis (RA) from the ALIGN study.
**Methods:** ALIGN was a global, cross-sectional, non-interventional study in adult pts with 6 inflammatory diseases, including RA. Clinical data were collected and validated pt questionnaires, including 4-item Morisky Medication Adherence Scale (© MMAS-4) and Beliefs About Medicines Questionnaire (BMQ), were administered at a routine visit. Results were compared between the following regions: West, including 16 countries from Western Europe, Canada, Australia and New Zealand; Eastern Europe (EE), including 6 countries; Middle East (ME), including Saudi Arabia and Lebanon; Latin America (LA), including 4 countries; Asia, including Korea and Taiwan. Associations between various factors, including geographic location, and medication adherence were assessed by multiple regression analysis.
**Results:** Data from 1943 pts [West, 1011 pts; EE, 322 pts; ME, 109 pts; LA, 367 pts; Asia, 134 pts; overall mean±SD age: 54.8±13.5 years (y); mean±SD disease duration, 9.2 ± 8.8 y] were analysed. 38.3–51.7% of pts had completely responded to current RA treatment. Duration of current treatment was longest in West region pts and shortest in Asian pts (6.1±5.6 y vs 2.3±2.0 y, $P<.0001$). Significantly more pts in the West region were highly adherent to their medication vs pts in other regions, with the fewest fully adherent pts in Asia and LA (Table). In general, similar observations were made across various treatment groups (Table). Depending on region, 17–60% of pts reported ever forgetting to take their RA medication; 24.6% of LA pts admitted having problems remembering to take their medication (Table). All groups had similar treatment necessity scores; however, Asian pts reported significantly lower necessity scores, but higher treatment concerns vs pts in all other regions (all $P<.05$). West region pts reported significantly lower concerns scores vs pts in other regions except EE pts (Table). In multiple regression analysis, higher treatment necessity beliefs were

associated with higher medication adherence, and higher treatment concerns with less adherence.

**Table. Patient-Reported Medication Adherence, Medication Necessity Beliefs and Concerns**

| | West pts (n=1051) | EE pts (n=322) | ME pts (n=309) | LA pts (n=367) | Asian pts (n=194) | P Value* |

Adj, adjusted; BMQ, Beliefs About Medicines Questionnaire; EE, Eastern Europe; GC, glucocorticoid; LA, Latin America(n); ME, Middle East; [b]MMAS-4, 4-item Morisky Medication Adherence Scale; OR, odds ratio; West, includes Western Europe, Canada, Australia and New Zealand; a. *P* value for comparison of all regions; b. High/full adherence: [a]MMAS-4 score = 4; c. n = no. of available questionnaire results: patients receiving multiple treatments rated their adherence to each treatment; d. OR from multiple regression analysis; e. Adjusted for age, gender, disease duration, current and prior disease severity, no. of comorbidities, cumulative treatment duration, response to current treatment, prior TNFi therapy, duration of formal education, and current primary occupation using analysis of covariance (ANCOVA); *Pr ≤ 05, **Pr ≤ 001, ***Pr ≤ 0001 for comparison vs West (reference) according to chi-square test ([a]MMAS-4); regression analysis ([b]MMAS-4) or ANCOVA (BMQ-Specific).

**Conclusions:** There were more RA pts reporting high medication adherence in the West vs other regions, with the fewest in LA and Asia. Asian pts may be less adherent to RA medication due to higher concerns and lower necessity beliefs towards systemic medication. Reasons for the low adherence rate in LA pts need to be explored further.

## THU0617 WORK PRODUCTIVITY AND DAILY ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN FOUR PHASE III RANDOMIZED CLINICAL TRIALS OF BARICITINIB

J.S. Smolen[1], A.M. DeLozier[2], S. de Bono[2], L. Yang[2], C. Gaich[2]. [1]*Division of Rheumatology, Medical University of Vienna, Vienna, Austria;* [2]*Eli Lilly and Company, Indianapolis, United States*

**Background:** Baricitinib (bari), an oral JAK1 and JAK2 inhibitor, was efficacious in Ph 3 studies in patients (pts) with active RA.[1–4]

**Objectives:** To assess effects of bari on workplace and daily activity with the Work Productivity and Activity Impairment-Rheumatoid Arthritis (WPAI-RA) questionnaire in adult RA pts.

**Methods:** In 4 Ph 3 trials (table), pts completed the WPAI-RA at baseline and ~every 4 wks. Least-squares mean (LSM) of change from baseline was compared with ANCOVA.

**Results:** Across studies, bari pts tended to have less absenteeism, presenteeism, and impairment in work productivity and daily activities at primary and final timepoints vs pts from comparator groups.

**Conclusions:** Across 4 Ph 3 studies, bari treatment improved workplace and daily activities in RA pts.

## THU0618 DISEASE ACTIVITY DURING AND AFTER PREGNANCY IN WOMEN WITH JUVENILE IDIOPATHIC ARTHRITIS: RESULTS FROM A PROSPECTIVE MULTICENTER STUDY

K. Ursin[1,2], S. Lydersen[3], J. Skomsvoll[2], M. Wallenius[1,2]. [1]*Department of Neuroscience, Norwegian University of Science and Technology;* [2]*Norwegian National Advisory Unit on Pregnancy and Rheumatic Diseases, Department of Rheumatology, Trondheim University Hospital;* [3]*Regional Centre for Child and Youth Mental Health and Child Welfare, Norwegian University of Science and Technology, Trondheim, Norway*

**Background:** Studies from the 1990s have demonstrated that the majority of women with juvenile idiopathic arthritis (JIA) experience decreased disease activity during pregnancy while about 50% flare post partum (1–3). However, these studies were retrospective studies without validated disease activity measures. DAS28 is a validated disease activity measure in women with JIA, and DAS28-CRP-3 is a validated disease activity measure during pregnancy in women with rheumatoid arthritis (4).

**Objectives:** The aim of this project was to prospectively study disease activity in women with JIA during pregnancy and until one year post partum with DAS28-CRP-3 as disease activity measure.

**Methods:** RevNatus is a Norwegian national research database, designed for the follow-up of women with inflammatory rheumatic diseases during and after pregnancy. The women have 6 or 7 visits at a rheumatology unit; before conception

if possible (visit 0), in each trimester (visit 1–3), and 6 weeks, 6 months and 12 months post partum (visit 4–6). RevNatus included 135 fullterm pregnancies in 114 women with JIA between 2006 and 2015. To explore disease activity throughout pregnancy and until one year post partum, DAS28-CRP-3-values registrered at each visit were analyzed in a three level linear mixed model.

**Results:** Analyzing DAS28-CRP-3-values from 6 time points throughout and after pregnancy in 135 pregnancies in 114 women with JIA, we found that disease activity 6 weeks post partum was significantly higher than disease activity in first trimester (p=0,004), in third trimester (p=0,011) and 12 months post partum (p=0,015). Results are displayed in figure shown below.

**Conclusions:** In 135 pregnancies in women with JIA disease activity increased significantly from pregnancy to 6 weeks post partum, and then decreased significantly between 6 weeks and 12 months post partum. The results call for tight follow-up of women with JIA in the first weeks after delievery.

## THU0619 LIFESTYLE BELIEFS OF 672 PATIENTS WITH RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS

L. Gossec[1,2], A. Saraux[3], P. Chauvin[4], M. Poussière[5], T. de Chalus[6], V. Saulot[7], F. Russo-Marie[7], J.M. Joubert[6], C. Hudry[8], F. Berenbaum[9]. *[1]UPMC Univ Paris 06; [2]Hôpital Pitié Salpêtrière, Paris; [3]CHU la Cavale Blanche and Université de Bretagne Occidentale, Brest; [4]INSERM, UPMC Univ Paris 06; [5]Independent Researcher, Paris; [6]UCB Pharma, Colombes; [7]Arthritis Fondation Courtin, Neuilly-sur-Seine; [8]AP-HP, Hôpital Cochin; [9]UPMC Univ Paris 06, AP-HP, Hôpital Saint-Antoine, Paris, France*

**Background:** In rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA), lifestyle factors such as physical exercise and smoking cessation are beneficial, whereas the impact of dietary factors is debatable. Is there a gap between what is known scientifically and what patients (pts) believe?

**Objectives:** To describe the most frequent lifestyle beliefs of pts with RA or axSpA, and identify the factors associated with erroneous lifestyle beliefs.

**Methods:** In this national cross-sectional study conducted in 2014–2015 in France, pts with RA (ACR/EULAR criteria) or axSpA (ASAS criteria) completed the self-reported "Opinions and fears of pts with chronic inflammatory rheumatism" (QOC-RIC) questionnaire,[1] which assessed pt beliefs through 19 questions. Of these, 11 questions were on lifestyle beliefs; each question was scored between 0–10, with 10 indicating "totally agree". For each lifestyle belief, descriptive analysis reported the percentage of pts with scores ≥7/10 in both RA and axSpA subpopulations. A multiple linear regression model with imputation of missing data explored the association between high levels of beliefs (≥7/10) and pt characteristics (including demographics, social and economic characteristics, disease status, and anxiety/depression levels through the Hospital Anxiety and Depression [HAD] and Arthritis Helplessness Index [AHI] scores).

**Results:** Overall, 672 pts recruited by 100 rheumatologists were analyzed: 432 with RA, 240 with axSpA. For RA and axSpA pts, respectively, 74.0% and 45.2% were female, average age was 58.3 (±13.1) and 47.0 (±13.2) years, and 77.3% and 72.7% were treated with biologics. Mean Disease Activity Score 28 (DAS28[ESR]) was 2.64 (±1.24) in RA pts and mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was 3.3 (±2.2) in axSpA pts. The belief (Table) of physical effort triggering flares (P2) was associated with higher anxiety levels (OR=1.80, p=0.005), whereas the opposite belief (P1) was associated with low depression levels (OR=0.56, p=0.007). Beliefs on alcohol (D3) were associated with underprivileged backgrounds (i.e. eligible for minimum social benefits; OR=4.27, p=0.027), whereas the belief on diet (D1) was associated with female gender (OR=2.17, p=0.014).

**Table:** Beliefs of RA and axSpA patients (% of patients that scored the belief ≥7/10)

| Lifestyle factors | Beliefs | RA | axSpA |
|---|---|---|---|
| Physical Lifestyle | P1 "I think that doing sport or a physical activity reduces my flares" | 31.4% | 45.8% |
| | P2 "I think that my flares are triggered by physical effort" | 31.1% | 43.3% |
| | P3 "I think that my disease was triggered by physically overdoing it" | 17.9% | 19.7% |
| Dietary Lifestyle | D1 "I think that eating certain foodstuffs can reduce my flares" | 10.5% | 9.7% |
| | D2 "I think that eating certain foodstuffs can trigger flares" | 10.3% | 9.7% |
| | D3 "I think that drinking alcohol (even in moderation) triggered my disease" | 6.2% | 0.8% |
| Other Lifestyle Factors | O1 "I think that smoking (even in moderation) or being exposed to passive smoking triggered my disease" | 6.2% | 1.7% |
| | O2 "I think that my disease was triggered by an environmental factor such as pollution" | 5.9% | 5.9% |
| | O3 "I think that my disease was triggered by a vaccination" | 8.3% | 8.4% |

**Conclusions:** Beliefs about physical activity are varied. Erroneous pt beliefs regarding physical activity were associated with anxiety, indicating that some beliefs may mirror psychological distress. Risks related to smoking were rarely perceived in this population of long-standing pts, and erroneous dietary beliefs were more frequent in female pts and those with underprivileged backgrounds. Physicians need to account for pt beliefs and pursue their educational efforts towards lifestyle modifications.

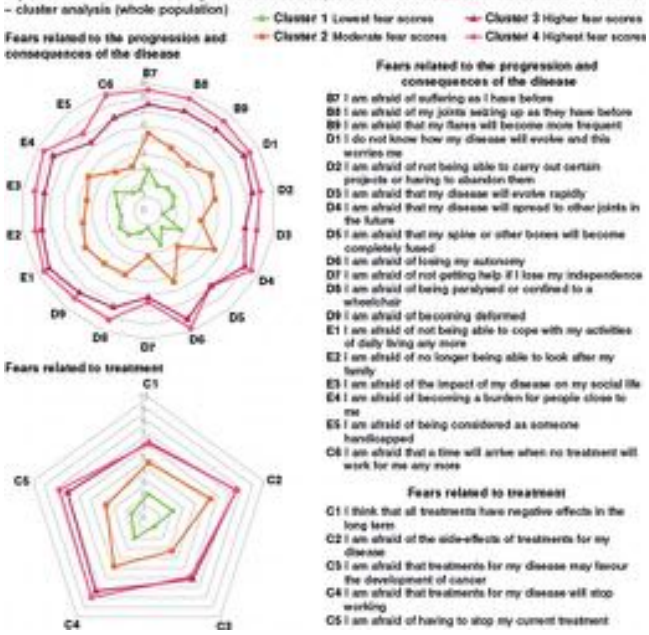
## THU0620 GENDER, DISEASE ACTIVITY, ANXIETY AND DEPRESSION LEVELS ARE RELATED TO THE LEVELS OF FEARS OF PATIENTS WITH RHEUMATOID ARTHRITIS OR AXIAL SPONDYLOARTHRITIS: A CROSS-SECTIONAL STUDY OF 672 PATIENTS

L. Gossec[1,2], P. Chauvin[3], C. Hudry[4], M. Poussière[5], T. de Chalus[6], V. Saulot[7], F. Russo-Marie[7], J.M. Joubert[6], A. Saraux[8], F. Berenbaum[9]. *[1]UPMC Univ Paris 06; [2]Hôpital Pitié Salpêtrière; [3]INSERM, UPMC Univ Paris 06; [4]AP-HP, Hôpital Cochin; [5]Independent Researcher, Paris; [6]UCB Pharma, Colombes; [7]Arthritis Fondation Courtin, Neuilly-sur-Seine; [8]CHU la Cavale Blanche and Université de Bretagne Occidentale, Brest; [9]UPMC Univ Paris 06, AP-HP, Hôpital Saint-Antoine, Paris, France*

**Background:** Patients (pts) with rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA) have personal fears related to their disease which can impact therapeutic strategy.[1] We previously reported high levels of fears in RA and axSpA pts in a French multicenter survey.[2]



**Objectives:** To identify factors associated with high levels of fears in RA and axSpA pts.

**Methods:** This national cross-sectional study was performed in 2014–2015 in France.[2] Rheumatologists recruited 6–20 pts with RA (ACR/EULAR criteria) or axSpA (ASAS criteria). Pts self-completed the "Opinions and fears of pts with chronic inflammatory rheumatism" (QOC-RIC) questionnaire[2] comprising 44 items including 23 questions on pt fears; each scored between 0–10 (10 = "totally agree"). Eighteen questions related to progression and consequences of the disease and 5 questions related to treatment. For each fear, descriptive analysis explored the percentage of pts with scores ≥7/10. A cluster analysis was run on the whole population to identify homogeneous groups (clusters) of pts according to their fears and beliefs (hierarchical ascendant classification). A multivariate multinomial logistic regression model using backward selection and multiple missing data imputation explored the variables (eg. epidemiological, socioeconomic, clinical) with $p<0.05$ on differences between clusters.

**Results:** Overall, 672 pts recruited by 100 rheumatologists were analyzed (432 RA, 240 axSpA). For RA and axSpA pts respectively, 74.0% and 45.2% were

female, average age was 58.3 (±13.1) and 47.0 (±13.2) years, and 77.3% and 72.7% were treated with biologics. Mean Disease Activity Score 28 (DAS28[ESR]) in RA pts was 2.64 (±1.24) and mean Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) in axSpA pts was 3.3 (±2.2).
Four pt clusters were identified corresponding to very high (31.6%), high (21.9%), moderate (32.7%) or low (13.8%) levels of fears (Figure). Variables related to the highest fear cluster were gender (female vs male; OR=2.38, p=0.013), high Pt Global Assessment of Disease Activity (PtGA [VAS]; >60 vs ≤30; OR=3.03, p=0.029), anxiety (HADS, anxiety score; >10 vs <8; OR=4.55, p<0.001) and depression (HADS, depression score; ≥8 vs <8; OR=3.23, p=0.011). Socioprofessional and family status did not have an associated p value <0.05 between populations with lowest and highest fears.

Figure: Fears related to the progression and consequences of the disease and fears related to treatment – cluster analysis (whole population)

**Conclusions:** Pts with the highest fears were most likely to be women with higher PtGA and anxiety/depression scores. Fears may reflect overall psychological distress in this population of pts and interventions to decrease these fears should be further assessed.

## THU0621 ONE THIRD OF PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS (RA) ARE CORRECTLY VACCINATED AGAINST INFLUENZA AND PNEUMOCOCCUS AND THIS IS INCREASING: 3 YEAR LONGITUDINAL ASSESSMENT OF 776 PATIENTS

L. Gossec, A. Molto, F. Foissac, F. Fayet, G. Mouterde, P. Gaudin, M. Soubrier, M. Dougados on behalf of COMEDRA Working Group. *COMEDRA Working Group, Paris, France*

**Background:** Influenza and pneumococcal vaccinations are recommended in all patients with RA. However, it is well known that a gap exists between recommendations and their implementation in real life.
**Objectives:** As EULAR recommendations for vaccinations are now widely disseminated, we took the opportunity of assessing vaccination rates of the patients who participated in the COMEDRA study [1], both at study entry and 3 years after the trial ended, to assess the progression of vaccination rate in this long-standing RA population undergoing a nurse-led program.
**Methods:** This was an open long term (3 years) extension of the COMEDRA 6 month randomized controlled trial in which patients with definite, stable RA were visiting a nurse for comorbidity counselling. Vaccination status was assessed during the RCT and nurses provided advice on vaccinations, and again 3 years later, during a face-to-face interview with a nurse. Agreement with the vaccination recommendations was defined as (a) influenza vaccination performed within the last 12 months and (b) pneumococcal vaccination performed within the last 5 years. The proportion of patients in accordance with the recommendations was compared between baseline and 3-year assessment using a McNemar test for paired data. The probability to be in accordance with recommendations was assessed by logistic mixed models including in the model the patient as random effect and as fixed effects: age, gender, disease duration, DAS28, educational level, work status, any biologic at baseline, and trial group and centre.
**Results:** Of the 970 recruited patients, 776 (80%) were followed up at 2–4 years and 759 (78%) had available data regarding both influenza and pneumococcal vaccination status: mean (±sd) age 61 (±11) years, median [IQR] disease duration 15 [10–23] years; 607 (80%) were women and 81% had ever received a biologic. The mean baseline and 3-year DAS28 scores were respectively 2.99±1.30 and 2.83±1.34.
At baseline, 337 (44.4%), 459 (60.5%) and 252 (33.2%) patients were in agreement with recommendations for influenza, pneumococcal and both vaccinations, respectively. After 3 years, this agreement increased for both vaccinations, to 420 (55.3%), 499 (65.7%) and 317 (41.8%) respectively (Table 1).
Having ever received a biologic (odds ratio, OR=4.73 [95% CI: 2.62- 8.52]), centre size (OR=2.8 [1.04–1.7]), university education (OR=1.79 [1.11–2.89]) and higher age (OR=1.07 [1.04–1.10]), were independently associated with being in accordance with both vaccinations recommendations.

Table 1. Adherence to vaccination recommendations

| | COMEDRA RCT study baseline* (month 0 for group I and month 6 for group II) | Follow-up at 3 years* | *p* value between baseline and follow up date |
|---|---|---|---|
| Influenza | 337 (44.4) | 420 (55.3) | p<0.0001 |
| Pneumococcus | 459 (60.5) | 499 (65.7) | p<0.01 |
| Both | 252 (33.2) | 317 (41.8) | p<0.0001 |

*N (% of 759).

**Conclusions:** The agreement with the EULAR vaccination recommendations is moderate but has increased in patients who had participated in a nurse-led program aiming at checking systematically for vaccination status.

## THU0622 EPIDEMIOLOGY AND OUTCOME OF DERMATOMYOSITIS IN NORTHWESTERN THRACE REGION IN TURKEY

M.A. Balci, F. Saritas, S. Donmez, O.N. Pamuk. *Department of Internal Medicine, Rheumatology, Trakya University Medical Faculty, Edirne, Turkey*

**Background:** Dermatomyositis (DM) is a rare disease that may affect the skeletal muscles and the skin. Literature data on its incidence and prevalence are limited. There is no data on its incidence or prevalence in Turkey.
**Objectives:** In our study, we determined the epidemiology, general clinical features and outcomes of DM based on hospital-based data in Thrace region, which is in northwestern Turkey.
**Methods:** Patients diagnosed with DM at the Trakya University Medical Faculty, Department of Rheumatology November 2004 and November 2014 were reviewed retrospectively. Patients' clinical features, laboratory measurements, demographics, treatments, follow-up durations, disease courses, outcomes and complications were evaluated. As a tertiary care center for rheumatologic diseases, our hospital serves approximately 620,447 adults (306,036 females and 314,411 males) from both rural and urban areas. The population number was obtained from the 2012 census data of the Turkish Statistical Institution, and this population remained stable during 2004–2014. Pediatric patients (<16 years) were not included. Edirne city is located in Thrace region, in northwestern part of Turkey; and it makes borders with Greece and Bulgaria. Our hospital is the only tertiary care reference center for rheumatic diseases for both Edirne and Kırklareli, another city to the north of Edirne.
**Results:** Our study included 23 patients with dermatomyositis. Of them, 14 (60.9%) were females and 9 (39.1%) were males (female to male ratio: 1.55). Over the course of the study, the annual incidence of dermatomyositis was 3.7/1,000,000 (95%CI: 0–18.8); and the overall prevalence was 32.2/1,000,000 (95%CI: 18.1–46.3). Incidence in women was higher 4.6/1,000,000 (95%CI: 0–28.6) compared to men 2.9/1,000,000 (95%CI: 0–21.6). Heliotrope rash (82.6%), gottron papules (87%), proximal myopathy (78.3%) and facial erythema (60.9%). As the first-line treatment, the classic dm patients were given steroid 18 (100%), hydroxychloroquine 16 (88.6%), methotrexate 11 (61.1%) or azathioprine 4 (22.2%) treatment and the amyopathic dm patients were given steroid 3 (60%), hydroxychloroquine 5 (100%) or azathioprine 1 (20%) treatment. The median duration of follow-up in all DM patients was 60 months (range 3–132 months). We observed recurrence in 7 patients during follow-up. We increased the dose of the steroid upon recurrence in all our recurring patients. We added a combination of hydroxychloroquine and methotrexate to treatment upon recurrence in 2 patients receiving steroid alone; and in 3 patients receiving a combination of steroid and

hydroxychloroquine at baseline, we added methotrexate upon recurrence and we added azathioprine to treatment in one patient with interstitial pulmonary disease upon recurrence. One patients who did not respond to current therapies, whose condition recurred frequently or had was given cyclosporine and intravenous immunoglobulin.
**Conclusions:** In conclusion, in our hospital-based study on DM for which very limited epidemiological data is available, we observed lower frequency than in North American studies. Female gender was more common in our series. Data in this study is the first epidemiological data on DM reported from Turkey.
**Disclosure of Interest:** None declared

## THU0623 PATIENT-REPORTED OUTCOMES FROM A PHASE 3 STUDY OF BARICITINIB IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS WHO HAD RECEIVED LIMITED OR NO TREATMENT WITH DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

M. Schiff[1], T. Takeuchi[2], C. Gaich[3], A.M. DeLozier[3], D. Schlichting[3], W.-L. Kuo[3], P. Durez[4], T. Carmack[5], J.-E. Won[3], R. Fleischmann[6]. *[1]University of Colorado School of Medicine, Denver, United States; [2]Keio University, Tokyo, Japan; [3]Eli Lilly and Company, Indianapolis, United States; [4]Université Catholique de Louvain, Brussels, Belgium; [5]Quintiles, Durham; [6]Metroplex Clinical Research Center, Dallas, United States*

**Background:** Baricitinib (bari), an oral JAK1 and JAK2 inhibitor, was efficacious in a Ph 3 study (RA-BEGIN) in RA patients (pts) who had limited or no exposure to methotrexate (MTX) and who were naïve to other csDMARDs and bDMARDs.[1]
**Objectives:** To evaluate patient-reported outcomes (PROs) from RA-BEGIN.
**Methods:** Pts were randomized to MTX QW, bari 4 mg QD, or bari 4 mg QD+MTX QW. PROs listed in the table and the Work Productivity and Activity Impairment-Rheumatoid Arthritis (WPAI-RA) questionnaire were collected on electronic tablets during study visits. Bari vs. MTX and bari+MTX vs. MTX were assessed with ANCOVA and logistic regression models.
**Results:** 584 pts were randomized. Mean baseline PROs for MTX, bari, and bari+MTX, respectively, were HAQ-DI:1.67, 1.64, 1.58; Pt's Global Assessment of Disease Activity (PtGDA):65.6, 65.0, 63.1; pt assessment of pain:65.2, 64.1, 62.6. Compared to MTX, bari and bari+MTX were superior in physical function, PtGDA, pain, and fatigue at Wks 24 and 52. Statistically significant improvements in all components of the WPAI-RA (absenteeism, presenteeism, work productivity loss and activity impairment) were seen in the bari and bari+MTX pts vs. MTX at Wk 24; statistically significant improvements were seen for work loss for bari+MTX vs. MTX at Wk 52 and for activity impairment for bari and bari+MTX vs MTX at Wk 52.
**Conclusions:** In this Ph 3 study of pts with early active RA, bari alone or with MTX was associated with significant improvements at 24 and 52 wks compared to MTX in most PROs.

## THU0624 SLEEP QUALITY IN PATIENTS WITH SEVERE KNEE OSTEROARTHRITIS

M. Nuñez[1], E. Nuñez[2], L. Lozano[3], J.M. Segur[3], J. Montañana[3], V. Segura[3], S. Salo[4], X. Alemany[3], S. Sastre[3]. *[1]Rheumatology and IDIBAPS Area 1, Hospital Clínic; [2]SAP Suport al Diagnòstic i al Tractament, Institut Català de la Salut; [3]Orthopedic Surgery and IDIBAPS; [4]Rheumatology, Hospital Clínic, Barcelona, Spain*

**Background:** Sleep disturbance is closely related to chronic musculoskeletal diseases. Reports suggest 55% of patients aged >55 years sleep <6 hours (15%) with deficient or poor quality sleep (29%), insomnia (56%) and diagnosed sleep disorders (18%). Osteoarthritis (OA) is one of the most prevalent of these diseases. Older adults with OA have poorer health, worse sleep quality, more limitations in activities of daily living and more pain compared with persons without OA. The prevalence of night joint pain and sleep problems increase with the severity of OA, which negatively impacts the quality of life.
**Objectives:** To determine whether sleep quality is associated with the health status in patients with severe knee OA.
**Methods:** Cross-sectional observational study. Consecutive patients with severe knee OA on a waiting list for arthroplasty were included. Sociodemographic and clinical variables were determined. Patients were asked the number of hours they usually sleep and about sleep quality (whether sleep was restorative) in the previous ≥6 months, using the question: How do you usually sleep? (by Likert scale: 1=good, 2=fair, 3=poor and 4=with medication). The health status was assessed using specific and generic health-related quality of life questionnaires (HRQOL) (WOMAC and SF-36, respectively). *Data analysis:* Multiple linear regression models were used to analyse the association between health and sleep quality (dichotomized as 1: reparative sleep (RS)=1 and non-reparative sleep (NRS)=2,3,4). Dependent variables were: total WOMAC scores (TW), SF-36 physical component (PC) and mental component (MC). Independent variables were: sleep quality, age, gender, BMI, severity OA number of comorbidities and depression/anxiety.
**Results:** 142 patients, (84% female, mean age 68.5 (SD 8.6), mean BMI 33.9 (SD 4.1), mean comorbidities 5.1 (SD 3.6) were included. The most-frequent comorbidities were hypertension 63.8%, back pain 47.5%, depression/anxiety 38.6%. Patients with RS (27%) slept a mean of 7.6 (SD 1) hours vs 6.6 (SD 1.4) hours in those with NRS ($p<0.001$). There was no association with the MC. Mean TW scores were 49.8 (SD 16.1) for patients with RS vs. 59.3 (SD 16.4) for patients with NRS (p=0.003). Mean PC scores were 36.1 (SD 9.5) for RS and 31.8 (SD 8.4) for NRS (p=0.009). Mean MC scores were 46.2 (SD 13.1) and 43.8 (SD 13.6) (p=0.343) for RS vs. NRS, respectively. Separate regression models showed RS was associated with better TW scores (p=0.002), with other variables not being significant, and that RS was associated with better PC scores (p=0.012) and female sex, the number of comorbidities and anxiety/depression were associated with worse PC scores (p=0.013 and p=0.004, respectively).
**Conclusions:** Reparative sleep is associated with a better health status in OA patients on a waiting list for TKA.

## THU0625 HEALTHCARE PROFESSIONALS' PERSPECTIVES ON THE DESIGN AND IMPLEMENTATION OF AN EARLY INTEGRATED CARE INTERVENTION FOR MUSCULOSKELETAL PAIN IN THE IRISH HEALTHCARE SETTING: A QUALITATIVE STUDY

N.M. Higgins[1], A. Cochrane[1], O. FitzGerald[2], P. Gallagher[3], J. Ashton[4], R. Breen[5], A. Brennan[6], O. Corcoran[7], D. Desmond[1]. *[1]Department of Psychology, Maynooth University, Maynooth; [2]School of Medicine and Medical Sciences, University College Dublin; [3]School of Nursing and Human Sciences, Dublin City University; [4]Physiotherapy Services, Beaumont Hospital; [5]Royal College of Physicians in Ireland; [6]Physiotherapy Services, AMNCH, Dublin; [7]Rheumatology Services, Waterford Regional Hospital, Waterford, Ireland*

**Background:** Musculoskeletal disorders are amongst the leading causes of disability in the working age population. Growing evidence suggests early screening and targeted interventions during the acute phase can promote work retention and prevent disability.

MCID, minimum clinically important difference; M/PCS, mental/physical component score; VAS, visual analog scale; *p≤0.05, **p≤0.01, ***p≤0.001 vs. MTX.

**Objectives:** This study aims to develop and feasibility test an early, case manager-led intervention focusing on work as a clinical outcome. Here we report qualitative findings from focus groups and interviews conducted to consider issues of content, delivery and optimal timing, and to explore key priorities and potential challenges in service delivery.
**Methods:** Two focus groups and three individual interviews were conducted, involving 17 experts representing the multidisciplinary team. Thematic analysis was used to summarise the views and ideas expressed.
**Results:** Participants highlighted the importance of early access to diagnosis, relevant investigations and referral to specialists as necessary in reducing the risk of long term disability; noting the critical importance of GPs in facilitating early access. The need to provide reassurance and education about the patient's condition was highlighted, as was the importance of screening for psychosocial risk factors. Patients most likely to benefit from the intervention were identified as those highly motivated to maintain their current work roles. Ready access to the MDT and the skill set of the case manager were noted as critical concerns, resource constraints pose considerable challenges.
**Conclusions:** Introduction of an early integrated care intervention that targets risk of work disability is warranted. Considerable "buy-in" is required from all stakeholders involved. The data will help to inform the planned feasibility study.
**Acknowledgement:** We would like to thank all of the individuals who participated in the interviews and focus groups.
**Disclosure of Interest:** None declared

## THU0626 DRUG ADHERENCE IMPACT ON SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS HEALTH

N.O. El-Azizi, A.A.M. Elhefny, M.A. Adb El-Rahman, M.A. Abou-Sheashaa.
*Internal Medicine & Rheumatology, Facilty of Medicine- Ain Shams University, Cairo, Egypt*

**Background:** Poor adherence to therapeutic regimens is a common and expensive problem in patients with chronic diseases including SLE and is associated with a higher risk of flares, morbidity, hospitalizations and poor renal outcome.
**Objectives:** To measure the prevalence of adherence to drug treatment and analyze its associations with medications prescribed, disease characteristics, health professionals performance and services, and socio-demographic issues in patients with SLE to improve patients' outcome and quality of service.
**Methods:** 100 SLE patients (with disease duration $\geq$1year) fulfilled the 2012 Systemic Lupus International Collaborating Clinics (SLICC) classification criteria recruited from the outpatient clinic and inpatient unit of Rheumatology & Internal Medicine Department at Ain Shams University Hospitals. After consent all patients subjected to detailed history taking and full clinical examination, ANA, Anti-dsDNA titers, urine analysis, CBC, ESR, assessment of disease activity by SLEDAI and assessment of disease damage using the SLICC/ACR damage Index. All patients completed the screening adherence survey questionnaire for assessment of adherence to SLE medications (in the previous 6 months).
**Results:** The prevalence of adherence to drug treatment was 76%. The cause of adherence in 44.74% of adherent patients was their fear of disease worsening if medications were stopped, while feeling of moral obligation and responsibility to others (family members) was the cause of adherence in 28.95%. The reasons for non-adherence were forgetfulness (66.66%), high medications cost and difficulty to obtain medications (54%), then the large number of tablets prescribed (50%). 8.3% of our non-adherent patients stopped taking their drugs when they felt better. Source of getting medications was a highly statistically significant factor in adherence ($P<0.001$) as 86.83% of the adherent patients were taking their medications at governmental expense, while 89.47% of non-adherent patients couldn't afford. The non-adherent group had statistically significant higher disease duration (7.71 Vs 5.7 years) (P=0.032), higher prevalence of development of side effects (especially gastritis and peptic ulcer) (P=0.047) and higher SLEDAI (36.92 ±11.93 Vs 6.8±1.9) & DI score (6.67±2.5 Vs 0.21±0.47) ($P<0.001$) than the adherent group. 87.5% of non-adherent patients didn't regularly attend the clinic (P=0.068); the median of number of drugs was 5.33 which was higher than that of adherent group 4.6 (P=0.015). 61% of our patients were satisfied with the standards of care at the clinic ($P<0.001$).
**Conclusions:** Longer disease duration, higher drug cost, forgetfulness and the large number of prescribed drugs are risk factors for SLE patients non adherence.

*[1]Department of Pharmacy & Pharmacology, University of Bath, Bath; [2]Centre for Musculoskeletal Research, University of Manchester, Manchester; [3]Department of Mathematical Sciences, University of Bath; [4]Rheumatology Department, Royal National Hospital for Rheumatic Diseases & Royal United Hospitals, Bath, United Kingdom*

**Background:** Disease activity in rheumatoid arthritis (RA) has traditionally been measured using the 28-joint count disease activity score (DAS28) using ESR. Use of DAS28 using C-reactive protein (CRP) in place of ESR is increasing. This study investigates the level of agreement between the DAS28-ESR and DAS28-CRP scores across different disease activity thresholds and identifies how patient characteristics may influence agreement.
**Objectives:** To identify the interscore agreement between the DAS28-ESR and DAS28-CRP scores and identify if gender or body mass index (BMI) influence the level of agreement.
**Methods:** Patients with concurrent measures of ESR and CRP were identified from the BSRBR-RA, enabling paired calculation of DAS28-ESR and DAS28-CRP. Paired scores were stratified by patients' baseline BMI and gender. Agreement between the scores was compared using Bland-Altman statistics and agreement matrices.
**Results:** 5457 patients (mean age 56 yrs, 76% female) with 31,084 data entries were identified where paired DAS28-ESR/DAS28-CRP scores could be calculated. Mean DAS28-ESR was 0.3 points (95% CI -0.8 - 1.4) greater than DAS28-CRP (4.4 (SD 1.7) and 4.1 (SD 1.6) respectively). Men had a lower mean difference between the two scores compared with women (DAS28-ESR $>$ DAS28-CRP by 0.2 points (95% CI -1.0 – 1.3) vs. 0.4 points (95% CI -0.7 – 1.4) respectively). The results stratified by BMI were similar to the overall mean difference. Agreement between the two scores according to disease activity thresholds are shown in Table 1.

Table 1. Overall agreement between DAS28-ESR and DAS28-CRP scores

| | DAS28-CRP | | | | |
|---|---|---|---|---|---|
| | Remission ($<$2.6) | LDA (2.6 to $\leq$3.2) | MDA (3.2 to $\leq$5.2) | HDA $>$5.2 | Totals |
| DAS28-ESR | | | | | |
| Remission ($<$2.6) | 4041 (66.7%) | 646 (15.8%) | 170 (1.4%) | 0 | 4857 (15.6%) |
| LDA (2.6 to $\leq$3.2) | 1541 (25.4%) | 1303 (32.0%) | 591 (4.9%) | 5 (0.1%) | 3440 (11.1%) |
| MDA (3.2 to $\leq$5.2) | 481 (7.9%) | 2128 (52.2%) | 8881 (73.7%) | 320 (3.6%) | 11810 (38.0%) |
| HDA $>$5.2 | 0 | 0 | 2414 (20.0%) | 8563 (96.3%) | 10977 (35.3%) |
| Totals | 6063 (19.5%) | 4077 (13.1%) | 12056 (38.8%) | 8888 (28.6%) | 31084 |

LDA, low disease activity; MDA, moderate disease activity; HDA, high disease activity.

**Conclusions:** Overall, the DAS28-ESR classifies fewer patients in remission (15.6% vs. 19.5%) giving a score, on average 0.3 points greater than the DAS28-CRP, with women having a greater difference between the two scores than men. When categorising scores by disease activity thresholds, the DAS28-ESR/DAS28-CRP have lowest agreement at LDA. 54.4% of DAS28-ESR scores were classified as MDA when the paired DAS28-CRP was LDA, which could influence results in clinical trial reporting. Conversely, 20% of patients were classified as being in MDA by DAS28-CRP when the paired DAS28-ESR demonstrated HDA. This is of importance given NICE biologics guidelines, and shows that up to 20% of patients may not satisfy the criteria for biologic therapy if DAS28-CRP were used instead of DAS28-ESR. These results highlight the impact of using the DAS28-ESR or DAS28-CRP interchangeably, and the importance of using a consistent version of the DAS28.

## THU0628 SOCIO-ECONOMICALLY DEPRIVED PATIENTS HAVE A HIGHER LIKELIHOOD FOR HAVING ANY TYPE OF RHEUMATIC AND MUSCULOSKELETAL DISEASES AND HAVE HIGHER HEALTHCARE COSTS - RESULTS FROM A POPULATION-BASED ADMINISTRATIVE DATABASE INCLUDING 1.9 MILLION PERSONS (BASQUE COUNTRY, SPAIN)

P. Putrik[1], S. Ramiro[2], J.F. Orueta[3], A. Keszei[4], E. Alonso-Morán[5], R. Nuño-Solinis[6], A. Boonen[1]. *[1]Rheumatology, Maastricht University, CAPHRI, MUMC, Maastricht; [2]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [3]Centro de Salud de Astrabudua, Osakidetza, Basque Health Service, Bilbao, Spain; [4]Medical Informatics, Uniklinik RWTH Aachen University, Aachen, Germany; [5]Freelance Biostatistician Researcher; [6]Universidad Deusto, Bilbao, Spain*

**Background:** Rheumatic and musculoskeletal diseases (RMDs) are prevalent and have a strong impact on health care costs. Some evidence in specific diseases

indicates that patients with lower socio-economic background are at higher risk to have the disease and incur more healthcare costs. However, knowledge whether these effects of socio-economic status are comparable across all RMDs is lacking.
**Objectives:** To compare the impact of socio-economic deprivation on occurrence of different RMDs and associated health care costs.
**Methods:** An administrative dataset linking clinical (based on ICD codes), socio-demographics (age, gender and deprivation index) and health care utilization costs information of the entire adult (≥18 y.o.) population of the Basque Country, Spain was used. Deprivation index was based on area employment and education status, and included five categories (1 to 5 (most deprived)). Costs included primary and specialist care, planned and acute hospital admissions, and ambulatory drug prescriptions. Thirty-six individual diseases were grouped into seven larger diagnostic groups: Rheumatoid Arthritis, Crystal Arthropathies, Osteoarthritis, Soft tissue diseases, Connective Tissue Diseases, and Vasculitis. Logistic and Poisson regression models were computed to explore the relation between the deprivation index and the occurrence of the disease (separately and grouped) and health care utilization costs, respectively. Models were adjusted for age, gender, and models with costs were also adjusted for comorbities, computed with the Rheumatic Diseases Comorbidity Index.
**Results:** In total, data from 1,923,156 individuals were analyzed. Mean age was 49.9 (SD18.4) years, 49% were males. Soft tissue diseases were the most prevalent (5.5%), third most costly in terms of health care utilization costs after vasculitis and rheumatoid arthritis. Socio-economic deprivation was associated with higher likelihood to have any of the RMDs, and gradients were of comparable magnitude. The strongest socio-economic gradient was seen for the occurrence of soft tissue diseases (OR 1.82 [95%CI 1.78;1.85], most vs. least deprived) (Figure). Deprivation was also associated with higher costs across the majority of the conditions, but a somewhat different pattern across diseases was seen. The strongest gradients were observed in patients with Spondyloarthritis (in particular. with Ankylosing spondylitis) and Vasculitis.

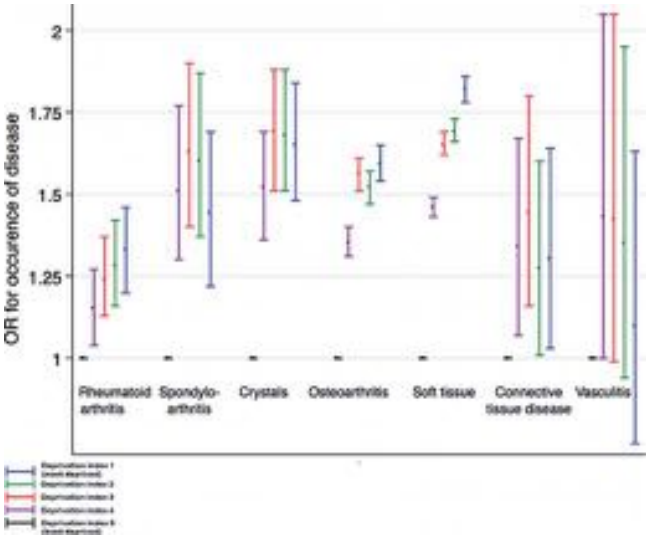

Figure 1. Association of the occurrence of rheumatic diseases with the socio-economic deprivation.

**Conclusions:** Socio-economic deprivation was consistently associated with higher occurrence and higher costs across most of the RMDs. Among major RMDs, the group of soft tissue diseases (comprising chronic low back and neck pain, fibromyalgia, and soft tissue disease), was the most prevalent and costly for the society, and occurred more often in individuals with lower socio-economic status.

## THU0629 THE COST-EFFECTIVENESS OF GOLIMUMAB AS AN ADD-ON TO CONVENTIONAL CARE COMPARED TO CC FOR THE TREATMENT OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN SCOTLAND

R.H. Borse[1], E. McCann[2], O. McGill[2], C. Black[3], S. Kachroo[3], R. Insinga[1]. *[1]Merck & Co., Inc., North Wales, PA, United States; [2]Merck & Co., Inc., Hoddesdon, United Kingdom; [3]Merck & Co., Inc., Rahway, NJ, United States*

**Background:** Golimumab (Gol) has been approved by the Scottish Medicines Consortium in the treatment of adults with severe active non-radiographic axial spondyloarthritis (nr-axSpA) with objective signs of inflammation, as indicated by elevated C-reactive protein and/or magnetic resonance imaging evidence, who have had an inadequate response to or are intolerant to nonsteroidal anti-inflammatory drugs.
**Objectives:** To evaluate the cost-effectiveness (CE) of Golimumab (Gol) in addition to conventional care (CC) in the treatment of nr-axSpA, in Scotland, from an NHS perspective.
**Methods:** We built a Markov model to assess CE in nr-axSpA patients over their lifetimes. Among the treated population, disease progression through 60 weeks was based on the GO-AHEAD trial. Post-week 60, BASDAI/BASFI scores were held constant until week 260, when assumed the disease deterioration rate to be 50% of CC. At week 12, patients were responders if they had a ≥50% improvement from baseline BASDAI scores, otherwise they discontinued. We applied a fixed discontinuation rate, post-week 12. Patients reached equivalent health states to those on CC 24 weeks, post-discontinuation. Utilities were linked to BASDAI/BASFI scores based on trial data. We used a published equation using BASFI scores to estimate long term health care costs. Discounting was applied at 3.5%/year. Uncertainty was explored through sensitivity analyses.
**Results:** The average baseline values for age, BASFI and BASDAI scores (based on GO-AHEAD data) was 31 years, 5.01 and 6.49, respectively. GoI when added to CC, led to an increase of 2.06 QALYs (8.98 vs. 6.92) per patient at an additional net cost of £39,770 (£146,908 vs. £107,138) compared with CC alone. GoI resulted in an incremental cost-effectiveness ratio (ICER) of £19,280/QALY. The ICER was sensitive to the correlation between BASDAI/BASFI and health-care costs and utilities in sensitivity analyses.
**Conclusions:** GoI+CC is cost-effective compared with CC alone for the treatment of nr-axSpA in Scotland.

## THU0630 TREATMENT FAILURE, TREATMENT SWITCHING AND HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS OR PSORIATIC ARTHRITIS: RESULTS FROM A LARGE MULTINATIONAL REAL-WORLD SAMPLE IN EUROPE AND THE USA

R. Alten[1], V. Strand[2], P.G. Conaghan[3], A. Deodhar[4], E. Sullivan[5], S. Blackburn[5], H. Tian[6], K. Gandhi[6], S. Jugl[7]. *[1]Schlosspark-Klinik, University Medicine, Berlin, Germany; [2]Stanford University, Palo Alto, CA, United States; [3]University of Leeds, Leeds, United Kingdom; [4]Oregon Health & Science University, Portland, OR, United States; [5]Adelphi Real World, Manchester, United Kingdom; [6]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [7]Novartis Pharma AG, Basel, Switzerland*

**Background:** Many patients with ankylosing spondylitis (AS) or psoriatic arthritis (PsA) do not receive advanced therapy (AT; a biologic or apremilast) or their first experience of AT is inadequate owing to lack of efficacy, intolerance or loss of benefit over time.
**Objectives:** To describe use of AT, treatment failure and switching, and assess implications of failure.
**Methods:** In this cross-sectional survey from five European countries and the USA, physicians with 3–30 years' experience were eligible if currently treating patients with AS or PsA. Physician-completed record forms included reasons for switching AT, including "primary lack of efficacy (PLE, initial non-response)" and "secondary lack of efficacy (SLE, loss of response over time)". Patients reported HRQoL (EQ-5D and SF-36), work productivity and activity impairment (WPAI) and HAQ-DI (PsA only). At analysis, current AT was assessed as "failed" if, after ≥3 months, disease severity had worsened since AT initiation or had remained severe, or if the physician was dissatisfied with disease control, perceived disease activity as "unstable" or "deteriorating", or did not consider treatment a "success".
**Results:** Data are presented from 599 physicians (457 EU/142 USA), 2018 patients with AS (1520/498) and 2436 with PsA (1839/597). Of 1889 AS patients with full treatment data, 33.5% had never received AT, 57.1% were receiving their first, 6.9% their second and 2.5% their third or later AT. Of the 2278 patients with PsA and full treatment data, the proportions were 40.8%, 48.0%, 7.9% and 3.2%, respectively.
Of the 190 AS patients with known reasons for switching from first AT, 15.8% switched owing to PLE and 46.8% to SLE. Of the 245 PsA patients, the proportions

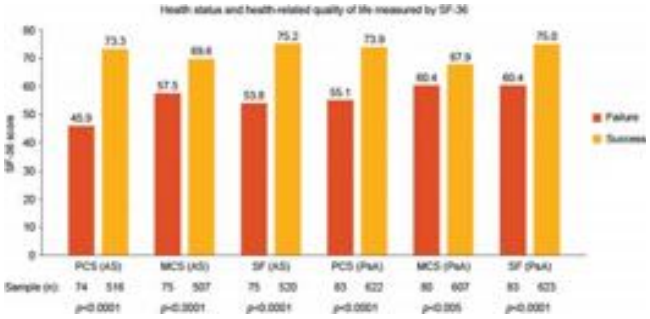

Figure 1

were 22.0% and 44.9%. Despite PLE, patients continued on first-line AT for a mean 12.1 months (AS, n=30) and 9.5 months (PsA, n=52).
The "failure" rate increased with successive ATs: 10.8% (116/1079) of AS patients on their first AT, 16.2% (21/130) on their second and 22.9% (11/48) on their third. For PsA, the rates were 11.0% (120/1094), 13.3% (24/181) and 19.2% (14/73).
AS patients failing AT had significantly worse EQ-5D utilities (0.55 vs 0.82) and SF-36 physical component summary (PCS; 45.9 vs 73.3), mental component summary (MCS; 57.5 vs 69.6) and social function scale (SF; 53.8 vs 75.2) scores than those not failing (all $p<0.0001$). PsA patients failing AT also had significantly worse EQ-5D (0.63 vs 0.80, $p<0.0001$), PCS (55.1 vs 73.9, $p<0.0001$), MCS (60.4 vs 67.9, $p=0.0024$) and SF (60.4 vs 75.0, $p<0.0001$) scores than those not failing. For AS failure, WPAI (44.0% vs 21.7%, $p<0.0001$) was higher, and for PsA failure, WPAI (29.7% vs 21.0%, $p=0.0112$) and HAQ-DI (0.96 vs 0.55, $p<0.0001$) were higher than non-failure.
**Conclusions:** This large multinational survey in AS and PsA showed that the main reason for switching AT is lack of efficacy. Failure of AT has significant negative effects on HRQoL and work productivity.

## THU0631 INCIDENCE OF SERIOUS ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS EXPOSED TO BIOLOGIC THERAPIES. RESULTS FROM BIOBADABRASIL REGISTRY

R. Ranza[1], I. Laurindo[1], D. Titton[1], M. Bertolo[1], W. Bianchi[1], C. Brenol[1], M. Bustamante[1], H. Carvalho[1], G. Castro[1], I. Costa[1], A. Duarte[1], V. Fernandes[1], M. Freire[1], P. Louzada-Jr[1], J. Maciera[1], J. Miranda[1], J. Moraes[1], I. Pereira[1], G. Pinheiro[1], M. Sauma[1], B. Stadler[1], R. Toledo[1], V. Valim[1], C. Baaklini[2], M. Descalzo[3]. *[1]BiobadaBrasil; [2]President, Brazilian Society of Rheumatology, São Paulo, Brazil; [3]Research Unit, Academia Española de Dermatología y Venereología, Madrid, Spain*

**Background:** The safety profile of biologic drugs might have substantial regional differences. Since 2009, the Brazilian Society of Rheumatology runs BiobadaBrasil, a registry for monitoring of biologic therapies in rheumatic diseases, in collaboration with other Latin America countries (BiobadaAmerica) and with Biobadaser
**Objectives:** To report the incidence of serious adverse events (SAE) in Rheumatoid Arthritis (RA) patients exposed to biologic drugs in Brazil
**Methods:** BiobadaBrasil counts on thirty two centers, from almost all Brazilian states, that prospectively include patients with active rheumatic diseases who started a biologic drug or a synthetic DMARD as a parallel control group. A constant three level monitory of data quality is maintained (online, by phone and "in situ"). This study focuses on SAE (for definition: Protocolo 1.1 at https://biobadaser.ser.es/biobadamerica/Brasil/cgi-bin/upload/documentacion.aspx) in RA patients exposed to biologics from January 2009 to June 2015. Time of exposure was set from start of the drug to the date of last administration or censorship. Continuous variables were expressed as mean with standard deviation (SD). SAE incidence rate was calculated per 1000 patient/years with 95%CI
**Results:** Out of a total of 1649 subjects with RA, 1121 were exposed to biologics (4735 p/y), 91% a-TNFs, follow-up 2.8 (2.2) yrs, 85% females, at baseline: age 50 (14) yrs, disease duration 9 (8) yrs, DAS28 5.4 (1.4). Controls were 528 (1971 p/y), follow-up 3.6 (2.2) yrs, 86% females, at baseline: age 54 (13) yrs, disease duration 6 (8) yrs, DAS28 5.1 (3.1). The incidence rates of SAE in the biologics and control groups were 86 [78, 94] vs 34 [27, 44] (ratio 2.5 [1.9, 3.3], $p<0.001$). There was no statistical difference in SAE incidence between a-TNFs and non-a-TNF biologics. Among a-TNFs, Adalimumab was associated with less SAE (64 [53,79]) compared with Etanercept (93 [77,113] $p<0.01$) and Infliximab (102 [86,122] p=0.0003). SAE were more frequent with subsequent a-TNF than with the first, 107 [87, 132] vs 79 [70, 90] (ratio 1.4 [1.1, 1.7] p=0.0078). Among SAEs with biologics, serious infections account for half of the events (43 [37–49])
**Conclusions:** In the BiobadaBrasil registry the incidence of SAE is 2 fold higher with biologics than with synthetic DMARDs, and higher with subsequent a-TNF than with the first

## THU0632 RETROSPECTIVE ANALYSIS OF THE ASSOCIATION BETWEEN ANTI-CYCLIC CITRULLINATED PEPTIDE POSITIVITY AND HEALTHCARE COSTS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING CONVENTIONAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

S. Johnston[1], C. Patel[2], K. Wilson[1], D. Spencer[1], L. Rosenblatt[2]. *[1]Truven Health Analytics, Bethesda; [2]Bristol-Myers Squibb, Princeton, United States*

**Background:** A recent retrospective analysis of US insurance claims data suggested that, among patients newly diagnosed with RA, those who were anti-cyclic citrullinated peptide (anti-CCP) and/or rheumatoid factor (RF) positive (+) had increased RA-related healthcare costs over a 6-month post-diagnosis period compared with those who were anti-CCP/RF negative (–).[1] Identification and treatment of this poor prognostic factor in the realm of RA diagnosis per the ACR guidelines appear to be of value.
**Objectives:** To investigate the potential role of anti-CCP status in association with clinical outcomes and healthcare costs in conventional (c)DMARD-naïve patients with RA using real-world data.
**Methods:** This was a retrospective, observational cohort study using the MarketScan® US administrative commercial claims and laboratory results databases. Patients included in this study had initiated cDMARD therapy between 1 January 2006 and 1 July 2014 (initiation=index), were aged ≥18 years at index, were continuously enrolled for 12 months before (baseline) and 12 months after (follow-up) index, did not receive cDMARDs or biologics during baseline, had an anti-CCP test result and had ≥2 medical claims with diagnoses of RA during baseline to 3 months after index. Patients were designated anti-CCP+ if their anti-CCP laboratory value was ≥20 IgG Ab units/mL. The study outcomes were all-cause and RA-related (i.e. medical claims with a diagnosis of RA or claims for cDMARDs and biologics) healthcare costs measured over the 12-month follow-up period. Generalized estimating equations were used to estimate the difference in healthcare costs from baseline to follow-up between anti-CCP+ and anti-CCP– patients (i.e. difference-in-difference [DiD]).
**Results:** The study included 635 patients: 391 anti-CCP+ (mean age 52 years; 81% female); 244 anti-CCP– (mean age 52 years, 80% female). Anti-CCP+ and anti-CCP– patients differed substantially with respect to baseline all-cause healthcare costs (mean [SD] anti-CCP+: $7650 [$12,901], anti-CCP–: $12,591 [$23,922]; p<0.001), but not RA-specific costs (mean [SD] anti-CCP+: $809 [$2683], anti-CCP–: $891 [$2629]; p=0.239). In the DiD analysis, which adjusts for baseline differences between groups, anti-CCP+ patients experienced increases in all-cause total healthcare costs that were $2756 greater (p<0.001) than those of anti-CCP– patients; this result was primarily driven by greater increases in outpatient costs ($2274; p<0.001; Table). Analyses of RA-related healthcare costs were directionally consistent across the categories.

| All-cause healthcare cost category | Difference-in-difference* |
|---|---|
| Total | $2756; p<0.001 |
| Inpatient medical | $(–234); p=0.089 |
| Outpatient medical | $2274; p<0.001 |
| Pharmacy† | $716; p=0.010 |

*Positive value indicates that anti-CCP+ patients' healthcare costs increased more than those of anti-CCP– patients from baseline to follow-up
†Includes outpatient pharmacy and infused biologics

**Conclusions:** After accounting for baseline differences between anti-CCP+ and anti-CCP– patients, anti-CCP+ patients' healthcare costs increased substantially more than anti-CCP– patients over a 12-month follow-up period. Among patients with RA who are newly initiating cDMARDs, anti-CCP positivity may serve as an identifiable predictor for markedly increased future healthcare costs, therefore establishing a need for a more appropriate treatment for cost reduction.

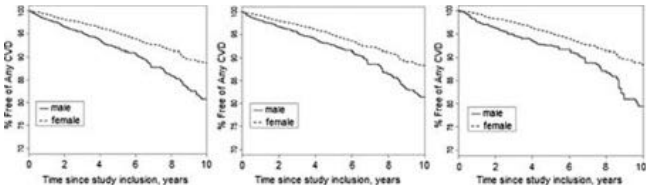
## THU0633 THE REVISED BRISTOL RA FATIGUE NRS, CONTAINING NEW NRS-COPING ANCHORS (BRAF-NRS V2 REVISED): VALIDITY ACROSS 6 EUROPEAN COUNTRIES

S. Hewlett[1], J. Nicklin[1], C. Bode[2], F. Cramp[1], L. Carmona[3], B. Davis[4], E. Dures[1], M. Engelbrecht[5], J. Fransen[6], L. Gossec[7], R. Greenwood[4], S. Hagel[8], M. van de Laar[2], I. Petersson[8], M. Redondo[9], A. Molto[7], G. Schett[5], J. Kirwan[10]. *[1]University of the West of England, Bristol, United Kingdom; [2]University of Twente, Twente, Netherlands; [3]3Instituto de Salud Musculoesquelética, Madrid, Spain; [4]Bristol Royal Infirmary, Bristol, United Kingdom; [5]University of Erlangen, Nuremburg, Germany; [6]Radboud University, Nijmegan, Netherlands; [7]University of Paris, Paris, France; [8]Lund University, Lund, Sweden; [9]Universidad Camilo, Madrid, Spain; [10]University of Bristol, Bristol, United Kingdom*

**Background:** BRAF-NRS are a trio of items for fatigue severity, impact and coping. At development, patients wanted the NRS-Severity & Impact anchors to read 0=No fatigue/effect, 10=Totally exhausted/Great deal of effect, but the NRS-Coping to read 0=Not at all well, 10=Very well.[1] Construct and criterion validity of the NRS-Coping-NRS are less strong than NRS-Severity and Impact;[2] cognitive interviewing shows patient confusion over Coping anchors.[3]
**Objectives:** Test construct and criterion validity of BRAF-NRS V2, which has Revised NRS-Coping anchors of 0=Very well, 10=Not at all well (NRS-Severity and Impact unchanged), in 6 EU countries.
**Methods:** RA patients from France, Germany, Netherlands, Spain, Sweden and UK completed the BRAF-NRS V2 Revised, BRAF-NRS Original, BRAF-MDQ, RAID, SF-36. Spearman's correlations assessed criterion and construct validity.
**Results:** Of 1276 patients 76% were female, median HAQ 1.0 (IQR 0.375–1.5). Mean BRAF-NRS-Coping Revised 4.0 (SD 2.66) vs Original 5.95 (SD 2.57), NRS-Severity 4.86 (SD 2.56), NRS-Impact 4.61 (SD 2.69). BRAF-NRS-Severity and Impact had appropriate validity with all 18 variables, overall and by country (r=0.46–0.96). Table shows BRAF-NRS-Coping Revised had better validity than NRS-Coping Original in all variables overall (stronger correlations bolded), and for 15–18/18 variables in all countrie except Spain (3/18). The difference in strength of correlations between the versions was large for the total sample, but minimal for Spain.

Table 1



| | BRAF-NRS Coping | | | |

**Conclusions:** BRAF-NRS V2 Revised has construct and criterion validity across 6 EU countries. Whilst the BRAF-NRS-Coping Original is acceptable, the BRAF-NRS-Coping Revised has greater validity. In Spain, the validity of both versions is lower but similar to each other. Further exploration of the concept and wording of "coping" in the Spanish population is warranted.

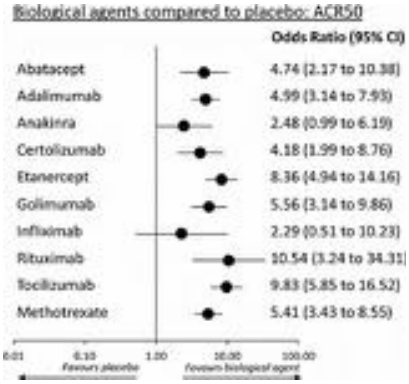
## THU0634 SEX DIFFERENCES IN CARDIOVASCULAR RISK FACTORS AND EVENT RATES IN PATIENTS WITH RHEUMATOID ARTHRITIS - DATA FROM 13 RHEUMATOLOGY CENTERS

S. Rollefstad[1], E. Ikdahl[1], C.S. Crowson[2], S.E. Gabriel[3], G.D. Kitas[4], P.L. van Riel[5], A.G. Semb[1] on behalf of A Trans-Atlantic Cardiovascular Consortium for Rheumatoid Arthritis (ATACC-RA). *[1]Preventive Cardio-Rheuma Clinic, Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [2]Division of Biomedical Statistics and Informatics, Department of Health Sciences Research and Division of Rheumatology, Department of Medicine, Mayo Clinic, Rochester,[3]Rutgers Robert Wood Johnson Medical School, New Brunswick, United States; [4]Dudley Group NHS Foundation Trust, West Midlands, United Kingdom; [5]Department of Rheumatic Diseases, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands*

**Background:** In the general population it is well documented that females have their CVD diagnosed at a later stage compared to males. Wether this is true also for rheumatoid arthritis (RA) patients is not known.
**Objectives:** To evaluate if cardiovascular disease (CVD) risk prediction and event rates differed between the sexes, and if adjustments for traditional and RA specific risk factors were of importance.
**Methods:** RA cohorts from 13 rheumatology centers were compared. Data on CVD risk factors and RA characteristics were collected at baseline; CVD outcomes were collected using standardized definitions. Standardized incidence ratios (SIR) were calculated with respect to sex using the following risk calculators FRS, SCORE, ACC/AHA and QRISK II.
**Results:** 5638 patients with RA and no prior CVD were included (mean age: 55.3 [SD: 14.0] years, 76% female). During a mean follow-up of 5.8 (SD: 4.4) years, 437 patients developed CVD events. SIRs (95% CI) using the various CVD risk calculators were for females and males: FRS: 1.02 (0.80, 1.31) and 0.86 (0.67, 1.12) (p=0.19), SCORE: 0.34 (0.17, 0.67) and 0.25 (0.11, 0.58) (p=0.98), ACC/AHA: 0.72 (0.50, 1.04) and 0.56 (0.36, 0.88) (p=0.74) and QRISKII 0.61 (0.47, 0.79) and 0.52 (0.35, 0.79) (p=0.42). The 10 year CVD-free survival differed significantly between the sexes, when adjusting for a) age, b) age and CVD risk factors and c) age, CVD risk factors and RA disease characteristics (Females [mean %±SD] 88.3±0.3, males 79.4±0.4), p<0.001 for all (Figure).



**Conclusions:** In a large international cohort of patients with RA, there was no sex difference in the ability of the various risk calculators to predict CVD. CVD-free survival was significantly higher in females, even after adjustments for both traditional and RA specific risk factors.

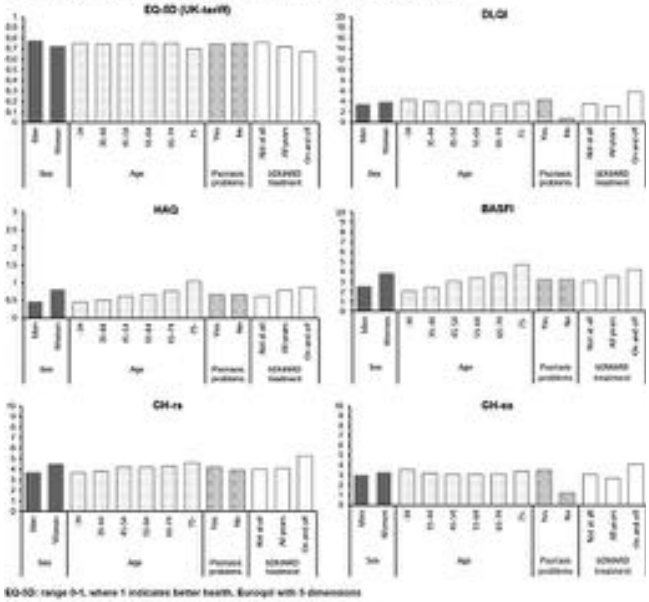
## THU0635 DEFINING THE OPTIMAL BIOLOGICAL MONOTHERAPY IN RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS OF RANDOMISED TRIALS

S. Tarp[1], D.E. Furst[2], A. Døssing[1], M. Østergaard[3], T. Lorenzen[4], M. Hansen[5], J. Singh[6], E. Choy[7], M. Boers[8], M. Suarez-Almazor[9], L. Kristensen[1], H. Bliddal[1], R. Christensen[1]. *[1]The Parker Institute, Copenhagen University, Copenhagen, Denmark; [2]David Geffen School of Medicine, University of California, LA, United States; [3]Center for Rheumatology and Spine Diseases, Copenhagen University, Glostrup; [4]Department of Rheumatology, Silkeborg Regional Hospital, Silkeborg; [5]ReumaKlinik Roskilde, Roskilde, Denmark; [6]Medicine Service and Center for Surgical Medical Acute care Research and Transitions, VA Medical Center, Birmingham, United States; [7]Section of Rheumatology, Cardiff University, Cardiff, United Kingdom; [8]Department of Epidemiology & Biostatistics; and Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands; [9]Section of Rheumatology and Clinical Immunology, University of Texas, Houston, United States*

**Background:** Many rheumatoid arthritis (RA) patients might not tolerate or adhere to conventional synthetic DMARDs, it is therefore important to evaluate use of biological agents as monotherapy.

**Objectives:** To summarise and compare the benefits and harms of biological agents used as monotherapy for RA.
**Methods:** We searched MEDLINE, EMBASE, the Cochrane Central Register of Controlled Trials and other sources for randomised trials that compared biological monotherapy with MTX, placebo, or other biological monotherapies. Primary outcomes were ACR50 and the number of patients who discontinued due to adverse events. Our network meta-analysis was based on mixed-effects logistic regression, including both direct and indirect comparisons of the treatment effects, whilst preserving the randomised comparisons within each trial.
**Results:** The analysis comprises 28 trials (8,602 patients), including all nine biological agents approved for RA. Of the included trials, 8 (29%) included "DMARD-naïve", and 20 (71%) "DMARD-Inadequate responder" (DMARD-IR) patients. All agents except anakinra and infliximab were superior to placebo with regard to ACR50 (Figure). Etanercept and rituximab were superior to anakinra. Tocilizumab was superior to adalimumab, anakinra, certolizumab, and golimumab. When including only DMARD-IR trials, the same statistical pattern emerged, complemented with superiority of etanercept and tocilizumab compared with abatacept. Focusing on recommended doses, both etanercept and tocilizumab were superior to adalimumab and certolizumab. No differences in benefit among etanercept, tocilizumab, and rituximab were found. However, because rituximab was evaluated in just 40 patients, our confidence in the estimates is limited, No statistically significant differences among biological agents were found with respect to harm.



**Conclusions:** This study suggests there are differences in effectiveness but not in harm among biological agents applied as monotherapy in RA. Patient-important benefits such as ACR50 occurred more frequently with etanercept or tocilizumab monotherapy than with other biological agents. Further, in recommended dose, both etanercept and tocilizumab were superior to adalimumab and certolizumab pegol. Despite no differences between rituximab and etanercept or tocilizumab were found, our confidence in these findings were limited. In conclusion evidence suggests etanercept or tocilizumab to be the most appropriate choice for RA patients treated with biological monotherapy.

## THU0636 ASSESSMENT OF FUNCTIONAL STATUS AND HEALTH-RELATED QUALITY OF LIFE INSTRUMENTS IN A POPULATION-BASED COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS

S. Löfvendahl[1], I.F. Petersson[1], E. Theander[2], Å. Svensson[3], K. Steen Carlsson[4]. [1]*Orthopedics, Clinical Sciences Lund, Lund;* [2]*Rheumatology;* [3]*Dermatology, Skåne University Hospital, Malmö;* [4]*Clinical Sciences Malmö, Lund University, Lund, Sweden*

**Background:** In addition to reduce joint destruction progress and pain, one goal in psoriatic arthritis (PsA) treatment is to improve functional status (FS) and health-related quality of life (HRQoL). Demand for data on patient-reported outcomes is partly driven by the needs of cost-effectiveness analyses for reimbursement decisions. Several outcome measures are used for assessing the complex impact of PsA, but there is need for more information from studies with parallel assessment of FS and HRQoL measures.
**Objectives:** To assess patient-reported functional status by HAQ (health assessment questionnaire) and by BASFI (Bath Ankylosing Spondylitis Functional Index), health-related quality of life by EQ-5D (EuroQol-five dimensions), by DLQI (Dermatology Life Quality Index) and by GH (general health) across sex, age, presence of psoriasis and drug treatment to explore trends of similarities.
**Methods:** A sub cohort of PsA patients from the Swedish SpAScania cohort (age≥15 years, spondyloarthritis between 2003 and 2007 in the Skåne region) was used. 1181/2003 eligible PsA patients (diagnosed with PsA once by rheumatologist/internist or at least twice by other physician) responded to a questionnaire in 2009. Sex, age, disease duration, presence of psoriasis, HAQ, BASFI, EQ-5D, DLQI, and GH regarding joint (GH-rs) and skin symptoms (GH-ss) were assessed. Information about biologic disease modifying antirheumatic drugs (bDMARDs) treatment during 2008–2011 was collected from the Swedish Prescribed Drug Register and from the Southern Swedish Arthritis Treatment Group Register. Differences between groups were tested by chi-squared test for categorical data and Students t-test for continuous data.
**Results:** Out of 1181 patients 43% were men. The mean age (standard deviation) was 58 (13) and 57 (17) years for men and women respectively. Mean disease duration was 13 (11) years. 77% of the patients reported psoriasis. bDMARD treatment during all 4 years was reported by 17% of the patients; 74% reported no use at all during the same period. Women reported significantly worse health across all six health status measures compared to men (Figure 1). Patients with irregular use of bDMARDs during the 4-year period reported significantly worse health compared to patients with use during the whole period or no use at all. There was a significant association between worse health and older age for HAQ, BASFI and GH-rs. Patients with psoriasis reported significantly worse health measured by DLQI and GH-ss.

Figure 1. Statistics of functional status, health-related quality of life and general health across sex, age, psoriasis problems and bDMARD treatment for PsA patients. Cross-sectional survey in 2009.

EQ-5D: range 0-1, where 1 indicates better health, Europol with 5 dimensions
DLQI: range 0-20, where 0 indicates better health, Dermatology Life Quality Index
HAQ: range 0-3, where 0 indicates better health, Health Assessment Questionnaire
BASFI: range 0-10, where 0 indicates better health, Bath Ankylosing Spondylitis Functional Index
GH-rs and GH-ss: range 0-10, where 0 indicates better health.

**Conclusions:** While all outcome measures seemed to capture differences in patient perceptions by treatment not all were sensitive to expected differences as to reporting psoriasis or age. This highlight the value of letting the choice of instrument match the decision problem. For reimbursement decisions, measures picking up differences by treatment group and direct disease related aspects such as skin problems seem important. This is also important knowledge in

cost-effectiveness analyses where choice of effectiveness measure may have large impact on the ratio between costs and effects. The finding that patients with irregular bDMARD treatment seem to have worse health than those with long-term regular or no bDMARD treatment at all will be further investigated.

## THU0637 IMPACT OF PSORIATIC ARTHRITIS: LINKING THE DOMAINS OF HEALTH WHICH ARE IMPORTANT FOR PATIENTS WITH PSORIATIC ARTHRITIS TO THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH

T.E. Gudu[1,2], U. Kiltz[3], M. de Wit[4], T.K. Kvien[5], L. Gossec[2]. *[1]Rheumatology, Sf Maria Hospital, RCRD; Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Rheumatology, Pitié Salpétrière Hospital; Paris 6 University, Paris, France; [3]Rheumazentrum Ruhrgebiet, Herne and Ruhr-Universität Bochum, Herne, Germany; [4]Patient Research Partner, Zurich, Switzerland; [5]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

**Background:** The impact of psoriatic arthritis (PsA) is wide-reaching and covers various aspects of life, e.g., physical, psychological and social. This impact could be categorised using a universally accepted, standardized reference system: the International Classification of Functioning, Disability and Health (ICF).
**Objectives:** The objective was to assess how the impact of PsA from the patient's perspective mapped to the ICF.
**Methods:** Data sources: Publications with dimensions of health important for PsA patients were identified through a systematic literature review using the following terms: ("psoriatic arthritis") AND ("quality of life" OR "impact"). Only studies related to impact from the patient's perspective, i.e., studies using qualitative methodology (e.g., focus groups, individual interviews) or instruments that were patient derived (patients included in the development task force, development based on qualitative methods) were included. Data extraction and interpretation: Domains of health important for patients were identified. Meaningful concepts were extracted from the publications and linked to the ICF categories, according to the updated linking rules [1] by 2 persons. The number of concepts linked to each ICF category and to each ICF level was calculated. The number of concepts not linkable was also calculated. Descriptive statistics were used.
**Results:** Eleven studies (13 articles) were included in the analysis, corresponding to 2893 patients (of whom 623 assessed qualitatively); two studies did not precisely define the population involved in their qualitative phases. Eight studies were exclusively on PsA and the other 5 included also patients with only psoriasis; only 5 studies were qualitative *per se.* Twenty-five domains of health were cited, of which Ability to work/volunteer and Social participation were most cited (both by 10 studies). In total 258 concepts were identified, of which 217 (84.1%) could be linked to 136 different ICF categories; 41 concepts (15.9%), mostly personal factors, namely coping with the disease (21 concepts; 51.21%) could not be linked. The most represented ICF component was Activities and Participation (42.6%) rather than Body functions (29.4%) or Body structures (10.3%). Ten studies (90.9%) reported impairments in Ability to work/volunteer and Social participation; 7 (63.6%) reported Leisure activities, Family and intimacy, Pain, Skin problems and Body image.
**Conclusions:** PsA widely impacts all aspects of patients' lives, in particular regarding activities and participation, reflecting the functional limitations, but also the psycho-social and societal burden of PsA. The ICF is a useful approach for the systematic classification of disease impact.

## THU0638 LEG LENGTH INEQUALITY AS A RISK FACTOR FOR DISABILITY IN A COMMUNITY-BASED LONGITUDINAL STUDY

Y.M. Golightly[1], C. Alvarez[1], J. Cantrell[1], J.B. Renner[1], C.G. Helmick[2], J.M. Jordan[1]. *[1]University of North Carolina, Thurston Arthritis Research Center, Chapel Hill, NC; [2]Centers for Disease Control and Prevention, Atlanta, GA, United States*

**Background:** Leg length inequality (LLI), a condition in which one limb is longer than the other, is associated with osteoarthritis (OA) and pain of the knee and hip. OA is a leading cause of disability, but it is not known whether LLI is a risk factor for disability when accounting for OA.
**Objectives:** This longitudinal analysis examined the hazard of incident and progressive disability by LLI in a large, bi-racial (African American and Caucasian) community-based study in the United States of men and women 45+ years old with and without OA.
**Methods:** Participants were enrolled from 1991–1997 (original cohort) or 2003–2004 (enrichment cohort); 2369 participants had complete baseline LLI and baseline and follow-up (1999–2003 or 2006–2010) disability data available for analyses. With the participant supine, right and left lower extremity lengths were measured by trained examiners using a tape measure from anterior superior iliac spine to distal medial malleolus. LLI was defined as a difference between limbs $\geq$2 cm at baseline. Self-reported disability was assessed with the Stanford Health Assessment Questionnaire (HAQ) Disability Index, which assesses 20 functions covering 8 domains (dressing, arising, eating, walking, reaching, gripping, chores, hygiene) scored on a scale of 0–3 (no difficulty to unable). HAQ scores were calculated by averaging the scores of the 8 domains. Incident Disability was present if baseline HAQ =0 and follow-up HAQ >0, and Progression of Disability was present if baseline HAQ < follow-up HAQ. Separate parametric Weibull time-to-event models estimated hazard ratios of the association of LLI and disability outcomes, adjusting for time of LLI assessment (1991–1997 or 1999–2004), age, sex, race, body mass index (BMI), radiographic knee or hip OA, knee or hip problems (injury, surgery, fracture, or congenital anomaly), and knee or hip symptoms (pain, aching, stiffness on most days). Interactions between LLI and covariates were examined ($p<0.05$ considered statistically significant).
**Results:** Characteristics of the total sample were: mean ± standard deviation (SD) baseline age 60 ± 9.7 years; 66% women; 31% African American; mean ± SD baseline BMI 30 ± 6.2 kg/m$^2$; 23% knee OA; 26% hip OA; 21% knee problems; 8% hip problems; 44% knee symptoms; 36% hip symptoms; median follow up time 7.6 years, range 3.6–17.8 years. 154 participants (6.5%) had a LLI $\geq$2 cm. Compared to those without LLI, the adjusted hazard of Incident Disability was 39% higher among participants with LLI (adjusted hazard ratio [aHR] 1.39, 95% confidence interval [CI] 1.002, 1.93). For the model with Progression of Disability, a statistically significant interaction was noted between baseline LLI and time of baseline LLI assessment; thus, results were stratified by time of assessment. Among participants with baseline LLI collected during 1999–2004, the adjusted hazard for Progression of Disability was 60% higher among participant with LLI vs. no LLI (aHR 1.60, 95% CI 1.12, 2.28).

Table. Adjusted* Hazard Ratio (HR) and 95% Confidence Interval (CI) of Baseline Leg Length Inequality (LLI) and Disability Outcomes.

| Disability Outcome | Sample | HR | 95% CI |
|---|---|---|---|
| Incident disability (baseline HAQ=0, follow-up HAQ >0) (n=1297) | Overall | **1.39** | **1.002, 1.928** |
| | Baseline LLI Assessment 1991-1997 | 0.96 | 0.73, 1.27 |
| Progression of disability (baseline HAQ < follow-up HAQ) (n=2369) | Baseline LLI Assessment 1999-2004 | **1.60** | **1.12, 2.28** |

*Adjusted for time of baseline LLI assessment, age, sex, race, body mass index, knee osteoarthritis (OA), hip OA, knee problems (injury, surgery, fracture, congenital anomaly), hip problems, knee symptoms (pain, aching, stiffness), hip symptoms

**Conclusions:** LLI appears to be a modifiable risk factor for incident and progressive disability outcomes when accounting for OA. Treatment for LLI, such as shoe lift therapy, should be examined as an approach to prevent disability progression.
**Disclosure of Interest:** None declared

## Cytokines and inflammatory mediators

### FRI0001 TREATING EXPERIMENTAL ARTHRITIS WITH THE INNATE IMMUNE INHIBITOR IL-37 REDUCES JOINT AND SYSTEMIC INFLAMMATION

G. Cavalli[1], M. Koenders[2], J. Kim[3], A.C. Tan[3], C. Garlanda[4], A. Mantovani[4], L. Dagna[1], L. Joosten[5], C. Dinarello[5,6]. [1]*Internal Medicine and Clinical Immunology, Vita-Salute San Raffaele University, Milan, Italy;* [2]*Rheumatology, Radboud University Medical Centre, Nijmegen, Netherlands;* [3]*Translational Bioinformatics, University of Colorado Denver, Aurora, United States;* [4]*Humanitas Research Institute, Rozzano, Italy;* [5]*Internal Medicine, Radboud University Medical Centre, Nijmegen, Netherlands;* [6]*Medicine, University of Colorado Denver, Aurora, United States*

**Background:** Recently characterized as a fundamental inhibitor of innate and adaptive immune responses, IL-1 family member IL-37 curbs excessive inflammation and prevents tissue damage by suppressing the production of pro-inflammatory cytokines (1).
**Objectives:** We investigated the effects of recombinant IL-37 on joint and systemic inflammation and joint pathology in a mouse model of arthritis. In addition, we explored the potential for therapeutic use in human joint inflammation.
**Methods:** Wild-type (WT) mice were treated systemically with a recombinant form of the naturally occurring human IL-37, and then arthritis was induced via instillation of streptococcal cell wall (SCW) fragments in the knee joints; joint inflammation, histology, and synovial and systemic cytokine levels were evaluated after 24 hours. Mice deficient in IL-1 family decoy receptor IL-1R8 were similarly treated. The effects of IL-37 treatment were also assessed in a model of SCW-induced peritonitis. Changes in circulating and bone marrow neutrophils were evaluated. Gene expression of IL-37 and IL-1R8 was determined in the synovia of patients with rheumatoid arthritis (RA).
**Results:** In WT mice, low doses (40 $\mu$g/kg) of IL-37 suppressed joint inflammation by 51.7% ($p<0.001$). In the synovial extracts of IL-37-treated mice, IL-1$\beta$ was reduced by 84% ($p<0.001$), IL-6 by 73% ($p=0.002$), TNF$\alpha$ by 33% ($p<0.001$). These reductions were associated with a lower recruitment of neutrophils into the joint, as also demonstrated by a 60% reduction in synovial levels of the neutrophil enzyme MPO ($p<0.001$). Consistently, IL-37 treatment was associated with a decrease in circulating and an increase in bone marrow neutrophils. Mechanistically, mice treated with IL-37 exhibited a marked decrease in synovial levels of main neutrophil chemo-attractants KC, CCL3/MIP1$\alpha$, and IL-1$\alpha$, and of circulating G-CSF. We show that the anti-inflammatory effects of IL-37 require the IL-1 family decoy receptor IL-1R8, as protective effects were abrogated in mice deficient for this receptor. These results were confirmed in a model of SCW-induced systemic inflammation, that is, peritonitis. We found that gene expression of IL-1R8, but not IL-37, is markedly increased in the synovia of patients with RA.
**Conclusions:** The present study demonstrates that by curbing excessive inflammation IL-37 exerts a protective role against arthritis. Short-term, low-dose treatment with recombinant IL-37 suppressed joint inflammation, reduced cell influx, and lowered histologic scores by more than 50%. These effects were associated with suppression of synovial and systemic inflammatory cytokines and chemokines, leading to a reduced recruitment of neutrophils to the joint. We also demonstrate that IL-37 is scarcely expressed in the diseased synovia of patients with RA, but expression of IL-1R8, the receptor transducing the anti inflammatory effects of IL-37, is elevated. Thus, while levels of endogenous IL-37 are too low to contain the overwhelming inflammatory reaction in the synovia of RA patients, exogenous administration may suppress the pathological process.

### FRI0002 SPINAL MICROGLIAL ACTIVATION IN A MURINE SURGICAL MODEL OF KNEE OSTEOARTHRITIS

A.-M. Malfait[1], P.B. Tran[1], R.E. Miller[1], S. Ishihara[1], R.J. Miller[2]. [1]*Rheumatology, Rush University;* [2]*Pharmacology, Northwestern University, Chicago, United States*

**Background:** Microglial cells are the resident macrophages of the central nervous system (CNS). Their activation (termed "microgliosis") is thought to modulate synaptic transmission in the dorsal horn, thereby promoting chronic pain. Fractalkine derived from the central termini of primary sensory afferents has been shown to contribute to microgliosis.
**Objectives:** The primary aim of this study was to document the temporal profile of dorsal horn microgliosis after destabilization of the medial meniscus (DMM) in the mouse. Further, we assessed fractalkine release from dorsal root ganglia (DRG) after DMM surgery. We evaluated these pathological events in the pain pathway in three strains of mice: wildtypes (WT), which develop slowly progressive osteoarthritis following DMM surgery, associated with sustained pain-related behaviours during the 16-week follow-up period[1]; *Ccr2* null mice, which are protected from persistent pain in spite of joint damage[1]; and *Adamts5* null mice, which are protected from joint damage and associated pain-related behaviours after DMM surgery[2].
**Methods:** DMM or sham surgery was performed in the right knee of 10-week old male wild type (WT), *Ccr2* null or *Adamts5* null C57BL/6 mice. Mechanical allodynia in the hindpaw was monitored using von Frey fibers. L4 dorsal horn microgliosis was assessed 4, 8 and 16 weeks after surgery, based on the morphology of Iba1-immunoreactive (ir) microglia: Iba1-ir cells were classified as "resting" if their process length was more than double the soma diameter, and as "activated" if their process length was less than double the soma diameter[3]. The observer was blinded to the treatment groups. DRG cells (L3-L5) from DMM, sham or naïve control mice were cultured and supernatants collected for fractalkine ELISA.
**Results:** Four weeks after surgery in WT mice, the number of activated microglia in the L4 dorsal horn was not different between naïve and DMM mice. In contrast, 8 weeks after DMM, there was a significant increase in the number of activated microglia compared to shams. By 16 weeks after DMM, activated microglia were increased compared to age-matched naïve controls. DRG cultures from WT mice showed increased fractalkine release 8 and 16 weeks, but not 4 weeks, after DMM. In contrast, DRG cultures from *Ccr2* null and *Adamts5* null mice did not release increased fractalkine and L4 dorsal horn microgliosis was absent in these mice.
**Conclusions:** DMM surgery leads to late stage dorsal horn microgliosis, 8–16 weeks after surgery. This suggests that involvement of the CNS is a late event in this experimental model. Further, the temporal correlation with fractalkine release by DRG cells suggests that fractalkine may contribute to microglial activation. Finally, reduced microgliosis in *Ccr2* null and *Adamts5* null mice, both of which fail to display persistent pain behaviors after DMM, suggests that microgliosis is associated with the persistence of OA pain. Joint protection and prevention of peripheral sensitization may attenuate one aspect of central sensitization.

### FRI0003 SYNOVIAL FLUID BIOMARKERS OF THE ACUTE KNEE INJURY RESPONSE ARE ASSOCIATED WITH EARLY CLINICAL OUTCOMES

F.E. Watt[1], E. Paterson[1], A. Freidin[1], M. Kenny[2], A. Judge[3], J. Saklatvala[4], A. Williams[2], T. Vincent[4]. [1]*Arthritis Research UK Centre for Osteoarthritis Pathogenesis, Kennedy Institute of Rheumatology, NDORMS, University of Oxford, Oxford;* [2]*Fortius Clinic, London;* [3]*NIHR Musculoskeletal Biomedical Research Unit, University of Oxford;* [4]*Arthritis Research UK Centre for Osteoarthritis Pathogenesis, Kennedy Institute of Rheumatology, University of Oxford, Oxford, United Kingdom*

**Background:** Acute knee joint injury is the single greatest risk factor for development of knee osteoarthritis, but only half of these individuals will develop symptomatic disease. Identifying biomarkers of an individual's joint injury response at the outset which are associated with patient relevant outcomes over both the short and long term may allow us to stratify and target therapies at those at highest risk. In a surgical mouse model, where meniscal destabilisation leads to osteoarthritis, we previously identified several molecules which are strongly upregulated in the joint tissues immediately after knee injury, 7 of which were likely to be secreted and detectable in human synovial fluids in clinical translational studies.
**Objectives:** We investigated whether molecules which were up-regulated within hours of surgical joint destabilisation in the mouse were also elevated in the analogous human setting of acute knee injury, how this molecular response varied between individuals, and whether it related to patient-reported outcome measures in the 3 months following injury.
**Methods:** 150 participants were recruited to the Knee Injury Cohort @ Kennedy (KICK), who had recent structural knee injury (<8 weeks from injury). Blood and synovial fluid (SF) at baseline visit, and where available, at 14 days and 3 months following baseline visit were analysed for the 7 candidate molecules. Knee injury and Osteoarthritis Outcome Score (KOOS) was collected at baseline and 3 months, and the summary $KOOS_4$ score analysed. Assays were by MesoScale Discovery™platform or ELISA, and compared for blood and synovial fluid with uninjured control samples.
**Results:** Median age of KICK participants was 25, median time from injury to baseline visit was 17 days and there was substantial pain and impairment by KOOS at baseline visit. 6/7 molecules were significantly elevated in human synovial fluid immediately after injury: IL-6, MCP-1, MMP-3, TIMP-1, activin A and TSG-6. 3/6 molecules were significantly associated with baseline $KOOS_4$ (those individuals with higher SF IL-6, TIMP-1 or TSG-6 had lower $KOOS_4$). These 3 molecules, MMP-3 and activin A were all significantly associated with greater improvement in $KOOS_4$ over 3 months, adjusting for relevant, pre-defined factors including time from injury to sampling, extent of injury, age and presence of heavy blood staining of synovial fluid. When these 5 synovial fluid biomarkers were included in a linear regression model, only synovial fluid IL-6 was independently

associated with either baseline $KOOS_4$ (Coeff.-4.0 (-5.92,-2.08), P<0.001), or difference in $KOOS_4$ over 3 months (Coeff.2.80 (0.89,5.52), P=0.043).
**Conclusions:** Our findings validate relevant human biomarkers of joint injury identified from a mouse model. The response, represented best by synovial fluid IL-6, is associated with clinically-relevant outcomes over this early period: a greater inflammatory response soon after the injury is associated with increased impairment and pain by $KOOS_4$ at that time, but does not appear to be an adverse prognostic factor, at least in the short-term, and in this predominantly surgically-managed cohort. Longitudinal outcomes will determine if these molecules are biomarkers of subsequent disease risk.

## FRI0004 INHIBITION OF PHOSPHODIESTERASE 4 (PDE4) REDUCES DERMAL FIBROSIS BY INTERFERING WITH THE RELEASE OF PRO-FIBROTIC CYTOKINES FROM M2-MACROPHAGES

C. Maier, A. Ramming, G. Schett, J.H. Distler, C. Beyer. *Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Germany, Erlangen, Germany*

**Background:** PDE4 catalyses the breakdown of cAMP and cGMP to modulate intracellular effects. PDE4 is mainly expressed in inflammatory cells, and its inhibition leads to reduced inflammatory cell activity. Activation of the cellular immune system and autoimmunity are hallmarks of the pathogenesis of systemic sclerosis (SSc).
**Objectives:** To study the disease-modifying, anti-fibrotic effects of PDE4 inhibition in preclinical models of SSc.
**Methods:** The effects of the PDE4-specific inhibitors rolipram and apremilast were studied in the models of bleomycin-induced skin fibrosis and sclerodermatous chronic graft versus host disease (sclGvHD), reflecting local and systemic inflammatory fibrotic disease. To better understand the disease-modifying activity of PDE4 blockade in preclinical SSc, we investigated fibrosis relevant genes and cytokines in fibroblasts and macrophages from healthy individuals and patients suffering from diffuse-cutaneous SSc upon blockade of PDE4.
**Results:** We first studied PDE4 inhibition by rolipram in a preventive bleomycin model. In this model, rolipram reduced skin thickening by 33% ($p$ <0.001), the amount of fibrotic tissue assessed by histomorphometry by 38% ($p$ =0.016) and the number of α-SMA-positive myofibroblasts by 45% ($p$ <0.001). We then wondered if the clinically approved PDE inhibitor apremilast did also show significant anti-fibrotic activity, and if PDE inhibition did not only prevent but also treat fibrosis once it was established. In a modified bleomycin model of established fibrosis, apremilast reduced skin thickness by 26% (p=0.001) the amount of fibrotic tissue by 21% (p=0.037) and the number of myofibroblasts by 73% (p=0.001). Taking advantage of a model of cGvHD, we investigated if PDE4 blockade could also reduce fibrosis in a model for systemic fibrotic disease. Indeed, rolipram reduced skin thickness by 33% ($p$ =0.002), the amount of fibrotic tissue by 35% (p=0.016) and of the number of α-SMA-positive myofibroblasts by 46% ($p$ =0.002).
In line with the general mode of action of PDE4 blockade, we observed significantly reduced leukocytic infiltration in the fibrotic skin of all three animal models. We further demonstrated that fibroblasts were not the direct targets of the anti-fibrotic effects of PDE4 blockage. By contrast, PDE4 inhibition decreased the release of pro-fibrotic cytokines interleukin-6 and 13 (IL-6, IL-13) and, transforming growth factor β1 and β2 (TGFβ1, TGFβ2) and fibronectin-1 (FN-1) from activated M2 macrophages obtained from both healthy volunteers and SSc patients, resulting in reduced fibroblast activation and collagen release.
**Conclusions:** PDE4 inhibition reduces inflammatory cell activity and the release of pro-fibrotic cytokines from M2 macrophages, which leads to decreased fibroblast activation and collagen release. Importantly, apremilast is already approved by the FDA and the EMA for the treatment of psoriatic arthritis. Therefore, our preclinical results might prompt the use of PDE4 inhibitors in clinical studies with patients suffering from SSc. Our findings suggest that particularly patients with inflammation-driven fibrosis might benefit from PDE4 blockade.

## FRI0005 A DISTINCT PROFILE OF SERUM FREE FATTY ACIDS IS ASSOCIATED WITH CLINICAL FEATURES AND SKEWED TH1 RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

J. Rodríguez-Carrio [1], M. Alperi-López [2], P. López [1], F.J. Ballina-García [2], A. Suárez [1]. *[1]Area of Immunology, University of Oviedo; [2]Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain*

**Background:** largely considered as mere sources of energy, metabolomics have revealed a role for lipid species in a number of biological processes. Among them, free fatty acids (FFA) are known to modulate cytokine transcription, expression of adhesion molecules and are involved in the production of proinflammatory and pro-resolving lipid compounds, such as prostaglandins and leukotrienes or protectins and resolvins, respectively. Recently, FFA were reported to modulate the function of CD4+ T-cells and macrophages in osteoarthritis. Thus, we hypothesize that altered FFA levels may underlie the initiation or perpetuation of pathogenic mechanisms in immune-mediated rheumatic diseases.
**Objectives:** to evaluate whether altered FFA levels can be found in RA patients linked to clinical features as well as CD4+ T-cell response.
**Methods:** serum levels of FFA (palmitic, stearic, palmitoleic, oleic, linoleic, γ-linoleic, arachidonic –AA–, linolenic, eicosapentaenoic –EPA– and docosahexaenoic –DHA–) were quantified by LC-MS/MS after methyl-tert-butylether (MTBE)-extraction in 124 RA patients and 56 healthy controls (HC). Total FFA serum levels were quantified by means of a colorimetric assay. CD4+ phenotype was studied by flow cytometry. TNFα, IL-8, VEGF, GM-CSF, IFNγ, IL-17, MCP-1, IP-10, leptin and resistin serum levels were quantified by immunoassays. The effect of FFA on IFNγ production by PBMC was evaluated in vitro.
**Results:** lower levels of palmitic (p<0.0001), palmitoleic (p=0.002), oleic (p=0.010), arachidonic (p=0.027), EPA (p<0.0001) and DHA (p<0.0001) were found in RA patients, some FFA being altered in patients at disease onset (n=18). Altered FFA exhibited distinct chemical properties, leading us to think that individual FFA within a given class followed distinct patterns and similar patterns were found among different groups of FFA. Total FFA levels did not differ between patients and controls (p=0.157), thereby supporting the existence of different profiles within the FFA pool. Cluster analysis identified a FFA profile (hallmarked by increased stearic and decreased EPA and DHA) overrepresented in RA patients compared to HC (p=0.002), being associated with clinical features (RF: p=0.029, shared epitope (2 copies): p<0.001 and erosions: p=0.003), increased IFNγ expression in CD4+ T-cells (p=0.002) and a Th1-biased serum milieu (IFNγ: p<0.001, MCP-1: p<0.0001 and IP-10: p=0.006). No associations with regulatory T cells or Th17 subsets were found. In vitro assays demonstrated that stearic/DHA/EPA-imbalanced FFA could underlie IFNγ production by CD4+ T-cells, in both resting and PHA-stimulated conditions. Finally, changes on FFA levels were associated with clinical response and CD4+ Th1 shift upon TNFα-blockade.
**Conclusions:** an altered FFA profile can be found in RA patients associated with clinical characteristics of aggressive disease, Th1-skewed response and poor clinical outcome upon TNFa-blockade. These results support the relevance of lipidomic studies in RA and provide a rationale for new therapeutic targets as well as for FA supplementation and stratification in RA.

## FRI0006 CLASS 3 SEMAPHORINS MODULATE THE INVASIVE CAPACITY OF RHEUMATOID ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTES

S. García Pérez [1], B. Malvar Fernandez [1], M.W. Tang [2], S.P. Newsom [2], T.R. Radstake [1], D.L. Baeten [2], P.P. Tak [3], K.A. Reedquist [1]. *[1]Laboratory of Translational Immunology (LTI) and Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht; [2]Department of Clinical Immunology and Rheumatology, Academic Medical Center Amsterdam, Amsterdam, Netherlands; [3]GlaxoSmithKline, Stevenage, United Kingdom*

**Background:** The semaphorin family is a large group of proteins initially described in axon guidance. However, semaphorins also play a role in other processes such as the regulation of immunity, angiogenesis, apoptosis and cell migration and invasion. Moreover, semaphorins have been related with the pathogenesis of multiple sclerosis, myocarditis, atherosclerosis and cancer. However, the potential role of class 3 semaphorins in rheumatoid arthritis (RA) remains unknown.
**Objectives:** The aim of this study was to analyze the role of class 3 semaphorins in the pathology of RA.
**Methods:** mRNA expression of class 3 semaphorins in the synovial tissue of early, DMARD-naive arthritis patients was analyzed by (q)uantitative PCR. RA FLS were stimulated for 4h with IL-1β, TNF or LPS. and mRNA and expression of class 3 semaphorins was analyzed by qPCR. RA FLS were stimulated with Sema3A, Sema3B or Sema3F in the presence or absence of PDGF. Cell migration and invasion were determined using wound closure motility and transwell invasion assays, respectively. Matrix metalloproteinase mRNA and protein expression was determined by qPCR array and luminex. PlexinA1 and neuropilin-1 expression were knocked-down by siRNA-mediated silencing. ERK and Rac1 activation were determined by immunoblot.
**Results:** mRNA expression of class 3 semaphorins in the synovial tissue of early arthritis patients negatively and significantly correlated with the mRNA expression of inflammatory mediators and the disease activity parameters of these patients. Moreover, Sema3B, Sema3C, Sema3F and Sema3G mRNA expression were significantly lower in early arthritis patients who developed persistent disease compared with patients with self-limiting disease after 2 years follow-up. Sema3F and Sema3B expression were significantly lower in patients that developed RA after 2 years of follow-up compared to those who remained as undifferentiated arthritis patients. FLS expression of Sema3A was significantly induced after IL-1, TNF or LPS stimulation, while the expression of Sema3B and Sema3F was down-regulated. Functional assays showed that Sema3A significantly induced the migration and invasion of FLS. In contrast, Sema3B and Sema3F reduced spontaneous FLS migration and PDGF-induced cell invasion. These effects were

associated withthe differential regulation of MMP-1, MMP-3 and MMP-8 by these semaphorins, and were mediated by the receptor PlexinA1 and the co-receptor NRP-1. Finally, we observed that class 3 semaphorins reduced the PDGF-induced ERK and Rac1 activation.

**Conclusions:** Our data demonstrate that class 3 semaphorins are differentially expressed in the synovium of early patients depending on the severity and the progression of the disease and that Sema3A, Sema3B and Sema3F play an important role in the invasive capacity of RA FLS. Together, class 3 semaphorins and their receptors could be useful biomarkers and promising therapeutic targets for the treatment of RA.

## FRI0007 EFFECT OF TYPE 1 AND 2 INTERFERONS ON NEUTROPHIL APOPTOSIS IN NAÏVE AND TNF ALPHA PRIMED NEUTROPHILS

S. Irwin[1], A. Midgley[1], R. Wright[1], M. Peak[2], M. Beresford[1]. [1]*Women's and Children's Health, University of Liverpool;* [2]*Alder Hey Children's NHS Foundation, Liverpool, United Kingdom*

**Background:** Juvenile-onset Systemic Lupus Erythematosus (JSLE) is a multisystem autoimmune disease characterised by the presence of autoantigens. These may result from increased numbers of apoptotic neutrophils and dysregulated clearance of these neutrophils by phagocytes. Serum from JSLE patients contains high levels of type 1 ($\alpha$ and $\beta$) and 2 ($\gamma$) interferons (IFN). In the context of JSLE being an inflammatory condition, JSLE neutrophils are likely to be more activated in comparison to healthy, non-inflammatory control neutrophils. Tumour necrosis factor (TNF)-$\alpha$ can prime neutrophils (demonstrated by CD62L shedding), and provides an inflammatory setting for neutrophils as seen in JSLE. Gene expression analysis has shown an IFN and granulocyte signature within SLE; however the interaction between IFN and neutrophils in regards to apoptosis, and the pathogenesis of JSLE, is yet to be elucidated.

**Objectives:** To investigate the effect of type 1 and 2 IFNs on neutrophil apoptosis of naïve and primed neutrophils

**Methods:** Neutrophils isolated from healthy control adult donors (n=5) were either unstimulated or primed with TNF-$\alpha$ (1$\mu$g/ml) for 30 mins. The neutrophils were subsequently incubated with IFN-$\alpha$ (10$\mu$g/ml), IFN-$\gamma$ (1$\mu$g/ml) or IFN-$\beta$ (1$\mu$g/ml) for 6hrs. The expression of CD62L after 30 min TNF-$\alpha$ incubation was measured using flow cytometry using CD62L-APC (DREG-56) antibody staining with IgG-APC isotype control. The percentage of apoptotic neutrophils were measured after 6hr IFN incubation using flow cytometry via annexin V FITC staining.

**Results:** CD62L expression was reduced in neutrophils exposed to TNF-$\alpha$ compared with unstimulated neutrophils (geometric mean: 1.61 ± 0.30 vs 11.43 ± 1.44). Apoptosis (% ± SEM) was significantly reduced upon IFN-$\alpha$ (6.57 ± 1.18%, p=0.04) and IFN-$\gamma$ (10.79 ± 1.92%, p=0.04) incubation compared to unstimulated (22.01 ± 3.18%), although IFN-$\beta$ (20.30 ± 5.10%, p=0.35) and TNF-$\alpha$ alone (26.40 ± 4.30%, p=0.50) had little effect. In neutrophils pre-treated with TNF-$\alpha$, there was significant increase in apoptosis when subsequently exposed to either IFN-$\alpha$ (48.91 ± 4.84%, p=0.04), IFN-$\gamma$ (43.09 ± 2.99%, p=0.04) or IFN-$\beta$ (39.41 ± 3.23%, p=0.04) compared to unstimulated neutrophils.

**Conclusions:** There is evidence that both type 1 and 2 IFNs contribute to the development of JSLE. Here we show a differential effect between IFNs on neutrophil apoptosis indicating a potential pro-apoptotic effect of IFNs on neutrophils in a JSLE environment through the pre-incubation with TNF-$\alpha$. IFNs may contribute to the increase in neutrophil apoptosis in JSLE and lead to an increase in autoantigens that are fundamental to JSLE pathogenesis.

## FRI0008 MOBILIZATION OF LYMPHATIC ENDOTHELIAL PRECURSORS CELLS AND LYMPHATIC NEOVASCULARIZATION IN PRIMARY SJÖGREN'S SYNDROME

A. Alunno[1], M. Manetti[2], O. Bistoni[1], L. Ibba Manneschi[2], I. Rosa[2], S. Caterbi[1], R. Gerli[1]. [1]*Department of Medicine, Rheumatology Unit, University of Perugia, Perugia;* [2]*Department of Experimental and Clinical Medicine, Section of Anatomy and Histology, University of Florence, Florence, Italy*

**Background:** Lymphatic neovascularisation is a key feature of chronic inflammation but is almost unexplored in primary Sjögren's syndrome (pSS). The two available studies that focused on lymphatic neovascularization in pSS minor salivary glands (MSGs) were limited to the assessment of glandular mature lymphatic endothelial cells and yielded conflicting results. A recent study in an experimental model of inflammation revealed that the pro-inflammatory cytokine IL-17 also displays a pro-lymphangiogenic function. IL-17 is a leading actor in the pathogenesis of pSS as it is involved in several steps of disease development and perpetuation

**Objectives:** On this basis, aims of this study were: i. investigation of lymphangiogenic mediators and characterization of lymphatic vasculature in pSS; ii. Identification of the possible association of IL-17 and lymphatic neovascularization in this disease.

**Methods:** Circulating lymphatic endothelial precursor cells (LEPCs) and Th17 cells were enumerated in 15 pSS and 15 healthy females. VEGF-C and IL-17 were assessed in paired serum samples by ELISA. Lymphatic vasculature, VEGF-C, VEGFR3 and IL-17 were evaluated by either immunofluorescence or immunohistochemistry in MSGs from 18 pSS MSGs compared to 8 non-specific chronic sialadenitis (NSCS) MSGs and 8 normal MSGs.

**Results:** Circulating LEPCs were increased in pSS ($p<0.0001$) and were directly correlated to Th17 cell percentage, serum IL-17 and serum VEGF-C concentration (Spearman's rho=0.6; 0.6 and 0.5 respectively, all $p<0.05$). In pSS MSGs, a newly formed lymphatic capillary network was found within periductal inflammatory foci and the number of lymphatic vessels within the interlobular connective tissue was significantly increased compared to normal and NSCS MSGs ($p<0.05$). A strong expression of VEGF-C was detected in pSS ductal epithelial cells, microvessels and periductal inflammatory cells, while VEGF-C was barely detectable in ductal epithelial cells and microvessels of normal and NSCS MSGs. The expression of VEGFR-3 was strongly increased in lymphatic capillaries of pSS MSGs with respect to normal and NSCS MSGs. Numerous VEGFR-3$^+$ infiltrating mononuclear cells were exclusively observed in pSS MSGs. IL-17$^+$ inflammatory cells were often observed closely to lymphatic vessels in pSS MSGs, while no IL-17 expression could be detected in normal or NSCS MSGs.

**Conclusions:** In this study, we investigated for the first time lymphvasculogenesis and lymphangiogenic mediators in pSS and demonstrated that they are associated to IL-17 axis in this disease. In addition, we reported increased and anatomically aberrant lymphatic neovascularization in pSS-MSGs. Our results suggest another pathogenic role of IL-17 in pSS, further supporting its therapeutic targeting in this disorder.

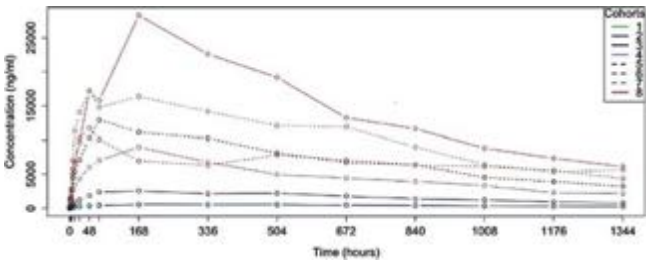
## FRI0009 SERUM 14-3-3 ETA IS AN RA SPECIFIC MECHANISTIC MARKER

B. Dasgupta[1], Y. Cherkas[1], S. Lamberth[1], K. Hayden[1], C. Brodmerkel[1], A. Marotta[2], M. Curran[3]. [1]*Janssen Research & Development, Spring House, United States;* [2]*Augurex Life Sciences Corp, Vancouver, Canada;* [3]*Janssen R & D, LLC, Spring House, United States*

**Background:** 14–3-3$\eta$ is an emerging soluble Rheumatoid Arthritis (RA) biomarker that activates intracellular pathways that lead to the upregulation of inflammatory and joint damage factors. It is reported to be highly specific and sensitive for RA as a diagnostic marker, higher levels are associated with greater joint damage progression risk and 14–3-3$\eta$'s modulation with treatment suggests a role in disease monitoring.

**Objectives:** In this study, we examine the specificity of 14–3-3$\eta$ in an independent, clinically well-characterized cohort of moderate to severe RA and disease control subjects.

**Methods:** Serum 14–3-3$\eta$ levels were measured in a total of 147 patients using the Augurex 14–3-3$\eta$ ELISA. The patient set comprised 36 with RA and 111 controls consisting of 20 with asthma (A), 20 with Crohn's Disease (CD), 12 presumed healthy (H), 16 with psoriasis (PsO), 20 with sarcoid arthritis (S),



and 23 with spondylarthropathies (SpA). Sample testing was done independently of Augurex. Mann-Whitney testing together with Kruskal-Wallis analysis with the post-hoc Dunn's multiple comparison test was performed to assess group differences. Receiver operator characteristic curve (ROC) analysis was performed to assess the specificity of 14–3-3η for RA.
**Results:** Median (IQR) serum 14–3-3η levels were significantly higher in RA [2.35ng/ml (0.28–19.41)] than all controls [0 (0–0)], $p<0.0001$. ROC curve analysis further underscored this differential expression yielding a significant area under the curve (AUC) of 0.86, $p<0.0001$. At the diagnostic positivity cut-off of $\geq$0.19 ng/ml, the ROC curve delivered a sensitivity of 81% with a corresponding specificity of 84%. Kruskal-Wallis testing revealed that serum 14–3-3η levels were significantly higher in RA in comparison to all other diseases, $p<0.0001$.
**Conclusions:** Serum 14–3-3η is a highly specific RA biomarker. As a novel mechanistic disease factor, 14–3-3η is expected to provide new insights and approaches to RA management and clinical studies.

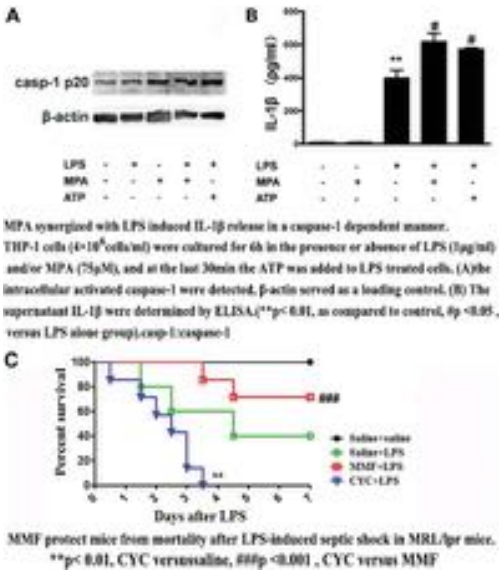
## FRI0010 PHARMACOKINETICS, SAFETY AND TOLERANCE OF BCD-085, A NOVEL IL-17 INHIBITOR, BASED ON THE RESULTS OF PHASE 1 CLINICAL STUDY IN HEALTHY VOLUNTEERS

E. Chernyaeva[1], A. Eremeeva[1], A. Galustyan[2], R. Ivanov[3]. *[1]Medical Department, BIOCAD; [2]Saint Petersburg State Pediatric Medial Academy; [3]BIOCAD, Saint Petersburg, Russian Federation*

**Background:** BCD-085 is an innovative humanized monoclonal antibody against interleukin-17 with genetically modified Fc- and CDR-regions, aimed to improve treatment outcomes in patients with several autoimmune disorders.
**Objectives:** To study pharmacokinetics and safety of a single SC injection of BCD-085 in ascending doses in healthy male volunteers.
**Methods:** A standard "3+3" first-in-human dose escalation phase 1 clinical study design was used. Different cohorts of healthy male volunteers 18 to 45 years of age received a single subcutaneous injection of BCD-085 in ascending doses (0.05 mg/kg, 0.025 mg/kg, 0.0825 mg/kg, 1.25 mg/kg, 1.75 mg/kg, 2.25 mg/kg and 3.0 mg/kg). After injection all participants underwent 57 days of observation which included assessment of the tolerance, safety, pharmacokinetics and immunogenicity of the studied medicine.
**Results:** 22 healthy male volunteers received a single SC injection of BCD-085. *Pharmacokinetics:* Pharmacokinetic data were available from 21 volunteers with median body weights of 73.6 kg (range; 65.2–84.8). 1 volunteer withdrew from the study due to SAE that was not related to study drug (car accident). Regardless of the cohort changes of BCD-085 concentration were linear: after SC injection it slowly increased and reached the maximum value at the end of the first week. Thus, dose dependency was observed, while the half-life was not dependent on the dose and was 15–22 days. Mean $C_{max}$ of BCD-085 amounted to 12,232.5 ng/ml (median – 10937.0 ng/ml), $T_{max}$ – 156.6 hours (median 168.0), $AUC_{0-t}$ – 8780483.5 (ng/ml)*h (median – 8169096.2 (ng/ml)*hr), $AUC_{0-inf}$ – 4786108616.7 (ng/ml)*h (median – 4275500952.5 (ng/ml)*h), the half-life – 387.9 hours (median – 383.7 hours). *Safety:* In total, 6 adverse events were registered during the study, the toxicity in all these cases was mild (grade 1 in accordance with CTCAE v.4.03). Transaminases increase was more common (9.09%); grade 1 neutropenia occurred just in one volunteer. Single SC injections of BCD-085 were well tolerated with no signs of any local reactions. Immunogenicity assessment did not detect occurrence of anti-drug antibodies.



Figgure 1

**Conclusions:** BCD-085 is safe when administered SC in a wide range of doses from 0.05 to 3.0 mg/kg. Pharmacokinetics of a novel IL-17 blocker is standard for therapeutic monoclonal antibodies. Further clinical evaluation of BCD-085 is underway.

## FRI0011 MYCOPHENOLIC ACID SYNERGIZES WITH LIPOPOLYSACCHARIDE TO INDUCE INTERLEUKIN (IL)-1β RELEASE VIA ACTIVATION OF CASPASE-1 AND PROTECTS MRL/LPR MICE AGAINST MORTALITY INDUCED BY ENDOTOXEMIA

X. Huang, Y. He, J. Zhuang, E. Sun. *Department of Rheumatology and Immunology, The Third Affiliated Hospital of Southern Medical University, Guangzhou, China*

**Background:** Mycophenolate mofetil (MMF), which inhibits T and B lymphocyte proliferation, is widely used to treat a variety of autoimmune diseases, such as systemic lupus erythematosus (SLE) and lupus nephritis (LN)[1]. Several studies have reported that in lupus nephritis induction therapy, MMF was more effective than intravenous cyclophosphamide (CYC) with a more safety profile [2], but the mechanism is still unclear. We are the first to show that mycophenolic acid (MPA), the active metabolite of MMF, in association with lipopolysaccharide (LPS), is able to promote the secretion of interleukin (IL)-1β[3], which contradicts the traditional conception that immunosuppressants inhibit the secretion of inflammatory factors. This may be related to patients who are treated with MMF exhibiting better clinical outcomes and a lower incidence of infection than patients treated with CYC.
**Objectives:** To investigate the mechanism and significance of MPA synergizing with LPS to induce IL-1β release.
**Methods:** Undiluted human blood, THP-1 cells or monocytes was stimulated with LPS and treated with or without MPA, and the supernatant IL-1β was detected by ELISA. The intracellular protein levels of THP-1cells were measured by Western blot. MRL/lpr mice were treated with saline, MMF or CYC for 2 months, then given an intraperitoneal (i.p.) injection of LPS or saline, the effect, survival and cytokines were observed.
**Results:** We found that MPA alone failed to induce IL-1β, whereas MPA synergized with LPS to increase IL-1β in a dose-dependent manner. MPA did not affect the intracellular p-p65 and pro-IL-1β protein levels. However, MPA augmented LPS-induced IL-1β release by activation of NLRP3 inflammasome (Fig. 1A,B). Ac-YVAD-cmk, the inhibitor of caspase-1, blocked the activation of caspase-1 and subsequently attenuated IL-1β secretion. Both MMF and CYC can prevent the development of LN in MRL/lpr mice. Only MMF can protect mice from mortality after LPS-induced septic shock (Fig. 1C).

MPA synergized with LPS induced IL-1β release in a caspase-1 dependent manner. THP-1 cells ($4\times10^6$cells/ml) were cultured for 6h in the presence or absence of LPS (1μg/ml) and/or MPA (75μM), and at the last 30min the ATP was added to LPS treated cells. (A)the intracellular activated caspase-1 were detected. β-actin served as a loading control. (B) The supernatant IL-1β were determined by ELISA.(**p< 0.01, as compared to control, #p <0.05 , versus LPS alone group).casp-1:caspase-1

MMF protect mice from mortality after LPS-induced septic shock in MRL/lpr mice. **p< 0.01, CYC versussaline, ###p <0.001 , CYC versus MMF
Figure 1

**Conclusions:** MPA synergizes with LPS to induce IL-1β release depended on the activation of caspase-1 rather than the enhanced production of pro-IL-1β. MMF protects mice against mortality induced by LPS. These findings suggest that patients immunosupressed with MMF may have overly activated caspase-1, which causes a more sensitive host defense response to invading germs by promoting the induction of IL-1β.

## FRI0012 IL-17 IN RHEUMATOID ARTHRITIS BONE MARROW. NOT ONLY TH-17 CELLS

E. Kuca-Warnawin[1], W. Kurowska[1], M. Prochorec-Sobieszek[2,3], A. Radzikowska[1], T. Burakowski[1], M. Plebanczyk[1], I. Słowinska[4], R. Gasik[4], W. Maslinski[1]. *[1]Department of Pathophysiology and Immunology; [2]Department of Pathology, National Institute of Geriatrics, Rheumatology, and Rehabilitation; [3]Department of Diagnostic Haematology, Institute of Haematology and Transfusion Medicine; [4]Departament of Rheumoorthopaedic Surgery, National Institute of Geriatrics, Rheumatology, and Rehabilitation, Warsaw, Poland*

**Background:** Inflammatory process in bone marrow (BM) observed on MRI scans of rheumatoid arthritis (RA) patients (called bone marrow oedema) together with autoantibodies production was shown to proceed joint destruction in RA. Our previous studies supported the concept that BM actively participate in the pathogenesis of RA by TLR triggered B cell activity (1) and increased number of activated T cells (2).
**Objectives:** In the present study we investigated IL-17 producers in BM.
**Methods:** BM and peripheral blood (PB) samples were obtained from RA and osteoarthritis (OA) patients during total hip replacement surgery. Levels of IL-17AF, IL-17FF, IL-17AA, GMCSF and IL-21 in bone marrow plasma were determined by specific ELISA. Th1/Th2/Th17 proportions were evaluated by flow cytometry. To confirm production of IL-17 in BM immunohistochemistry examination was done. Comparison between the groups of patients were analysed by two-tailed Mann-Whitney U test.
**Results:** We observed increased level of IL-17AF (147±104 pg/ml vs 115±74pg/ml, $p<0,05$) in bone marrow plasma from RA in comparison to OA. In contrast similar levels of IL-17FF were detected in RA BM (94± 115pg/ml) and OA BM plasma (44±66pg/ml). IL-17AA was not detected. Concentrations of both IL-17AF and IL-17FF were higher in BM than in PB. Surprisingly there were no differences between RA BM and OA BM levels of Th-17 related cytokines such IL-21 and GMCSF. We did not observe any statistically significant differences in percentage of IL-17, IFNγ or IL-4 producing lymphocytes in RA BM and OA BM. Immunohistological staining confirmed higher expression of IL-17 in RA BM in comparison to OA BM. We also observed strong IL-17 staining in granulocytes.
**Conclusions:** IL-17AF is overproduced in RA bone marrow. There are two main sources of these cytokine in RA BM: T cells and granulocytes

## FRI0013 IL-22 INDUCES AN INCREASE IN SFP3 EXPRESSION BY SYNOVIAL FIBROBLASTS IN INFLAMMATORY JOINT DISEASES

G. Resende[1], C. Machado[2], R. Macedo[2], M. Rocha[2], V. Nascimento[2], J. Bueno Filho[3], A. Kakehasi[2], M. Andrade[2]. *[1]Hospital das Clínicas - UFMG; [2]Faculdade de Medicina - UFMG, Belo Horizonte; [3]Ciências Exatas, UFLA, Lavras, Brazil*

**Background:** Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Ankylosing Spondylitis (AS) are inflammatory joint diseases (IJD) with different joint remodeling patterns [1]. TNFalfa, IL17 and IL22 indirectly through signaling pathways such as Wnt may play a role in these phenotypes distinctiveness [2,3]. Fibroblast-like synoviocytes (FLS) have been considered an innate immunity component implicated in the switch of an acute and reparable to a chronic and persistent inflammatory process with irreversible tissue damage in that diseases [4].
**Objectives:** The aim of this study was to evaluate the expression of two Wnt pathway extracellular modulators (sFRP3 and DKK1) by FLS of patients with different IJD, in response to IL17, IL22 or TNFalfa. Additionally, we analyze the concentrations of all these proteins directly in the synovial fluid of inflamed peripheral joints.
**Methods:** 25 patients with an IJD diagnosis and the indication of joint infiltration for disease activity, was selected, regardless their systemic treatment. FLS were cultivated from synovial fluid and this were also used to measure the concentrations of DKK1, sFRP3, TNFalfa, IL17 and IL22 by ELISA. DKK1 and sFRP3 levels were dosed in the supernatant of cell cultures after pro-inflammatory stimulation.
**Results:** The concentrations of IL22 and sFRP3 were positively correlated ($r=0.76$; $p<0.01$) in synovial fluid and the highest levels were observed among TNFalfa inhibitors users ($p=0.01$). sFRP3 and DKK1 are constitutively expressed by FLS. Lower values of DKK1 were detected in PsA ($p<0.01$) as well as sFRP3 in AS ($p=0.01$). IL22 was the only cytokine able to increase sFRP3 production by these cells ($p<0.01$). No cytokine was efficient in increasing the expression of DKK1 in this study.

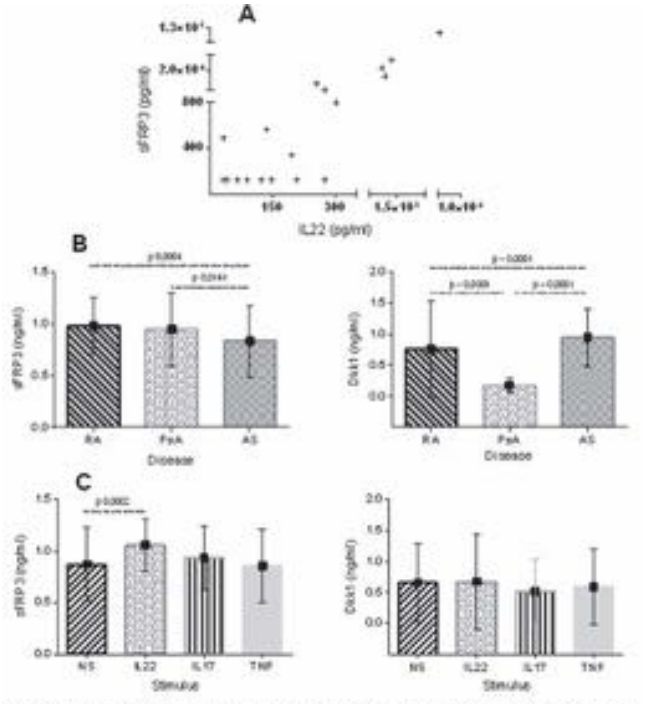

Fig 1 - Correlation between IL-22 and sFRP3 concentrations measured in synovial fluid (A). Concentrations in cell supernatant grouped by different diseases (B). Concentrations in cell supernatant grouped by different stimuli. NS - not stimulated (C). All values are presented as means with their standard deviations.

**Conclusions:** The high positive correlation between IL22 and sFRP3 in the synovial fluid of inflamed joints may be explained by the fact of that cytokine was capable of increasing this modulator production by FLS, in this experiment. Since sFRP3 is a canonical Wnt inhibitor and it blocks the osteoblastogenesis, different responses to IL22 may imply in different patterns of structural damage and joint remodeling.

## FRI0014 MULTIPLEX SCREENING OF CYTOKINES IN THE SEARCH FOR DISEASE ACTIVITY MARKERS OF SLE

S. Eketjäll[1], H. Idborg[2], J.T. Gustafsson[2], A. Zickert[2], M. Kvarnström[2], V. Oke[2], P. Susanne[2], P.-J. Jakobsson[2], I. Gunnarsson[2], E. Svenungsson[2]. *[1]Science for Life Laboratory, Personal Healthcare and Biomarkers, AstraZeneca Translational Sciences Centre; [2]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden*

**Background:** There is presently no consensus on how to best measure disease activity in systemic lupus erythematosus (SLE). Available validated measures, such as SLE Disease Activity Index (SLEDAI) and SLE Activity Measure (SLAM), are composite scores that in addition to laboratory tests require investigation by a physician. These scores are insensitive to change and have failed to differentiate treatment responses in clinical trials. It would be an important step forward, for clinical practice and for clinical trials, if one or several biomarkers could be used as proxies for disease activity in SLE.
**Objectives:** Our objective is to evaluate cytokines, in combination with basic laboratory tests, as potential disease activity biomarkers.
**Methods:** In a cross-sectional setting we examined 433 patients with SLE

(fulfilling four or more of the 1982 revised ACR criteria) and 322 age and gender matched population controls. Disease activity was assessed according to both SLEDAI and SLAM by a rheumatologist. Basic laboratory tests and analyses on MSD 30-plex cytokine assay (Mesoscale Discovery, K15054D) were performed on fasting blood samples (total >50 potential biomarkers). The discriminatory power for investigated biomarkers was tested between patients and controls. Spearman correlations with SLAM/SLEDAI scores were calculated among patients.
**Results:** Many potential biomarkers discriminated between patients and controls. Best discriminatory power was observed for TNF-α ($p=7x10^{-63}$), IL-6 ($p=2.5x10^{-40}$), orosomucoid ($p=7.1x10^{-38}$), plasma (P)-albumin ($p=1.6x10^{-36}$) and sedimentation rate (SR) ($p=5.6x10^{-34}$). The strongest correlations with SLEDAI/SLAM were observed for TNF-α (Spearman $\rho=0.32$, $p=6.0x10^{-12}$ for SLEDAI and Spearman $\rho=0.34$, $p=5.0x10^{-13}$ for SLAM), and for P-albumin (Spearman $\rho=-0.33$, $p=9.0x10^{-13}$ for SLEDAI and Spearman $\rho=-0.31$, $p=5.0x10^{-11}$ for SLAM). As SR is part of SLAM, expected positive correlations were observed (Spearman $\rho=0.27$, $p=7.7x10^{-9}$ for SLEDAI and Spearman $\rho=0.48$, $p=4.0x10^{-25}$ for SLAM).
**Conclusions:** Of more than 50 investigated biomarkers TNF-α was the best discriminator between SLE patients and controls. Furthermore TNF-α was the biomarker, which correlated best with disease activity. These correlations were further improved by the ratio between TNF-α and P-albumin. We propose that the TNF-α/P-albumin ratio merits further investigations as a clinically useful biomarker for diagnostic and surveillance purposes in SLE.

## FRI0015 LEUCINE RICH ALPHA-2 GLYCOPROTEIN (LRG) IS INVOLVED IN PULMONARY FIBROSIS BY ENHANCING TGF-β SIGNALING IN FIBROBLASTS

H. Honda, M. Fujimoto, H. Urushima, T. Ohkawara, S. Serada, T. Naka.
*Laboratory of Immune Signal, National Institutes of Biomedical Innovation, Health and Nutrition, Ibaraki, Osaka, Japan*

**Background:** Lung diseases related to collagen disorder are often accompanied by fibrosis and TGF-β is one of the essential mediators in tissue fibrosis. Leucine rich alpha-2 glycoprotein (LRG) is a novel serum protein that is increased in patients with inflammatory diseases, such as rheumatoid arthritis. LRG expression is increased in inflamed tissues, suggesting that the molecule is involved in the pathogenesis of the diseases. Since LRG has recently been reported as a modulator of TGF-β signals [1] [2], LRG may play a role in tissue fibrosis.
**Objectives:** In this study, we aimed to investigate the involvement of LRG in a murine model of lung fibrosis.
**Methods:** Wild type mice and LRG knockout (KO) mice were intratrachally treated with bleomycin and fibrosis were evaluated 21 days after the treatment. At the time of sacrifice, the lungs were harvested and processed for histological examination using hematoxylin and eosin staining, detection of collagen fibers using azan staining, and immunohistochemistry. Furthermore, the effect of LRG on TGF-β signaling was investigated using L929 mouse fibroblast cell line.
**Results:** Intratracheal administration of bleomycin increased LRG protein levels in bronchial alveolar lavage fluids (BALF) and lung tissues. When compared to wild type mice, fibrosis was markedly inhibited in LRG knockout (KO) mice, as evalulated by azan staining and by hydroxyproline assay. Although there was no significant difference in BALF TGF-β levels between WT and LRG KO mice, phosphorylation and nuclear translocation of Smad2 protein were attenuated in the lung of LRG KO mice. In vitro experiments using L929 revealed that LRG enhanced TGF-β-induced Smad2 phosphorylation and the expression of downstream genes, such as plasminogen activator inhibitor-1 (PAI-1) and alpha smooth muscle actin (SMA). Furthermore, TGF-β-induced Smad2 phosphorylation was enhanced by exogenous LRG protein in a dose-dependent manner. Although LRG has been reported to interact with endoglin, an accessory receptor of TGF-β, knockdown of endoglin showed no effect on LRG-induced enhancement of Smad2 activation.
**Conclusions:** These data demonstrate that LRG enhances TGF-β-induced activation of Smad2 cascade in fibroblasts leading to promote fibrosis in murine model of lung fibrosis.

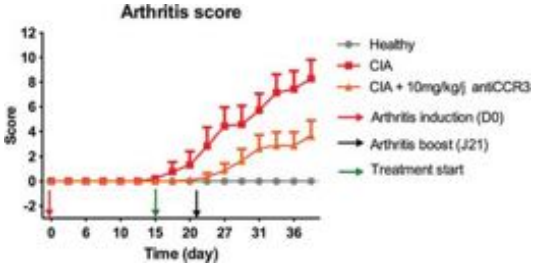
## FRI0016 REGULATION OF OSTEOCLAST DIFFERENTIATION BY ARGINASE I



J. Brunner[1], M. Hofamann[2], V. Saferding[2], K. Redlich[2], J.S. Smolen[2], G. Schabbauer[1], S. Blüml[2]. *[1]Institute for Physiology; [2]Rheumatology, Medical University Vienna, Vienna, Austria*

**Background:** Osteoclasts are giant, multi-nucleated cells that derive from the monocyte-macrophage linage and are involved in bone turnover. They are further known as the main effector cells for development of age-related osteoporosis.
**Objectives:** While the role of Arginase I within certain myeloid lineages such as macrophages is well appreciated, its role within osteoclasts is relatively unknown. Our aim was therefore to investigate the importance of the enzyme in the context of osteoclastogenesis.
**Methods:** We analyzed osteoclastogenesis of C57BL/6J or BALB/c wildtype cells in vitro in the presence and absence of recombinant Arginase I (recARG1) and its inhibitor nor-NOHA. This was complemented via qPCR analysis of marker genes. We further investigated the potential of the enzyme to induce cell death via flow cytometry analysis of 7-AAD and Annexin V.
**Results:** In osteoclast differentiation assays, we show that Arginase I is strongly downregulated during osteoclastogenesis, suggesting involvement of this enzyme in OC differentiation. We further show that addition of recArgI completely abolishes osteoclast formation without inducing cell death. The inhibitory effect of recArgI on osteoclastogenesis was completely dependent on the enzymatic function, as no decrease in osteoclast formation could be observed during combined addition of recArgI and its specific inhibitor nor-NOHA. We further demonstrate that recArgI specifically inhibits RANKL-mediated terminal differentiation of OCs, but has no effect on MCSF dependent generation of OC precursors. In line, we could show that addition of recombinant Arginase I negatively regulated the expression of classic RANKL induced osteoclastic marker genes such as TRAP and Cathepsin K.
**Conclusions:** We propose that recArgI might be a potent inhibitor of osteoclastogenesis and could prove itself to be useful for the treatment of osteoclast driven diseases, such as osteoporosis.

## FRI0017 PHARMACOLOGICAL BLOCKADE OF CCR3 REDUCES COLLAGEN-INDUCED ARTHRITIS SEVERITY

J. Hablot, M. Koufany, P. Reboul, J.-Y. Jouzeau, D. Moulin. *IMOPA, UMR7365 CNRS-Université de Lorraine, Vandoeuvre les Nancy, France*

**Background:** Chemokines are key pathophysiological mediators in the early phase of arthritis. Eotaxin-1 (Paquet and al., 2012) and its receptor, CCR-3 (CC Chemokine Receptor 3) (Haas and al., 2005), were previously shown to be highly expressed in the course of experimental arthritis. In human, CCR-3 positive monocytes are more abundant in the synovial fluid of arthritic patients than in healthy ones (Katschke and al., 2001). Moreover, RANTES, another chemokine with pathophysiological relevance to arthritis, is also a ligand of CCR-3, further suggesting that CCR-3 could be a potential therapeutic target for joint diseases.
**Objectives:** The main obective of this project was to study consequences of CCR-3 inactivation by a pharmacological antagonist in collagen-induced arthritis.
**Methods:** CIA was induced in 20 DBA/1J mice by intradermal injection of 100mg of bovine type II collagen in CFA at the basis of the tail, with a booster injection of 50mg by day 21. From day 15, mice were administered daily with antagonist of CCR-3 at a concentration of 10 mg/kg/day (i.p). Mice were regularly weighed and evaluated for the severity of arthritis with an arthritic score and by measuring hindpaw oedema by plethysmography. Mice were sacrificed at day 41, and histological analysis was performed on ankle joints after HES and safranin-O fast green staining. At that time, serum levels of IL-6 and IL-17F were measured by the multiplex technology.
**Results:** The clinical parameters showed that mice treated with a specific antagonist of CCR-3 develop less severe arthritis (respective clinical score 3.89 ± 1.25 vs 8.57 ± 1.63). Histological analyzes indicated that antagonist reduced the intensity of inflammatory process and limits cartilage degradation in arthritic joints. Blood level of IL-6 and IL-17F cytokines were reduced in mice treated with antagonist of CCR-3 compared to untreated arthritic mice.

**Conclusions:** Thus, our study shows that CCR-3 has an important role in arthritis development and designates it as a potential therapeutic target.

## FRI0018 SP1 INTERFERENCE PREVENTS JOINT DESTRUCTION OF RA THROUGH INHIBITORY EFFECTS OF GLIOSTATIN AND MATRIX METALLOPROTEINASE-3

K. Ikuta[1], Y. Waguri-Nagaya[2], N. Tatematsu[3], Y. Kawaguchi[3], T. Terazawa[1], M. Kobayashi[3], M. Aoyama[4], K. Asai[4], T. Otsuka[3]. *[1]Orthopaedic Surgery, Daido Hospital; [2]Joint Surgery for Rheumatic Diseases; [3]Orthopaedic Surgery; [4]Molecular Neurobiology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

**Background:** Gliostatin (GLS) has angiogenic and arthritogenic activities, which plays an important role in joint destruction as well as matrix metalloproteinase (MMP)- 3 in rheumatoid arthritis (RA). We previously reported that the expression of GLS in serum from RA patients was significantly correlated with disease activity, and that the expression of MMP-3 was induced by GLS in RA fibroblast-like synoviocytes (FLSs). The human GLS and MMP-3 gene promoter contains consensus binding sites for the DNA binding protein Sp1. Here we examined whether Sp1 was necessary for GLS and MMP-3 productions in RA.
**Objectives:** The purpose of this study was to investigate whether the effect of Sp1 interference using the Sp1 inhibitor mithramycin and RNA interference on GLS and MMP-3 productions in FLSs derived from patients with RA.
**Methods:** FLSs were cultured from synovial specimens obtained from 10 RA patients during total knee arthroplasty, and were stimulated by tumour necrosis factor (TNF)-α with or without treatment of mithramycin. The gene and protein expressions of GLS and MMP-3 were studied using the quantitative reverse-transcription polymerase chain reaction (RT-PCR) and an enzyme immunoassay. Intracellular signalling pathway activation was determined by a small interfering RNA (siRNA) transfection.
**Results:** GLS and MMP-3 productions were suppressed in FLSs by siRNA against Sp1 transfection. TNF-α (1 ng/ml) significantly increased GLS and MMP-3 expressions in RA FLSs; these effects were reduced by pre-treatment with mithramycin (300 nM).
**Conclusions:** Our results showed that pretreatment of mithramycin and Sp1 silencing resulted in a significant suppression of GLS and MMP-3 productions in TNF-α-stimulated FLSs compared to controls. The present study indicates that expression of the GLS and MMP-3 gene is mediated, in part, through the transcription factor Sp1.As physiological concentrations of mithramycin can regulate GLS and MMP-3 productions in RA, mithramycin is a promising candidate for anti-rheumatic therapy.

## FRI0019 DIVERGENT EFFECTS OF FREE FATTY ACIDS ON CELLS OF BONE METABOLISM

K. Frommer[1], A. Schäffler[2], U. Lange[1], S. Rehart[3], J. Steinmeyer[4], M. Rickert[4], U. Müller-Ladner[1], E. Neumann[1]. *[1]Department of Internal Medicine and Rheumatology, Justus-Liebig-University of Giessen, Bad Nauheim; [2]Department of Internal Medicine III, Endocrinology, Diabetes, Metabolism, Justus-Liebig-University of Giessen, Giessen; [3]Department of Orthopedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt; [4]Department of Orthopedics, University Hospital Giessen and Marburg, Giessen, Germany*

**Background:** Adipose tissue secretes numerous bioactive substances, which contribute to inflammation. Chronically elevated free fatty acid (FFA) levels are known to be associated with numerous inflammatory cardiovascular and metabolic diseases such as atherosclerosis, coronary heart diseases and type 2 diabetes. Conversely, inflammation can contribute to bone loss. FFA may therefore be a contributing factor in bone loss in osteoarthritis (OA) and/or rheumatoid arthritis (RA). Interestingly, obesity is associated with a higher risk of OA also in non-weight bearing joints and increased amounts of visceral fat are associated with lower bone density.
**Objectives:** To test the hypothesis that FFA affect cells of bone metabolism in the context of rheumatic diseases in a way that promotes bone loss.
**Methods:** Primary osteoblasts (OB) were isolated from cancellous bone of OA and RA patients undergoing knee joint surgery. Osteoclasts (OC) were differentiated from peripheral blood mononuclear cells (PBMC). OB and OC were stimulated with the saturated FFA palmitic acid (PA) and the unsaturated FFA linoleic acid (LA). Immunoassays were used to quantify protein secretion. mRNA expression levels were quantified by real-time PCR. Mineralization activity was quantified using Alizarin Red S staining, differentiated OC were quantified by counting TRAP-positive multinuclear cells. Toll-like receptor (TLR) 4 and TLR2 were blocked by neutralizing antibodies.
**Results:** Both PA and LA increased the secretion of the proinflammatory cytokine IL-6 (up to 9-fold) and the chemokines IL-8 (up to 221-fold), GRO-a (from below detection level to detectable levels) and MCP-1 (up to 16-fold). The degree of response was highly dependent upon the patient. RANKL as well as OPG, important regulators of osteoclastogenesis and OC activity, remained unaffected by FFA on protein and mRNA level. OB activity markers alkaline phosphatase (ALP) and collagen type I as well as markers of OB differentiation (e.g. osteocalcin) also remained unchanged after FFA stimulation. PA-induced IL-8 secretion by OB could be significantly reduced by TLR4 blockade (by 93%), while blocking TLR2 had no effect. Upon stimulation with PA and LA, secretion of IL-8 by RA OC was increased and MMP-9 reduced and the number of TRAP positive multinuclear cells decreased (by around 50%). Further markers of osteoclast activity (CLCN7, CTSK, TCIRG) remained unchanged.
**Conclusions:** The effect of FFA on cells of bone metabolism appears to be divergent: While FFA promote a pro-inflammatory phenotype in OB and may thus indirectly contribute to bone loss, the effects on OC mainly suggest an inhibitory effect on bone resorption.

## FRI0020 BMP-2 AND TGF-B INHIBIT IL-34 EXPRESSION IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

M. Chemel-Mary[1], B. Legoff[1], Y. Maugars[1], D. Heymann[1], F. Verrechia[2]. *[1]Rheumatology, CHU Nantes; [2]INSERM U957, Université de Nantes, Nantes, France*

**Background:** Interleukin-34 (IL-34) is a pro-osteoclastogenic cytokine, up-regulated by pro inflammatory cytokines, with a recently described role in rheumatoid arthritis (RA). TGF-b and BMP-2 are two members of the TGF-b family, whith an opposit role to the pro-inflammatory cytokines and that are also involved in rheumatoid synovitis.
**Objectives:** The present study aimed to assess the IL-34 expression in response to two members of the TGF-b family, TGF-b1 and BMP-2, in synovial fibroblasts from RA patients.
**Methods:** The IL-34, TGF-β1 and BMP-2 productions were measured in synovial fluids by ELISA. The IL-34 mRNA levels were quantified by qPCR in human synovial fibroblasts and murine mesenchymal stem cells (MSCs). Pharmacological inhibitions were used to determine the involvement of ALK1 and ALK5 downstream TGF-b1 and BMP-2.
**Results:** IL-34, TGF-b1 and BMP-2 were expressed in synovial fluids from RA patients. We found a significant correlation between IL-34 and TGF-b1 expressions. Levels of both IL-34 and TGF-b1 were thus correlated with the total leukocyte counts in the synovial fluids. TGF-b1 and BMP-2 decreased Il-34 expression in the synovial fibroblasts or in mMSC in a dose/time dependent manner through respectively ALK5 and ALK1 pathways. In addition, TGF-b1 antagonized TNFa-induced IL-34 gene expression.
**Conclusions:** This work identifies TGF-b1 and BMP-2 as potent inhibitors of IL-34 expression in RA synovial fibroblasts. These cytokines, as upstream inhibitors of IL-34, may thus contribute to antagonize inflammation and bone erosions in RA.

## FRI0021 CALPROTECTIN LEVELS CORRELATE WITH INFLAMMATION IN EARLY RA BEFORE DMARD TREATMENT AND AFTER 12 MONTHS OF TREATMENT

M.K. Jonsson[1,2,3], H.B. Hammer[2], H.H. Nordal[1,3], A.-B. Aga[2], I.C. Olsen[2], K.A. Brokstad[3], B.-T.S. Fevang[1,3], T.K. Kvien[2], S. Lillegraven[2], E.A. Haavardsholm[2] on behalf of ARCTIC Study Group. *[1]Department of Rheumatology, Haukeland University Hospital, Bergen; [2]Department of Rheumatology, Diakonhjemmet Hospital, Oslo; [3]Department of Clinical Sciences, University of Bergen, Bergen, Norway*

**Background:** Calprotectin (MRP8/MRP14, S100A8/A9) is a major leukocyte protein previously shown to be associated with disease activity in patients with established rheumatoid arthritis (RA), and some studies indicate that it may be a more accurate measure of joint inflammation than erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP).
**Objectives:** To compare the associations of calprotectin, ESR and CRP to clinical and ultrasound measures of inflammation in patients with early RA, both before and after 12 months of aggressive disease-modifying antirheumatic drug (DMARD) treatment.
**Methods:** RA-patients (n=238) who fulfilled the 2010 ACR/EULAR classification criteria were recruited to the ARCTIC trial between 2010 and 2013. All patients had symptom duration from first swollen joint <2 years and were DMARD-naïve with indication for DMARD treatment. Calprotectin in plasma was analyzed in 217 patients at baseline and 166 patients at 12 months by ELISA. Ultrasound (US) inflammation was evaluated using a standardized protocol with semi-quantitative scoring 0–3 for grey-scale (GS) and power Doppler (PD) in 32 joints (1). Clinical inflammation was assessed by 44 swollen joint count (SJC44), Ritchie Articular Index (RAI), ESR and CRP. Disease activity score (DAS) was calculated. Cross-sectional relationships were assessed by Spearman's correlations.
**Results:** A total of 217 patients were included: 61% female, 71% RF positive, 82% ACPA positive, mean (SD) age 53.5 (13.7) years, mean DAS 3.46 (1.17), median [25, 75 percentile] disease duration 5.7 [2.8, 10.4] months. At 12 months mean DAS was 1.25 (0.72); 74% were in remission according to DAS, 17% low, 9% moderate and 0% high DAS. The median baseline/12 month calprotectin was 1028 [567, 2158]/485 [293, 802] μg/L, ESR 19 [11, 31]/9 [5, 14] mm/h and CRP 7 [3, 18]/3 [1, 5] mg/L. Calprotectin was significantly correlated to clinical, laboratory and US measures of inflammation before treatment onset (table). After 12 months of treatment, calprotectin had a weaker, but statistically significant correlation to US scores, while no association between ESR/CRP and US scores was found.

Table 1. Spearman's correlation coefficients

| | Baseline (n=217) | | | 12 months (n=166) | | |
|---|---|---|---|---|---|---|
| | Calprotectin | CRP | ESR | Calprotectin | CRP | ESR |
| Calprotectin, μg/L | NA | 0.66** | 0.51** | NA | 0.33** | 0.43** |
| CRP, mg/L | 0.66** | NA | 0.63* | 0.33** | NA | 0.26** |
| ESR, mm/h | 0.51** | 0.63** | NA | 0.43** | 0.26** | NA |
| SJC44 (0–44) | 0.30** | 0.37** | 0.24** | 0.10 | 0.12 | 0.11 |
| RAI (0–78) | 0.21* | 0.32** | 0.16* | 0.10 | 0.16* | 0.12 |
| Ultrasound GS-score | 0.45** | 0.41** | 0.29** | 0.20* | 0.08 | –0.01 |
| Ultrasound PD-score | 0.42** | 0.35** | 0.35** | 0.26** | –0.02 | 0.03 |
| Ultrasound total score | 0.46** | 0.40** | 0.33** | 0.22* | 0.07 | 0.00 |

*p<0.05, **p<0.001.

**Conclusions:** Calprotectin was correlated to inflammation assessed by ultrasound before onset of DMARD treatment, and the association was also present after 12 months of DMARD treatment. The data support that calprotectin might be of interest when assessing disease activity in different stages of RA.

## FRI0022 INFLAMMATORY STATUS AND SERUM URIC ACID LEVELS DETERMINE HIGH-DENSITY LIPOPROTEIN–CHOLESTEROL LEVELS IN A NON-RHEUMATIC POPULATION

M. Andrés[1], M.A. Quintanilla[2], P. Morillas[2] on behalf of FAPRES Registry Investigators. *[1]Seccion de Reumatologia, Hospital General Universitario de Alicante, Alicante; [2]Servicio de Cardiología, Hospital General Universitario de Elche, Elche, Spain*

**Background:** In inflammatory disorders, highest incidence of cardiovascular (CV) events paradoxically occurs at lower lipid levels (1), especially in the case of high-density lipoprotein cholesterol (HDLc). Current data in general, non-inflammatory population suggest a similar but milder phenomenon (2). Serum uric acid (SUA) levels appear to determine the inflammatory status of the subjects, even in normouricemia (3).
**Objectives:** To assess whether inflammatory status and SUA levels associate with HDLc levels in a hypertensive population aged 65 years or older.
**Methods:** Retrospective analysis of the FAPRES study (cross-sectional study aimed at determining the prevalence of atrial fibrillation in hypertensive patients aged 65 years or older). Inflammatory status was considered based on serum leukocytes levels. A comparison between serum lipids levels (HDLc, low-density lipoprotein-cholesterol [LDL], total cholesterol [TCh], triglycerides [TG]) and different tertiles of leukocytes and SUA has been performed using ANOVA. In case of statistically significant differences, a multivariate linear regression model was built for each lipid parameter in order to adjust for potential confounders.
**Results:** A total of 1,003 patients were recruited, mean aged 72.9 years (SD±5.8), 52.5% females. In the sample median (±SD) leukocytes, SUA and HDLc were 6,719.6/mm$^3$ (±1773.1), 5.2 mg/dL (±1.1), and 52.8 mg/dL (±13.1), respectively. Table shows the distribution of lipids across leukocytes and SUA tertiles: lower HDLc and higher TG levels were found in upper tertiles of both leukocytes and SUA, with no differences on TCh and LDLc. After adjusting for potential confounder (age, gender, CV risk factors, renal failure, body mass index, use of diuretics or statins), an independent, inverse association of both leukocytes (β=-0.001, p=0.02) and SUA (β=-1.054, p=0.03) with HDLc levels was confirmed. For TG levels, an independent, direct association with SUA (β=8.254, p=0.004) was also found, as well as a trend for leukocytes (β=0.003, p=0.06).

Table 1

| Mean (±SD) | TCh | p | HDLc | p | LDLc | p | TG | p |
|---|---|---|---|---|---|---|---|---|
| Leukocytes | | | | | | | | |
| <5900 | 197.8 (±41.3) | 0.15 | 54.3 (±13.2) | 0.006 | 121.1 (±35.9) | 0.20 | 115.2 (±48.6) | 0.03 |
| 5900–7200 | 195.6 (±35.0) | | 53.1 (±12.7) | | 118.7 (±29.9) | | 132.7 (±88.3) | |
| >7200 | 191.7 (±41.7) | | 50.8 (±12.6) | | 116.1 (±34.7) | | 129.0 (±54.8) | |
| SUA | | | | | | | | |
| <4.7 | 198.1 (±40.5) | 0.32 | 56.6 (±13.8) | <0.001 | 119.6 (±36.6) | 0.60 | 111.6 (±47.9) | 0.001 |
| 4.7–5.8 | 194.3 (±36.3) | | 54.8 (±12.9) | | 117.5 (±32.5) | | 117.5 (±47.0) | |
| >5.8 | 191.7 (±37.1) | | 49.7 (±10.8) | | 116.6 (±31.3) | | 135.6 (±90.7) | |

**Conclusions:** In a non-rheumatic, hypertensive population aged 65 years or older, both inflammatory status and SUA levels showed an inverse, independent association with HDLc, following current data on patients with inflammatory disorders. This phenomenon might help to define a pro-atherogenic profile on the general population.

## FRI0023 EFFECTS OF IL-33/ST2 AXIS ON CYTOKINE GENE EXPRESSION AT THE SITE OF ACUTE INFLAMMATION

M. Stankovic[1], K. Janjetovic[2], N. Puskas[3], M. Milenkovic[2], I. Zaletel[3], S.R. De Luka[1], A.M. Trbovich[1], V. Trajkovic[2]. *[1]Department of Pathophysiology, School of Medicine University of Belgrade; [2]Institute of Microbiology and Immunology, School of Medicine University of Belgrade; [3]Institute of Histology and Embryology "Aleksandar Đ. Kostić", School of Medicine University of Belgrade, Belgrade, Serbia*

**Background:** Acute inflammation is an early response to a cell injury. Interleukin (IL)-33 is a new member of IL-1 cytokine family. It was discovered that IL-33 and its receptor ST2 have a role not only in Th2 mediated diseases, as firstly reported, but also in other diseases, such as rheumatoid arthritis, autoimmune uveitis, and squamous cell carcinoma. Effects of IL-33/ST2 axis in acute inflammation are still not completely understood.
**Objectives:** The aim of this study was to examine effects of IL-33/ST2 axis on cytokine gene expression at the site of acute inflammation.
**Methods:** Male mice were divided in groups: wild-type control group (WT-C), wild-type inflammatory group (WT-I), ST2 knockout control group (KO-C), and ST2 knockout inflammatory group (KO-I). Acute inflammation was induced in WT-I and KO-I by intramuscular injection of turpentine oil, whereas animals in

WT-C and KO-C were injected with saline. Mice were euthanized after 12 hours, and the treated tissue was collected for histopathological analysis, and gene expression determination (qRT-PCR) of IL-33, ST2 receptor, tumor necrosis factor alpha (TNF-alpha), IL-12p35, IL-23p19, and transforming growth factor-beta (TGF-beta). All experimental procedures were approved by the University of Belgrade School of Medicine Ethics Committee.
**Results:** Acute inflammation was histopathologicaly confirmed in WT-I and KO-I. IL-33 in the treated tissue was significantly higher in inflammatory groups, WT-I and KO-I, when compared to WT-C and KO-C, respectively. However, IL-33 was significantly higher in KO-I than in WT-I. ST2 significantly increased in inflamed tissue of wild-type mice, in comparison to WT-C. TNF-alpha, IL-12p35, and IL-23p19 in the treated tissue significantly increased in WT-I and KO-I, when compared to their corresponding control groups WT-C and KO-C. TGF-beta in the treated tissue was significantly higher in KO-I than in WT-I, whereas it did not significantly differ between WT-C and KO-C.
**Conclusions:** Results of this study indicated that IL-33/ST2-axis affected gene expression of cytokines at the site of acute inflammation, i.e. gene expression of IL-33, and anti-inflammatory cytokine TGF-beta. ST2 gene expression increased in acutely inflamed tissue, indicating importance of IL-33/ST2 axis in acute inflammation.

## FRI0024 OLIVE-DERIVED OLEUROPEIN AS A POTENTIAL TREATMENT FOR BONE AND CARTILAGE AGE-RELATED DISORDERS

M. Varela-Eirín[1], A. Casado-Díaz[2], J.M. Quesada-Gómez[2], M.D. Mayán[1]. *[1]CellCOM Research Group, Biomedical Research Institute of A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC-XXIAC). SERGAS. Universidade de A Coruña, A Coruña; [2]Clinical Management Unit of Endocrinology and Nutrition, Maimónides Biomedical Research Institute of Córdoba (IMIBIC). Hospital Universitario Reina Sofía – RETICEF. Universidad de Córdoba, Córdoba, Spain*

**Background:** Oleuropein is the major glycoside component in olives and is well known to have several beneficial effects on human health [1]. However, the mechanisms associated with its potential pharmacological properties are not clear yet. Human bone marrow mesenchymal stem cells (hMSCs) exhibit an age-dependent reduction in osteogenesis and an increased propensity toward adipocyte differentiation. This switch has been associated with different bone disorders characterized by reduced bone formation and increased bone marrow fat accumulation [2,3]. Connexin 43 (Cx43) is an integral membrane protein that forms gap junction channels (GJs) and it is implicated in multiple cellular functions including cellular differentiation and control of bone and cartilage remodelling.
**Objectives:** The aim of this study was to test if oleuropein could act as an adipogenic suppressor in order to promote cartilage and bone regeneration through a Cx43-dependent mechanism.
**Methods:** Human mesenchymal stem cells were obtained from bone marrow donors. Cells were grown in α-minimum essential medium (MEM) and differentiation was initiated before achieving confluence with specific differentiation media in the presence of different concentrations of oleuropein. Adipogenesis and osteogenesis was held in culture chambers for 21 days; chondrogenesis was performed as a micromass culture for 30 days. Cellular differentiation was evaluated using histological stains: Oil Red O for adipogenesis; Alizarin Red for osteogenesis; Toluidine Blue and Safranin O/Fast Green for chondrogenesis. Scrape loading assays and lucifer yellow were used to study the cellular communication through gap junction (GJ) and hemichannels formed by Cx43. Western-blot and immunohistochemistry (IHC) assays were performed to study the levels of Cx43 protein.
**Results:** hMSCs treated with oleuropein showed a two-folded decrease in adipogenic differentiation, while osteogenesis was significantly increased. Micromasses cultured in chondrogenic medium using 10 μM of oleuropein showed a more intense toluidine blue and Safranin O stain, suggesting an increase in chondrogenesis. Real-Time qPCR, western blot analysis and scrape loading assays showed changes in the levels of Cx43 and dye transference through GJ channels when the hMSCs were grown in the presence of oleuropein.
**Conclusions:** Our results suggest that oleuropein via Cx43 and GJ intercellular communication increases the propensity towards osteogenesis and chondrogenesis, reducing adipocyte differentiation. Our preliminary assay indicates that oleuropein may represent a potential therapeutic target for cartilage and bone age-related disorders such as osteoarthritis in order to promote cartilage and bone regeneration.

## FRI0025 NO REACTIVATION OF DORMANT MYCOBACTERIUM TUBERCULOSIS IN HUMAN IN VITRO GRANULOMA MODEL AFTER ANTI-IL-17A TREATMENT, IN CONTRAST TO ANTI-TNFα TREATMENT

N. Kapoor[1], M. Kammüller[2], P.E. Kolattukudy[1]. *[1]Burnett School of Biomedical Sciences - University of Central Florida, Orlando - Florida, United States; [2]Novartis Institutes of Biomedical Research, Basel, Switzerland*

**Background:** IL-17A inhibition has shown significant efficacy in the treatment of psoriasis, psoriatic arthritis and ankylosing spondylitis. Blocking critical mediators of innate and adaptive immunity may carry the risk of an increased susceptibility to infections. While *Mycobacterium tuberculosis* infections can be an important complication of anti-TNFα therapies, the role of the Th17/IL-17 pathway in host resistance to this intracellular pathogen is less clear. A comparison of tool antibodies neutralizing TNFα or IL-17A in an acute murine *M. tuberculosis* infection model, confirmed the importance of TNFα in host resistance to *M. tuberculosis*, and highlighted that anti-IL-17A treatment for four weeks *in vivo* does not impair immunity to this intracellular pathogen[1].
**Objectives:** To investigate the effect of adalimumab (anti-TNFα antibody) and secukinumab (anti-IL-17A antibody) on *M. tuberculosis* dormancy and reactivation, we utilized a novel *in vitro* human 3D microgranuloma model[2].
**Methods:** Human peripheral blood mononuclear cells were infected with *M. tuberculosis*. Dormant mycobacteria exhibited the following characteristics: (1) loss of acid-fastness, (2) accumulation of lipid bodies, (3) development of rifampicin-tolerance, and (4) gene expression changes[2]. We measured Auramine-O and Nile red staining indicative of *M. tuberculosis* membrane acid fastness and accumulating lipid bodies, respectively, and also investigated rifampicin resistance. In this *in vitro* human 3D microgranuloma model we studied the anti-TNFα antibody adalimumab at 10 ng/ml, and the IL-17A antibody secukinumab at 10, 100, and 1000 ng/ml.
**Results:** *M. tuberculosis* from granulomas treated with anti-TNFα antibody (adalimumab) showed increased staining for Auramine-O, decreased Nile red staining, and decreased rifampicin resistance, indicating *M. tuberculosis* reactivation. In contrast, anti-IL-17A antibody (secukinumab) treatment was comparable to control treatment indicating that the drug did not trigger *M. tuberculosis* reactivation in human microgranuloma *in vitro*.
**Conclusions:** Overall, these results confirm the importance of TNFα in host resistance to *M. tuberculosis* infection, and highlight that anti-IL-17A treatment *in vitro* does not reverse *M. tuberculosis* dormancy in this human granuloma model, in accordance with available clinical data[3,4].

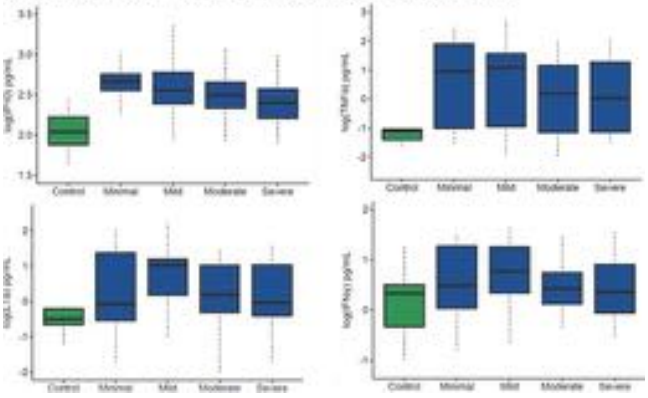
## FRI0026 A CYTOKINE-MEDIATED BIOLOGICAL BASIS FOR FATIGUE IN PRIMARY SJÖGREN'S SYNDROME



N. Howard Tripp[1], J. Tarn[1], C. Gillespie[2], D. Lendrem[1], W.-F. Ng[1]. *[1]Institute of Cellular Medicine; [2]Department of Mathematics and Statistics, University of Newcastle, Newcastle upon Tyne, United Kingdom*

**Background:** Fatigue is a common and problematic symptom in many chronic diseases including primary Sjögren's Syndrome (pSS).[1,2] Although the pathophysiological basis of fatigue is not fully understood and no biomarkers have yet been identified, emerging data implicates inflammatory pathways and immune dysregulation as potential mechanistic components.[3,4]
**Objectives:** The aim of this study is to investigate the relationship between cytokine levels and patient-reported levels of fatigue, using pSS as an example of a chronic immunological condition.
**Methods:** Blood levels of 22 cytokines were measured in 161 patients with pSS from the UK Primary Sjögren's Syndrome Registry (UKPSSR) and 28 healthy non-fatigued controls.[5] Differences between cytokines in cases and controls were evaluated using Wilcoxon test. Patient-reported scores for fatigue were evaluated,

classified according to severity, and compared with cytokine levels using ANOVA. Logistic regression was used to determine the most important predictors of fatigue levels.

**Results:** 13 cytokines were significantly higher in pSS patients compared to healthy controls, with a $p \leq 0.0001$ for 8 of these. Levels of four pro-inflammatory cytokines IP-10 (p=0.019), TNF-$\alpha$ (p=0.046), LT-$\alpha$ (p=0.034) and INF-$\gamma$ (p=0.022) decreased with increasing fatigue in the pSS cases. Serum levels of IFN-$\gamma$ and IP-10, and pain and depression scores were the best predictors of fatigue level with correct predictions of fatigue level in 67% of cases when these 4 parameters were used.

**Fig. 1a-d. Box-plot showing median cytokine levels and interquartile ranges for a) IP-10, b) TNF-α, c) LT-α, and d) IFN-γ in controls and pSS fatigue groups.** In all four cases the levels of anti-inflammatory cytokines are significantly higher in pSS patients. In addition, all four show an inverse relationship between fatigue severity and cytokine levels. Fatigue levels fall with increasing levels of the four cytokines.

**Conclusions:** 4 pro-inflammatory cytokines decrease as fatigue level increases in pSS patients. Research into anti-inflammatory pathways and cytokines may be insightful in understanding the pathophysiological basis of fatigue. Cytokines, pain and depression appear to be the most powerful predictors of fatigue. Further study is required to characterise the complex biochemical cascades underlying fatigue in pSS and other chronic conditions, as well as the influence of potential clinical confounding factors such as pain and depression

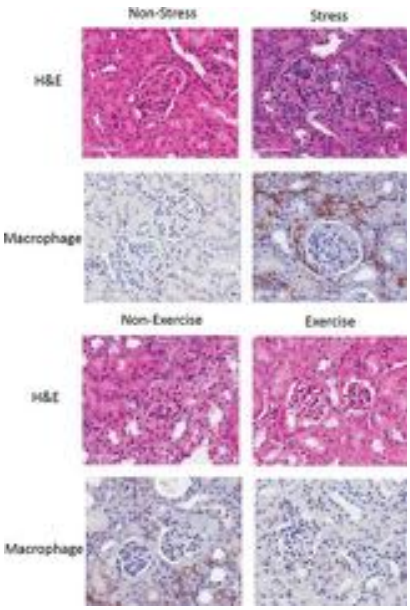
## FRI0027 THE INFLAMMATORY PATHOLOGY OF LUPUS NEPHRITIS IS SIGNIFICANTLY INDUCED WITH PSYCHOSOCIAL STRESS, SUPPRESSED WITH EXERCISE, AND CORRELATES WITH TNF-ALPHA AND MCP-1 EXPRESSION IN A MURINE MODEL



S. Aqel[1], J. Hampton[1], G. Valiente[1], J. Sheridan[2], W. Jarjour[1], N.A. Young[1]. *[1]Rheumatology and Immunology; [2]Institute for Behavioral Medicine Research, The Ohio State University Wexner Medical Center, Columbus, United States*

**Background:** Studies incorporating either regular exercise or stress modification programs have been efficacious in influencing the clinical disease course of systemic lupus erythematosus (SLE). We have previously demonstrated in mice that daily, moderate exercise limits inflammation systemically and that repeated social stress stimulates proinflammatory responses.

**Objectives:** To determine if daily moderate exercise (DME) or psychosocial stress can significantly affect chronic autoimmune-mediated inflammation, we examined the NZM2410 mouse model of lupus nephritis, which spontaneously develops severe, early-onset glomerulonephritis at 22–40 weeks of age.

**Methods:** All mice were removed from the study when experimental removal criteria was reached [blood urea nitrogen (BUN)>50 $\mu$g/mL; weight loss>20%]. The DME protocol consisted of daily 45 min treadmill walks at moderate intensity (8 m/min) beginning at 18 weeks of age. To disturb the social order within an established social hierarchy, an aggressive intruder was introduced to induce repeated social disruption stress (SDR). SDR was performed daily for 6 consecutive days beginning at 20 weeks of age. When SDR mice met experimental removal criteria, an age-matched control counterpart was selected at random for comparative analysis. Kidney tissue and serum were collected at experimental endpoint. Multi-plex ELISA measurements of cytokine expression were performed on serum samples.

**Results:** Glomerulonephritis was enhanced with SDR, but significantly improved with DME, as indicated by IgG and C3 complex deposition. Histopathological examination of renal tissue showed glomerular hypercellularity and hyperplasia of the Bowman's capsule. Furthermore, BUN and weight measurements showed a 42% improvement with DME at 43 weeks of age. Immunohistochemical analysis and digital image quantitation of macrophage-mediated inflammatory responses in the kidney revealed a significant induction with SDR and suppression with DME. Additionally, serum cytokine analysis showed up-regulation of IL-5, IL-6, IL-10, and TNF-$\alpha$ with SDR and in older NZM2410 mice relative to younger mice and wild-type controls. While levels of IL-6 were not reduced, expression of IL-5, IL-10, and TNF-$\alpha$ was suppressed with DME. Since TNF-$\alpha$ induces monocyte chemoattractant protein-1 (MCP-1) secretion, MCP-1 expression was measured and demonstrated a reduction with DME and enhancement following SDR.

**Conclusions:** Our data suggests that renal histopathology can be modified via exercise and stress reduction by suppressing TNF-$\alpha$ induction and expression of MCP-1. Thus, stress reduction and moderate exercise could be used therapeutically in adjunct to pharmacological therapy to help control the chronic inflammation associated with lupus nephritis and other autoimmune diseases.

## FRI0028 VASCULAR ENDOTHELIAL GROWTH FACTOR AS AN AID TO DIAGNOSIS OF GIANT CELL ARTERITIS

N. Goodfellow[1], J. Morlet[1], A. Floris[1], S. Singh[2], A. Sabokbar[1], A. Hutchings[3], V. Sharma[1], J. Vaskova[1], S. Masters[1], R. Luqmani[1] on behalf of TABUL Investigators. *[1]Botnar Research Centre; [2]Nuffield Department of Surgery, University of Oxford, Oxford; [3]London School of Hygiene and Tropical Medicine, London, United Kingdom*

**Background:** Giant Cell Arteritis (GCA) is a common vasculitis with significant risk of blindness. Although temporal artery biopsy (TAB) is currently performed for diagnosis, the sensitivity can be as low as 39%; ultrasound is emerging as a more effective and cheaper test. Vascular endothelial growth factor (VEGF) is present in inflamed arterial wall in GCA and elevated circulating levels have been reported in GCA compared to controls. Measurement of VEGF is less invasive than TAB, and cheaper than TAB or ultrasound.

**Objectives:** 1) Analyse performance of VEGF as a diagnostic marker for GCA

2) Combine VEGF with ESR and CRP to assess performance
3) Assess local expression of VEGF in TAB

**Methods:** We used samples from patients recruited to a large multi-centre study comparing temporal artery biopsy with ultrasound for diagnosis of suspected giant cell arteritis. We randomly selected 26 patients with TAB-positive GCA and 26 controls (negative TAB and final diagnosis not GCA). Most patients were receiving high doses of glucocorticoid therapy at recruitment. Serum VEGF concentration was measured at weeks 0, 2 and 26 by ELISA (Quantikine R&D systems). Week 0 values were plotted on a Receiver Operating Characteristic (ROC) curve to identify the most effective cut-off for an abnormal result. Sections of TAB were stained by immunohistochemistry for VEGF expression (Polyclonal Rabbit anti-human VEGF, AbCAM).

**Results:** Patients were significantly older than controls (mean age 76 SD 7.3 vs 66 SD 11.3, p=0.003). but had similar gender (62% females each). The mean (95% CI) baseline VEGF concentration was 873 pg/ml (631–1110) in GCA vs 476 pg/ml [328–625] in controls (p=0.017). This difference between groups was not observed at any other timepoint. The area under the ROC curve for VEGF concentration at week 0 was 0.73. The optimal cut off was 713pg/ml, providing a sensitivity of 65% and a specificity of 88%. These values compare favourably with reported performance of other available tests such as ESR and CRP (sensitivity 86% and 84%; specificity 30% and 29% respectively), TAB (sensitivity 40%, specificity 100%), and ultrasound (sensitivity 54%, specificity 81%).

VEGF concentration was combined with ESR and CRP values to assess if this improved its performance. High ESR was defined as ≥22 in men, ≥29 in women, and high CRP was ≥8. These results are summarised in Figure 1. ESR+CRP LOW had a 94% Negative predictive value to exclude GCA. ESR/CRP High + VEGF High had 95% Positive predictive value to diagnose GCA. For 27% of patients a further diagnostic test is needed.

VEGF expression by immunohistochemistry in TAB sections from 3 patients with GCA was higher than 2 controls, implying that VEGF is upregulated in GCA and may signal locally to drive the vasculitic process. Furthermore, serum concentration appears to reflect local concentration in the temporal artery; therefore measuring serum VEGF concentration is a valid surrogate for local inflammation.

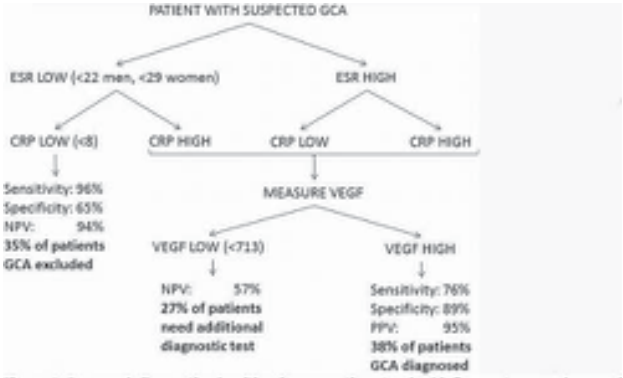

**Figure 1.** Proposed diagnostic algorithm incorporating standard inflammatory markers and VEGF. NPV = Negative Predictive Value, PPV = Positive Predictive Value, CRP = C-reactive protein, ESR = Erythrocyte Sedimentation Rate

**Conclusions:** In this study, serum VEGF was a useful test to support a diagnosis of GCA and potentially avoid the cost of TAB or ultrasound in over 60% of patients. Further studies will evaluate this in a larger cohort of suspected cases of GCA. Furthermore, VEGF could potentially be effective as a prognostic marker, or as a therapeutic target.

**Disclosure of Interest:** None declared

Condino-Neto[1]. *[1]Department of Immunology, University of São Paulo, Sao Paulo, Brazil; [2]Rheumatology, University of Lübeck, 23562 Lübeck, Germany; [3]The Central Laboratory of High Performance Technologies, State University of Campinas, Campinas; [4]6Pediatric Allergy & Immunology Clinic, 6Pediatric Allergy & Immunology Clinic, Caixa do Sul; [5]Albert Sabin Hospital, Albert Sabin Hospital, Fortaleza; [6]Pediatric Immunology Clínic, Unit of Pediatrics, Hospital de Base do Distrito Federal, Distrito Federal; [7]Division of Allergy-Immunology and Rheumatology, Federal University of São Paulo, Sao Paulo, Brazil; [8]Department of Pediatrics, University of Washington, Seattle, United States*

**Background:** CD40 ligand (CD40L) deficiency predisposes to opportunistic infections including those caused by fungi and intracellular bacteria. Studies of CD40L-deficient patients reveal the critical role of CD40L-CD40 interaction for the function of T, B, and dendritic cells. However, the consequences of CD40L deficiency on macrophage function remain poorly understood.

**Objectives:** To analzye the role of CD40L-CD40 interaction in macrophages immune response.

**Methods:** MDMs were challenged with *Paracoccidioides brasiliensis* (Pb18, a highly virulent isolate) and the microbicidal activity determined by counting colony forming units (CFU). MDMs oxidative burst was measured by luminol-dependent chemiluminescence (LDCL). Supernatants of macrophages treated or untreated with rhIFN-γ or sCD40L were harvested 48 hours after *P. brasiliensis* or *M. tuberculosis* incubation and the Cytokine levels were evaluated by luminex. The analysis of *M. tuberculosis* (H37Rv strain) phagocytosis and proliferation control by MDMs were carried out by CFU counting. Macrophage transcriptome profiles from three CD40L deficient patients and three healthy controls were analyzed by RNAseq. All the experiments were performed before and after IFN-gamma *in vitro* treatment.

**Results:** Here we show that macrophages from CD40L-deficient patients exhibit defective fungicidal activity and reduced oxidative burst, which improved in the presence of IFN-γ but not soluble CD40L (sCD40L). In contrast, both IFN-γ and sCD40L ameliorate impaired production of multiple inflammatory cytokines. Comparing the gene expression signature of macrophages from CD40L-deficient patients to that of controls, we identified 109 differentially expressed genes (DEGs). *In vitro* treatment of macrophages with IFN-γ decreased the number of DEGs to only 11, and similarly affected the expression of 528 non-DEGs (140 genes down-regulated and 388 up-regulated) comparing patients and healthy controls. Finally, the addition of IFN-γ reversed defective control of *M. tuberculosis* proliferation by patient macrophages.

**Conclusions:** Our findings demonstrate that absence of CD40L impairs macrophage development and function. In addition, the improvement of macrophage immune responses by IFN-γ suggests this cytokine as a potential new therapeutic option for patients with CD40L deficiency.

## FRI0030 ANTI-TNF-α ANTIBODY TARGETED TO INFLAMED SYNOVIAL TISSUE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS

F. Colombo[1], D. Sblattero[1], L. De Maso[1], P. Durigutto[1], S. Biffi[2], B. Belmonte[3], C. Tripodo[3], P.L. Meroni[4], F. Tedesco[5], P. Macor[1]. *[1]Dept of Life Sciences, University of Trieste; [2]Institute for Maternal and Child Health, IRCCS "Burlo Garofolo", Trieste; [3]Department of Health Sciences, University of Palermo, Palermo; [4]University of Milan, Istituto Auxologico Italiano; [5]Istituto Auxologico Italiano, Milan, Italy*

**Background:** TNF-α neutralizing molecules represent one of the most efficient therapeutic approaches to control inflammation in rheumatoid arthritis (RA). The widespread distribution in the body induces the inhibition of TNF-α in all the tissues, requesting the use of high dose of this expensive drug. Another problem that has not yet been solved in the management of RA patients is how to reduce and possibly avoid the side effects, particularly the increased risk of common and opportunistic infections, which may be associated with long-term administration of these therapeutic drugs.

**Objectives:** The aim of the present investigation was to show that a recombinant protein obtained by fusing a synovial targeting peptide to an anti-TNF-α neutralizing antibody has a distinctive homing property for inflamed synovium and is effective in controlling joint inflammation in experimental models of arthritis.

**Methods:** The modified anti-TNF-α antibody specific for the synovial tissue (MC13) was generated by cloning the sequence for a synovial homing peptide (CKSTHDRLC) downstream of the cDNA for the variable regions of anti- TNF-α antibody adalimumab in the context of a miniantibody (scFv-Hinge-CH2-CH3 domains). Immunofluorescence technique was used to initially assess the ability of fluorescent-MC13 to target only inflamed synovial tissue. The biodistribution and the efficacy of the treatment with MC13 were evaluated in a rat model of antigen-induced arthritis (AIA).

**Results:** In vitro studies have shown that adalimumab and MC13 maintain the ability to neutralize human TNF-α and bind to rat and mouse TNF-α. Based on these findings, we used a rat model of arthritis to evaluate their in vivo therapeutic effect. The ability of MC13 to selectively target inflamed synovial tissues was evaluated by immunofluorescence analysis. A rat model of antigen-induced mono-arthritis was used to analyse the in vivo distribution of MC13 labelled with the near-infrared probe cyanine 5.5 using time-domain near infrared optical imaging. The results showed that the labeled-MC13 preferentially localized in the inflamed synovium with a peak at 4 days and persisted for more than 3 weeks, while failing to bind to healthy synovial tissue.

MC13 was able to prevent inflammation in the rat model of antigen-induced arthritis, as evaluated by the measurement of joint swelling, the count of PMN number and the level of IL6 in synovial tissue and the histologic assessment of tissue damage.

Intravenous injection of MC13 prevents acute inflammation in all the animals while the same dose of adalimumab was almost ineffective. MC13, administred i.v. 4 days after arthritis induction, was also able to cure joints analysed 7 days after the induction of inflammation.

**Conclusions:** Our results demonstrated that MC13 can selectively target inflamed and abrogate the inflammation in a model of antigen-induced arthritis with no sign of toxicity.

## FRI0031 TARGETING SIALIC ACID-MODIFIED RECEPTORS AS A POTENTIAL THERAPY FOR OSTEOARTHRITIS

P. Carpintero Fernández[1], R. Gago-Fuentes[1], A. Lacetera[2], M. Varela-Eirin[1], B. Acea[1], E. Fonseca[1], S. Martin-Santamaria[2], M.D. Mayán[1]. *[1]CellCOM Research Group, INIBIC, Hospital Universitario A Coruña (CHUAC-XXIAC) SERGAS, University of A Coruña. Xubias de Arriba 84, A Coruña; [2]Chemical and Physical Biology, Centro de Investigaciones Biológicas, CIB-CSIC. C/ Ramiro de Maeztu, 9, Madrid, Spain*

**Background:** Osteoarthritis (OA) is one of the most common diseases worldwide. Its prevalence and severity increase with age, but treatments only provide symptomatic relief. The articular cartilage consists of a collagen-proteoglycan matrix containing highly glycosylated proteins synthesized by chondrocytes. A notable shift from glycoproteins containing a-2,6-linked sialic acids to those containing a-2,3-linked sialic acids has been associated with progressive cartilage degeneration and with the onset of disorders such as rheumatoid arthritis (RA) and OA[1–3]. However, the pathophysiology of a-2,3-sialylation in cartilage has not yet been elucidated.
**Objectives:** Lectins recognize specific terminal aspects of glycan chains and the *Maackia amurensis* seed lectin (MASL) is a plant lectin that can bind to sialylated glycoproteins. Here, we study the effects of the lectin MASL on chondrocytes and cartilage integrity from healthy donors, OA patients and animal models of arthritis.
**Methods:** Cell viability, cell adhesion and growth were performed using commercial kits. Reactive oxygen species (ROS) levels were measured by DCFH-DA and by Flow Cytometry. Gene expression was analyzed by quantitative real-time PCR. Staining methods were used to study cartilage integrity. Oligomycin and LPS were used to induce cartilage degeneration *in vitro* and *in vivo* (human cartilage and mouse model, *Mus musculus* BALC/c).
**Results:** he expression of the a-2,3-sialylated transmembrane mucin receptor podoplanin (PDPN) is induced in cartilage from osteoarthritic patients. Co-immunofluorescence technique showed that MASL can be used to target PDPN. Nanomolar concentrations of MASL protected primary chondrocytes and prevented cartilage breakdown in human tissue from OA patients *ex vivo* and in an animal model of OA initiated by ROS, inflammatory cytokines, and metalloproteinases. Besides, the increased levels of the $\alpha$-2,3 sialyltransferase isoforms and the corresponding increase in the levels of a-2,3-sialylated glycoproteins in osteoarthritic chondrocytes may shed mechanistic light on the pathophysiology of OA. These findings based on various experimental models of arthritis reveal that specific lectins that target a-2,3-sialylated transmembrane receptors, such as PDPN on chondrocytes, may effectively inhibit cartilage destruction in the face of various arthritic insults. We also provide a three-dimensional molecular model for such an interaction.
**Conclusions:** The ability of MASL to target a-2,3-sialylated glycoproteins, such as PDPN, and to protect chondrocytes from insults leading to cartilage degradation might offer further possibilities for therapeutic interventions and novel arthritis treatments that may include the regulation of sialylation during acute disease stages.

## FRI0032 RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS ADHESION TO ENDOTHELIAL CELLS IS CHANGED BY STIMULATION WITH ADIPOKINES

R. Hasseli[1], K.W. Frommer[1], M. Schönburg[2], S. Rehart[3], U. Müller-Ladner[1], E. Neumann[1]. *[1]Department of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff-Clinic Bad Nauheim, Giessen; [2]Department of Cardiac Surgery, Kerckhoff-Clinic, Bad Nauheim; [3]Department of Orthopedics and Trauma, Markus Hospital, Frankfurt, Germany*

**Background:** Rheumatoid arthritis (RA) is a chronic polyarticular inflammatory disease, in which RA synovial fibroblasts (SF) play a key role. These cells are able to migrate long distances *in vivo* via the vasculature as previously shown in our SCID mouse migration model. Adipose tissue, as an endocrine organ, plays an important role in inflammatory processes. Some of its effects may be mediated by adipokines, which can also act as immunomodulatory factors. In RA, these adipokines have been shown to affect RASF and endothelial cells (EC). The interaction between RASF and EC may be a crucial process in the migration of RASF through the vasculature.
**Objectives:** To investigate whether adipokines affect the adhesion of RASF to EC under flow conditions simulating the *in vivo* situation in blood vessels and to identify relevant adhesion molecules whose expression is altered by adipokines, glucocorticoids and methotrexate.
**Methods:** RASF adhesion to EC was studied under flow conditions (flow rates: 18.4/30.5/60.5 ml/h) in a dynamic adhesion assay as flow conditions are required for selectins to be obtain their active conformation. The expression of selected adhesion molecules from RASF and EC was analyzed by real-time PCR. For this purpose, primary RASF and EC were stimulated with adiponectin (10 $\mu$g/ml), visfatin (100 ng/ml) and resistin (20 ng/ml), and "therapeutically" with methotrexate (1.5 $\mu$M) and the glucocorticoids prednisolone (1 $\mu$M) and dexamethasone (1 $\mu$M).
**Results:** Using the dynamic adhesion assay to simulate the blood flow *in vivo*, RASF showed an increased adhesion to EC after stimulation with visfatin (+156%/+87%/+89%) and TNF-$\alpha$ (+61%/+18%+19%). Dexamethasone (-9%/-39%/-53%) and prednisolone (-31%/-64%/-53%) on the other hand decreased the adhesion of RASF to EC. The expression of integrin $\alpha$2 was upregulated after stimulation with resistin (2.8-fold; n=7) and TNF-$\alpha$ (13-fold; n=6). Only TNF-$\alpha$ increased the expression of ICAM-1 (40-fold; n=5) in RASF, while both visfatin (2.9-fold; n=10) and TNF-$\alpha$ (59-fold; n=9) increased the expression of VCAM-1 in RASF. In EC, TNF-$\alpha$ upregulated the expression of ICAM-1 (47-fold; n=9), while adiponectin decreased it (-2.9-fold; n=5). The expression of VCAM-1 was slightly decreased after stimulation with adiponectin (-1.3-fold; n=5) in EC, whereas TNF-$\alpha$ led to a strong upregulation (235-fold; n=7). P- Selectin was down-regulated after stimulation with TNF-$\alpha$ (-8.6-fold; n=7) in EC.
**Conclusions:** Under dynamic flow conditions, adipokines increase the adhesion of RASF to EC. Adhesion of RASF to EC most likely plays a role in the migration of RASF *in vivo*. The influence of adipokines on adhesion molecules and their strengthening effect on adhesion of RASF to EC could therefore enhance the migration of RASF and thus the spreading of RA to different joints. Glucocorticoids showed the opposite effect, which could explain some of the benefits observed in patients. The expression of adhesion molecules is influenced by adipokines. Yet, how they influence these expressions appears to differ between RASF and EC.
**Disclosure of Interest:** None declared

## FRI0033 TNFALPHA PRODUCTION IN CULTURED HUMAN MACROPHAGES AFTER CTLA4-IG (ABATACEPT) IN VITRO TREATMENT

R. Brizzolara, P. Montagna, S. Soldano, A.C. Trombetta, S. Paolino, C. Pizzorni, A. Sulli, B. Ruaro, D. Camellino, V. Tomatis, M. Cutolo. *Research Laboratory and Academic Division of Clinical Rheumatology, DIMI, University of Genova, Genova, Italy*

**Background:** Proinflammatory cytokines and particularly tumor necrosis factor alpha (TNFalpha) are abundantly expressed in rheumatoid arthritis (RA) synovitis. Our recent data showed that CTLA4-Ig (abatacept), by interacting with the CD86 molecule on RA synovial macrophages, may induce reverse signaling with anti-inflammatory effects, involving NFkB intracellular pathway [1–4].
**Objectives:** We investigated the expression and production of TNFalpha on cultured human activated macrophages before and after *in vitro* CTLA4-Ig treatment.
**Methods:** THP-1 human monocytes, differentiated with phorbol myristate acetate (0.05 $\mu$g/ml for 24 hrs) into activated macrophages, were cultured in multiwells bottoms or flexiperm slides for 3, 24 and 48 hrs, in the absence (cells untreated) and in the presence of CTLA4-Ig (500 $\mu$g/ml). TNFalpha gene expression was investigated by quantitative real time polymerase chain reaction (qRTPCR), after 3 and 24 hrs from CTLA4-Ig treatment. Intracytoplasmatic TNFalpha protein expression was investigated by immunocytochemistry (ICC) analysis after 24 and 48 hrs from treatment. Extracellular TNFalpha production was evaluated in the culture surnatants, by immunoassay (ELISA) analysis, after 24 hrs from treatment. Experiments were done in triplicate.
**Results:** Interestingly, at gene level, qRTPCR showed already after 3 hrs (and 24 hrs) from CTLA4-Ig treatment a significant downregulation of TNFalpha gene expression ($p<0.05$ for both 3 and 24 hrs), compared to the untreated cells. ICC analysis showed that TNFalpha production resulted decreased (not significant) both after 24 hrs and 48 hrs from CTLA4-Ig (500 mg/ml) treatment, compared to the untreated cells. Extracellular evaluation by ELISA at 24 hrs, also demonstrated a reduction (not significant) of TNFalpha levels, compared to the untreated condition.
**Conclusions:** In cultured activated macrophages TNFalpha production was significantly reduced by CTLA4-Ig *in vitro* treatment at gene level, already after 3 hrs and still evident at 24 hrs. Regarding the protein synthesis, as expected, a trend for their reduction was observed on longer time (24–48 hrs).

## FRI0034 RAGE ACTIVITY INFLUENCES CO-DEVELOPMENT OF JOINT AND VASCULAR DISEASE IN RA

S. Yu[1], C.-K. Wong[2], E.K. Li[3], L.-S. Tam[3]. *[1]Rheumatology, The Second Affiliated Hospital of Guangzhou Medical University, Guangzhou; [2]Chemical Pathology; [3]Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, China*

**Background:** RAGE is expressed by many cells in blood and joints of RA and interacts with a variety of pro-inflammatory ligands, especially HMGB1 that are enriched in inflamed joint. The RAGE-ligand interaction leads to a sustained inflammatory response. Soluble RAGE (sRAGE) lacks the transmembrane and cytoplasmic domain of the cell surface full-length RAGE (flRAGE) and function as a decoy for RAGE ligand. Relatively little is known about factors that regulate sRAGE levels in human subjects and whether circulating levels reflect tissue RAGE expression and activity is unclear. The relationship between the up-regulation of flRAGE/HMGB1 and the level of "protective" sRAGE levels in RA is of obvious clinical interest.
**Objectives:** To elucidate the balance between the expression of flRAGE on peripheral blood monocyte and dendritic cell (DC), and the plasma concentration of sRAGE and HMGB1 in patients with active RA compare to controls; To ascertain whether flRAGE expression profiles, plasma sRAGE and HMGB1 level correlated with disease activity or inflammatory markers in RA patients.
**Methods:** 40 consecutive patients attending the rheumatology clinic at Prince of Wales Hospital, who fulfilled the 2010 ACR/RULAR classification criteria with active RA (28 joint disease activity score 28–4 [CRP] (DAS28)>3.2) and 40 age- and sex-matched healthy volunteers were recruited for this cross-sectional study. The expression profile of cellular transmembrane RAGE on peripheral blood monocyte ($ILT3^+CD123^-$), total DC ($ILT3^+CD14^-CD16^-$), myeloid DC ($ILT3^+CD14^-CD16^-CD123^-$) and plasmacytoid DC ($ILT3^+CD14^-CD16^-CD123^+$), plasma levels of HMGB1 and soluble RAGE in all RA patients and healthy controls were measured at baseline using flow cytometry and ELISA. In RA patients, associations with disease activity and severity variables were analyzed by simple and multiple linear regressions.
**Results:** Protein expression of flRAGE on peripheral blood monocytes ($ILT3^+CD123^-$), total DCs ($ILT3^+CD14^-CD16^-$) and myeloid DCs ($ILT3^+CD14^-CD16^-CD123^-$) were significant increased in RA patients with active disese compared with control subjects (all $p<0.01$) (no enough cells for flRAGE detection on plasmacytoid $ILT3^+CD14^-CD16^-CD123^+$DCs). Also, the flRAGE was more common in patients with cardiac affection. There was no statistically significant difference of the plasma level of HMGB1 from active RA patients as compared healthy controls ($p>0.05$). The plasma sRAGE level was significantly lower in patients compared to healthy controls ($p<0.001$), which correlated negatively with serum levels of CRP, ESR, DAS28 and high-density lipoprotein (HDL) (all $p<0.05$). Linear regrssion analysis detected CRP as significant predictors for sRAGE level.
**Conclusions:** Autoimmunity-mediated inflammation might induce aberrant expression and activation of flRAGE while decreasing the plasma level of sRAGE in RA patients, subsequently leading to the augmented inflammatory response. Moreover, membrance flRAGE and sRAGE were associated not just with RA inflammation and autoantibody protein, but also with classical vascular risk factors for end-organ damage. These data suggest that RAGE activity influences co-development of joint and vascular disease in RA patients.

## FRI0035 JOINT INFLAMMATION AND CARTILAGE DESTRUCTION IN EXPERIMENTAL OSTEOARTHRITIS IS NOT MEDIATED BY INTERLEUKIN-1

S. Van Dalen, A. Blom, L. Joosten, A. Sloetjes, M. Helsen, W. van den Berg, P. van Lent. *Experimental Reumatology, Radboud university medical center, Nijmegen, Netherlands*

**Background:** Osteoarthritis (OA) is a degenerative disease of the joint characterized by severe cartilage destruction, with a putative role for synovial macrophages. Up to 50% of the patients also show low grade joint inflammation reflected by a thickened synovial lining and elevated release of macrophage-derived mediators like interleukin-1 (IL-1) and S100A8/A9. The deteriorating role of S100A8/A9 in OA has been studied extensively (1), but the contribution of IL-1 to OA pathology is still unclear. IL-1 mediates cartilage destruction by degrading existing proteoglycans through stimulating degradative enzyme production, and by inhibiting new formation of proteoglycans. However, treatment of OA patients with IL-1 inhibitors has so far been disappointing.
**Objectives:** To investigate the role of IL-1$\alpha/\beta$ in synovitis and cartilage destruction during experimental collagenase-induced OA (CiOA).
**Methods:** Experimental OA was induced by intra-articular injection of collagenase into WT and IL-1$\alpha\beta^{-/-}$ mice. At day 7 and 42 after CiOA induction, total knee joints were stained with haematoxylin/eosin (H&E) to score synovial activation (arbitrary score from 0–3). Cartilage destruction was determined in knee sections stained with safranin O/fast green using a modified Pritzker score. Gene expression in inflamed synovium was analyzed using qPCR with primers for several cytokines. Serum protein levels of inflammatory mediators were measured with Luminex.
**Results:** At early stage (day 7) of CiOA, gene expression of IL-1 within inflamed synovium of knee joints was elevated 65 times compared to synovium of naïve control knees. However in later stages (day 21 and 42), IL-1 expression levels were reduced to basal levels. This is in contrast to pro-inflammatory mediators like S100A8 and S100A9 which remained elevated at day 21 and 42 (30–35-fold and 66–69-fold, respectively). Histological examination of knee joints showed a moderate synovitis at day 7 which waned thereafter but was still significant at day 21 and 42.
Remarkably, synovial inflammation at day 7 in IL-1$\alpha\beta^{-/-}$ mice was not different from WT controls (2.89±0.15 vs. 2.71±0.44), suggesting that IL-1 does not aggravate synovitis. Absence of IL-1$\alpha/\beta$ had no effect on the synovial gene expression levels of pro-inflammatory factors KC, S100A8 and S100A9. IL-6 mRNA levels, however, were significantly decreased in the synovium of IL-1$\alpha\beta^{-/-}$ mice (3-fold reduction). The lack of IL-1$\alpha/\beta$ also did not affect gene expression of anti-inflammatory cytokines IL-10, TGF$\beta$ and iNOS. Moreover, serum protein levels of KC, IL-6, MCP-1, IL-10 and S100A8/A9 at day 7 of CiOA in IL-1$\alpha\beta^{-/-}$ mice were not different compared to WT mice. Cartilage destruction in CiOA clearly aggravated over time, but we found no significant differences between IL-1$\alpha\beta^{-/-}$ mice and WT controls. No difference in cartilage damage was measured at day 42 of CiOA when compared to WT (medial femur (95.3±42.0 vs. 65.5±54.5), medial tibia (84.5±36.6 vs. 55.1±38.9), lateral femur (69.6±43.9 vs. 60.8±35.8), and lateral tibia (49.8±26.3 vs. 55.4±17.1)).
**Conclusions:** IL-1 does not affect synovial inflammation and cartilage destruction during collagenase-induced osteoarthritis, implicating that other macrophage-derived mediators such as S100A8/A9 are responsible for the joint damage.

## FRI0036 META-IMMUNOLOGICAL PROFILING OF PATIENTS WITH BEHÇET'S DISEASE REVEALS NOVEL BIOMARKERS OF DISEASE ACTIVITY, PROGRESSION AND RESPONSE TO THERAPY

V. Pucino[1,2], A. Vitale[3], O.M. Lucherini[3], R. Talarico[4], G. Marone[1], M. Galeazzi[3], G. Matarese[5], L. Cantarini[3]. *[1]Dipartimento di Scienze Mediche Traslazionali, Università di Napoli "Federico II", Naples, Italy; [2]William Harvey Research Institute, Barts and The London School of Medicine, Queen Mary University of London, London, United Kingdom; [3]Research Center of Systemic Autoinflammatory Diseases and Behcet's Disease Clinic, Department of Medical Sciences, Surgery and Neurosciences, Università degli Studi di Siena, Siena; [4]Unità di Reumatologia, Dipartimento di Medicina Clinica e Sperimentale, Università degli Studi di Pisa, Pisa; [5]Dipartimento di Medicina Molecolare e Biotecnologie Mediche, Università degli Studi di Napoli "Federico II", Naples, Italy*

**Background:** Behçet's disease (BD) is a rare and poorly understood condition characterised by systemic inflammation. Current biomarkers are still largely insensitive and unable to predict disease progression and response to treatment in BD patients.
**Objectives:** The specific aims of this study were i) to explore serum levels of soluble CD40L (sCD40L), soluble intracellular-adhesion-molecule (sICAM-1), monocyte-chemoattractant-protein-1 (MCP-1), myeloperoxidase (MPO), leptin, resistin, osteoprotegerin (OPG), soluble-type 1 tumour-necrosis-factor-receptor (sTNFR), interleukin-6 (IL-6) and serum-amyloid-A (SAA); ii) to evaluate potential correlations between the putative circulating biomarkers with the demographic profile, disease activity, organ involvement, genetical background, and different therapeutic regimes.
**Methods:** 57 serum samples were collected from 27 BD patients and 35 healthy controls (HC) after written consent. Demographic and clinical data are summarized in Table 1. Adipocytokines were analyzed using the bead-based-analyte-detection-system. Data were acquired by flow-cytometry. SAA serum concentration was determined with a enzyme linked-immunosorbent assay (ELISA). We used ANOVA test to identify statistical differences. $P<0.05$ was considered statistically significant.
**Results:** BD patients showed higher levels of circulating sTNFR (p=0.008), leptin (p=0.0011), sCD40L (<0.0001), and IL-6 (p=0.0154) than HC while no difference was found in MCP-1, MPO, sICAM, and resistin serum levels. Patients HLA-B51- had higher sTNFR and sICAM-1 serum levels than HC (p=0.0034, p=0.0037, respectively), while sICAM levels were significantly higher in patients HLA-B51- than in patients HLAB51+ (p=0.0010) as well as leptin was significantly higher in both HLA-B51+ and HLA-B51- BD patients than in HC (p=0.0183, p=0.0303, respectively). Patients treated with biologic-agents showed significantly higher sTNFR and leptin serum levels when compared to DMARDs-treated-patients (p=0.0246,p=0.0023, respectively). Moreover, sTNFR was found higher in patients with inactive disease and in patients over 40 years than HC (p=0.0104, p=0.0329, respectively).
**Conclusions:** The identification of a specific meta-immunological profile associated with disease status and response to therapy may contribute to our

Table 1. Demographic and clinical data of BD patients

## FRI0037 CHONDROITIN SULPHATE INHIBITION OF NF-κB ACTIVITY: ATTENTUATION OF HYALURONAN FRAGMENT INDUCED INFLAMMATORY RESPONSE IN MACROPHAGES BY CHONDROITIN SULPHATE IS MEDIATED BY REDUCTION IN NF-κB ACTIVITY

T. Stabler[1], E. Montell[2], J. Vergés[2], V.B. Kraus[1]. *[1]Duke Molecular Physiology Institute, Durham, United States; [2]Bioibérica, Barcelona, Spain*

**Background:** NF-κB activation serves as a master regulatory switch for an inflammatory response in macrophages. Chondroitin sulphate (CS), a natural glycosaminoglycan of the cartilage extracellular matrix, has been shown to have clinical benefit in osteoarthritis (OA) producing anti-inflammatory and positive effects on the joint (1). We have previously shown that hyaluronan (HA) fragments induce an inflammatory response, in the form of IL-1β release, in macrophages that have been primed with the Toll-Like Receptor 4 (TLR4) agonist, lipopolysaccharide (LPS) and that CS can attenuate this response. We further demonstrated that this attenuation by CS occurred upstream of the inflammasome (2).

**Objectives:** Determine if this inhibition is acting at the level of NF-κB activation.

**Methods:** The THP1-Lucia NF-κB reporter monocyte cell line (InvivoGen) was grown as recommended. $10^5$ cells/well were plated along with varying concentrations of CS (0, 10–200 μg/ml) and either 1 μg/ml LPS or $10^7$ heat killed listeria monocytogenes (HKLM). In a 2nd experiment, cells were set up similarly but with the addition of 10 μg/ml ultralow molecular weight (ULMW) HA. In a 3rd experiment cells were set up as above with ULMW HA but substituting a caspase-1 inhibitor (EMD Millipore,10 μM) for CS. After 24 hours, media were tested for the NF-κB activity using QUANTI-Luc reagent (Invivogen) and for cell viability using PrestoBlue reagent (Invitrogen).

After normalizing for cell viability, all results were expressed as fold change from the media only control. One-way ANOVA with Dunnett's post-hoc test and inhibition dose response curves were performed.

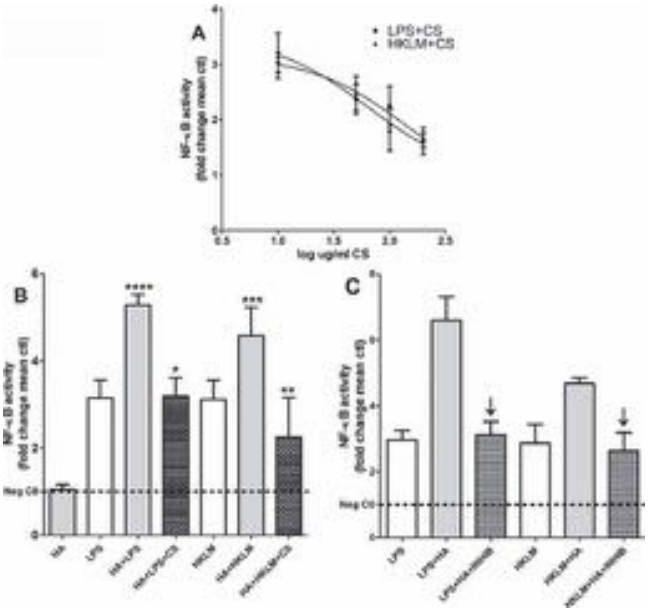

Figure 1

**Results:** NF-κB activity increased significantly ($p<0.0001$) in THP1-Lucia NF-κB reporter monocytes treated with either TLR4 or TLR2 agonists (i.e. 1 μg/ml of LPS or $10^7$ HKLM bacteria). CS (50–200 μg/ml) produced a dose dependent (p=0.02 to p=0.0005) reduction in NF-κB activity in LPS treated cells. In HKLM treated cells, CS (100–200 μg/ml) also produced a similar dose dependent (p=0.004 to p=0.01) reduction in NF-κB activity. Dose response curves indicated a 50% inhibition concentration (IC50) of 146 μg/ml CS for LPS (●) stimulated cells and 64 μg/ml for HKLM (▲) stimulated cells (Fig. 1A). HA fragments alone produced no increase in NF-κB activity but were found to have an additive effect through either the TLR4 or TLR2 pathway (i.e. LPS or HKLM). The combination of TLR activation and HA produced greater NF-κB activity than either LPS or HKLM alone ($p<0.0001$**** and p=0.0017***, Fig. 1A). CS (200 μg/ml) was still an effective inhibitor under these conditions (p=0.045* and p=0.02**, Fig. 1B). Inhibiting caspase-1 activity, and thus blocking IL-1β production, completely blocked the additive effect of HA fragments (↓, Fig. 1C). Caspase inhibition had no effect on LPS or HKLM alone.

**Conclusions:** The inflammatory response induced by HA fragments in the presence of TLR2 or TLR4 activation can be attenuated by CS at physiologically achievable concentrations via inhibition of NF-κB activation. HA's synergistic effect on NF-κB is due to positive feedback through inflammasome mediated active IL-1β production. These data provide a plausible explanation for the clinical effects of CS in OA.

## FRI0038 ANTI-HINGE ANTIBODIES RECOGNIZE IGG SUBCLASS- AND PROTEASE-RESTRICTED HINGE NEO-EPITOPES

W. Falkenburg[1,2], D. van Schaardenburg[1,3], P. Ooijevaar-de Heer[2], M. Tsang-A-Sjoe[4], I. Bultink[4], A. Voskuyl[4], A. Bentlage[5], G. Vidarsson[5], G. Wolbink[1], T. Rispens[2]. *[1]Rheumatology, Amsterdam Rheumatology and immunology Center, Reade; [2]Immunopathology, Sanquin Research; [3]Rheumatology, Amsterdam Rheumatology and immunology Center, Academic Medical Center; [4]Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical Center; [5]Experimental Immunohematology, Sanquin Research, Amsterdam, Netherlands*

**Background:** Anti-hinge antibodies (AHAs), autoantibodies that target neo-epitopes exposed in the hinge of IgG molecules after cleavage by proteases, can be found in healthy individuals but more frequently and at higher levels in rheumatoid arthritis (RA) patients. Recently, our group reported that AHAs in RA patients specifically target pepsin-cleaved hinge of IgG4.

**Objectives:** Determine the presence of AHAs and their specificity for protease- and IgG subclass-restricted neo-epitopes in healthy donors (HDs) and patients with RA or systemic lupus erythematosus (SLE).

**Methods:** Presence of AHA-reactivity and specificity of AHAs for protease- and IgG subclass-restricted neo-epitopes was determined with newly developed enzyme-linked immunosorbent assays (ELISAs) that measure AHA-reactivity against the hinge of F(ab')2-fragments generated by cleaving the four IgG subclasses with pepsin or IdeS, an IgG-degrading enzyme of Streptococcus pyogenes (Figure 1). Inhibition experiments were performed to investigate cross-reactivity and results were confirmed using a novel Surface Plasmon Resonance imaging (SPRi) array.

**Results:** Reactivity against at least one of eight F(ab')2-targets was found in 68% (51/75) of HDs, 65% (47/72) of SLE patients, and 83% (59/73) of RA patients. Individual AHA responses targeted protease-restricted neo-epitopes. Reactivity against IdeS-generated F(ab')2-targets was found more frequently in

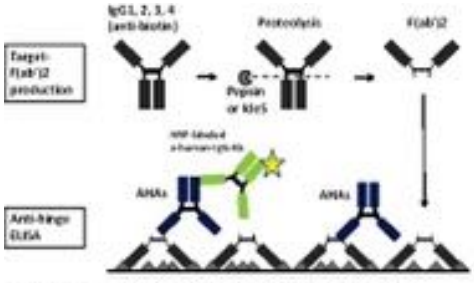

Figure 1: Set-up of newly developed anti-hinge ELISAs

F(ab')2s specific for biotin were produced by cleaving recombinant anti-biotin IgG1-, IgG2-, IgG3- and IgG4 molecules with the proteases pepsin or IdeS. The anti-biotin F(ab')2s were then used to opsonize ELISA plates coated with biotinylated human serum albumin (HSA, grey triangles). AHAs binding to the exposed hinge of the F(ab')2s were detected with horseradish peroxidase (HRP)-labeled anti-human-IgG detection antibodies.

all three groups, but reactivity against pepsin-generated F(ab')2-targets better discriminated between RA patients and HDs or SLE patients, with significantly higher levels of AHAs against pepsin-cleaved IgG1 and IgG3 in RA compared to SLE and HDs respectively. The most discriminatory AHA-reactivity in RA was against pepsin-cleaved IgG4, with at least 5x more positive sera compared to HDs and SLE and significantly higher levels ($P<0.0001$). Cross-reactivity for different IgG subclasses was only observed for subclasses having homologous F(ab')2 C-termini (IgG1, IgG3, IgG4).

**Conclusions:** Anti-hinge antibodies specifically recognize IgG subclass- and protease-restricted hinge neo-epitopes, possibly generated under (chronic) inflammatory conditions. The protease-restricted specificity of AHAs suggests that different AHA responses have developed under distinct inflammatory or infectious conditions and may be markers of -and participants in such conditions. In the proteolytic environment of the inflamed joint AHAs may contribute to immune complex formation, promoting further tissue destruction and inflammation.

## FRI0039 SYNOVIAL MACROPHAGES PROMOTE TGF-BETA SIGNALING BUT PROTECT AGAINST INFLUX OF S100A8/S100A9-PRODUCING CELLS FOLLOWING INTRA-ARTICULAR INJECTIONS OF OXIDIZED LOW-DENSITY LIPOPROTEINS

W. De Munter[1], E.J. Geven[1], A.B. Blom[1], B. Walgreen[1], M.M. Helsen[1], L.A. Joosten[2], J. Roth[3], T. Vogl[3], F.A. van de Loo[1], M.I. Koenders[1], W.B. van den Berg[1], P.M. van der Kraan[1], P.L. van Lent[1]. *[1]Experimental Rheumatology; [2]Department of Medicine, Radboud university medical center, Nijmegen, Netherlands; [3]Institute of Immunology, University of Muenster, Muenster, Germany*

**Background:** In previous studies we found that synovial macrophages regulate joint pathology during experimental osteoarthritis (OA) and, more recently, we found that high systemic levels of low-density lipoproteins (LDL) aggravate joint pathology during experimental OA with synovitis. LDL in inflamed synovium is oxidized and taken-up by macrophages, leading to an activated macrophage phenotype.

**Objectives:** In this study, we investigate whether injection of oxidized LDL directly into a murine knee joint induces joint pathology and elucidate the role of synovial macrophages in that process.

**Methods:** Synovium was obtained from end-stage OA patients and stained for apolipoprotein B (APOB). Murine knee joints were injected five consecutive days with oxLDL, LDL, or an equal volume of vehicle (PBS). This procedure was repeated in mice depleted of synovial macrophages by intra-articular injection of clodronate liposomes seven days prior to the consecutive injections. Joint pathology was investigated by immunohistochemistry and flow cytometry (FCM) analysis, and RNA expression and protein production by synovium were determined using RT-PCR and luminex, respectively. Aggrecanase activity was measured using NITEGE-staining and active TGF-β was measured using a functional CAGA-luciferase assay. Data are depicted as mean ± standard deviation.

**Results:** Synovial macrophages and fibroblasts of end-stage OA patients showed extensive accumulation of APOB, the main protein present in LDL and oxLDL. Multiple injections of oxLDL in murine knee joints significantly increased TGF-β activity in synovial wash-outs by 28% [from 16562 ± 2326 relative light units (RLU) to 21151 ± 3823 RLU; $P<0.05$], but did not induce catabolic or inflammatory processes. In contrast, repeated injections of oxLDL in macrophage-depleted knee joints led to a 3.1 fold increase of synovial thickening, compared with injection of PBS ($P<0.01$), while LDL injections did not alter synovial thickening. Protein and RNA levels of chemokines CCL2 and CCL3 were significantly upregulated in macrophage-depleted joints after oxLDL injections (6.7 fold and 4.6 fold, respectively; $P<0.01$). Furthermore, FCM-analysis revealed increased presence of monocytes (from 1422 ± 1105 to 3029 ± 1644 cells) and neutrophils (from 4014 ± 3511 to 12708 ± 7829 cells) in the synovium of macrophage-depleted joints after injection of oxLDL ($P<0.05$), which was confirmed by immunohistochemical staining. Also protein levels of S100A8/A9, markers for inflammation, were significantly increased in synovial wash-outs of oxLDL-injected joints compared with LDL (fold increase 5.6; $P<0.05$) or PBS (fold increase 8.3; $P<0.01$) injection, as was NITEGE expression (fold increase 1.92; $P<0.05$). Interestingly, no raise in active TGF-β was measured in these macrophage-depleted joints.

**Conclusions:** Synovial macrophages promote anabolic processes after intra-articular oxLDL injections. In absence of synovial macrophages, however, oxLDL induces production of pro-inflammatory mediators and aggrecanase activity, in combination with increased influx of monocytes and neutrophils.

## FRI0040 PROTEIN BIOMARKERS IMPROVES THE PREDICTION OF CLINICAL RESPONSE TO METHOTREXATE STEP-UP STRATEGY IN EARLY RA PATIENTS

X.M. Teitsma[1], J.W. Jacobs[1], P.M. Welsing[1], T.G. Woodworth[2], A. Pethö-Schramm[3], M.E. Borm[4], C. Bernasconi[3], J.M. van Laar[1], J.W. Bijlsma[1], F.P. Lafeber[1]. *[1]Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands; [2]Rheumatology, David Geffen School of Medicine, Los Angeles, United States; [3]Roche, Basel, Switzerland; [4]Roche, Woerden, Netherlands*

**Background:** International guidelines for treatment-to-target in rheumatoid arthritis (RA) recommend methotrexate (MTX) as first line therapy because of its favorable benefit/risk ratio and long-term safety. However, about 50% of patients fail to achieve remission and require other treatment. Identification and application of predictors of inadequate response to MTX may improve clinical outcome by enabling timely step-up treatment in those who need it.

**Objectives:** To evaluate the added predictive value of protein biomarkers compared to use of clinical variables alone, to identify early RA patients failing a MTX step-up strategy, including hydroxychloroquine (HCQ).

**Methods:** In the treat-to-target U-ACT-EARLY trial, 108 DMARD-naïve RA patients initiated MTX step-up therapy (10 mg to 30 mg or maximum tolerable dose) until remission (DAS28 $<2.6$ with SJC $\leq 4$) was achieved. If no remission after 20 weeks, HCQ was added, which after 12 weeks was replaced by tocilizumab (TCZ) if remission still was not achieved. Clinical assessments at baseline were analyzed and missing values were imputed using multiple imputations (n=20). Additionally, serum was collected before treatment and analyzed for 85 inflammatory proteins using Luminex® xMAP technology. Predictors for failing the MTX step-up strategy (MTX+HCQ) were selected using univariate preselection ($p\leq 0.15$) followed by multivariate backward selection ($p\leq 0.10$). A model including only clinical predictors was developed and subsequently, a second model in which protein biomarkers was added. The Area Under the Receiver Operator Curve (AUC-ROC), Net Reclassification Index (NRI, quantifies the improvement in prediction between two models) and Likelihood-ratio (LLR) test were used to assess both models.

**Results:** Within 1 year, 56 (52%) of the 108 patients failed the strategy for various reasons: adverse events (n=4), added TCZ according to treatment protocol (n=42), withdrawal from study because of inefficacy (n=10). Multiple logistic regression identified baseline DAS28, current smoking and alcohol consumption as clinical predictors (*model 1*, AUC-ROC 0.75, 95%>CI 0.66–0.84) and in addition MCP1, IL6, IL33, sCD14 and PD1 (*model 2*, AUC-ROC 0.87, 95%>CI 0.80–0.94) as significant protein biomarkers (Table 1). The LLR test showed a better fit of *model 2* (59.83, $p<0.001$). When using a risk of non-response >80% as cut off, *model 1* correctly predicted 24/51 patients not failing the strategy and *model 2* predicted 15 (29% improvement) extra patients not failing the strategy (Table 2). In those failing the strategy, 50/56 patients were correctly predicted by *model 1* and 4 (-7%) patients less was correctly predicted by *model 2*.

Table 1: Factors predicting the need of other treatment within the first year after starting a MTX step-up strategy.

| | OR (95% CI) | P value |
|---|---|---|
| MODEL1 | | |
| DAS28 | 2.1 (1.4 – 3.2) | 0.001 |
| Current smoking, yes | 3.0 (1.1 – 8.0) | 0.027 |
| Alcohol consumption, yes | 0.4 (0.1 – 0.9) | 0.021 |
| MODEL2 | | |
| DAS28 | 1.6 (1.0 – 2.7) | 0.067 |
| Current smoking, yes | 3.9 (1.1 – 13) | 0.033 |
| Alcohol consumption, yes | 0.2 (0.1 – 0.6) | 0.005 |
| MCP1 | 1.0 (1.0 – 1.0) | 0.013 |
| IL6* | 1.9 (1.1 – 3.1) | 0.017 |
| IL33* | 2.2 (1.2 – 3.7) | 0.010 |
| sCD14* | 9.3 (0.8 – 106) | 0.073 |
| PD1* | 0.5 (0.2 – 1.01) | 0.051 |

OR: odds ratio, CI: confidence interval, DAS28: disease activity score in 28 joints, MCP: monocyte chemoattractant protein, IL: interleukin, sCD: soluble cluster of differentiation, PD: programmed death-ligand, * log transformed data.

Table 2: Classification of MODEL1 and MODEL2 of patients failing the MTX step-up strategy versus those not failing the strategy.

| | | MODEL2 NF | MODEL2 F | trial result |
|---|---|---|---|---|
| MODEL1 | NF | 23 | 1 | not failing n=51 |
| | F | 16 | 11 | |
| | NF | 3 | 3 | failing n=56 |
| | F | 7 | 43 | |

NF: number of patients classified as not failing the strategy, F: numbers of patients classified as failing the strategy, in grey cells numbers with correct reclassification by model 2 and in framed cells numbers with incorrect reclassification by model 2 when compared to model 1.

**Conclusions:** Adding protein biomarkers to clinical predictors increases the predictive accuracy of identifying patients at baseline who will need other treatment after initiating a MTX step-up strategy. These findings could contribute too more personalized treatment in early RA patients to optimize long-term outcomes.

FRI0041 **THE JAK INHIBITOR (TOFACITINIB) INHIBITS TNF-INDUCED GLIOSTATIN/THYMIDINE PHOSPHORYLASE EXPRESSION IN HUMAN FIBROBLAST-LIKE SYNOVIOCYTES**

Y. Kawaguchi[1], Y. Waguri-Nagaya[2], K. Ikuta[1], N. Tatematsu[1], M. Kobayashi[1], H. Goto[1], M. Nozaki[1], K. Asai[3], T. Otsuka[1]. *[1]Orthpaedic Surgery; [2]Joint Surgery for Rhuematic Diseases; [3]Molecular Neurobiology, Nagoya City University Graduate School of Medical Sciences, Nagoya-City, Japan*

**Background:** The JAK/STAT signaling pathways mediate the effects of many cytokines and growth factors related rheumatoid arthritis (RA). Tofacitinib is a novel oral JAK inhibitor and it has demonstrated high efficacy in RA, even in non-responder to anti-TNF treatment. Gliostatin/thymidine phosphorylase (GLS/TP) is known to have angiogenic and arthritogenic activities. GLS/TP was expressed in inflamed synovial tissues of patients with RA. In cultured fibroblast-like synoviocytes (FLSs), GLS/TP expression was found to be up-regulated by inflammatory cytokines, such as IL-1β, TNFα. GLS acted as a cytokine in FLSs, augmenting its own synthesis, and also induced the extracellular secretion of matrix metalloproteinase (MMP)-1, and MMP-3. Therefore the suppression of GLS production might be an effective therapy in RA. Tofacitinib inhibits the function of T cells, however the mechanism of the action of tofacitinib had not been determined in fibroblast- like synoviocytes.
**Objectives:** The purpose of this study was to investigate the effect of tofacitinib on GLS production in FLSs derived from patients with RA (RAFLSs).
**Methods:** RAFLSs were cultured and stimulated by tumor necrosis factor (TNF)-α with or without treatment of tofacitinib. The expression levels of GLS were determined using reverse transcription-polymerase chain reaction (RT-PCR), enzyme immunoassay and immunocytochemistry.
**Results:** In cultured RAFLSs, GLS mRNA and protein levels were significantly induced by stimulation with TNFα alone and these GLS/TP inductions were significantly suppressed by treatment of tofacitinib in a dose-dependent manner.
**Conclusions:** Our data demonstrated that JAK/STAT activation play a pivotal role in TNF mediated GLS up-regulation in RAFLSs. Suppression of GLS production in inflamed synovia has been suggested as one of the anti-inflammatory effects of tofacitinib.

## Rheumatoid arthritis - etiology, pathogenesis and animal models

FRI0042 **ALTERED PROFILES OF HISTONE LYSINE METHYLATION AFFECT MMP GENE TRANSCRIPTION IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS**

Y. Araki[1,2], T.T. Wada[1,2], Y. Aizaki[1,2], H. Kajiyama[1], K. Yokota[1], K. Sato[1], Y.F. Asanuma[1], Y.-T. Kim[3], H. Oda[3], T. Mimura[1,2]. *[1]Department of Rheumatology and Applied Immunology, Faculty of Medicine, Saitama Medical University; [2]Project Research Lboratory, Research Center for Genomic Medicine, Saitama Medical University; [3]Department of Orthopaedic Surgery, Faculty of Medicine, Saitama Medical University, Saitama, Japan*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that causes progressive joint destruction. A line of evidence suggests that synovial fibroblasts (SFs) play an important role in the pathogenesis of RA. RASFs produce matrix metalloproteinases (MMPs) that degrade articular cartilage. Although interleukin-6 (IL-6) is an inflammatory cytokine and is proved to be involved in the pathogenesis of RA, it is unknown whether IL-6 affects MMPs gene transcription in RASFs. Furthermore, recent advances have revealed that epigenetic mechanisms, including histone modifications, are considered to be important regulators in gene transcription. We hypothesized that epigenetic dysregulation might induce RASF activation.
**Objectives:** The aim of this study is to examine whether IL-6 regulates MMPs expression in RASFs and whether histone modifications are associated with the MMPs gene activation in RASFs.
**Methods:** We compared MMPs gene expression by quantitative RT-PCR and histone methylation in the MMP promoters by chromatin immunoprecipitation (ChIP) assay after stimulation with IL-6 and/or soluble IL-6 receptor α (sIL-6Rα) in RASFs and control, osteoarthritis (OA) SFs. Chromatin structures in the MMP promoters were evaluated with micrococcal nuclease (MNase) assay in RASFs and OASFs. We investigated the change in the MMPs gene expression after silencing of WDR5 that is required for generating H3K4me3, an active histone marker. IL-6 signal induces Signal Transducer and Activator of Transcription 3 (STAT3) activation. To elucidate the mechanisms of IL-6-induced MMPs gene activation in RASFs, we investigated cell surface expression of the IL-6 receptor (gp130 and membrane-bound IL-6Rα) by flow cytometry, phospho-STAT3 (p-STAT3) expression by immunoblotting, and binding of STAT3 to the MMPs 1, 3, 9, and 13 promoters after IL-6 stimulation by ChIP assay in RASFs and OASFs.
**Results:** MMPs 1, 3, 9 and 13 genes were actively transcribed in RASFs. The histone methylation profiles (H3K4me3 and H3K27me3) and the result of MNase assay indicated that chromatin structures were open in the MMPs 1, 3, 9 and 13 promoters in RASFs. The depletion of WDR5 reduced the levels of H3K4me3 as well as the MMPs 1, 3, 9 and 13 gene expression. Interestingly, IL-6 and sIL-6Rα significantly increased the expression of MMPs 1, 3 and 13, but not MMP-9, in RASFs. Although the expression levels of gp130 as well as membrane-bound IL-6Rα were comparable and STAT3 was similarly phosphorylated after IL-6 stimulation in RASFs and OASFs, STAT3 bound to the MMPs 1, 3 and 13 promoters, but not the MMP-9 promoter, after stimulation with IL-6 and sIL-6Rα only in RASFs. It was suggested that binding of STAT3 to the promoters resulted in MMPs 1, 3 and 13 gene activation after IL-6 stimulation in RASFs.
**Conclusions:** Our data indicate that altered profiles of histone methylation and binding of STAT3 to the promoters regulate constitutive and IL-6-induced MMPs gene activation in RASFs and possibly arthritogenic properties of RASFs.

FRI0043 **SYNOVIAL MAST CELLS CORRELATE WITH LOCAL AND SYSTEMIC INFLAMMATION AND ARE FUNCTIONALLY ASSOCIATED WITH ECTOPIC LYMPHOID STRUCTURES IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

F. Rivellese[1,2], F. Humby[1], S. Kelly[1], A. Nerviani[1], D. Mauro[1], V. Rocher-Ros[1], M.E. El Shikh[1], A. de Paulis[2], G. Marone[2], C. Pitzalis[1]. *[1]Centre for Experimental Medicine & Rheumatology, William Harvey Research Institute, Barts and The London School of Medicine & Dentistry, London, United Kingdom; [2]Department of Translational Medical Sciences and Center for Basic and Clinical Immunology Research (CISI), University of Naples Federico II, Naples, Italy*

**Background:** Mast cells (MCs) are immune cells present in the synovial membrane, and many evidences suggest that they contribute to the inflammatory response in Rheumatoid Arthritis (RA). However, their exact role in the pathogenesis of RA is still controversial. In particular, their presence in synovia and their association with the various histological patterns (pathothypes) described in RA have never been analysed systematically.
**Objectives:** To evaluate the presence of MCs in the synovial membrane of early RA patients and their correlation with synovial inflammation and cellular infiltration.
**Methods:** Sections of paraffin embedded synovial tissue obtained by ultrasound-guided synovial biopsy from DMARD-naïve patients with early (<12 months) RA (n=90) were stained with H&E and underwent semi-quantitative (SQ) scoring (0–9) to determine the degree of synovitis. Sequentially cut sections were stained by IHC for CD117+ MCs and immune cells (CD20+ B cells, CD3+ T cells, CD68+ macrophages and CD138+ plasma cells). Upon SQ scoring (0–4), sections were stratified into synovial pathotypes according to the degree of immune cell infiltration: (i) Lymphoid- grade 2/3 B cell aggregates, CD20≥2 and/or CD138>2 ii) Myeloid- CD68 SL≥2, CD20≤1 and/or CD3≥1, CD138≤2 and iii) Fibroid- CD68 SL<2 and CD3, CD20, CD138<1). Additionally, cellular interactions were assessed by double IF in tonsils and in RA synovia (n=6). Finally, naïve B cells isolated from tonsils were co-cultured with MCs.
**Results:** MCs were positively correlated with synovial inflammation ($r_S$=0.657) and infiltrating T cells ($r_S$=0.629), B cells ($r_S$=0.666), macrophages (lining: $r_S$=0.502; sub-lining $r_S$=0.454) and plasma cells ($r_S$=0.623), p<0.0001. In particular, synovial MCs were significantly higher in patients with a lymphoid pathotype (mean MC density in lymphoid 41.06/mm$^2$ Vs fibroid/myeloid 11.66/mm$^2$, p<0.0001). Similarly, when patients were stratified according to MC number, the proportion of lymphoid pathotype was significantly higher in patients with high vs intermediate vs low MC count (83.9% vs 44.8% vs 10.3%, respectively, p<0.0001). Double immunofluorescence showed MCs bordering the germinal centres in secondary lymphoid organs and in close contact with B and T cell aggregates in synovia. Finally, MCs supported naïve B cells survival, proliferation, and differentiation in vitro, as demonstrated by the increased AID expression and the induction of IgG class switching upon co-culture of B cells with MCs.
**Conclusions:** Our study demonstrates that MCs strongly associate with the lymphoid synovial pathotype in early RA patients. Their ability to support B cell survival, activation and differentiation in vitro suggests that they may contribute to functional activation of lymphoid aggregates in vivo. Additional studies are

warranted to establish the role of MC interaction with B cells and assess their usefulness as biomarker for patient stratification in RA.

## FRI0044 SMOKING INDUCES IRREVERSIBLE DEREGULATION OF MICRORNA EXPRESSION IN RHEUMATOID ARTHRITIS

K. Andersson, M. Turkkila, S. Töyrä, M. Bokarewa. *Dept rheumatology and inflammation research, Inst Medicine, Göteborg, Sweden*

**Background:** MicroRNA (miR) represent a part of epigenetic contol of autoimmunity and gain increasing attention in the pathogenesis of RA. Genome-wide and candidate miR surveys indicated deregulation of selected miRs in RA blood and synovial tissue. Smoking belongs to enviromental factors with the ability to reprogram epigenetic control. It is also the most studied risk factor in RA being tightly connected to the production of autoantibodies, high levels of oncoprotein survivin, and resistance to antirheumatic therapy (1,2).
**Objectives:** The aim of this study was to determine effect of smoking on the expression of miRs in leukocytes of RA patients.
**Methods:** Leukocytes of the peripheral blood of 46 female RA patients (age 21–69 years, disease duration 1–22 y) were used as a source of miR. Information about smoking status was collected via a questionnaire and identified current smokers (CS, n=12), former smokers (FS, n=21) and never smokers (NS, n=13). We used the Toray 3D-Gene microRNAs assay-based approach to compare the levels of 2598 miRs between the RA patients with different smoking status. For the comparison between the groups we used only miRs with abundant (raw values >100) expression in leukocytes. Smoking and RA-associated miRs were retrived from the available comprehensive reviews (3,4).
**Results:** The number of detectable miR was highest in the PBMC samples of NS. Former and current smoking was associated with a step-wise decreased global miR expression being most severe in CS. We identified 267 miRs, which had an abundant expression in NS. The expression of 93 of these miRs was significantly affected by smoking being 1.75-times lower in FS and CS (p=0.0002). Analyses of miRs, which had previously been reported sensitive to smoking showed that FS+CS had lower expression of the miRs belonging to the let-7 family compared to NS (2.43 times, p=0.034). Additionally, FS had low expression of the miR-17/92 cluster, where miR-17 family was affected most, reduced 2.05 times (p=0.066), followed by miR-19 and 18 families (1.74 times) and miR-92 family (1.56 times). FS had also 2.1 times lower expression of the miR-16 family. The analysis of miRs described in relation to RA showed that 20 of 30 RA-related miRs were abundantly expressed in the studied samples. The expression of miR-16–5p, miR-126–3p, miR-142–3p, miR-150–5p, miR-22–3p and miR-221–3p showed more then 1.75 times difference between FS and NS.
**Conclusions:** Smoking is associated with a global reduction in miR expression in RA patients, where the members of let-7; miR-17/92 and miR-16 families with key roles in regulation of cell cycle progress, tissue development and immune responses clusers are most affected.

## FRI0045 THERAPEUTIC BLOCKADE OF INTERLEUKIN-6 TRANS-SIGNALLING RESTORES VASCULAR FUNCTION IN MURINE COLLAGEN INDUCED ARTHRITIS

R. Davies[1], J. Williams[1], K. Sime[1], E. Hughes[2], L. Jordan[1], C. Rawlings[1], D. Lang[3], S. Jones[1], S. Rose-John[4], A. Williams[1], E. Choy[1]. *[1]CREATE Centre, Division of Infection and Immunity, Cardiff University; [2]Immunology & Cancer Immunotherapy, Infection and Immunity; [3]Institute of Molecular and Experimental Medicine, Cardiff University, Cardiff, United Kingdom; [4]Institüt of Biochemistry, Christian-Albrecht Universität, Kiel, Germany*

**Background:** Mortality is increased in rheumatoid arthritis (RA), mainly due to cardiovascular disease (CVD). While molecular mechanisms underlining this observation are unknown, systemic elevations in inflammatory cytokines, eg interleukin (IL)-6 frequently correlate with increased cardiovascular risk. IL-6 plays roles in both immune homeostasis and driving chronic disease progression. Control of these processes is regulated by two modes of IL-6 signalling; classical IL-6 signalling and IL-6 trans-signalling. Cellular responses controlled by IL-6 trans-signalling are mediated via soluble IL-6 receptor (sIL-6R) and is widely considered to promote pro-inflammatory outcomes. Importantly, a genetic polymorphism within IL6R enhances circulating sIL-6R level and is associated with CVD incidence in the general population. Biological drugs against IL-6 or IL-6R block both classical and trans-signalling. However it is advocated that selective inhibition of IL-6 trans-signalling may reduce clinical complications associated with a more global intervention strategy. Murine collagen induced arthritis (mCIA) is associated with vascular dysfunction, with reduced aortic constriction to 5-HT. Here, we found systemic alterations in vascular tone, as a response to mCIA, was attributable to IL-6 trans-signalling.
**Objectives:** Investigations assessed whether inhibition of IL-6 trans-signalling using the selective antagonist sgp130Fc affected aortic constriction as an index of vascular dysfunction in mCIA.
**Methods:** Arthritis was induced in 8 week old male DBA/1 mice by type-II collagen, as previously described[1]. Animals were administered IV sgp130Fc (2.5mg/kg) or PBS weekly from day 21. Arthritis severity was monitored daily from day 21–30. Vasoconstriction of aortic rings in response to 5-HT was monitored as an index of vascular function using isometric tension myography. Results are expressed as mean ± SEM (n=10).
**Results:** When compared with PBS controls (Arthritis Index:4.3±1.1), disease severity was significantly ($P<0.05$) reduced in sgp130Fc (1.5±0.6) treated mice (Fig1A). PBS control mice with mCIA had reduced vasoconstriction (developed tension 8.5±0.6mN for non-immunised mice, 5.8±0.8mN for mCIA mice; $P<0.05$). Significantly, improvement of disease activity observed for sgp130Fc treated animals was associated with normalisation of vascular function (developed tension 8.1±0.6mN).

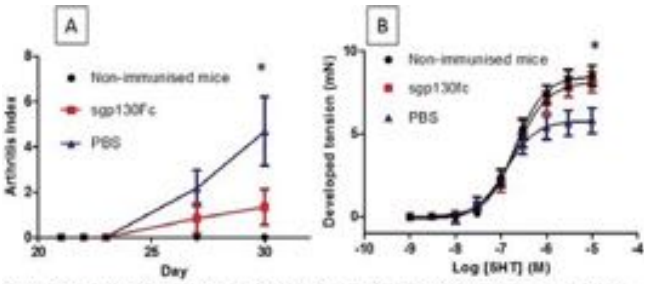

Figure 1 (A) Significant difference in Arthritis Index over time in mice administered sgp130Fc compared with PBS. (B) Vasoconstriction concentration-response curves to 5-HT in aortic rings. N=10

**Conclusions:** Consistent with previous reports[1], sgp130Fc reduced arthritis in mCIA. Sgp130Fc also restored vascular function. Selective IL-6 trans-signaling blockade by sgp130Fc is a promising therapeutic strategy for both RA and its associated CVD. Further work is needed to elucidate the role of IL-6 trans-signaling in pathogenesis of vascular dysfunction in mCIA and RA.

## FRI0046 TCZ ATTENUATES ATHEROTHROMBOSIS THROUGH THE SPECIFIC INHIBITION OF NETOSIS AND MONOCYTE-MEDIATED PROINFLAMMATORY ACTIVITY

P. Ruiz-Limon, N. Barbarroja, R. Ortega, C. Perez-Sanchez, Y. Jimenez-Gomez, M.C. Abalos-Aguilera, I. Arias de la Rosa, P. Font, M.A. Aguirre, M.C. Castro, J. Calvo, E. Collantes-Estevez, A. Escudero, C. Lopez-Pedrera. *Rheumatology service, IMIBIC/University of Cordoba/Reina Sofia Hospital, Cordoba, Spain*

**Background:** Inhibition of the interleukin IL6 receptor pathway by tocilizumab (TCZ) is an effective treatment for rheumatoid arthritis (RA). TCZ reduces atherosclerosis markers and improves endothelial function. In peripheral blood, TCZ increases the percentage of natural killer and regulatory T cells and decreases the number of inflammatory Th1/Th17 lymphocytes. Monocytes activation and neutrophil extracellular traps (NETs) are key players in the development of cardiovascular disease; however, the specific effect of TCZ on these cells has not been described yet.
**Objectives:** To analyze the molecular changes (focused on monocyte and neutrophil abnormalities) underlying the beneficial effect of TCZ on atherosclerosis and endothelial dysfunction in rheumatoid arthritis.
**Methods:** Fifteen RA patients received 162 mg/week subcutaneous TCZ as combined therapy. Endothelial function was measured through post occlusive hyperemia using Laser-Doppler. To analyze the specificity of TCZ, blood samples

from 5 RA patients with high disease activity no taking TCZ was used to perform in vitro studies. Isolated monocytes and neutrophils were treated in vitro with IL6 and blocking FCRII plus TCZ for 18 and 6 hours, respectively. Oxidative stress markers in leukocytes were analyzed by flow cytometry. NETosis was measured through Sytox staining of DNA fibers. Myeloperoxidase (MPO) and neutrophil elastase (NE) were analyzed in neutrophils by flow cytometry. mRNA expression of peptidyl arginine deiminase (PAD4) was measured by RT-PCR. Percentage of low density granulocytes (LDGs) was analyzed through flow cytometry. mRNA expression of genes involved in monocyte activation, prothrombotic state, lipid uptake and insulin resistance was analyzed in monocytes through RT-PCR. Activation of intracellular pathways was analyzed in monocytes using pathscan intracellular signaling array. Expression of miRNAs was evaluated in plasma.

**Results:** After 6 months of treatment, TCZ reduced clinical parameters of inflammation, autoimmunity and joint damage. Endothelial function was significantly restored. TCZ decreased peroxide and peroxinitrite levels in RA leukocytes, most significantly in monocytes and neutrophils. Percentage of LDGs was also reduced after treatment. TCZ in vivo treatment reduced the expression of MPO, NE and PAD4 in RA neutrophils. The generation of in vitro induced NETs was also inhibited by TCZ. The expression of inflammatory and prothrombotic molecules, genes involved in lipid uptake and cellular activation and insulin signaling and the activation of various intracellular pathways were modulated in monocytes after in vivo TCZ treatment. All these results were recapitulated after in vitro TCZ treatment of RA monocytes and neutrophils. Plasma levels of miRNA-223, miRNA-146 and miRNA-23, previously reported to be modified by anti-TNFalpha drugs, were also upregulated after TCZ treatment.

**Conclusions:** TCZ improves endothelial dysfunction and atherothrombosis through the restoration of the oxidative status, inhibition of the monocyte prothrombotic and inflammatory profile and the generation of NETosis

## FRI0047 HISTAMINE AND HISTAMINE H4 RECEPTOR PROMOTES OSTEOCLASTOGENESIS IN RHEUMATOID ARTHRITIS

H.-R. Kim[1], K.-A. Lee[1], K.-W. Kim[2], B.-M. Kim[2], S.-H. Lee[1]. *[1]Konkuk University School of Medicine; [2]Catholic university of Korea, Seoul, Korea, Republic Of*

**Background:** The biological function of histamine is mediated through four types of histamine H1∼H4 receptors. Histamine H4 receptor (H4R) has immune-modulatory and chemotaxic effects and various immune cells express H4R.

**Objectives:** This study aimed to determine the osteoclastogenic role of H4R in rheumatoid arthritis (RA).

**Methods:** The expression of H4R in RA synovial fluid mononuclear cells (SFMCs), synovial fibroblasts and peripheral blood mononuclear cells (PBMCs) using real-time polymerase chain reaction (PCR). After RA SFMCs and PBMCs were treated with histamine, Th17 cytokines, such as IL-17, IL-21 and IL-22, and H4R antagonist (JNJ7777120), the gene expression and protein production of H4R and RANKL were determined by real-time PCR and ELISA. Osteoclastogenesis was assessed by counting tartrate-resistant acid phosphatase–positive multinucleated cells in peripheral blood CD14+ monocytes cultured with histamine, Th17 cytokines and JNJ7777120.

**Results:** The synovial fluid and serum concentration of histamine was higher in RA, compared with osteoarthritis and healthy controls, respectively. The expression of H4R was increased in RA PBMCs compared with healthy controls. Histamine, IL-17, IL-21 and IL-22 stimulated the expression of H4R and RANKL in PBMCs and JNJ7777120 reduced the histamine and Th17 cytokine-induced RANKL expression. Histamine and Th17 cytokines also induced the osteoclast differentiation from peripheral blood monocytes and JNJ7777120 decreased the osteoclastogenesis.

**Conclusions:** H4R mediates RANKL expression and osteoclast differentiation induced by histamine and Th17 cytokines. The blockage of H4R could be a new therapeutic modality for prevention of bone destruction in RA.

## FRI0048 CONCENTRATIONS OF ANTIBODIES AGAINST PORPHYROMONAS GINGIVALIS ARE INCREASED BEFORE THE ONSET OF SYMPTOMS OF RHEUMATOID ARTHRITIS

L. Johansson[1], N. Sherina[2], N. Kharlamova[2], B. Larsson[2], L. Israelsson[2], S. Rantapää-Dahlqvist[1], K. Lundberg[2]. *[1]Public Health and Clinical Medicine, Rheumatology, UMEÅ UNIVERSITY, Umeå; [2]Department of Medicine Solna, Rheumatology unit, Karolinska Institutet, Stockholm, Sweden*

**Background:** Citrullination by the periodontal pathogen *Porphyromonas gingivalis* has been hypothesized to play a role in RA aetiology, by contributing to the production of anti-citrullinated protein antibodies (ACPA). We have previously shown that the ACPA response precedes RA by several years, and we have recently demonstrated elevated anti-*P. gingivalis* antibody levels in patients with RA compared with controls (1–3).

**Objectives:** The aim of the present study was to investigate the link between *P.gingivalis* and RA further, by analysing whether anti-*P. gingivalis* antibodies predate RA diagnosis and ACPA production.

**Methods:** A case-control study was performed within the Medical Biobank and the Maternity cohort of Northern Sweden including 251 individuals who had donated 422 blood samples predating the onset of symptoms of RA, and 198 population-based controls from the same cohorts. The median (IQR) predating time until onset of symptoms was 5.2 (6.2) years. For 192 individuals diagnosed with RA, blood samples were available from the time of diagnosis. Samples were analysed using in-house ELISAs for presence of antibodies to the virulence factor arginine gingipainB (RgpB) purified from *P. gingivalis*, and to a citrullinated peptide (CPP3) derived from the *P. gingivalis* peptidylarginine deiminase enzyme *P.*PAD.

**Results:** The concentration of anti-RgpB IgG levels was significantly increased in pre-symptomatic individuals (mean±SEM; 152.7±14.8 AU/ml) and in RA patients (114.4±16.9 AU/ml), compared with controls (82.2±12.1 AU/ml, $p<0.001$ for both). Antibodies against CPP3 were detected in 5% of the pre-symptomatic individuals and in 8% of the RA-patients, with elevated levels in both pre-symptomatic individuals (4.33±0.59 AU/ml) and RA-patients (9.29±1.81 AU/ml) compared with controls (2.36±0.58 AU/ml, $p<0.001$ for both). The anti-CPP3 antibody response followed the ACPA response, with increasing antibody concentrations over time, whilst the anti-RgpB IgG response was elevated and stable in pre-symptomatic individuals during the pre-dating time and showed a trend towards lower levels after RA diagnosis.

**Conclusions:** Anti-*P. gingivalis* antibody concentrations were significantly increased in RA compared with controls and these antibodies were detected years before the onset of symptoms of RA, supporting an aetiological role for *P. gingivalis* in the development of RA.

## FRI0049 PRECLINICAL CHARACTERIZATION OF GS-9876, A NOVEL, ORAL SYK INHIBITOR THAT SHOWS EFFICACY IN MULTIPLE ESTABLISHED RAT MODELS OF COLLAGEN-INDUCED ARTHRITIS

J. Di Paolo[1], P. Blomgren[2], M. Dolton[3], R. Jones[1], J. Kropf[2], T. Lee[2], S. Mitchell[2], B. Murray[4], K. Suekawa-Pirrone[5], S. Wise[5], J. Xu[2], Z. Zhao[2], K. Currie[2]. *[1]Biology; [2]Chemistry; [3]Clinical Pharmacology; [4]DMPK; [5]HTS, Gilead Sciences, Foster City, United States*

**Background:** Spleen Tyrosine Kinase (SYK) mediates signaling in a range of hematopoietic cells involved in the initiation and progression of RA including B cells, monocytes, macrophages, dendritic cells, and osteoclasts. There is strong preclinical validation for SYK as a therapeutic target for RA based on cellular data and animal models of disease. We have identified GS-9876 as a potent and selective SYK inhibitor with pharmaceutical properties compatible with once daily oral dosing in human.

**Objectives:** To characterize the cellular activity of GS-9876 on pathologically relevant pathways in RA, and establish target inhibition requireements for efficacy in rat models of arthritis.

**Methods:** The potency and selectivity of GS-9876 were characterized in biochemical and cellular assays. Effects in B cells were measured by inhibition of BCR-mediated protein phosphorylation, CD69 and CD86 expression, and in macrophages by inhibition of immune-complex (IC)-stimulated cytokine release. Cellular selectivity was demonstrated by comparing the inhibition of B cell proliferation versus T cell proliferation. GS-9876 potency in human blood was evaluated by inhibition of phosphorylated SYK (pSYK), CD63 expression on basophils, and CD69 expression on B cells. The in vivo efficacy of GS-9876 was tested in rat models of collagen-induced arthritis (CIA).

**Results:** GS-9876 is a potent SYK inhibitor ($IC_{50}$=9.5±4.3 nM) and is highly selective against a panel of 456 other kinases. GS-9876 inhibited anti-IgM stimulated phosphorylation of AKT, BLNK, BTK, ERK, MEK, and PKCδ in human B cells with $EC_{50}$ values of 24–51 nM. Functionally, GS-9876 inhibited anti-IgM mediated CD69 and CD86 expression on B-cells ($EC_{50}$=112±10 nM and 164±15 nM, respectively) and anti-IgM /anti-CD40 co-stimulated B cell proliferation ($EC_{50}$=108±55 nM). In human macrophages, GS-9876 inhibited IC-stimulated TNFα and IL-1β release ($EC_{50}$=121±77 nM and 9±17 nM, respectively). Anti-CD3/anti-CD28 stimulated T cell proliferation was weakly inhibited ($EC_{50}$=1291±398 nM), with selectivity >10-fold versus the inhibition of B cell proliferation. In human blood, GS-9876 blocked SYK phosphorylation, CD69 expression on B cells, and CD63 expression in basophils. GS-9876 demonstrated a dose-dependent improvement in clinical

score and histopathology parameters with once-daily dosing in short and long term rat CIA models. Significant efficacy could be achieved with GS-9876 doses that produced trough pSYK inhibition of <50%.
**Conclusions:** GS-9876 is a novel SYK inhibitor that potently inhibits multiple cellular events implicated in RA pathogenesis and displays excellent in vivo efficacy in rat CIA models after once-daily dosing. GS-9876 has markedly improved selectivity over competitor SYK programs. Our data support the development of GS-9876 in inflammatory diseases, with potential for an improved safety profile.

## FRI0050 DIFFERENTIAL EXPRESSION OF OPG/RANKL/TRAIL SYSTEM IN RHEUMATOID ARTHRITIS

S. Remuzgo-Martínez[1], F. Genre[1], R. López-Mejías[1], B. Ubilla[1], V. Mijares[1], T. Pina[1], A. Corrales[1], R. Blanco[1], J. Martín[2], J. Llorca[3], M.Á. González-Gay[1,4,5]. *[1]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Department, IDIVAL, Santander; [2]Institute of Parasitology and Biomedicine López-Neyra, IPBLN-CSIC, Granada; [3]Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiology and Public Health (CIBERESP), IDIVAL, Santander, Spain; [4]Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa; [5]School of Medicine, University of Cantabria, Santander, Spain*

**Background:** Osteoprotegerin (OPG)/ receptor activator of nuclear factor-κB ligand (RANKL)/ tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) system is involved in the pathophysiology of rheumatoid arthritis (RA) [1–2]. Moreover, this system has been related to cardiovascular (CV) disease and, therefore, these molecules have been proposed as potential biomarkers of CV disease [3–4].
**Objectives:** To evaluate for the first time the differential expression of OPG/RANKL/TRAIL system in RA patients, with and without ischemic heart disease (IHD), and healthy controls, in order to confirm the role of this system in the pathogenesis of RA, the clinical and demographic characteristics of RA patients, and CV disease, assessed by IHD.
**Methods:** *OPG*, *RANKL* and *TRAIL* messenger RNA (mRNA) expression was quantified by quantitative real-time PCR in peripheral blood from 26 RA patients (12 with and 14 without IHD) and 10 healthy controls. Correlation coefficients were also assessed between *OPG*, *RANKL* and *TRAIL* expression levels in RA patients and their clinical and demographic characteristics, as well as the influence of *OPG* expression on its ligands.
**Results:** While *OPG* and *OPG/TRAIL* ratio expression was significantly increased in RA patients compared to controls (fold change=1.79, p=0.01 and 2.07, p=0.03, respectively), *RANKL/OPG* ratio was significantly decreased (fold change=0.50, p=0.02). Additionally, *OPG* mRNA levels were associated with *OPG/TRAIL* ratio (r=0.75, p=0.0002) and inversely related to *RANKL/OPG* ratio (r=-0.70, p=0.0008) in RA. No significant differences were found between patients and controls in *RANKL* and *TRAIL* expression. Interestingly, *TRAIL* mRNA expression was significantly higher in RA patients with compared to those without IHD (fold change=1.46, p=0.03). Moreover, biologic disease-modifying antirheumatic drugs (DMARDs) significantly decreased *RANKL* expression in RA patients (r=-0.54, p=0.02).
**Conclusions:** Our study supports a key role for *OPG* in RA disease and *TRAIL* in IHD in RA patients. Furthermore, it highlights the important modulation of *RANKL* in RA patients treated with biologic DMARDs.

## FRI0051 IN VIVO IMAGING TO CHARACTERISE THE SPECIFICITY, FUNCTION AND BEHAVIOR OF THE CD4+ T CELLS INITIATING ARTICULAR INFLAMMATION

R.A. Benson, C.T. Prendergast, I.B. McInnes, J.M. Brewer, P. Garside. *Institute of Infection, Immunology and Inflammation, University of Glasgow, Glasgow, United Kingdom*

**Background:** It is widely accepted that $CD4^+$ T cells are important contributors to the pathogenesis of Rheumatoid Arthritis (RA). The presence of activated T cells in the inflamed synovium, GWAS defined associations with HLA-DR4, ptpn22, ctla4 and cd28, together with the clinical success of CTLA-4-Ig, all implicate a significant contribution (1). Yet it remains unclear when and where $CD4^+$ T cells mediate this pathogenic effect and whether the specificity of the cells is important.
**Objectives:** Characterise the specificity and function of the $CD4^+$ T cells mediating the initiation of experimental arthritis. To relate this to an analysis of the migratory behaviour of $CD4^+$ T cells in the inflamed articular environment thereby defining interactions with antigen presenting cells (APCs) that may control their activation in the joint.
**Methods:** Antigen-induced arthritis using ovalbumin (OVA) as the inciting challenge was used to model articular inflammation (2). Th1 OVA specific fluorescent (DsRed) OT-II TcR transgenic T cells were adoptively transferred and expanded *in vivo* by challenge with OVA/CFA. This allowed analysis and in tracking of antigen-specific T cells as they were recruited to the joint following periarticular injection of heat aggregated OVA (HAO). Flow cytometry allowed phentoyping of cells recruited to the inflamed articular environment. The T cell receptor (TcR) diversity of infiltrating endogenous T cells was assessed by PCR of Vβ genes. Dynamic interactions of responding DSRed T cells with joint residing YFP dendritic cells (DCs) were visualized using intravital multiphoton microscopy.
**Results:** Low numbers of the inciting OVA specific $CD4^+$ T cells could be found in the joint tissue. However, a large influx of endogenous $CD4^+$ T cells of unknown antigen specificity was also detected. This recruited articular T cell population expressed surface activation markers, exhibited a narrower range of T cell receptor Vβ usage and upon *ex vivo* restimulation produced TNFα and IFNγ. Intravital imaging of the inflamed joint revealed that a sub-population of this infiltrate demonstrated slower motility speeds and longer periods of contact with articular DCs, while others rapidly migrated throughout the tissue.
**Conclusions:** We define for the first time the *in vivo* kinetics of early T cell induction of articular inflammation. Numbers of the inciting antigen-specific population recruited to the joint tissue is small, but is associated with a subsequent influx of a large endogenous population of $CD4^+$ T cells of unknown antigen specificity that acquired the ability to secrete pro-inflammatory cytokines. The narrower usage of TcR Vβ genes by the $CD4^+$ T cells in the inflamed joint suggests some degree of antigen-specificity in recruitment while intravital imaging reveals that some of this infiltrate exhibits behaviour consistent with recognition of cognate peptide-MHCII.

## FRI0052 TARGETING TRISTETRAPROLIN TO TREAT INFLAMMATORY ARTHRITIS

E. Ross[1], A. Naylor[1], G. Kollias[2], A. Filer[1], J. Dean[3], C. Buckley[1], A. Clark[1]. *[1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom; [2]Division of Immunology, BSRC Alexander Fleming, Vari, Greece; [3]Kennedy Institute of Rheumatology, University of Oxford, Oxford, United Kingdom*

**Background:** Aberrant activation of MAPK p38 signalling contributes to pathogenesis of RA[1]. MAPK p38 promotes expression of inflammatory mediators via phosphorylation of the mRNA destabilising protein Tristetraprolin (TTP) at two serine residues. These phosphorylations a) protect TTP protein from destruction by the proteasome, and b) inactivate it, resulting in stabilisation of target mRNAs such as TNF[2,3]. Dephosphorylation and activation of TTP is mediated by the phosphatase PP2A. Disruption of the murine TTP gene (*Zfp36*) causes a severe, pervasive inflammatory syndrome, including erosive arthritis. The phenotype is largely due to increased stability of TNF mRNA and overexpression of TNF protein[4]. TTP protein is reported to be strongly expressed in the RA synovium[5]. However, the cells expressing TTP were not identified, and the relationship with inflammation was not explored.
**Objectives:** To test the hypothesis that synovial inflammation requires phosphorylation and inactivation of TTP, and that, conversely, synovial inflammation may be inhibited by promoting the dephosphorylation and activation of TTP.
**Methods:** The expression of TTP and its relationship with p38 activation in normal and RA synovial tissue were examined by confocal microscopy. A knock-in

mouse strain (*Zfp36aa/aa*) was generated, in which sites of p38-dependent phosphorylation were subsituted by non-phosphorylatable alanine residues[3]. Experimental arthritis was induced by K/BxN serum transfer. *In vitro* and *in vivo* experiments were performed to test anti-inflammatory effects of a compound that activates the phosphatase PP2A.

**Results:** TTP expression was significantly higher in RA than non-inflamed synovium, detected in macrophages, vascular endothelial cells and some synovial fibroblasts, and co-localised with MAPK p38 activation. The *Zfp36aa/aa* mouse, in which TTP is non-phosphorylatable and constitutively active, were resistant to induction of experimental arthritis. Protection against arthritis was dependent on constitutive TTP function in both haematopoietic and non-haematopoietic compartments. *In vitro*, a PP2A activating compound impaired the expression of TNF in a manner dependent on the modulation of TTP function. *In vivo*, it reduced inflammation and prevented bone erosion in the K/BxN serum transfer model of RA.

**Conclusions:** The phosphorylation state of TTP is a critical determinant of inflammatory responses, and a tractable target for novel anti-inflammmatory treatments.

## FRI0053 AMELIORATION OF EXPERIMENTAL ARTHRITIS BY DISSOCIATING THE BINDING OF P53 FAMILY MEMBERS WITH INHIBITORY APOPTOSIS STIMULATING PROTEIN OF P53 TO INDUCE APOPTOSIS IN SYNOVIAL FIBROBLAST

C.-R. Wang[1], S.-Y. Chen[1], A.-L. Shiau[2], I.-M. Jou[3], M.-F. Liu[1], C.-L. Wu[4]. *[1]Internal Medicine, National Cheng Kung University Hospital and Medical College; [2]Microbiology and Immunology, National Cheng Kung University Medical College; [3]Orthopedics, National Cheng Kung University Hospital and Medical College; [4]Biochemistry and Molecular Biology, National Cheng Kung University Medical College, Tainan, Taiwan*

**Background:** In rheumatoid arthritis (RA), apoptosis-resistant synovial fibroblasts (SFs) constitute the major cell component of pannus tissues [1]. 37 amino acid (37AA), a hybrid small peptide corresponding to p53 residues, inhibits the binding of p53 family members with inhibitory apoptosis stimulating protein of p53 (iASPP), thus activating the downstream apoptosis signaling pathway in tumor cells [2].

**Objectives:** We hypothesized that iASPP is involved in the RA pathogenesis, and examined whether dissociating the binding of p53 family members with this molecule can ameliorate experimental arthritis.

**Methods:** Synovial tissues and SFs from RA and osteoarthritis patients were subjected to immunohistochemical (IHC) and immunofluorescent staining, respectively, for expression of iASPP and p73, a p53 family member molecule. Synovial tissues from male Sprague-Dawley rats immunized with type II collagen, were analyzed by IHC staining and real-time RT-PCR for expression of iASPP and p73. SFs transfected with adenoviral vectors encoding 37AA (Ad37AA), were subjected to TUNEL assay for apoptotic status and real-time RT-PCR for expression of p53 upregulated modulator of apoptosis (PUMA), a downstream apoptosis signaling molecule. The association of iASPP with p73 in Ad37AA-transfected SFs was identified by immunoprecipitation with anti-iASPP, followed by immunoblot with anti-p73. Therapeutic effects of intra-articular (i.a.) injection with Ad37AA on arthritis rats were evaluated by articular index and histological score. IHC staining was performed to analyze synovial expression of cadherin-11 (a specific SF marker), PUMA and IL-6, and apoptotic cells were detected by the TUNEL assay.

**Results:** There were increased levels of iASPP with co-localized p73 expression in synovial lining layers and purified SFs from RA patients and arthritis rats. Enhanced cell apoptosis and increased PUMA expression were identified in Ad37AA-transfected SFs with lower iASPP-associated p73 levels. Articular indexes and histologic scores were reduced in Ad37AA-injected joints with decreased SF densities, increased apoptotic cells, higher PUMA expression and lower IL-6 levels.

**Conclusions:** Our results demonstrate amelioration of experimental arthritis by dissociating the i.a. binding of p53 family members with iASPP to induce apoptosis in SFs, implicating this molecule as a potential therapeutic target in RA patients.

## FRI0054 MICROPARTICLES FROM RHEUMATOID ARTHRITIS PATIENTS INDUCE APOPTOSIS AND AUTOPHAGY IN CULTURED ENDOTHELIAL CELLS

C. Barbati, C. Alessandri, T. Colasanti, F. Ceccarelli, M. Pendolino, M. Vomero, D. Sabatinelli, F.R. Spinelli, F. Miranda, G. Valesini, F. Conti. *Department of Internal Medicine and Medical Specialties, Arthritis Center, Sapienza University of Rome, Rome, Italy, roma, Italy*

**Background:** Microparticles (MPs) are small membrane vesicles released by many cell types under physiological conditions or pathological situations. Increased levels of MPs have been reported in patients with autoimmune diseases, such as Rheumatoid Arthritis (RA) (1) which is characterized by an accelerated atherosclerosis. TNF is the main cytokine involved in the pathogenesis of RA and many studies agree on the pro-atherogenic role of TNF in RA patients (2). Furthermore, MPs could have a role in endothelial dysfunction, contributing to atherosclerosis in RA patients. Many studies have also shown that an imbalance of the mechanisms of apoptosis and autophagy seems to be involved in endothelial dysfunction.

**Objectives:** The aim of this study was to analyze total and platelet (PMPs)-, endothelial (EMPs)-, leucocyte (LMPs)-derived MPs in RA patients. Moreover, in vitro studies were performed to estimate the effects of serum RA-MPs on vascular endothelium, before and after three months of treatment with TNF inhibitors (TNFi), with special focus on apoptosis and autophagy pathways.

**Methods:** Twenty RA patients and ten sex and age matched Healthy Controls (HC) were enrolled in this study. Experiments were performed using flow cytometry and western blot techniques according to consensus guidelines. MPs were expressed as MPs/microl; autophagy and apoptosis were expressed as LC3II/beta-actin ratio and percentage of annexin V double positive cells respectively.

**Results:** At baseline the total number of MPs was significantly increased in RA patients compared with HC (p=0.002). Only the EMPs subset was increased in RA patients compared with HC (p=0.017). After three months of treatment with TNFi, either the total number of MPs and the EMPs were significantly decreased compared with baseline (p=0.003 and 0.04 respectively). In vitro studies showed that at baseline serum RA-MPs significantly increased, in a dose-dependent manner, both apoptosis and autophagy levels in the human umbilical vein cell line EA.hy926 (p=0.005 and p=0.02, respectively versus untreated cells). After three months of treatment this effect was not more evident ($p>0.05$, versus untreated cells for both parameters). Furthermore, co-treating EA.hy926 cells with RA-MPs and 3-methyl-adenine (3-MA), a pharmacological inhibitor of autophagy, induced a significant increase of apoptosis (p=0.007 versus MPs-treated cells without 3-MA).

**Conclusions:** Our data demonstrate that the total number as well as the EMPs are significantly increased in RA patients and their levels significantly decreased after TNFi. Moreover, MPs are able to modulate apoptosis and autophagy in EA.hy926 cells. After three months of treatment with TNFi, MPs decrease their harmful effects. The results with 3-MA suggest a protective role of autophagy on apoptosis induction by RA-MPs on endothelial cells. Therefore, these results confirm the potential contribution of MPs to endothelial dysfunction.

## FRI0055 SP1 INHIBITOR MODULATES THE AUTOCRINE ACTION OF GLIOSTATIN/THYMIDINE PHOSPHORYLASE (GLS/TYMP) IN RHEUMATOID FIBROBLAST-LIKE SYNOVIOCYTES

N. Tatematsu[1], Y. Waguri-Nagaya[2], Y. Kawaguchi[1], K. Ikuta[1], M. Kobayashi[1], M. Nozaki[1], K. Asai[3], M. Aoyama[4], T. Otsuka[1]. *[1]Department of Orthopaedic Surgery; [2]Department of Joint Surgery for Rheumatic Diseases; [3]Department of Molecular Neurobiology, Nagoya City University Graduate School of Medical Sciences; [4]Department of Pathobiology, Nagoya City University Graduate School of Pharmaceutical Sciences, Nagoya, Japan*

**Background:** Gliostatin/thymidine phosphorylase (GLS/TYMP) is known to have angiogenic and arthritogenic activities, and aberrant GLS production has been observed in the synovial membranes of rheumatoid arthritis (RA) patients. GLS induces its own expression in cultured fibroblast-like synoviocytes from RA patients (RA-FLSs). The promoters of GLS gene contain binding sites for the DNA binding protein Sp1. Previously, we have reported that the Sp1 transcription factor is essential for the expression of GLS in RA-FLSs and that the Sp1 inhibitor, mithramycin, inhibits the TNF-$\alpha$-induced expression of GLS in cultured RA-FLSs.

**Objectives:** In this study we examined the inhibitory effect of the Sp1 inhibitor

mithramycin on the autocrine activity of GLS expression induced by GLS in cultured RA-FLSs.
**Methods:** Samples of synovial tissue were obtained from 11 patients with RA who were undergoing total knee or elbow arthroplasty or arthroscopic synovectomy. RA-FLSs were cultured with GLS, with or without mithramycin. The expression levels of GLS were determined using reverse transcription-polymerase chain reactions (RT-PCR) and enzyme immunoassay.
**Results:** We investigated GLS mRNA and protein expressions in RA-FLSs treated with or without mithramycin, followed by incubation with GLS. Measuring GLS mRNA and protein levels showed significant induction by GLS alone compared with the control with no GLS. Pre-incubation with mithramycin significantly suppressed this induction.
**Conclusions:** The Sp1 inhibitor, mithramycin, down-regulated the increased expression of GLS in RA-FLSs treated with GLS. Because GLS plays a pathological role in RA, blocking GLS stimulation using mithramycin may suggest novel approaches to anti-rheumatic therapy.

## FRI0056 ALTERED MICRORNA EXPRESSION PATTERN IN SYNOVIAL AND BLOOD NEUTROPHILS IN RHEUMATOID ARTHRITIS REVEALS THE PATHOGENIC PROFILE OF THESE CELLS

P. Ruiz-Limon, C. Perez-Sanchez, I. Arias de la Rosa, Y. Jimenez-Gomez, M.C. Abalos-Aguilera, M.A. Caracuel, P. Font, R. Ortega, J. Calvo, M.C. Castro, E. Collantes-Estevez, A. Escudero, C. Lopez-Pedrera, N. Barbarroja.
*Rheumatology service, IMIBIC/University of Cordoba/Reina Sofia Hospital, Cordoba, Spain*

**Background:** MicroRNAs (miRNA) have recently emerged as a new class of modulators of gene expression. Several studies have shown a deregulation of miRNAs in peripheral blood mononuclear cells or T lymphocytes, in synovial tissue and fibroblasts that might contribute to inflammation, degradation of extracellular matrix and invasive behavior of the resident cells in rheumatoid arthritis (RA). Neutrophils are key cells participating in the joint destruction.
**Objectives:** To investigate the miRNA expression profile in synovial and blood neutrophils in RA and its role in the pathogenesis of this disorder.
**Methods:** Neutrophils were isolated from peripheral blood of 20 healthy donors and 20 RA patients. Synovial neutrophils were isolated from paired synovial fluid of 10 RA patients. nCounter microRNA Assay was used to detect simultaneously 800 human microRNAs in each sample.100 ng of RNA from peripheral blood and synovial neutrophils were prepared by ligating a specific DNA tag (miR-tag) onto the 30 end of each mature microRNA according to the manufacturer's instructions. Altered miRNAs were analyzed for potential mRNA targets using Ingenuity pathways analysis (IPA) software. miRNA expression levels were validated through RT-PCR. Several mRNA targets of these miRNAs were analyzed by RT-PCR. Healthy neutrophils were treated in vitro with anti-CCPs isolated from RA patients. mRNA expression of DICER, Ago1, Ago2, exportin was evaluated through RT-PCR. DICER protein expression was analyzed by western blot.
**Results:** Among 800 miRNAs analyzed, 121 were detected in neutrophils from peripheral blood or synovial fluid. Using a 2 fold change cut off, 97 miRNAs were altered in peripheral blood neutrophils from RA patients compared to healthy donors. Most of them were downregulated (94 downregulated and 3 upregulated). Accordingly, RA neutrophils showed a downregulation of the proteins participating in miRNA biogenesis, including DICER, Ago1, Ago2, exportin 5. In addition, treatment of healthy neutrophils with IgGs anti-CCPs isolated from RA patients decreased the expression of these proteins, thus pointing at these autoantibodies as main modulators of microRNA neutrophil expression. Functional IPA analysis showed that altered miRNAs regulated cellular functions such as development, growth, proliferation and movement and were mainly involved in immunological disease. Among the miRNAs found deregulated blood, 34 miRNAs were found even more significantly reduced in synovial neutrophils compared to paired blood neutrophils from RA patients. These miRNAs were mainly involved in inflammatory response, suggesting the abnormal activation of this cell subtype in the joint.
**Conclusions:** 1) RA neutrophils exhibit a defect in the miRNAs processing, showed by a decrease in most of the detected miRNAs and the concomitant downregulation of proteins involved in their biogenesis. This defect seems to be modulated, at least partially, by anti-CCPs antibodies. 2) miRNA downregulation is even more pronounced in synovial resident neutrophils, which may contribute to the high inflammatory profile of these cells in the joint.

## FRI0057 HUMAN MESENCHYMAL STEM CELL CIRCULATION AFTER SURGICAL BONE MANIPULATION BUT ABSENCE OF MSC PERIPHERAL BLOOD CIRCULATION IN RHEUMATOID ARTHRITIS AND HEALTH

S.M. Churchman[1,2], P.V. Giannoudis[1,3], P. Emery[1,2], E. Jones[1,2], D. McGonagle[1,2]. *[1]LIRMM, University of Leeds; [2]NIHR-LMBRU, Chapel Allerton Hospital; [3]Trauma and Orthopaedics, Leeds General Infirmary, Leeds, United Kingdom*

**Background:** Despite the realisation that rheumatoid arthritis (RA) is an autoimmune disease there is still considerable interest in the idea that widespread dissemination of synovial fibroblasts with "transformed" characteristics may play a role in polyarticular joint destruction. An animal model indicated that fibroblast-like synoviocytes (FLS) implanted in one location next played a role in cartilage destruction at remote sites with the circulation the most likely conduit[(1)]. In man FLS are thought to be derived from multipotential mesenchymal stromal stem cells (MSCs) and whilst circulating MSCs have been reported in animal models, this is more contentious in man.
**Objectives:** To use simultaneous superficial and deep venous blood in cases undergoing orthopaedic skeletal manipulation of long bones (lower extremity) prior to definitive stabilisation to explore the basis for potential MSC circulation in skeletal injury, health and RA.
**Methods:** Deep (femoral) and matched anticubital vein blood was collected from 36 patients undergoing lower limb orthopaedic procedures. Peripheral blood was also taken from 11 early RA cases (EULAR/ACR criteria) and 12 healthy controls. CFU-F assays were performed on all samples. Cytometric phenotyping and molecular characterisation of genes related to osteo-, chondro- and adipogenesis were undertaken. To exclude the possibility that CFU-Fs obtained from peripheral vein were merely syringe-trapped fibroblasts, control skin fibroblasts were also used in the molecular analysis.
**Results:** 17/36 femoral vein samples contained CFU-Fs but only 6/59 peripheral vein samples (p=0.0002). Only orthopaedic cases showed peripheral blood MSC circulation which often, but not exclusively, were associated with concomitant presence in the femoral vein. In the 17 femoral vein samples with CFU-Fs their mean frequency was 0.00001% of MNCs. The frequency was higher when sampling post manipulation compared to before/during ($9.7x10^{-8}$ compared to $3.1x10^{-8}$ in femoral vein, $4.0x10^{-8}$ compared to $1.2x10^{9}$ in the periphery). We confirmed the MSC nature of the CFU-Fs by expansion and phenotype: CD105/CD73/CD90 positivity and CD19/CD31/CD33/CD34/CD45/CD61 negativity. Their molecular profiles were typical of MSCs with 39/80 genes (including *ALPL, COL1A1, POU5F1, NGFR, SPARC, SOX9*) showing similarity across multiple MSC tissue controls (iliac crest and femoral marrow-, cortical bone-, periosteum- and adipose-derived MSCs) and neither had profiles that suggested they represented fibroblasts from dermis.
**Conclusions:** There is no evidence that MSCs circulate in early RA. Although MSCs are present in deep veins their presence appears to be, at least in part, linked to skeletal manipulation. Their numbers are so low that a biological role seems unlikely. Biophysical micro-damage to the trabecular vascular architecture, permitting circulation, is a likely explanation. These findings challenge the idea that circulating MSCs or their progeny play a role in early RA or other autoimmune diseases and also challenges the idea that intravenous injection of MSCs with "homing" to sites of injury is a valid strategy since physiological MSC circulation does not occur naturally to a significant degree.

## FRI0058 PRODUCTION OF AN ANTI-TYPE II COLLAGEN IGG2B MONOCLONAL ANTIBODY CAPABLE OF INDUCING DESTRUCTIVE POLYARTHRITIS IN MICE

S. Yoshino, N. Mizutani, T. Koobkokkruad. *Kobe Pharmaceutical University, Kobe, Japan*

**Background:** A mouse model of destructive antibody-mediated polyarthritis (AMPA) induced by a combination of four or five different monoclonal antibodies (mAbs) specific for type II collagen (CII) was previously established. However, it has not been well defined whether an anti-CII mAb is able to induce AMPA.
**Objectives:** The present study aimed to produce an anti-CII mAb that induced destructive AMPA in mice.
**Methods:** To establish anti-CII mAb-producing hybridomas, DBA mice were repeatedly sensitized with chicken CII plus CFA and then CII-sensitized spleen cells were fused with myeloma cells before cloning fused-cells producing mAbs

against mouse CII. To induce arthritis, DBA mice were i.p. injected with various doses of each produced anti-CII mAb (day 0), followed by i.p. administration of LPS on day 3. To evaluate the severity of the arthritis, lesions of the four paws were each graded from 0 to 3 according to the increasing extent of erythema and edema of the periarticular tissue. Histological analysis of inflamed joints and measurement of C3 in serum were also performed.

**Results:** A number of hybidomas producing different isotypes of anti-CII mAbs including IgG1, IgG2a, IgG2b, IgG3, and IgM were established. I.p. injection of various doses of each anti-CII mAb into DBA mice revealed that only two mAbs (C2B-9 and C2B-14) induced arthritis by the injection without a combination of the mAbs. The incidence of AMPA was 100% in the 5 mice injected with either C2B-9 or C2B-14. However, C2B- 9 induced only mild arthritis while C2B-14 induced moderate joint inflammation, although injection of both C2B-9 and C2B-14 induced severe arthritis. The isotype of C2B-9 and C2B-14 was IgG2b. Histologically, marked hyperplasia of the synovium as well as destruction of cartilage and bone was observed in mice injected with C2B-14 but not C2B-9. Significant decreases in C3 in serum were also observed in C2B-14- but not in C2B-9 -injected animals.

**Conclusions:** We successfully produced an anti-CII IgG2b mAb, C2B-14, that induced destructive AMPA. The destructive AMPA by C2B-14 was associated with low levels of C3 in serum, suggesting a role of complement activation in C2B-14-induced AMPA.

## FRI0059 COMPLEMENT-MEDIATED NEUTROPHIL LYSIS - A MECHANISM PROMOTING HYPERCITRULLINATION IN RHEUMATOID ARTHRITIS?

T. Gazitt, C. Lood, J. Ledbetter, K.B. Elkon. *Rheumatology, University of Washington, Seattle, United States*

**Background:** Protein citrullination, the post-translational conversion of arginine to citrulline, is thought to participate in the development of anti-citrullinated protein antibodies (ACPA) in patients with rheumatoid arthritis (RA). Recently, synovial fluid cells from RA patients were found to have citrullination of several intracellular proteins, a process named hypercitrullination. This unique form of citrullination did not occur in other types of cell death such as apoptosis or NETosis, but was proposed to be induced only through pore-forming membranolytic pathways, including complement-mediated cell lysis through the membrane attack complex.

**Objectives:** To explore the *naturally occurring* humoral mechanisms required for induction of complement-mediated neutrophil lysis in the RA joint.

**Methods:** Neutrophils (PMNs) isolated from synovial fluid (SF) (n=4) or peripheral blood (PB) (n=25) of ACPA-positive RA patients as well as PB of healthy controls (HC) (n=12) were analyzed for anti-PMN binding IgG, C3bi and C5b-9 complement deposition, as well as PMN viability using Annexin V and propidium iodide staining by flow cytometry analysis. In addition, PMNs isolated from HC were incubated with 4 matched RA serum and SF samples as well as 7 additional unmatched RA SF samples, or normal human serum (NHS); complement deposition, complement regulatory protein CD46 expression, and PMN viability were then measured. Finally, the kinetics by which HC PMNs underwent cell death upon stimulation with complement-fixing antibodies (Abs) and NHS were analyzed using the IncuCyte ZOOM® live cell imaging system.

**Results:** In the periphery, RA PMNs had highly increased mean fluorescence intensity (MFI) ratio for C3bi cell-surface deposition as compared to HC (p=0.0183), but no differences were seen for C5b-9 deposition. However, in SF, RA PMNs had elevated MFI ratio for both C5b-9 deposition (p=0.0121) as well as anti-PMN binding IgG deposition (p=0.0011) as compared to PB PMNs from HC, or paired PB PMNs from RA patients (p=0.0177, p=0.0113, respectively). Consistent with the selective increase in complement C5b-9 deposition in SF, we observed a decrease in the expression of CD46 in SF, but not PB PMNs of RA patients (p=0.0270), suggesting a potential mechanism through which SF PMNs are sensitized to complement-mediated lysis. Further, PMNs isolated from SF were, to a higher extent than PB PMNs, undergoing secondary necrosis, supporting the notion of complement-mediated lysis of SF PMNs *in vivo*. Finally, adding RA SF, but not RA serum, to HC PMNs induced markedly elevated C3bi and C5b-9 deposition, reduction in CD46 levels and PMN cell death, clearly demonstrating the PMN cytotoxic properties of RA SF in 10/11 samples, as well as suggesting an important role of complement activation in this process. IgG- and complement-mediated lysis of PMNs was also verified *in vitro* by live cell imaging.

**Conclusions:** RA SF PMNs demonstrate increased complement deposition associated with PMN cell death both *in vivo* and *in vitro*. Elucidating the cause of complement deposition and the role of CD46 in promoting PMN lysis may help to uncover a mechanism for hypercitrullination, ACPA formation and RA disease propagation.

## FRI0060 EXTRACELLULAR MACROPHAGE MIGRATION INHIBITORY FACTOR (MIF) IS ESSENTIAL FOR HYPOXIA-INDUCED ANGIOGENESIS IN A HIF-1-AND HIF-2-INDEPENDENT MANNER

M. Mursell[1,2], M. Hahne[1,2,3], P. Kunath[1,2], C. Strehl[1,2], F. Buttgereit[1], T. Gaber[1,2]. *[1]Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin; [2]German Rheumatism Research Center (DRFZ); [3]Miltenyi Biotec GmbH, Berlin, Germany*

**Background:** Angiogenesis is a hallmark of the pathogenesis of rheumatoid arthritis (RA) but also of other inflammatory processes, tissue regeneration and progressing tumors. In RA, the neovascular network is dysfunctional and fails to restore tissue oxygen homeostasis, so that the inflamed joint remains markedly hypoxic. The hypoxia-induced multifunctional and pro-inflammatory protein macrophage migration inhibitory factor (MIF) participates in the regulation of hypoxia-induced angiogenesis. At cellular level, hypoxia is detected by a mechanism that regulates the amount of the oxygen-sensitive $\alpha$-subunits of the transcription factors, hypoxia-inducible factor (HIF)-1 and -2, which activate a gene program associated with angiogenesis and glycolysis.

**Objectives:** Here, we focus on the role of MIF and its mechanism of action in the process of hypoxia-induced angiogenesis and in the regulation of HIFs.

**Methods:** Therefore, we developed a specific knockdown of MIF and its receptor CD74 in Human Microvascular Endothelial Cell (HMEC) using lentiviral-based shRNA technology allowing us to analyse the role of MIF in hypoxia-induced angiogenesis. We investigated the adaption of these cells towards pathophysiologic hypoxic conditions (1% $O_2$) analysing protein-levels of HIF-1$\alpha$ and HIF-2$\alpha$, HIF-target gene expression, angiogenesis and VEGFA release. To further identify the underlying mechanisms angiogenesis assay was performed with HMECs treated with anti-CD74-IgG, rhMIF and 4-IPP, a small molecule inhibitor of MIF.

**Results:** Lentiviral-mediated reduction of MIF in HMEC led to significantly decreased angiogenesis ($p<0.01$) which could be restored by adding extracellular rhMIF. Interestingly, reduction of MIF did not influence hypoxia-induced (i) protein-levels of HIF-1$\alpha$ and HIF-2$\alpha$, respectively, and (ii) HIF-target gene expression of *PGK1*, *GAPDH* and *VEGFA* but (iii) induced secretion of pro-angiogenic VEGFA and IL8. Moreover, addition of 4-IPP also decreased angiogenic response of non-transduced HMECs but enhanced the hypoxia-induced HIF-target gene expression of *PGK1* and *VEGFA*. Inhibiting MIF-signalling by the addition of extracellular anti-CD74-IgG also reduced angiogenic potential of HMEC ($p<0.001$), which was not restorable by the addition of extracellular rhMIF. Furthermore, lentiviral-mediated reduction of CD74 in HMEC also decreased angiogenesis ($p<0.01$) without influencing HIF-target gene expression of *PGK1*, *GAPDH* and *VEGFA*.

**Conclusions:** Our findings reveal an essential regulatory function of MIF upon the angiogenic potential of HMECs which is independent of the hypoxia-induced HIF-mediated adaptation process activating a gene program associated with angiogenesis and glycolysis. These findings open new possibilities for therapeutic approaches in RA and other inflammatory disorders by targeting specific MIF mediated signalling events.

FRI0061 **INVOLVEMENT OF REGULATORY T CELLS AND MICRORNAS IN REGULATION OF COLLAGEN-INDUCED ARTHRITIS IN MICE TREATED WITH IL-2/ANTI-IL-2 IMMUNE COMPLEXES**

Y. Yokoyama[1], T. Iwasaki[2], A. Satake[3], S. Shibasaki[4], M. Karasaki[4], N. Moriya[2], S. Kitano[1], K. Matsui[1], H. Sano[1]. *[1]Division of Rheumatology, Departmet of Internal Medicine, Hyogo College of Medicine, Nishinomiya; [2]Department of Pharmacy, Hyogo University of Health Sciences, Kobe; [3]1st Department of Internal Medicine, Kansai Medical University, Hirakata; [4]General Education Center, Hyogo University of Health Sciences, Kobe, Japan*

**Background:** Interleukin-2 (IL-2) induces regulatory T cells (Tregs) and reduces disease activity such as graft-versus-host disease and systemic lupus erythematosus. IL-2/anti-IL-2 monoclonal antibody immune complex (IL-2IC) increases the half-life of IL-2 in vivo and strongly induces Tregs. We previously demonstrated that administration of IL-2IC suppressed collagen-induced arthritis (CIA) in mice (EULAR 2015).
**Objectives:** To clarify complex regulatory network of IL-2IC in autoimmune arthritis we examined the effects of IL-2IC on Th1, Th17, Treg inductions and microRNAs (miRNAs) expressions which regulate T cell inductions.
**Methods:** Male DBA/1 mice were immunized by injection of 200μg of Type II collagen emulsified with an equal volume of Complete Freud Adjuvant intradermally at the base of the tail of mice (first immunization). Second immunization was given 21 days after first immunization. IL-2ICs were prepared by mixing 5μg of anti-IL-2 antibody (clone JES6–1D) with 1μg of mouse IL-2 for 15 minutes. The mice were injected with either PBS as a control or IL-2IC (5μg /mouse) intraperitoneally for 3 days. Mouse paws were scored for arthritis using a macroscopic scoring system ranging from 0 to 4 (0, no swelling or redness; 1, swelling/redness of paw or one joint; 2, two joints involved; 3, more than two joints involved; and 4, severe arthritis of the entire paw and joints). The arthritic score for each mouse is the sum of the scores of all four paws. Peripheral blood cells were stained with anti-CD25 (PC61), anti–CD4 (RM4–5), anti-Foxp3 (FJK-16s) and CD4+CD25+Foxp3+ Tregs were analyzed by flow cytometry. Th1 and Th17 cells infiltrating in the synovium were examine by immunohistochemistry stained with anti-IFN-g and IL-17 mAb. MiRNAs expressions in the serum from CIA mice were analyzed using panel real-time PCR analysis (miRCURY LNATM microRNA PCR). Statistical analysis was performed by paired t test.
**Results:** To define the effect of IL-2IC on established CIA, IL-2IC was administered for 3 days from day 21 to day 23 after the first immunization (day 0 to day 2 after the second immunization) of CIA. To define the effect of IL-2IC on early stages of disease induction we administered IL-2IC from day 0 to day 2 after first immunization. We observed a significant decrease in both the incidence and severity of arthritis in these CIA mice. Injection of IL-2IC effectively elicited more than 2-fold expansion of CD4+CD25+Foxp3+ Tregs in peripheral blood cells than control mice. Th1 and Th17 cells infiltrations in the synovium were significantly inhibited by IL-2IC treatment. We identified 24 differentially expressed miRNAs (fold change >2.0) and 72 differentially expressed miRNAs (fold change <0.5) comparing untreated mice. Of note, we observed miR-17–5p and miR-19b-3p which inhibits iTreg induction was significantly augmented in CIA mice but decreased in CIA mice treated with IL-2IC. In addition, miR-326–3p which induces Th17 was significantly augmented in CIA mice but decreased in CIA mice treated with IL-2IC.
**Conclusions:** These observations indicate that IL-2IC might play a complex regulatory role in autoimmune arthritis by regulating Th1, Th17, Tregs and miRNAs which regulate these T cell inductions.

## Rheumatoid arthritis - prognosis, predictors and outcome

FRI0062 **OBESITY IS ASSOCIATED WITH WORSE CLINICAL OUTCOMES YET LIMITED RADIOGRAPHIC PROGRESSION IN EARLY RHEUMATOID ARTHRITIS**

A. Levitsky[1], S. Saevarsdottir[2], K. Brismar[3], K. Hambardzumyan[1], C. Lourdudoss[1], R.F. van Vollenhoven[1,4]. *[1]Unit for Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Karolinska Institutet; [2]Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital; [3]Unit of Growth and Metabolism, Karolinska Institutet, Stockholm, Sweden; [4]Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands*

**Background:** In RA, being overweight or obese has previously been shown to be associated with worse clinical outcomes (1, 2), yet also less radiographic damage (2, 3).
**Objectives:** To confirm if body mass index (BMI) is associated with worse clinical disease activity or inversely associated with radiographic outcomes in early RA.
**Methods:** BMI, categorized as normal (<25, n=141), overweight (25–29.9, n=74), and obese (≥30, n=43), was available in 258 patients who were enrolled in the Swedish pharmacotherapy (SWEFOT) trial. After initial methotrexate for 3 months, non-responders were randomized to triple therapy or anti-TNF therapy, while responders continued on methotrexate. Disease activity (DAS28), functional impairment (HAQ), VAS-pain, and radiographic damage (Sharp van der Heijde score, SHS) were evaluated regularly. Here, results are shown at 24 months of follow-up.
**Results:** Treatment allocation and baseline outcome measures did not differ across the BMI categories. In a dose-response manner, higher BMI at baseline was associated with worse clinical outcomes over 24 months (DAS28, HAQ, and VAS-pain) (Table). Patients with normal (58%) or overweight (50%) BMI had a proportionally greater chance of attaining 24-month clinical remission (DAS28<2.6) than obese patients (23.1%) (OR 3.2 [95% CI 1.6–6.3], p<0.001; OR 2.2 [95% CI 1.2–4.1], p=0.007, respectively). Among absolute radiographic scores, no significant differences were observed, yet radiographic progression (ΔSHS≥1, baseline-24 months) was halted more frequently (56.3%) among obese patients than normal/overweight patients combined (37.6%) (OR 1.9 [95% CI 1.0–3.6], p=0.049) (obese vs. normal (40%), OR 1.7 [95% CI 0.9–3.1], p=0.101; obese vs. overweight (32.7%), OR 1.8 [95% CI 1.1–3.2], p=0.032).

Table 1. Outcome measures after 24 months of disease-modifying antirheumatic agents

| Outcomes [Medians (IQR)] | Normal (n=141) | Overweight (n=74) | Obese (n=43) | P value[a] |
|---|---|---|---|---|
| DAS28 | 2.4 (1.7, 3.4)* | 2.6 (2.2, 3.8)† | 3.2 (2.8, 4.8)†* | p<0.001 |
| HAQ | 0.3 (0.0, 0.8)* | 0.5 (0.0, 1.0)† | 0.8 (0.4, 1.3)†* | p<0.001 |
| VAS-pain | 18.5 (6.0, 35.0)* | 25.0 (8.0, 47.0)† | 39.0 (22.0, 61.0)†* | p<0.001 |
| ESR | 10.0 (6.0, 18.0)* | 13.5 (8.0, 23.0) | 18.0 (11.0, 26.0)* | p=0.008 |
| SHS | 7.0 (2.0, 16.3) | 6.5 (2.0, 14.0) | 5.0 (0.8, 13.0) | p=0.519 |

[a]Kruskal-Wallis test (individual comparisons: Mann-Whitney U test; post-hoc comparisons: Dunn-Bonferroni (DB) correction). †Overweight vs. Obese: DAS28, p=0.012 (DB, p=0.020; adjusted, p=0.060); HAQ, p=0.030 (DB, p=0.021; adjusted. p=0.062); VAS Pain, p=0.025 (DB, p=0.023, adjusted: p=0.069). *Normal vs. Obese: Mann-Whitney or DB + adjustment, p<0.001 (erythrocyte sedimentation rate (ESR): p=0.003 (DB, p=0.003, adjusted: p=0.009)).

**Conclusions:** Obesity at diagnosis was found to be a strong predictor of worse long-term clinical outcomes in early RA – including disease activity, functional impairment, and pain; thus confirming previous findings. Nonetheless – as has also been previously shown – obesity was associated with a better chance of halting radiographic progression.

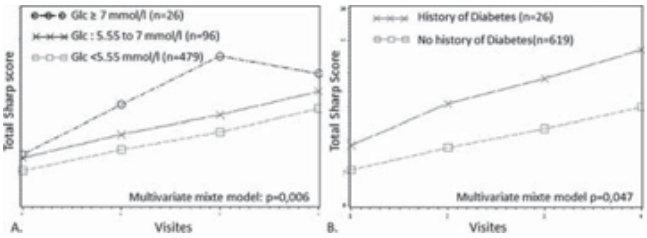
FRI0063 **PREDICTORS OF FLARE IN A COHORT OF RA IN REMISSION AFTER 12 MONTHS OF FOLLOW-UP**

A. Cuervo, J. Ramírez, V. Ruíz-Esquide, R. Celis, M.V. Hernández, J. Inciarte-Mundo, R. Sanmartí, J.D. Cañete. *Arthritis Unit, Rheumatology Dpt, Hospital Clínic de Barcelona, Barcelona, Spain*



**Background:** Definitive biomarkers have not been identified to predict flares in patients with RA in clinical remission.
**Objectives:** To determine clinical, serological and ultrasonografic variables predicting disease relapse at 12 months of follow-up in a cohort of RA patients in clinical remission.
**Methods:** We included consecutively RA patients in clinical remission defined as DAS28-ESR <2.6 for >6months evaluated by two independent rheumatologist from our Arthritis Clinic. Complete clinical and biological assessment, determination of serum levels of angiogenic and proinflamatory cytokines, and ultrasound scans of both hands were performed at baseline and after 12 months of follow-up. Risk factors odds ratio (OR) related with 12 months flare were adjusted with multivariate logistic models.
**Results:** Sixty patients with RA in remission were included; 78.3% were female. Median age was 53 years (range: 31–74), weight was 67 kg (47–108). Disease and remission mean duration were 111.9 ± 86.4 and 37 months, respectively. 71% of patients were RF positive and 81% were ACPA positive. Patients taking low-dose prednisone, csDMARDs and bDMARDs were 16 (26%), 47 (78%) and 28 (46.7%), respectively. At baseline, 66% had power-doppler (PD) signal and 48% also had synovial hyperplasia grade ≥2, so fulfilling the criteria previously defined of ultrasound defined active sinovitis (UdAS). Twenty-six (43%) patients had disease flare during the follow-up.
In the univariate analysis, disease flares were more frequent in patients with PD signal (p=0.056) or UdAS (p=0.117), and significantly less frequent in patients with mild-moderate intake of alcohol. However, in the multivariate analysis, only higher ESR levels (OR: 1.1, 95%CI: 1–1.1), higher weight (OR: 3.1, 95%CI: 1.4–7) and low-dose prednisone treatment (OR: 1.8, 95%CI: 1.2–2.8) were independent risk factors at baseline for disease flares. This model has a sensitivity of 76.9% (95%CI: 56.4–91), a specificity of 76.5% (95%CI: 58.8–89.3), a predictive positive value of 71.40% (95%CI: 52.4–88.4), a predictive negative value of 81.3% (95%CI: 62.7–91.7) and a good predictive power (ROC: 0.849, IC 95%: 74.4–95.4%). We did not find differences between angiogenic or proinflammatory cytokine serum levels and not differences in RAMRIS between patients relapsing or maintaining the remission at baseline.

**Conclusions:** This prospective study suggests that higher ESR levels, higher weight and low-dose prednisone treatment are relevant independent risk factors for development of disease flares in patients with RA in clinical remission. However, imaging data (Ultrasound or MRI) or angiogenic/cytokine serum levels were no predictors of flare in this study.

## FRI0064 HYPERGLYCEMIA IS A PEJORATIVE PROGNOSTIC FACTOR OF CLINICAL OUTCOME AND RADIOGRAPHIC PROGRESSION IN EARLY RHEUMATOID ARTHRITIS: RESULTS OF THE ESPOIR COHORT

C.I. Daien[1], J. Sellam[2], N. Rincheval[3], B. Fautrel[4], A. Saraux[5], J. Morel[1], F. Berenbaum[2], J.-P. Daurès[3], B. Combe[1]. *[1]Rheumatology, CHRU Lapeyronie and UMR5535 CNRS, Montpellier; [2]Rheumatology, Saint-Antoine teaching hospital, DHU i2B, Univ Paris 06, Paris; [3]INSERM, Inserm, Montpellier; [4]Rheumatology, Pitie Salpetrieres, Paris; [5]Rheumatology, CHU, Brest, France*

**Background:** Diabetes was found to be increased in patients with rheumatoid arthritis (RA).
**Objectives:** The objective of this study was to evaluate the impact of hyperglycemia and diabetes on clinical activity and radiographic progression within the first 3 years in patients with early RA.
**Methods:** Patients of the ESPOIR cohort with early RA meeting the ACR/EULAR 2010 criteria and with data available for fasting blood sugar at baseline were analyzed. Glycemic status was analyzed with 2 different definitions: i) history of type I or II diabetes; ii) baseline blood sugar splitted into 3 categories: normal (<5.55 mol/l), pre-diabetes (between 5.55 and 7 mmol/l) and diabetes (≥7 mmol/l). DAS28 and total Sharp score evolution during the first 3 years were compared between groups using multivariate mixed models. The multivariate models included the following variables: body mass index, age, gender, presence of rheumatoid factor and/or ACPA, glucorcorticoids. For DAS28 model, CRP was added in the model and for total Sharp score model, DAS28 and total Sharp were included.
**Results:** 26 patients were known to be diabetic and 619 patients were non-diabetic. At baseline, 479 patients had normal blood sugar; 96 had pre-diabetic levels and 26 had diabetic levels. These three groups initially differed on age, body mass index, presence of rheumatoid factor, and score DAS28 Sharp erosion. In multivariate analysis, DAS28 during the first three years were significantly higher in patients with hyperglycemia (p<0.0001) and in patients with history of diabetes (p=0.05). Similarly, the structural progression was greater in patients with hyperglycemia inclusion with a dose-dependent effect (Figure 1A; p=0.006) and in patients with history of diabetes (Figure 1B; p=0.047).

**Conclusions:** In early RA, blood sugar level is an independent predictor of disease activity and structural progression at 3 years, with a dose-dependent effect. Beyond cardiovascular complications, the measurement of blood sugar in patients with early RA may also help to assess more precisely the prognosis of the disease.

## FRI0065 PRESENCE, GRADE AND LOCATION OF POWER DOPPLER PREDICT PROGRESSION OF RADIOGRAPHIC DAMAGE IN TNFα BLOCKER INDUCED CLINICAL REMISSION IN RHEUMATOID ARTHRITIS PATIENTS

B. Raffeiner[1,2], E. Grisan[3], G. Rizzo[3], C. Botsios[2], A. Doria[2], F. Ometto[2], L. Punzi[2]. *[1]Rheumatology Unit, Department of Medicine, General Hospital of Bolzano, Bolzano; [2]Rheumatology Unit, Department of Medicine; [3]Department of Information Engineering, University of Padova, Padova, Italy*

**Background:** Functional outcome of patients with rheumatoid arthritis (RA) depends from control of disease activity and arrest of radiographic damage. Clinical remission can be achieved in the majority of RA patients by combinations of steroids, DMARDs and TNFα blockers. Recent imaging studies identified residual subclinical inflammation in many patients in treatment with DMARDs: active synovitis was demonstrated by magnetic resonance imaging (MRI) and ultrasound (US). Power Doppler (PD) positivity correlated best with radiographic progression (1). On the other hand, TNFα blockers are much more efficacious in blocking radiographic damage by direct inhibition of osteoclasts, but it is not known if PD positivity predicts on-going damage also in RA patients in remission by TNFα blockers.
**Objectives:** To determine the usefulness of PD study to predict structural damage in patients considered in clinical remission by TNFα blocker therapy.
**Methods:** A prospective observational study was performed on 121 consecutive RA patients in therapy with TNFα blockers and in DAS28 remission since 6 months. At baseline US examination was performed in all patients on the metacarpophalangeal, proximal interphalangeal, wrist and metatarsophalangeal joints. Active synovitis was identified by PD positivity. Semi-quantitative PD scoring 0–3 and number of positive joints were registered. The location of PD was scored as follows: capsular and within synovia without bone contact (location 1) or with bone contact and penetrating bone cortex (location 2). At baseline and after one year X-rays of hands and feet were executed. Radiographic progression was expressed as difference in total Sharp Score modified by van der Heijde (ΔTSS) >0. Risk ratios for presence, grade and location of PD relative to radiological progression were calculated.
**Results:** Among the 121 patients, 62 (51,3%) showed no PD signal at the time of remission, whereas 59 (48,7%) had PD signal: in 57,6% of cases grade was 1, in 23,7% grade 2 and in 18,6% grade 3. 38 patients showed PD positivity in one joint, 21 in more joints. Among all PD positive joints 92,4% were at the level of the hands. 74,6% of PD signals were in contact with articular bone surface (location 2). All patients without PD signal did not show radiographic progression. 28,8% of patients showing PD positivity (corresponding to 14% of all patients in clinical remission) underwent radiographic progression. Radiographic progression occurred in 20,6% of patients with PD grade 1, 42,8% with grade 2 and 36,3% with grade 3. Whereas only 6,6% of patients with PD in location 1 progressed, 36,3% of patients with PD in location 2 showed deterioration of radiographic damage. Despite presence of PD, higher PD grades (2 and 3) and PD with contact to bone surface (location 2) determined a significantly increased risk for radiographic progression; PD in location 1 resulted protective.
**Conclusions:** PD demonstrated to be very useful in evaluating patients considered in remission. Absence of PD signal guarantees arrest of radiological progression, whereas patients with PD signal are at risk for progression despite TNFα blockers. This risk increases with higher PD grades and with PD in contact or penetrating bone profile.

## FRI0066 THE 28-JOINT DISEASE ACTIVITY SCORE (DAS28) USING C-REACTIVE PROTEIN YIELDS LOWER THRESHOLDS COMPARED TO CONVENTIONAL DAS28 WITH ERYTHROCYTE SEDIMENTATION RATE IN EARLY RHEUMATOID ARTHRITIS

B. Kuriya[1], O. Schieir[2], D. Lin[1], J. Pope[3], G. Boire[4], B. Haraoui[5], C. Thorne[6], D. Tin[6], C. Hitchon[7], E. Keystone[1], V. Bykerk[8] on behalf of CATCH Investigators. *[1]Medicine, Mount Sinai Hospital, University of Toronto; [2]Dalla Lana School of Public Health, University of Toronto, Toronto; [3]Medicine, St. Josephs Health Care, University of Western Ontario, London; [4]Medicine, Universite de Sherbrooke, Sherbrooke; [5]Medicine, Institut de Rhumatologie, Montreal; [6]Medicine, Southlake Regional Health Centre, Newmarket; [7]Medicine, University of Manitoba, Winnipeg, Canada; [8]Medicine, Hospital for Special Surgery, New York, United States*

**Background:** The interchangeability of Disease Activity Score 28 joints (DAS28) calculated using the erythrocyte sedimentation rate (ESR) versus C-reactive protein (CRP) has been questioned (1).
**Objectives:** To compare the 28-Joint Disease Activity Score (DAS28) calculated using C-reactive protein (CRP) with that using erythrocyte sedimentation rate (DAS28-ESR) in a multi-centre, usual care, early rheumatoid arthritis (ERA) cohort.
**Methods:** The present study analyzed baseline and 12-month follow up data from the Canadian Early Arthritis Cohort. The study sample included patients with RA with symptom duration less than 12 months and complete data on DAS28-ESR and DAS28-CRP at both time points. The linear association between continuous DAS28-ESR and DAS28-CRP scores was estimated using Pearson's correlation coefficient and differences across the range of DAS28 scores were examined with Bland-Altman Plots. Receiver operating characteristic (ROC) analysis was used to identify optimal thresholds for disease activity for DAS28-CRP scores that would best correspond with established DAS28-ESR thresholds in the total sample as well as in stratified samples by age and sex. Agreement between newly calculated DAS28-CRP and established DAS28-ESR thresholds was examined (kappa statistic).
**Results:** The study sample included 995 ERA patients. Sample baseline mean (SD) age was 53.7 (14.5) with 5.8 (2.9) months of symptom duration and 738 (74%) were female. Though continuous DAS28-CRP and DAS28-ESR scores were highly correlated ($r$=0.92, p<0.0001), Bland-Altman plots showed that DAS28-ESR scores were higher than DAS28-CRP scores across the spectrum of disease activity, with larger positive discrepancies at lower values. Positive discrepancies between DASCRP and DASESR were higher for women and patients over 60 years old. Optimal thresholds identified for the DAS28-CRP were 2.4 for remission, 2.9 for low disease activity, and 4.6 for high disease

activity. Overall, there was moderate to good agreement between newly calculated DAS28-CRP and DAS28-ESR thresholds (k=0.6).
**Conclusions:** Results from this large observational study of "real-world" ERA patients showed that DAS28-CRP and DAS28-ESR scores were strongly correlated but that DAS28-CRP scores were consistently lower than DAS28-ESR scores. Differences between DAS28-CRP and DAS28-ESR were greater at lower ranges of the DAS28 and were most pronounced in women and older patients. This suggests that substituting one continuous score for the other is likely reasonable for research purposes in data analysis and that interpreting the DAS28-CRP using established DAS28-ESR thresholds may be acceptable for higher levels of disease activity, but not for lower levels, particularly not for remission.

## FRI0067 CHANGES IN MULTI-BIOMARKER DISEASE ACTIVITY (MBDA) SCORE CORRELATE WITH CHANGES IN ESTABLISHED DISEASE ACTIVITY MEASUREMENTS IN PATIENTS WITH EARLY RA FROM THE OPERA STUDY

C.H. Brahe[1], M. Østergaard[1], J. Johansen[1], N. Defranoux[2], C.-C. Hwang[2], R. Bolce[2], E. Sasso[2], K. Hørslev-Petersen[1], K. Steengaard-Pedersen[1], P. Junker[1], T. Ellingsen[1], P. Ahlquist[1], H. Lindegaard[1], A. Linauskas[1], A. Schlemmer[1], M.Y. Dam[1], I. Hansen[1], T. Lottenburger[1], C. Ammitzbøll[1], A. Jørgensen[1], S. Krintel[1], J. Raun[1], M.L. Hetland[1]. *[1]Departments of Rheumatology in Copenhagen, Herlev, Gråsten, Aarhus, Odense, Silkeborg, Vejle, Hjørring, Aalborg, Viborg, Copenhagen, Denmark; [2]Crescendo Bioscience Inc., San Francisco, CA, United States*

**Background:** No single biomarker has yet been able to predict disease course in patients with rheumatoid arthritis (RA). However combinations of biomarkers and changes therein early during treatment may be predictive of later treatment response.
**Objectives:** Investigate correlations between early changes (Δ) in the validated multi-biomarker disease activity (MBDA) score and Δ in disease activity measurements – Disease Activity Score (DAS28-CRP), Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI) and C-reactive protein (CRP) – in early RA patients (the OPERA cohort).
**Methods:** In the randomized double-blinded OPERA trial, 180 treatment-naive patients were randomized to an adalimumab (ADA) group (oral methotrexate (MTX) in combination with ADA) or a placebo group (oral MTX and placebo-ADA). Intra-articular glucocorticoids were also injected into swollen joints (1). DAS28-CRP, CDAI, SDAI, and CRP were measured at baseline (BL) and at 3, 6 and 12 months. MBDA score, calculated based on serum concentrations of CRP, interleukin-6, chitinase-3-like protein 1, vascular endothelial growth factor A, matrix metalloproteinase 1 and 3, vascular cell adhesion molecule 1, epidermal growth factor, tumor necrosis factor receptor type I, serum amyloid A, leptin and resistin, with a range of 1–100, was determined retrospectively at the same time points on banked serum samples (2).
Correlations between ΔMBDA scores and Δ disease activity measurements were analyzed by Spearman's correlation coefficient.
**Results:** Patients had a median age of 55.2 (range: 18.7–86) years, disease duration of 84 (range: 42–214) days; 66% were female; 72% and 65% were RF and anti-CCP positive, respectively. At BL, median DAS28-CRP was 5.6 (3.3–8.6) and median MBDA score was 59 (12–90). MBDA scores were low (<30) in 8 (4%) patients, moderate (30–44) in 25 (14%) and high (>44) in 147 (82%) patients. There were no statistically significant correlations between BL MBDA score and

Table 1: Spearman correlations between change in MBDA score at 3 months and change in disease activity measures at 6 and 12 months

| | Δ0-6 months | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | DAS28-CRP | | CDAI | | SDAI | | CRP | |

| | Δ0-12 months | | | | | | | |
| | DAS28-CRP | | CDAI | | SDAI | | CRP | |
| | Placebo | ADA | Placebo | ADA | Placebo | ADA | Placebo | ADA |
| ΔMBDA score$_{0-3m}$ | Rho=0.301 (p=0.005) | Rho=0.428 (p=0.001) | Rho=0.322 (p=0.004) | Rho=0.254 (p=0.022) | Rho=0.395 (p=0.001) | Rho=0.306 (p=0.005) | Rho=0.390 (p=0.001) | Rho=0.429 (p=0.001) |

Δ: change; 0-3 m: 0-3 months; ADA: adalimumab; DAS28-CRP: Disease Activity Score (0-9.4); CDAI: Clinical Disease Activity Index; SDAI: Simplified Disease Activity Index; serum C-reactive protein (mg/L) measured in a clinical laboratory; MBDA: multi-biomarker disease activity; Rho: Spearman correlation coefficient; p: p-values.

other disease activity measurements at 3 or 6 months in the placebo or ADA groups.
Median ΔMBDA scores from BL to 3 months (ΔMBDA score$_{0-3m}$) and to 6 months (ΔMBDA score$_{0-6m}$) were -16.5 and -20, respectively. Median ΔDAS28-CRP from BL to 6 months (ΔDAS28-CRP$_{0-6m}$) and to 12 months (ΔDAS28-CRP$_{0-12m}$) were -2.9 and -3.2, respectively. ΔMBDA score$_{0-3m}$ and ΔDAS28-CRP$_{0-6m}$ were significantly correlated in the placebo and ADA groups, as were ΔMBDA score$_{0-6m}$ and ΔDAS28-CRP$_{0-12m}$. ΔMBDA score$_{0-3m}$ also significantly correlated with ΔDAS28-CRP, ΔCDAI, ΔSDAI and ΔCRP from BL to 6 months and from BL to 12 months (Table 1).
**Conclusions:** In patients with early RA from the OPERA cohort, ΔMBDA score from BL to 3 or 6 months were correlated with longer-term ΔDAS28-CRP, ΔCDAI, ΔSDAI and ΔCRP. Correlations were generally similar between treatment groups.

## FRI0068 CONTRIBUTIONS OF SOCIAL DETERMINANTS OF HEALTH ON REMISSION IN RHEUMATOID ARTHRITIS PATIENTS

K. Cui[1,2], C. Bombardier[2,3,4,5], G. Tomlinson[6,7] on behalf of Ontario Best Practices Research Initiative (OBRI) Investigators. *[1]Medicine, University of Toronto; [2]Toronto General Research Institute, University Health Network; [3]Institute of Health Policy, Management, and Evaluation; [4]Division of Rheumatology, University of Toronto; [5]Division of Rheumatology, Mount Sinai Hospital; [6]Medicine, University Health Network/Mount Sinai Hospital; [7]Institute for Health Policy, Management and Evaluation, University of Toronto, Toronto, Canada*

**Background:** Treatment responses vary among rheumatoid arthritis (RA) patients. There is limited evidence on the contribution of social determinants of health (SDH) to treatment responses and disease outcomes in RA.
**Objectives:** This study aimed to determine the contribution of social determinants of health (SDH) to remission in RA.
**Methods:** Data were collected from the Ontario Best-practices Research Initiative (OBRI) Rheumatoid Arthritis Registry, a clinical registry of early and established adult RA patients followed in routine care. Treatment response at 6 and 12 months was assessed by the 2011 ACR/EULAR Simple Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI) remission criteria. The SDH assessed include patient demographics, socioeconomic status, health behaviors, living condition, marital status, and depression. Variables with a $p<0.2$ in univariate analyses were included for multivariable regression. The association between SDH and remission was evaluated by logistic regression, controlling for baseline clinical RA confounders such as RA duration and baseline RA medications, presence of X-ray erosion, antibody status, extra articular features, baseline disease activities, and functional disability. All statistical analyses were performed in SAS9.4.
**Results:** Among 2209 patients with baseline CDAI, 1832 and 1583 reached the 6- and 12-month follow-up, respectively. Among 1778 patients with baseline SDAI, 1505 and 1286 reached the 6- and 12-month follow-up. At 6 months, 14.8% and 15.5% of the patients achieved CDAI and SDAI remission. At 12 months, 18.9% and 19.8% of the patients achieved CDAI and SDAI remission.
After adjusting for clinical confounders, higher neighborhood income was associated with 6-month CDAI remission (OR 1.04 per $10,000; 95%CI 1.00–1.07), while having private insurance was associated with 6-month SDAI remission (OR 0.63 95%CI 0.40–0.99 for non-insurer). At 12 months, smoking and not living alone were both associated with CDAI and SDAI remission (CDAI: OR 0.65 95%CI 0.44–0.96 for non-smoker, OR 3.02 95%CI 1.27–7.15 for not living alone; SDAI: OR 0.62 95%CI 0.40–0.96 for non-smoker, OR 2.87 95%CI 1.11–7.40 for not living alone). Living in a rural community was also associated with SDAI remission at 12 months (OR 1.79 95%CI 1.12–2.86).
**Conclusions:** Socioeconomic factors appear to have an effect on remission at 6 months. Health behavior and living environment appear to be associated with remission at 12 months. Different SDH may affect treatment response and disease outcome at different time points and this study highlights the complexity in studying SDH.

## FRI0069 DISCORDANT CLASSES OF INFLAMMATION AND PAIN IN EARLY AND ESTABLISHED RHEUMATOID ARTHRITIS: RESULTS FROM THE EARLY RHEUMATOID ARTHRITIS NETWORK AND THE BRITISH SOCIETY FOR RHEUMATOLOGY BIOLOGICS REGISTER

D.F. Mcwilliams[1,2], E. Ferguson[3], A. Young[4], P.D. Kiely[5], D.A. Walsh[1,2,6]. *[1]Arthritis Research UK Pain Centre; [2]Academic Rheumatology; [3]Psychology, University of Nottingham, Nottingham; [4]Rheumatology, West Hertfordshire Hospitals NHS Trust, St Albans; [5]Rheumatology, St George's University Hospitals NHS Foundation Trust, London; [6]Rheumatology, Sherwood Forest Hospitals NHS Foundation Trust, Sutton-in-Ashfield, United Kingdom*

**Background:** Rheumatoid arthritis (RA) disease activity is measured using DAS28 – consisting of patient-reported, clinician-observed and laboratory measures. A higher proportion of DAS28 attributed to patient-reported measures (1), fatigue, anxiety and depression might reflect augmented central pain processing.
**Objectives:** We hypothesised that subgroups of people with RA showed different contributions from inflammation and central pain mechanisms, and had different clinical needs.
**Methods:** Data were analysed from (1) The Early RA Network (ERAN) inception cohort (n=828); and British Society for Rheumatology Biologics Register (BSRBR) cohorts (2) commencing anti-TNF (n=9905) or (3) using non-biologic (control) DMARDs (n=2581). Subgroups were defined by latent class analysis (LCA) using erythrocyte sedimentation rate (ESR), swollen joint count (SJC), tender joint count (TJC), visual analogue scale-general health (VAS), and SF36 Bodily Pain, Vitality and Mental Health. Scores were standardised to permit graphical comparison. Latent classes were named with reference to disease activity and discordance/concordance of patient-reported variables with externally-measured variables. Prognosis was examined using MANOVA.
**Results:** Five, 4 and 4 latent classes were found respectively in ERAN, BSRBR anti-TNF and control cohorts. The latent classes displayed either concordance across different measures; discordantly higher patient-reported measures despite less markedly elevated ESR/SJC; or discordantly lower patient-reported measures despite elevated ESR/SJC. Latent classes with discordantly higher patient-reported measures represented 12%, 32% and 22% of the ERAN, BSRBR anti-TNF and BSRBR control cohorts respectively. The 5 latent classes found in the ERAN cohort are shown in figure 1. The proportion of people assigned with >80% probability into latent classes were 76% in ERAN, 58% in the anti-TNF and 72% in the control cohort. The latent classes showing discordantly higher patient-reported variables contained more females, and showed worse function.
In those latent classes with higher scores at baseline, the DAS28, HAQ and SF36 bodily pain scores improved over the first 12 months of follow up ($p<0.001$ for all comparisons), such that scores differed between latent classes less at follow up than at baseline. Patients in the concordant latent classes with low patient-reported measures, low SJC and ESR at baseline did not further improve after 1 year in ERAN or BSRBR-Control cohorts, and displayed clinically important worsening of Bodily Pain scores in the BSRBR anti-TNF cohort (mean at baseline: 46, at 1 year: 41; $p<0.001$).

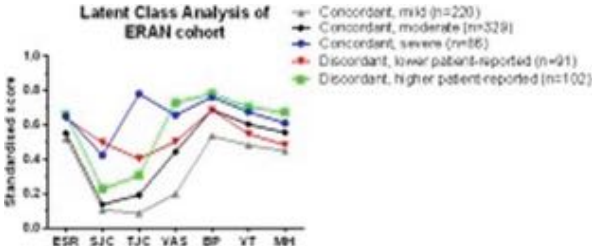

Figure 1. Latent classes showing the mean levels of each variable.

**Conclusions:** Discordant latent classes can be identified in people with RA. There might be a sizeable discordant subgroup with active RA (12 to 32%), and also a group of people with mild disease being considered for anti-TNF treatment, for whom pain management strategies might add benefit to DMARD therapy.

## FRI0070 TRAJECTORIES OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS AFTER ABATACEPT INITIATION AND THEIR ASSOCIATION WITH CLINICAL CHARACTERISTICS

D.S. Courvoisier[1], J.-E. Gottenberg[2], M.V. Hernandez[3], F. Iannone[4], E. Lie[5], H. Canhao[6], K. Pavelka[7], M. Hetland[8], C. Turesson[9], X. Mariette[10], D. Choquette[11], A. Finckh[12]. *[1]Rheumatology, University Hospitals of Geneva, Geneva, Switzerland; [2]Strasbourg University Hospital, Strasbourg, France; [3]Hospital Clinic of Barcelona, Barcelona, Spain; [4]University Hospital, Bari, Bari, Italy; [5]Diakonhjemmet Hospital, Oslo, Norway; [6]Lisbon School of Medicine, Lisbon, Portugal; [7]University Hospital, Prague, Prague, Czech Republic; [8]Rigshospitalet, Glostrup, Denmark; [9]Skåne University Hospital, Malmö, Sweden; [10]Hôpitaux Universitaires Paris-Sud, Paris, France; [11]Institute of Rhumatology, CHUM, Montreal, Canada; [12]University Hospitals of Geneva, Geneva, Switzerland*

**Background:** While the effect of disease modifying antirheumatic drugs (DMARDs) in rheumatoid arthritis (RA) is generally presented using population means, the response to DMARDs is heterogeneous. As anti-rheumatic therapy aims to become more personalized, identifying common treatment response trajectories to DMARDs is becoming more important and has major implications for clinical practice.
**Objectives:** To identify different types of trajectories in RA disease activity (DAS28) following the initiation of abatacept (ABA), a T cell costimulation inhibitor, and to examine the determinants of responders' type.
**Methods:** In this pooled analysis of nine RA registries (ARTIS, ATTRA, RHEUMADATA, DANBIO, GISEA, NOR-DMARD, ORA, SCQM, Reuma.pt), inclusion criteria were: diagnosis of RA, initiation of ABA treatment, and at least two assessments of DAS28. Patients were followed until end of ABA treatment. We used growth mixture models to identify groups of patients with similar courses of treatment response and derive empirically based trajectory subgroups. We then examined the association of these groups with socio-demographic-, disease-, and treatment-related predictors.
**Results:** 3898 patients were on ABA (mean DAS28 assessments: 5.2). Trajectory analysis identified three types of treatment response trajectories (Figure). The largest group (3576 patients, 91.7%) can be considered as "classic responders" (CR), with a mean DAS28 at baseline of 3.9 and a progressive improvement over time. The second group (219 patients, 5.6%) can be described as "rapid responders" (RR), with high DAS28 values at baseline (mean 6.4), and a marked improvement in the first two years. The third group (103 patients, 2.6%) seemed composed of "non-responders" (NR) with low DAS28 values at baseline (mean 3.8), a deterioration during the first 2 years, followed by improvement, generally related to a change in therapy.
The three groups were similar in age, sex, BMI, disease duration, and comorbidities (ie. cardiovascular, infectious, metabolic disease, smoking and cancer). However, "classic responders" group had better function at baseline (mean HAQ score: CR: 1.1; RR: 1.7; NR: 1.3, $p<0.001$), and less previous biologics failures (median [Interquartile range] previous bDMARDs: CR: 1 [1; 2]; RR: 2 [1; 3]; NR: 2 [1; 3.5], $p<0.001$).
There were more ABA discontinuation in the "non-responder" group (CR: 55.4%, RR: 61.6%, NR: 77.6%, $p<0.001$). Finally, the proportion of patients with low disease activity (DAS28<3.2) at 6 months were higher among classic responders (CR: 20.5%, RR: 3.7%, NR: 1.9%, $p=0.04$).

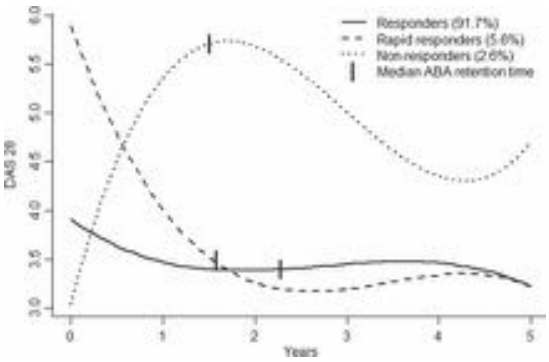

Figure 1

**Conclusions:** There are different types of responders to Abatacept treatment. However, the available baseline information did not allow determination of which trajectory the patient will follow after ABA initiation.

## FRI0071 PREDICTORS FOR THE DEVELOPMENT OF ANTI-CITRULLINATED PROTEIN ANTIBODIES IN INDIVIDUALS GENETICALLY AT RISK FOR RHEUMATOID ARTHRITIS

D. Alpizar-Rodriguez[1], L. Brulhart[1], R. Müller[2], B. Möller[3], J. Dudler[4], A. Ciurea[5], U. Walker[6], I. Von Mühlenen[6], D. Kyburz[6], P. Zufferey[7], M. Mahler[8], S. Bas[1], D. Gascon[1], C. Lamacchia[1], P. Roux-Lombard[1], K. Lauper[1], M. Nissen[1], D. Courvoisier[1], C. Gabay[1], A. Finckh[1]. *[1]HUG, Geneve; [2]KSSG, St Gallen; [3]Inselspital, Bern; [4]HFR, Fribourg; [5]USZ, Zurich; [6]USB, Basel; [7]CHUV, Lausanne, Switzerland; [8]Inova Diagnostics, San Diego, CA, United States*

**Background:** In genetically susceptible individuals, environmental factors induce a pathological activation of the immune system that may eventually lead to systemic autoimmunity and subsequent clinical manifestations. Different risk factors may be relevant for the development of this systemic autoimmunity, representing one of the phases preceding the onset of rheumatoid arthritis (RA) (1).
**Objectives:** To identify predictors for the development of systemic autoimmunity associated with RA in individuals genetically at increased risk.
**Methods:** This is an ongoing prospective cohort study of individuals at increased risk of developing RA, namely first degree relatives of patients with autoimmune diseases (FDRs). Individuals without clinical evidence of RA were enrolled and followed-up yearly. We included all individuals with available anti-citrullinated protein antibodies (ACPA) status (anti-CCP 2, 3.0, or 3.1). We used logistic regression to analyze univariable and multivariable associations between ACPA positivity and putative risk factors or symptoms, including the Connective Tissue Disease Screening Questionnaire (CSQ), 3 or more positive responses represented possible RA (2).
**Results:** A total of 1064 of FDRs were analyzed, of which 57 (5%) were ACPA-positive. FDRs had a median age of 45 (interquartile range (IQR): 34–56) years, 76% were female, 25% had at least one self-reported episode of joint swelling, however on examination only 12% had ≥1 swollen joint (Table 1). In univariable analyses, ACPA-positivity was associated with older age, female sex, tender joints (self reported, ≥1 on examination and mean count), mean swollen joint count, CSQ score and self-reported symptoms associated with possible RA by CSQ. Other variables such as tobacco smoking, alcohol consumption, obesity or tooth loss were not significantly associated with ACPA status. In women, ACPA-positivity was significantly associated with age (OR: 1.1, 95%CI: 1.0–1.1), but not in men (OR: 1.0, 95%CI: 0.9–1.1). In the multivariable adjusted analysis, older age and self-reported symptoms associated with possible RA by CSQ remained independently associated with ACPA positivity. Female sex and tobacco smoking ever had a strong but not significant association.

Table. Characteristics of analyzed FDRs

| Predictors | ACPA negative (n=1007) | ACPA positive (n=57) | Univariable OR (95% CI)[a] | Multivariable OR (95% CI)[b] |
|---|---|---|---|---|
| Age, median (IQR) | 45 (33-55) | 54 (46-60) | 1.0(1.0-1.1)[c] | - |
| Age groups, n(%) | | | | |
| <34 | 262 (26) | 6 (11) | 1 | 1 |
| 34-46 | 258 (26) | 6 (11) | 1.0 (0.3-3.2) | 0.9 (0.2-3.9) |
| 46-56 | 246 (24) | 21 (36) | 3.7 (1.6-8.4)[c] | 3.2 (1.2-8.0)[c] |
| ≥56 | 242 (24) | 24 (42) | 4.3 (1.7-10.8)[c] | 3.4 (1.3-8.5)[c] |
| Sex (female), n(%) | 759 (75) | 50 (88) | 2.3 (1.0-6.2)[c] | 2.1 (0.9-4.9) |

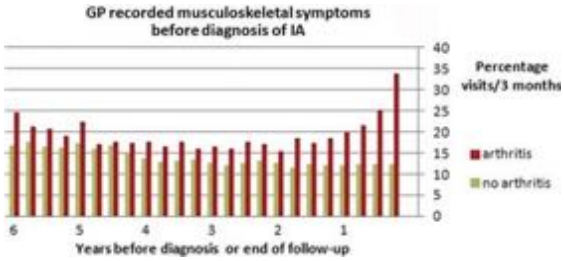
(a) Univariable logistic regression analysis
(b) Multivariable logistic regression analysis
(c) P<0.05
(d) Presence of gingivitis or toothbleeding or mobile teeth or lost bone
(e) FDRs, first degree relatives; CSQ, Connective Tissue Disease Screening Questionnaire; SE, shared epitope.



**Conclusions:** In individuals at high risk for RA, the development of ACPAs was associated with older age and self-reported symptoms related with possible RA. We found a trend for an association between female sex and tobacco smoking with ACPA positivity, which did however not reach statistical significance. These findings suggest similar risk factors for the development of ACPAs and for classifiable RA, suggesting that the development of ACPAs is a valid proxy for RA development.

## FRI0072 EARLY DETECTION OF INFLAMMATORY ARTHRITIS: THE ROLE OF MUSCULOSKELETAL SYMPTOMS, INFECTIONS AND RHEUMATOID ARTHRITIS-RELATED COMORBIDITIES IN PRIMARY CARE

M.H.V. Beers-Tas[1], M.M. Nielen[2], J.C. Korevaar[2], D.V. Schaardenburg[1]. *[1]Amsterdam Rheumatology & immunology Center, Amsterdam; [2]Nivel, Utrecht, Netherlands*

**Background:** Rheumatoid arthritis is characterized by clinically apparent inflammatory arthritis (IA). A preclinical phase has been recognized in which symptoms arise and ambulatory care utilization increases. However, information on location and timing of symptoms before IA diagnosis is still largely lacking.
**Objectives:** The present study was undertaken to identify pathogenetic clues to the development of IA and to assist early identification of future IA patients with a focus on musculoskeletal symptoms, infections and chronic comorbidities.
**Methods:** We conducted a nested case-control study using data from electronic medical records of general practitioners, participating in NIVEL Primary Care Database, to evaluate timing and numbers of visits for symptoms linked to above mentioned groups before a diagnosis of IA. Cases were adults who received a newly diagnosis of IA between 2012 and 2014, in total 2772. Retrospective follow-up had a median of 3.4 years (range 1–9). Controls were matched 1:2 on age, gender, general practice and retrospective duration of follow-up. We studied a total of 192 different symptoms or (chronic) diseases using the International Classification of Primary Care (ICPC-1) coding system. The frequency of primary care visits between the IA patients and controls were compared using logistic regression in different time periods before date of diagnosis. To investigate which of the individual symptoms or diseases were seen often, chisquare tests (chi2) were performed to evaluate the difference in frequency of these symptoms in the IA-patients compared to the controls.
**Results:** The consultation rate for musculoskeletal symptoms was increased in IA patients within the last 1.5 years before diagnosis with odds ratios (ORs) of 1.8 (confidence interval; CI: 1.6–2.1, p-value<0.05), 1.4 (CI 1.2–1.6, p<0,05) and 1.3 (CI 1.1–1.5, p<0.05), respectively, at 6, 12 and 18 months before diagnosis. For infections, the consultation rate was significantly higher 6 and 18 months prior to diagnosis (OR=1.2; both CI: 1.1–1.4, p-value<0.05). Finally, for IA-related disease and other chronic diseases a significant difference was observed only 3 months before diagnosis with ORs of 1.2 (CI 1.02–1.3, p<0.05) and 1.3 (CI 1.1–1.5, p<0.05) respectively. All ORs are corrected for age and gender. Important contributors to the above mentioned significance levels were presence of shoulder complaints (16.1% in the IA-patients versus 9.6% in the controls; chi2 73.9, p<0.001), hand/finger complaints syndrome (12.2% versus 5.6%; chi2 112.5, p<0.001), carpal tunnel syndrome (5% versus 2.5%; chi2 37.1, p<0.001) and foot/toe complaints (15.2% versus 9.2%; chi2 67.0, p<0.001). Numbers of individual infections were too small to find any statistical differences between the groups.

**Conclusions:** We found significantly increased consultation rates in general practice for musculoskeletal symptoms and infectious diseases prior to the diagnosis of IA. This diverging trend started 4–6 years before diagnosis, but becomes statistically significant around 1.5 years preceding diagnosis. IA-related comorbidities and chronic diseases also show this trend, however this did not reach significance until nearly at the IA date. Possibly, these symptoms can be used to develop methods for earlier detection of IA in general practice.

## FRI0073 FIRST REPORT OF SYMPTOMS USING THE SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS (SPARRA) QUESTIONNAIRE

M.V. Beers-Tas[1], L.V. Tuyl[1], K. Raza[2], R. Stack[2], A. Finck[3], D. Courvoisier[3], A. Catrina[4], A. Hensvold[4], E. Mosor[5], T. Stamm[5], D.V. Schaardenburg[1].
*[1]Amsterdam Rheumatology & immunology Center, Amsterdam, Netherlands; [2]Institute of Inflammation and Ageing, University of Birmingham, United Kingdom; [3]University hospital of Geneva, Geneva, Switzerland; [4]Karolinska university, Stockholm, Sweden; [5]Section for Outcomes Research, CeMSIIS, University of Vienna, Austria*

**Background:** Persons at risk of rheumatoid arthritis (RA) may experience a variety of symptoms[1,2]. However, information on location, timing, severity and predictive value of these symptoms is largely lacking. The Symptoms in Persons At Risk of Rheumatoid Arthritis (SPARRA) questionnaire has been developed with support of EULAR to provide more insight into these symptoms.
**Objectives:** Report the symptoms and symptom complexes using the SPARRA questionnaire in an international group of arthralgia patients at risk of developing RA.
**Methods:** The SPARRA questionnaire contains questions on presence, severity, impact and location of 13 symptoms derived from a qualitative study in seropositive arthralgia patients[1]. The items are: joint pain or swelling, joint stiffness, burning and tingling sensations, numbness, changes in skin colour, muscle cramps, weakness, fatigue, emotional distress, concentration difficulties and sleep problems. Answers are given on an ordinal scale. If present, number of days with a symptom per month (0, 1–5, 6–15, 16–30 days), severity (none, mild, moderate and severe) and influence (no, small, moderate or high impact) were recorded. Secondly, we recorded the location of joint pain. Finally, patients were asked to describe the pattern of symptom development over time. Patients were included in the Netherlands (N=68), United Kingdom (N=16), Sweden (N=15), Austria (N=11) and Switzerland (N=21). Validation of the questionnaire is ongoing.
**Results:** Of 131 arthralgia patients included, 85 were positive for anti-citrullinated protein antibodies (ACPA), 29 were positive for rheumatoid factor only, and 17 were seronegative with clinically suspect arthralgia. Most symptoms were present in a high percentage of patients, with pain as the most often experienced symptom and change of skin color rarely reported. When a symptom was present, it was usually experienced as moderate to severe, and with moderate impact by half of the patients (Table 1). The mean presence of symptoms was similar in the ACPA positive and negative groups, however, ACPA positive patients more often had severe symptoms (mean 61% versus 54%, NS) with higher impact (48% versus 41%, NS). Joint pain was most frequently located in the fingers. The most frequently reported pattern of symptoms was "coming and going, but always present" (32%).

Table 1. First results from the SPARRA questionnaire (N=131)

| Items | Duration At least 1 day in the past month | Severity If present, moderate to severe | Influence If present, moderate or high impact |
|---|---|---|---|
| Joint pain | 79% | 66% | 54% |
| Joint swelling | 35% | 52% | 50% |
| Joint stiffness | 69% | 68% | 44% |
| Burning sensations | 29% | 63% | 60% |
| Tingling sensations | 39% | 56% | 39% |
| Numbness | 27% | 49% | 44% |
| Change in skin colour | 15% | 40% | 25% |
| Muscle cramps | 41% | 41% | 21% |
| Weakness or loss of strength | 62% | 67% | 54% |
| Fatigue | 72% | 76% | 65% |
| Emotional distress | 52% | 54% | 43% |
| Concentration difficulties | 37% | 56% | 48% |
| Sleep problems | 54% | 70% | 52% |

**Conclusions:** The first results of the SPARRA questionnaire show multiple symptoms to be present in a high percentage of persons at risk for RA. These are often experienced as severe, with a high impact.

## FRI0074 THE PATIENT GLOBAL ASSESSMENT OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: IDENTIFICATION OF UNDERLYING LATENT FACTORS USING PRINCIPAL COMPONENTS ANALYSIS

D.N.V. Challa, Z. Kvrgic, C.S. Crowson, E.L. Matteson, T.G. Mason, S.T. Persellin, C.J. Michet Jr., T. Wampler Muskardin, K. Wright, J.M. Davis III.
*Rheumatology, Mayo Clinic, Rochester., Rochester., United States*

**Background:** The patient global assessment of disease activity is a crucial component of validated disease activity scores, response criteria, and the ACR/EULAR definition of remission in rheumatoid arthritis (RA). Recent work has shown that the patient global reflects persistent undifferentiated symptoms of pain, fatigue, and functional disability, occasionally despite seeming attainment of low inflammatory disease activity. The absence of a conceptual framework for evaluating patients in this scenario is a critical barrier to improving patient-centered outcomes.
**Objectives:** To identify underlying latent factors driving the patient global assessment of disease activity using a quantitative, multivariable data reduction approach.
**Methods:** This was a prospective cross-sectional study of 70 patients with RA fulfilling the ACR/EULAR 2010 classification criteria. Data were collected from the most recent rheumatology visit, including the patient and provider global assessments of disease activity (0–100 mm), tender and swollen joint counts, and current RA drug therapies. The patient sample was stratified to include 50 "discordant" patients (i.e., patient global assessments of disease activity were $\geq$25 mm higher than the provider global assessments) and 20 "concordant" patients. Co-morbid anxiety, depression, osteoarthritis, and fibromyalgia by provider diagnosis were abstracted from the complete electronic medical records. Participants completed several validated patient-reported outcome measures (PROMs), including measures of pain and pain interference, fibromyalgia, physical function, ability to participate, anxiety, depression, and fatigue. Data were evaluated using exploratory principal component analysis (PCA) as a data reduction method to determine the latent constructs in the data. Linear regression models were then used to determine the variability in patient global assessment explained by the PCA scores.
**Results:** The 70 patients had a mean age of 61 years, mean RA duration of 8.0 years, and 73% were female. The mean Clinical Disease Activity Index was 12.9. The mean (SD) for the patient global assessment of disease activity was 44.6 (22.7) and for the provider global assessment was 20.1 (17.7). PCA yielded 8 factor scores that represented domains of pain, fatigue, anxiety, depression, advanced age and degenerative arthritis, physical disability, fibromyalgia, and unknown. Linear regression analysis showed that pain explained the greatest variability in the patient global assessment of any of the factor scores (adjusted R-squared value: 0.06). The factor scores for pain, depression and anxiety, inability to participate, fibromyalgia, and advanced age were all significantly associated with the patient global assessment and altogether explained 33% of the variability in the patient global assessment.
**Conclusions:** Pain, depression and anxiety symptoms, inability to participate, fibromyalgia, and advanced age are key drivers of the patient global assessment. Future studies are warranted to develop a standardized approach to management of these factors toward the realization of patient-centered treat-to-target strategies for RA.

## FRI0075 EFFECTS OF DMARDS ON CITRULLINATED PEPTIDE AUTOANTIBODY LEVELS IN RA PATIENTS- A LONGITUDINAL ANALYSIS

G. Schett[1], C. Wunderlich[2], C. Figueiredo[3], J.F. Cobra[4], A.J. Hueber[1], A. Kleyer[1], J. Rech[5]. *[1]University of Erlangen-Nuremberg, Erlangen, Germany; [2]Department of Rheumatology and Clinical Immunology, University of Erlangen-Nuremberg; [3]Universiy of Erlangen-Nuremberg, Erlangen, Germany; [4]Instituto de Reumatologia de São Paulo, São Paulo, Brazil; [5]Department of Rheumatology and Clinical Immunology, Universiy of Erlangen-Nuremberg, Erlangen, Germany*

**Background:** Anti-citrullinated cyclic peptide 2 (CCP2) antibodiy levels are considered to be highly stable during disease-modifying anti-rheumatic drug (DMARD) therapy of rheumatoid arthritis (RA). However, no studies have actually analyzed sequential anti-CCP2 antibody levels during various DMARD therapies in a controll manner
**Objectives:** To study whether stable treatment with DMARDs affects anti-CCP2 antibody levels in patients with rheumatoid arthritis.
**Methods:** In this longitudinal observational study 100 RA patients were followed for anti-CCP2 IgG antibody (U/L) and total IgG level (mg/dL) every 6 months for a total period of 2.5 years. All patients received stable DMARD treatment during this period. Five groups comprising each 20 patients were analysed: (1) methotrexate (MTX) alone, (2) tumor necrosis factor inhibitors (TNFi), (3) tocilizumab (TCZ), (4) rituximab (RTX) and (5) abatacept (ABA).
**Results:** Baseline demographic and disease-specific characteristics were comparable between the 5 groups. Anti-CCP2 antibody levels did not show significant changes in patients treated with MTX (mean±SEM: -24.1±8.1%), TNFi (-14.0±11.1%) or TCZ (-24.3±11.3%) between baseline and the 2,5 years follow up. In contrast, anti-CCP2 antibody levels significantly decreased during treatment with RTX (-75.6±4.4%) and ABA (-82.5±3.7%). With respect to total IgG levels, no significant changes were observed with MTX (-24.1±8.1%), TNFi (-14.0±11.1%) or TCZ (-24.3±11.3%) over 2,5 years. In contrast, anti-CCP2 antibody levels significantly decreased during treatment with RTX (-75.6±4.4%) and ABA (-82.5±3.7%). Date for individual patients are summarized in Figure 1.
**Conclusions:** DMARDs targeting the adaptive immune response such as ABA and RTX significantly lowered anti-CCP2 IgG levels, while cytokine inhibitors and methotrexate had no significant effects on anti-CCP2 IgG levels. RTX is the only DMARD, which also lowers total IgG level. Lowering anti-CCP2 IgG levels is a step towards sero-conversion and immunological remission of disease.

## FRI0076 LOW DISEASE ACTIVITY OR DAS-REMISSION AS TREATMENT TARGET IN EARLY RHEUMATOID ARTHRITIS PATIENTS

G. Akdemir[1], I.M. Markusse[1], A.A. Schouffoer[2], P.B. de Sonnaville[3], B.A. Grillet[4], P.J. Kerstens[5], W.F. Lems[5,6], T.W. Huizinga[1], C.F. Allaart[1].
*[1]Rheumatology, LUMC, Leiden; [2]Rheumatology, Haga Hospital, The Hague; [3]Rheumatology, ADRZ, Goes; [4]Rheumatology, Zorgsaam, Terneuzen; [5]Rheumatology, Reade; [6]Rheumatology, Amsterdam Rheumatology and immunology Centre VUMC, Amsterdam, Netherlands*

**Background:** It is unknown what the optimum treatment target for early rheumatoid arthritis (RA) patients is.
**Objectives:** To assess which treatment target, low disease activity or disease activity score (DAS)-remission is more effective in early RA patients.
**Methods:** The BeSt study included early (≤2 years symptom duration) active (≥6 of 66 swollen joints, ≥6 of 68 tender joints, and either erythrocyte sedimentation rate ≥28 mm/hour or a visual analogue scale global health score ≥20mm) RA (1987 criteria) patients to compare 4 treatment strategies, targeted at DAS≤2.4. In arm 3 treatment started with a combination of methotrexate (MTX), sulfasalazine and a tapered high dose of prednisone. In the IMPROVED study, early arthritis patients started with MTX and a tapered high dose of prednisone, with subsequent treatment options aiming at DAS-remission (<1.6). We compared clinical outcomes during 5 years in 133 BeSt patients randomized to arm 3 with 175 IMPROVED patients who fulfilled the inclusion criteria of the BeSt study. Predictive factors for DAS<1.6 at year 1 and drug-free remission (DFR) at year 5 were assessed by logistic regression analysis.
**Results:** At baseline IMPROVED patients had a significantly lower mean±SD DAS compared to BeSt patients (4.1±0.7 vs 4.4±0.9, p=0.012) and a shorter median (IQR) symptom duration (17 (8–28) vs 23 (15–53) weeks, p<0.001) (figure). At 3 months in the BeSt study, DAS decreased by 2 to 2.4±1.0, functional ability improved from 1.4±0.7 to 0.6±0.6, 56% of patients achieved DAS≤2.4 and 20% were in DAS-remission. At 4 months in IMPROVED patients, DAS decreased >2 to 1.8±1.0, functional ability improved from 1.5±0.6 to 0.5±0.6, 72% of patients achieved DAS≤2.4 and 53% were in DAS-remission. At year 1, DAS was decreased by 2.5 in IMPROVED and 2.4 in BeSt compared to baseline, to 1.6±1.0 and 2.0±0.9, p=0.004, and more IMPROVED patients than BeSt patients had achieved DAS<1.6 (51% vs 30%, p<0.001). Similar percentages in both studies achieved DAS≤2.4 (73% in IMPROVED vs 67% in BeSt, p=0.333). By protocol, BeSt patients could not achieve DFR at year 1. DFR was achieved in 15% of IMPROVED patients. At year 5, DAS was decreased by 2.7 in IMPROVED and 2.6 in BeSt compared to baseline, to 1.5±0.8 and 1.7±0.8, respectively (p=0.014). DAS≤2.4 was achieved in 61% of IMPROVED patients and in 61% of BeSt patients (p=0.092), DAS<1.6 was achieved in 43% vs 32%, p=0.003, and DFR was achieved in 18% vs 8%, p=0.003.
Predictive factors for DAS<1.6 at year 1 were type of treatment study (OR for IMPROVED (95% CI) 2.16 (1.27–3.68)), male gender (2.31 (1.34–3.98)) and baseline tender joint count (0.94 (0.90–0.99)). IMPROVED study (3.33 (1.44–7.66)) and absence of RF (rheumatoid factor) and ACPA (anti-citrullinated protein antibodies) 4.24 (1.71–10.51) were predictive factors for DFR at year 5.
**Conclusions:** Although the treatment target was less often achieved for DAS<1.6 compared to DAS≤2.4, irrespective of baseline disease activity, patients with early active RA had better outcomes after DAS<1.6 than DAS≤2.4 targeted therapy. Male gender, low baseline tender joint count and absence of RF and ACPA were also associated with more favourable treatment outcomes.

DAS: disease activity score, ESR: erythrocyte sedimentation rate, VAS: visual analogue scale, HAQ: health assessment questionnaire, RF: rheumatoid factor, ACPA: anti-citrullinated protein antibodies, SD: standard deviation, IQR: interquartile range. Δ DAS was calculated by extracting the baseline DAS.

## FRI0077 ADHERENCE TO DISEASE ACTIVITY SCORE STEERED TREATMENT PROTOCOLS IN EARLY ARTHRITIS PATIENTS

G. Akdemir[1], I.M. Markusse[1], H.K. Ronday[2], I. Speyer[3], J.B. Harbers[4], P.J.S.M. Kerstens[5], W.F. Lems[5,6], T.W.J. Huizinga[1], C.F. Allaart[1].
*[1]Rheumatology, LUMC, Leiden; [2]Rheumatology, Haga Hospital; [3]Rheumatology, Bronovo, The Hague; [4]Rheumatology, Franciscus Hospital, Roosendaal; [5]Rheumatology, Reade; [6]Rheumatology, Amsterdam Rheumatology and immunology Centre VUMC, Amsterdam, Netherlands*

**Background:** Adherence to treatment-to-target in early arthritis patients may be target dependent.
**Objectives:** To compare physicians' adherence to treatment protocols targeted at Disease Activity Score (DAS)≤2.4 or <1.6.
**Methods:** The BeSt study compared 4 treatment strategies in 508 early rheumatoid arthritis (RA, 1987 criteria) patients, 3-monthly targeted at DAS≤2.4. Seven years later in roughly the same clinic, the IMPROVED study started with induction therapy in 479 early RA (2010 criteria) and 122 undifferentiated arthritis (UA) patients, followed by 2 treatment arms 4-monthly targeted at DAS remission (<1.6). DAS were measured by trained nurses. Physicians adjusted treatment according to the DAS. We evaluated physicians' adherence to the protocols and assessed associated opinions and conditions during 4 years by Generalized Linear Mixed Models.
**Results:** Protocol adherence (PA) over 4 years was higher in BeSt than in IMPROVED (mean over time 88% and 73%, respectively). PA decreased over time in both studies from 100% to 77% (BeSt) and to 61% (IMPROVED). Protocol violations (PV) were against treatment intensification/restart 47% in BeSt vs 67% in IMPROVED and against treatment tapering/discontinuation (42% vs 33%). If physicians did not intensify/restart, measured DAS was median 0.7 (IQR0.3;1.3) above ≤2.4 (BeSt) and 0.5 (IQR 0.2;0.8) above <1.6 (IMPROVED). If they did not taper/stop, measured DAS was 0.7 (-1.2;-0.3) lower than ≤2.4 (BeSt) and 0.6 (-0.9;-0.3) lower than <1.6 (IMPROVED). In BeSt the odds ratio (OR) for PV were higher if physicians were not satisfied with the current treatment effect 1.4 (95% CI 1.0;1.9), however in IMPROVED this was associated with less PV 0.6 (0.5;0.7) (figure). Disagreement with DAS was reported slightly more often in IMPROVED than in BeSt (mean over time 18% vs 13%). In both studies the odds for PV were

Figure: Generalized Linear Mixed Models analysis with protocol violation as outcome variable

| | BeSt n=508 | | IMPROVED n=410 | |
|---|---|---|---|---|
| **Opinion** | **OR (95% CI)** | **p-value** | **OR (95% CI)** | **p-value** |
| Not satisfied with current treatment effect | 1.4 (1.0;1.9) | 0.028 | 0.6 (0.5;0.7) | <0.001 |
| Disagreement with how DAS represents disease activity | 2.5 (2.0;3.0) | <0.001 | 4.4 (3.6;5.3) | <0.001 |
| Not satisfied with the next treatment step | 2.8 (2.3;3.4) | <0.001 | 3.5 (2.8;4.4) | <0.001 |
| **Conditions** | | | | |
| Swollen Joint Count ≤1 and Tender Joint Count ≥1 | 1.0 (0.8;1.2) | 0.898 | 3.0 (2.6;3.4) | <0.001 |
| Swollen Joint Count ≤1 and ESR ≥28 | 1.0 (0.8;1.4) | 0.787 | 1.7 (1.3;2.1) | <0.001 |
| Swollen Joint Count ≤1 and VAS patient ≥20mm | 1.1 (0.9;1.3) | 0.340 | 2.1 (1.8;2.3) | <0.001 |
| VAS patient ≥20mm higher than VAS physician | 1.4 (1.2;1.7) | <0.001 | 2.2 (1.8;2.6) | <0.001 |
| VAS physician ≥20mm higher than VAS patient | 1.4 (1.0;1.9) | 0.065 | 0.8 (0.5;1.1) | 0.191 |

DAS: disease activity score; ESR: erythrocyte sedimentation rate; VAS: visual analogue scale; OR: odds ratio; CI: confidence interval

higher if physicians disagreed with the DAS or with the next treatment step and if the visual analogue scale general health of the patient (VASpt) was ≥20 mm higher than that of the physician (VASph). In IMPROVED PV was also higher if the swollen joint count (SJC) was ≤1 but tender joint count (TJC)≥2 (3.0 (2.6;3.4)) or erythrocyte sedimentation rate (ESR) ≥28 (1.7 (1.3;2.1)), or VASpt ≥20 (2.1 (1.8;2.3)).

**Conclusions:** Adherence to DAS steered treatment protocols was high, but PV increased over 4 years. This increase was more distinct in a DAS<1.6 steered protocol, where PV were more likely if the physician disagreed with the measured DAS. This was more often against required treatment intensification than against required tapering, whereas with a target DAS≤2.4 this was balanced. Also, in a DAS<1.6 steered protocol PV occurred more often in case of potential discrepancies between detected joint swelling, pain and ESR. In a DAS≤2.4 steered protocol there were more PV if physicians were not satisfied with the current treatment effect, however in a DAS<1.6 steered protocol this was associated with less PV. These results may indicate that adherence to DAS steered protocols appears to depend at least in part on the height of the target, and in addition on how physicians feel the DAS reflects RA activity.

## FRI0078 SYMPTOM RECOGNITION AND ITS EFFECT ON HELP-SEEKING IN RHEUMATOID ARTHRITIS, BOWEL CANCER AND ANGINA: A MIXED METHODS APPROACH

G. Simons[1], J. Belcher[2], C. Morton[2], K. Kumar[3], M. Falahee[1], C.D. Mallen[2], R.J. Stack[4], K. Raza[1]. *[1]Institute of Inflammation and Ageing (IIA), College of Medical & Dental Sciences, University of Birmingham, Birmingham; [2]Keele University, Keele; [3]University of Manchester, Manchester; [4]Nottingham Trent University, Nottingham, United Kingdom*

**Background:** Rheumatoid arthritis (RA) requires treatment in its earliest stages in order to reduce the likelihood of permanent joint damage and disability. However, this therapeutic window is often missed as a result of delayed help-seeking by patients. In order to understand symptom recognition by members of the general public in the context of RA, we conducted two studies which compared symptom recognition and its effect on help-seeking for RA symptoms with symptom recognition in the context of angina and bowel cancer.

**Objectives:** To investigate the role of symptom recognition in the decision to seek appropriate and timely medical attention for RA and other illnesses.

**Methods:** We conducted a qualitative interview study with 31 individuals and a postal survey of 1088 members of the general public. Both studies used vignettes developed specifically for this study describing the symptoms of RA, bowel cancer and angina. In the case of RA one vignette described joint pain and stiffness in hands and wrists; one had joint swelling as an additional feature and we included a variation with symptoms in feet and ankles instead of hands and wrists. For each vignette, participants made causal attributions and rated the seriousness of the symptoms and the urgency with which they would seek medical attention.

**Results:** Participants were less likely to recognise the symptoms of RA than those of other conditions. This effect was more pronounced when the symptoms did not include joint swelling. In contrast, the symptoms of bowel cancer and angina were more readily recognised and were considered to be more serious than those of RA. Survey respondents rated bowel cancer and angina symptoms to be significantly more serious than any of the given combinations of RA symptoms ($Z$ values of 16.3 to 25.3, all $p<0.001$). They would also seek help faster for the symptoms of bowel cancer or angina compared to symptoms described in any of the RA vignettes (Z values of 14.7 to 34.2, all $p<0.001$). Correct causal attribution of symptoms further had more effect on the perceived urgency of help-seeking for angina and bowel cancer than it had for any of the RA vignettes.

**Conclusions:** Accurate symptom attribution and the perception that symptoms are indicative of a serious underlying condition are both important drivers for rapid help seeking. In the case of angina and bowel cancer, recent public health campaigns have promoted not only symptom recognition and seriousness, but have also emphasised the consequences of not seeking timely help. Our results suggest that these consequences should also be addressed in any public health campaign for RA.

**Acknowledgement:** This research is supported by The Dunhill Medical Trust (grant number R226/1111). The authors would also like to thank the interviewees, survey respondents and the patient research partners who have been involved in the development of the research.

## FRI0079 THE EFFECTIVENESS OF INITIAL TIGHT DISEASE CONTROL AND PAIN CONTROL FOR ACHIEVING LONG STANDING COMPREHENSIVE DISEASE REMISSION (CDR) IN RHEUMATOID ARTHRITIS TREATMENT

I. Yoshii. *Orthopaedics, Yoshii Hospital, Shimanto City, Japan*

**Background:** In recent years, comprehensive disease control (CDC) or comprehensive disease remission (CDR) is being new target of rheumatoid arthritis (RA) treatment. CDR is defined that all of three indices, 28-joint disease activity score (DAS28) less than 2.3 with C-reactive protein (CPR), yearly progress of Sharp/van der Heijde score (dSHS) within 0.5, and Health Assessment Questionnaire Disability Index (HAQ-DI) less than 0.5, are evaluated as remission. Several reports have commented that it is important to control disease activity tightly, in order to achieve CDR. However, how tight is enough to achieve is still unclear.

**Objectives:** This study is designed to clarify comparable level of DAS28 in order to achieve long-lasting CDR.

**Methods:** 421 RA patients who have been treated consecutively for more than three years, were recruited for this study. Treatment term was divided by one year's period. Patients average DAS28, dSHS, and HAQ-DI were calculated and evaluated as remission when each of indices matched as remission, while all of the three matched remission, CDR was evaluated as achieved. Probability for remission of each of the three and CDR from one year's period to the next is calculated. Probability for remission of the four indices from first year to the year after fourth was also evaluated. Sensitivity and specificity were also evaluated in the same manner.

Average DAS28 in the first year period was divided according to level for 0.1 on scale, and sensitivity and specificity of CDR in the year after fourth was evaluated for each level. Patient's average pain score measured with visual analogue scale (PS-VAS) was also calculated according to treatment year period. PS-VAS was divided by 10mm, and sensitivity and specificity of CDR in the year after fourth was evaluated for each level.

**Results:** Probability ratio for each indices were approximately 75% for DAS28, 75% for dSHS which had not changed as years passes, while 75% to 70% as years passes as gradually decreased for HAQ-DI, and 55% to 48% for CDR.

Sensitivity and specificity demonstrated more than 90% for both probabilities in every treatment year term.

CDR achievement ratio demonstrated that sensitivity gradually decreased as DAS28 increased, while specificity increased as increased. Same tendency demonstrated for PS-VAS. When DAS28 was 1.1, sensitivity demonstrated 10%, and specificity demonstrated 50%. When DAS28 was within 1.6, sensitivity kept more than 70%, however when DAS28 was 1.8, sensitivity and specificity had crossed at approximately 63% (Figure1). When PS-VAS was within 10mm, sensitivity demonstrated 80%, and specificity demonstrated 50%. When PS-VAS raised 20mm, sensitivity and specificity had crossed at approximately 58%.

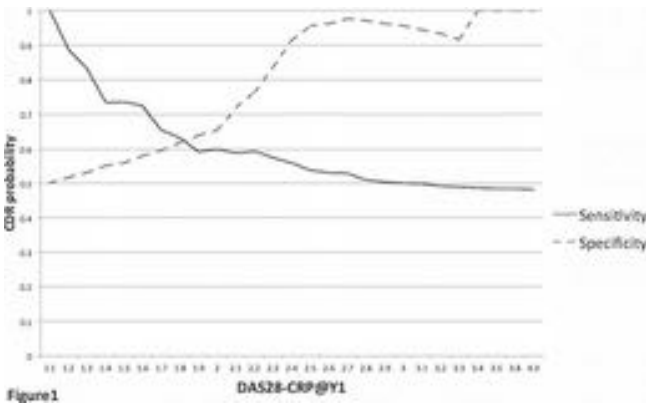

Figure1

**Conclusions:** These results suggest that initial tight disease activity control is most important in order to achieve long lasting CDR. DAS28 is controlled within 1.6 in the first year, CDR is guaranteed more than 70%. PS-VAS can perform as supplemental parameter, whereas PS-VAS is kept within 10mm, probability of CDR is maintained 80%.

## FRI0080 EFFECTS OF IL-6 RECEPTOR INHIBITION THERAPY ON THE SERUM LEVELS OF IL-33 AND IL-6 IN PATIENTS WITH RHEUMATOID ARTHRITIS

I.A. Choi[1], S.J. Lee[1,2], W. Park[3], S.H. Park[4], S.-C. Shim[5], H.J. Baek[6], D.-H. Yoo[7], H.A. Kim[8], S.K. Lee[9], Y.J. Lee[10], Y.E. Park[11], H.-S. Cha[12], E.Y. Lee[1], E.B. Lee[1], Y.W. Song[1,2]. *[1]Division of Rheumatology, Seoul National University Hospital; [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Medical Research Center, Seoul National University, Seoul; [3]Division of Rheumatology, Inha University Hospital, Incheon; [4]Division of Rheumatology, The Catholic University of Korea Seoul St. Mary's Hospital, Seoul; [5]Division of Rheumatology, Eulji University Hospital, Daejeon; [6]Division of Rheumatology, Gachon University Gil Medical Center, Incheon; [7]Division of Rheumatology, Hanyang University Medical Center, Seoul; [8]Division of Rheumatology, Hallym University Medical Center, Anyang; [9]Division of Rheumatology, Yonsei University Health System, Seoul; [10]Division of Rheumatology, Seoul National University Bundang Hospital, Seongnam; [11]Division of Rheumatology, Pusan National University Hospital, Busan; [12]Division of Rheumatology, Sam Sung Medical Center, Seoul, Korea, Republic Of*

**Background:** Several pro-inflammatory cytokines such as TNF-α, IL-1, IL-6, IL-8 and IL-15 are known to be critical in synovial inflammatory process in RA and successful results have been obtained in RA treatment with targeting pro-inflammatory cytokines including TNF-α, IL-1 and IL-6.
**Objectives:** This study sought to investigate the role of IL-33 and IL-6 in RA patients receiving IL-6 receptor inhibition therapy.
**Methods:** We analyzed the association of the IL-33 and IL-6 level with disease activity and serologic features in 83 patients with RA. We also measured the serum level of IL-33 and IL-6 before and after the administration of tocilizumab for 24 weeks in 40 patients.
**Results:** Serum IL-33 level showed significant correlation with RF (rho =0.660, $p<0.001$) but did not correlate with DAS28, ESR, hsCRP or RA duration. IL-6 level was significantly correlated with hsCRP (rho =0.482, $p<0.001$) but not correlate with DAS28, ESR, RF or RA duration. There was no correlation between serum IL-6 and IL-33 levels.
Serum IL-33 level significantly decreased after 24 weeks of IL-6 receptor inhibition in patients with RA ($p<0.001$). When comparing subgroups according to ACR20 response, serum IL-33 levels were significantly decreased after 24 weeks of IL-6 receptor inhibition therapy in ACR20 responders ($p<0.001$) but not in the non-responders (p=0.084). Baseline IL-33 levels were not significantly different between the two subgroups (p=0.765).
Serum IL-6 levels were not significantly changed after 24 weeks of IL-6 receptor inhibition therapy (median 7.1 to 8.9 pg/mL, p=0.503). Changes of IL-6 levels were insignificant both in ACR20 responders and non-responders after 24 weeks of IL-6 receptor inhibition therapy. Baseline IL-6 levels were not different between ACR20 responders and non-responders.
**Conclusions:** The use of IL-6 receptor inhibitor decreased the serum level of IL-33 and this effect seems to be led by the responder group. IL-33 could be a useful indicator to monitor the response in IL-6 receptor inhibition therapy.

## FRI0081 COMPARISON OF DISEASE BURDEN IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA), RA WITH SECONDARY OSTEOARTHRITIS (OA), AND OA IN ROUTINE CARE

I. Castrejon, J. Chua, A.M. Malfait, J.A. Block, T. Pincus. *Rheumatology, Rush University Medical Center, Chicago, United States*

**Background:** Recent data indicate that the disease burden experienced by patients with osteoarthritis (OA) is similar to or greater than in rheumatoid arthritis (RA)[1]. Many patients with RA may have secondary OA, which may affect disease burden and clinical management.
**Objectives:** To compare disease burden in patients with RA, RA with 2° OA, and OA, according to scores on a multi-dimensional health assessment questionnaire (MDHAQ) and physician RheuMetric checklist
**Methods:** At one academic rheumatology center, all patients with all diagnoses complete an MDHAQ. The MDHAQ includes 0–10 scores for physical function (FN), pain (PN), and patient global estimate (PATGL), compiled into a 0–30 composite routine assessment of patient index data (RAPID3), and a 0–48 RA disease activity index (RADAI) self-reported joint count. In addition, physicians complete a RheuMetric checklist, which includes four 0–10 visual analog scales (VAS) for overall physician global (DOCGL), inflammation or reversible findings (DOCINF), damage or irreversible findings (DOCDAM), and patient distress unexplained by DOCINF or DOCDAM (e.g. fibromyalgia, depression) (DOCSTR). Patients were classified as RA, RA with 2° OA, and OA, according to medical record diagnoses. Measures were compared in the 3 groups by MANOVA, adjusted for age.
**Results:** 669 patients seen in routine care between September 2014 and June 2015 were studied, including 248 with RA, 47 with 2° OA (16% of all RA), and 374 with OA. Patients with OA were significantly older, but no differences were seen in formal education or gender. MDHAQ scores indicated substantial disease burden in all 3 diagnosis groups, although least in RA patients with no 2° OA, intermediate in RA patients with 2° OA, and greatest in patients with primary OA, e.g., RAPID3 was 11.0±7.7, 12.3±6.7, and 15.1±6.3 in the 3 groups, respectively (Table) ($p<0.001$ adjusted for age). Among RheuMetric checklist scores, DOCGL did not differ significantly in the 3 groups; DOCDAM was higher than DOCINF in all 3 groups, but differed by 0.7 /10 units in RA vs 1.6 units in RA with secondary OA and 3.2 units in patients with primary OA (Table).

| | RA N=248 | RA with secondary OA N=47 | OA N=374 | P |
|---|---|---|---|---|
| Demographic measures | | | | |
| Age, mean, years | 56.8 | 62.4 | 66.3 | <0.001 |
| Education level, mean, years | 13.7 | 14.1 | 13.5 | 0.48 |
| Female, % | 85.8% | 80.6% | 88.1% | 0.20 |
| MDHAQ: Mean patient self-report scores | | | | |
| MDHAQ-Function | 2.4 | 2.8 | 2.8 | 0.12 |
| MDHAQ-Pain | 4.7 | 5.0 | 6.3 | <0.001 |
| MDHAQ-PATGL | 4.2 | 4.5 | 5.6 | <0.001 |
| RAPID3 (0–30) | 11.0 | 12.3 | 15.1 | <0.001 |
| RADAI (0–48) | 10.7 | 10.5 | 12.1 | 0.32 |
| RheuMetric: Mean physician estimates | | | | |
| DOCGL | 3.7 | 3.9 | 4.0 | 0.28 |
| DOCDAM | 2.9 | 3.4 | 4.1 | <0.001 |
| DOCINF | 2.2 | 1.8 | 0.9 | <0.001 |
| DOCSTR | 1.1 | 0.5 | 1.6 | 0.03 |

**Conclusions:** Patients with OA appear to have a greater disease burden than those with RA; the disease burden is intermediate in RA patients who have 2° OA. The low DOCINF relative DOCDAM in RA patients may help explain why RA remission rates are well below 100% even though inflammation appears to be effectively controlled. Patient MDHAQ and physician RheuMetric are useful and feasible to assess and monitor rheumatic diseases in busy clinical settings

## FRI0082 SUBCLINICAL MRI INFLAMMATION DOES NOT PREDICT RELAPSE RISK IN RHEUMATOID ARTHRITIS PATIENTS TAPERING DMARDS

I. dOliveira[1], W. Mensing[1], C. Figueiredo[1], M. Englbrecht[1], J. Haschka[1,2], A. Hueber[1], A. Kleyer[1], A. Cavallaro[3], G. Schett[1], J. Rech[1]. *[1]Rheumatology Immunology, University Erlangen-Nuremberg, Erlangen, Germany; [2]Medical Department II, St Vincent Hospital, Vienna, Austria; [3]Department Radiology, University Erlangen-Nuremberg, Erlangen, Germany*

**Background:** Tapering and stopping DMARD treatment attracts growing interest due to the steady increase in rheumatoid arthritis (RA) patients achieving sustained disease remission. Since only a subset of RA patients in remission can successfully taper or stop these drugs, reliable predictors, which can help to identify patients with high risk for relapse, need to be detected. In the randomized controlled RETRO study[1] we recently showed that a serum marker (MBDA) indicating residual inflammation was able to predict the relapse risk in the context of DMARD tapering[2].
**Objectives:** To test whether presence of residual inflammation in the magnetic resonance imaging (MRI) is associated with a higher relapse risk in RA patients tapering or stopping DMARD treatment.
**Methods:** Baseline MRI scans were available from 55 patients of the randomized controlled RETRO study. All patients had RA (ACR/EULAR 2010 criteria) in sustained remission (DAS28 <2,6 for at least 6 months) with stable DMARD treatment for at least 6 months. Patients either continued on their DMARD regimen (Arm1), tapered it by 50% (Arm 2) or stopped it after a 6 month tapering phase (Arm3). Follow-up period was 12 months. MRI scans were scored for synovitis, osteitis and tenosynovitis according to RAMRIS and Haavardsholm scores[3,4].
**Results:** MRI synovitis was found in 58%, MRI osteitis in 26% and MRI tenosynovitis in 24% of the patients. Prevalence of baseline MRI changes did not differ between patients experiencing relapse of RA or remaining in remission (62% in both groups, p=0,981). Also, baseline MRI scores were not different between patients relapsing or not relapsing: Median (IQR) total RAMRIS scores in the relapse group were 9 (3,5–48) and in the non-relapse group 8 (2,75–14,5) (p=0,27), median synovitis scores were 3 (0–7) and 1 (0–6) (p=0,65), median osteitis scores 0 (0–0,25) and 0 (0–3,5) (p=0,48) and tenosynovitis scores 0 (0–0,25) and 0 (0–0,5) (p=0,82) respectively. Furthermore, MRI synovitis, osteitis and tenosynovitis scores were not different between ACPA+ than ACPA- individuals (p=0,80, 0,82, and 0,95, respectively).
**Conclusions:** Subclinical MRI changes are frequent in RA patients in sustained remission but do not predict the risk of disease relapse during DMARD tapering.

## FRI0083 FACTORS ASSOCIATED WITH THE NEED FOR BIOLOGICAL THERAPIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Cuadros, J.L. Andreu, I. Millan, M. Bascuas, C. Ramos, M. Espinosa, B.J. Flores, J. Campos, J. Sanz. *Rheumatology, H.U. Puerta de Hierro Majadahonda, Majadahonda, Spain*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disorder that leads to an irreversible destruction of diarthrodial joints. Early diagnosis and treatment with disease-modifying antirheumatic drugs (DMARDs) are considered essential in order to achieve an optimal suppression of disease activity and prevent structural and functional deterioration. Biological therapy (BT) is the second-line treatment in case of inadequate response to DMARDs. BT has excellent safety and efficacy profiles. However, its economic burden is high.
**Objectives:** The goal of our study was to identify clinical, epidemiological and analytical characteristics, as well as the delay of diagnosis, DMARD treatment, and inflammatory activity, associated with the need to initiate BT in RA patients.
**Methods:** This is a single-center case-control study. We included patients who were diagnosed with RA from January 1, 2000, fulfilling the 2010 ACR/EULAR criteria. The main outcome (dependent variable) was the need for a first biological drug. The independent variables were time to diagnosis, time to treatment with the first DMARD, time to clinical remission, time to low activity, age, gender, number of swollen joints (NSJ) and tender joints (NTJ) at the time of diagnosis, positivity of RF and ACPA, CRP, ESR, radiologic erosions, smoking, body mass index, education level, and job status. The study was approved by the research ethical committee of our center. Descriptive statistics was used to present the results; chi-square test, Student t test, and Mann-Whitney U test were used to define statistical significance in the univariate analysis; and logistic regression for multivariate analysis. A *P*-value $<0.05$ was predefined as statistical significance. Statistical analyses were performed by using the SPSS v14.0.
**Results:** One hundred and thirty-nine patients were included (mean age 53 years; 82% women; 83% white; 82% RF+; 74% ACPA+). Sixty-one patients (44%) had received BT. The univariate analysis demonstrated significant association between the need for BT and NTJ ($p<0,001$), NSJ (p=0,004), ESR (p=0,026), time to low disease activity ($p<0,001$) and time to remission ($p<0,001$). The multivariate logistic regression indicated that the NTJ at diagnosis, the time to low activity and the time to remission were independently associated with the need for BT during follow-up.
**Conclusions:** In RA patients, the number of tender joints at the time of diagnosis and the time to low disease activity and clinical remission are associated with the need for BT during the course of the disease.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3016

## FRI0084 CLINICAL, ULTRASONOGRAPHIC AND IMMUNOLOGIC BIOMARKERS OF RAMRIS PROGRESSION IN RA PATIENTS IN CLINICAL REMISSION: A PROSPECTIVE STUDY OF 12 MONTHS OF FOLLOW-UP

J. Ramírez[1], J.A. Narvaez[2], V. Ruiz-Esquide[1], J. Hernández[2], R. Celis[1], A. Cuervo[1], M.V. Hernández[1], J. Inciarte-Mundo[1], R. Sanmartí[1], J.D. Cañete[1]. *[1]Arthritis Unit, Rheumatology Dpt, Hospital Clínic de Barcelona; [2]Radiology, Musculoeskeletal section, Hospital de Bellvitge, Barcelona, Spain*

**Background:** A high proportion of patients with rheumatoid arthritis (RA) in clinical remission (CR) present subclinical synovitis when evaluated by sonography. Most prospective studies on baseline biomarkers of radiographic progression in this patients not include immunological biomarkers that could be of interest to better identify the residual inflammatory activity.
**Objectives:** To determine clinical, serological and ultrasonografic variables predicting progression of structural damage as evaluated by MRI at 12 months (mo.) of follow-up in a cohort of RA patients in CR.
**Methods:** We included 42 RA patients in CR defined as DAS28-ESR$<2.6$ for $>6$ mo. Complete clinical and biological assessment, ultrasonography of two hands and MRI of dominant hand were performed at baseline and after 12 mo. We analyzed risk factors related with RAMRIS progression with multivariate lineal models.
**Results:** 42 patients were included (76.7% female). Mean age was 53.5 years, body mass index (BMI) 26.7 kg/m$^2$. Disease and remission median duration were 94 and 37 mo. respectively. 73.8% RF[+] patients and 85.7% ACPA [+]. RAMRIS 10.3 and erosion (RAMRIS) 18.8. At baseline, 66.7% had power-doppler (PD) signal and 45.2% also had synovial hyperplasia grade $\geq 2$, so fulfilling the criteria of previously defined ultrasound defined active synovitis (UdAS)[1]. The risk factors more related with RAMRIS progression at 12 mo. were baseline RAMRIS, BMI, disease duration, low-dose prednisone treatment, absence of csDMARDs treatment and presence of UdAS. Synovitis as defined by only PD positive signal was no associated to erosions.
We excluded the baseline RAMRIS in the multivariate model because it was the strongest predictor factor. We observed that higher serum levels of calprotectin and ENA78 at baseline were significant predictors. Absence of csDMARD treatment, disease duration and the presence of UdAS also remained as independent predictive factors (Table 1).

Table 1. Risk factors and prognostic biomarkers associated with a higher score at one year RAMRIS

| Risk factor | Unadjusted | | Adjusted | |
|---|---|---|---|---|
| | β (95% CI) | p-value | β (95% CI) | p-value |
| Baseline calprotectin levels | r=0.195 | 0.216 | 4.6 (1.2–8) | 0.009 |
| Baseline log2(ENA78) levels | r=0.342 | 0.027 | 5.7 (0.4–11.1) | 0.037 |
| Longer disease evolution | 0.08 (0.003–0.15) | 0.043 | 0.07 (0.01–0.13) | 0.027 |
| No treatment with DMARDs | 19.9 (2.6–37.2) | 0.026 | 18.6 (3.8–33.3) | 0.015 |
| UdAS | 16.7 (3.1–30.3) | 0.017 | 17.1 (6.1–28.2) | 0.003 |
| Predictive value of the model | Model indexes | | | |
| R, R2 (R2 adjusted) | 70%, 49%, (41.9%) | | | |
| Overall significance of the model | <0.0001 | | | |

**Conclusions:** This prospective study confirms a high prevalence of UdAS in patients with RA in CR, which is an independent risk factor to develop structural damage progression at 12 months of follow-up. Baseline RAMRIS, BMI, disease duration, absence of csDMARDs therapy, UdAS, and baseline levels of calprotectin and ENA78, were independent predictors of RAMRIS progression.

## FRI0085 FOREFOOT DISEASE ACTIVITY HAS THE IMPACT ON BOOLEAN REMISSION IN JAPANESE RHEUMATOID ARTHRITIS PATIENTS

K. Tokunaga[1], A. Shiraishi[2], S. Takenouchi[1], R. Yokochi[1], K. Muranaka[1], M. Shinozaki[1], N. Hagino[1], J. Nishino[3], S. Tohma[4]. *[1]Department of Rheumatology, Teikyo University Chiba Medical Center, Ichihara City, Chiba; [2]Trauma and Acute Critical Care Medical Center, Medical Hospital of Tokyo Medical and Dental University; [3]Department of Orthopaedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo; [4]Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, Sagamihara National Hospital, Sagamihara, Japan*

**Background:** Treat-to-target (T2T) is recommended and a widely accepted management strategy for rheumatoid arthritis (RA), which aims for remission or low disease activity. Disease activity is valuated by some composite measures which includes patient's and physician's global assessment, finding of joints and C reactive protein (CRP) etc. Patient's global assessment (PGA) is often the limiting factor for achieving remission. It remains unclear what is the factor contributing to elevation of PGA when finding of 28 joints and CRP implement the Boolean remission criteria.
**Objectives:** To detect the factor contributing to elevation of PGA among Japanese RA patients whose scores on the tender joint count, swollen joint count and CRP (in mg/dl) are all 1 or less.
**Methods:** We performed an analysis of data from 15032 RA patients registered in the large database (NinJa: National Database of Rheumatic Diseases by iR-net in Japan) of 2014 (1). Patients whose scores of the tender joint count, swollen joint count and CRP (in mg/dl) were all 1 or less were included. Patients whose PGA was 1 or less and patients whose PGA was more than 1 were compared with a probabilistic approach employing logistic regression to investigate factor contributing to elevation of PGA among Japanese RA patients whose scores on the tender joint count, swollen joint count and CRP are all 1 or less.
**Results:** Seven thousand and two hundred and twenty-four patients were included; 5754 were women (79.7%) with a median age 65 years, a median disease duration 9 years, 826 (11.4%) had swelling or tenderness of forefoot joints which are not included in 28 joints (forefoot disease activity), 2313 (32.0%) were prescribed glucocorticoid, methotrexate 4993 (69.1%), biologic DMARDs 1986 (27.5%). In two groups; PGA $\leq 1$ 3584 (49.6%) and PGA $>1$ 3640 (50.4%), the median modified health assessment questionnaire (mHAQ) was 0 (interquartile range: 0–0) and 0.13 (0–0.63), hospital anxiety and depression scale (HADS)-anxiety (A) was 2 (1–4) and 4 (2–7), HADS-depression (D) was 4 (2–6) and 5 (3–8), forefoot disease activity was 226 (6.3%) and 600 (16.5%), respectively. We

performed the logistic regression analysis with age, Steinbrocker's stage, mHAQ, HADS-A, HADS-D and forefoot disease activity. Thereafter all variables were found factors of associating to elevation of PGA (Table).

| Variable | OR (95% CI) | VIF |
|---|---|---|
| age, per decade | 1.08 (1.02, 1.13) | 1.05 |
| mHAQ | 3.62 (2.94, 4.49) | 1.21 |
| Steinbrocker's stage | 1.20 (1.13, 1.28) | 1.12 |
| HADS-A | 1.07 (1.04, 1.09) | 1.37 |
| HADS-D | 1.04 (1.02, 1.07) | 1.36 |
| forefoot disease activity | 2.56 (2.05, 3.20) | 1.01 |

**Table. Logistic regression analysis model for PGA elevation**
CI: confidence interval; HADS-A: hospital anxiety and depression scale-anxiety; HADS-D: hospital anxiety and depression scale-depression; mHAQ: modified health assessment questionnaire; OR: odds ratio; PGA: patient's global assessment; VIF: variance inflation factor

**Conclusions:** Forefoot disease activity, mHAQ, HADS-A and HADS-D contribute to elevation of PGA in patients who implement the Boolean remission criteria except PGA in Japanese rheumatoid arthritis patients. We should care about the foot joints in addition to functional disability and psychological distress for implementation of T2T strategy.

## FRI0086 BEFORE CLINICALLY DETECTABLE ARTHRITIS DEVELOPS, ACPA-POSITIVE AND ACPA-NEGATIVE ARTHRALGIA PATIENTS HAVE DIFFERENT SYMPTOMS

L.E. Burgers, H.W. van Steenbergen, L. Mangnus, T.W.J. Huizinga, A.H.M. van der Helm-van Mil. *Rheumatology, Leiden University Medical Centre, Leiden, Netherlands*

**Objectives:** Anti-citrullinated protein antibody (ACPA)-positive and ACPA-negative rheumatoid arthritis (RA) have different genetic risk factors and underlying biological mechanisms. Therefore, we hypothesized that patients' characteristics in the symptomatic phase before clinical arthritis has emerged are also different. We investigated this by studying the arthralgia phase of ACPA-positive and ACPA-negative patients.

**Figure 1: Duration of symptomatic disease phase before arthritis development split up in (1) the time between start of symptoms and inclusion in the CSA cohort and (2) the time between inclusion and development of clinically detectable arthritis**

The left bottom graph presents the time between the onset of first symptoms and inclusion in the CSA cohort (p=0.32). The right upper graph presents the time between inclusion in the CSA cohort and conversion to arthritis (p= 0.04). In the left lower graph the curve increases when symptoms start. In the right upper graph every step up indicates a patient developing arthritis.
Inclusion in CSA cohort generally coincided with first presentation at the outpatient clinic.

**Methods:** Patients included in a clinically suspect arthralgia (CSA)-cohort were followed for 2 years or until arthritis development. At inclusion, information on initial symptoms and current symptoms was obtained, physical examination and MRI performed and blood samples taken. A comparison was made between ACPA-positive and ACPA-negative CSA-patients that later developed arthritis.

**Results:** 35 patients (17-ACPA-positive, 18 ACPA-negative) included between April 2012 and May 2015 developed arthritis. 88% of ACPA-negative patients experienced morning stiffness as an initial symptom, compared to 40% of ACPA-positive patients (p=0.01). ACPA-positive patients more often had symptoms in both upper and lower extremities than ACPA-negative patients (35% versus 6%, p=0.03). Important reasons for rheumatologists to identify CSA was morning stiffness in ACPA-negative patients (38% versus 7%, p=0.04) and inflammatory-type arthralgia in ACPA-positive patients (67% versus 19%, p=0.01). ACPA-positive patients had a longer symptom duration at first presentation (median of 22.4 weeks versus 10.6 weeks, Figure 1) but converted to arthritis quicker (median 6.9 versus 15.9 weeks after inclusion, p=0.04, Figure 1). A combination of variables clustered ACPA-positive and ACPA-negative patients in PLS-analysis.

**Conclusions:** In the phase preceding clinical arthritis, ACPA-negative and ACPA-positive arthralgia patients have different characteristics. This contributes to the notion that ACPA-positive and ACPA-negative RA are different disease subsets.

## FRI0087 PREDICTORS FOR ATTAINING REMISSION AT TWO CONSECUTIVE VISITS IN NEWLY DIAGNOSED EARLY RA PATIENTS

M. Kuijper[1,2], J. Luime[2], P. de Jong[1], A. Gerards[3], J. van Zeben[4], I. Tchetverikov[5], P. de Sonnaville[6,7], M. van Krugten[8], B. Grillet[9], M. Hazes[2], A. Weel[1]. *[1]Rheumatology, Maasstad Ziekenhuis; [2]Rheumatology, Erasmus Mc, Rotterdam; [3]Rheumatology, Vlietland Ziekenhuis, Schiedam; [4]Rheumatology, Sint Franciscus Gasthuis, Rotterdam; [5]Rheumatology, Albert Schweitzer Ziekenhuis, Dordrecht; [6]Rheumatology, Reumazorg Zuid West Nederland; [7]Rheumatology, Admiraal de Ruyter Ziekenhuis, Goes; [8]Rheumatology, Reumazorg Zuid West Nederland, Vlissingen; [9]Rheumatology, Reumazorg Zuid West Nederland, Terneuzen, Netherlands*

**Background:** Early and intensive treatment with DMARDs are essential for remission induction in newly diagnosed RA patients. However, demographic, psychosocial and disease related factors may play a role as well.

**Objectives:** To investigate which demographic, psychosocial and disease related factors are associated with attaining remission at two consecutive visits in early RA patients treated in a treat-to-target manner

**Methods:** We used 12 months follow-up data from patients participating in the tREACH trial[1,2] in which induction therapy strategies were compared:

**Table 1 Predictors for attaining remission**

* Backward selection, variables with p<0.20 in univariate analysis were entered

(A) combination high dose conventional therapy ((MTX + sulfasalazine + hydroxychloroquine or (B) MTX. Both groups had glucocorticoid (GCs) bridging. Disease activity (DAS) was assessed every 3 months. Remission was defined as DAS<1.6 at 2 consecutive visits (3 months). Univariate and multivariate logistic and Cox regression analyses were performed including demographic, disease related and psychosocial factors evaluated at baseline as predictors for attaining remission during 12 months of follow-up.

**Results:** 281 patients (68% female; mean DAS 3.4, median HAQ 1.00) were included. During 1 year of follow-up, 129 of 281 (46%) patients (group A: 90 (49%), group B: 39 (40%)) attained remission at 2 consecutive visits. 76/281 (27)% achieved remission within 6 months. Univariate analyses revealed that female sex was associated with a lower chance of attaining remission (demographic factors). Similar relations were observed for higher DAS, HAQ and worse physical functioning (disease factors) and higher levels of anxiety, depression, fatigue and passive coping with pain and lower levels of mental functioning and internal locus of control (psychosocial factors). In multivariate analyses, female sex, treatment and higher levels of fatigue were associated with a lower chance to attain remission within 6 months, whereas older age, female sex and higher levels of depression were associated with increased time to remission within 12 months.

**Conclusions:** In the tREACH trial, 46% of early RA patients attained remission within 1 year of follow-up. Female sex, higher baseline DAS, HAQ, and several psychosocial factors were predictors for attaining remission, but in the final models age, sex, baseline DAS, fatigue and depression remained. Results suggest that high levels of fatigue and depressive symptoms may prevent patients from attaining remission despite treatment according to a tight control and treat-to-target strategy.

## FRI0088 COMPARISON OF RHEUMATOID FACTOR, ANTI-CITRULLINATED PROTEIN ANTIBODIES, ANTI-CARBAMYLATED PROTEIN ANTIBODY, ANTI-PEPTIDYL ARGININE DEIMINASE TYPE-3 ANTIBODIES AND CALPROTECTIN IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS

M.J. Nissen[1], C. Lamacchia[1], S. Bas[1], P. Roux-Lombard[1], D. Courvoisier[1], D. Kyburz[2], B. Moeller[3], A. Ciurea[4], R. Mueller[5], P. Zufferey[6], C. Bentow[7], A. Finckh[1], M. Mahler[7], C. Gabay[1]. *[1]University Hospital, Geneva; [2]University Hospital, Basel; [3]University Hospital, Berne; [4]University Hospital, Zurich; [5]Hospital, Saint Gallen; [6]University Hospital, Lausanne, Switzerland; [7]Inova Diagnostics, San Diego, United States*

**Background:** A significant proportion of patients with Rheumatoid Arthritis (RA) are negative for rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA). There is a unmet need for new biomarkers to better define the severity and prognosis of RA.

**Objectives:** To study the sensitivity and specificity of numerous auto-antibodies and calprotectin in RA patients compared with patients with spondyloarthritis (SpA) and to investigate the relationship between these biomarkes and measures of disease activity and severity.

**Methods:** Data was obtained from the "Swiss Clinical Quality Management" (SCQM) registry which recruits adults with RA, psoriatic arthritis (PsA) and axial spondylarthritis (axSpA). All patients with a Biobank sample were tested for RF (IgM and IgA, QUANTA Flash (QF), Inova), ACPA (anti-CCP2 (Eurodiagnostica) and anti-CCP3 (IgG QF and QUANTA Lite (QL) and IgA QF, Inova), anti-carbamylated proteins (anti-CarP, carbamylated fetal calf serum, prototype ELISA, Inova), anti-peptidyl arginine deiminase type-3 antibodies (anti-PAD3-E.Coli QF and anti-PAD3-insect QF, Inova) and serum calprotectin (QL prototype ELISA, Inova). The control group consisted of patients with PsA (CASPAR criteria positive) and axSpA (ASAS criteria positive). In univariable analyses we tested for associations between the biomarkers and the 28-joint disease activity score (DAS28) and the presence of erosive disease at inclusion. Multivariable analyses were corrected for age, sex, disease duration and anti-CCP2 positivity.

**Results:** A total of 1471 patients were included, 969 with RA and 502 in the SpA control group (317 with axSpA and 185 with PsA). Statistical measures of the biomarkers for the diagnosis of RA are shown in Table 1. In univariable analyses, RA patients positive for anti-PAD3-E.Coli, anti-PAD3-insect or calprotectin were significantly more likely to have a moderate to high DAS28 (DAS28>3.2) than patients with negative values (68.2% vs. 54.8%, p=0.001, 67.7% vs. 56.0%, p=0.027 and 70.4% vs. 56.2%, p=0.020 respectively). RA patients positive for anti-CarP, anti-PAD3-E.Coli or anti-PAD3-insect were significantly more likely to demonstrate joint erosions compared with patients with negative values (66.3% vs. 57.7%, p=0.037, 68.5% vs. 57.7%, p=0.015 and 71.6% vs. 58.3%, p=0.020 respectively). In multivariable analyses, the odd ratios (and 95% confidence intervals) for the association of anti-PAD3-E.Coli, anti-PAD3-insect or calprotectin with a moderate to high DAS28 were 1.65 (1.15, 2.39), 1.64 (1.02, 2.64) and 1.90 (1.08, 3.35) respectively, and for the association of anti-CarP, anti-PAD3-E.Coli or anti-PAD3-insect with joint erosions were 1.32 (0.90, 1.93), 1.43 (0.95, 2.15) and 1.82 (1.05, 3.15) respectively.

**Table 1**: Frequencies of the different biomarkers in patients with RA, PsA and axSpA, and the sensitivities, specificities, PPV and NPV for a diagnosis of RA as defined by the treating rheumatologist.

| Biomarker | Cut-off (units) | % of samples positive | | | | Sens (%) | Spec (%) | PPV (%) | NPV (%) |
|---|---|---|---|---|---|---|---|---|---|
| | | Overall N=1471 | RA N=969 | PsA N=185 | axSpA N=317 | | | | |
| Anti-CCP2 | 25 U/ml | 55.0 | 77.2 | 11.4 | 12.3 | 70.9 | 88.0 | 92.0 | 61.0 |
| Anti- CCP3 IgG QL | 20 U/ml | 41.1 | 61.8 | 0.5 | 1.6 | 61.7 | 98.9 | 99.0 | 57.2 |
| Anti-CCP3 IgG QF | 20 U/ml | 40.8 | 61.3 | 1.1 | 1.3 | 61.3 | 98.8 | 99.0 | 56.9 |
| Anti-CCP3 IgA QF | 20 U/ml | 18.1 | 26.8 | 1.6 | 1.3 | 26.7 | 98.6 | 97.4 | 41.1 |
| RF IgM QF | 10344 RLU | 48.6 | 67.1 | 14.1 | 12.3 | 67.2 | 87.1 | 90.9 | 57.9 |
| RF IgA QF | 7425 RLU | 27.8 | 40.9 | 10.8 | 3.5 | 40.9 | 97.4 | 96.8 | 46.0 |
| Anti-CarP QL | 20 U/ml | 18.6 | 22.3 | 11.9 | 11.0 | 22.3 | 88.6 | 79.1 | 37.1 |
| Anti-PAD3 (E.coli) QF | 20000 RLU | 15.6 | 18.5 | 9.7 | 10.4 | 18.5 | 89.8 | 77.8 | 36.3 |
| Anti- PAD3 (insect) QF | 8300 RLU | 7.2 | 10.2 | 1.6 | 1.3 | 10.2 | 98.6 | 93.4 | 36.3 |
| Calprotectin QL | 473 mg/kg | 5.8 | 7.3 | 1.6 | 3.5 | 7.3 | 97.2 | 83.5 | 35.2 |

QL = Quanta Lite, QF= Quanta Flash, Sens=sensitivity, Spec=specificity, PPV=positive predictive value, NPV=negative predictive value, RLU=relative light unit

**Conclusions:** Although anti-PAD3 and calprotectin are only present in a minority of RA patients, they are significantly associated with more active disease and anti-PAD3-insect is significantly associated with the presence of joint erosions, independently of ACPA (anti-CCP2).

**Disclosure of Interest:** None declared

## FRI0089 C4M – A BLOOD-BASED BIOMARKER – IS AN OBJECTIVE MARKER OF DISEASE ACTIVITY AND RADIOGRAPHIC STATUS: REPLICATION AND VALIDATION OR PREVIOUS FINDINGS IN THE OSKIRA RHEUMATOID ARTHRITIS STUDIES

N.S. Gudmann[1], A. Platt[2], M. Karsdal[1], A.C. Bay-Jensen[1]. *[1]Nordic Bioscience, Herlev, Denmark; [2]AstraZeneca, Cambridge, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is an inflammatory joint disease affecting multiples tissues including the soft connective tissue surrounding the joints as well as the cardiovascular system. C4M is a biomarker of type IV collagen degradation, which is solely released from the basement membrane of, for example, the vasculature system. C4M was tested in the phase III clinical trial LITHE and was found to be a biomarker of disease activity and radiographic burden.

**Objectives:** The aim of this study was to replicate and validate previous findings of C4M by measuring patient samples from the OSKIRA phase III clinical trials.

**Methods:** OSKIRA 1, 2 and 3 (NCT01197521; NCT01197534; NCT01197755) (n=543) were all phase 3, randomized, double-blind, placebo-controlled studies of fostamatinib on a MTX background including RA patients with moderate to severe disease. Only baseline serum samples from the placebo arms were assessed. Patient population differed between the studies in that patients had inadequate response to: MTX (OSKIRA 1), DMARDs (OSKIRA 2) and single anti-TNF-$\alpha$ treatment (OSKIRA 3). Disease activity was assessed by disease activity score 28 (DAS28), swollen joint count 28 (SJC28), tender joint count 28 (TJC28) and health assessment questionnaire (HAQ). Radiographic Status was evaluated by joint space narrowing (JSN), erosion score (ERN) and mTSS. Serum C4M was measured in fasting serum by solid-phase competitive ELISA. Spearman rank correlations were applied to investigate the association between C4M and clinical parameters. Independent t-tests were applied for intergroup comparisons. Data that did not meet the criteria of normal distribution were log transformed prior to t-tests.

**Results:** Demographics were comparable for the three OSKIRA studies and the placebo groups of each were therefore pooled together. Baseline levels of C4M were significantly correlated with the disease activity parameters DAS28 (r=0.377, p=0.0001), HAQ (r=0.206, p<0.0001), TJC28 (r=0.117, p=0.0068) and SJC28 (r=0.166, p=0.0001) and radiographic scores: ERN (r=0.135, p=0.003), mTSS (0.151, p=0.001) and JSN (r=0.152, p=0.001). There were no significant correlations between C4M and sex, age or BMI. There were no significant differences in C4M2 measurements in escapers versus non escapers or at baseline compared to the concentrations measured at week 24.

**Conclusions:** The OSKIRA studies support previous findings of the LITHE study. C4M is highly associated with disease activity as well as radiographic progression level in patients with RA. Basement membrane remodelling, measured by C4M, appears to be highly important to the pathogenesis of RA. Further studies may reveal if alterations in basement membrane are linked to vascular dysfunction in patients with RA.

## FRI0090 BMI AND TENDER JOINTS ARE PREDICTORS OF NOT REACHING SUSTAINED REMISSION IN PATIENTS PARTICIPATING IN AN AGGRESSIVE TREAT-TO-TARGET STUDY

N.P. Sundlisater[1], S. Lillegraven[1], A.-B. Aga[1], I.C. Olsen[1], T. Uhlig[1], H.B. Hammer[1], D. van der Heijde[2], T.K. Kvien[1], E.A. Haavardsholm[1] on behalf of the ARCTIC Study Group. *[1]Diakonhjemmet Hospital, Oslo, Norway; [2]Leiden University Medical center, Leiden, Netherlands*

**Background:** Modern rheumatoid arthritis (RA) care is based on early DMARD initiation, tight control and treat-to-target strategies aiming for abrogation of inflammation to optimize long term outcomes. However, even in the most aggressive treatment studies a substantial proportion of patients do not reach sustained remission.
**Objectives:** We aimed to identify predictors of not reaching sustained DAS remission in early RA patients followed by a treat-to-target algorithm with pre-specified DMARD adjustments.
**Methods:** RA patients who fulfilled the ACR/EULAR 2010 classification criteria, with <2 years from first swollen joint and who were DMARD naïve with indication for DMARD treatment were included in the ARCTIC trial between 2010 and 2013. Patients were followed by a structured tight control algorithm aiming for a target of DAS<1.6 and no swollen joints, and in half the patients the treatment target also included no joints with ultrasound power-Doppler signal. For patients with established risk factors for joint destruction (ACPA or RF positive with radiographic erosions or MRI bone marrow edema at baseline) treatment could be escalated more rapidly to biologic therapy. Data collection included 44 SJC, Ritchie articular index (RAI), laboratory tests, patient reported outcomes, ultrasound examination and radiographs. Multivariate logistic regression was used to assess the associations between baseline variables and not being in sustained DAS remission at 16 to 24 months. A univariate p-value of <0.25 was used for variable selection, and a p-value of <0.05 to keep the variable in the model. Patient reported physical function and physician global were not included in the model building because of collinearity.
**Results:** A total of 221 patients were included, with mean [SD] age 51.1 [13.7] years, disease duration 7.2 [5.4] months, DAS 3.5 [1.2]. 63% were female, 72% RF- and 82% ACPA positive, and 16% escalated treatment more rapidly to biologic therapy. 103 (47%) did not reach sustained DAS remission between 16 and 24 months. Tender joints assessed by RAI (OR 1.11 per unit, p<0.001) and BMI (OR 1.07 per unit, p=0.046) were independent predictors for not reaching sustained DAS remission.

Table 1. Baseline predictors for not being in sustained DAS remission between 16 and 24 months. Variables included in multivariate model building shown, with the final model highlighted. The model was adjusted for age and gender

| Baseline variables variables | Not in sustained DAS remission between 16 and 24 months (N=103/221) | | | |
|---|---|---|---|---|
| | Univariate Analysis | | Multivariate Analysis | |
| | OR [CI] | P-value | OR [CI] | P-value |
| Tender joints (RAI) | 1.11 [1.06, 1.17] | <0.001 | 1.11 [1.06, 1.16] | <0.001 |
| BMI | 1.06 [1.00, 1.13] | 0.05 | 1.07 [1.00, 1.14] | 0.046 |
| Patient global | 1.02 [1.00, 1.03] | 0.005 | | |
| RF pos (IgM+IgA) | 1.78 [0.98, 3.25] | 0.06 | | |
| Female gender | 1.51 [0.87, 2.62] | 0.15 | | |
| ESR | 1.01 [0.99, 1.02] | 0.24 | | |

**Conclusions:** In early RA patients treated by an aggressive treat-to-target strategy, tender joints assessed by Ritchie articular index and BMI at time of diagnosis were independent predictors for not reaching sustained DAS remission. Our results are supported by previous studies indicating that overweight decreases the chance of achieving treatment success in early RA (1).

## FRI0091 THE RELATIONSHIP OF ULTRASONOGRAPHIC SIGNS OF INFLAMMATION AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

O. Alekseeva, M. Severinova, A. Smirnov, E. Aleksandrova, A. Novikov, E. Luchikhina, D. Karateev, A. Volkov, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

**Background:** Rheumatoid arthritis (RA) – is a chronic inflammatory disease, which by natural course of the disease results in erosive polyarthritis, i.e. destruction and dysfunction of joints.
**Objectives:** To investigate the relationship between ultrasonographic (US) evidence of "active" inflammation and radiographic progression in patients with RA and assess the potential of ultrasonographic imaging in evaluation of prognosis of patients with RA.
**Methods:** The study included 83 patients with early RA (median age 54 [45;61] years. All patients were administered methotrexate (MTX) and/or biologic therapy in accordance with the treat-to-target concept (REMARCA study). Clinical and laboratory parameters were analyzed at baseline, in 12,24,36 and 48 weeks after initiation of therapy. Treatment efficacy was assessed using EULAR criteria and indices of activity. Ultrasound with gray scale (GS) and power Doppler (PD) were performed at baseline, 12,24,36 and 48 weeks after initiation of therapy. The wrist, MCP2, MCP3, PIP2, PIP3, MTP2 and MTP5 joints of the clinically dominant side were examined by US according to the European League Against Rheumatism (EULAR) guidelines. ESAOTE MyLabTwice and GE Logiq 9 US machines with 13–18 MHz-transducer were used. Plain X-rays were taken before treatment and at week 48 of therapy. Modified Sharp van der Heijde (SHS) scale was used to quantify the radiographic findings. Structural damage progression was evaluated based on changes in the SHS (ΔSHS) between baseline and 1 year.
**Results:** At 48th weeks 56% patients had remission according to DAS28. The proportions of PD(+) and PD(–) patients were 47% and 53%, respectively. There was a correlation between ΔSHS by 48th week of treatment and PD at the 36 and 48th weeks (r=0,31 *p*=0,005;r=0,3 *p*=0,003 respectively) and GS at the 36th week (r=0,31 p=0,006). In patients, who had PD(+) synovitis at 48th week ΔSHS was significantly higher (r=0,01) as compared to patients without synovitis. Thus, in the group of PD(+) patients baseline radiological changes were more pronounced, than in patients without synovitis, but differences weren't statistically significant. The difference between the two groups of patients, based on the degree of radiological progression by 48th week of therapy, was significant for DAS28 at the 36th week: the DAS28 was higher in the group with radiological progression (r=0,004), while all other used clinical activity indices did not show any difference between the two groups. TJS and SJS were higher at the 12th week of therapy (r=0,04 and r=0,02, respectively), and CRP level at the 24th week was also higher in PD(+) group (r=0,03). PD synovitis score was higher at the 36 and 48th weeks (r=0,04 and r=0,000, respectively), and difference by GS synovitis score was established between the groups at the 36th week (r=0,02). Linear regression model revealed that GS synovitis score at week 24 correlated with ΔSHS during the first year of the therapy (OR=0,15, 95%CI: 0,023–0,207; *p*=0,015). The similar trend, though not significant, was noticed with PD synovitis score after 24 weeks of therapy (OR=0,104, 95%CI:-0,043–0,251; r=0,16).
**Conclusions:** Thus, the analysis of annual structural damage progression confirmed that US (PD and GS synovitis) have prognostic value to predict future radiographic damage.

## FRI0092 INFLUENCE OF TEMPERATURE AND HUMIDITY ON DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

P. Mandl[1], F. Alasti[1], R. Kaltenberger[2], T. Krennert[2], G. Supp[1], U. Landesmann[1], J.S. Smolen[1,3], D. Aletaha[1]. *[1]Division of Rheumatology, Medical University of Vienna; [2]Central Institute for Meteorology and Geodynamics; [3]Rheumatology, Krankenhaus Hietzing, Vienna, Austria*

**Objectives:** To evaluate whether meteorological parameters influence disease activity in patients with rheumatoid arthritis (RA).
**Methods:** We assessed correlations between individual meteorological variables and clinical measures of disease activity: clinical disease activity index (CDAI), self-reported pain (by visual analogue scale), tender- and swollen 28 joint counts (TJC and SJC). Assessments documented in our RA database as well as the average temperature and relative humidity, obtained from the Central Institute for Meteorology and Geodynamics, were matched on a daily basis for a period of 10 years between 2005 and 2015, and analyzed using generalized estimating equations (longitudinal data analysis).
**Results:** A total of 1437 patients with RA (average disease duration at first visit: 4.88±8.63 years; 77% female, mean CDAI 17.8±11.7, mean time in study: 75 month, mean number of visits during study period: 19) were analyzed. Higher temperature and lower humidity were significantly associated with lower CDAI (p=0.0002, and p=0.0332, respectively). Regarding pain, the effects of temperature showed an interaction with humidity: while lower temperatures were associated with higher pain levels at the low and middle tertile of relative humidity, they corresponded to a lower pain level at the high tertile of relative humidity. Temperature showed a significantly negative correlation with TJC (p<0.0001), while relative humidity showed a significantly positive correlation with SJC (p=0.0321). Similar to pain, there was again an interaction of temperature and humidity in the SJC analysis.
**Conclusions:** In this largest association study of meteorological parameters with RA specific outcomes both temperature and relative humidity were shown to have significant effects on disease activity. Individual measures of disease activity and pain correlated either with temperature or humidity, while the composite CDAI measure correlated with both meteorological variables. These aspects may have to be taken into account in longitudinal analyses of disease activity of RA.

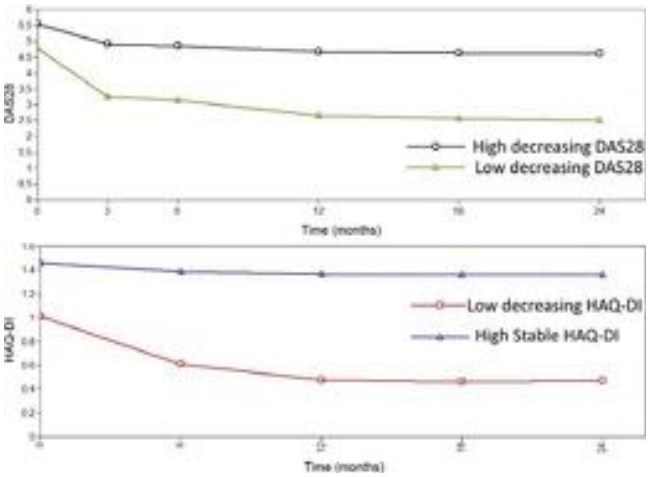
FRI0093 **IMMUNOGENICITY OF TNF INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS OR POLYARTICULAR PSORIATIC ARTHRITIS IN CLINICAL REMISSION OR LOW DISEASE ACTIVITY: A ONE-YEAR MULTICENTRE PROSPECTIVE STUDY (THE INMUNOREMAR STUDY)**



R. Sanmarti[1], J. Inciarte-Mundo[1], P. Estrada-Alarcón[2], M. García-Manrique[3], J. Narvaez[2], A. Gómez-Centeno[3], J. Rodríguez-Moreno[2], M. Pascal[4], J. Yagüe[4]. *[1]Rheumatology, Hospital Clinic, Barcelona; [2]Rheumatology, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat; [3]Rheumatology, Hospital Parc Taulí, Sabadell; [4]Immunology, Hospital Clinic, Barcelona, Spain*

**Objectives:** To determine drug trough serum levels and anti-drug antibodies (Ab) in rheumatoid arthritis (RA) or polyarticular psoriatic arthritis (PsA) patients in clinical remission (CR) or low disease activity (LDA) receiving TNF inhibitors [adalimumab (ADA), etanercept (ETN) and infliximab (IFX)], to correlate trough serum levels and Ab with disease flare after a 1-year follow-up, and to determine predictive factors of disease flare.
**Methods:** Prospective, multicentre study of RA and PsA patients attended in 3 hospital outpatient clinics (Catalonia, Spain) treated with ADA, ETN or IFX for ≥3 months in CR or LDA measured by DAS28-ESR at ≥2 consecutive visits. Ab and trough serum levels (ELISA Kit Promonitor®, Progenika SA, Spain) were determined at 0, 4, 8 and 12 months. Disease flare was defined as DAS28>3.2 and a delta DAS28 >0.6 during the 1 year follow-up compared with visit 0. Variables collected: demographic data; disease activity, diagnosis; disease duration; biologic drug; reduced dose, and concomitant csDMARD therapy. Differences between patients with and without disease flare were studied by univariate analysis. Multivariate Cox regression analysis was used to establish associations between baseline variables and disease flares.
**Results:** 187 patients (RA 103 [57%], PsA 81 [43%]), 66% female, mean age 57±12 years, were included. 138 (74%) patients were in CR, 49 (26%) with LDA, 69 ADA, 83 ETN, and 35 IFX. Mean treatment duration was 60±41 months. 34% and 58% of RA and PsA patients were on reduced doses of TNFi, and 75% and 44% on concomitant csDMARD, respectively. Thirty-two patients (17.1%: 9 ADA, 13 ETN, 10 INF) had a disease flare during follow-up: 15 at month 4, 12 at month 8 and 5 at month 12. Ab (2ADA, 2IFX) were detected in 12.5% of these patients. Patients with disease flares had lower mean baseline trough serum TNFi levels (2.36±0.45 μ/ml vs. 3.92±0.29 μ/ml p<0.01), although the difference was significant only for ADA (2.2±1.4 μ/ml vs. 6.6±4.1 μ/ml p=0.02), higher baseline DAS28 (2.42 vs. 2.04 p<0.001), and CDAI (5.80 vs. 4.15 p=0.001) and a lower frequency of remission (53% vs. 78% =0.003). During flares, trough serum levels of the three TNFi decreased, although the different was significant compared with baselines only in ETN (0.9±1.2 μ/ml vs. 2.3±1.26 μ/ml p=0.02). Cox multivariate analysis showed associations between disease flares and serum levels of TNFi (hazard ratio (HR) =0.84), glucocorticoids use (HR=2.11), and higher DAS28 (HR=2.19) and CDAI (HR=1.14) levels. Other baseline variables were not associated with disease flares.
**Conclusions:** Over a one-year follow up disease flares were observed in 17% of RA and PsA patients treated with TNFi for a prolonged period who achieved clinical remission/low disease activity. Anti-drug antibodies explained only 12.5% of disease flares. Low drug trough serum levels and high disease activity levels at baseline were associated with disease flares.

FRI0094 **DISABILITY IN EARLY RHEUMATOID ARTHRITIS MAY PERSIST DESPITE IMPROVEMENT IN DISEASE ACTIVITY: EVIDENCE FROM YORKSHIRE EARLY ARTHRITIS REGISTER**

S. Twigg[1], E. Hensor[1], P. Emery[1], A. Tennant[2], A.W. Morgan[1] on behalf of YEAR Consortium. *[1]Leeds Institute Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [2]Swiss Paraplegic research, Schweizer Paraplegiker-Forschung, Nottwil, Switzerland*

**Background:** Disability adversely affects the wellbeing of individuals with rheumatoid arthritis (RA) and contributes to direct and indirect health care costs (1). However, owing to substantial advances in drug treatment for RA, management often focuses on suppression of inflammation. In the United Kingdom, treatment with biological agents is guided by disease activity score from counts of 28 joints (DAS28) (2) and EULAR guidance recommends treatment goals of low disease activity or remission (3). Although these targets are of undoubted importance, the relationship between the treatment target (inflammation or disease activity) and disability is not well described.
**Objectives:** 1. Describe the relationship between disease activity and disability over 2 years in early RA
2. Identify predictors of adverse outcome.
**Methods:** Cases with rheumatologist-confirmed early RA were recruited to Yorkshire Early Arthritis Register (YEAR). Data from 1415 patients were applied to separate latent growth curve models of change in DAS28 and disability index of Health Assessment Questionnaire (HAQ-DI) over 2 years. A parallel process growth curve model described how HAQ-DI varied with DAS28. Dual trajectory analysis (4) was used to describe distinct dual trajectories of change in both variables. Predictors of likely dual trajectory group membership were identified using multinomial logistic regression.
**Results:** Two trajectories of DAS28 (high decreasing DAS28 and low decreasing DAS28) and HAQ-DI (high stable HAQ-DI and low decreasing HAQ-DI) were identified, shown in Figure 1. Four distinct dual trajectory groups were: group 1, high decreasing DAS28 and high stable HAQ-DI (23% of cohort); group 2, high decreasing DAS28 and low decreasing HAQ-DI (1%); group 3, low decreasing DAS28 and high stable HAQ-DI (26%); group 4, low decreasing DAS28 and low decreasing HAQ-DI (50%). Predictors of group 1 membership (compared to group 4) were similar to known predictors of poor outcome in RA: female gender, social deprivation and greater baseline fatigue. Predictors of group 3 membership were the same as group 1, but also included older age and greater overall contribution of tender joint count and visual analogue score to baseline DAS28.

**Conclusions:** Persistence of disability despite improvement in disease activity was more likely in older patients and those with greater subjective components of baseline DAS28. This suggests that current therapies, which target inflammation, may not be sufficient to reduce disability in early RA. Future work should examine the impact of comorbidity and pain on function in early RA.

FRI0095 **DIVERSITY OF THE PERIPHERAL IMMUNOLOGICAL PHENOTYPE AFTER BIOLOGIC DMARD THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS**

S. Nakayamada, S. Kubo, M. Yoshikawa, Y. Miyazaki, N. Yunoue, S. Iwata, K. Nakano, K. Saito, Y. Tanaka. *The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan*

**Background:** In the pathogenesis of rheumatoid arthritis (RA), T cells can differentiate into functionally distinct subsets, leading to the persistent inflammation and immune abnormality associated with the interactive activation between B cells, monocytes and dendritic cells. However, little is known about pathological immune cell subsets targeted by biologic DMARDs (bDMARD) therapy.
**Objectives:** The aim of this study was to assess the relationship between the phenotype of peripheral immune cells with clinical manifestations and responsiveness to bDMARD therapy in patients with RA.
**Methods:** Peripheral blood mononuclear cells were obtained from 108 patients with bio-naïve RA and 26 healthy controls (HC). The study included 46 patients

treated with TNF inhibitors such infliximab, etanercept and adalimumab, 40 patients treated with abatacept, and 22 patients treated with tocilizumab. The blood samples were taken at baseline and week 24 after treatment. The peripheral immune cell subset was defined based on comprehensive 8-color flow cytometric analysis for human immune system termed "the Human Immunology Project" by NIH and FOCIS, and the correlation with clinical characteristics and responsiveness to bDMARD therapies were evaluated.

**Results:** The frequency of $CD3^+CD4^+CD45RA^-CCR7^-$ effector memory, $CD3^+CD4^+CD45RA^+CCR7^-$ effector T helper cells and $CD4^+CXCR5^+ICOS^+$ T follicular helper (Tfh) cells was higher in patients with active RA than that in HC. The frequency of $CD3^+CD8^+CD45RA^-CCR7^+$ central memory cytotoxic T cells or $CD3^+CD4^+CXCR3^-CCR6^+$ Th17 cells was correlated with RF titers and that of $CD19^+CD20^-CD27^+CD38^+$ plasmablast was correlated with disease activity scores such as DAS28-ESR and SDAI. The proportion of Tfh cells and $CD19^+CD20^+CD27^-IgD^-$ effector B cells made statistical clusters with that of plasmablast. All of bDMARDs markedly improved the disease activity scores after 24 week treatment. TNF inhibitors decreased $CD3^+CD4^+CD45RA^+CCR7^+$ naïve T cells but increased effector memory T cells and Th17 cells, and tocilizumab increased $CD4^+CCR4^+CD25^+CD127^{low}$ T regulatory (Treg) cells and decreased effector B cells. However, abatacept characteristically decreased the proportions of T helper cell subsets which consisted of Tfh, Th17, and Treg cells and consequently the proportion of naïve T cells increased.

**Conclusions:** These results indicated that the abnormal T cell differentiation correlated with autoantibody production while plasmablast did with disease activity of RA. In addition, the molecular targeted therapies may alter contradictory changes of T helper cell subsets, i.e. abatacept decreases activated Tfh, Th17 and Treg cells whereas TNF inhibitor increases Th17 cells and tocilizumab increases Treg cells. The peripheral immunophenotyping might be useful in evaluating the pathogenesis and in determining the therapeutic target of each patient.

## FRI0096 PREDICTIVE VALUE OF THE MULTI-BIOMARKER DISEASE ACTIVITY (MBDA) SCORE FOR FLARE AND SUSTAINED REMISSION IN THE HONOR STUDY

S. Hirata[1,2], S. Tang[3], C.C. Hwang[3], I. Miyagawa[1], S. Kubo[1], K. Nakano[1], S. Nakayamada[1], K. Saito[1], N.A. Defranoux[3], Y. Tanaka[1]. *[1]The First Department of Internal Medicine; [2]Department of Laboratory and Transfusion Medicine, University Hospital, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan; [3]Crescendo Bioscience Inc., South San Francisco, United States*

**Objectives:** To determine the predictive value of the multi-biomarker disease activity (MBDA) (Vectra® DA) score for flare and sustained clinical remission after discontinuation of adalimumab (ADA) in patients with rheumatoid arthritis (RA) from the HONOR study [1,2].

**Methods:** This retrospective sub-analysis was conducted on 42 RA patients from the HONOR study. Patients receiving ADA and methotrexate (MTX) who maintained DAS28-ESR remission ($<2.6$) for $\geq 24$ weeks and who subsequently agreed to discontinue ADA were enrolled. Clinical disease activity, functional status, and joint damage were recorded at ADA discontinuation (baseline), and after 24 and 52 weeks. MBDA scores (remission, $\leq 25$; low, 26–29; moderate, 30–44; high, $>44$) were determined from serum samples collected at baseline. The ability to predict flare (DAS28-ESR $\geq 3.2$) or sustained clinical remission (SC-REM) (absence of flare with DAS28-ESR $<2.6$ at all visits) by MBDA score and patient characteristics were determined.

**Results:** At ADA discontinuation, all patients had DAS28-ESR $<2.6$ with 81% female, 69% RF+, 81% ACPA+ and 30-month mean disease duration. The median MBDA score was 24.5 [quartile; 14.3, 30.8] with 22 (52.4%) patients in remission, and 6 (14.3%) low, 9 (21.4%) moderate and 5 (11.9%) high MBDA score. At 52 weeks, flare and SC-REM were observed in 12/42 (28.6%) and 19/42 (45.2%) patients, respectively. Rate of flare and percentage of SC-REM by MBDA category (remission/low/moderate/high) were 13.6%/50.0%/33.3% and 60.0% (p=0.033) and 63.6%/33.3%/33.3% and 0% (p=0.0066), respectively (P-value by two-sided Cochran-Armitage trend test). Univariate regression analyses identified MBDA score, DAS28-ESR and disease duration as predictors of flare at 52 weeks ($p \leq 0.05$).

**Conclusions:** These findings suggest that the MBDA score could predict flare and SC-REM in RA patients in stable clinical remission, undergoing ADA withdrawal while maintaining MTX treatment.

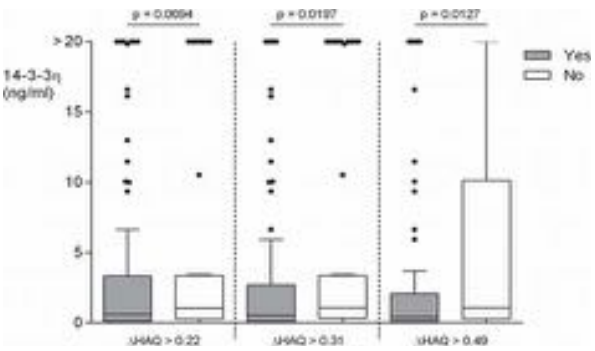
## FRI0097 BASELINE SERUM 14-3-3 ETA INDEPENDENTLY PREDICTS CLINICALLY IMPORTANT IMPROVEMENTS IN HAQ-DI IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOCILIZUMAB

S. Hirata[1,2], K. Hanami[1], A. Marotta[3], Y. Tanaka[1]. *[1]The First Department of Internal Medicine, School of Medicine; [2]Department of Laboratory and Transfusion Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan; [3]Augurex Life Sciences Corp., Vancouver, Canada*

**Background:** Serum 14–3-3η is a mechanistic marker that is involved in the pathogenesis of RA and is a direct and potent up-regulator of IL-6.[1] We previously reported that baseline 14–3-3η levels were significantly lower in a cohort of 49 established RA patients who achieved better clinical outcomes when treated with Tocilizumab.[2] Recently there has been increased interest in assessing therapy response using alternative measures to DAS that are independent of CRP, including patient reported outcomes such as HAQ-DI.

**Objectives:** The aim of this study was to evaluate whether baseline measurement of 14–3-3η was associated with and independently predicted clinical response, in a cohort of 106 RA patients treated with tocilizumab.

**Methods:** Serum 14–3-3η levels were measured in a cohort of 106 Japanese patients prior to the initiation of tocilizumab therapy (BL). 14–3-3η positivity was defined by the diagnostic cut-off of $\geq 0.19$ ng/ml, and 2 and 4 times that, at 0.40 and 0.80 ng/ml, respectively. Patients were sub-grouped according to changes in HAQ-DI based on the minimal clinically important difference (MCID) of $\geq 0.22$, $\geq 0.31$, and $\geq 0.49$. Group differences were assessed by Mann-Whitney U-test. ROC curve analysis was performed to identify the optimal 14–3-3η cut-point for a $\Delta$HAQ-DI $\geq 0.49$. Uni- and multi-variable analysis controlling for baseline HAQ-DI was used to assess 14–3-3η's independence of other clinical/serological variables at informing patient reported outcomes.



**Results:** At baseline, 75 (71%) of the 106 patients were 14–3-3η positive. At year 1, 70 (66%), 58 (55%) and 52 (40%) of the 106 patients achieved changes in HAQ-DI of $\geq 0.22$, $\geq 0.31$, and $\geq 0.49$, respectively. Baseline HAQ-DI values were significantly higher in those patients that achieved a $\Delta$ HAQ-DI $\geq 0.22$ when compared with those that did not; p=0.009. The HAQ-DI values were also significantly higher at the two other HAQ-DI cut-points ($\geq 0.31$, and $\geq 0.49$), $p<0.0001$.

As shown in the Figure, serum 14–3-3η levels were significantly lower in patients that achieved HAQ-DI MCID of $>0.31$ and $>0.49$.

In patients who achieved a DHAQ-DI $\geq 0.49$, ROC analysis returned the best cut-off of $\leq 0.18$ ng/ml yielding a specificity of 83.3% (95%CI: 70.7–92.1) and sensitivity of 42.3% (95%CI: 28.7–56.8), LR =2.5. By univariate analysis, all three 14–3-3η cut-points were significantly associated with better clinical outcomes.

| | ≤0.19 ng/ml | | ≤0.40 ng/ml | | ≤0.80 ng/ml | |
| | LR | p-value | LR | p-value | LR | p-value |
| ΔHAQ >0.22 | 6.75 | 0.0098 | 2.36 | 0.0950 | 0.94 | 0.2222 |
| ΔHAQ >0.31 | 9.57 | 0.0021 | 6.18 | 0.0114 | 3.56 | 0.0456 |
| ΔHAQ >0.49 | 8.61 | 0.0034 | 6.61 | 0.0090 | 3.88 | 0.0382 |

Multi-variable modeling controlling for BL HAQ-DI indicated that lower levels of 14–3-3η, age and disease duration, but not CRP, were independent predictors of achieving the HAQ-DI MCID outcomes.

**Conclusions:** Lower serum 14–3-3η levels prior to the initiation of therapy are associated with and independently predict better patient reported outcomes in patients treated with tocilizumab. The predictive capacity of 14–3-3η at informing

therapy response to anti-IL-6 therapy should be investigated across all anti-IL-6 compounds.

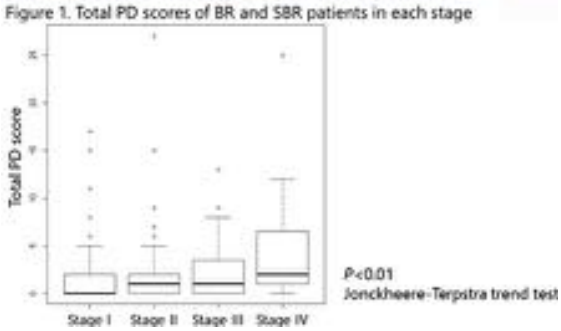
## FRI0098 A CERTAIN PORTION OF ACTIVE ESTABLISHED RHEUMATOID ARTHRITIS PATIENTS WITH SIGNIFICANT JOINT DESTRUCTION ARE MISCLASSIFIED AS BEING IN BOOLEAN REMISSION: A CROSS-SECTIONAL STUDY USING ULTRASOUND SONOGRAPHY

S. Nakabo[1], Y. Tsuji[2], M. Inagaki[2], H. Tsuji[1], T. Nakajima[1], M. Hashimoto[3], M. Furu[3], H. Ito[4], T. Fujii[1,5], C. Terao[6], W. Yamamoto[7], Y. Fujii[2], T. Mimori[1].
*[1]Department of Rheumatology and Clinical Immunology; [2]Human Health Sciences Clinical Physiology and Ultrasound Labo; [3]Department of the Control for Rheumatic Diseases; [4]Department of Orthopaedic Surgery, Kyoto University, Kyoto; [5]Department of Clinical Immunology and Rheumatology, Wakayama Medical University, Wakayama; [6]Genomic Center, Kyoto University, Kyoto; [7]Kurashiki Sweet Hospital, Kurashiki, Japan*

**Background:** The goal of the treatment of rheumatoid arthritis (RA) is remission, however the remission induction for established RA (eRA) patients with long disease duration and significant radiographic damage is difficult. One of the reasons for this is that Patient Global Assessment score (PtGA) continues to be high even after the synovitis resolves through appropriate treatment, because of disability or pain from the structural damage. Although such high PtGA of eRA patients is thought to be acceptable, there is little evidence which supports this concept.

**Objectives:** To evaluate whether high PtGA of eRA patients is acceptable by assessing synovitis using ultrasound sonography (US).

**Methods:** Three hundred and thirty two RA patients were recruited with informed consent. Bilateral 2–5 MCP, wrist, ankle, and 2–5MTP joints were scanned by using the Aplio500 (TOSHIBA) with a 12 MHz transducer. Power Doppler (PD) images were obtained by Superb Micro-vascular Imaging (SMI). Gray scale (GS) and PD images were scored using a 0–3 semi-quantitative scale. Clinical information was obtained from the Kyoto University Rheumatoid Arthritis Management Alliance (KURAMA) database, which is based on the assessment by physicians who were blind to the US results. We defined "Semi-Boolean remission (SBR)" as the condition which is composed of 3 elements of Boolean remission (BR) criteria, excluding PtGA. All the patients were classified into 1–4 Steinbrocker stages according to their joint X-rays.



**Results:** The number of patients who fulfilled BR or SBR criteria were 99 and 122, respectively. As shown in table 1, age, disease duration, total GS score, and total PD score were virtually the same between the two groups. PtGA become higher in accordance with the stages ($P<0.01$, Jonckheere-Terpstra trend test. Mean values of PtGA of stage I, II, III, and IV were 13.6±15.6, 19.6±21.0, 26.6±26.1, and 28.0±22.0, respectively). PtGA and total PD score showed no correlation in BR+SBR patients, or in each of the stages (Spearman's rho=0.14, 0.16, 0.04, 0.03, or 0.07, respectively). The median values of total GS scores of each stage were, 10.0 (8.0–15.0), 12.0 (9.0–16.0), 11.0 (8.0–15.0), and 12.0 (7.5–17.0). There is no significant difference between stages. On the other hand, the median values of total PD scores of each stage were 0.0 (0.0–2.0), 1.0 (0.0–2.0), 1.0 (0.0–3.5), and 2.0 (1.0–6.5), respectively (figure 1). There was significant accordance between total PD score and stages ($P<0.01$, Jonckheere-Terpstra trend test).

Table 1. Comparison between Boolean remission (BR) and Semi-Boolean remission (SBR) groups

| Total N=221 | BR N=99 | SBR N=122 | P |
|---|---|---|---|
| Age, mean±SD years | 62.9±12.1 | 62.3±14.4 | 0.87* |
| Women, % | 80.8 | 77.0 | 0.50¶ |
| Disease duration, mean±SD years | 10.7±10.7 | 11.1±10.5 | 0.59* |
| Steinbrocker stage (I/II/III/IV) | 39/30/14/16 | 32/38/21/31 | 0.02*¶ |
| PtGA, mean±SD mm | 4.1±2.9 | 34.0±20.3 | <0.01*¶ |
| Total GS score, median (IQR) | 11.0 (8.0-15.0) | 11.5(8.0-16.0) | 0.35* |
| Total PD score, median (IQR) | 1.0 (0.0-2.0) | 1.0 (0.0-4.0) | 0.08* |

IQR: Interquartile range, *P<0.05, *Mann–Whitney U test, ¶Chi-Square test, ¶Cochran-Armitage trend test

Figure 1. Total PD scores of BR and SBR patients in each stage

**Conclusions:** PtGA did not always reflect the activity of synovitis. This was not limited to eRA but also to RA without radiographic damage. However, we must be careful as higher total PD scores were seen in eRA patients even though they were thought of as being in BR or SBR. This result means that a certain portion of active eRA patients are misclassified as being in remission. Before accepting the high PtGA, we should use US for correct evaluation of eRA.

## FRI0099 INDICATIONS OF REVERSIBILITY OF CENTRAL SENSITIZATION ACCORDING TO THE PAINDETECT QUESTIONNAIRE IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM THE PROSPECTIVE FRAME-COHORT STUDY

S. Rifbjerg-Madsen[1], A.W. Christensen[1], M. Boesen[2], R. Christensen[1], B. Danneskiold-Samsøe[1], H. Bliddal[1], L. Dreyer[3], H. Locht[4], K. Amris[1]. *[1]Dept. of Rheumatology, Copenhagen University Hospital, Bispebjerg-Frederiksberg; [2]Dept. of Radiology, Copenhagen University Hospital, Bispebjerg-Frederiksberg, The Parker Institute, Frederiksberg; [3]Dept. of Rheumatology, Copenhagen University Hospital, Gentofte-Herlev, The Parker Institute, Gentofte; [4]Dept. of Rheumatology, Copenhagen University Hospital, Bispebjerg-Frederiksberg, Frederiksberg, Denmark*

**Background:** Pain in rheumatoid arthritis (RA) is typically regarded as related to on-going synovial inflammation in peripheral joints. However, in a subgroup of patients evidence indicates that pain can become an entity of its own caused by central sensitization (CS), elicited by but in time not directly related to ongoing inflammation. The painDETECT questionnaire (PDQ) was developed to differentiate neuropathic pain from unclear and non-neuropathic pain. In several studies it has been used to indicate CS owing to similarities in somatosensory profiles. Magnetic resonance imaging (MRI) can be used as an objective inflammation marker, quantified by the RA MRI Score (RAMRIS).

**Objectives:** To evaluate the prognostic value of a PDQ score >18 on DAS28 response in RA patients taking a possible interaction with inflammation defined by RAMRIS synovitis scores into account.

**Methods:** RA patients were included when they were to: 1) initiate a disease modifying antirheumatic drug (DMARD) or 2) initiate or switch a biological agent. At baseline and after 4 month of follow up patients went through an examination program incl. standard demographics, clinical examination, hand MRI, patient reported outcomes (incl. PDQ), and blood samples. Least-Squares Mean change (95% CI) was calculated using ANCOVA adjusting for the value at baseline. Multivariable regressions with DAS28 or RAMRIS synovitis change as outcome were performed to determine the prognostic variables. The model included PDQ-category, RAMRIS synovitis score and their interaction. Possible confounders were: gender, disease duration, baseline DAS28, and initiation group. PDQ score was interpreted as: >18 indication of CS, 13–18 unclear pain mechanism, <13 nociceptive pain. Pain classification consistency was explored.

**Results:** 102 patients were included, 75 had an MRI scan performed. Mean changes stratified by PDQ-group are presented in the table showing the greatest changes in the CS-group (>18). Only baseline DAS28 was a significant predictor of DAS28 change ($P<0.001$) with a β-estimate (95%CI) of -0.65 (-88;-0.41). Baseline DAS28 and RAMRIS synovitis were significant predictors of RAMRIS synovitis change (P=0.01, P=0.02) with β-estimates of -0.67 (-1.17;-0.17) and -0.19 (-0.35;-0.03). Among the 12 patients with indication of CS (>18) at baseline all had changed classification-group at follow-up (8 to nociceptive pain and 4 to unclear).

Table: Mean change stratified by PDQ-group adjusted for baseline value

| | PDQ-score <13 (n = 66) | PDQ score 13-18 (n=23) | PDQ score > 18 (n = 12) | p-value |
|---|---|---|---|---|
| Classification consistency N (%)* | 64 (97) | 19 (83) | 0 (0) | <0.001† |
| Δ 28 SJC | -2.71 | -2.27 | -2.48 | 0.71 |
| Δ 28 TJC | -4.63 | -4.36 | -5.57 | 0.28 |
| Δ CRP, mg / mL | -6.93 | -2.81 | -6.28 | 0.04a |
| Δ DAS28 | -1.47 | -0.8 | -1.62 | 0.03b |
| Δ Tender point count | -2.70 | -1.56 | -3.83 | 0.35 |
| Δ VAS-fatigue | -18.31 | -8.19 | -22.20 | 0.09 |
| Δ VAS-pain | -23.27 | -12.99 | -26.86 | 0.07 |
| Δ VAS-global health | -26.20 | -13.49 | -31.72 | 0.01b |
| Δ HAQ-DI | -0.34 | -0.15 | -0.74 | <0.001c |
| Δ RAMRIS H synovitis | -1.68 ¹ | -1.75² | -2.46 ³ | 0.72 |
| Δ RAMRIS H oedema | -2.14 ¹ | -0.62² | -3.43 ³ | 0.58 |

* No change of PDQ classification group from baseline to follow up. † Chi square. 1: N=51. 2: N=18. 3: N=6. a; no difference between PDQ-score <13 and >18, and 13-18 and >18. b; no difference between PDQ score <13 and PDQ score >18. c; no difference between PDQ score <13 and 13-18.

**Conclusions:** In this pragmatically sampled population of RA patients, pain classification by PDQ at treatment initiation had no prognostic value with regard to change in DAS28 or RAMRIS synovitis. In contrast, all patients classified with indication of CS by PDQ at baseline changed classification group and were even to gain most from treatment start in net changes. This might indicate that in RA, CS reflects normal neuroplasticity that is reversible with reduction of inflammation.

## FRI0100 APOLIPOPROTEIN A1 IS PROTECTIVE FOR JOINT DAMAGE PROGRESSION IN ACPA-POSITIVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

S. Ajeganova[1], B. Svensson[2], I. Hafström[1]. *[1]Department of Medicine Huddinge, Karolinska Institutet, Stockholm; [2]Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund, Sweden*

**Background:** Lipoproteins are considered to excess pleiotropic functions in inflammation and autoimmunity. Apolipoprotein (apo) A1 has been reported to associate with arthritis development and hypercholesterolemia with radiographic progression in patients with rheumatoid arthritis (RA). Although a higher risk for more destructive RA in the presence of anti-citrullinated protein antibodies (ACPA) is recognized, responses driving the joint damage and protective mechanisms that could inhibit the pathological process are not defined.

**Objectives:** We hypothesized that radiological joint damage progression would be influenced by lipoproteins. We aimed firstly to explore association between lipoproteins and radiographic damage, and secondly, to investigate if this association was different in ACPA+ and ACPA- patients.

**Methods:** In all, 114 patients with early RA were included, 68% women, 71% ACPA+, mean age 50.6 (11.2) years. Apolipoproteins and oxidized low-density lipoprotein (oxLDL) were assessed in baseline serum and at 3, 12, 24 and 60 month after RA diagnosis. Radiographs of hands and feet were taken at inclusion, 12, 24 and 60 months and scored by the Sharp-van der Heijde (SHS) method. There were no differences between ACPA+ and ACPA- patients by age, sex, initial treatment, baseline DAS28, levels of lipoproteins and SHS, but ACPA+ patients had a longer symptom duration at inclusion, mean 6.8 (3.1) months vs. 4.8 (3.3), p=0.002. Normal regression was performed with adjustments for age, sex and initial treatments. Constant effects were tested in the final analyses as interaction with time was not significant. Significant associations were assessed within ACPA stratum.

**Results:** Higher apoA1 at inclusion was associated with lower SHS over 5 years, β=-0.204 (-0.400; -0.008), p=0.042. When stratified by ACPA status, this association was shown in ACPA+ patients, β=-0.237 (-0.456; -0.017), p=0.035, after additional adjustment for baseline disease duration, β=-0.207 (-0.421; 0.012), p=0.064. In ACPA- patients, association between baseline apoA1 and SHS overtime were not found, p=0.99. There was a trend for association between apoB/apoA1 at baseline and SHS over follow-up, β=0.351 (-0.055; 0.758), p=0.090.

Higher levels of apoA1 over 5 years were associated with lower SHS progression (ΔSHS = SHS 5 years – SHS inclusion), β=-0.004 (-0.006; -0.002), p<0.001. This association was confirmed in ACPA+ patients, β=-0.004 (-0.006; -0.001), p=0.002, but not in ACPA-, p=0.39. The result in ACPA+ stratum was unchanged after adjustment for disease duration, β=-0.004 (-0.006; -0.001), p=0.002. Further, a positive relationship was observed between apoB/apoA1 over 5 years and ΔSHS, β=0.002 (0.001; 0.003), p=0.006, also valid for ACPA+ patients, β=0.002 (0.001; 0.003), p=0.021, but not ACPA- patients, p=0.79. The finding in ACPA+ stratum was stable after adjustment for disease duration, β=0.002 (0.001; 0.003), p=0.016.

There were no significant associations between apoB and oxLDL and radiographic outcome, p>0.05.

**Conclusions:** We observed associations between apolipoproteins and radiographic outcome in patients with early RA. Apolipoprotein A1 showed a protective effect for radiographic joint damage in ACPA positive patients. Further exploring role of apolipoproteins may contribute to the understanding of immune-specific pathways.

## FRI0101 ASSESSMENT OF LARGE JOINT DESTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY USING FDG-PET/CT AND ARASHI SCORING METHOD

T. Suto, Y. Yonemoto, K. Okamura, C. Okura, K. Takagishi. *Department of Orthopaedic Surgery, Gunma University Graduate School of Medicine, Maebashi, Japan*

**Background:** Larsen method has been widely used to assess large joint destruction in patients with rheumatoid arthritis (RA). In that method, various changes might be included within one grade. 18F-fluorodeoxyglucose positron emission tomography combined with computed tomography (FDG-PET/CT) can visualize the disease activity in large joints affected by RA.

**Objectives:** The associations between destruction of the large joint and FDG-PET/CT findings were investigated using a new radiographic evaluation method "ARASHI Scoring system"[1].

**Methods:** A total of 260 large joints (shoulder, elbow, hip, knee and ankle) in 26 RA patients (six males and 20 females; mean age of 66.9 years) were assessed in this study. FDG-PET/CT was performed at baseline and six months after the initiation of biological therapy. The extent of FDG uptake in large joints was analyzed using the maximum standardized uptake value (SUVmax). Radiographs of the 10 large joints per patient obtained at baseline and after three years were evaluated according to the ARASHI change score. A multiple regression analysis was performed to determine the factors most significantly contributing to the progression of large joint destruction within three years.

**Results:** Eighteen joints had previously been treated with joint replacement surgery at baseline and nine joints were treated with joint replacement surgery in three years. They were excluded from this study, so we evaluated 233 large joints. The ARASHI status score (score at baseline), SUVmax at baseline, DAS28-ESR and ΔSUV (SUVmax at baseline – SUVmax at six months) were significantly associated with high level changes of ARASHI change score. A multiple regression analysis revealed ΔSUV was found to be the most associated factor with joint destruction at three years (p<0.05).

**Conclusions:** We investigated large joint destruction in RA patients using FDG-PET/CT and ARASHI scoring method. This study suggested the importance to decrease SUV value in RA patients with high level of SUVmax at baseline for the prevention of large joint destruction.

## FRI0102 CHARACTERISTICS OF FUNCTIONAL IMPAIRMENT IN PATIENTS WITH LONG-STANDING RHEUMATOID ARTHRITIS BASED ON RANGE OF MOTION OF JOINTS: MULTICENTER PROSPECTIVE COHORT STUDY FOR EVALUATION OF JOINT SURGERY ON PHYSICAL FUNCTION

T. Kojima[1], H. Ishikawa[2], K. Nishida[3], S. Tanaka[4], N. Haga[5], M. Yukioka[6], H. Miyahara[7], J. Hashimoto[8], T. KImura[9], H. Oda[10], Y. Niki[11], M. Liu[12], M. Kojima[13], N. Ishiguro[1]. *[1]Orthopedic Surgery, Nagoya University Hospital, Nagoya; [2]Orthopedic Surgery, Niigata Rheumatic Center, Niigata; [3]Human Morphology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama; [4]Orthopaedic Surgery and Spinal Surgery; [5]Rehabilitation Medicine, The University of Tokyo Hospital, Tokyo; [6]Yukioka Hospital, Osaka; [7]Orthopedic Surgery, National Hospital Organization Kyushu Medical Centre, Fukuoka; [8]Rheumatology, National Hospital Organization Osaka Minami Medical Centre, Osaka; [9]Orthopedic Surgery, Toyama Univeristy Graduate School of Medicine, Toyama; [10]Orthopedic Surgery, Saitama Medical Univeristy, Saitama; [11]Orthopedic Surgery, Keio Univerisity School of Medicine; [12]Rehabilitation Medicine, Keio University School of Medicine, Tokyo; [13]Medical Education, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

**Background:** Even now, in clinical practice, most of RA patients have long-standing disease and structural damage in their joints. Reconstructive joint surgery should be needed for further improvements of physical function for long-standing RA patients. It is very important to understand how much range of motion (ROM) should be needed to gain better physical function in each case.

**Objectives:** The purpose of this study is to explore the characteristics of functional impairment in RA patients who were needed joint surgery based on ROM of joints using multicenter prospective cohort.

**Methods:** We conducted this prospective study from 2012 to2015 (Study registration: UMIN000012649) We collected data on age, sex, disease duration, drug therapies, disease activity, and physical functional including HAQ-DI. Joint range of motion including shoulder, elbow, wrist, hip knee ankle was also measured. ROM in each joint by disability in HAQ-DI categories was compared by ANOVA with adjustment of age and sex. Association between ROM of each joint and no disability of daily activity in each 8 HAQ-DI categories was determined using ROC curve and logistic regression analysis.

**Results:** 460 patients who have data of ROM of any joints in registry were analyzed. Mean values for age, disease duration, DAS28-CRP and sex were 64.6 years, 16.9 years, 3.17, and 86.3% female, respectively. Median values for CRP was 0.2 mg/dl. We could find significant association between ROM and disability in HAQ-DI category based on area under the ROC curve. ROM of each joints had different impact on disability of each category (ie, ROC curve for category Arising, Fig. 1). The cut-off values of ROM of each joints for daily activity in each HAQ-DI category was shown in Table 1 using ROC curves (Table 1). Multivariate analysis

adjusting disease activity, age, and sex, showed which joint had significant impact on disability of each category (Table 2).

Table 1: Cut off value of ROM of each joint for no disability in daily activity based on HAQ-DI

| | HAQ-DI category | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | Dressing | Arising | Eating | Walking | Hygiene | Reach | Grip | Activity |
| shoulder abduction | 134.5 | 142.8 | 131.3 | 141.0 | 141.0 | 133.5 | 131.3 | 131.3 |
| elbow flex-extension | 120.5 | 125.5 | 118.8 | 126.5 | 126.5 | 113.8 | 120.5 | 120.5 |
| wrist supination-pronation | 153.3 | | 150.8 | | 153.3 | 156.0 | 144.5 | 144.5 |
| wrist flexion-extension | 78.8 | 69.5 | 76.3 | | 78.8 | 86.3 | 89.0 | |
| knee flexion-extension | 133.8 | 133.8 | | 133.8 | 131.3 | 123.8 | 123.8 | 123.8 |
| hip flexion-extension | 126.3 | 131.3 | 131.3 | 126.3 | 126.3 | 113.8 | 131.3 | 131.3 |
| ankle flexion-extension | 53.8 | 61.3 | 56.3 | 58.8 | 56.3 | 56.3 | 53.8 | 53.8 |

Cut off values were determined using ROC curve, when it showed significant association of the ROM to disability in each category.

Fig.1: Association of ROM of each joint in Arising

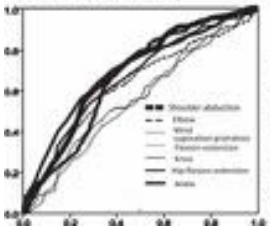

Table 2: Association of ROM of each joint to disability in daily activity based on HAQ-DI category

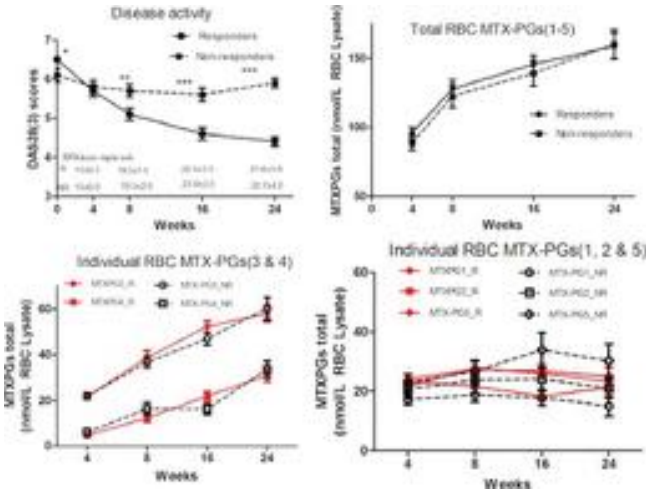
| | HAQ-DI category | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | Dressing OR | Arising OR | Eating OR | Walking OR | Hygiene OR | Reach OR | Grip OR | Activity OR |
| shoulder abduction | .98 | .99 | .91 | .99 | .97 | .97 | .98 | .97 |
| wrist flexion-extension | | .89 | .94 | | .89 | .99 | .99 | 1.00 |
| knee flexion-extension | | .96 | 1.01 | .96 | | | | |
| hip flexion-extension | | .98 | .91 | .96 | | .97 | | .97 |
| ankle flexion-extension | | | | .97 | | | | |



Only significant independent factors [OR /increase 1 degree of ROM] were shown.

**Conclusions:** ROMs of the joints were significantly associated with functional impairment. The information should be important for assessment of disability in patients with long-standing RA. The cut-off of ROM as shown in this study could be target of surgical procedure. It will be validated by further analysis of longitudinal data of this study.

## FRI0103 ERYTHROCYTE METHOTREXATE POLYGLUTAMATE LEVELS DO NOT DETERMINE EFFICACY AND TOLERABILITY OF METHOTREXATE IN RHEUMATOID ARTHRITIS

V. Dhir[1], A. Sandhu[1], A. Bhatnagar[2], V. Dhawan[3], J. Kaur[4], A. Sood[3], A. Sharma[3], S. Sharma[3]. *[1]Internal Medicine (Rheumatology Unit), Post Graduate Institute of Medical Education and Research; [2]Biochemistry, Punjab University; [3]Post Graduate Institute of Medical Education and Research; [4]GMCH 32, Chandigarh, India*

**Background:** Methotrexate (MTX), a mono-glutamate, by addition of 2–6 more glutamate moieties, is converted to methotrexate polyglutamates (MTX PGs) intracellularly. These are the active compounds mediating folate pathway inhibition and increase in adenosine. Erythrocyte polyglutamate levels (RBC MTX PGs) are surrogate markers for levels inside lymphocytes and hepatocytes.Variability in RBC MTX PGs formed intracellularly (despite similar MTX dose) may be one of the factors determining variability in efficacy of MTX. Previously, contrasting results have been found on their association with efficacy and few prospective studies exist.
**Objectives:** To assay levels of erythrocyte methotrexate polyglutamate (1–5) levels in patients with rheumatoid arthritis and assess their relationship to efficacy and adverse effects.
**Methods:** Prospective study that included patients of RA (fulfilling 1987 ACR), aged 18–65 years with active disease (DAS28–3v>3.2) and not on methotrexate. Oral MTX was started at 15 mg/week and increased to 25 mg/week at 8 weeks. Disease activity measured using DAS28 (3 variables), and at 24 weeks patients classified into responders (EULAR good or moderate response) or non-responders. MTX-PG levels (PGs 1–5) assayed in deproteinised packed RBCs by HPLC using reverse phase (C18 column) and post-column derivitization using UV photo-oxidation followed by fluorescent detection (ex 274; em 470 nm).
**Results:** Included 117 patients, with mean (±SD) age of 42.7±11.9 years, disease duration 2.0±1.7 years, 71.8% RF+ and 85.7% CCP+. At 24 weeks, there were 57 responders and 33 non-responders with no significant difference in mean (±SD) MTX dose (21.7±3.9, 22.7± 4.1mg/week, p=ns), age, disease duration, but with lower BMI (21.7±3.9, 24±4.5 kg/m$^2$, p=0.02) and higher baseline DAS28(3) (6.5±0.7, 6.1±0.9, p=0.02). There was an early and sustained gap between the curves of DAS28(3) between responders and non-responders (Figure, left upper quadrant). Methotrexate PG levels increased till 24 weeks (mainly PG3 and PG4), with reasonable correlation between dose and MTX PG levels (r=0.38, p<0.05). There was no significant difference in the mean methotrexate polyglutamate levels (sum of pgs 1–5) nor individual PGs between responders and non-responders at any of the visits (4, 8, 16 and 24 weeks) ((Figure, right upper quadrant and lower panel). Symptomatic adverse effects occurred in 34 patients (57 episodes)

– most commonly nausea. There was no significant difference in MTX-PG levels between patients with and without symptomatic adverse effects. Mild transaminitis occurred in 43 patients (at atleast one visit) and mild thrombocytopenia in 16 patients; with no difference in methotrexate polyglutamate levels.
**Conclusions:** Our study suggests that MTX-PG levels is not a determinant for response to MTX or their adverse effects. This is different from a previous prospective study, we think the differnce lies in MTX dose and clear classification as reponder and non-responders in our study.

## FRI0104 LONG-TERM FOLLOWUP OF BIOLOGIC AGENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Kaneko, H. Kondo, M. Ohta, T. Takeuchi. *Keio University, Tokyo, Japan*

**Background:** Biologic agents have altered treatment strategy and improved outcome in rheumatoid arthritis (RA). More than 10 years have passed since the emergence of the first biologic agent, and the switch to alternative agent for insufficient efficacy and intolerance is not infrequent. However, the continuation rate of biologic agents and reasons for discontinuation in a long-term are unclear.
**Objectives:** To evaluate followup data for more than10 years of biologic agents in patients with RA.
**Methods:** Patient who started biologic agents including infliximab, etanercept, adalimumab, tocilizumab and abatacept for RA between 2003 and 2013 were enrolled in the study. The continuation rate was calculated by Kaplan-Myere analysis, and reasons for discontinuation were retrospectively investigated. Factors contributory to the continuation rate were identified. The analyses were performed in all patients, and subsequently in patients on individual biological agents.
**Results:** A total of 1500 biologic agents were introduced in 1036 patients with RA for the 11 years. At the initiation of biologic agents, the mean age was 57.2 years old, the rate of female 82.5%, disease duration 103 months, rheumatoid factor positivity 78.8% DAS28 4.90, and health assessment questionnaire 1.09. Methotrexate (MTX) was used in combination with biologic agents in 81.1%. Overall continuation rate was 68.7% at year 3, 58.8% at year 5, and 27.6% at year 10. Reasons for discontinuation were insufficient efficacy in 64.3% and adverse effect in 45.7%. Baseline characteristics to predict the continuation of biologic agents were the concomitant use of MTX (OR=1.61, P=0.03), lower baseline values for 28 joints (DAS28, OR=1.14, P=0.02) and shorter disease duration (OR=1.01, P=0.03). In bio-naïve patients, continuation rate was 69.3% at year 3, 59.4% at year 5, and 28.5% at year 10). In terms of individual biologic agents, high continuation rate was ascribed to lower disease activity for infliximab (OR=1.32, P=0.001), the concomitant use of MTX for etanercept (OR=1.22, P=0.03) and adalimumab (OR=1.53, P=0.04), shorter disease duration for abatacept (OR=1.00, P=0.05). No specific factor for tocilizumab continuation was found.
**Conclusions:** In the initiation of biologic agents, patients using concomitant MTX with shorter disease duration in lower disease activity were inclined to continue the biologic agents. Factors for good continuation rate were different among biologic agents. The present study can contribute optimal usage of biologic agents in the treatment of RA.

### FRI0105 LOW THORACIC BONE MINERAL DENSITY AND GLUCOCORTICOID ARE RISK FACTORS FOR CLINICAL FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS: FIVE-YEAR FINDINGS OF THE TOMORROW STUDY

Y. Yamada[1], K. Inui[2], K. Mamoto[1], T. Okano[1], Y. Sugioka[3], M. Tada[4], T. Koike[3,5], H. Nakamura[1]. *[1]Department of orthopedics surgery; [2]Department of Rheumatosurgery; [3]Center for Senile Degenerative Disorders (CSDD), Osaka city university medical school; [4]Department of orthopedics surgery, Osaka City General Hospital, Osaka city; [5]Search Institute for Bone and Arthritis Disease (SINBAD), Wakayama, Japan*

**Background:** Patients with rheumatoid arthritis (RA) who have muscle weakness and stiff or painful joints might be at increased risk of falls and fracture.
**Objectives:** The present study aimed to prospectively determine the incidence of clinical fractures and associated risk factors in patients with RA who participated in the TOMORROW study (UMIN000003876) that started in 2010.
**Methods:** We evaluated anthropometric parameters, bone mineral density (BMD), disease activity, RA medication, and the incidence of clinical fractures over a five-year period in 202 patients with RA (mean age, 58.6 y; medication with biological agents, 54.9%) and 202 age- and sex-matched healthy volunteers (controls; mean age, 57.4 y). We compared the incidence of clinical fractures between patients and controls between 2010 and 2015 and analyzed associated risk factors in the patients using multivariate regression analysis.
**Results:** The incidence of clinical fractures did not significantly differ between patients with RA (0.042/person-years; py) and controls (0.034/py) within the five-year period (p=0.35). Fractures sites also did not significantly differ between the two groups. Multivariate logistic regression analysis adjusted for fracture risk factors including age, sex, smoking, and body mass index revealed that low BMD at the thoracic vertebrae (<0.7 g/cm$^2$) was significantly associated with the incidence of clinical fractures (odds ratio [OR], 2.95) in all participants group (Table 1). Although medication with glucocorticoid (GC) at entry was also a significant risk factor for fractures (OR, 2.58), RA morbidity was not (Table 1). Among patients with RA, low BMD at the thoracic vertebrae (<0.7 g/cm$^2$) was the most prominent risk factor for fractures (OR, 4.44; Table 1). Additionally, medication with GC at entry (OR, 2.58) was a significant risk factor for fractures in the patients. A mean GC dose of ≥2 mg/day during the five-year period increased risk for fractures in the patients (OR, 3.48; Table 1).

Table 1. Multivariate logistic regression analysis of risk factors for fractures

| | | Odds ratio | 95% CI | *p* |
|---|---|---|---|---|
| All participants | History of fractures | 1.68 | 0.97–2.89 | 0.064 |
| N=404 | Morbidity of RA | 1.22 | 0.71–2.11 | 0.478 |
| | GC use | 2.58 | 1.22–5.44 | 0.013 |
| | Bisphosphonate medication | 3.37 | 1.51–7.54 | 0.003 |
| | Low BMD at thoracic vertebrae (<0.7 g/cm$^2$) | 2.95 | 1.59–5.48 | 0.001 |
| RA patients | History of fractures | 1.99 | 0.95–4.16 | 0.069 |
| N=202 | GC medication | 2.58 | 1.22–5.44 | 0.013 |
| | Average GC dose ≥2 mg/day/5 y | 3.48 | 1.19–10.21 | 0.023 |
| | Bisphosphonate medication | 3.37 | 1.51–7.54 | 0.003 |
| | Low BMD at thoracic vertebrae (<0.7 g/cm$^2$) | 4.44 | 1.69–11.64 | 0.002 |

CI, confidence interval; RA, rheumatoid arthritis; GC, glucocorticoid; BMD, bone mineral density.

**Conclusions:** The incidence of clinical fractures did not significantly differ between patients with RA and controls during a period of five years. Low BMD at the thoracic vertebrae and low GC doses are apparently significantly associated with an increased frequency of fractures among patients with RA.
**Disclosure of Interest:** None declared

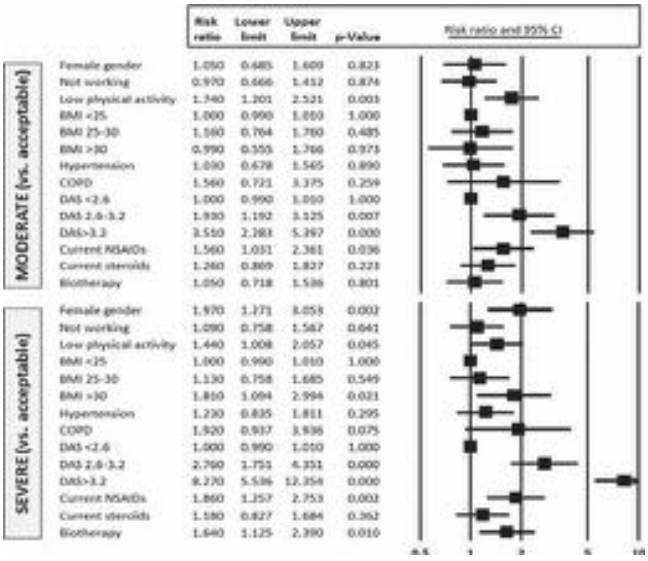
## Rheumatoid arthritis - comorbidity and clinical aspects



### FRI0106 THE ASSOCIATION OF FATIGUE, COMORBIDITIES AND ANTI RHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS: RESULTS FROM THE COMEDRA STUDY

A. Tournadre[1], B. Pereira[2], L. Gossec[3], M. Soubrier[1], M. Dougados[4]. *[1]Rheumatology; [2]DRCI, CHU, Clermont Ferrand; [3]Paris 6 University; [4]Rheumatology B, APHP Cochin Hospital, Paris, France*

**Background:** The mechanisms of fatigue in rheumatoid arthritis (RA) are still unclear and the effect of antirheumatic drugs on fatigue not fully established.
**Objectives:** To analyse in a large cohort of RA the factors associated with fatigue focusing on social aspects, comorbidities and treatment intake.
**Methods:** Cross sectional analyses were performed on RA patients from the French cohort study of comorbidities COMEDRA (1). Fatigue was assessed as a quantitative variable (RAID3 0–10 numeric scale) or by class (acceptable <3; moderate 3–4; severe ≥5 out of 10). Relationship with demographic, social, disease characteristics, treatments, comorbidities, physical activity, quality of life was investigated in univariate analyses (Table) and multivariate polynomial regression (Figure).
**Results:** 962 patients were analysed (age 57.7 ± 11.1 years, disease duration 11.1 years [6.2–19.1], mean DAS28 3.1 ± 1.3), 763 (79%) were female. The mean fatigue score was 3.8± 2.7. Severe fatigue was more frequent in women, in patients not working, with less physical activity and more obesity. Fatigue was correlated with disease duration (p=0.05), all disease activity index (p<0.001), pain (p<0.001), mHAQ (p<0.001), sleep (p<0.001) and emotional well-being (p<0.001). Among comorbidities, hypertension, chronic obstructive pulmonary disease (COPD), fracture history and RA-related surgery were associated with fatigue. Fatigue was more severe in patients with current NSAID, steroid, biologic treatments. Methotrexate use and the type of biologic did not impact fatigue score.

| Biotherapy alone or in combination (n=672) | 0.46 [0.07; 0.84]* | 0.96 [0.67; 1.38]<br>1.45 [1.04; 2.01]** |

***p<0.001; **p<0.01; *p<0.05.

**Conclusions:** Beyond the expected association of fatigue with disease activity, female gender, pain, sleep and emotional well-being, comorbidities and less physical activity could contribute to the frequent fatigue noted in RA. Fatigue was

associated with steroids, NSAIDs, biotherapies but not with methotrexate and did not depend of the type of biotherapy.

## FRI0107 NO INCREASED RISK OF HIGH GRADE CERVICAL DYSPLASIA IN WOMEN WITH RHEUMATOID ARTHRITIS

L. Chadwick[1], L. Kearsley-Fleet[1], N. Brown[2], K. Watson[1], M. Lunt[1], D. Symmons[1], K. Hyrich[1,2]. [1]*Arthritis Research UK Centre for Epidemiology, The University of Manchester;* [2]*Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom*

**Background:** There is concern that women with rheumatoid arthritis (RA) are at increased risk of high-grade cervical dysplasia (HGCD) detected via cervical smear. There is also controversy regarding the effect of chronic disease/disability on routine cancer screening attendance in this population.
**Objectives:** To (1) compare uptake of cervical screening for women with RA in the British Society for Rheumatology Biologics Register for Rheumatoid Arthritis (BSRBR-RA) with the general population and (2) compare frequency of HGCD between RA and the general population and between patients with RA ever versus never exposed to biologics.
**Methods:** The BSRBR-RA, a prospective cohort study, was linked to the NHS Cervical Screening Programme England (CSPE). Data from 2004–2014 was analysed in line with CSPE methods who publish coverage analysis annually; coverage is defined as the number of women who have been adequately screened at the defined age-dependent review period out of the total number of women eligible for screening in this period. Annual coverage was calculated for the eligible BSRBR-RA population and compared to national statistics. Within the BSRBR-RA, coverage was also compared between those patients with mild/moderate disability (mean Health Assessment Questionnaire (HAQ) scores $<2$) and high disability (HAQ $\geq 2$).
Rates of HGCD (moderate dyskariosis or greater) and low grade cervical dysplasia (LGCD, borderline or mild dyskariosis) were compared to rates of negative smears using risk difference calculations between the BSRBR-RA and national statistics, and between the biologic naïve (standard DMARD therapy) and biologic exposed cohorts within the BSRBR-RA.
**Results:** Of 13565 linked records, 12939 women had RA of which 12785 had cervical screening data, 2132 (17%) on nbDMARD therapy and 10653 (83%) with biologic exposure. Between 2004–2014 mean five-year coverage was higher in the BSRBR-RA population at 82.5% (95% CI 81.9, 83.1) compared to 79.0% (95% CI 78.5, 79.6) nationally. This mostly reflects significantly higher age appropriate coverage in the 25–49 year group for the BSRBR-RA population: 77.2% (95% CI 75.9, 78.6) compared to 71.4% (95% CI 70.2, 72.6) nationally. Coverage was higher among women with HAQ $<2$ (n=6631) compared to those with HAQ $\geq 2$ (n=5163): 85.4% (95% CI 84.7, 86.1) and 78.1% (95% CI 77.3, 78.8) respectively. The risk of HGCD was lower in the BSRBR (0.9%) compared to the general population (1.3%) with a risk difference of -0.004 (95% CI -0.005, -0.002). The risk of LGCD was higher in the BSRBR (7.5%) compared to the general population (5.4%) with a risk difference of 0.021 (95% CI 0.017, 0.025). There was no significant risk difference for HGCD between the biologic and nbDMARD cohorts at 0.009 (95% CI -0.003, 0.021).
**Conclusions:** Women in the BSRBR-RA in England have higher rates of cervical screening attendance than the general population, although high HAQ scores had a negative effect on screening attendance. Those aged 25–49 years had markedly higher attendance; this may reflect familiarity with accessing healthcare. Cytology analysis suggests lower risk for HGCD in the RA group but higher risk for LGCD; this may reflect increased screening attendance. Women receiving biologic therapy were not at an increased risk of HGCD compared to those receiving standard DMARD therapy.

## FRI0108 RHEUMATOID ARTHRITIS IS ASSOCIATED WITH INCREASED RATE OF MALIGNANCY: A CROSS-SECTIONAL ANALYSIS OF 69755 PATIENTS

S. Tiosano[1,2], G. Segal[2,3], A. Dagan[2,3], D. Comaneshter[4], A.D. Cohen[4,5], H. Amital[1,2]. [1]*Department of Medicine 'B', Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Ramat-Gan;* [2]*Sackler School of Medicine, Tel-Aviv University, Tel-Aviv;* [3]*Department of Internal Medicine 'T', Sheba Medical Center, Ramat-Gan;* [4]*Chief Physician's Office, Clalit Health Services, Tel-Aviv;* [5]*Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel*

**Background:** Rheumatoid Arthritis (RA) is a common autoimmune disease, which carries a wide variety of comorbidities. The risk of developing malignancy amongst RA patients is of increased both due to the constant inflammatory activity (1) and disease therapies.
**Objectives:** To evaluate the association between RA and malignancies.
**Methods:** In this cross-sectional population based study, data were collected from Israel's largest HMO database, comprising over 4 million patients. Study sample included all RA patients (n=11,782) and sex and age matched controls (n=57,973), total of 69755 patients. Medical records were scanned for anthropometric measurements and diagnosis of malignancy. Logistic regression was used to adjust for age, gender, BMI and socioeconomic status.
**Results:** The total malignancy rate was higher among RA patients comparing to controls (21.4% vs. 11.2%, respectively; $p<0.001$). In multivariate analysis, Hodgkin's and non-Hodgkin's lymphoma, multiple myeloma, sarcomas and malignancies of thyroid and cervix were found to be independently associated with RA. Following multivariate analysis lung carcinoma were not found to be independently associated with RA.

| | Malignancy of: | | | | | | |
|---|---|---|---|---|---|---|---|
| | Non Hodgkin Lymphoma | Hodgkins Lymphoma | Lung | Thyroid | Cervix | Sarcoma | Multiple Myeloma |
| Age (Per year) | 1.04 (1.03, 1.04) | 1.01 (1.00, 1.03) | 1.06 (1.05, 1.07) | 1.02 (1.01, 1.03) | 1.01 (1.00, 1.02) | 1.04 (1.02, 1.05) | 1.05 (1.04, 1.07) |

## FRI0109 INFLUENCE OF AROMATASE INHIBITORS THERAPY ON THE OCCURRENCE OF RHEUMATOID ARTHRITIS IN WOMEN WITH BREAST CANCER. RESULTS FROM A LARGE POPULATION BASED STUDY OF THE ITALIAN SOCIETY FOR RHEUMATOLOGY

M. Caprioli[1], G. Carrara[2], S. Pennetta[1], C.A. Scirè[2] on behalf of RECORD. [1]*Department of Medicine, Istituti Clinici di Pavia e Vigevano, Pavia;* [2]*Epidemiology Unit, Italian Society for Rheumatology, Milan, Italy*

**Background:** Though aromatase inhibitors (AIs) and tamoxifen are an essential part of estrogen receptor-positive breast cancer therapy, many patients discontinue the treatment for musculoskeletal symptoms [1]. Whether the musculoskeletal symptoms can be attributed to an underlying rheumatologic disease remain unknown. Sporadic case reports have described the onset of rheumatoid arthritis (RA) in patients who started therapy with tamoxifen or AIs [2].
**Objectives:** The purpose of this study was to evaluate the risk of developing rheumatoid arthritis (RA) in the population of patients with breast cancer treated with AIs.
**Methods:** Data were collected from the administrative health-care database of Lombardy Region, Italy, from 2004 to 2013. This study follows a nested case-cohort design, including women with diagnosis of breast cancer (ICD9-CM codes 174) starting treatment tamoxifen, anastrozole, exemestane or letrozole. Level of neoplasia was defined according to relevant ICD9-CM codes as localized, node-positive, metastatic, unspecified. The risk of RA related to the prescription of the different drugs was estimated by survival models for competing risks and the results are presented as hazard ratios (HRs) and 95% confidence interval (95% CI), adjusted for age and disease duration. Interaction with age and time varying effects were also explored.
**Results:** Out of a total of 10493 women with breast cancer with a median (IQR) age of 66 (57–74), 7533 (71.8%) started an active treatment with adjuvant endocrine therapy. In this subgroup of patients a total of 113 new cases of RA developed during the 26105.9 person-year of 10186 exposure periods, including time varying exposures in the same patient. Using tamoxifen as reference

category, AIs therapy was associated with an increased risk of RA [adjusted HR 1.62 (95%1.03–2.56)], in particular due to anastrozole, even after adjusting for age and level of neoplasia (Table). Interaction with age was not statistically significant, and no time varying effects were observed.

| | Crude HR | Adjusted HR (95% CI)* | Adjusted HR (95% CI)*§ |
|---|---|---|---|
| Tamoxifen | reference | reference | reference |
| Anastrozole | 1.77 (1.10–2.85) | 1.73 (1.06–2.81) | 1.75 (1.07–2.86) |
| Letrozole | 1.51 (0.89–2.56) | 1.49 (0.87–2.56) | 1.47 (0.86–2.51) |

*Adjusted for age at surgery, level of neoplasia; §Competitive risk survival model.

**Conclusions:** In a large population-based sample of women with breast cancer, the exposure to AI therapy compared with tamoxifen is associated with a significantly increased risk of developing RA, which is not influenced by the cancer severity and the relationship of age with indication to specific drugs. In patients with breast cancer treated with AIs and presenting arthralgia referral to rheumatologist is useful to exclude the onset of rheumatoid arthritis.

## FRI0110 ASSESSMENT OF IMMUNOGENICITY OF LIVE ZOSTER VACCINATION IN RHEUMATOID ARTHRITIS PATIENTS ON BACKGROUND METHOTREXATE BEFORE AND AFTER INITIATING TOFACITINIB OR PLACEBO

K. Winthrop[1], A. Wouters[2], E. Choy[3], K. Soma[2], J. Hodge[2], C. Nduaka[2], P. Biswas[2], L. McNeil[2], S. Passador[2], C. Mojcik[2], W. Rigby[4]. *[1]Oregon Health and Sciences University, Portland; [2]Pfizer Inc, New York, United States; [3]CREATE Center, Institute of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom; [4]Geisel School of Medicine at Dartmouth, Lebanon, United States*

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of RA. Clinical guidelines recommend live zoster vaccine (LZV) to prevent shingles in RA, but this has not been studied in RA patients (pts) and the effect of tofacitinib on humoral or cell-mediated responses to LZV is unknown.

**Objectives:** To evaluate the effect of tofacitinib upon the immune response (IR) and safety of LZV.

**Methods:** Pts were aged ≥50 years with active RA (≥4 tender/painful joints and ≥4 swollen joints) despite methotrexate (MTX) ≥4 months (15–25 mg/wk before screening) (study NCT02147587). Pts with prior history of zoster vaccination were excluded, as were those receiving any vaccine in the 6 wks prior to randomisation. After screening, eligible pts on background MTX received LZV and then either tofacitinib 5 mg BID or placebo (PBO) starting 2–3 wks post-vaccination. Both humoral (varicella-zoster virus [VZV]-specific IgG via gpELISA) and cell-mediated responses (VZV-specific T cell enumeration via ELISPOT) before vaccination (baseline [BL], day of vaccination), and then at 2, 6 and 14 wks post-vaccination were measured. Primary endpoint: geometric mean fold rise (GMFR) in VZV-specific IgG titre at 6 wks post-vaccination. Secondary endpoint: proportion of pts achieving a ≥1.5 fold rise in VZV-specific IgG titre 6 wks post-vaccination. Exploratory endpoint: GMFR in VZV-specific T cells (spot-forming cells/$10^6$ peripheral blood mononuclear cells) by ELISPOT between BL and 6 wks post-vaccination. Pts were followed for 12 wks after randomisation for safety.

**Results:** 112 pts were randomised to PBO (n=57) and tofacitinib (n=55). Most PBO (93%) and tofacitinib (98%) pts were evaluable for IR endpoints. Pts were similar with regard to sex, age, baseline disease activity and baseline VZV immune measures (i.e. IgG, ELISPOT). The GMFR in VZV-specific IgG titre at 6 wks was 2.11 for tofacitinib and 1.74 for PBO. GMFRs in tofacitinib and PBO pts were comparable with GMFRs in healthy people ≥50 years as indicated in the LZV labels. The proportion of pts with a 1.5 fold rise in IgG titre at 6 wks post-vaccination rise trended higher for tofacitinib (57.4%) vs PBO (43.4%). The VZV-specific T cell GMFR at 6 wks increased similarly for tofacitinib (1.50) and PBO (1.29). SAEs occurred in 0 and 3 (5.5%) of PBO and tofacitinib arms respectively. One pt had cutaneous dissemination with vaccine-strain VZV (Oka strain virus) 2 days after starting tofacitinib (16 days post-vaccination). This pt was found to lack pre-existing immunity to VZV, consistent with vaccine-induced disease. The event resolved after tofacitinib discontinuation and antiviral therapy.

**Conclusions:** Pts starting tofacitinib had similar VZV-specific humoral and cell-mediated IRs to LZV as compared to PBO-treated pts. Vaccination appeared safe in pts subsequently treated with tofacitinib; however, one patient who lacked pre-existing VZV immunity developed vaccine-induced disease.

## FRI0111 DENTAL ASSOCIATION OR INCIDENTAL FINDING? A META-ANALYSIS AND SYSTEMATIC REVIEW OF THE RELATIONSHIP BETWEEN RHEUMATOID ARTHRITIS AND PERIODONTITIS

N.R. Fuggle[1], T.O. Smith[2], A. Kaul[3], N. Sofat[1]. *[1]Musculoskeletal Research Group, St George's University of London, London; [2]Faculty of Medicine and Health Sciences, University of East Anglia, Norwich; [3]Department of Rheumatology, St George's University Hospital's NHS Foundation Trust, London, United Kingdom*

**Background:** Rheumatoid arthritis (RA) and periodontitis are both chronic inflammatory diseases sharing potential mechanisms including histopathology and demography. An association between these conditions has been demonstrated previously but published studies have not been subjected to meta-analysis with respect to large populations worldwide to fully unravel associations across distinct ethnicities.

**Objectives:** The aim of this analysis was to interogate the relationship between rheumatoid arthritis and periodontitis in the context of the earliest to the most recent literature.

**Methods:** The published databases MEDLINE, EMBASE and PsycINFO were searched using search terms related to RA and periodontitis. Articles were selected if they included data on the number of people with RA diagnosed with periodontitis (or periodontal disease parameters) compared to a control comparison group. Review articles, case reports, animal model studies, non-English language and articles with unavailable abstracts were excluded. Data was extracted, critically appraised using the Downs and Black appraisal tool and a fixed-effect Mantel-Haenszel meta-analysis was performed.

**Results:** A total of 21 papers met the eligibility criteria and provided data for the meta-analysis; 17 studies (including a total of 153,492 participants) comparing RA to healthy controls and 4 (including a total of 1378 participants) comparing RA to osteoarthritis (OA) were evaluated. Studies included patients populations from diverse geographical locations including Taiwan, Japan, India, Holland and the United States. There was a significantly increased risk of periodontitis in people with RA compared to healthy controls (RR: 1.13; 95% CI: 1.04, 1.23; p=0.006; N: 153,277) with a significantly raised mean probing depth, risk of bleeding on probing (BOP) and absolute value of clinical attachment loss in those with rheumatoid arthritis (Figure 1). When comparing RA and OA, there was no significant difference in the prevalence of periodontitis, however the risk of BOP was greater in OA than RA.

Figure 1. Forest-plot representing risk ratio of periodontitis between people with RA and healthy control comparisons.

**Conclusions:** The very strong association between RA and periodontitis is supported by the results of our systematic review and meta-analysis of studies comparing RA to healthy controls Our data show that the association of RA and periodontitis is a significant observation seen worldwide across a range of ethnicities, suggesting common shared mechanisms in both conditions. Future work is required to unravel the basic molecular pathways underlying RA and periodontitis.

**Disclosure of Interest:** None declared

## FRI0112 PERIODONTITIS AND RHEUMATOID ARTHIRTIS: CHARACTERISTICS OF CHRONIC PERIODONTITIS AND ITS ASSOCIATION WITH RHEUMATOID ARTHRITIS

B. Rodríguez-Lozano[1], J. González Febles[2], S. Dadlani[3], J.L. Garnier Rodríguez[4], E. Trujillo[1], V. Hernández Pérez[1], J.F. Díaz González[1]. *[1]Rheumatology, Hospital Universitario de Canarias, Prov. Santa Cruz Tenerife; [2]Periodontology, UCM, Madrid; [3]Periodontology; [4]Odontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife, Spain*

**Background:** Recent clinical-epidemiological data suggest that periodontitis (P) shows higher prevalence in patients with rheumatoid arthritis (RA). However, the strength of association is limited, with odds ratios (OR) ranging from 1,82–8,05. Meanwhile, prevalence of P in adult Spanish population[1] varies from 16–30%,with smaller prevalence of severe P (5–11%). Nevertheless, there is no evidence of the P prevalence in RA patients in Spanish population.
**Objectives:** 1.To describe the prevalence of P and its association with RA in patients located in our reference area. 2.To explain the characteristics of P in RA patients.
**Methods:** Observational, descriptive, cross-sectional, case-control study of RA patients ≥18 years old (ACR/EULAR 2010) in a hospital Rheumatology Service, and a control group with a non-inflammatory joint disease, who had at least 4 teeth, had not received dental prophylaxis or antibiotic intake 6 months before study. Socio-demographic and anthropometric variables with smoking status, Graffar scale, stress level, annual dental prophylaxis, and co-morbidities such as osteoporosis (OP),diabetes mellitus (DM),dyslipidemia (DS),ischemic cardiovascular disease (ICD). Periodontal Variables: plaque index (PI), bleeding on probing (BoP), probing pocket depth (PPD), recession (REC), clinical attachment level (CAL). Dental team: 2 periodontists/2 general dentists with inter-observer variability <30%. Full mouth CAL, PPD and periapical x-rays were taken. CAL was classified according to the European Workshop in 2005 (Tonetti), into level 0 (absence), N1T (mild), N2T (severe). Statistical Analysis: t-student, Kruskal Wallis, Chi-square. Statistical program: Stata 13.1.
**Results:** 344 patients:187 RA (147 F/40 M) and 157 control (101F/56M). Both groups were comparable in age 54,9 (17,9), BMI 27,8 (4,6), stress level, DM and ICD. Differences in gender (>n° of males in controls), socioeconomic status (lower level in RA), >n° of current and former smokers RA (19,25%vs 8,92%/ 24,6%vs 11,46%),OP (23,45% RA vs 7,8%), DS (hipertrygliceridemia 11,23% RA vs 4,46%). There were182/187 (97, 33%) RA patients with P vs 104/157 (66,24%) patients with P in controls; N1T 52,41% RA vs 54,14%; N2T 44,92% RA vs 12,1% controls p<0,001, OR 18,55 (CI 95% 7,188–47,872),which is maintained after adjusting by confounding variables: OR 16,248 ± 9,295 (CI95% 5,295–49,858).Moreover, there was a poor periodontal status in RA patients with a dramatic increase in all periodontal parameters: PI, PPD, n° and percentage of PPD ≥5mm and BoP (p<0,001) compared with control group.
**Conclusions:** 1.Our study shows a strong association between RA and P with an adjusted OR 16,25 2.RA patients presented an increased prevalence of severe P compared to controls with statistical significance, and estimated prevalence in Spanish population. 3. RA patients showed a more severe periodontitis than control patients.4. there were no differences in the prevalence of mild periodontitis between both groups.

## FRI0113 POSTOPERATIVE COMPLICATIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING A BIOLOGICAL AGENT – A SYSTEMATIC REVIEW AND META-ANALYSIS

H. Ito. *Department of Orthopaedic Surgery, Kyoto University Graduate School of Medicine, Kyoto, Japan*

**Objectives:** To evaluate through a systematic review of the literature the association between the use of biological disease-modifying antirheumatic drugs (bDMARDs) and surgical site infection or wound healing delay after orthopedic surgery in patients with rheumatoid arthritis (RA).
**Methods:** A systematic review was performed of articles indexed in the Cochrane Library, PubMed, and Web of Science from 1992 to 2012. The search aimed to identify studies describing surgical site infection (SSI) or wound healing delay in patients with RA treated with or without bDMARDs. Articles fulfilling the predefined inclusion criteria were reviewed systematically and their quality appraised.
**Results:** There was no Cochrane review on this subject. We found 75 articles through specific searches of PubMed and Web of Science, and hand searching. After inclusion and exclusion by full-text review, 10 articles were found for SSI, and five articles for delayed wound healing. The use of bDMARDs appeared to increase the rate of SSI slightly, especially in large joint-replacement surgery. Delayed wound healing was not increased by the use of bDMARDs. However, the definitions of SSI and delayed wound healing varied between the reviewed articles. Most of the articles focused on tumor necrosis factor-a inhibitors.
**Conclusions:** bDMARDs slightly increase the relative risk of SSI but not that of delayed wound healing after orthopedic surgery and should be used with appropriate caution.
**Disclosure of Interest:** None declared

## FRI0114 DEVELOPMENT OF THE PATIENT MOTIVATION QUESTIONNAIRE: CONCEPTUALIZING AND MEASURING MOTIVATION IN PATIENTS WITH INFLAMMATORY ARTHRITIS

Y. El Miedany[1], M. Maha El Gaafary[2], S. Youssef[3], D. Palmer[4]. *[1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; [2]Public Health and community; [3]Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt; [4]Rheumatology, North Middlesex University Hospital, London, United Kingdom*

**Background:** Motivation is literally the desire to do things, and patient motivation was reported to play an important role in determining the outcome of therapy. Measuring patients' motivation reflects their proactivity, engagement and activation to self-manage their disease which is of value both at the individual level (e.g. tailoring management and interventions) and at the educational program evaluation (e.g. monitor efficacy in enhancing activation).
**Objectives:** to develop a questionnaire for evaluating the patient's "motivation" and assess the psychometric properties of that measure in patients with chronic inflammatory arthritis.
**Methods:** the conceptualization stage identified that inflammatory arthritic patients who are likely to have better health outcomes are those who: (1) Understand the nature of their disease, 2. Are involved in treatment and diagnostic choices through a shared decision process; 3. Are aware of the patient's health-engagement role; 4. Able to self-manage symptoms/problems; 5. Able to collaborate with providers; 6. Can find solutions; 7. Able to maintain functioning and reduce health declines; 8. Can engage in activities; 9. Able to administer medications; 10. Able to find resources and select providers based on performance or quality.
Using Rasch analysis and 76 questions item pool; content analysis and semi structured group discussion, the questionnaire was developed including: 10-items scale (0–10 on VAS scale). Construct validity was assessed by correlating the score of the questionnaire to parameters of disease activity (DAS-28, ASDAS and DAPSA scores), functional disability, quality of life, patient self-helplessness measure [1] as well as the patients' compliance to therapy [2]. Reliability and comprehensibility and sensitivity to change were also assessed.
**Results:** The questionnaire was assessed in 432 RA, 415 Psoriatic arthritis patients, and 232 Ankylosing spondylitis patients. Dimensionality analysis revealed a 1-factor solution, explaining 98% of the total variance. It showed acceptable validity as it correlated significantly with disease activity measures: DAS-28: r = -0.85; ASDAS: r = -0.86, DAPSA: r= -0.89. It also correlated significantly with Functional disability score: r= -0.91, and QoL: r= -0.90 as well as patient self-helplessness r= -0.88. The questionnaire was reliable (Cronbach's alpha 0.958) and had no misfitting items. In addition, it was comprehensible (9.4) and sensitive to change (p<0.01). The patient motivation score showed significant (p<0.01) variation with the medication compliance.
**Conclusions:** The Patient Motivation Measure is a patient-reported tool that is valid, reliable, comprehensible and unidimensional scale that reflects the patients': (1) awareness of their role in their disease management, (2) confidence and knowledge necessary to take action, (3) actual ability of taking action to maintain and improve one's health, and (4) staying the course even under stress, (5) ability to find reliable resources. The measure has good psychometric properties indicating that it can be used at the individual patient level to tailor management and monitor changes.

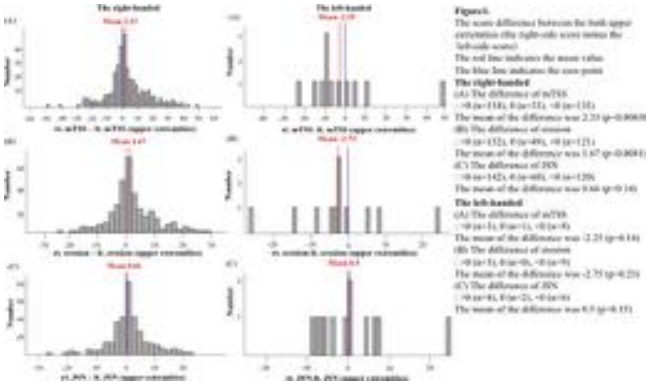
## FRI0115 THE INFLUENCE OF HANDEDNESS TO THE LATERALITY OF CLINICAL AND RADIOLOGICAL ARTICULAR INVOLVEMENT IN RHEUMATOID ARTHRITIS



A. Yaku[1], C. Terao[2], M. Hashimoto[3], M. Furu[3], H. Ito[4], N. Yamakawa[5], W. Yamamoto[6], T. Fujii[1], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology; [2]Center for Genomic Medicine; [3]Department of the Control for Rheumatic Diseases; [4]Department of Orthopaedic Surgery, Kyoto University Graduate School of Medicine; [5]Department of Rheumatology, Kyoto-Katsura Hospital, Kyoto; [6]Department of Health Information Management, Kurashiki Sweet Hospital, Kurashiki, Japan*

**Background:** Mechanical stress would play an important role on inflammation of rheumatoid arthritis (RA). Some studies reported that the dominant hand joints were more affected than the non-dominant ones, but many of them led to the conclusion by evaluating only the right-handed subjects.[1–3]Therefore, it is still inconclusive whether right or dominant hand gets more damaged in RA.
**Objectives:** To clarify the relationship of handedness with clinical and radiological joint involvement in RA.
**Methods:** We enrolled a total of 334 patients from the KURAMA (Kyoto University Rheumatoid Arthritis Management Alliance) cohort.[4] Clinical and radiological joint involvement were compared between the right and left sides, using the tender

joint count (TJC) and swollen joint count (SJC) of the 28 joints evaluated for the Disease Activity Score-28, and erosion and joint space narrowing (JSN) of X-rays scored by the modified Total Sharp Score (mTSS). The right-handed and the left-handed groups were separately evaluated.

**Results:** The right-handed were 96% (n=322) and the left-handed were 4% (n=12). Clinical and radiological involvement of upper extremities tended to be worse in dominant hands than in non-dominant ones. (The mean of the score difference (the right-side score minus the left-side score); mTSS 2.33 (p=0.00030), erosion 1.67 (p=0.0081), JSN 0.66 (p=0.14), SJC 0.32 (p=0.00080) and TJC 0.26 (p=0.00010) in the right-handed. mTSS -2.25 (p=0.14), erosion -2.75 (p=0.23), JSN 0.5 (p=0.15), SJC -0.05 (p=0.95) and TJC -0.03 (p=0.72) in the left-handed). There was a statistical significance in the number of affected joints between the right and left upper extremities in the right-handed group. Although this tendency was also seen in the left-handed group, it was not statistically significant likely due to the smaller sample size.

On the contrary, non-dominant foot showed more damage than dominant foot in the right-handed subjects (The mean of the score difference (the right-side score minus the left-side score); mTSS-1.11 (p=0.57), erosion -0.89 (p=0.37), JSN -0.22 (p=0.63)

**Conclusions:** Handedness influences the laterality of clinical and radiological joint involvement in RA. Laterality of damage in foot may be different from that in hand. This might be because the right-handed usually pivot with the left foot.[5]

## FRI0116 HABITUAL PHYSICAL ACTIVITY IN PEOPLE WITH RHEUMATOID ARTHRITIS WITHIN THE FIRST FIVE YEARS OF DIAGNOSIS

A.S. Elramli[1], L. Paul[1], J.M. Gill[2], C.M. Gray[3], D. Porter[4], A.K. McFadyen[5].
*[1]School of Medicine; [2]Institute of Cardiovascular and Medical Sciences; [3]Institute of Health and Wellbeing; [4]Consultant in Rheumatology and Senior Clinical Lecturer; [5]Statistical Consultant, University of Glasgow, Glasgow, United Kingdom*

**Background:** Physical activity (PA) plays an important role in the management of RA in improving function, reducing risk of CVD and promoting a sense of well-being.

**Objectives:** To identify habitual PA profiles, including time spent sedentary, and self-efficacy to perform exercise. To investigate the association between PA and demographic variables, functional status, quality of life and self-efficacy.

**Methods:** Data were obtained from 76 people within the first five years of RA diagnosis and who were attending Rheumatology clinics in Glasgow, UK. Demographic data (age, sex, level of education, and employment) were recorded. Anthropometric data (Waist to hip ratio (WHR) and body mass index (BMI)) were assessed. PA profiles; the number of steps per day (step count) and time spent sedentary (sitting or lying down) were recorded for seven days using an ActivPAL activity monitor. Quality of life was measured with the Rheumatoid Arthritis Quality of Life questionnaire (RAQoL); functional status was assessed with a six minute walk test (6MWT), Health Assessment Questionnaire (HAQ) and hand grip strength (using a dynamometer). Self-efficacy was evaluated using the Self-efficacy to Regulate Exercise Scale. The data were analysed using Pearson's correlations, t test and ANOVA as appropriate. A multiple linear regression model was developed to investigate the baseline variables that contributed significantly to PA. Statistical significance was accepted at $p<0.05$.

**Results:** Of the 76 participants, 63 were women, mean age was 56 (± 15) years, 42.1% were in employment, WHR was 0.84 (± 0.09) and BMI was 27.4 (± 5.6) kg/m$^2$. The mean 6MWT was 351 (±122.7) m and hand grip strength was 21.6 (±11.3) kg, the RAQoL score was 11.7 (±8.7) and HAQ score was 1.1 (±0.84). Self-efficacy was 40.3% (± 25%). Step count was 7236 (± 2142) steps/day, and time spent sedentary was 18 (± 1.7) hrs. There were weak but statistically significant relationships between step count and: sedentary time (r =-0.238, P=0.039), HAQ (r =-0.318, P=0.005), 6MWT (r=0.265, P=0.021) and self-efficacy, (r=0.284, P=0.013). A multiple linear regression model showed significant association between step count and sedentary time (P=0.033), HAQ (P=0.002) and WHR (P=0.045). There was a significant weak association between sedentary time and self-efficacy (r=-0.262, P=0.022). No other variables showed significant correlations with step count or sedentary time.

**Conclusions:** PA, as determined by steps count is about 30% lower than 10.000 steps/day recommended for health benefits. A higher step count was associated with reduced sedentary time, lower physical disability and WHR. Other variables not included in this analysis, such as pain, and fatigue may also be associated. Participants were within the first five years of being diagnosed with RA however, it is important to maintain/improve levels of PA as the disease progresses to improve the cardiovascular health and functioning of the individual.

## FRI0117 THE PREVALENCE OF DIABETES MELLITUS AMONG RHEUMATOID ARTHRITIS PATIENTS IS MORE THAN TWICE THE PREVALENCE IN THE DANISH POPULATION

A. Emamifar[1], I.M.J. Hansen[1,2]. *[1]Rheumatology, Svendborg Hospital, Odense University Hospital, Svendborg; [2]DANBIO, Herlev University Hospital, Copenhagen, Denmark*

**Background:** Rheumatoid arthritis (RA) is a systemic, autoimmune disease that mainly affects the joints.[1] Furthermore, patients with RA may suffer from different concurrent comorbidities. These comorbidities should be considered when treating RA patients, as they are closely related to treatment response and long-term prognosis.[2] Earlier studies were in favor of increased prevalence of diabetes mellitus (DM) among RA patients; however the association of RA disease characteristic and DM has not previously been evaluated.[3] Considering the prevalence of DM in Denmark (5.7%), patients with RA are at higher risk of DM, possibly due to autoimmunity and RA treatment e.g. steroids.

**Objectives:** To determine the association between clinical characteristics of RA and DM as well as estimate the prevalence of DM among RA patients.

**Methods:** A cross sectional study of the prevalence and association of DM and RA was conducted on all RA patients who had been diagnosed with RA since 1st of January 2010 at the department of Rheumatology. For each patient, data on demographics (age, sex, year of diagnosis), serology test results including rheumatoid factor (RF), anti-cyclic citrullinated peptide antibody (anti-ccp) and antinuclear antibody (ANA) as well as disease activity score in 28 joints (DAS28) at the time of diagnosis and after 4 months (±1–2 months) of treatment were collected in December 2015. To identify patients with concurrent diagnosis of DM, we consequently evaluated all patients' previous medical history, medications and laboratory tests. Chi-square test and t-test were used to compare different variables in patients with/without diabetes.

**Results:** 439 patients were included in this study. Of all included patients 60.14% were female and the mean of age and disease duration were 64.64±15.03 and 2.59±1.66 years respectively. Prevalence of DM was 57/439 (13%). Of 57 patients, 9 patients had hemoglobin A1C $\geq$48 mmol/mol without receiving antidiabetic medication and 9 patients had been prescribed prednisolone with an average of 6.4±2.4 mg daily. The results of our study revealed that longer RA disease duration is associated with higher prevalence of DM, since patients who were diagnosed before 2012 had higher prevalence of DM in comparison with patients who were diagnosed within 2012 and later (P=0.05). We did not find any association between presence of DM and gender, RF, anti-ccp, ANA as well as $\Delta$DAS28.

**Conclusions:** DM is more prevalent among patients with RA compared to general population (13% versus 5.7%). Routine measurement of hemoglobin A1C, at diagnosis and on a yearly basis, in patients with RA should be taken into consideration leading to earlier diagnose of DM and better overall prognosis.

## FRI0118 CAROTID ULTRASONOGRAPHY AND ANKLE-BRACHIAL INDEX IN THE CARDIOVASCULAR RISK ASSESSMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS

A. Ricioppo[1], A. Menghini[1], H. Polo Friz[1,2], G. Marano[3], L. Primitz[1], M. Molteni[1], G. Arpaia[4], P. Boracchi[5], C. Cimminiello[6]. *[1]Internal Medicine, Vimercate Hospital, Vimercate; [2]Research and Study Center, the Italian Society of Angiology and Vascular Pathology (SIAPAV), Milan, Italy; [3]Department of Clinical Sciences and Community Health, Laboratory of Medical Statistics, Epidemiology and Biometry G. A. Maccacaro, University of Milan, Milan, Iraq; [4]Internal Medicine, Carate Hospital, Carate; [5]Department of Clinical Sciences and Community Health, Laboratory of Medical Statistics, Epidemiology and Biometry G. A. Maccacaro, University of Milan; [6]Research and Study Center, Italian Society of Angiology and Vascular Pathology (SIAPAV), Milan, Italy*

**Background:** Rheumatoid arthritis (RA) associates with higher mortality rates than general population, mostly due to cardiovascular (CV) disease [1]. Guidelines recommend CV risk assessment in all RA patients. The European League against Rheumatism (EULAR) has proposed a modified version of SCORE risk estimation system (mSCORE) [2]. Few studies assessed the impact of an increased carotid intima media thickness (cIMT), carotid plaques, and ankle-brachial index (ABI) on the CV risk assessment in patients with RA.
**Objectives:** To assess whether the value of carotid ultrasonography and ABI in the stratification of CV risk in RA.
**Methods:** All RA patients who consecutively attended the outpatient rheumatology clinic of our hospital were enrolled. Exclusion criteria: diabetes mellitus, history of cardio and cerebrovascular events and age>75 years old.
**Results:** The study population was represented by 78 patients, 61 women (78.2%), median age 60 years old and disease duration 6.0 years. The SCORE (median) and EULAR mSCORE were 1.25 and 1.5.

Table 1. ABI and carotid ultrasound findings according to CV risk stratification

| SCORE CV risk (n) | mSCORE | Abnormal ABI | cIMT >0.90 mm | Carotid plaques | cIMT >0.90 mm and/or carotid plaques |
|---|---|---|---|---|---|
| Low (23) | 23 | 2/23 (17.4) | 0/23 (0.0%) | 0/23 (0.0%) | 0/23 (0.0%) |
| Moderate (48 | 47 | 2/47 (4.3%) | 3/47 (6.4%) | 15/47 (31.9%) | 15/47 (31.9%) |
| High (7) | 8 | 0/8 (0.0%) | 1/8 (12.5%) | 4/8 (50.0%) | 4/8 (50.0%) |
| Total (78) | 78 | 4/78 (5.1%) | 4/78 (5.1%) | 19/78 (24.4%) | 19/78 (24.4%) |

All patients with an abnormal ABI had a normal cIMT. 27/78 (34.6%) patients had High CV risk defined as a)mSCORE ≥5% or b)mSCORE<5% plus cIMT>0.90 mm and/or plaques or an abnormal ABI. A SCORE>5% had a Sensitivity of 29.6% (8/27), an Abnormal ABI 14.8% (4/27), a cIMT>0.90mm plus carotid plaques 70.4% (19/27), a mSCORE<5% plus Abnormal ABI 14.8% (4/27), a mSCORE<5% plus cIMT>0.90mm and/or carotid plaques 55.6% (15/27) and an Abnormal ABI plus cIMT>0.90mm and/or carotid plaques 85.2% (23/27).
**Conclusions:** SCORE showed a low sensitivity to identify high risk RA patients, and mSCORE did not improve it. Carotid ultrasonography assessment showed a higher sensitivity than mSCORE and ABI to detect high CV risk. Despite its low sensitivity, an abnormal ABI identify high risk patients not discriminated by using mSCORE nor cIMT. Carotid ultrasound seems to be more sensitive than ABI, SCORE and mSCORE to identify high CV risk in patients with RA.

## FRI0119 THE ASSOCIATION BETWEEN QTC INTERVAL AND MYOCARDIAL ABNORMALITIES IN RHEUMATOID ARTHRITIS PATIENTS WITHOUT CARDIAC SYMPTOMS, BY ASSESSED USING CARDIAC MAGNETIC RESONANCE IMAGING

A. Nishiwaki, H. Kobayashi, Y. Nagasawa, K. Sugiyama, N. Ikumi, T. Nozaki, H. Inomata, H. Karasawa, H. Shiraiwa, M. Iwata, N. Kitamura, M. Takei. *Division of Hematology and Rheumatology, Nihon University School of Medicine, Tokyo, Japan*

**Background:** Individuals with rheumatoid arthritis (RA) have a twofold higher risk of developing sudden death than age and gender matched controls without RA. The underlying mechanisms have not yet been clarified.
**Objectives:** The aim of this study was to prospectively investigate the association of myocardial involvement assessed by a cardiac magnetic resonance imaging (CMR) and the QTc interval in RA without cardiac symptoms.
**Methods:** RA patients and control subjects with no history and/or clinical findings of systemic and pulmonary hypertension, coronary artery disease, valvular heart disease, atrial fibrillation, diabetes mellitus, and dyslipidemia were enrolled and underwent CMR. RA patients received conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) or biologic DMARDs (bDMARDs). Late gadolinium enhancement (LGE) was obtained for the assessment of myocardial fibrosis. Using a black-blood T2-weighted image (T2-WI), myocardial inflammation could be assessed. The QTc intervals were manually measured on a 12-lead electrocardiogram, according to standard criteria. The QTc interval of 440 ms was considered to be prolonged in this study. We compared the patients and controls in terms of prevalence of CMR abnormalities and the QTc interval, and explored possible associations between CMR abnormalities and the QTc interval.
**Results:** Sixty-seven patients (mean age, 54.2 ± 1.7 years; 89% female) and 30 controls (mean age 53.6 ± 2.5 years; 87% female) were enrolled. Thirty-one RA patients received csDMARDs [25, methotrexate (MTX) (9.7±2.1 mg); 7, other drugs)] and 36 RA patients received bDMARDs [(15, infliximab; 15, tocilizumab; 6, abatacept, plus MTX respectively. (9.6±1.4 mg)]. The control group showed no myocardial abnormalities. Twenty seven RA patients (40%) demonstrated myocardial abnormalities. T2-WI was seen in seven RA patients (10%). LGE-positive was found in 20 RA patients (30%), six of whom also demonstrated T2-WI. All RA patients and control patients displayed a normal QTc interval. However, there was significant difference in the QTc interval between the control and LGE-positive (p=0.013). Also LGE-positive was significant higher in the QTc interval than LGE -negative. LGE-positive was associated with the QTc interval. The use of bDMARDs was significantly associated with LGE-negative findings (p=0.001) and the QTc interval. (p=0.001). High titer of anticitrullinated protein antibodies was associated with the QTc interval (p=0.04). Receiver operating characteristic analysis showed the QTc interval reliably detected myocardial abnormalities (area under the curve 0.898; 95% confidence interval, 0.830–0.900). Considering patients with RA and a normal QTc interval and using a cutoff of 420 ms, sensitivity and specificity were 91% and 70% in the detection of myocardial abnormalities.
**Conclusions:** Subclinical myocardial inflammation and fibrosis are common in active RA patients without cardiac manifestation. Abnormal CMR findings were associated with a QTc interval. Even if the QTc interval is normal, we should keep in mind the possibility of subclinical myocardial involvement in RA.
**Disclosure of Interest:** None declared

## FRI0120 THE INCIDENCE OF HERPES ZOSTER (HZ) IN A POPULATION OF PATIENTS WITH INFLAMMATORY ARTHRITIS: A 12-YEAR ANALYSIS FROM THE RHUMADATA CLINICAL DATABASE AND REGISTRY

B. Haraoui[1], L. Bessette[2], J. Brown[2], L. Coupal[1], F. Massicotte[1], J.-P. Pelletier[1], J.-P. Raynauld[1], M.-A. Rémillard[1], D. Sauvageau[1], É. Villeneuve[1], D. Choquette[1]. *[1]Rhumatologie, Institut de rhumatologie de Montréal, Montreal; [2]Rhumatologie, Centre d'ostéoporose et de rhumatologie de Québec, Québec, Canada*

**Background:** Herpes Zoster (HZ) is caused by the reactivation of the varicella zoster virus. It is more prevalent in older populations. Post-herpetic neuralgia, defined as pain lasting longer than 90 days post-eruption, is the most common serious complication of HZ. Immunosuppression from any cause including immunosuppressive treatments increases the risk by a minimum of ten times. Vaccination against HZ in patients with auto-immune diseases appears to be safe and effective[1].
**Objectives:** To describe the 12-year incidence of HZ in a population of patient with either rheumatoid arthritis (RA), ankylosing spondylitis (AS) or psoriatic arthritis (PsA) with and without any biologic treatment.
**Methods:** All treatment episodes of patients with RA, AS, or PsA recruited in the RHUMADATA database from January 1, 1998, to October 1, 2015, were included in the analysis. All episode of HZ as reported by the patient to the healthcare provider were tabulated. Two cohorts were created. Patients with AS and PsA were pooled, and RA patients were analysed separately. Demographics included age, gender and disease duration. Data on exposure biologic agents, nbDMARDs, and to recent corticosteroid use (90 days before HZ or censoring) were also extracted. The incidence rates of HZ were estimated in biologic exposed and naïve patients from both cohorts. Univariate and multivariate Cox models were used to assess the relationship between age, biologic, nbDMARD and recent corticosteroid use, and the development of HZ.
**Results:** RA patients (n=3431) were mostly women (77%) while AS/PsA patients (n=1,727) were mostly men (55%). RA patients were older than AS/PsA patients (53.3 years (SD=12.6) vs. 45.4 years (SD=12.1)) and also had longer disease duration (5.5 years (SD=8.5) vs. 4.8 years (SD=25.1)).
Thirty-six and 119 HZ episodes were observed in the AS/PsA and RA cohorts respectively. Among AS/PsA patients, the incidence rate of HZ per 100 patient-years was 0.80 (95% CI=0.53–1.16) among patients taking biologics and 0.29 (0.12–0.56) for biologic naïve patients (p-value=0.0071). The incidence rate of HZ among biologics treated RA patients was 1.08 (0.83–1.37) per 100 patient-years

and 0.55 (0.41–0.72) among biologic naïve patients (p-value=0.0002). Overall, RA patients and AS/PsA patients had similar HZ incidence rates (0.62 (0.52–0.73) vs 0.53 (0.37–0.71), p-value=0.3460). The hazard ratios for "biologic use" among RA and AS/PsA patients were estimated at 1.866 (1.275–2.733) and 3.467 (1.529–7.859) respectively, after adjusting for age at treatment initiation, concurrent use of nbDMARDs and recent corticosteroid use.

**Conclusions:** Biologic agents doubled the risk of HZ episodes in RA and AS/PsA patients. Significant predictors of HZ episodes among RA patients included age and use of biologics. Among AS/PsA patients, use of biologics and recent use of corticosteroids were significantly associated with the development of HZ. HZ immunization should be considered in patients before initiating biologic agents.

## FRI0121 PROSPECTIVE ASSESSMENT OF CARDIOVASCULAR RISK FACTORS IN RELATION TO DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Targońska-Stępniak, M. Piotrowski, R. Zwolak, M. Majdan. *Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Lublin, Poland*

**Background:** Rheumatoid arthritis (RA) is a chronic, inflammatory joint disease, characterized by accelerated atherosclerosis and increased cardiovascular (CV) morbidity, with cardiovascular disease (CVD) as the leading cause of death. Chronic systemic inflammation responsible for the joint damage, along with traditional CV risk factors, are synergistically involved in the development of progressive atherosclerosis. Carotid intima-media thickness (cIMT) has been approved as a surrogate marker of early atherosclerosis.

**Objectives:** The goal of the study was to assess prospectively traditional CV risk factors and cIMT in patients with established RA; to evaluate relationship between cIMT and RA activity, estimated by clinical examination and ultrasonography of joints.

**Methods:** The study group consisted of 40 consecutive RA patients, 33 (82,5%) female and 7 male (17,5%), with the mean (SD) age 52.3 (9.8) (range 24–68) and disease duration 18.6 (9.6) years (range 6.5–45). The assessment of cIMT was performed twice, at an interval of 6 years [the initial in 2008 (visit 1, V1) and consecutive in 2014 (visit 2, V2)] and was determined by high-resolution B-mode ultrasonography. The activity of RA was estimated by clinical examination at V1 and V2 [with disease activity score in 28 joints (DAS28)] and ultrasonography of joints at V2 (synovial hypertrophy in 24 small joints). At V1 and V2 body mass index (BMI), lipid profile and atherogenic index (AI) were assessed. During the 6 years between V1 and V2, 35 (87,5%) patients were treated with biological disease modifying antirheumatic drugs (DMARDs); nothing by synthetic DMARDs were used in 5 (12,5%) patients. At V2, high disease activity was observed in 7 (17,5%) patients; low RA activity or remission in 23 (57,5%).

**Results:** The mean (SD) cIMT value was significantly greater at V2 than V1 assessment [0.86 (0.45) vs 0.75 (0.13) mm, p=0.02]. The number of RA patients with advanced atherosclerosis (presence of plaques) increased from 6 (15%) at V1 to 9 (22,5%) at V2 (NS). The number of patients without atherosclerosis (cIMT $<$0.6 mm) decreased from 4 (10%) at V1 to 3 (7,5%) at V2. There were positive correlations between cIMT value and the age of patients at V1 and V2 ($p<0.001$). The value of cIMT at V2 correlated negatively with HDL-cholesterol at V1 (p=0.02) and positively with AI at V1 (p=0.01), as well as DAS28 at V1 (p=0.02). There was no correlation between cIMT value and parameters of RA activity at V2 (DAS28, synovial hypertrophy in ultrasonography). A positive correlation was found between DAS28 value and number of joints with synovial hypertrophy assessed in ultrasonography. Lipid profiles and AI value did not differ significantly between V1 and V2. The value of BMI increased significantly between V1 and V2 [24.7 (3.1) vs 25.8 (3.5) kg/m$^2$, p=0.002].

**Conclusions:** During the six-years course of established RA, progression of atherosclerosis was observed, estimated by significantly greater mean cIMT value, as well as increased number of patients with atherosclerotic plaques. In patients with long-standing RA, treated intensively with DMARDs, progressing atherosclerosis seems not to be correlated with the current RA joint activity. The atherosclerotic burden seems to be dependent on the age, previous disease activity and unfavorable lipid profiles associated with high grade inflammation.

## FRI0122 EULAR 2015 RECOMMENDATIONS FOR CARDIOVASCULAR RISK COULD RADICALLY CHANGE PATIENTS CARE IN CHRONIC INFLAMMATORY RHEUMATISMS

C. Daien[1], A. Tubery[1], G. Du Cailar[2], T. Mura[3], M.C. Picot[3], R. Bourret[4], F. Roubille[5], J. Bousquet[4], J. Morel[1], P. Fesler[2], B. Combe[1]. *[1]Rheumatology Department; [2]Internal Medecine Department, CHRU Lapeyronie; [3]Clinical Research and Epidemiology Unit, CHRU la Colombiere; [4]CHRU; [5]Department of Cardiology, CHRU A de Villeneuve, Montpellier, France*

**Background:** Patients with chronic inflammatory rheumatic disease have a greater risk of cardiovascular (CV) diseases. European recommendations of cardiology propose to classify patients with asymptomatic atheromatous plaques as high CV risk patients. New EULAR recommendations about CV risk management propose the use of supra-aortic vessel ultrasound for atheromatous plaques detection and total CV risk estimation. Moreover, EULAR-2015 recommendations suggest multiplying by a 1.5 factor the global CV risk for all patients with Rheumatoid Arthritis (RA) unlike 2010 recommendations.

**Objectives:** The objective of our study was to evaluate the impact of these new recommendations on CV management, especially on indication of statin use, in patients with RA in daily practice, in comparison to EULAR-2010 recommendations.

**Methods:** Total CV risk estimation included physical examination, glucidic and lipidic blood tests, supra-aortic and abdominal vessels ultrasound, echocardiography and global risk SCORE calculation. Heart-SCORE was multiplied according to EULAR-2010 (mSCORE2010) or EULAR-2015 (mSCORE2015) recommendations. For EULAR-2015 recommendations, patients with ultrasound carotid plaques were classified at high CV risk. LDL targets and immediate need of statin use were defined according to European cardiology recommendations with need of statin when LDL $>$0.7 g/L for patients at very high CV risk and $>$1 g/L for those at high risk. In moderate and low risk patients, statins are not immediately recommended.

**Results:** 157 RA patients underwent the screening with a mean disease duration of 13 (6–19) ± 9 years and mean age of 61 ± 11 years. 56/76 (73.7%) of patients classified as moderate risk with Heart-SCORE and 3/12 (25%) of patients with low risk had asymptomatic carotid plaques. Application of the EULAR 2010 recommendations should lead to immediate statin prescription in 42 patients (28%) whereas applications of the EULAR 2015 recommendations should lead to statin prescription in 92 (61%) patients.

**Conclusions:** In our experience, the use of carotid ultrasound to estimate total CV risk and thus to define LDL targets led to prescribe statins in 61% of patients with RA.

**Disclosure of Interest:** None declared

## FRI0123 CLINICAL CORRELATES, OUTCOMES AND PREDICTORS OF INFLAMMATORY OCULAR DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS

C. Caimmi[1], W.M. Smith[2], C.S. Crowson[3], E.L. Matteson[4], A. Makol[4]. *[1]Unit of Rheumatology, Department of Medicine, University of Verona, Verona, Italy; [2]Department of Ophthalmology, Mayo Clinic; [3]Department of Health Sciences Research; [4]Division of Rheumatology, Mayo Clinic College of Medicine, Rochester, MN, United States*

**Background:** Inflammatory ocular disease (IOD) has traditionally been regarded as a severe extra-articular manifestation (ExRA) of rheumatoid arthritis (RA) with high mortality.

**Objectives:** This study aims to evaluate IOD, namely scleritis (SC), episcleritis (EP), peripheral ulcerative keratitis (PUK) and uveitis (UV), identified in a large single-institution cohort of patients with RA to determine clinical correlates, outcomes and risk factors.

**Methods:** A retrospective review was performed to assemble a cohort of patients with IOD among patients with RA evaluated between Jan. 1, 1996-Dec. 31, 2013. All cases met the 1987 ACR criteria for RA. Cases were compared to age- and sex-matched comparators with RA without IOD to identify risk factors. Chi-square and rank sum tests were used to compare characteristics between groups. Kaplan-Meier methods were used to analyze outcomes.

**Results:** A total of 92 patients (69% female; mean age 62 y) were identified with IOD (33 SC, 23 EP, 21 PUK, 14 UV). Median follow-up was 4.1 years (IQR 1.5–9.4 y). Patients with EP were younger than those with UV (p=0.032). More than 80% of SC, EP and PUK patients were seropositive compared to only 62% of UV (p=0.048). Severe extra-articular (ExRA) manifestations (Malmö criteria) before IOD were more common in SC and EP than in UV and PUK, but the latter had a higher prevalence of Sjögren's syndrome (20%). Only 8% of UV had rheumatoid nodules as compared to 35% and 36% of PUK and SC. PUK and SC were more symptomatic compared to EP. EP and UV were primarily treated with topical therapy while SC and PUK often required systemic glucocorticoids, cyclophosphamide, additional DMARDs or biologic therapy.

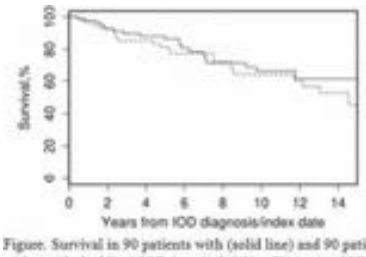

Figure. Survival in 90 patients with (solid line) and 90 patients without (dashed line) IOD (survival 64% ± 7% in non-IOD vs 66% ± 7% in IOD at 10 years after IOD diagnosis/index date; hazard ratio: 0.84; 95% CI: 0.48 – 1.50, p=0.56).

Time to resolution for first episode of IOD was significantly different between various IOD (p=0.015) and in particular longer in SC than in EP (p=0.010). More than 58% of patients with PUK, SC or UV showed a vision loss of at least 2 Snellen lines, as compared to only 11% of EP (p=0.045).
Ninety IOD patients were compared to 90 age, sex and disease duration matched RA subjects without IOD (median disease duration 10.2 y vs. 9.9 y, p=0.612; median follow up 5.7 y (IQR 1.9–10.2) for IOD patients and 4.4 y (IQR 2.0–9.0) for comparators). Cases had a higher prevalence of severe ExRA (18% vs 4%, p=0.004) and dry eye syndrome (42% vs 26%, p=0.024). Ten year survival was 66% for IOD vs 64% for non-IOD subjects (HR 0.84: 95% CI: 0.48–1.50, p=0.56) (figure). No differences were found between IOD after correcting for age. The incidence of new ExRA in 5-year follow up was higher among cases (29% vs 11%, p=0.002).
**Conclusions:** The clinical presentation and treatments differ among the different forms of IODs in RA. Severe ExRA and dry eye syndrome increase the risk for IOD. IOD further predispose patients to develop more ExRA, increasing disease burden. In contrast to older literature, survival among IOD patients is now at least as good as in those without IOD, perhaps due to modern RA treatment strategies or secular disease trends.

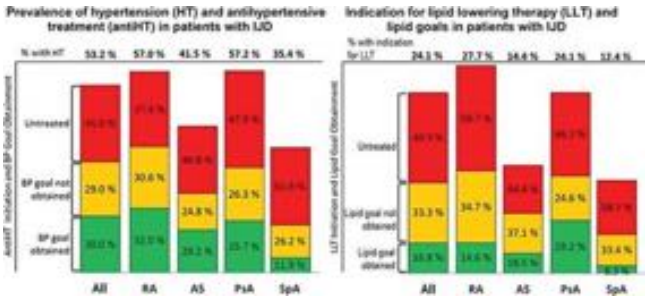
## FRI0124 NONTUBERCULOUS MYCOBACTERIAL INFECTION IN RHEUMATOID ARTHRITIS PATIENTS: A SINGLE-CENTER EXPERIENCE IN SOUTH KOREA

D.-H. Lim[1], S.M. Ahn[1], S. Hong[1], W.J. Seo[2], Y.-G. Kim[1], C.-K. Lee[1], B. Yoo[1]. *[1]Division of rheumatology, department of internal medicine, Asan medical center, University of Ulsan College of Medicine; [2]Division of rheumatology, department of internal medicine, Seoul Veterans Hospital, Seoul, Korea, Republic Of*

**Background:** The incidence of nontuberculous mycobacteria (NTM) infection has been increasing worldwide in both general population and in immunocompromised patients, including rheumatoid arthritis (RA) patients. However, most of previous studies focused on clinical features of NTM infection during treatment with anti-tumor necrosis factor (TNF) or were conducted in western countries, where NTM infection is more common than tuberculosis (TB) infection.
**Objectives:** The aims of our study were to identify the incidence and clinical characteristics of NTM infection in RA patients who live in the TB endemic area.
**Methods:** We performed a retrospective analysis of cases with NTM infection in the RA registry at a tertiary referral center from January 1995 to December 2013. The clinical features of the NTM cases were compared to those of 52 patients with TB infection.
**Results:** Among 1,397 patients with RA, NTM infection was newly developed in 26 (1.86%) patients and the incidence of NTM infection was 164.8 per 100,000 patient-years. The mycobacterium avium complex was the most frequent isolate (76.9%). None of the NTM infections had extrapulmonary involvement, which was rather common in TB infection (26.9%) (Table). Patients with NTM infection were older, received higher cumulative doses of corticosteroid, had higher rates of history of TB infection, and had higher incidence of concomitant interstitial lung disease (ILD) than cases with TB infection.

Table 1. Clinical and laboratory characteristics of the study patients with NTM infection and TB

| Characteristic | NTM (n=26) | TB (n=52) | *p* value |
|---|---|---|---|
| Sex, female (%) | 18 (69.2) | 34 (65.4) | 0.803 |
| Age at diagnosis of RA , years | 54.7±10.3 | 50.2±13.7 | 0.108 |
| Age at infection, years[a] | 63.2±7.7 | 57.5±12.0 | 0.014 |
| Duration of RA , years | 8.5±4.9 | 7.2±7.2 | 0.803 |
| Ever-smoker (%) | 9 (34.6) | 13 (25) | 0.374 |
| History of TB (%)[a] | 10 (38.5) | 6 (11.5) | 0.008 |
| Concomitant ILD (%)[a] | 11 (42.3) | 5 (9.6) | 0.001 |
| Extrapulmonary infection (%)[a] | 0 (0) | 14 (26.9) | 0.003 |
| Antirheumatic drugs at infection | | | |
| Biologics (%) | 6 (23.1) | 5 (9.6) | 0.165 |
| PD (%) | 20 (76.9) | 40 (76.9) | 1.000 |
| MTX (%) | 21 (80.8) | 32 (61.5) | 0.123 |
| Leflunomide (%) | 4 (15.4) | 4 (7.7) | 0.430 |
| Others (%) | 10 (38.5) | 22 (42.3) | 0.810 |
| Dosage of PD at infection (mg/day)[b] | 3.6±2.7 | 3.1±4.4 | 0.682 |
| Cumulative dose of PD at infection (g)[a,b] | 4.5±3.3 | 2.9±3.1 | 0.042 |
| ACPA, U/mL | 697.9±1311.4 | 415.47±1097.4 | 0.340 |
| RF, IU/mL | 199.3±142.7 | 187.19±143.3 | 0.780 |



NTM: nontuberculous mycobacteria; TB: tuberculosis; BMI: body mass index; ILD: interstitial lung disease; PD: prednisolone; [a]$p<0.05$; [b]equivalent dose with prednisolone.

**Conclusions:** In South Korea, NTM infection is not rare in RA patients. Physicians should be cautious about NTM infection in patients with history of TB infection or concomitant ILD, even in endemic areas of TB.
**Disclosure of Interest:** None declared

## FRI0125 EXPLORING THE INADEQUATE CARDIOVASCULAR DISEASE PREVENTION IN INFLAMMATORY JOINT DISEASES: RESULTS FROM THE NOCAR PROJECT

E. Ikdahl[1], S. Rollefstad[1], G. Wibetoe[1], F. Krøll[2], D.M. Soldal[3], I.C. Olsen[1], T.K. Kvien[1], G. Haugeberg[4], A.G. Semb[1]. *[1]Dept. Rheumatology, Diakonhjemmet Hospital, Oslo; [2]Dept. Rheumatology, Lillehammer Hosital of Rheumatic Diseases, Lillehammer; [3]Dept. Rheumatology, Hospital of Southern Norway, Kristiansand; [4]Dept. Rheumatology, Martina Hansen's Hospital, Bærum, Norway*

**Background:** Antihypertensives (antiHT) and lipid lowering therapies (LLT) prevent cardiovascular disease (CVD) effectively. It has been reported that patients with rheumatoid arthritis (RA) receive suboptimal CVD-prevention, possibly contributing to their increased CVD risk. Whether other inflammatory joint diseases (IJD), such as ankylosing spondylitis (AS), psoriatic arthritis (PsA) and other spondyloarthropathies (SpA), also receive inadequate CVD management remains unknown.
**Objectives:** In a large IJD cohort we aimed to evaluate 1) Rate of indications for antiHT and/or LLT, 2) rate of antiHT and/or LLT initiation, and 3) blood pressure (BP) and low-density lipoprotein cholesterol (LDL) goal attainment in patients treated with antiHT or LLT, respectively.
**Methods:** The present IJD cohort is derived from the Norwegian COllaboration on Cardiovascular disease in patients with Rheumatic joint diseases (NOCAR). In NOCAR, CVD risk factors are collected in daily rheumatology practice. Need for antiHT was defined as systolic BP (sBP) $\geq$140mmHg, diastolic BP (dBP) $\geq$90 mmHg or self-reported hypertension (HT). sBP/dBP levels $<$140/90 mmHg were recognized as BP goal attainment. The 10-year risk of a fatal CVD event was estimated by the Systematic COronary Risk Evaluation (SCORE). According to guidelines, patients with diabetes, hyperlipidemia (total cholesterol $>$8 mmol/L, LDL $>$6 mmol/L) or SCORE $\geq$5% are at high CVD risk and should receive LLT (LDL target $<$2.6 mmol/L); whereas established CVD or SCORE $\geq$10% imply a very high CVD risk (LDL target $<$1.8 mmol/L). Rates were calculated for the whole cohort, and compared across IJD entities using logistic regression, age and sex adjusted.
**Results:** Fifty-eight% of the 2647 patients (RA: n=1696, AS: n=445, PsA: n=376, SpA: n=130) were females and the median (inter-quartile range [IQR]) age and disease duration was 57.4 years (46.8–66.8) and 8.0 years (3.8–15.9), respectively. In total, 53.2% had indication for antiHT, and this was significantly higher in RA (57.0%) and PsA (57.2%). Among patients for whom antiHT was indicated, 59.0% received treatment (comparable across IJD entities) and half of the patients on antiHT had obtained BP goal. There was indication for LLT in 24.1%, which was comparable across the IJD entities except for AS (14.4%) ($p<0.0001$). In the group with indication for LLT, 55.6% had high CVD risk which was most frequently seen in PsA (p=0.02), whereas 43.7% had very high CVD risk, which was more common in AS patients (p=0.02). Half of the patients with indication for LLT received this therapy, and treatment rates were higher for patients with very high CVD risk compared to those with high CVD risk ($p<0.001$). In total, 16.8% had achieved LDL treatment targets; LDL goal attainment was particularly high in PsA patients ($p<0.01$), and higher in patients with high CVD risk than in those with very high CVD risk ($p<0.001$).

**Conclusions:** CVD-preventive medication is often indicated, but infrequently initiated in IJD patients. Moreover, when antiHT and LLT are started, quite few patients obtain treatment goals. There is a need for improving CVD risk assessment, initiation of proper CVD-prevention and careful monitoring of target achievements to successfully reduce the excess CVD risk in IJD patients.

## FRI0126 WHO IS AT GREATER RISK FOR MYOCARDIAL INFARCTION IN RHEUMATOID ARTHRITIS?

E. Stumbra Stumberga, H. Mikažane. *rheumatology, RSU, Riga, Latvia*

**Background:** Patients with rheumatoid arthritis (RA) have increased mortality and morbidity due to premature cardiovascular disease (CVD). Some factors involved in the development of RA-associated CVD have not yet been fully delineated.
**Objectives:** The aim of the study was to verify whether female gender, the reproductive period, smoking history, atherosclerotic lesions in brachiocephalic

vessels, carotid intima-media thickness (IMT), traditional CV risk factors, as well as RA disease activity and disease duration influence excess CVD and cerebrovascular disease in patients with RA.
**Methods:** A case-control study was performed within the prospective cohort of 94 RA patients (female: 84%; age: 20–82). Cases were 26 patients who developed their first myocardial infarction (MI) after the diagnosis of RA. Controls and cases had comparable disease duration. Traditional (BMI, smoking history, diabetes mellitus), pulmonary arterial hypertension (PAH) and disease-specific risk factors for MI were assessed. Atherogenic Index of Plasma (AIP; log TG/HDL-C) calculated. Carotid artery hemodynamic parameters, IMT and plaques were assessed using high resolution B-mode and Doppler-mode ultrasound in order to detect blood flow velocities, maximal IMT and size of atherosclerotic plaques, respectively. RA activity and severity were determined by DAS28, CDAI, SDAI scores, ultrasonography of synovitis and HAQ questionnaires. Statistical analysis was performed by using IBM SPSS 21.0
**Results:** Patients with MI were mostly females (96%), with a median age of 61 (54–69) years. The mean disease duration was 3.5 (1–9) years. About 34% of cases were smokers. The risk of MI in RA women was 3.91 (OR). In female patients, who smoked it was 1.36. Patients with MI were not significantly older compared to control RA patients (p=0.316). Interestingly, 88% of RA cases with MI and 100% of non-MI conrtols (p=0.005). High RA disease activity (DAS28 above 4,17) was observed in 46% of patients with MI. Seropositivity was found in 92%, while erosions in small joints in 58% of cases. Joint replacement surgery was necessary in 13% of MI cases. Strokedeveloped in 13% of cases and 10% of controls. PAH was detected in 75%, of patients with MI. No statistically significant difference in IMT between MI cases and controls could be found (p=0.217). Furthermore, atherosclerotic lesions were not more pronounced in RA patients with versus without MI (p=0.874).
Altogether 91,7% patients with MI had atherosclerotic plaques in brachiocephalic vessels resulting in $<$50% luminal stenosis, while 8,3% of patients had plaques causing $>$50% lumen obstruction. IMT exerted significant correlation with age ($p<0,001$), plaques in brachiocephalic vessels (p=0.045), PAH (p=0.001), joint erosions ($p<0.05$) and symptom onset in RA ($p<0.05$). PAH also correlated with brachiocephalic vessel plaques (p=0.01). Bivariate logistic regression revealed that in females with late onset menarche ($>$16 years) and early menopause ($<$45 years) had lower, while patients with late onset menopause had greater risk for developing MI
**Conclusions:** In our case-control study, brachiocephalic plaques, PAH, the onset of menarche and menopause may be associated with the development of MI in RA patients. These preliminary observations indicate the existence of less evident risk factors, which should be further characterized in future studies

## FRI0127 ANGIOGENIC PLACENTAL FACTORS DURING PREGNANCY IN RHEUMATOID ARTHRITIS

F. Förger[1], M. Baumann[2], L. Risch[3], L. Raio[2], D. Surbek[2], U. Wiedemann[3], A. Zbinden[4]. *[1]Rheumatology, Inselspital, University of Bern; [2]Obstetrics and Gynecology, Inselspital, University of Bern; [3]Labormedizinisches Zentrum Dr. Risch; [4]Rheumatology, Inselspital, University of Bern, Bern, Switzerland*

**Background:** Reduced birth weight in infants born to women with rheumatoid arthritis (RA) is often related to active maternal disease during pregnancy.
**Objectives:** We hypothesized that RA might have an influence on placental function and investigated whether pro-angiogenic and anti-angiogenic placental proteins such as placental growths factors (PLGF) and soluble fms-like tyrosine kinase-1 (sFlt-1) were differently regulated in patients with RA compared to healthy controls.
**Methods:** Sera of 27 pregnancies in RA patients and of 10 aged-matched healthy women were analyzed for PLGF and sFLT-1 by ELISA once at each trimester (gestational week 10–12, 20–22 and 30–32). Disease activity of all RA patients was measured by DAS28-CRP and CRP. Neonatal birth weights and birth weight percentiles were correlated with PLGF- and sFLT-1- levels.
**Results:** Of the 37 pregnancies there was no case of preeclampsia, neither in the group of RA patients nor in the group of healthy controls. Median birth weight of the newborns from RA patients was 2890 g (range 1250–4000). Among all pregnancies of RA patients, the levels of PLGF and sFLT-1 were similar in active and inactive disease. At the third trimester of pregnancy, RA patients showed lower levels of the pro-angiogenic placental protein PLGF than healthy controls (P=0.021). By contrast, levels of the anti-angiogenic protein sFLT-1 did not differ between RA patients and healthy women. The sFLT-1/PLGF ratio was lower in healthy women than in RA patients (P=0.021). Moreover the sFLT-1/PLGF ratio showed a negative correlation with the birth weight percentile.
**Conclusions:** RA patients showed reduced levels of the pro-angiogenic placental protein PLGF which might reflect a dysfunction of the placenta with an effect on birth weight in this disease.
**Disclosure of Interest:** None declared

## FRI0128 EFFICACY AND SAFETY OF 23-VALENT PNEUMOCOCCAL VACCINE IN SLE PATIENTS (PRELIMINARY RESULTS)

G.M. Tarasova, B.S. Belov, M.S. Naumtseva, S.K. Soloviev, E.A. Aseeva, N.G. Klyukvina, T.V. Popkova, E.N. Alexandrova, A.A. Novikov. *V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Comorbid infections (CI) appear to have detrimental effect on the course and the prognosis of systemic lupus erythematosus (SLE) as current rheumatology practice indicates. These CIs become not only the predictors of lethal outcome, but also number two among known causes of death after the activity of the disease as the cause number one. Pneumonia remains the leading clinical entity among infectious diseases in SLE pts, thus immunization of SLE pts with pneumococcal vaccine is an essential issue in clinical practice.
**Objectives:** To study the relevance of 23-valent pneumococcal vaccine for immunization of SLE pts, receiving immunosuppressive therapy.
**Methods:** The study included 24 SLE patients, 22 females, 2 males aged 19 - 62 years. Low disease activity was documented in 18 patients, moderate – in 3 patients, and drug-induced remission – in 3. 23 patients were getting glucocorticoids (GCs) (4 pts - metipred - 24 mg/day.), 19 pts – plaquenil 200–400 mg/day, 13 pts – cytostatic (CS) drugs, including 8 – mycophenolate mofetil 1–2 g/day, 3 – methotrexate 10–15 mg/week, 1- mycophenolic acid 1080 mg/day, 1-azathioprine 50 mg. Eight patients were on biologic diseases modifying anti rheumatic drugs (bDMARDs), including 5 – on rituximab at 500–1000 mg per course of treatment, 3 – on belimumab at doses of 720, 480 and 400 mg per infusion. One or two episodes of lower respiratory tract infections occurred in 4 pts during the year prior to vaccination. One dose (0,5 ml) of 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously without discontinuation of GCs and CSs, or 1 months before initiation of bDMARDs /6 mo after the last injection of bDMARDs. The duration of FUP was 1–10 months.
**Results:** Vaccine tolerability was good in 10 (41,7%) patients, local injection site reactions of varying intensity without accompanying fever were registered in 13 (54,2%) patients, lasting 2 to 7 days; they completely resolved spontaneously without additional treatment. One patient (4,2%) developed hyperergic reaction in the form of Arthus phenomenon (hyperemia, induration and swelling of the injection site up to 10 cm in diameter, pain and subfebrile fever). These symptoms subsided within 7 days with 3 days intake of antihistaminic drug and local use of GCs. These reactions were typical and assessed as having casual relationship with vaccination. In one patient with SLE and interstitial lung disease, manifesting as recurrent bronchitis and pneumonia, non-severe bilateral bronchopneumonia was documented 9 months post-vaccination, which resolved after 7 days of antibiotic therapy in the out-patient setting. One patient developed post- stress non-severe SLE exacerbation 5,5 months after vaccination, requiring GC dose escalation from 4 to 8 mg/day. Casual relationship of this exacerbation with vaccination was very unlikely.
**Conclusions:** Thus preliminary results are indicative of good 23-valent pneumococcal vaccine tolerability in SLE patients. Further studies are required for comprehensive assessment of vaccine efficacy and safety in this group of patients.

## FRI0129 ASSOCIATION BETWEEN HEARING LOSS AND CAROTID SUBCLINICAL ATHEROSCLEROSIS IN FEMALE RHEUMATOID ARTHRITIS PATIENTS

G.-T. Kim[1], H.-S. Tag[1], E.-K. Park[2], S.-G. Lee[2], D.-W. Koo[2], S.-H. Kim[3], J.-W. Lee[4]. *[1]Department of Internal Medicine, Kosin University College of Medicine; [2]Department of Internal Medicine, Pusan National University Hospital; [3]Department of Internal Medicine, Inje University College of Medicin; [4]Department of Internal Medicine, Busan St. Mary's Hospital, Busan, Korea, Republic Of*

**Background:** The incidence of hearing loss (HL) has been on the rise in patients with rheumatoid arthritis (RA). However, limited information exists regarding the pathogenic mechanisms of HL in RA patients[1,2].
**Objectives:** This study sought to evaluate the prevalence and characteristics of HL in RA patients compared with a control group and to identify factors associated with the degree of HL in RA patients.
**Methods:** We enrolled 64 RA patients and 70 healthy controls in a prospective manner. Each subject was tested with pure tone audiometry including high frequencies ranging from 0.5 to 16 kHz. For each set of tests, mean values for air conduction at each frequency and tympanometric values were calculated to exclude middle ear disease. In the RA group, auto-antibodies, erythrocyte sedimentation rate, high-sensitivity C-reactive protein, and RA disease activity were measured, and carotid ultrasonography was performed for the detection of indicators of subclinical atherosclerosis, including arterial stiffness index beta ($\beta$-index) and carotid intima-media thickness (cIMT).
**Results:** The prevalence of HL was higher in the RA group than the control group (37.1% vs. 65.6%, p=0.001). The hearing threshold value difference between groups was significant at frequencies of 0.5, 1, 2, 4, and 8 kHz ($p<0.05$). Age showed the strongest correlation to HL at all frequencies in RA patients ($p<0.01$). cIMT was also strongly related to HL at all frequencies, whereas $\beta$-index was related to HL only at high frequencies (8, 12, and 16 kHz), acting as an early marker of HL (both $p<0.05$).

**Conclusions:** HL was more prevalent in the RA group than the control group. cIMT and β-index were strongly correlated with HL in the RA group, which implies that subclinical atherosclerosis may play an important role in HL in RA patients.

## FRI0130 EFFICACY OF A COMPREHENSIVE CARDIOVASCULAR RISK REDUCTION PATIENT EDUCATION PROGRAMME IN PATIENTS WITH EARLY INFLAMMATORY ARTHRITIS FOLLOWING A TREAT TO TARGET THERAPEUTIC REGIME

H. Inomata, L.-A. Bissell, K. Naraghi, J. Nam, A. Burska, E. Hensor, P. Emery, M. Buch, J. Andrews. *NIHR-Leeds Musculoskeletal Biomedical Research Unit and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

**Background:** Evidence suggests cardiovascular disease (CVD) risk in patients (pt, pts) with Inflammatory arthritis (IA), Rheumatoid arthritis (RA) is equivalent to that of type II diabetes mellitus[1]. The accepted guidance is lifestyle factor modifications should be addressed in IA[2], but little is known of the impact of CVD risk reduction pt education programmes delivered to pts with IA within a Rheumatology service setting.
**Objectives:** To describe the utility of a comprehensive CVD risk reduction pt education programme in pts with newly diagnosed IA following a treat to target standard therapeutic regime.
**Methods:** 387 pts with IA (RA and Undifferentiated Inflammatory Arthritis: UIA) were assessed at baseline (BL) for CV risk factors (RFs) (see Table 1) Pts were; RA; pts (1987 or 2010 ACR criteria) (n=237) and UIA; pts not meeting ACR RA criteria (n=150). A standardized co-morbidity pt education programme, which included CVD risk reduction, was delivered throughout the first 12 months (M). The impact on modifiable CVD RFs was assessed at 12M.
**Results:** 108 RA, 34 UIA pts had complete datasets (see Table 1). Of those smoked at BL, 15% reported being ex-smokers at 12M and the number smoked had decreased in 44%. 10% who reported being ex-smokers at BL altered their status to never having smoked by 12M and their reported number previously smoked reduced by 43% at 12M. Alcohol use reduced in 39% and increased in 24% (overall decrease, p=0.033). At BL, 56% of pts reported doing no moderate exercise at all; at 12M around a third of the pts had either increased or decreased the amount of exercise (no overall change). Disease activity generally decreased ($p<0.001$) and mobility increased (p=0.004).

Table 1. Changes in cardiovascular disease risk factors at 12 months

| Risk factors | N | Baseline | Change at 12 months | % of patients whose 12 months value was | | | P value |
|---|---|---|---|---|---|---|---|
| | | | | Improved | Unchanged | Worse | |
| BMI | 117 | 26.7 (23.9, 30.1) | 0.2 (–0.6, 1.0) | 44% | 1% | 55% | 0.145 |
| Smoking | | | | | | | |
| Never | 62 | 46% | – | – | 95% | 5% | 0.725 |
| Ex-smoker | 41 | 30% | – | 10% | 83% | 7% | |
| Current | 33 | 24% | – | 15% | 85% | – | |
| Number smoked/day | | | | | | | |
| Ex-smokers | 35 | 15 (7, 20) | 0 (–5, 0) | 43% | 34% | 23% | 0.810 |
| Current smokers | 32 | 15 (6, 20) | 0 (–5, 3) | 44% | 22% | 34% | 0.262 |
| Alcohol, units/week | 123 | 2 (0, 12) | 0 (–2, 0) | 39% | 37% | 24% | 0.033 |
| Moderate exercise, mins/week | 114 | 7 (0, 120) | 0 (–60, 30) | 34% | 30% | 36% | 0.861 |
| DAS28-CRP (3)[a] | 126 | 3.6 (2.5, 4.9) | –1.0 (–2.5, 0.0) | 74% | 4% | 22% | <0.001 |
| Mobility (EQ5D) | | | | | | | |
| No problems | 209 | 50% | – | – | 84% | 16% | 0.004 |
| Some problems | 206 | 50% | – | 30% | 70% | – | |

Figures are median (interquartile range) or number (%). BMI: Body Mass Index, DAS28: Disease Activity Score 28 Joints, CRP: C-Reactive Protein, EQ5D: European Quality of Life-5 Dimensions, a DAS28-CRP 3 variables.

**Conclusions:** A significant reduction in alcohol units and improvement in smoking habits were seen. However, despite significant improvements in IA disease activity and mobility, there was no improvement in exercise from the low level reported at BL. The need to address modifiable CVD RFs in IA is widely accepted by Rheumatologists but effecting lifestyle change is challenging. Behavioural change in exercise is complex, particularly in chronic disease. Further studies are required to optimise the approach in IA.

## FRI0131 ATTITUDES AND BARRIERS OF USING ELECTRONIC DATA COLLECTION TO TRACK DISEASE ACTIVITY OUTSIDE OF CLINICAL SETTINGS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

I. Navarro Millan[1], A. Zinski[2], S.L. Shurbaji[2], B. Johnson[1], L. Fraenkel[3], J. Willig[2], M.M. Safford[4], J.R. Curtis[1]. *[1]Rheumatology; [2]Infectious Diseases, University of Alabama at Birmingham, Birmingham; [3]Medicine, Yale University, New Haven; [4]Medicine, Cornell University, New York, United States*

**Background:** Effective use of patient reported outcomes (PROs) is important for ensuring high quality care in rheumatoid arthritis (RA). The current standard of care is to measure PROs at the point of care. However, more frequent measures may provide a more accurate representation of disease activity. How best to encourage patients to report PROs outside of the clinical setting is not known.
**Objectives:** Initiate a qualitative assessment of RA patients' preferences for engagement in PRO collection and electronic health communication outside of clinical settings.
**Methods:** RA patients were recruited from one academic medical center to participate in a series of focus groups from December 2014-April 2015. Session topics were modeled using the Andersen and Newman Individual Determinants of Health Service Utilization Framework, emphasizing predisposing, enabling, and illness-level factors that may influence patient willingness to share data on Smartphones and the web as well as uptake and utilization of RA clinical and support services related to electronic data collection such as assistance with computer for electronic data entry. Ninety minute sessions were audio-recorded, transcribed, independently coded, and analyzed for themes in combination with post-session survey responses.
**Results:** A total of 31 patients participated in 7 groups. Median age was 51 years, 94% Female, 52% Black, 11% Hispanic, 37% Caucasian. In post-session surveys, 58.1% of respondents were "very" or "extremely" comfortable sharing arthritis information with persons outside their healthcare team, 54.8% were very/extremely likely to use electronic or online tools to share RA information, and 64.5% reported that their RA was "high" or "essential/highest" health priority.
Preliminary qualitative data from the first two focus groups showed several predisposing beliefs, enabling factors and illness level factors (Figure). RA patients expressed willingness to logging RA disease activity data for sharing with healthcare providers and other patient generated data via Smartphone. However, few participants had experience sharing RA information or seeking support for RA outside of their family/partner, such as another RA patient or group support, to assist with understanding RA, use a computer or explain knowledge of PRO evaluation. These patients expressed willingness to participate with other RA patients in these areas to expand their knowledge.

Figure: Individual determinants of health service utilization

**Conclusions:** Incorporating these aspects and even the experience of sharing RA data information guided by another trained RA patient (peer-coach), as a facilitator for PRO collection, will help overcome some of the barriers to RA data collection expressed by patients. These aspects can improve the patient willingness to collect RA disease activity data and PRO that can lead to improvement in the clinical care of these patients.

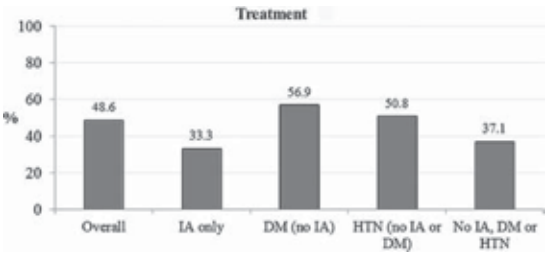
## FRI0132 LIPID MANAGEMENT AMONG INDIVIDUALS WITH INFLAMMATORY ARTHRITIS IN THE NATIONAL REASONS FOR GEOGRAPHIC AND RACIAL DIFFERENCES IN STROKE COHORT



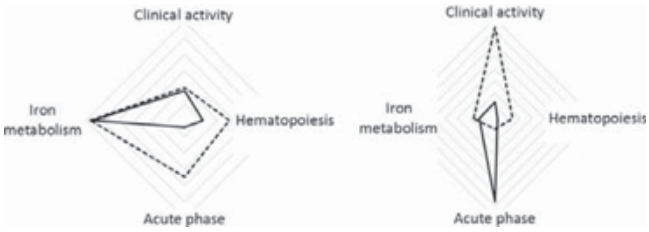
I. Navarro-Millan[1], C. Gamboa[2], J.R. Curtis[1], M.M. Safford[3]. *[1]Rheumatology; [2]Preventive Medicine, University of Alabama at Birmingham, Birmingham; [3]Internal Medicine, Cornell Medical Center, New York, United States*

**Background:** Cardiovascular (CVD) risk factor management may be suboptimal in people with inflammatory arthritis (IA) (rheumatoid arthritis [RA], psoriatic arthritis [PsA], ankylosing spondylitis [AS]).

**Objectives:** We compared hyperlipidemia treatment of participants with and without IA, controlling for individual-level factors that influence health services utilization.
**Methods:** The REasons for Geographic And Racial Differences in Stroke (REGARDS) cohort includes 30,239 community dwelling black and white adults from the 48 contiguous US states recruited between 2003–7 and assessed with a telephone survey and in-home visit that included a blood draw and pill bottle review.[1] IA was identified through medications specific to autoimmune disease. Individuals with IA (without diabetes or hypertension) were compared to those with diabetes (but no IA), hypertension (but no diabetes or IA), or IA, diabetes, or hypertension. Logistic regression models examined odds of treatment among those with hyperlipidemia after accounting for predisposing, enabling, and need factors guided by Andersen and Aday's model.[2]
**Results:** IA participants were younger and predominately women, with lower Framingham risk scores, and lower functional status (Table 1). Proportionately fewer IA patients were treated than others (Figure 1). The fully adjusted odds of treatment for those with IA were 27% lower but not significantly different from those without IA, hypertension, or diabetes. Participants with diabetes and HTN were 2-times more likely to be managed for hyperlipidemia than those without IA, diabetes, or hypertension.

Table 1. Characteristics of REGARDS participants with hyperlipidemia at the time of enrollment

| Demographic | IA only (no DM or HTN) n=39 | DM (no IA) n=5,423 | HTN (no IA or DM) n=7,534 | No IA, DM or HTN n=5,288 |
|---|---|---|---|---|
| Women, n (%) | 23 (59.0) | 2896 (53.4) | 4063 (53.9) | 2312 (43.7) |
| Mean age, years ±SD | 63.3±9.4 | 65.7±8.7 | 66.7±9.1 | 64.3±9.2 |
| Aware of high cholesterol, n (%) | 23 (59.0) | 3829 (71.1) | 5355 (71.6) | 3235 (61.9) |
| Perfect medication adherence, n (%) | 28 (71.8) | 3539 (67.9) | 5009 (69.3) | 3175 (70.6) |
| Current smoking, n (%) | 10 (25.6) | 736 (13.6) | 1083 (14.4) | 900 (17.0) |
| Low HDL, n (%) | 11 (28.2) | 2662 (49.1) | 2879 (38.2) | 1837 (34.7) |
| Mean LDL, mg/dL ±SD | 122.6±35.2 | 108.4±35.9 | 120.9±36.9 | 132.7±37.7 |
| Median Pysical Component Summary Score [25th, 75th%] | 42.3 [33.2, 52.1] | 44.3 [33.2, 52.0] | 48.8 [39.2, 53.8] | 52.6 [46.2, 55.7] |
| Median Framingham Risk Score [25th, 75th%] | 5.0 [2.0, 12.0] | 10.0 [4.0, 16.0] | 11.0 [5.0, 17.0] | 8.0 [3.0, 12.0] |



**Conclusions:** In this study, hyperlipidemic participants with IA were less likely to be treated for hyperlipidemia than participants with diabetes or hypertension - diseases well known to increase CVD risk – even after accounting for levels of CVD risk. This study was limited by power. If confirmed in larger samples, these results reflect a potential gap in the management of hyperlipidemia for IA patients.

## FRI0133 UNDERSTANDING ANEMIA IN RHEUMATOID ARTHRITIS: THE ASSOCIATION OF HEMOGLOBIN AND HEPCIDIN LEVELS WITH CLINICAL DISEASE ACTIVITY AND ACUTE PHASE RESPONSE

I. Padjen[1,2], H. Radner[2], L. Öhler[3], J. Smolen[2,4], D. Aletaha[2]. *[1]Division of Clinical Immunology and Rheumatology, Department of Internal Medicine, University Hospital Centre Zagreb and University of Zagreb, School of Medicine, Zagreb, Croatia; [2]Division of Rheumatology, Medical University of Vienna; [3]Department of Internal Medicine 1, St. Josef's Hospital; [4]2nd Department of Medicine, Hietzing Hospital, Vienna, Austria*

**Background:** Hepcidin is an important link between inflammation and anemia in patients with rheumatoid arthritis (RA); hemoglobin itself is considered a negative acute phase measure in chronic inflammatory conditions like RA. However, the longitudinal association of hepcidin and hemoglobin with RA disease activity and acute phase remains to be explored.
**Objectives:** We aimed to explore these associations in patients with RA.
**Methods:** We consecutively included RA outpatients in a routine academic setting. Each patient was evaluated at baseline and 12 weeks thereafter using the clinical disease activity index (CDAI) and extensive peripheral blood tests, including serology, acute phase response (erythrocyte sedimentation rate, ESR; C reactive protein, CRP; and fibrinogen) and measures of iron metabolism (ferritin; transferrin; transferrin saturation, TS; hepcidin; and peripheral erythroid burst forming units, BFU-E). We analyzed baseline and week 12 values cross-sectionally in all patients; and change scores from baseline to week 12 in a subset of active patients with CDAI≥10 and a new DMARD initiation at baseline. We performed principal component analysis (PCA) to identify themes for all included variables. The strength of association of hepcidin and hemoglobin with the identified themes from the PCA was then analyzed.
**Results:** Eighty-eight patients (68 females, 77%) were included (mean±SD age: 58±12 years; disease duration: 9.3±9.6 years). PCA identified four themes for all included parameters: clinical activity, acute phase, iron metabolism and hematopoiesis. At baseline and week 12 (steady state), both hepcidin and hemoglobin levels were ascribable primarily to the theme "iron metabolism". Hemoglobin was also ascribable to "clinical activity" – to a similar extent as other acute phase parameters; but even more to the theme "acute phase". Conversely, 12-week changes in hepcidin levels were ascribable to "changes in acute phase", while changes in hemoglobin levels were ascribable to "changes in clinical activity" (Figure). In multivariable analysis CDAI changes were negatively, and BFU-E changes were positively, associated with hemoglobin changes ($R^2$=0.615, $p<0.05$ for both); hepcidin changes were not associated with hemoglobin changes.
Figure: Loadings of hepcidin (solid lines) and hemoglobin (dotted lines) to the themes identified by principal component analysis, for baseline values (left), and for changes between baseline and week 12 (right)

**Conclusions:** In patients with RA, changes in hepcidin levels reflect changes in acute phase response, but not changes in clinical disease activity; changes in hemoglobin levels occur in conjunction with changes in clinical disease activity, but not with changes of the acute phase response. The association of clinical disease activity with hemoglobin seems to be stronger than its association with other acute phase parameters.

## FRI0134 INTERLEUKIN-6 BLOCKADE RAISES LDL VIA REDUCED CATABOLISM RATHER THAN VIA INCREASED SYNTHESIS – A CYTOKINE-SPECIFIC MECHANISM FOR CHOLESTEROL CHANGES IN RHEUMATOID ARTHRITIS

J. Robertson[1], D. Porter[2], N. Sattar[3], C. Packard[3], M. Caslake[3], I.B. McInnes[4], D. McCarey[5]. *[1]NHS Ayrshire & Arran, Ayr; [2]Dept of Rheumatology, Gartnavel General Hospital; [3]University of Glasgow, Glasgow, United Kingdom; [4]Institute of Infection, Immunity and Inflammation, University of Glasgow; [5]Center for Rheumatic Diseases, Glasgow Royal Infirmary, Glasgow, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is associated with significant alteration in circulating lipids, in particular reduced serum total cholesterol and low-density lipoprotein cholesterol (LDL-c) levels. Various RA modulatory therapeutics can increase serum LDL-c; mechanisms underlying this phenomenon are poorly understood but may be mediated via cytokine signalling, particularly JAK dependent pathways. Herein we have explored the effects of IL-6 receptor blockade upon cholesterol metabolism in a clinical experimental study using tocilizumab.
**Objectives:** We sought to define the metabolic pathways (i.e. synthesis versus clearance) whereby specific inhibition of IL-6R signalling in patients with active RA modulates circulating LDL levels.
**Methods:** We performed kinetic studies of LDL metabolism in 12 patients with severe, active RA (DAS28 ≥5.1) eligible for biologic DMARD therapy – one patient withdrew from the study and did not contribute evaluable data. A stable isotope of d3-leucine was administered and incorporated into newly-synthesised apoB; the formation and catabolic rates of apoB-containing lipoproteins were then assessed using an established multi-compartmental model. Kinetic studies were performed at baseline and after at least three consecutive infusions of IV tocilizumab 8mg/kg every 4 weeks. Changes in kinetic parameters (fractional catabolic and synthesis rates, FCR and FSR, respectively), serum lipids and measures of disease activity from baseline were assessed using student's t-test or Wilcoxon matched-pairs

test as dictated by normality of data. Correlations between parameters were assessed by Pearson's or Spearman's coefficient as appropriate.
**Results:** In 11 evaluable patients who completed the study, profound reductions were observed after treatment in mean CRP (19 vs 0.75 mg/l, p=0.015) and ESR (38 vs 3mm/hr, p=0.004), with significant changes in CDAI (29.9 v 8.0, p<0.001). Elevations were seen in total cholesterol (4.9 vs 5.7mmol/l, p=0.003), HDL-cholesterol (1.2 vs 1.6mmol/l, p=0.006) and LDL-cholesterol (2.9 vs 3.5mmol/l, p=0.014).
The FCR of LDL fell significantly following IL-6 blockade (median 0.53 vs 0.27 pools/day, p=0.006, with median change of -30% from baseline). No significant change was observed in the FSR of LDL (median 0.45 vs 0.72 mg/kg/day, p=0.41). FCR correlated inversely with LDL-c at baseline (r=-0.77, p=0.007) and after treatment (r=-0.66, p=0.031). At baseline, FCR also associated with CRP (r=0.74, p=0.012), but not CDAI (r=0.04, p=0.91).
**Conclusions:** IL-6 blockade increases serum LDL-c primarily by reducing the fractional catabolic rate of LDL from a state of hypercatabolism to levels seen previously in healthy cohorts. Of note, FCR of LDL is most closely associated with the acute phase response rather than with RA disease activity as quantified by CDAI. Normalisation of this acute phase-driven increased catabolism largely explains the LDL-c elevations observed following tocilizumab therapy. Our study for the first time clearly defines IL-6 as the key driver of the increased catabolism of LDL which results in low serum LDL-c levels in RA.

## FRI0135 INCREASED INTRINSIC BRAIN CONNECTIVITY BETWEEN AFFECTIVE PAIN PROCESSING REGIONS AND BILATERAL SENSORIMOTOR CORTEX IN RA PATIENTS COMPARED TO HEALTHY CONTROLS

J. Lampa[1], P. Flodin[2], S. Martinsen[2], R. Altawil[1], E. Waldheim[1], E. Kosek[2], P. Fransson[2]. *[1]Dept of Medicine, Rheumatology Unit; [2]Dept of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden*

**Background:** Rheumatoid arthritis (RA) is commonly accompanied by pain that is discordant with the degree of peripheral pathology. Very little is known about the cerebral processes involved in pain processing in RA.
**Objectives:** To investigate resting state brain connectivity associated with prolonged pain in RA.
**Methods:** 24 RA subjects and 19 matched controls were compared with regard to both behavioral measures of pain perception and resting-resting state fMRI data acquired subsequently to fMRI sessions involving pain stimuli. The resting-state fMRI brain connectivity was investigated using 159 seed regions located in cardinal pain processing brain regions. Additional principal component based multivariate pattern analysis of the whole brain connectivity pattern was carried out in a data driven analysis to localize group differences in functional connectivity.
**Results:** When RA patients were compared to controls, we observed significantly lower pain resilience for pressure on the affected finger joints (i.e. P50-joint) and an overall heightened level of perceived global pain in RA patients.
Relative to controls, RA patients displayed increased brain connectivity predominately for the supplementary motor areas, mid-cingulate cortex and the primary sensorimotor cortex. Additionally, we observed an increase in brain connectivity between the insula and prefrontal cortex as well as between anterior cingulate cortex and occipital areas for RA patients. None of the group differences in brain connectivity were significantly correlated with behavioral parameters.
**Conclusions:** Our study provides experimental evidence of increased connectivity between frontal midline regions that are implicated in affective pain processing and bilateral sensorimotor regions in RA patients.
**Disclosure of Interest:** None declared

## FRI0136 RISK FOR LUNG CANCER IN RA AND DIFFERENT RA PHENOTYPES: RESULTS FROM A POPULATION-BASED CASE-CONTROL STUDY

K. Chatzidionysiou[1], G. Reynisdottir[1], V. Joshua[2], T. Frisell[3], J. Askling[3], A. Catrina[1]. *[1]Rheumatology Department, Karolinska University Hospital, Karolinska Institute; [2]Unit of Rheumatology, Department of Medicine Solna, Karolinska Institute; [3]Clinical Epidemiology Unit, Department of Medicine, Karolinska Institute, Stockholm, Sweden*

**Background:** It has been shown that patients with Rheumatoid Arthritis (RA) are at increased risk for certain malignancies, among them lung cancer.
**Objectives:** To investigate the association between lung cancer and different RA phenotypes based on rheumatoid factor (RF) and anti-citrullinated peptide antibody (ACPA) status.
**Methods:** We used the population-based case-control study EIRA (Epidemiological Investigation of Risk factors for Rheumatoid Arthritis). Patients with RA and controls (matched for age, sex, calendar period and area of residence) were included during 1996–2013. The data were linked to the Swedish nationwide cancer register. Cox regression was used to calculate RR. Due to the significant correlation between smoking and RA as well as presence of RF and ACPA, stratified analyses based on smoking status were performed, in order to account for effect modification.
**Results:** A total of 3547 RA patients and 5586 controls were included in the study. The mean age (SD) was 52 (13) years and the percentage of female was 72%. Significantly more RA patients than controls were diagnosed with lung cancer after RA diagnosis (58 vs. 26 per 100,000 patient-years, respectively, p=0.002). RA itself gave twice an increased risk for developing lung cancer when adjusted for age and sex (RR=1.9, 95% CI=1.2–3.2, p=0.01), but the statistical significance disappeared when smoking was included in the model. However, after stratification according to smoking status, RA was significantly associated to lung cancer development in never or ex-smokers (RR=2.4, 95% CI=1.0–6.2, p=0.05) but not in current smokers (RR=1.2, 95% CI=0.6–2.3, p=0.6). In RA patients, higher age, smoking, RF positivity, RF and/or ACPA positivity and double seropositivity were significant risk factors for lung cancer (table 1). In a stratified analysis RF positivity was significantly associated to lung cancer in non-smokers (table 2).

Table 1. Cox regression analysis (adjusted for age and sex) with lung cancer after RA diagnosis as the dependent variable and several potential risk factors as independent variables

| Variable | RR (95% CI) | P-value |
|---|---|---|
| Sex (female vs. Male) | 0.6 (0.3–1.2) | 0.64 |
| Age | 1.1 (1.1–1.2) | <0.0001 |
| Smoking (current vs. Never/ex) | 3.2 (1.6–6.6) | 0.002 |
| Smoking (ever vs. Never) | 3.6 (1.1–12.0) | 0.03 |
| Silica | 2.2 (0.7–6.9) | 0.18 |
| RF (pos vs. Neg) | 4.6 (1.6–13.0) | 0.004 |
| ACPA (pos vs. Neg) | 1.9 (0.9–4.0) | 0.11 |
| ACPA and/or RF pos vs. neg | 7.0 (1.7–28.9) | 0.008 |
| Double pos (RF and ACPA) vs. Double neg. | 6.8 (1.6–28.8) | 0.01 |

Table 2. Risk for development of lung cancer for different RA phenotypes

| Variable | Non-Smokers (never or ex-smokers) | | Smokers (current) | |
|---|---|---|---|---|
| | No. of patients (seropositive with lung ca/total with lung ca) | RR (95% CI) | No. of patients (seropositive with lung ca/total with lung ca) | RR (95% CI) |
| RF (pos vs neg) | 11/12 | 7.4 (1.0–57.4) | 17/20 | 2.4 (0.7–8.2) |
| ACPA (pos vs neg) | 9/12 | 2.3 (0.6–8.7) | 14/20 | 1.2 (0.4–3.1) |
| ACPA and/or RF pos vs double neg | 11/12 | 5.5 (0.7–42.5) | 19/20 | 5.8 (0.8–43.2) |
| Double pos (RF and ACPA) vs double neg | 9/10 | 6.1 (0.8–47.9) | 12/13 | 4.8 (0.6–36.5) |

**Conclusions:** In this study RA, especially RF positive RA, was associated to the development of lung cancer in never or ex-smokers. Although not statistically significant, patients who developed lung cancer were more often positive for RF and/or ACPA irrespective of smoking status.
**Disclosure of Interest:** None declared

## FRI0137 ASSOCIATION BETWEEN NUMBER AND TYPE OF DIFFERENT ACPA FINE SPECIFICITIES AND PARENCHYMAL LUNG CHANGES IN HIGH RESOLUTION COMPUTED TOMOGRAPHY IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

V. Joshua[1], K. Chatzidionysiou[2], G. Reynisdottir[1], A.H. Hensvold[1], M. Hansson[3], L. Nogueira[4], A. Eklund[5], G. Serre[4], J. Grunewald[5], A.I. Catrina[2]. *[1]Rheumatology Unit, Department of Medicine, Solna, Karolinska Institute; [2]Unit of Rheumatology, Department of Medicine Solna, Karolinska University Hospital, Karolinska Institutet; [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; [4]Unité Différenciation Épidermique et Autoimmunité Rhumatoïde, Unité Mixte de Recherche, INSERM, Toulouse, France; [5]Division of Respiratory Medicine, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden*

**Background:** Anti-CCP2 antibodies are associated with parenchymal lung changes in early RA.
**Objectives:** To examine the association between ACPA fine specificities and parenchymal lung changes in early RA.
**Methods:** Patients with newly diagnosed RA, glucocorticoids and DMARDs-naive, were included. High-resolution computed tomography (HRCT) was performed to assess parenchymal lung changes (ground glass changes, nodules, infiltrates or fibrosis). ImmunoCAP was used to detect RF IgA, RF IgM, anti-CCP2 IgA, anti-CCP2 IgG and ISAC microarray system was used to detect antibodies against 10 citrullinated (Cit) peptidic antigens: CCP-1 (Filaggrin), CEP-1 (α-enolase), Vim 2–17, Vim 60–75 (Vimentin), Fib β 36–52, Fib α 573, Fib α 591, Fib α 36–50, Fib β 60–74, Fib α 621–635 (Fibrinogen). Logistic regression was performed to examine associations between lung changes and autoantibodies, adjusted for age and sex. Due to risk for effect modification of smoking and co-linearity between smoking and Cit peptides, we stratified the cohort according to ever vs. never smokers.
**Results:** A total of 106 patients were included. The mean (SD) age was 57 (14) years. 69% were females; 73% were ever smokers; 70% were RF positive and 69% were positive for anti-CCP2. Parenchymal lung changes were found in 58

patients (54.7%). Higher age [≥65 vs <65, OR (95% CI) =2.5 (1.1–5.9)], pos RF IgA [OR (95% CI) =2.7 (1.2–5.9)], pos CCP2 IgG [OR (95% CI) =2.3 (1.0–5.4)], ever smoking [OR (95% CI) =2.6 (1.1–6.2)] and pack-years above 24 [OR (95% CI) =6.9 (2.0–23.5)], were significant predictors of parenchymal lung changes. Some ACPA fine specificities were associated to parenchymal lung changes in ever smokers (table 1). Having five or more ACPA specificities at the time of diagnosis increased the risk of having lung changes in ever smokers by 6.6 times (table 1).

Table 1. Association between ACPA fine specificities and parenchymal lung changes according to smoking status

| | Non-smokers [N=29] | | Ever smokers [N=77] | |
|---|---|---|---|---|
| | OR (95% CI) | P-value | OR (95% CI) | P-value |
| Cit Fibrinogen peptides | 2.3 (0.4–13.1) | 0.35 | 3.0 (1.0–8.8) | 0.05 |
| Fib β 36–52 cit | 1.1 (0.2–5.9) | 0.87 | 2.7 (0.9–7.6) | 0.07 |
| Fib α 573 cit | 2.3 (0.4–13.0) | 0.35 | 3.9 (1.3–12.5) | 0.02 |
| Cit Vimentin peptides | 3.5 (0.5–24.9) | 0.22 | 2.9 (1.0–8.5) | 0.06 |
| Vim 2–17 cit | 1.2 (0.2–6.5) | 0.80 | 2.9 (1.0–8.6) | 0.05 |
| Vim 60–75 cit | 4.9 (0.7–32.7) | 0.10 | 2.2 (0.8–6.3) | 0.15 |
| CEP-1 (α-enolase) | 0.4 (0.06–2.4) | 0.30 | 2.0 (0.7–6.0) | 0.20 |
| N. ACPAs 0 (ref) | | | | |
| 1–4 | 2.6 (1.9–35.9) | 0.47 | 5.2 (1.3–21.2) | 0.02 |
| >4 | 3.6 (0.3–44.7) | 0.32 | 6.6 (1.6–27.3) | 0.009 |

**Conclusions:** RF IgA, anti-CCP2 IgG, antibodies to Cit Fib and Cit Vim peptides were strongly associated to parenchymal lung changes in ever smokers with early RA. The more ACPA fine specificities, the higher the risk of parenchymal lung changes.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3170

## FRI0138 S100A12 AND CALPROTECTIN IN SERUM AND THE AORTA OF PATIENTS WITH CARDIOVASCULAR DISEASE AND INFLAMMATORY RHEUMATIC DISEASE: A BIOPSY STUDY

K.M.C. Tjørve[1], M. Fagerhol[2], M. Wang-Fagerland[3], K. Mikkelsen[4], S.M. Almdahl[5], I. Hollan[4,6,7] on behalf of Feiring Heart Biopsy Network. *[1]Økorg, Lillehammer University College, Lillehammer; [2]Prof. Fagerhol's Research Laboratory, Oslo; [3]Akershus University Hospital, Lørenskog; [4]Hospital for Rheumatic Diseases, Lillehammer; [5]Department of Cardiothoracic and Vascular Surgery, University Hospital of North Norway, Tromsø, Norway; [6]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital; [7]Havard Medical School, Boston, United States*

**Background:** Increased serum calprotectin (s-calprotectin) and S100A12 (s-S100A12) levels are associated with inflammatory rheumatic disease (IRD), and might be involved in the pathogenesis of cardiovascular disease (CVD).
**Objectives:** To compare s-calprotectin and s-S100A12 levels in CVD patients with and without IRD, to IRD patients without CVD, and to healthy controls (HC). Furthermore, to search for relationships between s-calprotectin levels and calprotectin expression in the aortic adventitia.
**Methods:** We examined s-calprotectin and s-S100A12 in patients from the Feiring Heart Biopsy Study: 69 IRD (CVD-IRD group) and 53 non-IRD (CVD group) patients undergoing coronary artery bypass grafting (CABG), 32 IRD patients without any clinical or laboratory sign of CVD (IRD group) and 30 HC. Using immunohistochemistry, we scrutinized biopsies taken during CABG from the aortic adventitia in 19 CVD-IRD and 20 CVD patients for the presence and extent of inflammatory cell infiltrates (ICIs) and calprotectin expression.
**Results:** We found no significant differences in levels of s-S100A12 between the four groups (p=0.56). There was not a significant difference in the calprotectin levels between the CVD-IRD and the IRD (1.30 vs 1.73 mg/l; p=0.16) groups. The groups with CVD (CVD and CVD-IRD) had significantly higher s-calprotectin level than the HC group (1.47 vs. 0.30 mg/l; p<0.0001), and a statistically non-significant trend towards a higher s-S100A12 level (44.12 vs 25.36 mg/l; p=0.13). The groups with IRD (IRD and CVD-IRD) had a significantly higher s-calprotectin level than the CVD (without IRD) group (1.42 vs. 0.25 mg/l; p<0.0001) and the HC group (1.42 vs. 0.29 mg/l; p<0.0001). CVD was not independently related to s-calprotectin (p=0.36) neither in the total population nor in the RA subgroup. Calprotectin expression in the aortic adventitia was significantly related to the presence of inflammatory cell infiltrates (ICI; p=0.05), but not to s-calprotectin levels (p=0.95).

Table 1. S-calprotectin and S100A12 values for the four groups in the study: CVD-IRD, CVD, IRD, and HC

| | CVD-IRD (n=69) | CVD (n=53) | IRD (n=32) | HC (n=30) | p† |
|---|---|---|---|---|---|
| s-calprotectin, mg/l | 1.30±1.5 | 0.25±0.17 | 1.73±1.42 | 0.30±0.15 | <0.001 |
| s-S100A12, μg/l | 20 (19.75) | 16 (27.5) | 17 (32.33) | 16.0 (20.85) | 0.56 |

s-calprotectinis reported as the mean ± SD whereas S100A12 is reported as the median (IQR). Numbers may not add up to the expected total due to missing data for some variables. †P values for continuous dependent variables are from analysis of variance (ANOVA).

**Conclusions:** s-Calprotectin is independently related to IRD, but not to CVD (neither in the general population nor in RA). Thus, in theory, the previously observed association between s-calprotectin and CVD might be caused by the underlying inflammatory process, e.g. IRD, not by a causal role of calprotectin in the CVD pathogenesis.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2615

## FRI0139 RISK OF TYPE 2 DIABETES MELLITUS DEVELOPMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Kondratyeva, T. Popkova, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Rheumatoid arthritis (RA) is associated with insulin resistance (IR), a precursor to type 2 diabetes mellitus (DM). However, IR indexes are uncomfortable to examine the DM risk in clinical practice. International Diabetes Federation recommends the use of patient questionnaires to quickly identify people who may be at a higher risk of DM development.
**Objectives:** To determine the 10-years risk of DM development in patients with RA by questionnaire Finnish Type 2 Diabetes Risk Assessment Form (FINDRISK).
**Methods:** The study included 234 RA patients without DM (202 women, 32 men, 56 [42; 64] years old). The median disease duration was 7 [2,14] years, DAS28 was 4,73 [3,5;5,5]. The majority of pts were seropositive for IgM RF (75%) and anti-CCP (80%). RA pts were treated with glucocorticoids (43%), methotrexate (52%) or other disease-modifying antirheumatic drugs (19%), and biological agents (26%). The control group consisted of 100 subjects without inflammatory arthritis or DM, matched by age and sex with RA patients. Eight factors for FINDRISK questionnaire (increasing age, overweight, abdominal obesity, family history of diabetes, physical inactivity, eating habits, high blood pressure, history of hyperglycemia) were taken into account to calculate the total test score (TS). The risk of DM development within following 10 years is regarded as low (1%) or slightly elevated (4%) with TS ≤11 points, as moderate (17%) with TS =12–14 points, as high (33%) or very high (50%) with TS ≥15 points. Fasting glucose level was investigated in 230 RA pts after the interview.
**Results:** The risk of DM development was low or slightly elevated in 133 (56,8%) RA pts, moderate in 51 (21,8%) pts, and high or very high in 50 (21,4%) pts. Hyperglycemia (≥6,1mmol/l) was observed in 5/131 (3,8%) pts with low or slightly elevated DM risk, 5/50 (10,0%) pts with moderate risk, and 10/49 (20,4%) pts with high or very high risk (p<0,01 for low vs high risk group). The median TS of RA pts (10 [5;14] points) was not differ from these of control subjects (11 [7;15] points). DM risk factors profile were similar in two groups, excluded more higher prevalence of unhealthy diet (51% vs 37%, p=0,02) and trend to more frequently physical inactivity (73% vs 62%, p=0,053) in RA. There were correlations between TS and fasting glucose level (r=0,38, p<0,01), HAQ (r=0,13, p=0,04), but no DAS28. Currently glucocorticoids use did not effect on TS in RA. Men had increased TS and number of risk factors compared with women with RA (13 [9;16] vs 10 [5;14] points and 5 [4;6] vs 4 [2;5] factors, p<0,01 for all cases). The number of risk factors was correlated with CRP (r=0,14, p=0,05), ESR (r=0,14, p=0,05), DAS28 (r=0,16, p=0,02) in women, but no men with rheumatic disease.
**Conclusions:** Risk of DM development in RA pts caused by traditional risk factors as the same as in general population and partly by the presence of inflammation. Clarification of RA-specific phenomena in DM pathogenesis requires further research. FINDRISK is simple, inexpensive and effective way to identify RA pts who should be carefully observed with lifestyle change to lower their DM risk, and who need additional examination to determine if they have DM without symptoms.

## FRI0140 IMMUNOGENICITY AND SAFETY OF 23-VALENT PNEUMOCOCCAL VACCINE FOR PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM 1-YEAR FOLLOW UP

M.S. Naumtseva, B.S. Belov, G.M. Tarasova, E.N. Alexandrova, A.A. Novikov, M.V. Cherkasova, D.E. Karateev, E.L. Luchikina, Y.V. Muravyev. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Comorbid infections have significant impact on morbidity and mortality, especially in autoimmune diseases. Prevention of infection is an integral part of supervision of these patients.
**Objectives:** To investigate immunogenicity and safety of 23-valent polysaccharide pneumococcal vaccine in patients with rheumatoid arthritis (RA) treated with diseases modifying anti rheumatic drugs (DMARDs) and biologic diseases modifying anti rheumatic drugs (bDMARDs).
**Methods:** Out of 110 subjects (81 females (73,6%), 29 males (26,4%) aged 23–76 years) included into the study, 79 were RA patients and 31 were controls (GK) with a history of ≥2 episodes of lower respiratory tract infections (bronchitis, pneumonia). 52 patients with RA were on methotrexate (MTX), 14 were on leflunomid (LEF), 13 were on tumor necrosis factor alpha (iTNF-α) inhibitors+MTX. One dose (0,5 ml) of 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously without discontinuation of MTX/LEF or 28–30 days prior to initiation of iTNF-α. Totally four study visits were preplanned: initial vaccination visit and 3 control visits in 1, 3 and 12 months after vaccination. Routine evaluation during each visit included physical exams and laboratory tests. Levels of antibodies to pneumococcal capsular polysaccharide were measured

using VaccZymeTM PCP IgG 2 kit (The Binding Site Group Ltd, Birmingham, UK). Post-immunization response coefficient was calculated for each participant as the ratio of AB levels during visits II, III, and IV to baseline AB level at Visit I.
**Results:** Not a single case of clinically or radiographically confirmed pneumonia was documented during the follow up period. Dynamics of post-immunization response coefficient in RA patients on different therapeutic modalities and in the controls are presented in the Table. Pronounced positive immune reaction after administration of the vaccine under investigation was documented in RA patients during different therapies, i.e., significant post-immunization response coefficient increase. There were 61% responders among RA patients and 70% responders among the controls. Good tolerability of the vaccine was documented in 65% of cases, satisfactory (injection site pain, swelling and hyperemia of the skin up to 2 cm in diameter and subfebrile fever) in 35% of cases. As these reactions had no casual relationship with current RA therapy, and fully resolved within 24 hours without additional treatment, no RA therapy modification was required. Univariate analysis of total 21 variables showed that negative results at Visit II (in one month after vaccination, OR 5,47, 95% CI 1,3–22,9) and Visit III (in three months after vaccination, OR 4,49 95% CI 1,6 -12,7) may cause negative response to vaccination in RA patients after 12 months follow up. Pronounced DAS28 positive dynamics in RA patients (4,32 and 3,31 at Visit I and Visit IV, respectively, $p<0{,}001$) indicates the absence of any negative impact of vaccination on disease activity).

Table. Post-immunization response coefficient dynamics in RA and control subjects during 1 year follow up.

| Treatment groups | Post-immunization response coefficient dynamics, M±σ. | | |
|---|---|---|---|
| | Visit II (1 month) | Visit III (3 Month) | Visit IV (12 month) |
| MTX (n=52) | 2,4 ±1,2 | 3,4±3,56 | 2,7±2,02 |
| Lef (n=10) | 5,01±4,7 | 6,9±2,1 | 4,3±1,8 |
| iTNF-α+MTX (n=10) | 2,6±0,3 | 3,5±1,7 | 3,14±2,86 |
| GK (n=30) | 2,15±0,25 | 3,49±2,27 | 2,2±1,78 |

**Conclusions:** Thus, all given prove the sufficient immunogenicity and safety of 23-valent pneumococcal vaccine in RA patients, getting different therapeutic regimens.

## FRI0141 BONE MINERAL DENSITY OF WHOLE BODY CAN PREDICT FRACTURES IN PATIENTS WITH RHEUMATOID ARTHRITIS: FINDINGS FROM THE TOMORROW STUDY

M. Tada[1], K. Inui[2], T. Okano[2], Y. Sugioka[3], K. Mamoto[2], T. Koike[3], H. Nakamura[2]. *[1]Orthopaedic Surgery, Osaka City General Hospital; [2]Orthopaedic Surgery; [3]Center for Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka, Japan*

**Background:** Rheumatoid arthritis (RA) is an independent risk factor for osteoporosis. Patients with RA have a higher risk of fractures than healthy individuals[1]. We previously reported that bone mineral density (BMD) is lower in patients with RA than in healthy individuals[2]. Whether or not BMD and fracture correlate in patients with RA has remained unclear.
**Objectives:** We aimed to determine whether whole body BMD could predict fracture during five years of follow in patients with RA.
**Methods:** This prospective cohort study analyzed data collected over a period of five years from the TOMORROW study (TOtal Management Of Risk factors in Rheumatoid arthritis patients to lOWer morbidity and mortality clinical trial (registration number, UMIN000003876)), which is a 10-year prospective study of 208 age and sex matched patients with RA and 213 volunteers (controls). The BMD, lean body mass, and fat ratio (%) were measured using whole body dual-energy X-ray absorptiometry (DXA). Patients and volunteers who had received metal implants were excluded. We measured BMD, lean mass, and fat ratio (%) at baseline between groups with and without fractures, to identify a cut-off for increased risk of fracture using ROC curve analysis.
**Results:** Fracture rates did not significantly differ between RA patients and controls (14.9% vs. 10.4%; p=0.231) over the five-year period. The DXA data derived from a total of 358 participants (158 patients and 200 controls) identified 39 individuals with and 319 without fracture. The BMD was significantly lower in the group with fracture, than that without (0.914 vs. 0.995 g/cm$^2$, respectively: p=0.001 and the tendency was the same in the patients with RA (0.873 vs. 0.977 g/cm$^2$, respectively; p=0.002). Lean mass and fat percentage did not significantly differ between the groups with and without fracture. At a BMD cut-off of 0.869 g/cm$^2$, the area under the curve was 0.734, sensitivity was 72.2% and specificity was 65.7% (p=0.01) in patients with RA (Figure 1 and Table 1). The odds ratio of fracture among the patients with RA over a period of five years was 5.3 when the BMD was <0.869 g/cm$^2$.

Table 1. AUC of parameters

| | AUC | 95% CI | P |
|---|---|---|---|
| Bone mineral density | 0.734 | 0.628–0.839 | 0.01 |
| Lean mass | 0.531 | 0.431–0.632 | 0.583 |
| Fat percentage | 0.606 | 0.493–0.720 | 0.063 |

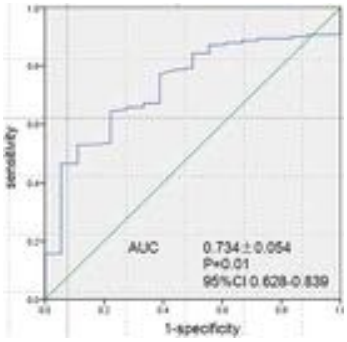

Figure 1

**Conclusions:** The baseline BMD was significantly lower in the group with, than without fracture. However, lean mass and fat percentage did not significantly differ between them. Baseline total BMD was more useful than lean mass and the fat percentage to predict fracture within five years among patients with RA.

Kleinert, Rapp, Ronneberger, Schuch u. Wendler, Erlangen, Germany*

**Background:** Depression is a frequent if not the most frequent comorbidity in patients with rheumatoid arthritis (RA) [1].
**Objectives:** To investigate the prevalence of depressive symptoms in RA patients in a standardized manner in the clinical setting using two previously validated questionnaires and to test for clinical characteristics associated with depressive symptomatology.
**Methods:** To assess depressive symptoms the validated 9 item version of the patient health questionnaire (PHQ-9) and the Beck-Depression Inventory II (BDI-II) were used. In addition, demographic background, RA disease activity according to DAS28, RA disease symptoms according to the RAID questionnaire, comorbidities and anti-rheumatic as well as anti-depressive treatment were recorded. Cut-off values for depressive symptomatology were PHQ-9≥5 or BDI-II≥14 (ie mild depressive symptoms or worse). Numbers for frequency of depressive symptomatology were derived by frequency analysis while factors independently associated to depressive symptomatology were investigated by odds ratios and 95% confidence intervals using multiple logistic regression analyses. IRB approval was obtained and all patients completed an informed-consent form prior to participation.
**Results:** In 1004 RA-patients (75.1% female, mean age: 61.0±12.9 years, mean disease duration: 12.2±9.9 years, DAS28(ESR): 2.5±1.2) the prevalence of depressive symptoms was 55.4% according to predefined cut-offs (more restrictive cut-offs indicating moderate depressive symptoms at least, i.e. PHQ-9 ≥10 or BDI-II ≥20 still classified 22.8% of our patients as being depressed). Characteristics independently associated with depressive symptomatology were: age >60 years (OR=0.62 (95%CI: 0.46, 0.83)), DAS28(ESR) ≥3.2 (OR=1.52

(95%CI: 1.03, 2.27)), RAID score >5 (OR=8.28 (95%CI: 5.36, 12.80)) and presence of chronic pain (OR=2.55 (95%CI: 1.42, 4.57)). Only 11.7% of patients classified as having depressive symptoms received anti-depressive drug therapy.
**Conclusions:** More than half of RA patients showed symptoms of depression, which were associated with age, RA disease activity, a high impact of RA symptoms on the life of patients and the presence of chronic pain. However, only a small number of RA patients were receiving appropriate anti-depressive therapy. These findings strongly suggest the need for better assessment of depression in routine rheumatologic care.

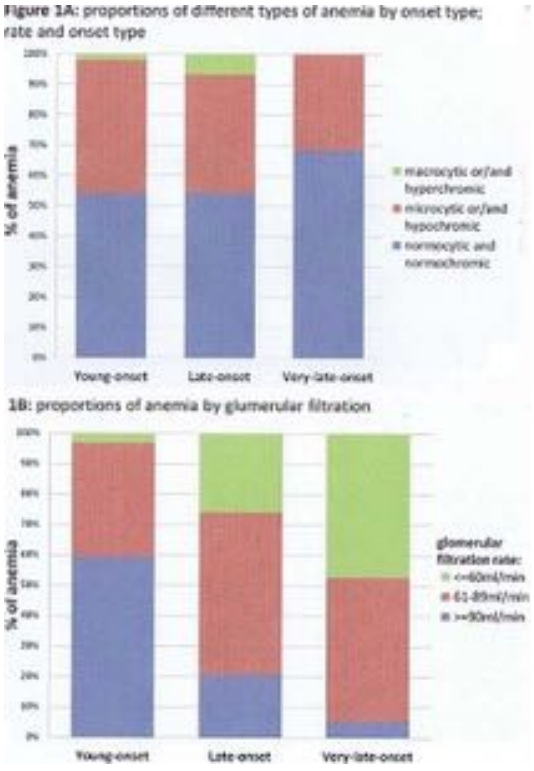
## FRI0143 RISK FACTORS FOR MALIGNANCY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON THE IORRA COHORT DURING A 14-YEAR OBSERVATION PERIOD



N. Sugimoto, E. Tanaka, E. Inoue, Y. Shimizu, K. Shidara, A. Nakajima, A. Taniguchi, S. Momohara, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** As treatments for rheumatoid arthritis (RA) such as methotrexate (MTX) and biological agents have made dramatic progress in this decade, it is desirable to improve patient quality of life and prognosis, including management of various comorbidities. Malignancy is an important comorbidity in patients with RA[1,2]. No significant difference in the overall incidence of malignancies in Japanese patients with RA (standardized incidence ratio [SIR] 0.96, 95% confidence interval [CI] 0.90–1.03) was noted compared with the general Japanese population[3]. However, a markedly significant increase in the incidence of malignant lymphoma was observed (SIR 5.10, 95% CI 4.21–6.13), and the incidence of lung cancer in males was also increased significantly[3]. In contrast, the incidence of gastric cancer and colorectal cancer was decreased significantly[3]. It is important to investigate the risk factors for malignancies to examine the prognosis of patients with RA.
**Objectives:** To investigate the risk factors for overall and site-specific malignancies in a large observational cohort of Japanese patients with RA over a long-term period.
**Methods:** Among Japanese patients with RA enrolled in the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort from April 2000 to September 2013, all malignancies were extracted from patients' self-reporting and confirmed by medical records. Patients who dropped out of the IORRA cohort were asked about comorbidities, including malignancies, by follow-up mail. With regard to overall malignancies and malignancies at frequently involved sites (lung cancer, malignant lymphoma, breast cancer, gastric cancer and colorectal cancer), risk factors were analysed with time-dependent Cox regression adjusted by age, gender, smoking history and BMI.
**Results:** Among 11,106 Japanese patients with RA representing 122,706 person-years, a total of 830 overall malignancies, including 114 lung cancers, 114 malignant lymphomas, 105 breast cancers, 95 gastric cancers and 90 colorectal cancers, were confirmed. RA disease duration was a significant risk factor for lung cancer (hazard ratio [HR] 0.95, $P$ =0.001) and malignant lymphoma (HR 0.95, $P$ =0.004). RF positivity was a significant risk factor for lung cancer (HR 2.26, $P$ =0.018). DAS28 score was a significant risk factor for overall malignancies (HR 1.10, $P$ =0.008), lung cancer (HR 1.25, $P$ =0.012) and malignant lymphoma (HR 1.22, $P$ =0.049). Neither MTX nor biological agent use was a significant risk factor for overall malignancies or malignancies at specific sites.
**Conclusions:** Higher disease activity was a risk factor for overall malignancies, lung cancer and malignant lymphoma in Japanese patients with RA. However, treatment with MTX and biological agents was not a risk factor for malignancy. These results suggest that tight control of RA disease activity would protect against the occurrence of malignancies in patients with RA.

## FRI0144 ANEMIA IS A MORE COMMON SYMPTOM IN LATE-ONSET RA COMPARED TO YOUNG-ONSET RA AND IS STRONGER RELATED TO IMPAIRED KIDNEY FUNCTION

P. Studenic[1], D. Aletaha[2], H. Haslacher[3], M. Unger[2], J. Smolen[2], M. Köller[4,5]. *[1]Internal Medicine 3, Division of Rheumatology and Geriatric Medicine; [2]Internal Medicine 3, Division of Rheumatology; [3]Department of Laboratory Medicine; [4]Internal Medicine 3, Division of Geriatric Medicine, Medical University Vienna; [5]Sophienspital, Vienna, Austria*

**Background:** Rheumatoid arthritis is an inflammatory musculoskeletal disease, which presents mainly by joint swelling and pain, but also with a variety of other symptoms. Anemia has already been detected as additional marker for disease activity but there is no evidence about the differences between young- (YO) and late-onset (LO) (onset of disease after 60 years of age) RA patients.
**Objectives:** To investigate differences in the prevalence of anemia between YO-RA and LO-RA over the course of the disease and find factors that can be linked to anemia.
**Methods:** We selected an inception cohort of RA patients that was treated with DMARDs for at least a year from a prospective longitudinal database and used data of the first 20 blood draws of these patients, which were performed over up to 7 years of disease course. We used longitudinal, logistic regression and chi-square analyses to determine different aspects of anemia. We evaluated the risk for developing anemia, as well as factors associated with different types of anemia based on the mean corpuscular volume, the mean haemoglobin, kidney function, and disease activity.

**Results:** 326 RA patients were included in this study, 126 patients were late-onset RA (mean±SD: age: 69.4±6.6 years, 71% female, glomerular filtration rate (GFR) 72.5±15.6ml/min, haemoglobin (HB) 13.1±1.3g/dl, 47% rheumatoid factor (RF) positive and 42% anti-citrullinated antibodies (ACPA) positive) and 200 patients young-onset RA (mean±SD: age: 47.4±9.6 years, 75% female, glomerular filtration rate (GFR) 86.6±16.5ml/min, haemoglobin (HB) 13.3±1.4g/dl, 55.5% RF positive and 50% ACPA positive). At baseline there was no significant difference in composite measures of disease activity, however LO-RA showed significant higher acute phase reactants and swollen joints and lower GFR than YO-RA. Over the observation period there was a significant higher prevalence of anemia in LO than in YO (23.4% vs. 17.6%), this relates to an odds ratio (OR) of 1.4 (CI: 1.2–1.7, $p<0.001$). When using the time point of the lowest haemoglobin level, there was even a higher OR of 1.67 (1.09–2.54) for LO to have anemia. 45% of YO have at least one incident episode of anemia over the follow-up period, whereas this is the case in 54% of LO (p=0.03). This difference increased when looking at the very late-onset patients (age at onset >75years, n=20) to 70%. Anemia was present during 24.2±31.5% versus 17.6±27.6% of the observed time period. Haemoglobin levels were also significantly lower in patents with later onset of RA ($p<0.001$).
Normocytic normochromic anemia tended to be more prevalent in very-late-onset RA. (see figure 1A). Among patients with anemia impaired kidney function (GFR<60ml/min) was observed in 26% of LO patients and 47% of very-late-onset patients, which was significantly higher compared to 3% in YO (p=0.015; figure 1B).
**Conclusions:** RA patients with late-onset disease show a greater risk of anemia. Anemia in late-onset RA patients is more strongly associated with decreased kidney function, and anemic episodes are longer and more severe.
**Disclosure of Interest:** None declared

## FRI0145 MANAGEMENT OF GOUT IN PRIMARY CARE: WHAT ARE THE FACTORS ASSOCIATED WITH ADHERENCE? RESULTS FROM THE ADAGIO COHORT

R.-M. Flipo[1], L. Martinez[2], P. Maigret[3], G. Reach[4]. *[1]CHRU, Lille; [2]UMPC, Paris; [3]Menarini, Rungis; [4]APHP, Paris, France*

**Background:** According to EULAR recommendations, long term management of gout encompasses pharmacological and non pharmacological treatments. Patient education and adherence to medication and lifestyle advices are key factors of management [1].
**Objectives:** An observational and cross-sectional study was conducted by general practitioners (GP). The main objective was to determine factors associated with adherence to treatment of gout. Secondary objectives were to analyse adherence to lifestyle recommendations and achievement of therapeutic goal for uricaemia, and also to describe the perception of the disease and treatments.
**Methods:** Adult patients with gout, taking a urate lowering therapy for more than 3 months, were included by 630 GP. Data were collected during a unique visit. Adherence to treatment was assessed through a 5-item self-questionnaire [2,3]. Factors associated with adherence were analysed using a multivariate logistic regression. Adherence to lifestyle recommendations were assessed via questions on alcohol, beer and soda intake. Patients also completed the Brief Illness Perception Questionnaire (B-IPQ) [4] and the Beliefs about Medicines Questionnaire (BMQ) [5].
**Results:** 1441 patients with gout (85% male, age: 64.4 ± 11.4 years) were retained in the analysis. Main symptoms were pain and swelling (85%), podagra (60%) and erythema (49%). Mean serum uric acid level was 63.4 ± 16.4 mg/L (42% were below the therapeutic goal of 60 mg/L); 85% of patients were overweighted (including 38% obese); 70% had hypertension; 62% had dyslipidemia; 24% had type 2 diabetes; they took 4.9 ± 3.5 tablets daily in average. Overall, 80% of patients were assessed as adherent to medicines and 32% to lifestyle recommendations. Main factors associated with a good adherence to medicines were: being more than 70 years (OR=1.9; CI95%: [1.2–2.9]), having an uricaemia below the therapeutic goal (OR=1.8; CI95%: [1.3–2.5]), regularly checking uricaemia (OR=1.5; CI95%: [1.0–2.1]), and taking few tablets daily (OR/unit=0.9; CI95%: [0.9–1.0]). Besides, good adherence to medicines was associated with a better perception of the disease and treatments (lower impact on quality of life, better control of gout) and a better relationship with health care professionals.
**Conclusions:** The ADAGIO study indicates that a good adherence to the pharmacological treatment of gout is associated with regular uricaemia controls and achievement of the recommended therapeutic goal, i.e. maintaining serum uric acid below 60 mg/L [1]. The data suggests that patients under multiple medications would benefit from special attention to help improving gout management.

## FRI0146 INCIDENCE RATE AND THE RISK OF HERPES ZOSTER IN PATIENTS WITH RHEUMATOID ARTHRITIS USING JAPANESE HEALTH INSURANCE DATABASE

R. Sakai[1], S. Kasai[2], F. Hirano[2], M. Kihara[2], W. Yokoyama[2], M. Tsutsumino[1], K. Nagasaka[2], R. Koike[2], H. Yamanaka[1], N. Miyasaka[2], M. Harigai[1]. *[1]Institute of Rheumatology, Tokyo Women's Medical University; [2]Tokyo Medical and Dental University, Tokyo, Japan*

**Background:** A high risk of herpes zoster (HZ) in patients with rheumatoid arthritis (RA) has been reported[1]. The risk of HZ in Asian patients, especially Japanese, on tofacitinib was higher than that of Western countries [2]. It is essential for rheumatologists to diagnose and manage HZ early not only to prevent post-herpetic neuralgia but also hamper developing cutaneous dissemination and visceral end organ involvement. However, there are no reports investigating the incidence rate (IR) and risk of HZ in RA patients using large population-based data in Asia.
**Objectives:** To compare the IR of HZ between RA cases and non-RA cases, and estimate the risk of HZ during three years using Japanese health insurance database.
**Methods:** This retrospective longitudinal population-based study was conducted using claims data provided by the Japan Medical Data Center Co., Ltd. We defined individuals as RA cases if they met all of the following: 1) had at least 6 months of continuous enrollment in the health insurance database; 2) had at least one RA diagnostic code (ICD10 codes; M05, M060, M062, M063, M068, and M069); 3) had at least one prescription of disease-modifying antirheumatic drugs (DMARDs) between January 2005 and December 2013; and 4) were 18 years old or older (RA group, n=6,712). Among individuals who met above criteria 1), but did not meet 2) to 4), we selected age- (±5 years), gender-, calendar year of the observation start, and observation length-matched non-RA cases at 1:5 ratio (RA cases: non-RA cases) (non-RA group, n=33,560). The start of the observation in the RA group was defined by the month of the first prescription of DMARDs with RA diagnostic code after the first 6 months of the enrollment in the health insurance database. Observation stopped either 3 years after the start of the observation, or on the month individuals withdrew from the health insurance or on December 2014, whichever came first. Patients who had the ICD 10 codes for HZ (B02) and were prescribed antivirus drugs for HZ at least one time during observation term were deemed as developing HZ. We compared the IR of HZ between the two groups and investigated the association between RA and HZ using conditional logistic regression analysis.
**Results:** The median age was 52, and 75.6% were female in the both groups. Biological DMARDs were prescribed in 13.9% of RA cases, methotrexate in 58.3%, synthetic DMARDs other than methotrexate in 46.9%, and oral corticosteroids in 35.0% at baseline. The IR of HZ in the RA group [14.1/1,000 person-years (PY)] was significantly higher than that of the non-RA group (8.3/1,000 PY). The odds ratio [95% confidence interval] of RA for HZ was 1.5 [1.2–1.8] after adjusting for past history of HZ, pulmonary and renal comorbidities at baseline, and use of oral corticosteroids at baseline.
**Conclusions:** This study revealed that patients with RA had significantly higher risk of HZ than non-RA individuals using health insurance database for the first time in Asia.

## FRI0147 SERUM RANKL LEVEL AND FRACTURE RISK USING FRAX TOOL IN POST-MENOPAUSAL RHEUMATOID ARTHRITIS PATIENTS

S.I. Nasef[1], H.H. Omar[2], H.M. Abdalla[3]. *[1]Rheumatology and Rehabilitation; [2]Clinical Pathology; [3]Radiology, Faculty of Medicine, Suez Canal University, Ismailia, Egypt*

**Background:** Osteoporosis and related fragility fractures are one of the most common complications seen in patients with rheumatoid arthritis (RA). Increased osteoclast activity contributes to local and systemic abnormalities of bone remodelling, including bone erosions and focal and systemic osteoporosis. Receptor Activator of Nuclear Factor Kappa Beta Ligand (RANKL) is essential for osteoclast formation, function, and survival, and it is a key mediator of increased osteoclast activity in RA. As fracture prevention is the major target in prevention and diagnosis of osteoporosis, we are evaluating fracture risk in RA patients using the fracture risk assessment (FRAX) tool developed by the WHO. Moreover, we are searching for a potential association between serum RANKL and fracture risk aiming at identifying patients at high risk of fractures.
**Objectives:** To assess the level of serum RANKL in post-menopausal rheumatoid arthritis patients and its correlation with fracture risk using Fracture Risk Assessment Tool (FRAX).
**Methods:** We recruited 116 individuals (78 postmenopausal RA patients and 38 age-matched post-menopausal control subjects). All patients and controls were not receiving osteoporosis treatment. We measured serum RANKL, C reactive protein (CRP) and Rheumatoid Factor (RF). Disease activity score (DAS)-28 was used to assess RA activity. We measured bone mineral density (BMD) at lumbar spine (L1- L4), right femur neck and right forearm radius with dual-energy X-ray absorptiometry. We have calculated the absolute 10-year major osteoporotic fracture and hip fracture risks with FRAX tool.
**Results:** Mean age was 54.83± 6.6 years in RA patients versus 55.05± 6.2 years in controls. Mean body mass index (BMI) of the patients was 30± 5.6. Mean disease duration was 10.53± 6.6 years. Mean DAS was 3.94± 1.3, mean CRP level was 8± 5.2 mg/L and 76.9% of patients were on steroids. Two of the patients were smokers and no one was taking alcohol. One of the patients reported history of fragility fracture at the forearm but no one reported parent hip fracture. Serum RANKL was significantly higher in RA patients versus controls (971.0pmol/L vs. 177.85 pmol/L, P value $<0.0001$). Mean BMD of RA patients at lumbar spine was 0.990± 0.2 g/cm$^2$, at femur neck was 0.870±0.19 g/cm$^2$ and at forearm was 0.568± 0.14 g/cm$^2$. Prevalence of osteoporosis in RA patients at lumbar spine was 34.6%, at femur neck was 23.1% and at forearm was 42.3%. Risk of major osteoporotic fracture in RA patients was 8.62% and the risk of hip fracture was 3.3%. There was a highly significant positive correlation between serum RANKL and the risk of major osteoporotic fracture (r =0.736, P value$<0.0001$). There was a highly significant positive correlation between serum RANKL and the risk of hip fracture (r =0. 859, P value $<0.0001$). Serum RANKL was negatively correlated with femur neck BMD (r= -0.529, P value $<0.001$) and negatively correlated with forearm BMD (r= -0.289, P value $<0.01$). No significant correlation was found between serum RANKL and BMD at lumbar spine, RF, CRP level or DAS-28.
**Conclusions:** In post-menopausal RA patients, increased serum RANKL level is associated with an increased risk of major osteoporotic and hip fractures. Therefore, serum RANKL could be a marker to identify post-menopausal RA patients at high risk of fractures.
**Disclosure of Interest:** None declared

## FRI0148 DETERMINATION OF THE LIPID PROFILE IN ACTIVE DISEASE LEADS TO INCORRECT CARDIOVASCULAR RISK PREDICTION IN EARLY RA PATIENTS

S.A. Turk[1], D. van Schaardenburg[1,2], W.F. Lems[3], M.T. Nurmohamed[1,3]. *[1]Amsterdam Rheumatology and immunology Center, location Reade; [2]Amsterdam Rheumatology and immunology Center, location AMC; [3]Amsterdam Rheumatology and immunology Center, location VU university medical center, Amsterdam, Netherlands*

**Background:** Rheumatoid arthritis (RA) is associated with increased cardiovascular morbidity and mortality. This cardiovascular risk is mainly determined by the lipid profile, which may change during the course of the disease (1). For a proper cardiovascular risk assessment stable lipid values should be used and in cardiovascular risk prediction models mostly lipid ratios are applied.
As the increased cardiovascular risk is already present at the time of diagnosis, it is important to initiate cardiovascular risk management as early as possible in the disease (2). However, first it is necessary to know if measurement of the lipid profile is adequate (i.e. stable lipid values) early in the disease.
**Objectives:** The aim of this study was to 1) investigate the change in lipid profile during the first 4 weeks of RA treatment 2) analyse the association between the alteration in the lipid profile and the change in ESR.
**Methods:** In 66 consecutive DMARD-naive early RA patients lipid profile and disease activity were measured. This was repeated after four weeks of treatment with methotrexate (3 weeks 10 mg, 4th week 17.5 mg) and prednisolone (30 mg tapered to 10 mg). Lipid profile assessment comprised TC, HDL-C, LDL-C, triglycerides and apolipoprotein A and B (Apo A and Apo B). Disease activity was assessed by the disease activity score of 44 joints (DAS44), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Patients on statins were excluded. The change in lipid profile (week 4 minus week 0) versus change in ESR was analysed in 2 patient groups: a group with high (median -31.0 mm/hour) and a group with low (median -3.0 mm/hour) improvement in ESR.
**Results:** Three patients on statins were excluded, analyses were thus performed on 63 early RA patients. All components of the lipid profile increased significantly during treatment, except for Apo B. In addition, ratios of lipid values, particularly the TC/HDL cholesterol ratio improved significantly (table 1). The group with high ESR versus the group with low ESR improvement had a significantly higher increase in TC, HDL-C, LDL-C and Apo A levels. The spearman rho test showed a correlation between delta ESR and delta TC, HDL, LDL and Apo A of r=0.456, r=0.313, r=0.507 and r=0.281, respectively (all p$<0.05$).

Table 1

| | Baseline samples | Week 4 samples | P-value |
|---|---|---|---|
| Total cholesterol, mmol/l (mean, SD) | 4.9 (1.1) | 5.6 (1.3) | 0.000 |
| Triglycerides, mmol/l (mean, SD) | 1.3 (0.6) | 1.4 (0.8) | 0.023 |
| HDL, mmol/l (mean, SD) | 1.3 (0.4) | 1.9 (0.6) | 0.000 |
| LDL, mmol/l (mean, SD) | 3.1 (0.9) | 3.3 (1.1) | 0.020 |
| Apo A, g/l (mean, SD) | 1.4 (0.3) | 1.8 (0.3) | 0.000 |
| Apo B, g/l (median, IQR) | 0.9 (0.8–1.1) | 0.9 (0.8–1.1) | 0.740 |
| TC/HDL ratio (mean, SD) | 4.0 (1.4) | 3.2 (1.1) | 0.000 |
| Apo B/ Apo A ratio (mean, SD) | 0.7 (0.2) | 0.6 (0.2) | 0.007 |

**Conclusions:** Lipid levels increased significantly after four weeks of methotrexate and prednisolone treatment after RA diagnosis and this change is associated with the improvement in ESR. In both groups ratios of lipid values improved substantially.
Hence, cardiovascular risk management in early arthritis should be postponed until low disease activity has been obtained, as assessment during active disease leads to an inappropriately high cardiovascular risk estimation.

## FRI0149 ATTRIBUTES OF MAXIMUM RELEVANCE IN THE CHOICE OF A BIOLOGICAL DMARD IN THE FIRST LINE TREATMENT OF RHEUMATOID ARTHRITIS. ACORDAR 2015 PROJECT

S. Muñoz-Fernandez[1], S. Bustabad[2], J. Calvo[3], M. Castaño[4], E. Chamizo[5], H. Corominas[6], N. Fernández-Llanio[7], M.C. Hidalgo[8], J.J. Pérez[9], J.M. Rodríguez[10], S. Romero[11], V. Ruiz-Esquide[12]. *[1]Rheumatology, Hospital Universitario Infanta Sofía. Universidad Europea de Madrid, Madrid; [2]Rheumatology, Hospital Universitario de Canarias, Tenerife; [3]Rheumatology, Hospital Sierrallana, Santander; [4]Rheumatology, Hospital Universitario Virgen de la Arrixaca, Murcia; [5]Rheumatology, Hospital de Mérida, Badajoz; [6]Rheumatology, Hospital Moisés Broggi, Barcelona; [7]Rheumatology, Hospital Arnau de Vilanova, Valencia; [8]Rheumatology, Hospital Clínico de Salamanca, Salamanca; [9]Rheumatology, Hospital de Jerez de la Frontera, Cádiz; [10]Rheumatology, Hospital Universitario de Getafe, Madrid; [11]Rheumatology, Complejo Hospitalario Universitario de Pontevedra, Pontevedra; [12]Rheumatology, Hospital Clinic i Provincial, Barcelona, Spain*

**Background:** According to clinical guidelines, treatment with a DMARD should be initiated as soon as possible, and any patient who does not improve with at least one relevant synthetic DMARD is a candidate for a biological one. However, up to one third of the patients treated with a biological DMARD do not accomplish the therapeutic objective.
**Objectives:** To identify and assess the attributes of the biological DMARDs which determine the most suitable treatment of patients with RA.
**Methods:** We performed a systematic search with the following MeSH terms: rheumatoid arthritis, biologic, DMARD, characteristic, efficacy, safety, side effects, pharmacology, route–administration, adherence y cost. More than 500 publications were reviewed, from which we selected 77 attributes: 7 about general aspects, 5 about pharmacological aspects, 18 about efficacy, 31 about safety, 6 administration aspects and 10 related with cost. Between May and September 2015, 12 meetings were held, followed by a Delphi process of 2 rounds in which the degree of importance was awarded to each attribute on a Likert scale from 1 (minimum) to 9 (maximum). The consistency and concordance of the agreement were determined and they were circulated, obtaining the percentage supported for each one of them.
**Results:** 83 Spanish rheumatologists participated, reaching a high degree of agreement with the attributes, 75 with a high importance (97.4%) and none of low importance. Fifteen attributes were ratified by all the participants:
– Product with approved indication in RA as first-line biological.
– Product recommended in the guidelines as first-line biological.
– Product that shows efficacy following the failure of another biological.
– Treatment accompanied by a reduction in articular damage progression.
– Treatment that reduces comorbidities associated with RA.
– Treatment characterised by a sustained long-term response.
– Safe product (globally).
– Proven long-term safety.

– Treatment with a low incidence of serious infections.
– Product that does not increase the incidence of solid malignancies.
– Product that does not increase the incidence of haematological neoplasms.
– Safe product in patients with cardiovascular pathology.
– Safe product in patients with interstitial pulmonary disease.
– Product that has demonstrated a reduction in mortality.
– Product that presents a scant incidence of serious adverse events.

**Conclusions:** There was a high degree of agreement with the selected attributes, none of which were regarded as being of low importance; 15 of them received the full support of the work group. These attributes would help to define the ideal profile of the biological DMARD following the failure of a synthetic or previous biological DMARD.

## FRI0150 DEPRESSION, INFLAMMATION AND MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Kleinert[1,2], A. Marx[3], H. Faller[4], H.-P. Tony[1], M. Feuchtenberger[5], C. Kneitz[6], S. Lehmann[3], C. Angermann[3,7], G. Ertl[7], S. Störk[3,7], M. Breunig[3,7].
*[1]Rheumatology/Clinical Immunology, University Hospital Würzburg, Würzburg; [2]Rheumatology and Nephrology (Medical Practice) Erlangen, Erlangen; [3]Comprehensive Heart Failure Center; [4]Medizinische Psychologie und Psychotherapie, University of Würzburg, Würzburg; [5]Department of Internal Medicine 2, Hospital Burghausen, Burghausen; [6]Klinik für Innere Medizin II, Klinikum Südstadt Rostock, Rostock; [7]Department of Internal Medicine I – Cardiology, University Hospital Würzburg, Würzburg, Germany*

**Background:** Patients with rheumatoid arthritis (RA) have a high prevalence of depressive symptoms and an increased mortality.
**Objectives:** The current prospective follow-up study investigates prevalence of depression, its association with inflammation and mortality in RA patients.
**Methods:** 764 consecutive patients attending the rheumatology outpatient department of the University Hospital Würzburg underwent a comprehensive cardiovascular (CV) risk assessment. Inflammation in RA patients was characterized by DAS28 and CRP. Quality of life and depressive symptoms were investigated by SF-36 and PHQ-9 (range 0–27 score points), respectively. A PHQ score $\geq$15 points is considered indicative for severe depressive symptoms.
**Results:** 352 subjects suffered from rheumatoid arthritis (RA: 79.5% female, 64.9% RF positive, mean age 54.3 (SD 14.3)), Severe or moderate depressive symptoms were prevalent in 6.6%, respectively 14.4% of RA patients. DAS28, but not CRP, was significantly associated with the prevalence of depressive symptoms (r=0.26 (p<0.001), figure A, table 1).

| PHQ9 | DAS28 | | | |
|---|---|---|---|---|
| | Mean | SD | Median | IQR |
| 0–4 | 2.99 | 1.35 | 2.8 | 2.05–3.87 |
| 5–9 | 3.45 | 1.53 | 3.56 | 2.41–4.5 |
| 10–14 | 3.81 | 2.07 | 4.1 | 2.44–4.93 |
| 15–27 | 4.31 | 1.7 | 4.2 | 2.85–4.86 |

Patients with severe depressive symptoms (PHQ 9 $\geq$15) had an increased a HR of 6.42 (95% CI, 2.04 – 20.2, p=0.004) for mortality compared to patients with a PHQ $\leq$14 (figure B).

**Conclusions:** DAS28 in RA patients was associated with severity of depressive symptoms. Severely depressed patients had an increased mortality.

## FRI0151 THE ASSOCIATION BETWEEN AGE AND INFLAMMATORY FINDINGS ON HAND AND FOOT MRI IN EARLY ARTHRITIS, RHEUMATOID ARTHRITIS AND SYMPTOM-FREE CONTROLS

W.P. Nieuwenhuis[1], L. Mangnus[1], H.W. van Steenbergen[1], E.C. Newsum[1], T.W.J. Huizinga[1], M. Reijnierse[2], A.H.M. van der Helm-van Mil[1].
*[1]Rheumatology; [2]Radiology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** A recent MRI study performed in symptom-free persons from the general population showed that MRI-detected inflammation is present in the general population and that the prevalence increases with age.[1] The relation between age and the severity of MRI-detected inflammation is unexplored in early arthritis patients. Therefore this study explored the association between age and MRI-detected inflammation in early arthritis and early rheumatoid arthritis (RA). Furthermore, the localization of inflammatory findings in RA-patients presenting at young and old age were compared.
**Methods:** Unilateral, contrast-enhanced 1.5T MRI of the metacarpophalangeal, wrist and metatarsophalangeal joints was performed at baseline in 589 patients of the Leiden Early Arthritis Clinic (EAC); of these 230 patients fulfilled the 2010-criteria for RA at presentation. MRIs were scored according to RAMRIS. The sum of the bone marrow edema, synovitis and tenosynovitis scores yielded the total MRI-inflammation score. The association with age in early arthritis patients and RA patients was compared to the association previously observed in 193 symptom-free controls.[1] Linear regression analyses were performed on log-transformed MRI-inflammation scores. The localization of the inflammation was studied in different age groups (<40, 40–60, >60 years).
**Results:** Patients with early arthritis and RA-patients had more severe MRI-inflammation than symptom-free controls, they had respectively 2.6 (95%CI 2.3–3.0 p<0.001) and 3.7 (95%CI 3.2–4.3 p<0.001) times more inflammation. A higher age was associated with more MRI-detected inflammation in both early arthritis and RA-patients (in both groups: 1.03 fold increase in inflammation per year, p<0.001). These effect sizes were similar to the association observed in symptom-free controls (1.03 fold increase in inflammation per year, p<0.001). The interaction term between age and group (symptom-free controls and (rheumatoid) arthritis) was non-significant, demonstrating that the effect of age was similar in (rheumatoid) arthritis and symptom-free controls. The localization of MRI-inflammation was similar in RA-patients of the different age groups, indicating no different preferential locations in different age groups.
**Conclusions:** Older patients have more MRI-detected inflammation. Although early arthritis and RA patients have more severe inflammation than symptom-free controls, the effect of age is similar in early arthritis, RA and symptom-free controls. Thus, the effect of age is not disease specific. This study indicates that age should be considered when interpreting MRI-results.

## FRI0152 RELATIONSHIP BETWEEN BIOLOGICAL DMARDS TREATMENT AND COMPLICATIONS AFTER SURGICAL TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Hirano[1], S. Hirabara[1], M. Isono[1], N. Ishiguro[2], T. Kojima[2]. *[1]Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [2]Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** Biological DMARDs (bDMARDs) have changed prognosis of rheumatoid arthritis (RA) dramatically and it is possible to reduce RA synovitis and to inhibit progression of joint destruction using bDMARDs. However, surgical treatment such as arthroplasty is still the important procedure in especially long-standing established RA patients. Information about safety and specific adverse events in surgical treatment under bDMARD treatment is lacking.
**Objectives:** This retrospective study investigated difference of complications between surgical treatment under bDMARDs treatment and that under conventional synthetic DMARDs (csDMARDs) treatment in RA patients.
**Methods:** 122 surgical operations for RA patients except operation to treat infectious conditions in our institute from 2010 to 2015 were included. 45 operations were performed under bDMARDs treatment (BG) and 77 operations were performed under csDMARDs treatment (nonBG). Patients' characteristics, usage of dDMARDs, surgical site infection (SSI) and delayed wound healing (DWH) were compared between two groups. Time courses of hemoglobin (Hb), total protein, DAS28-CRP, SDAI and mHAQ after surgical operations were also compared between two groups.
**Results:** Mean age in BG was significantly younger than that in nonBG (60.1 years old vs. 66.9 years old). MTX usage in BG was significantry higher than that in nonBG (82.2% vs. 64.9%). 48 total knee arthroplasties, 14 total hip arthroplasties, 17 operation in hand and wrist, 29 operations in foot and ankle and 14 others were included. Used bDMARDs were etanercept in 24 cases, infliximab in 7 cases, abatacept in 6 case, adalimumab in 4 cases, tocilizumab in

3 cases and golimumab in 2 cases. Mean duration between stopping bDMARDs and surgical operation was 20.5 days. There was no significant difference in occurrences of SSI cases between two groups (BG: 0.0%, nonBG: 1.3%). There was no significant difference in occurrences of DWH between two groups (BG: 4.4%, nonBG: 11.7%). SDAI and mHAQ at 1–2 months after operation in nonBG were better than that in BG. mHAQ and recovery of Hb in nonBG were also better than that in BG. A SSI occurred in operation of ankle (1/29, 3.4%). DWH were frequently observed in foot and ankle operations (6 cases, 20.7%) and hand and wrist operations (3 cases, 17.6%) (Fig1).

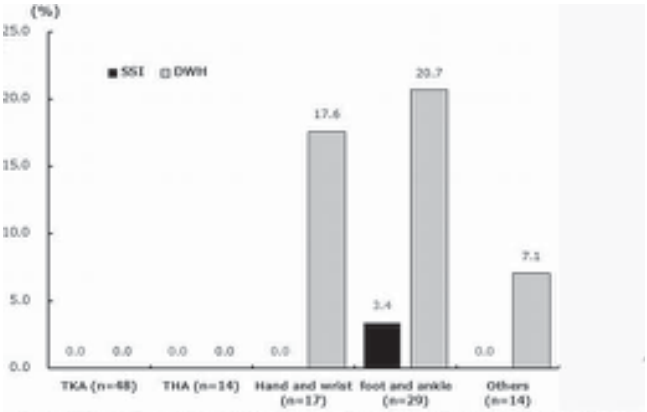

Fig 1. Rates of Complications after Surgical Operation in Respect to Surgical Regions

SSI: Surgical Site Infection, DWH: Delayed Wound Healing, TKA: Total Knee Arthroplasty, THA: Total Hip Arthroplasty

**Conclusions:** There were no significant differences in SSI and DWH between BG and nonBG. mHAQ and Hb recovery after surgical operations in BG were slightly inferior to that in nonBG. This may be due to RA flare after operation in BG or differences of characteristics of patients. It was suggested that surgical region influences the occurrences of SSI and DWH and more complications were observed in foot and ankle operations.

### FRI0153 RELATIONSHIP BETWEEN SERUM OXYTOCIN LEVELS AND DISEASE ACTIVITY, DEPRESSIVE STATE, ADL, AND QOL IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Miwa[1], R. Takahashi[1], S. Isojima[1], M. Saito[1], Y. Miura[1], S. Ishii[1], Y. Ikari[1], T. Tokunaga[1], T. Kasama[1], Y. Toyoshima[2], K. Inagaki[2]. *[1]Division of Rheumatology, Department of Medicine; [2]Department of Orthopedics, Showa University School of Medicine, Tokyo, Japan*

**Background:** Oxytocin, which is also called a happy hormone, has been reported to be related to various conditions including depressive state. However, the positioning of oxytocin in rheumatoid arthritis (RA) remains unclear.
**Objectives:** The objective of this study was to investigate the relationship between serum oxytocin levels and disease activity, depressive state, activity of daily life (ADL), and quality of life (QOL) in RA.
**Methods:** The study included 20 patients with RA who received treatment with a biological agent. We measured the following items before and at 6 months after the start of treatment. The baseline characteristics included the age, sex, prednisolone dose, methotrexate dose, duration of disease, anti-cyclic citrullinated peptide antibody (anti-CCP antibody), rheumatoid factor (RF), serum matrix metalloproteinase-3 (MMP-3), erythrocyte sedimentation rate, and C-reactive protein (CRP). The disease activity of rheumatoid arthritis was assessed using the Simplified Disease Activity Index (SDAI), depressive state using Hamilton Depression Rating Scale (HAM-D), ADL using the Health Assessment Questionnaire (HAQ), and QOL using the 36-Item Short Form Health Survey (SF-36). Serum oxytocin levels were determined by enzyme-linked immunosorbent assay (ELISA). The correlation between each item and the serum oxytocin levels were examined.
**Results:** The serum oxytocin levels before the start of treatment were correlated with RF (r=–0.529), HAQ (r=0.446), HAM-D (r=0.508), and among the 8 categories of the SF-36, physical function (r=–0.676), role function (physical) (r=–0.801), pain (r=–0.506), general health perception (r=–0.787), role function (emotional) (r=–0.844), and mental health (MH) (r=–0.516). On the other hand, the serum oxytocin levels did not correlate with the SDAI (r=–0.078). The serum oxytocin levels after the start of treatment were correlated with the age (r=–0.549), SDAI (r=–0.539), HAQ (r=0.813), HAM-D (r=0.584), and all of the SF-36 categories except for MH (r=0.038) ($r>0.4$). Other items did not correlate to the serum oxytocin levels.
**Conclusions:** The serum oxytocin levels before the start of treatment were correlated with depressive state, ADL, and QOL but not with disease activity. Those after the start of treatment were correlated with the SDAI, depressive state, ADL, and QOL.

## Rheumatoid arthritis - anti-TNF therapy

### FRI0154 ARE THERE NEGATIVE EFFECTS ON DISEASE ACTIVITY AND FUNCTION ASSOCIATED WITH FAILED ANTI-TNF DOSE REDUCTION STRATEGIES FOR RA PATIENTS?

L. Serhal[1], C. Holroyd[1,2], J. Zarroug[1], R. Armstrong[3], B. Davidson[3], N. Harvey[2], E. Dennison[2], C. Cooper[2], C.J. Edwards[1,3]. *[1]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton; [2]MRC Lifecourse Epidemiology Unit, University of Southampton; [3]MSK Research Unit, University Hospital Southampton, Southampton, United Kingdom*

**Background:** We have previously described a strategy for Tumour Necrosis Factor inhibitor (TNFi) dose reduction (TDR) for patients with rheumatoid arthritis (RA) that selects patients with “deep remission” using combined clinical and ultrasound (US)[1].
**Objectives:** The aim of this study was to assess the consequences of this TDR strategy [1] on the HAQ, DAS28-CRP and Area Under the Curve of CRP ($AUC_{CRP}$) after follow-up (mean 28 months).
**Methods:** A longitudinal observational study was performed. Patients with RA (ACR-EULAR 2010), on TNFi for >1 year, not taking oral corticosteroids, DAS28 ≤2.6 for >6 months and absent power Doppler synovitis on US underwent TDR by one third. Patients failing TDR (clinically/on US) were re-escalated to full dose. Patients were divided into 3 groups: Non-reducers (group A), sustained dose reducers (group B) and failed dose reducers (group C). We investigated the initial (TNFi start date) and the last HAQ, DAS28 and $AUC_{CRP}$, as well as before and after TDR.
**Results:** 152 patients with RA receiving TNFi were included. Between Oct 2011 & May 2015, 67 (44%) underwent TDR. 3 patients were lost to follow-up. Dose reducers have been followed-up for a mean 30.5 months after TDR. A total of 29 (45%) failed the TDR after a mean (SD) of 9.5 (7.9) months. By a mean (SD) of 22.4 (11.6) months following dose re-escalation, 27 (93%) continued to receive their TNFi, while 2 (7%) had switched to a different biologic.
Baseline characteristics of all groups were similar. However, we found that the initial HAQ score on starting TNFi was significantly higher for group A compared to groups B and C (mean 1.59 versus 0.95 and 1.28, respectively, $p<0.05$) and was higher for group C compared to group B ($p=0.05$).
When compared before and after reduction, both groups B and C showed a similar pattern of functional capacity and $AUC_{CRP}$. Nevertheless, group B had lower last DAS28 ($p<0.05$). While analysing the most recent DAS28 of group C following dose re-escalation, 32% had achieved DAS28 remission, 20% developed lower (LDA), 44% moderate (MDA) and 4% severe disease activity (SDA).
Finally, we assessed the changes over time of DAS28 and HAQ scores. Group B had a higher DAS28 reduction then groups A and C (mean 3.6 vs. 2.43 and 2.75, respectively) ($p<0.05$), who both had similar changes. Nonetheless, HAQ score changed similarly between all patients.
**Conclusions:** RA patients who fail dose reduction appear to have a higher DAS28 than those who were successful despite reintroduction of a standard dose of TNFi. However, in the majority of cases the level of DAS28 was <3.2 (LDA or better). Failed dose reduction did not appear to cause loss of functional capacity (HAQ) or a greater cumulative exposure to inflammation ($AUC_{CRP}$) compared to successful reduction. The functional capacity (HAQ) at TNFi initiation appears to predict the likelihood of successful dose reduction.

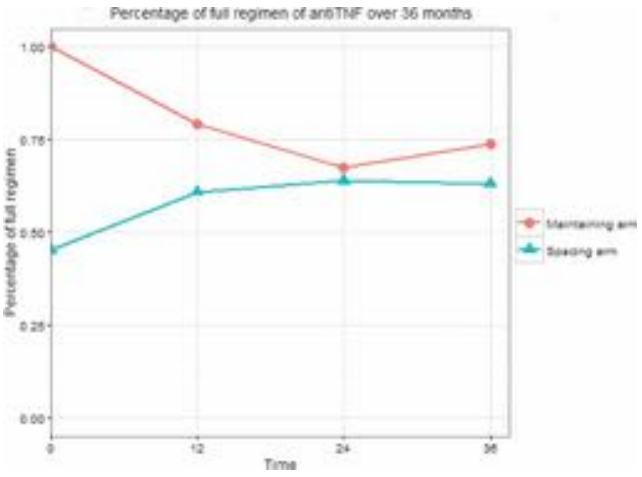
### FRI0155 FIFTY PERCENT OF PATIENTS WHO TAPERED TNF-BLOCKERS WHILE IN STABLE REMISSION ARE ABLE TO MAINTAIN A TAPERED REGIMEN AT 3 YEAR: LONG TERM FOLLOW-UP EXTENSION OF THE STRASS TRIAL



J. Sigaux, F. Bailly, L. Gossec, T. Alfaiate, F. Gandjbakhch, V. Foltz, J. Morel, E. Dernis, P. Gaudin, O. Brocq, J.-M. Berthelot, J.-C. Balblanc, X. Mariette, F. Tubach, B. Fautrel. *STRASS investigator group, Paris, France*

**Background:** Step-down strategy of spacing anti-tumor necrosis factor (TNF)

agents in patients with rheumatoid arthritis (RA) in remission are feasible in the context of randomized clinical trials (RCTs). However, we lack information on the long-term sustainability of a DAS driven step down strategy in clinical practice.
**Objectives:** This long-term extension study of a tapering RCT (STRASS trial (1)) aimed to assess the rate of patients who maintained the tapered regimen of etanercept (ETA) or adalimumab (ADA) in the in S-arm (progressive injection spacing) and M-arm (full regimen) and to evaluate the rate of treatment switch for inefficacy during the 3 years following the trial.
**Methods:** This observational 36 months follow-up considered all patients who completed the STRASS RCT (1). During the follow-up, the physicians were completely free of therapeutic decision making. Physicians were contacted between April and October 2015 and the data on the 36-month period after the end of trial retrospectively collected. The co-primary outcomes were the rate of patients who were taking their initial biologic at tapered regimen and the switch rate for loss of efficacy or safety. Percentage of full regimen anti-TNF intake was calculated over the 3 first years after trial end in both arms, using data from 12-monthly follow-up time points.
**Results:** 96 patients (70.1% of patients completing the RCT) had follow-up data available up to 3 years. At the end of the STRASS RCT (Table), 72 (75%) were in LDA or remission: 47 (48.9%) were taking ETA, 35 (36.5%), ADA, 2 (2.1%) another biologic and 12 (12.5%) no biologic because of remission. In addition, amongst patients still on their initial TNF blockers, 59/80 (74%) were treated at full regimen, 21/80 (26%) at tapered regimen. 3 years later, 65/96 (67.7%) were still on their initial anti-TNF: 73.1% vs 61.4% respectively in M and S-arm, p=0.23), either at full regimen 36/96 (38%), tapered regimen 29/96 (30%, 32% vs 29%, p=0.75), or completely stopped (11.5%: 5.8% vs 18.2%, p=0.06). 28 patients (29.2%, 25% vs 34.1%, p=0.33) had switched for another biologic. The mean percentage of full regimen of antiTNF over 3 years was 70.1±30.4%: respectively 74.3±28.2% vs 64.6±32.9% (p=0.19). DAS28-VS was not different between M and S-arm (2.42 vs 2.01 (p=0.23)).

Table 1. Disease activity and treatment strategy

| | | Initial M-arm (n=52) | Initial S-arm (n=44) |
|---|---|---|---|
| RCT end | LDA or remission, n (%) | 42 (80.8) | 30 (68.2) |
| | Treatment spaced or no biologic, n (%) | 0 (0) | 33 (75.0) |
| At 3 years | LDA or remission, n (%) | 31 (72.1) | 27 (73.0) |
| | Full dose of initial antiTNF, n (%) | 23 (44) | 13 (30) |
| | Spacing initial antiTNF without stop, n (%) | 15 (29) | 14 (32) |
| | No biologic, n (%) | 3 (6) | 8 (18) |
| | Switch rate over 3 years due to relapse, n (%) | 12 (32) | 10 (20) |

**Conclusions:** Maintenance of anti-TNF was high (68% at 3 years) in this cohort of patients with established RA treated according to the treat-to-target paradigm, with no difference between the 2 initial RCT arms. More than 1/3 of patients were received tapered anti-TNF regimen.

## FRI0156 EFFECTIVENESS OF TUMOR NECROSIS FACTOR-INHIBITORS IN THE TREATMENT OF RHEUMATOID ARTHRITIS: A COMPARISON BETWEEN RANDOMIZED CONTROLLED TRIALS AND ROUTINE CLINICAL PRACTICE

K.J. Aaltonen[1], S. Ylikylä[1], J. Joensuu[1], P. Isomäki[2], L. Pirilä[3], M. Kauppi[4], T. Rannio[5], K. Eklund[6,7], M. Blom[8], D. Nordström[6,7] on behalf of ROB-FIN.
*[1]Faculty of Pharmacy/Division of Pharmacology and Pharmacotherapy, University of Helsinki, University of Helsinki; [2]Department of Medicine, Tampere University Hospital, Tampere; [3]Department of Medicine, Turku University Hospital, Turku; [4]Department of Medicine, Lahti Central Hospital, Lahti; [5]Department of Medicine, Jyväskylä Central Hospital, Jyväskylä; [6]Department of Medicine, Helsinki University Central Hospital; [7]Faculty of Medicine; [8]Faculty of Pharmacy/Division of Pharmacology and Pharmacotherapy, University of Helsinki, Helsinki, Finland*

**Background:** Efficacy of Tumor Necrosis Factor (TNF)-inhibitors in treatment of rheumatoid arthritis (RA) measured in randomized controlled trials (RCTs) may not be fully generalizable to routine care owing to the stringent inclusion criteria [1].
**Objectives:** The objective of this study was to observe the effectiveness of TNF-inhibitors in Finland and to assess the real-world patients' potential eligibility for the RCTs.
**Methods:** RA patients starting a TNF-inhibitor as their first, second or third biologic treatment between 2004 and 2014 were identified from the National Register for Biologic Treatment in Finland (ROB-FIN), which is an observational cohort study. Effectiveness was measured using the American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) response criteria and as the proportion of patients reaching Disease Activity Score 28 (DAS28) remission. Logistic regression was employed to identify any predictors of achieving EULAR response. The patients' baseline characteristics were compared against the inclusion criteria of 28 RCTs identified from two systematic reviews [2,3]. Treatment responses measured in the RCTs were compared to those achieved by routine care patients either eligible or not eligible for the same RCTs.
**Results:** Of the 4067 TNF-inhibitor treatment periods, 2259 periods from 1899 patients with valid baseline visit were included in this study. The included patients were predominantly female (73%) with a median age of 55. Adalimumab, etanercept infliximab, golimumab and certolizumab pegol accounted for 41%, 40%, 9.7%, 5.1% and 4.6% of the medication periods, respectively.
Moderate and good EULAR responses at 6 months were achieved by 69% and 40% of the users of the first biologic drug, respectively. ACR20, ACR50 and ACR70 responses were reached by 47%, 25% and 13%, respectively. DAS28 remission was reached by 45%. Concomitant use of methotrexate (MTX) was associated with higher odds of achieving at least moderate EULAR response (odds ratio 1.8, 95% confidence interval 1.1– 3.0) as compared to TNF-inhibitor monotherapy. Golimumab and certolizumab pegol were possibly more effective than infliximab, depending on whether the discontinuers were included in the analysis or not.
Only 3.8% to 50% of the patients would have been eligible for the included RCTs. The eligible patients had generally better ACR50 responses as compared to the non-eligible ones.
**Conclusions:** Different TNF-inhibitors were mostly equipotent in routine clinical practice, but the use of MTX co-therapy had a major influence on treatment response. The efficacy of TNF-inhibitors measured in RCTs cannot be directly generalized into Finnish routine healthcare.

## FRI0157 A BASELINE PREDICTION MODEL FOR RESPONSE TO CERTOLIZUMAB-PEGOL: ROLE OF SYNOVIAL HISTOPATHOLOGY

A. Nerviani, M. DiCicco, F. Humby, S. Kelly, L. Zou, M. Lewis, R. Hands, V. Rocher, K. Blighe, M. Bombardieri, C. Pitzalis. *Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Queen Mary University of London, London, United Kingdom*

**Background:** Rheumatoid Arthritis (RA) is a severe joint disease characterized by chronic inflammation of synovial tissue. The inflammatory infiltrate within the rheumatoid synovium may be differently arranged, defining three distinct histopathotypes: myeloid (prevalent macrophage infiltration), lymphoid (B/T lymphocyte aggregates), and fibroid (fibroblastic infiltration with paucity of immune cells)[1]. Despite enabling a remarkable improvement of the disease's outcome, biologics are not effective in around 30–40% of treated patients. To date, no reliable pre-therapy predictors of response have been identified. The histological characterization of synovitis may represent a valuable tool in predicting response to biologics prior to treatment.
**Objectives:** To evaluate the role of synovial pathology in predicting clinical response to certolizumab-pegol combined with DMARD.

**Methods:** 32 RA patients fulfilling UK NICE criteria for starting TNF-inhibitors were enrolled at Barts Health Trust. Patients underwent a baseline US-guided biopsy prior to commencing certolizumab-pegol and a second biopsy after 12 weeks of treatment. Synovial immune infiltrate was assessed through immunohistochemical staining for CD3/CD20/CD68/CD138 and quantified using a semi-quantitative scoring system (0–4); accordingly, patients were classified as lymphoid (B cells aggregates grade $\geq$2), myeloid (sub-lining macrophages $>$2, +/– grade 1 aggregates) and fibroid (sub-lining macrophages $\leq$2). Therapeutic response was evaluated at 3 months according to EULAR criteria. Logistic regression model was performed to identify factors associated with good EULAR response at 3 months; the factors included clinical and biochemical parameters (ESR, CRP) as well as histopathology. The model selection was implemented using forward processes by AIC with 5-fold cross-validation (error=0.25).
**Results:** Out of 32 baseline biopsies, 53% were classified as lymphoid, 19% myeloid and 28% fibroid. Decrease in the number of sub-lining CD68-positive macrophages significantly correlated with clinical response ($p<0.05$). Baseline demographic and clinical parameters were comparable between the three histological groups; the CRP level was significantly higher in the myeloid compared to fibroid. The histological pathotype adjusted for baseline VAS pain and patient global health score, ESR, HAQ score and concomitant steroid treatment, was identified as a significant predictor of good response to certolizumab-pegol by forward selection (AUC 0.97, CI 0.92–1). The chance of achieving a good EULAR response to certolizumab-pegol was 91% lower in patients classified as a fibroid pathotype at baseline compared to myeloid/lymphoid pathotypes (OR 0.09, CI 0, 1.75).
**Conclusions:** Our study shows that patients with a fibroid pathotype at baseline are less likely to respond to Certolizumab-pegol. Moreover, we identified a novel prediction model of response based on clinical parameters and synovial histopathological classification. Histological assessment of synovial tissue may be of critical importance for developing personalised treatment for RA.

## FRI0158 CLINICAL EVALUATION USEFULNESS OF STANDARDIZED PROTOCOL STRATEGIES OF DOSE REDUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL REMISSION TREATED WITH BIOLOGIC THERAPIES. THE OPTIBIO STUDY

C. Bejerano [1], N. Oreiro [1], C. Fernandez-Lopez [1], J.A. Pinto-Tasende [1], A. Atanes [1], B. Aspe [1], G. Graña [1], M. Freire [1], M. Acasuso [2], J. De Toro [1], F.J. Blanco [1]. *[1]Rheumatology Department, INIBIC-Hospital Universitario A Coruna; [2]Centro de Salud San Jose, XAP Coruna, A Coruna, Spain*

**Objectives:** The OPTIBIO study is a clinical trial whose primary endpoint is to evaluate the proportion of patients that after one year are maintained in clinical remission with a dose reduction treatment regimen of biological therapy in patients with Rheumatoid Arthritis, and to evaluate if the proportion of patients in remission with new regimen dose of treatment is not inferior to patients in remission with standard dose regimen. In our present work, we describe the preliminary results obtained so far.
**Methods:** Open, randomized and controlled study of patients in clinical remission (DAS 28 $<$2.6 or SDAI $<$5 or ACR/EULAR 2011 criteria) at least 6 months followed in Third level Hospital Rheumatology Department. Patients treated with TNF inhibitors therapies (Etanercept, Infliximab, Adalimumab, Certolizumab, Golimumab), Tocilizumab and Abatacept.
Patients are assigned to two groups randomly. Intervention group: according to a standardized protocol of dose reduction of biological therapies. Control group: according to standard dose regimen. Flare is considered when DAS28$>$2.6 or SDAI$>$5 or ACR/EULAR criteria are not fulfilled. Patients are following during after a minimum period of one year and maximum period of 3 years. The frequency of visits is every 12 weeks.
**Results:** 58 patients have been included from 14 April 2014 to 11 January 2016. Forty-eight women (82,76%) and 10 men (17,24%) with an average age of 59,34 ± 11,28 years. Twenty-nine in standard regimen dose and 29 patients in dose reduction regimen. None of the patients had tender or swollen joints at the beginning. At baseline, ESR and CRP values were 16,84 mm/1hour y 0,22 mg/dl respectively. DAS 28-ESR value was 1,84 ± 0.72 and DAS28-CRP was 1.34 ± 0.26. Rheumatoid Factor is positive in 79.31%. Forty-one patients have erosive disease. Seventeen patients have presented a flare: 24,13% in control group and 34,48% in intervention group without statistical signification (p=0.5640). The characteristics of the patients are described in table 1. Statistic differences were not found.
**Conclusions:** Preliminary results show that dose reduction of biological therapies with a standardized protocol it does not seem to increase reactivation risk of disease activity.

## FRI0159 PERSISTENCE WITH BIOLOGIC MONOTHERAPY IN COMPARISON WITH COMBINATION THERAPY WITH DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS; RESULTS FROM AN ONTARIO RHEUMATOID ARTHRITIS COHORT

A.N. Lau [1], M. Movahedi [2], M. Tatengelo [2], C. Bombardier [3] on behalf of Ontario Best Practices Research Initiative (OBRI) Investigators. *[1]Rheumatology, McMaster University, Hamilton; [2]Toronto General Hospital Research Institute; [3]Rheumatology, University of Toronto, Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation, Toronto, Canada*

**Background:** Clinical evidence suggests concomitant treatment with a biologic Disease-Modifying Antirheumatic Drug (bDMARD) and a conventional synthetic DMARD (csDMARD), especially with methotrexate (MTX), has greater efficacy than treatment with a bDMARD as monotheapy in patients with rheumatoid arthritis (RA). However, not all patients are able to tolerate a csDMARD.
**Objectives:** Our objective was to compare the persistence of a bDMARD used as monotherapy, versus combination therapy in patients with active RA.
**Methods:** Physician data were collected from the Ontario Best Practices Research Initiative Rheumatoid Arthritis Registry (OBRI-RA), a clinical registry of RA patients followed in routine care. Inclusion criteria comprised of patients over age 18 years, active RA (defined as $\geq$1 swollen joint) and started on their 1st bDMARD within 30 days before registry enrolment, or started after enrolment. Combination therapy was defined as treatment with a bDMARD plus at least one csDMARD, while monotherapy was defined as treatment with only a bDMARD.
The primary outcome was persistence with 1st bDMARD therapy, which was defined as the length of time the patients continued to receive their first bDMARD therapy. Persistence of treatment was examined using Kaplan-Meier survival analysis. Patients were censored at date of 1st bDMARD stop, switch to another bDMARD or at date of last follow-up, whichever came first.
**Results:** Among 2591 RA patients, 701 patients started their 1st bDMARD within 30 days before cohort enrolment or after enrolment with the mean (standard deviation) of follow-up 1.9 (1.6) person-years. A total of 598 (85.3%) patients were on combination therapy, and 103 (14.7%) patients were on monotherapy. At baseline, there was a similar mean age, proportion of females between the two groups. A TNF$\alpha$ inhibitor was the biologic used in 22.6% and 14.5% of the monotherapy and combination group respectively.
The mean time to failure of 1st bDMARD was 4.3 years (95%CI: 3.7–4.9) and 4.6 years (95%CI: 4.3–4.8) in the monotherapy and combination group respectively. At 12 months follow-up, 74% (95%CI: 64–81) in the monotherapy group and 81% (95%CI: 77 -84) in the combination group remained on their first bDMARD (table 1).

**Table 1: Survival function (95% CI) for patients stopping their initial bDMARD therapy by year of follow-up for the monotherapy versus combination group in patients with active rheumatoid arthritis**

| Time (year) | Whole cohort N=701 | Monotherapy N=103 | Combination therapy N=598 |
|---|---|---|---|
| 1 | 0.80 (0.76-0.83) | 0.74 (0.64-0.81) | 0.81 (0.77-0.84) |
| 2 | 0.72 (0.69-0.76) | 0.67 (0.56-0.76) | 0.73 (0.69-0.77) |
| 3 | 0.69 (0.65-0.73) | 0.67 (0.56-0.76) | 0.70 (0.65-0.74) |
| 4 | 0.65 (0.61-0.70) | 0.64 (0.52-0.74) | 0.66 (0.60-0.70) |
| 5 | 0.60 (0.53-0.65) | 0.55 (0.38-0.69) | 0.61 (0.54-0.67) |

**Conclusions:** Our study demonstrates that a higher proportion of patients on monotherapy failed therapy at 12 months, and the mean time to treatment failure was shorter with monotherapy, but these results were not statistically significant. Although combination therapy is recommended, these real-world results suggest that patients who are unable/unwilling to continue on a csDMARD, bDMARD monotherapy can still provide an efficacious option.

## FRI0160 ANTI-TNF THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS DOES NOT ATTENUATE CUTANEOUS TNF ACTIVITY FOLLOWING A TUBERCULIN SKIN TEST

R. Byng-Maddick[1], C. Haas[1], M. Ehrenstein[2], M. Noursadeghi[1]. *[1]Division of Infection and Immunity; [2]Division of Medicine, UCL, London, United Kingdom*

**Background:** Anti-TNF therapy has revolutionised treatment of rheumatoid arthritis (RA). This success is partly tempered by the substantially increased risk of granulomatous infectious diseases, particularly tuberculosis (TB). However the mechanisms underlying the effectiveness of the treatment are poorly understood. We used the tuberculin skin test (TST) as an in vivo challenge model to investigate whether TNF activity is attenuated by anti-TNF therapy in a prototypic cell mediated immune response.
**Methods:** 50 stable RA patients (treated with Adalimumab, Etanercept or Methotrexate) and healthy volunteers with immunological memory to TB antigens were identified using an interferon-gamma ELISpot of peripheral blood. TST or saline (controls) was injected into the forearm of study participants and 3mm punch skin biopsies were taken from the injection site after 72 hours. Samples were collected for RNA analysis and histology. Genome wide transcriptional profiling was performed to compare gene expression changes in response to the TST challenge between treatment groups. As a surrogate marker for TNF activity the expression of TNF-regulated genes was quantified using a modular approach.
**Results:** Clinical TST responses were significantly diminished in RA patients compared to healthy controls. Anti-TNF therapy did not have a further significant effect on skin induration compared to those treated with methotrexate. However clinical TST skin induration did not correlate with peripheral blood response to TB antigens, as interferon-gamma responses to TB antigens in peripheral blood were not attenuated by rheumatoid disease or treatment. Genome wide transcriptional profiling showed that TNF was induced following the TST, and this was not attenuated by anti-TNF therapy, compared to RA patients treated with methotrexate or healthy controls. Furthermore, downstream activity of this induced TNF was preserved in patients on anti-TNF therapy.
**Conclusions:** Attenuated clinical TST responses have been previously shown in RA patients with active disease. Our results expand these findings to patients with stable disease, where the clinical TST responses were also diminished. Intriguingly, based on the transcriptional response to a TST challenge, we did not observe any reduction in TNF activity in patients on anti-TNF therapy. We conclude that anti-TNF therapy is unable to block a surge in TNF activity following an acute challenge. Therefore we infer that anti-TNF therapy is more likely to have biological effects on basal levels of TNF activity in steady state and rather than blocking TNF activity at the site of acute inflammation.
**Disclosure of Interest:** None declared

**Background:** SB5 is a biologic agent developed as a biosimilar of the adalimumab reference product (ADL). The 24-week results of Phase III study results have been reported[1].
**Objectives:** To evaluate the efficacy, safety, and immunogenicity in patients with RA who transitioned from ADL to SB5 vs. patients who maintained ADL and patients who continued to receive SB5 during the transition period after Week 24 up to Week 52.
**Methods:** Patients with RA were randomised in a 1:1 ratio to receive either SB5 or ADL 40 mg every other week (EOW) via subcutaneous injection. At Week 24, patients receiving ADL were re-randomised in a 1:1 ratio to either be transitioned to SB5 or continue on ADL EOW up to Week 50. Patients receiving SB5 continued to receive SB5 but they also followed the randomisation procedure to maintain blinding. Efficacy, safety, and immunogenicity were assessed up to Week 52.
**Results:** At Week 24, 254 patients from SB5 continued to receive SB5 (SB5/SB5), 125 patients from ADL were transitioned to SB5 (ADL/SB5), and the 129 patients from ADL continued to receive ADL (ADL/ADL). The ACR responses at Week 52 in per-protocol set were comparable between SB5/SB5, ADL/SB5, and ADL/ADL (76.9% vs 81.1% vs 71.2% for ACR20, respectively). Other efficacy endpoints were also comparable across the treatment groups. The change of modified total Sharp score was comparable with mean change of 0.17 in SB5/SB5 vs 0.25 in ADL/SB5 vs 0.50 in ADL/ADL. The safety profile during the transition period was comparable. Two patients newly reported injection site reactions only in ADL/ADL. The incidence of anti-drug antibody was 15.7% in SB5/SB5, 16.8% in ADL/SB5, and 18.3% in ADL/ADL during the transition period.

Table 1. Safety profile of the study population during the transition period (from Week 24 to Week 52)

| Number of patients with | SB5/SB5 (N=254) | | ADL/SB5 (N=125) | | ADL/ADL (N=127) | |
|---|---|---|---|---|---|---|
| | n | (%) | n | (%) | n | (%) |
| At least 1 TEAE | 82 | (32.3) | 47 | (37.6) | 42 | (33.1) |
| At least 1 SAE | 6 | (2.4) | 4 | (3.2) | 4 | (3.1) |
| Serious infections | 0 | (0.0) | 2 | (1.6) | 0 | (0.0) |
| Active tuberculosis | 0 | (0.0) | 0 | (0.0) | 0 | (0.0) |
| Injection site reactions[a] | 0 | (0.0) | 0 | (0.0) | 2 | (1.6) |
| Malignancy[b] | 1 | (0.4) | 1 | (0.8) | 1 | (0.8) |
| Death | 0 | (0.0) | 0 | (0.0) | 0 | (0.0) |

SAE: serious adverse event; TEAE: treatment-emergent adverse event. [a]Defined as high level group terms of administration site reactions. [b]Small cell lung cancer, Glioblastoma multiforme, and Seminoma were reported in SB5/SB5, ADL/SB5 and ADL/ADL, respectively.

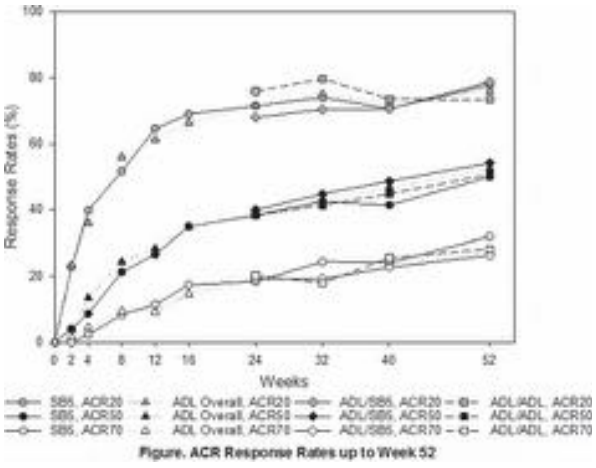

Figure. ACR Response Rates up to Week 52

**Conclusions:** During the transition period after Week 24 up to Week 52, the efficacy, safety, and immunogenicity profiles were comparable between SB5/SB5, ADL/SB5, and ADL/ADL. There were no treatment emergent issues or clinically relevant immunogenicity precipitated by switching.

## FRI0162 COMPARABLE SAFETY AND IMMUNOGENICITY AND SUSTAINED EFFICACY AFTER TRANSITION TO SB2 (AN INFLIXIMAB BIOSIMILAR) VS ONGOING INFLIXIMAB REFERENCE PRODUCT IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS OF PHASE III TRANSITION STUDY

J.S. Smolen[1], J.-Y. Choe[2], N. Prodanovic[3], J. Niebrzydowski[4], I. Staykov[5], E. Dokoupilova[6], A. Baranauskaite[7], R. Yatsyshyn[8], M. Mekic[9], W. Porawska[10], H. Ciferska[11], K. Jedrychowicz-Rosiak[12], A. Zielinska[13], J. Choi[14], Y.H. Rho[14]. *[1]Medical University of Vienna, Vienna, Austria; [2]Daegu Catholic University Medical Center, Daegu, Korea, Republic Of; [3]Clinical Center Banja Luka, Banja Luka, Bosnia and Herzegovina; [4]Medica Pro Familia Sp. z o.o. S.K.A, Warszawa, Poland; [14]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

**Background:** SB2 is developed as a biosimilar of the infliximab reference product (INF). The 30-week and 54-week results of Phase III study have been reported[1,2].
**Objectives:** To evaluate the safety, immunogenicity, and efficacy in patients with RA who transitioned from INF to SB2 vs maintained INF and who continued to receive SB2 after Week 54 up to Week 78.
**Methods:** This study is a randomised, double-blind phase III transition study. Patients with moderate to severe RA were randomised in a 1:1 ratio to receive either SB2 or INF at Weeks 0, 2, 6, and then every 8 weeks thereafter until week 46. At Week 54, patients previously receiving INF were re-randomised in a 1:1 ratio to either receive SB2 (INF/SB2) or continue INF (INF/INF) up to week 70; patients receiving SB2 continued to receive SB2 (SB2/SB2) up to Week 70. Safety, immunogenicity and efficacy were assessed up to week 78.
**Results:** At Week 54, 94 patients from INF were transitioned to SB2 (INF/SB2), 101 patients from INF continued to receive INF (INF/INF), and 201 patients from SB2 continued to receive SB2 (SB2/SB2). The safety profile during the transition period was comparable between INF/SB2, INF/INF, and SB2/SB2. The incidence of adverse events during the transition period was 36.2% in INF/SB2, 35.6% in INF/INF, and 40.3% in SB2/SB2. The incidence of infusion related reaction during the transition period was 3.2%, 2.0%, and 3.5%, respectively. Among the patients with overall negative anti-drug antibodies (ADA) results up to Week 54, ADAs were newly developed in 14.6% (6/41) in INF/SB2, 14.9% (7/47) in INF/INF, and 14.1% (11/78) in SB2/SB2. The efficacy was sustained and comparable between the treatment groups.

Table 1. Safety Profile During the Transition Period (From Week 54 to Week 78)

| Number of patients with | INF/SB2 (N=94) | | INF/INF (N=101) | | SB2/SB2 (N=201) | |
|---|---|---|---|---|---|---|
| | n | (%) | n | (%) | n | (%) |
| At least 1 treatment-emergent adverse event | 34 | (36.2) | 36 | (35.6) | 81 | (40.3) |
| At least 1 serious adverse event | 6 | (6.4) | 3 | (3.0) | 7 | (3.5) |
| Serious infections | 2 | (2.1) | 1 | (1.0) | 1 | (0.5) |
| Active tuberculosis | 0 | (0.0) | 0 | (0.0) | 0 | (0.0) |
| Infusion-related reaction | 3 | (3.2) | 2 | (2.0) | 7 | (3.5) |
| Malignancy | 0 | (0.0) | 0 | (0.0) | 0 | (0.0) |
| Death | 0 | (0.0) | 0 | (0.0) | 0 | (0.0) |
| Overall ADA positive | 43 | (45.7) | 51 | (50.5) | 104 | (53.6)[a] |
| Newly ADA positive[b] | 6 | | 7 | | 11 | |

[a]Percentage is based on 194 patients with available ADA results. [b]Newly developed ADA in patients with negative overall ADA up to Week 54.

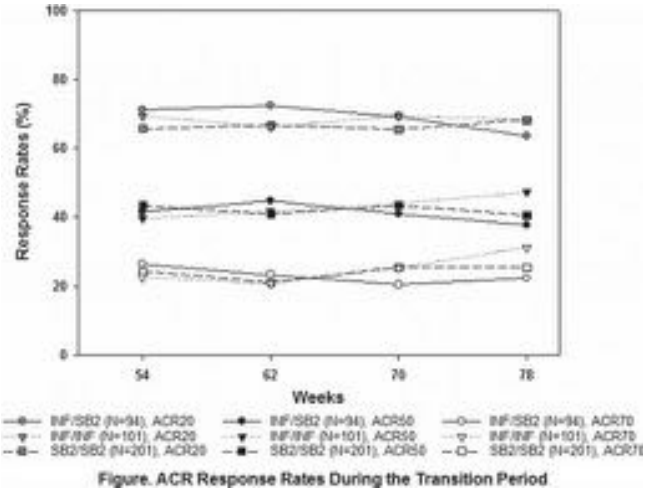

Figure. ACR Response Rates During the Transition Period

**Conclusions:** The safety, immunogenicity, and efficacy profiles remained comparable between the INF/SB2, INF/INF, and SB2/SB2 up to Week 78, revealing that there were no treatment emergent issues or clinically relevant immunogenicity after switching from INF to SB2.

## FRI0163 EFFICACY OF THE BIOSIMILAR BOW015, COMPARED TO ORIGINATOR INFLIXIMAB, INITIATED AT MODERATE AND SEVERE DISEASE ACTIVITY THRESHOLDS IN RHEUMATOID ARTHRITIS

P. Taylor[1], M. Wyand[2], A. Knight[3], C. Costantino[2], C. Lassen[4]. *[1]Kennedy Institute of Rheumatology, University of Oxford, Oxford, United Kingdom; [2]Clinical Research, Epirus Biopharmaceuticals Inc., Boston, United States; [3]Data Management and Statistics, Evicom, Twickenham, United Kingdom; [4]Clinical Research, Epirus Biopharmaceuticals Inc., Zug, Switzerland*

**Background:** In 2010 the British Society of Rheumatology guidelines[1] adjusted the recommended threshold for biologic therapy in rheumatoid arthritis (RA) to a DAS28 score of >3.2, from a DAS28 score of >5.1. However, adoption of this recommendation for the use of TNF-inhibitors such as infliximab in RA patients with moderate disease activity despite methotrexate may be limited, especially in regions that wish to minimise biologic usage due to cost.
**Objectives:** To examine the effectiveness of Remicade (rIFX) in RA patient subgroups with severe or moderate disease activity, and to compare the efficacy of this treatment to BOW015, an infliximab biosimilar.
**Methods:** Sub-groups of RA patients on a stable dose of methotrexate which included a EULAR diagnostic criteria ≥6 and a CRP≥10 mg/L were identified from within the cohort of a randomised double-blind, group comparison of BOW015 compared to rIFX (2:1) treated with 3 mg/kg IV at Week 0, 2, 6, 14, 22, 30, 38, and 46. Subject responses to treatment (ACR20, 50 and 70) were followed up until the end of the blinded phase (Week 16) and also following the switch to a BOW015 in an open-label phase (until Week 54). Severe and moderate patient sub-groups were determined by DAS28 (>5.1, ≤5.1 - >3.2) and CRP (≤10, >10 - ≤20, and >20mg/L) status at Week 0 pre-treatment. Analysis of the difference in the proportions of subjects achieving ACR20, 50 and 70 between subgroups and within treatments were performed by Fisher's exact test and 95% confidence intervals by exact method for the difference in proportions.
**Results:** 189 subjects entered the study, 127 were dosed with BOW015 and 62 with rIFX. At the end of the double-blind period, patients were transitioned to open label BOW015 (104 continued BOW015 and 53 switched to BOW015). ACR20 responses by both high and low-activity DAS28 subgroups were comparable (Figure 1). There was no significant difference in proportions of ACR20 response to BOW015 or rIFX during the double-blind period and in the open-label period for those continuing on BOW015. Comparisons of ACR20 response by CRP sub-group were not significantly different during the double-blind or open-label period between CRP categories for each treatment or previous treatment.

**Conclusions:** The proportion of ACR20 responders to BOW0I5 is comparable across subgroups of RA with severe or moderate disease activity, as assessed by DAS28 and CRP. The increased financial burden of widening access of biologics to patients with moderate disease activity could be offset by use of less expensive biosimilars.

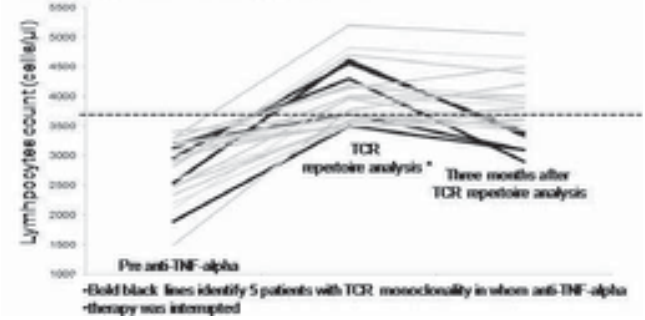
## FRI0164 T CELLS EXPANSION IN RHEUMATOID AND PSORIATIC ARTHRITIS PATIENTS UNDER ANTI-TNF-ALPHA AGENTS

A. Picchianti-Diamanti[1], M.M. Rosado[2], E. Pilozzi[3], M. Markovic[1], R. D'Amelio[1], B. Laganà[1]. *[1]Clinical and Molecular Medicine, "Sapienza" University, School of Medicine and Psychology, S. Andrea University Hospital, Rome, Italy; [2]Immunology Unit, Ospedale Pediatrico Bambino Gesù, IRCSS; [3]Pathological Anatomy, "Sapienza" University, School of Medicine and Psychology, S. Andrea University Hospital, Rome, Italy, Rome, Italy*



**Background:** An increased risk for lymphoproliferative disorders, specially Hodgkin's and non- Hodgkin's lymphoma has been reported in Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) patients.Several factors such as the genetic background, the persistent stimulation of T and B cells by unknown antigens and immunosuppressive therapies can be involved in increasing the risk of malignancies in these patients. A role for anti- TNF-α therapy is still controversial

**Objectives:** To analyse the induction of lymphocytosis in RA and PsA patients under anti-TNF-α therapy and explore its possible malignant evolution

**Methods:** RA and PsA patients under anti-TNF-alpha therapy that presented a de novo lymphocytosis (circulating lymphocytes >3400 cells/μl for at least 3 months) were evaluated for lymphocyte subpopulations: total T cells (CD3+), T helper (CD3+CD4+CD45+), T suppressor (CD3+CD8+CD45+), natural killer (CD16+CD56+CD45+) and B cells (CD19+CD45+). Molecular analysis of the T Cell Receptor (TCR) was also performed as follow: total DNA was extracted from PB using Qiagen DNA Kit Extraction; molecular evaluation of TCRγ gene rearrangements was performed using a multiplex PCR with fluorescent labelled oligonucleotides; PCR reactions for TCRγ gene were carried out using "TCRγ rearrangements molecular analysis kit" and amplifications products analyzed on a 3130 Genetic Analyzer. The lengths of the Vγ1–8/Jγ1·3/2·3 and Vγ1–8/Jγ1·1/2·1 PCR products were 145–230 base pairs (bp) and 230–255bp, respectively. Samples were scored as monoclonal if one unequivocal peak in the expected range was observed

**Results:** 25/208 patients (12%) (15 RA and 10 PsA) showed a de novo appearance of a mild persistent lymphocytosis (from 2800 to 4000 mean cells/ul; p<0.001). 11 patients were treated with Etn, 7 with Ada, 4 with Ifx and 3 patients with GoI. The analysis of PBL subsets revealed that B and NK cells were not the cause for the lymphocytosis because the distribution of these populations was at the lowest limit of the normal range (9.6% and 10% respectively). In contrast, we observed a mild increase in the mean percentage of CD3+CD4+ cells (51%). TCRγ gene rearrangement showed a polyclonal distribution in 11 patients (44%), oligoclonal in 9 patients (36%), whereas in 5 patients (20%) we observed the predominance of a monoclonal peak. Lymphnodes ultrasonography did not reveal any sign of malignant proliferation. Despite of this result in the absence of clear guidelines we decided to interrupt the biological therapy in these 5 patients to reduce the risk of developing malignancy. Three months after biological suspension a significant decrease in the total lymphocyte count was observed (mean value from 4134 to 3168cells/μl; P<0.008), whereas TCRγ repertoire maintained its monoclonality

**Figure 1**
Total lymphocyte count (cells/μl) in 25 patients with lymphocytosis before anti-TNF-alpha therapy, at the moment of TCR repertoire analysis and three months after. Dashed line indicates the upper limit of normal lymphocyte count

**Conclusions:** We observed in both RA and PsA a de novo appearance of lymphocytosis in a relevant percentage of patients within which five showed the emergence of a single TCR clone. Strict follow-up of the RA and PsA disease activity and of TCR diversity evolution will allow the early detection of lymphoma or the re-establishment of TCR diversity thus permitting the application of a more targeted therapy

## FRI0165 EFFECTIVENESS AND SAFETY OF BIOSIMILAR INFLIXIMAB (CT-P13) IN A REAL-LIFE SETTING IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

C. Codreanu[1], K. Šírová[2], K. Jarošová[3], A. Batalov[4]. *[1]Rheumatology, Clinical Center of Rheumatic Diseases, Bucharest, Bucharest, Romania; [2]Rheumatology, Revmatologie MUDr. Klara Sirova, s.r.o., Ostrava; [3]Rheumatology, Institute of Rheumatology, Praha, Praha, Czech Republic; [4]Rheumatology, Medical University of Plovdiv, MHAT "Kaspela", Plovdiv, Bulgaria*

**Background:** Over the past decade, the introduction of biologics has significantly changed the management of rheumatoid arthritis (RA) and ankylosing spondylitis (AS). However, the high cost of biologics imposes limits on their use, particularly in developing countries. The development and commercialization of biosimilars can help address unmet medical needs by improving access to well-established therapeutic interventions while improving healthcare affordability. Biosimilar infliximab (CT-P13) was the first monoclonal antibody biosimilar approved in the EU.

**Objectives:** To demonstrate the safety and effectiveness of CT-P13 when administered in a real-life setting in adults with active RA or AS.

**Methods:** This multicenter, non-interventional, observational study was conducted in Romania, Czech Republic, Poland, Bulgaria and Latvia in patients with active RA with an inadequate response to methotrexate (MTX) or other DMARDs, or active AS with inadequate response to NSAIDs. Patients received CT-P13 at baseline (visit 1), weeks 2 (visit 2), 6 (visit 3), and between weeks 12 and 14 (visit 4: month 3). Dosages were established according to CT-P13 SPC. Safety was assessed by early dropouts and adverse events (AEs). Effectiveness was assessed at baseline and visit 4 (month 3) using the Disease Activity Score (DAS28) for RA patients and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for AS patients.

**Results:** By January 1st 2016, 122 subjects (49% male, mean [SD] age 48.2 [14.6] years) have been enrolled in the study, with a median follow-up of 165 days. At visit 4 (month 3), mean (SD) CT-P13 doses were 246 (52) mg/3.3 (0.6) mg/kg for RA, and 372 (82) mg/5.1 (0.5) mg/kg for AS. A total of 20 AEs were recorded: 4 definitely related, 3 possibly related, and 13 unrelated to CT-P13 treatment. Among these AEs, 2 were serious (a spontaneous pneumothorax, unrelated to CT-P13, and a dyspnea due to allergic infusion reaction, definitely related to CT-P13; both resolved without sequelae) and a total of 4 dropouts were reported due to AEs (3 definitely-related allergic infusion reactions and 1 possibly related). Currently, 59 patients (RA: 26; AS: 33) have baseline and follow-up primary effectiveness measurements at month 3. Patients who terminated the study prematurely were excluded from effectiveness analyses. After 3 months of CT-P13 treatment, patients showed significant improvements in disease activity relative to baseline in terms of DAS28 (baseline: mean [SD]=6.7 [1.1], month 3: mean [SD]=2.7 [1.4]; t=8.1, df=25, p<0.0001, Cohen's d=2.5) and BASDAI (baseline: mean [SD]=6.5 [1.7], month 3: mean [SD]=2.8 [2.1]; t=10.5, df=32, p<0.0001, Cohen's d=2.0). Patients with RA (baseline: mean [SD]=23 [16.3], month 3: mean [SD]=9.3 [19.8]; t=2.5, df=25, p=0.02, Cohen's d=0.9) or AS (baseline: mean [SD]=26.7 [26.3], month 3: mean [SD]=5.5 [8.6]; t=5, df=38, p<0.0001, Cohen's d=1.2) also showed a significant decrease in C-reactive protein (CRP) levels after 3 months of treatment.

**Conclusions:** Biosimilar infliximab (CT-P13) is safe and effective in a real-life setting in patients with RA or AS.

**Disclosure of Interest:** None declared

## FRI0166 PERSISTENCE OF BIOLOGIC THERAPY FOR PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: DATA FROM THE ROMANIAN REGISTRY OF RHEUMATIC DISEASES

C. Codreanu[1], C. Mogosan[1], M. Parvu[2], S. Rednic[3], R. Ionescu[4]. *[1]Rheumatology, Clinical Center of Rheumatic Diseases, Bucharest; [2]Rheumatology, Colentina Hospital, Bucharest; [3]Rheumatology, County Hospital, Cluj Napoca; [4]Rheumatology, Sfanta Maria Hospital, Bucharest, Romania*

**Background:** Data on the efficacy and safety of biological therapies for Rheumatoid Arthritis (RA) that come from Patient Registries present the results of clinical practice all over the world. In terms of efficacy, treatment persistence

in RA is largely related to reaching the therapeutic target, i.e. remission or low disease activity.
**Objectives:** To measure drug persistence with tumor necrosis factor alpha (TNF) antagonists and anti CD20 monoclonal antibody, among RA patients in Romania, as well as identify/determine additional factors that could influence it.
**Methods:** Population-based cohort study carried out with RA patients in Romania. Data was gathered from the Romanian Registry of Rheumatic Diseases. The study cohort included RA patients who initiated the first course of a TNF antagonist or anti CD20 monoclonal antibody, anytime between 2004 and 2015. Persistence was measured as the time period during which the drug had been administered to a patient. Drug discontinuation was defined as drug treatment being interrupted due to adverse events, primary or secondary non-responder, or switching to another molecule. The influence of any other factors on persistence used T test and persistence was estimated using survival analysis.
**Results:** The study cohort included 4,395 RA patients, mean age 59.55 yrs, 85.3% women, mean RA duration 14.37 yrs, treated with etanercept (29.7%), adalimumab (23.5%), infliximab (original 7.1%, biosimilars 0.7%), rituximab (38.9%); 23.1% used steroids (19.8% with <7.5mg dayli); mean current DAS28 score 3.08 (±1.20) and mean SDAI 3.62 ((±7.39). The persistence estimated in weeks (95% confidence interval) with infliximab was 330.8 (303.8–357.8), with rituximab it was 301.0 (262.2–339.8), with etanercept it was 240.6 (232.7–248.4) and with adalimumab it was 200.4 (191.0–209.9). There was a poor positive correlation between general persistence and RA duration (r=0.2, $p<0.001$) and a negative association with DAS28 (r= - 0.3, $p<0.001$). The use of methotrexate resulted in longer persistence (170.5±139.8) compared to other csDMARDs (152.0±120.2), $p<0.001$. Using steroids in dosages less than 7.5mg/day resulted in a significantly longer persistence compared to larger doses (131.2±121.3 vs 100.1±110.7), $p<0.005$. Patients being in remission or LDA maintained the biologics significantly longer than those with MDA or HAD (190.9±139.0 vs 121.1±107.8), $p<0.001$. All other factors that were analysed (age, sex, residency, education, work status, disease characteristics) had no significant effect on drug persistence. Adverse events, primary non-responders, and secondary non-responders were comparable among these molecules.
**Conclusions:** Longer persistence was observed with infliximab, followed by rituximab, etanercept, and adalimumab in RA patients in Romania, for more than 10 years of biologics use. Reaching the state of remission or LDA, as well as low steroids regimens and long-standing disease seem to positively correlate with drug persistence.

## FRI0167 LOW LEVELS OF INFLIXIMAB AT EARLY STAGES PREDICT THE LOSS OF DRUG LEVELS AND THE CLINICAL RESPONSE AT ONE YEAR OF TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Jurado[1], C. Plasencia[2], A. Martínez-Feito[1], V. Navarro-Compán[2], E. Olariaga[1], C. Diego[1], E. Martin-Mola[2], A. Balsa[2], D. Pascual-Salcedo[1]. *[1]Department of Immunology; [2]Department of Rheumatology, Hospital Universitario de La Paz, Madrid, Spain*

**Background:** The anti-TNF monoclonal antibody Infliximab (Ifx), has proven effective in treating rheumatoid arthritis (RA), although in 40% of cases may fail, mainly due to immunogenicity. A good clinical response is usually associated with high serum drug levels; however, it is not clear why some patients have a faster drug clearance since the beginning of the therapy. Formation of immunocomplexes between antibodies to Ifx (ATI) and Ifx can increase drug clearance, leading to treatment failure.
**Objectives:** To analyze whether serum Infliximab trough levels (ITL) at the induction phase were related to Ifx disappearance and clinical outcomes at week (w) 54. The early development of immunogenicity as a related factor with low ITL was also investigated.
**Methods:** In this observational retrospective study ITL were measured from 66 RA patients from the prospective biological cohort of La Paz Hospital. Serum samples were taken at w2, w6, w14 and w22. Serum-dependent receiver operating characteristics (ROC) curves were used to establish the ITL value that better predicts the absence of Ifx at w54. ATI were measured by bridging ELISA and by an acid-dissociation method without drug interference IDK (Immundiagnostik®, Germany). Patients were grouped as ITLpos if they had detectable Ifx at w54 and ITLneg otherwise.
**Results:** ITLneg patients (n=25) had significantly lower levels at all time points than ITLpos (n=41). Based on ROC values ITL at w6 (4.44 μg/ml) had the best predictive value for disappearence of Ifx at w54 with a 70% sensitivity (95%CI 45.7–88.1), 95% specificity (95%CI 83.1–99.4) and positive likehood ratio of 14. Most patients in low disease activity or remission at w54 had at w6 ITL upper the predictive cut-off [20/44 (45%) upper cut-off vs 3/20 (15%) under cut-off p=0.02] and most EULAR responder at w54 had ITL upper the predictive cut-off at w6 [33/43 (77%) vs 10/21 (48%); p=0.08]. Treatment survival of patients with ITL upper 6w cut-off was longer: 5 years (1.6–5.0) vs 1.7 years (0.2–0.6); p=0.012.
In the multiple logistic regression analysis, after adjusting for confounders (age, sex, body mass index, baseline DAS28, PCR, TNF and IL6) with ITL at w2 and at w6, the absence of Ifx levels at w54 was significantly associated with ITL under the cut-off at w2 (OR: 15.85; 95%IC 2.95–85.03; p=0.01), at w6 (OR: 86.64; 95%IC 6.58–1139.99; p=0.001) and no MTX use (OR: 12.26; 95%IC 1.83–82.22; p=0.001 for w2; OR: 6.9; 95%IC 1.04–45.84; p=0.04 for w6)
Most patients with ITL under the cut-off at w6 were positive for ATI along the first year [15/20 (75%) under cut-off vs 5/44 (11%) upper cut-off, $p<0.0001$]. Most ATI were detected earlier by the IDK than with bridging.
**Conclusions:** Low ITL at early stages (w2 and w6) are associated with the Ifx absence, the early drop-out of the treatment and the clinical outcome at w54, being the presence of ATI the main reason for the low early circulating drug levels. We also conclude that the cut-off value at w6 (4.44 μg/ml) provides the clinicians with a useful prognostic tool of treatment efficacy.

## FRI0168 EFFECT OF METHOTREXATE IN THE PRESENCE OF DRUG AND THE APPEARANCE OF ANTIBODIES AGAINST TNF INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Martínez-Feito[1], C. Plasencia[2], A. Villalba[2], T. Jurado[1], A. Mezcua[1], E. Martín-Mola[2], G. Bonilla[2], A. Balsa[2], D. Pascual-Salcedo[1]. *[1]Department of Immunology; [2]Department of Rheumatology, Hospital Universitario de La Paz, Madrid, Spain*

**Background:** Several factors influence pharmacokinetics of TNFinhibitors (TNFi). One relevant factor is the formation of anti drug- antibodies (ADA) associated with low drug levels and a worse clinical response. Recent publications in rheumatoid arthritis (RA) [1,2] have demonstrated a beneficial effect of concomitant use of anti-TNF drugs and methotrexate (MTX), with a dose-dependent effect.
**Objectives:** To analyze the MTX influence on the presence of drug and appearance of ADA in a cohort of RA patients treated with Infliximab (Ifx), Adalimumab (Ada) or Etanercept (Etn) with a long follow-up (3 years).
**Methods:** This is a retrospective study that analyzed patients with RA treated with Ifx (112 patients), Ada (71 patients) and Etn (110 patients), in a prospective observational biological cohort from the University Hospital La Paz, Madrid, Spain. Patients were grouped according to the use of MTX: no MTX, low dose (≤12.5 mg/week), intermediate dose (12.5–20 mg/week) and high dose (≥20 mg/week). Levels of drug and ADA were measured by capture and bridging ELISA respectively at baseline, 0.5, 1, 2 and 3 years. All samples were obtained just before drug administration. Statistical analysis was performed using GraphPad Prism 5.0 software.
**Results:** Out of 293 RA patients with a TNFi treatment; 184 (71 with Ifx, 40 with Ada and 73 with Etn) were included. In this cohort, 111 (61%) were on MTX and 72 (39%) were on monotherapy. Most patients with high dose of MTX had levels of drug over 3 years of treatment (93% with MTX ≥20 mg/week vs 77% without MTX; p=0.01) being significant since 0.5 years (≥60% with MTX 20 mg/week vs 39% without MTX; p=0.02)
To analyze the ADA development, patients treated with Ifx and Ada were grouped and we observed a trend to a higher percentage of ADA in the group which did not receive MTX (n=37) compared to those who received high-dose MTX (n=27) although not statistically significant (32% vs 19%, p=0.21). Analysing by separate drugs MTX significantly reduced the immunogenicity of Ada, (53% in patients with MTX vs 15% in monotherapy; p=0.02).
When we study the lack of circulating drug (Ifx, Ada and Etn) as an indicator of immunogenicity, patients who did not receive MTX (n=56) had higher absence of drug than patients with high-dose MTX (n=61) (34% vs 10%, respectively; $p<0.01$). This effect was significant since 0.5 years of treatment (16% MTX ≥20 mg/week vs 3% without MTX; p=0.017)
**Conclusions:** In our cohort of RA patients the concomitant use of MTX has a positive effect in the persistence of TNFi levels together with a decrease of immunogenicity. Furthermore, the MTX has a dose-dependent effect being greater at high dose of MTX.

## FRI0169 INFLUENCE OF BODY MASS INDEX (BMI) ON SERUM LEVELS OF INFLIXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

A. Villalba Yllan[1], M.V. Navarro Compan[1], C. Plasencia Rodriguez[1], D. Peiteado Lopez[1], G. Bonilla Hernan[1], L. Nuño Nuño[1], D. Pascual-Salcedo[2], E. Olariaga[2], A. Balsa Criado[1], E. Martin Mola[1]. *[1]Rheumatology Dept; [2]Immunology Dept., Hospital Universitario La Paz, Madrid, Spain*

**Background:** Loss of response of TNFα inhibitors (TNFi) over time resulting in discontinuing of this therapy is a major issue in RA, but underlying reasons for this remains unknown. A few studies suggest the influence of BMI on serum levels of subcutaneous TNFi. However, there is no available data on the possible influence

of BMI on infliximab (IFX) serum levels, which is intravenously administred and adjusteing the dose according to patient weight.
**Objectives:** To determine the possible influence of BMI on serum IFX levels in patients with RA.
**Methods:** Retrospective observational study incluiding 72 patients with RA treated with infliximab, at 3 mg/kg dose in a standard regimen, in our department between 2000 and 2015. Serum IFX levels were determined by ELISA in 3 visits: i)2 weeks, ii)six months and iii)one year after treatment onset. BMI (kg/m$^2$) was classified in four categories: underweight ($<$18,5), normal ($\geq$18,5- $<$25), overweight ($\geq$25-$<$30) and obesity ($\geq$30). Descriptive analysis was used to compare drug levels between these four groups at each visit. To analyse the relationship between BMI and IFX drug levels, generalized estimation equation models adjusted for age, gender and concomitant treatment were employed.
**Results:** Characteristics of patients included in the study when initiating IFX therapy were: 88% female, median (range) age 52 (21–82) years, 71% RF+, 79% ACPA+, disease duration 10,4 (1,0–39,0) years, 79% with concomitant methotrexate and 57% with other DMARDs. Median (range) BMI was 25,5 (16,7–40,2) kg/m$^2$. According to BMI, patients with underweight, normal, overweight and obesity were 2 (2,7%), 35 (48,6%), 23 (31,9%) and 12 (16,7%), respectively. Median (range) IFX serum levels, in ng/ml, for each of the four BMI categories,and for each of the visits, are presented in Table 1.

| | At 2 weeks | At 6 months | At 1 year |
|---|---|---|---|
| Underweight | 34.977 (20.992–48.962) | 7.500 (0–15.000) | NA |
| Normal | 24.576 (2.944–150.000) | 776 (0–12.800) | 2.012 (0–14.336) |
| Overweight | 26.213 (768–50.000) | 661 (0–3.456) | 486 (0–9.416) |
| Obesity | 22.033 (9.891–34.816) | 315 (0–5.344) | 1.088 (0–3.904) |

In the longitudinal analysis, an inverse statistically significant relationship between BMI and drug serum levels was observed: $\beta$: -441,7; 95%CI (-829,7 to -53,8). This relationship remained despite of adjusting the model for potential confounders: $\beta$: -457,3; 95%CI (-858,8 to -55,8).
**Conclusions:** BMI influences serum IFX levels in patients with RA treated with infliximab. Higher BMI values are associated with lower serum drug levels.

## FRI0170 TREATMENT WITH BIOLOGICAL AND NON-BIOLOGICAL DMARDS IS A MODIFIER CONDITION OF PERIODONTAL DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Giraldo Q[1,2], C. Romero-Sanchez[1,2,3,4], C. Rodriguez[3], P. Santos Moreno[5], A.M. Mesa[1], G.I. Lafaurie[3], J. De Avila[3], D.M. Castillo[3], P. Chalem[6], J.M. Bello-Gualtero[1,2], R. Valle-Oñate[1,2,4]. *[1]Department of Rheumatology and Inmunology, Hospital Militar Central; [2]School of Medicine, Universidad Militar Nueva Granada; [3]Unit of Oral Basic Investigation, Universidad El Bosque; [4]Sponyloarthropaty Group, Rheumatology Department, Hospital Militar Central/Universidad de la Sabana; [5]Center for Rheumatoid Arthritis, Biomab; [6]Foundation Institute of Rheumatology, Fernando Chalem, Bogotá, Colombia*

**Background:** Periodontitis and rheumatoid arthritis (RA) are two chronic destructive inflammatory diseases with significant worldwide prevalence. Periodontal disease and RA are characterized by the destruction of articular and periodontal tissue, and they share several biological and pathological features.
**Objectives:** Evaluate the effects of conventional drug treatment and anti-TNF therapy in patients with RA on periodontal condition and subgingival microbiota, establishing the association of markers of periodontal infection with indexes of rheumatic activity.
**Methods:** A cross-sectional study was conducted in two groups of RA patients with more than two years of diagnosis. The first group used conventional therapy, and the second group used anti-TNF treatment. An association analysis was performed to observe the relationship between clinical and microbiological markers of periodontal infection, and RA activity. A comparative analysis was performed to assess clinical and microbiological periodontal markers and RA activity.
The data were released to STATA v11. Frequencies of nominal variables and means and standard deviations for continuous variables were calculated for sociodemographic, periodontal and rheumatological data. Associations between periodontal status and rheumatological variables by Chi square/Fisher's exact test and Mann-Whitney U tests. The results were considered statistically significant at p$\leq$0.05. The ethics committee of institution approved the study.
**Results:** An overall high frequency of periodontal disease 91%, in most cases from moderate to severe, was observed in all subjects. The frequency of periodontal disease was 93.22% in the anti-TNF-alpha group and 88.7% in the conventional treatment group. The percentage of sites with clinical attachment loss $\geq$4 mm was significantly associated with the group receiving methotrexate and leflunomide p=0.05. Steroid therapy was associated with the presence of teeth p=0.027. Significant associations were observed with the use of more than one DMARD and the presence of P. gingivalis p=0.004. *T. denticola* was found in the anti-TNF-$\alpha$ therapy group compared to the conventional therapy group p=0.001.
**Conclusions:** Different pharmacological treatments for RA affect the clinical condition and sub-gingival microbiota. Patients treated with more than one DMARD promote the increase subgingival microbiota. Therefore, a more strict periodontal monitoring is necessary in these RA patients

## FRI0171 EVALUATING TREATMENT EFFICACY IN RHEUMATOID ARTHRITIS: INTERRELATION DISEASE ACTIVITY – FUNCTIONAL STATUS – UTILITY

C. Mogosan[1], C. Codreanu[1], L. Enache[1], M. Parvu[2], S. Rednic[3], R. Ionescu[4]. *[1]Rheumatology, Clinical Center of Rheumatic Diseases; [2]Rheumatology, Colentina Hospital, Bucharest; [3]Rheumatology, County Hospital, Cluj Napoca; [4]Rheumatology, Sfanta Maria Hospital, Bucharest, Romania*

**Background:** Rheumatoid Arthritis (RA) treatment targets remission or low disease activity. Patient Registries offer real-world data about effectiveness on long term. Comparing different tools for assessing effectiveness (disease activity, functional status and utility) could provide a more comprehensive approach on the term "achieve and maintain" the therapeutic goal, as a measure of efficacy.
**Objectives:** To evaluate interrelations of disease activity – functional status – utility in a group of RA patients, treated with tumor necrosis factor alpha (TNF) antagonists and anti CD20 molecule, as well as any factor that could influence it.
**Methods:** Cross-sectional study carried out over a cohort of RA patients in Romania. Data was gathered from the Romanian Registry of Rheumatic Diseases and included only RA patients treated with biologics, for who were available all three variables under study: EQ5D (for utility), HAQ score (for functional status), and DAS28 and SDAI (for disease activity). The interrelations of the efficacy parameters were analyzed using correlation tests, T test, ANOVA.
**Results:** The study cohort included 777 RA patients, mean age 58.72 (±12.37) yrs, 84.4% women, mean RA duration 14.08 (±8.33) yrs, 77.1% retired, treated with etanercept (30.6%), adalimumab (22.7%), infliximab (original 6.3%, biosimilars 0.7%), rituximab (26.3%) with a mean treatment duration 174.90 (±143.40) weeks; 27.3% used steroids (20.2% with $<$7.5mg daily); mean current DAS28 score = 3.66 (±1.52), mean delta DAS28 = 0.13 (±1.28), mean SDAI = 14.27 (±13.79), mean HAQ score = 1.14 (±0.64), mean EQ5D = 0.61±0.31. There was a strong positive correlation between HAQ score and DAS28, as well as SDAI: r=0.5 (p$<$0.001) and a negative association between HAQ and EQ5D: r= -0.6 (p$<$0.001). Utility score showed a strong negative association with DAS28 and with SDAI: r= -0.7 (p$<$0.001), whereas disease activity dynamics (delta DAS28 for the last 6 months) had a poor negative association with EQ5D: r= -0.2 (p$<$0.01), but not with HAQ. Patient global assessment (PGA) on disease activity had a significant association both with HAQ (r=0.6, p$<$0.001) and EQ5D (r= -0.6, p$<$0.01). Analyzing distribution of EQ5D and HAQ in DAS28 categories, there was a significant difference between categories (p$<$0.001); for EQ5D-DAS28: $<$2.6 = 0.81 (±0.19), 2.6–3.2 = 0.68 (±0.17), 3.2–5.1 = 0.63 (±0.18), $>$5.1 = 0.16 (±.38); for HAQ-DAS28: $<$2.6 = 0.73 (±0.57), 2.6–3.2 = 0.98 (±0.5), 3.2–5.1 = 1.25 (±0.52), $>$5.1 = 1.76 (±0.56). Steroids use belongs to more active disease; doses $>$7.5 mg/day represent a cutoff for patients with severe disease activity [HDA]. Disease duration had not any influence on EQ5D, HAQ or DAS28, as well as all other factors (age, sex, residency, education, work status).
**Conclusions:** Disease activity influences the patient well-being and functionality. Considering the dynamics of disease activity over time and the fluctuating values of utility and HAQ score within DAS28 categories, analyzing treatment efficacy from a combined perspective may be helpful in evaluating the time trends on achieving and maintaining the therapeutic goals.

## FRI0172 PRIMARY AND SECONDARY NON-RESPONSE IN RA PATIENTS TREATED WITH AN ANTI-TNF: AN ANALYSIS FROM A PROSPECTIVE, OBSERVATIONAL REGISTRY

E. Keystone[1], P. Baer[2], W. Olszynski[3], M. Baker[4], B. Haraoui[5], W. Bensen[6], R. Faraawi[7], E. Rampakakis[8], J. Sampalis[8], A. Lehman[9], F. Nantel[9], B. Osborne[9], C. Tkaczyk[9], K. Maslova[9]. *[1]Mount Sinai Hospital; [2]Private Practice, Toronto; [3]Rheumatology Associates, Saskatoon; [4]University of Victoria, Victoria; [5]Université de Montréal, Montreal; [6]McMaster University, Hamilton; [7]McMaster University, Kitchener; [8]JSS Medical Research, Montreal; [9]Janssen Inc., Toronto, Canada*

**Background:** Despite the well documented effectiveness of anti-TNF treatment in rheumatoid arthritis (RA), some patients can be refractory to treatment (primary [1ry] failure) or may lose responsiveness (secondary [2ry] failure). In such cases, switching to another anti-TNF or a different biologic class can often restore therapeutic response.

**Objectives:** The aim of this analysis was to assess the rate of non-response among RA patients treated with anti-TNFs in Canadian routine clinical practice.
**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for RA, ankylosing spondylitis, or psoriatic arthritis with infliximab (IFX) or golimumab (GLM). RA patients treated with IFX since 2002 or with GLM since 2010 who had at least one post-baseline assessment were eligible. Patients with available information on DAS28 or EULAR response in at least one post-baseline visit were included in the respective analyses.
**Results:** 1,127 patients (75.6% female) were included with mean (SD) age of 56.1 (13.4) years and disease duration of 8.4 (8.9) years at baseline. The majority were biologic naïve (93.2%), treated with IFX (76.0%), and received a concomitant DMARD (86.2%) at baseline. Mean (SD) disease parameters at baseline were: CDAI: 33.9 (17.6); HAQ: 1.6 (0.7); SJC: 9.8 (6.8); TJC: 11.5 (8.0).
After a mean (SD) follow-up of 35.5 (36.8) mos, 764 (67.8%) patients were discontinued overall and 226 (20.1%) due to effectiveness reasons (lack of response: n=67; loss of response: n=83; disease progression: n=76). Among the patients discontinued due to effectiveness reasons, the majority were discontinued after 12 months (54.4%) and had achieved prior good EULAR response (66.2%). Among patients discontinued due to lack of response, 17.7% and 45.5% had previously achieved DAS28 low disease activity (LDA) and good EULAR response, respectively; whereas, among patients discontinued due to loss of response, 46.9% and 76.8% had a previously documented achievement of the two targets, respectively.
**Conclusions:** The results of this analysis have shown a low rate of failure during treatment with IFX and GLM. Non achievement of DAS28 LDA was a good predictor of lack of response and more predictive than good EULAR response; non-achievement of good EULAR response, on the other hand, was a better predictor of loss of response. Overall, significant variation exists depending on each investigator's definition of 1ry and 2ry failure, which highlights the importance of establishing standardized definitions of these terms.

## FRI0173 ROLE OF METHOTREXATE AS COMBINATION THERAPY WITH ADALIMUMAB AND ETANERCEPT IN RHEUMATOID ARTHRITIS: RETROSPECTIVE ANALYSIS FROM A LOCAL REGISTRY

E.G. Favalli[1], A. Becciolini[1], M. Biggioggero[2], C. Crotti[2], N. Ughi[2], A.E. Penatti[2], A. Marchesoni[1], P.L. Meroni[3]. *[1]Department of Rheumatology, Gaetano Pini Institute; [2]Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milan and Gaetano Pini Institute; [3]Department of Clinical Sciences and Community Health, University of Milan and IRCCS Istituto Auxologico Italiano, Milano, Italy*

**Background:** The role of methotrexate (MTX) in association with TNF inhibitors (TNFi) for the treatment of rheumatoid arthritis (RA) is well defined, although the optimal MTX dose is still unclear.
Recently the CONCERTO randomized controlled trial demonstrated efficacy and safety of ascending MTX doses in combination with adalimumab (ADA) for the treatment of MTX-naïve RA [1], but observational data from real-life registries are still lacking.
**Objectives:** The aim of our study is to retrospectively evaluate the effect of different MTX regimen as combination therapy with 1st line ADA and etanercept (ETN) on 6- and 12-month clinical response and safety profile in RA patients.
**Methods:** We selected all RA patients treated with ADA or ETN as 1st line biotherapy in our Rheumatology Department from January 2000 to October 2015. The analysis was performed only on subjects with at least 1-year follow-up and the study population was stratified according to concomitant MTX regimen in 3 subgroups: TNFi as monotherapy (group 1), TNFi in association with low MTX dose ($\leq$10 mg/week, group 2), and TNFi combined with high MTX dose ($\geq$12.5 mg/week, group 3). Six- and 12-month clinical response was evaluated as mean change from baseline of disease activity score 28 (DAS28) and as DAS28 remission/low disease activity (LDA) rates, comparing the 3 subgroups by Kruskal-Wallis and Dunn tests.
**Results:** The study population included 322 RA patients (265 [82.3%] female, mean age [± standard deviation] 55.4 [±12.8] years, disease duration 11.4 [±9.4] years, positive rheumatoid factor 248 [77%], mean baseline DAS28 5.39 [±1.18]) treated with ADA (n=166) or ETN (n=156). According to concomitant MTX regimen, 108 patients were assigned to subgroup 1, 110 to subgroup 2, and 104 to subgroup 3. No significant differences were found in baseline characteristics among the 3 subgroups. The mean change from baseline of DAS28 was significantly higher in subgroup 3 compared with subgroup 1 and 2 at both 6 (2.14, 1.2, and 1.44, respectively; $p<0.0001$) and 12 months (2.33, 1.26, and 1.46, respectively; $p<0.0001$). Similarly, in the subgroup 3 we found a significantly higher proportion of patients achieving 1-year remission (44.1, 23.1, and 24.1%, respectively; $p<0.0001$) or LDA (57.3, 31.7, and 36.1%, respectively; $p<0.0001$). Treatment withdrawals due to adverse events were significantly more frequent in both subgroup 1 and 2 compared with subgroup 3 (19.3, 16.5, and 9.2%, respectively; p=0.02).
**Conclusions:** Our retrospective analysis demonstrated that in a real life setting the 6- and 12-month clinical response of ADA and ETN was significantly improved by combination strategy only when MTX has been used at high doses ($\geq$12.5 mg/week). Interestingly, increasing MTX dose was also associated with a more favorable safety profile.

## FRI0174 TWO-YEAR RETENTION RATE OF SUBCUTANEOUS ANTI-TUMOR NECROSIS FACTOR AGENTS FOR RHEUMATOID ARTHRITIS: A RETROSPECTIVE ANALYSIS OF THE LORHEN REGISTRY

E.G. Favalli[1], R. Caporali[2], S. Monti[2], P.C. Sarzi Puttini[3], F. Atzeni[3], E. Fusaro[4], P.A. Rocchetta[5], G. Paolazzi[6], R. Pellerito[7], R. Gorla[8], L. Sinigaglia[1]. *[1]Department of Rheumatology, Gaetano Pini Institute, Milano; [2]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; [3]Rheumatology, University Hospital Sacco, Milan; [4]Rheumatology, Azienda Ospedaliera Universitaria Città della Salute e della Scienza, Torino; [5]Rheumatology, A.S.O. "SS. Antonio e Biagio e C.Arrigo", Alessandria; [6]Rheumatology, Santa Chiara Hospital, Trento; [7]Rheumatology, Ospedale Mauriziano, Torino; [8]Rheumatology, Spedali Civili, Brescia, Italy*

**Background:** To date four subcoutaneus TNF inhibitors (TNFis) have been licensed for the treatment of rheumatoid arthritis (RA). Although data from real-life registries have largely confirmed the favourable long term retention rates of adalimumab (ADA) and etanercept (ETN), data on golimumab (GOL) and certolizumab pegol (CZP) drug survival are still lacking.
**Objectives:** The aim of the study is to evaluate the 2-year retention rate of TNFis used as 1st or 2nd line biotherapy in RA patients in a multicentric observational cohort (the LORHEN registry).
**Methods:** Data of all RA patients treated with a TNFi were retrospectively extracted from the LORHEN registry, including a cohort of more than 3000 RA subjects who received at least one biologic agent since 1999. The analysis was limited to patients who received ADA, ETN, CZP, or GOL as first- or second-line biotherapy in the period when all the considered TNFis were available in Italy (from January 2010 to November 2015). The 2-year retention rate was calculated by Kaplan-Meier method and the comparative risk for discontinuation among individual TNFi was compared by a stratified log-rank test. Sub-analyses according to first or second line treatment have been performed.
**Results:** The study population included 677 RA patients (79.7% female, mean age [±SD] 54.3 [±13.5] years, mean disease duration 8.9 [±8.8] years, mean baseline disease activity score 28 4.9 [±1.3]), treated with a first (n=444) or a second line (n=233) TNFi. In the biologic naïve group, 141 patients received ADA, 88 CZP, 130 ETN, and 85 GOL, whereas in the switcher group 68 patients have been treated with ADA, 38 with CZP, 76 with ETN, and 51 with GOL. The overall 2-year retention rate was 58.5% (63.3 and 49.4% in first- and second-line group, respectively; $p<0.001$). The 2-year drug survival of individual TNFi was 46% for ADA, 66% for CZP, 56% for ETN, and 53% for GOL (p=0.006 for CZP vs ADA, p=n.s. for other comparisons). Sub-analyses according to line of TNFi treatment demonstrated 2-year retention rate of ADA, ETN, CZP, and GOL to be 57.4, 66.9, 73.9, and 56.5%, respectively (p=0.048 for CZP vs ADA, p=n.s for other comparisons) in biologic naïve patients and 38.2, 46.1, 60.5, and 60.8%, respectively (p=0.017 for GOL vs ADA, p=n.s for other comparisons) in switchers.
**Conclusions:** In the real-life scenario of the Lorhen registry, overall 2-year retention rate of TNFis was about 60% with a significantly higher persistence in biologic naïve patients compared with switchers. In the comparison among individual TNFis, no significant differences were found with the exception of a lower drug survival of ADA compared with CZP in biologic naïve subjects and with GOL in switchers.

## FRI0175 TWO-YEAR RETENTION RATE OF GOLIMUMAB FOR RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND ANKYLOSING SPONDYLITIS: A RETROSPECTIVE ANALYSIS OF THE ITALIAN LORHEN REGISTRY

M. Manara[1], E.G. Favalli[1], R. Caporali[2], P. Sarzi Puttini[3], A. Marchesoni[1], L. Sinigaglia[1]. *[1]Rheumatology, Gaetano Pini Institute, Milan; [2]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; [3]Rheumatology, University Hospital L. Sacco, Milan, Italy*

**Background:** Golimumab (GLM), a subcutaneous TNF inhibitor, has been licensed for the treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Data from real-life registries on long term retention rates of GLM in these diseases are scarce.

**Objectives:** To assess the 2-year retention rate of GLM in RA, PsA and AS patients from a multicentre observational cohort (the LORHEN registry).
**Methods:** We performed a retrospective analysis of data from all patients with RA, PsA and AS included in the LORHEN registry who started GLM from October 2010 to September 2015. Only patients with at least one reported visit of follow-up were included. The 2-year retention rate was calculated by Kaplan-Meier method for each disease. The risk of discontinuation between patients who received GLM as first- or second-line biotherapy was compared by a stratified log-rank test.
**Results:** Overall 410 subjects were included in the analysis: 180 patients with RA, 110 with PsA and 120 with AS.
RA patients had a mean (Standard Deviation, SD) age of 54,6 (13,6) years and a mean (SD) disease duration of 9,5 (9,3) years; most of them were female (81,6%). Among them, 79 patients stopped the treatment with GLM due to inefficacy or adverse events before 24 months of treatment; the overall 2-year retention rate was 48%. GLM was given as first and second line treatment in 85 and 51 patients, with a 2-year retention rate of 49% and 53%, respectively; the comparison between first and second line treatment groups did not show any significant difference in mean survival time (p=0.724).
Among PsA patients, 50% were male, with a mean (SD) age of 47,9 (12,8) years and a mean (SD) disease duration of 7,9 (6,7) years. Among them, 42 patients stopped the treatment with GLM due to inefficacy or adverse events before 24 months of treatment; the overall 2-year retention rate was 48%. GLM was given as first and second line treatment in 47 and 30 patients, with a 2-year retention rate of 66% and 54%, respectively; the comparison between first and second line treatment groups did not show any significant difference (p=0.333).
SA patients had a mean (Standard Deviation, SD) age of 45,2 (12,2) years and a mean (SD) disease duration of 9,7 (10) years; 56,7% of patients were male. Among them, 33 patients stopped the treatment with GLM due to inefficacy or adverse events before 24 months of treatment; the overall 2-year retention rate was 65%. GLM was given as first and second line treatment in 51 and 42 patients, and the 2-year retention rate was of 57% and 76%, respectively; the comparison between first and second line treatment groups did not show any significant difference (p=0.127).
**Conclusions:** GLM showed a similar 2-year retention rate in first and second line treatment of patients with RA, PsA and SA in real-world data from the LORHEN registry. The 2-year retention rate was higher in SA patients than in RA and PsA patients.

## FRI0176 SAFETY OF ANTI-TNF ALFA AGENTS DURING PREGANCY AND BREASTFEEDING: LONGTERM FOLLOW UP OF EXPOSED CHILDREN IN A CASE-SERIES OF MOTHERS WITH CHRONIC ARTHRITIDES

F. Dall'ara[1], R. Reggia[1], C. Bazzani[1], L. Andreoli[1], M. Agosti[2], G. Mazza[1], M.G. Lazzaroni[1], A. Lojacono[3], M. Motta[4], A. Tincani[1]. *[1]Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia; [2]Rheumatology Unit, Istituto Ortopedico Gaetano Pini, Milan; [3]Obstetrics and Gynaecology; [4]Neonatology and NICU, Spedali Civili and University of Brescia, Brescia, Italy*

**Background:** Anti-TNFalfa agents are used to control disease activity in patients with Chronic Arthritides (Rheumatoid Arthritis, Psoriatic Arthritis, Ankylosing Spondylitis), often during the wash-out period of teratogenic DMARDs and are usually discontinued at positive pregnancy index. However, the presence of a moderate to severe maternal disease activity during pregnancy or puerperium may require the use of the drugs also in the 2nd-3rd trimester and/or in the postpartum period. Few data are available in literature regarding their use in pregnancy and only anecdotal during lactation.
**Objectives:** To compare the health and developmental conditions of children exposed in utero and/or with breastfeeding to anti-TNFalfa agents with non-exposed children born to women with the same disease.
**Methods:** Data on birth, lactation, weaning, growth parameters, developmental milestones, vaccinations and disease conditions were collected submitting an ad-hoc created questionnaire to women affected by chronic arthritides treated with an anti-TNF alfa agent during one or more trimesters of gestation and/or during breastfeeding (cases). Data have been compared to those obtained from mothers affected from the same disease but not exposed to anti-TNF alfa therapy (controls)
**Results:** The table reports the characteristics of 34 cases (15 male, 19 female) (26 exposed to Etanercept, 5 to Adalimumab, 2 to Golimumab and 1 to Certolizumab) and 34 controls (19 M, 15 F). Twenty-six children were exposed during the first trimester (discontinuation of anti-TNFalfa agent at positive pregnancy index), while 8 during the 2nd-3rd trimester (discontinuation at 34th-37th week, mean exposure of 81 days). Both cases and controls underwent vaccinations without any severe complications. Vaccinations were protective; only one child with periconception exposure to etanercept developed chicken-pox despite vaccination. Seven children were breastfed during maternal anti-TNFalfa therapy (5 etanercept, 2 adalimumab): no differences in growth parameters, developmental milestones, vaccinations and diseases in the first year of life were highlighted in comparison to those not exposed to the drugs with lactation.
**Conclusions:** No differences in birth parameters, congenital malformations, and developmental steps in the first 24 months of life have been found between cases and controls. Growth parameters were within the curves of the general population. Cases received more vaccinations than controls. This may be due to the feeling by either parents or paediatricians that these children exposed to immunosuppressive agents could be more susceptible to infectious diseases. No relevant infectious diseases nor post-vaccine complications have been noted in the 6 children exposed to anti- TNFalfa during the 2nd-3rd trimester of gestation nor in the 5 exposed during lactation. Globally, the long-term follow-up of children supports the safety of use of anti-TNFalfa agents, either preconceptionally or during the 2nd-3rd trimester of pregnancy. Data on use during breastfeeding are still anecdotal but can be helpful for counseling the patients who are strongly motivated to breastfeed.

## FRI0177 TIME TO ACHIEVE REMISSION PREDICTS LONG TERM SURVIVAL OF LOW-DOSE ETANERCEPT: AN OBSERVATIONAL STUDY

F. Ometto, B. Raffeiner, C. Botsios, L. Friso, D. Astorri, L. Bernardi, L. Punzi, A. Doria. *Rheumatology Unit, Medicine Department - DIMED, University of Padova, University of Padova, Padova, Italy*

**Objectives:** To investigate survival of low-dose etanercept (ETN) (25 mg weekly) and possible predictors.
**Methods:** We collected retrospectively data of RA patients starting ETN between April 2001 and September 2014 who achieved and maintained low-dose ETN for at least 12 months. Patients were evaluated every 3 months. Patients who achieved and maintained remission (DAS28 <2.6) for at least 6 months started low dose ETN. If remission was lost *in two consecutive visits* the patient returned to full dose. We recorded the time to achieve remission (TTR), the time in which ETN dose was reduced since remission (TRL) and the time in which patients returned to full dose or were switched to other biologics. Variables collected are reported in Table I. Survival was analysed with Cox-regression.
**Results:** Among 532 patients, 276 were excluded because of missing data or because they were lost from follow-up leaving 256 patients eligible. After 11.28±4.05 years, 151/256 (59.0%) maintained half dose (Table 1). TTR, and TRL were associated to low-dose failure (Table 1) and correlated with each other (TTR and TRL R 0.45, p<0.001). We run two separate analyses for TTR and TRL, covariates were positive rheumatoid factor or anti-citrullinated peptides and mean prednisone dose. TTR was a significant predictor of low-dose failure (OR 1.50 per year increase, 95% C.I. 1.34–1.68, p<0.001) while TRL was not (Table 2).
**Conclusions:** A shorter TTR is a predictor of long-term survival of low-dose ETN.
**Disclosure of Interest:** None declared

## FRI0178 ANTI-ETANERCEPT ANTIBODIES AND ETANERCEPT LEVES LEVELS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH LOW AND FULL-DOSE ETANERCEPT IN DAS28 REMISSION

F. Ometto[1], M. Beggio[2], L. Friso[2], D. Astorri[2], B. Raffeiner[2,3], C. Botsios[2], L. Bernardi[2], R. Padoan[2], L. Punzi[2], A. Ghiraldello[2], A. Doria[2]. *[1]Rheumatology Unit, Medicine Department - DIMED, University of Padova; [2]Rheumatology Unit, Medicine Department - DIMED, University of Padova, PADOVA; [3]Rheumatology Unit, Internal Medicine, General Hospital of Bolzano, Bolzano, Italy*

**Objectives:** To investigate etanercept (ETN) serum levels and anti-etanercept antibodies (AEA) and evaluate whether ETN levels are associated with SDAI remission in rheumatoid arthritis patients in DAS28 remission treated with full-dose (25 mg twice weekly) and low-dose (25 mg once weekly) ETN.

**Methods:** We selected 70 patients in stable (≥12 months) full-dose (35) or low-dose (35) ETN, in remission (DAS28<2.6 for ≥12 months) and with a treatment duration ≥5 years. AEA and basal ETN levels were tested by ELISA. A cut-off >142AU/ml was adopted for defining positive AEA. A concentration of ETN ≥3.1μg/mL was considered as a high ETN level [1]. Multivariate regression analysis was used to investigate whether high ETN levels were associated with SDAI remission.

**Results:** One blood sample in the low-dose group resulted inadequate. AEA were present in 1 patient in low-dose (1/34, 2.9% low-dose ETN vs 0/35, 0% full-dose ETN, p=0.507). Full-dose and a lower weight were associated with high ETN levels: 15/35, 42.9% vs 3/34, 8.8% p=0.001 and 55.0 kg (57.0;80.0) and 65.0 (51.0;69.8), p=0.014 for high and low ETN levels respectively. Lower ETN levels, low-dose and a longer low-dose duration were associated with SDAI remission but were not confirmed with multivariate regression (Table 1).

**Conclusions:** AEA are almost absent in patients in stable remission, patient with full-dose ETN and lower weight have higher ETN levels. ETN levels are not predictive of SDAI remission.

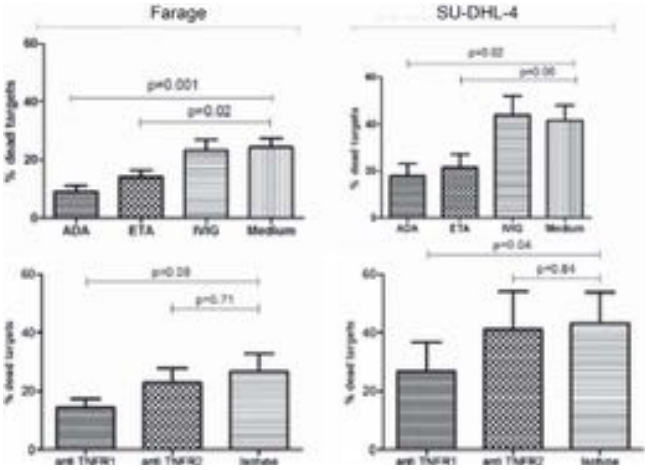
## FRI0179 ANTI-TNF THERAPY IS ASSOCIATED WITH AN IMPAIRED FUNCTION OF NK CELLS AND A DEFECTIVE IMMUNOSURVEILLANCE AGAINST B-CELL LYMPHOMAS

G. Nocturne[1], B. Ly[2], S. Boudaoud[2], R. Seror[1], L. Zitvogel[3], X. Mariette[1]. *[1]INSERM 1184 and APHP; [2]INSERM 1184, le Kremlin Bicetre; [3]IGR, Villejuif, France*

**Background:** Rheumatoid arthritis (RA) is associated with an increased risk of lymphoma linked to activity of the disease. Immunosuppressive drugs have been suspected to induce an additional risk. Since, NK cells have been recently shown to participate to anti–lymphoma immunosurveillance, we aimed to assess if anti-TNF might impact their anti-lymphoma activity.

**Methods:** NK cells have been assessed ex vivo in patients with RA treated with methotrexate (MTX) with (n=19) or without (n=20) anti-TNF. Phenotype has been studied by flow cytometry and function (degranulation and IFNg production) has been assessed after NKp30-cross linking. Then, we have studied the consequences of in vitro exposure of NK to anti-TNF, to TNF-R inhibitors or to controls during 6 days: phenotype has been studied and then cytotoxicity against 2 B non-Hodgkin lymphoma cell lines [Farage (EBV+) and SU-DHL4 (EBV-)] was assessed. Results are shown as median [interquartile range (IGR)]. The Mann Whitney test was used to compare independent samples.



**Results:** Firstly, in patients, we found that the proportion of activated NK cells, assessed by the expression of CD69, was significantly decreased in patients treated with anti-TNF + MTX compared to patients treated with MTX alone (8.9% [2.9–40.7] vs 48.4% [27.4–58.3], p=0.005). Moreover, we found that NK cells exhibited an impaired function in patients treated with anti-TNF compared to patients treated with MTX alone as assessed by the percentage of degranulation (20.9% [18.5–32.9] vs 31.3% [21.5–49.1], p=0.04) and the loss of capacity of IFN-γ secretion ((17.4% [8.9–25.9] vs to 29.7% [22.5–43.1], p=0.007). Secondly, we have confirmed that in vitro exposure to anti-TNF negatively impact NK cells activation and function leading to an impaired anti-lymphoma activity (figure 1A). In all these experiments, no difference was observed between etanercept and monoclonal anti-TNF. Last, we have demonstrated that negative impact of anti-TNF on NK cells may be the consequence of inhibition of TNF-R1 signaling (figure 1B).

**Conclusions:** Even if meta-analysis of randomized controlled trials and of

## FRI0180 NO PREDICTION OF RELAPSE BY TNF BLOCKER CONCENTRATIONS OR DETECTION OF ANTIBODIES AGAINST ANTI-TNF: DATA FROM STRASS STUDY

H. Marotte[1,2], M. Rinaudo[3], S. Paul[3], B. Fautrel[4]. [1]*SANBIOSE U1059;* [2]*Rheumatology;* [3]*Immunology laboratory, CHU Saint-Etienne, Saint-Etienne;* [4]*Rheumatology, AP-HP Pitié-Salpêtrière Hospital, Paris, France*

**Background:** The goal of rheumatoid arthritis (RA) strategy is to reach remission or at least a low disease activity. When this gaol is reached, no clear guideline exist to manage therapy. Recently, STRASS (*Spacing TNF-blocker injections in RA Study*) provided evidence of step-down therapeutic strategy with adalimumab or etanercept (1).

**Objectives:** We investigated if drug dosages and their antidrug antibodies (ADAb) could predict relapse during the 18 months of STRASS study.

**Methods:** We assessed 131 serum among the 137 included in STRASS study (60 and 71 for adalimumab and etanercept, respectively). Serum were collected at the time of randomisation. Adalimumab and etanercept blood concentrations and theirs ADAb were assessed by ELISA (Theradiag, Marne-La-Vallee, France). For this study, relapse was defined as DAS28>2.6 with DAS28 increase >0.6 since the previous study visit.

**Results:** Characteristics of the 131 patients similar to 137 from the initial STRASS study (data not shown). The median age was 54.5 [48.3–61.8] years. One hundred and two (77%) were female. The median disease duration was 6.5 [4.5–12.4] years. The median DAS28, ESR, and CRP were 2.0 [1.5–2.3], 10 [6–17], and 3 [2–4]mg/mL, respectively. Methotrexate was the main DMARDs used (n=91; 70%). No baseline characteristics were associated with relapse during tapering or not. In patients treated with etanercept, etanercept level was similar in case of relapse or not. Similarly, adalimumab level was comparable in case of relapse or not. However, in patients treated with adalimumab, ADABs was significantly higher in case of relapse compared to no relapse (0.94±0.27 ng/ml *vs.* 0.27±0.76 ng/ml; P=0.03, respectively). However, this difference was not clinically pertinent.

**Conclusions:** No difference was observed in adalimumab or etanercept blood level to predict relapse in RA patients with low disease activity. However, a slight increased of ADAb for adalimumab was observed. Its signification needs further investigation.

## FRI0181 CHANGING USE OF METHOTREXATE (MTX) AND BIOLOGICS IN THE TREATMENT OF RHEUMATOID ARTHRITIS (RA) IN THE UNITED STATES (US): RESULTS OF A COMPREHENSIVE PHARMACEUTICAL CLAIMS ANALYSIS

J.R. O'Dell[1], S. Cohen[2], C. Thorne[3], T.R. Mikuls[4]. [1]*Internal Medicine, University of Nebraska Medical Center, Omaha;* [2]*Metroplex Clinical Research Center, Dallas, United States;* [3]*Department of Medicine, Southlake Regional Heath Centre, University of Toronto, Toronto, Canada;* [4]*Internal Medicine, University of Nebraska Medical Center & VA Nebraska - Western Iowa Health Care System, Omaha, United States*

**Background:** European and US guidelines recommend MTX as part of initial treatment for patients with RA.[1,2] Biologic agents are recommended for patients with poor prognostic indicators and those who fail to achieve treatment goals after 3–6 months of conventional therapy.[1,2] Currently, it is not clear how closely these recommendations are being followed in the US.

**Objectives:** To assess patterns of treatment for patients who initiated DMARD treatment in the US in either 2009 or 2012 and were followed for at least 2 years.

**Methods:** The analysis used Symphony Health Solutions' anonymized patient-level claims data which captures ~274 million US patients. Analysis included RA patients identified by ICD-9 codes 714.0 and 714.30 who initiated treatment with either oral MTX or a biologic therapy in 2009 or in 2012 and were followed for 2 years. Information obtained included: demographic characteristics, initial treatments, switches from oral to subcutaneous (SC) MTX and/or biologics (with or without concomitant MTX), timing of treatment changes, and oral MTX or SC MTX dosing at the times of switches/additions or end of follow-up.

**Results:** The study included 48,910 patients who initiated treatment in 2009 and 107,636 who started treatment in 2012 (Table). For the RA patients who started treatment in 2009, 27.1% initiated therapy with a biologic and 72.9% started on oral MTX. The respective values for patients initiating therapy in 2012 were 35.6% and 64.4%. Over the first 2 years of follow-up, 35.2% of patients who started MTX in 2009 and 21.6% of those started on MTX in 2012 switched to a biologic or had one added to MTX. A small percentage of patients in each cohort switched from oral to SC MTX. The median duration of oral MTX treatment prior to switching to or adding a biologic was 60 days for patients who initiated treatment in 2009 and 177 days for those who initiated MTX in 2012.

**Conclusions:** In the US, a large percentage of RA patients receive a biologic without a prior trial of MTX and this approach to treatment increased from 2009 to 2012. While there is a trend toward underuse of MTX as initial treatment from 2009 to 2012, a higher percentage of patients who started MTX in 2012 remained on this treatment for at least 2 years vs those started in 2009. This suggests many clinicians may not be following best practice with regard to the use of SC MTX.

## FRI0182 A SINGLE DOSE STUDY COMPARING PHARMACOKINETICS, SAFETY, AND IMMUNOGENICITY OF M923 (A PROPOSED BIOSIMILAR TO ADALIMUMAB), US-SOURCED ADALIMUMAB, AND EU-SOURCED ADALIMUMAB IN HEALTHY SUBJECTS

J. Hillson[1], T. Mant[2], T. Ganguly[1], M. Rosano[1], C. Huntenburg[1], M. Alai-Safar[3], S. Darne[3], D. Palmer[3], B. Pavlova[3], J. Doralt[3], R. Reeve[2], N. Goel[2], D. Weilert[2], P. Rhyne[2], J. Caminis[3], J. Roach[1]. [1]*Momenta Pharmaceuticals, Inc., Cambridge;* [2]*Quintiles Inc., Durham;* [3]*Baxalta Inc., Cambridge, United States*

**Background:** M923 is being developed as a biosimilar to the reference product HUMIRA® (adalimumab). An extensive panel of tests were used to characterize the physicochemical, functional, and in vivo attributes to support the initiation of clinical testing.

**Objectives:** The primary objective of this study was to evaluate pharmacokinetic (PK) equivalence between M923 and US-sourced adalimumab, between M923 and EU-sourced adalimumab, and between US- and EU-sourced adalimumab. Safety and immunogenicity were also assessed.
**Methods:** This was a randomized, double-blind, 3-arm, parallel group, single-dose study. A total of 324 healthy volunteers were randomized 1:1:1 to receive a single 40 mg dose of M923, US-sourced adalimumab, or EU-sourced adalimumab by subcutaneous injection on Day 1. Subjects were then followed for a total of 71 days; serum concentration of adalimumab, anti-drug antibodies (ADAs), and adverse events (AEs) were recorded. The primary PK endpoints were: $C_{max}$, $AUC_{0\text{-}inf}$, and $AUC_{0–336}$. PK bioequivalence was achieved if 90% confidence intervals for the geometric least squares (LS) mean ratios for all comparisons were within the confidence bounds (CI) of 80.00 to 125.00%.
**Results:** Bioequivalence was observed for all primary PK endpoints. Specifically, for the comparison of M923 with US-sourced adalimumab, the geometric LS mean ratios (90% CI) were $C_{max}$ =102.58 (97.31–108.14); $AUC_{0\text{-}inf}$=104.20 (96.47–112.54); and $AUC_{0–336}$=102.94 (97.88–108.27). Similarly, for the comparison of M923 with EU-sourced adalimumab, the geometric LS mean ratios (90% CI) were $C_{max}$ =99.39 (94.25–104.81); $AUC_{0\text{-}inf}$=100.90 (93.48–108.90); and $AUC_{0–336}$=100.51 (95.55–105.73). Lastly, for the comparison of US-sourced with EU-sourced adalimumab, the geometric LS mean ratio (90% CI) were $C_{max}$=103.21 (97.85–108.86); $AUC_{0\text{-}inf}$=103.27 (95.50–111.67); and $AUC_{0–336}$=102.42 (97.30–105.81). Similar concentration-time profiles were observed across groups (graph). The incidence, type, and severity of AEs were comparable across groups. The incidence, titer, and time to emergence of ADAs at any time during the study were similar across groups (proportion of subjects with confirmed positive titers: M923 =78.0%; US-sourced adalimumab =80.6%; EU-sourced adalimumab =78.5%).

**Conclusions:** Bioequivalence was observed for all treatment comparisons (M923/US-sourced adalimumab; M923/EU-sourced adalimumab; EU-sourced adalimumab/US-sourced adalimumab). In addition, the safety and tolerability profile of M923 was demonstrated to be comparable to what has been established in previous studies of EU-sourced adalimumab and US-sourced adalimumab.

## FRI0183 PREGNANCY OUTCOMES IN WOMEN EXPOSED TO INFLIXIMAB (INNOVATOR)

J. Slater[1], J. Phillips[1], C.-Y. Guo[1], M. Clark[1], A. Geldhof[2], N. Gearhart[1], R. Nissinen[2]. *[1]Janssen Research & Development, Horsham, United States; [2]Janssen Biologics Europe, Leiden, Netherlands*

**Background:** Rheumatologic, dermatologic and inflammatory bowel disorders (IBD) can affect women of childbearing potential. Infliximab ([IFX], Innovator) is approved for the treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), Crohn's disease (CD), ulcerative colitis (UC) and psoriasis (PsO).
**Objectives:** To characterize pregnancy outcomes in patients treated with IFX (Innovator), data obtained from maternal exposure to IFX (Innovator) are presented.
**Methods:** Dataset includes individual patient cases within the company safety database through 23 August 2015. Cases originated from various sources, including spontaneous reporting, clinical studies, and registries. Cases include prospectively reported (ie, pregnancy outcome not known when first reported) maternal exposures to IFX (Innovator) during pregnancy or within 2 months prior to conception with a known pregnancy outcome in RA, PsA, AS, CD, UC, or PsO pts. Birth outcome was stratified by grouped indication.
**Results:**

Table 1. Summary of pregnancy reports with known outcomes in patients treated with IFX (Innovator) for RA, PsA, AS, CD, UC and PsO

| Pregnancy outcome | All IFX (Innovator)-exposed pregnancies n, (%) | T1 IFX (Innovator)-exposed pregnancies n, (%) |
|---|---|---|
| Total no of reports with known outcome | 1362 | 695 |
| Live birth | 1115 (81.9) | 592 (85.2) |
| Congenital anomalies | 25 (2.2) | 11 (1.9) |
| Preterm birth | 85 (7.6) | 40 (6.8) |
| Abortion | | |
| Spontaneous | 147 (10.8) | 68 (9.8) |
| Elective/Induced | 72 (5.3) | 23 (3.3) |
| Scheduled | 12 (<1) | 4 (<1) |
| Unspecified | 1 (<1) | 0 |
| Ectopic pregnancy | 9 (<1) | 3 (<1) |
| Still birth | 2 (<1) | 1 (<1) |
| C-section | 3 (<1) | 3 (<1) |
| Molar pregnancy | 1 (<1) | 1 (<1) |

**Conclusions:** Pregnancy outcomes among pregnancies with T1 IFX (Innovator)-exposure did not differ from the pregnancy outcomes among all prospectively reported pregnancies exposed to IFX (Innovator). Higher percentages of CA were reported among rheumatological indications in comparison to IBD and PsO. The combined rate of CA among pregnancies with IFX (Innovator) exposure was comparable to US general population (3%)[1]. Potential confounders will be further characterized. Limitations of this analysis include lack of a direct comparison group and missing data in the reports.

## FRI0184 INCREASING TREATMENT TIME ON INFLIXIMAB IS PREDICTIVE OF INCREMENTALLY BETTER LONG-TERM RETENTION IN STABLE INFLIXIMAB RHEUMATOLOGY PATIENTS IN CANADA

M. Khraishi[1], J. Foley[2], E. Stein[2]. *[1]Memorial University of Newfoundland, St. John's; [2]Janssen Inc. Canada, Toronto, Canada*

**Background:** A high percentage of patients treated with TNF antagonists discontinue therapy mainly due to lack of efficacy or side effects. Recent studies of stable infliximab (IFX) patients switched to biosimilar infliximab (INB) seem to suggest similar safety and efficacy outcomes as IFX[1,2]. However, these studies often have small sample sizes, short follow-up periods and, where reported, high discontinuation rates post-switch.
**Objectives:** To demonstrate long-term retention patterns of stable Canadian rheumatic disease (RD) patients treated with originator IFX.
**Methods:** We conducted a population cohort study using IMS health™|Brogan's longitudinal Canadian patient claims database, the largest such database in Canada. The analysis captured a robust sample of thousands of claims from private insurers across Canada, and public claims from Ontario and Quebec. The retention analysis included RD patients with: a) an initial IFX claim during the selection period of Jan 2008-May 2015; b) absence of IFX claims in the 12 months prior to the initial claim; c) ≥1 claim for any drug other than IFX drug during that 12-month period; and d) ≥1 claim in the 4 months following the end of the longitudinal patient tracking period. Retention was measured at 12-month intervals and analyzed accordingly. Unadjusted odds ratios were then calculated based on retention data and 10 pairwise comparisons were calculated at the 95% confidence interval.
**Results:** The analysis captured 3,131 IFX RD patients in the selection period of which 1,822 had ≥2 years of claims history and had been on IFX for ≥1year. The table below demonstrates that the patient's probability of being retained on IFX

| # Years on Originator IFX | # Patients | # Retained 12 months later (%) | OR (vs. 1 year on on Originator IFX) | CI (95%) | *P* value |
|---|---|---|---|---|---|
| 1 | 1,822 | 1,338 (73.4%) | | | |
| 2 | 1,102 | 898 (81.5%) | *1.5923* | *1.3245–1.9143* | *<0.0001* |
| 3 | 721 | 610 (84.6%) | *1.9879* | *1.5836–2.4955* | *<0.0001* |
| 4 | 465 | 396 (85.2%) | *2.0760* | *1.5753–2.7359* | *<0.0001* |
| 5 | 248 | 204 (82.3%) | *1.6771* | *1.1914–2.3609* | *0.0030* |

in the subsequent 12 months increases concurrently with elapsed time on IFX. Specifically for patients on IFX for 2, 3, 4 and 5 years, retention in subsequent 12 month periods was significantly higher than for patients retained for 1 year ($P<0.005$).

**Conclusions:** Real world patients treated with IFX have excellent long term treatment retention. Incrementally longer time on IFX appears to be predictive of better future retention. This becomes statistically significant for patients who are retained on therapy for ≥2 years. Stability on IFX is a factor to consider when deciding whether to switch stable patients to another biologic (including biosimilars) for non-medical reasons. Studies in which stable patients receiving IFX are switched to INB for non-medical reasons have claimed similar safety and efficacy outcomes as IFX, albeit with much higher INB discontinuation rates[1,2]. Safety and efficacy outcomes need to consider an intention to treat population that includes patients who discontinue INB after switching and retention results need to be further investigated with larger sample sizes and longer follow-up periods to better understand what drives post-switch discontinuation from INB.

## FRI0185 ARE THERE DIFFERENCES IN BASELINE CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TUMOR NECROSIS FACTOR INHIBITORS ACCORDING TO THE PRESENCE OF COMORBIDITIES?

M.V. Hernández[1], C.A. Sánchez-Piedra[2], J.A. Gómez-Puerta[3], F. Sánchez-Alonso[2], J. Manero-Ruiz[4], E. Cuende[5], R. Rosello Pardo[6], E. Perez-Pampin[7], C. Rodriguez-Lozano[8], R. Sanmartí[1], J.J. Gómez-Reino[7] on behalf of BIOBADASER 2.0 Study Group. *[1]Arthritis Unit. Rheumatology Dpt, Hospital Clínic, Barcelona; [2]Research Unit, Spanish Society of Rheumatology, Madrid, Spain; [3]Group of Cellular Immunology and Immunogenetics, Universidad de Antioquia, Medellín, Colombia; [4]Rheumatology Dpt, Hospital Universitario Miguel Servet, Zaragoza; [5]Rheumatology Dpt, Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Madrid; [6]Rheumatology Dpt, Hospital General San Jorge, Huesca; [7]Rheumatology Dpt, Hospital Clínico Universitario, Santiago de Compostela; [8]Rheumatology Dpt, Hospital Dr. Negrín, Gran Canaria, Spain*

**Background:** Rheumatoid arthritis (RA) is often associated with comorbidities that may affect the therapeutic choice or a different management in clinical practice. It is unclear whether patients with comorbidities have a different profile from those without

**Objectives:** To analyze differences in the baseline characteristics of RA patients treated with tumor necrosis factor inhibitors (TNFi) according to the presence or not of concomitant comorbidities

**Methods:** All patients from the BIOBADASER 2.0 register with a diagnosis of RA treated with TNFi from January 2008 to December 2014 were selected and divided into 2 groups according to the presence or not of comorbidities. Comorbidity was defined as ≥1 of the following at initiation of TNFi: ischemic heart disease; malignancy; diabetes; chronic pulmonary obstructive disease; smoking; hypercholesterolemia; hypertension; heart failure; renal failure; osteoporosis; Epstein Barr, hepatitis B or C virus infection; and others. Variables analyzed were: age; gender; disease duration; disease activity at initiation of biological therapy measured by the DAS-28 score; number of previous biological agents (0, 1, ≥2); concomitant glucocorticoids or synthetic DMARD; and biological duration. Differences between groups were analyzed

**Results:** From January 2008 to December 2014, 640 RA treated with TNFi were included in the BIOBADASER 2.0 register. Baseline characteristics are shown in Table 1. Patients with associated comorbidities were significantly older, less frequently female, had received a higher number of previous biologics, and had a higher baseline DAS-28 compared with patients without comorbidities

Table 1

| Variable | Total (n=640) | With baseline comorbidity (n=322) | Without baseline comorbidity (n=318) | p-value |
|---|---|---|---|---|
| Age at initiation of first biologic agent (years), mean (SD) | 54.7 (13.7) | 60.1 (11.8) | 49.1 (13.3) | <0.001 |
| Women, n (%) | 497 (77.7) | 237 (73.6) | 260 (81.8) | 0.013 |
| Disease duration (years), mean (SD) | 7.3 (8.0) | 7.6 (8.1) | 7.0 (7.9) | 0.330 |
| Number of previous biologic agents | | | | |
| 0 | 578 (90.3) | 290 (90.1) | 288 (90.6) | 0.706 |
| 1 | 50 (7.8) | 22 (6.8) | 28 (8.8) | 0.381 |
| ≥2 | 12 (1.9) | 10 (3.1) | 2 (0.6) | 0.049 |
| Baseline DAS28, mean (SD) | 4.68 (1.62) | 4.98 (1.43) | 4.48 (1.75) | <0.001 |
| Concomitant sDMARD (%) | | | | |
| 0 | 130 (20.3) | 65 (20.2) | 65 (20.4) | 0.891 |
| 1 | 411 (65.9) | 205 (63.7) | 206 (64.8) | |
| ≥2 | 99 (15.5) | 52 (16.1) | 47 (14.8) | |
| Concomitant corticosteroids (%) | 378 (59.1) | 202 (62.7) | 176 (55.3) | 0.057 |
| Duration of TNFi (months)* | 13.9 (13.5) | 13.3 (13.1) | 14.5 (13.9) | 0.446 |

*From TNFi initiation to switch to other biologic.

**Conclusions:** RA patients treated with TNFi with baseline comorbidities are significantly older, have a higher baseline DAS 28 and had received more previous biologics, suggesting a RA population with higher activity than those without comorbidities. Whether this higher baseline activity favors the development of comorbidities, or whether comorbidities limited therapy in these patients, requires analysis.

## FRI0186 RETENTION OF FIRST-LINE ANTI-TNF TREATMENTS AND IN CASES OF FAILURE RETENTION RATES OF ANTI-TNF DRUG OR A NON-TNF-TARGETED BIOLOGIC IN A MONOCENTRIC COHORT OF 200 RHEUMATOID ARTHRITIS PATIENTS

M. Soubrier[1], B. Pereira[2], A. Tournadre[1], S. Malochet-Guinamand[1], M. Couderc[1], S. Mathieu[1], Z. Tatar[1], D. Abdi[1], T. Frayssac[1], A. Fan[1], J.-J. Dubost[1]. *[1]Rheumatology department; [2]Biostatistics Unit, CHU Clermont-Ferrand, Clermont-Ferrand, France*

**Background:** While several registries have already evaluated the retention of first-line anti-TNF therapy in RA, divergent conclusions have at times been reported. Following treatment failure with a first-line anti-TNF agent, a non-TNF-targeted biologic is recommended rather than a second anti-TNF drug.

**Objectives:** This study sought to compare the retention rate (RR) of a first-line anti-TNF treatment in routine care and in patients with inadequate or insufficient response the RR of either a second-line anti-TNF drug or a non-TNF-targeted biologic, in a monocenter cohort from Auvergne.

**Methods:** All RA patients treated with anti-TNF between 2008 and 2015 were enrolled.

**Results:** In total, 200 RA patients were analyzed, including 37 men and 163 women (81.5%). The mean age was 55.1 ± 13.1 years and disease duration was 8 years [3–15]. 89 (70.1%) patients had RF and 75 (72.8%) anti-CCP antibodies; 96 cases were erosive (69.6%). DAS-ESR was 4.87 ± 1.30. The first-line anti-TNF drugs were etanercept (ETA) (61%), adalimumab (ADA) (24%) or infliximab (IFM) (15%), either as monotherapy (14.6%) or associated with a DMARD (85.4%) (MTX: 64.5%). 131 patients had corticosteroids (mean dose: 7.5 mg/day). At 6 months, 73.8% were EULAR responders (27.8%: moderate; 46%: good). The overall median retention time (RT) was 55.1 months (ADA: 73.9 [19.3 -136.2], ETA 59.3 [17.1 –NA], IFM: 31.1 [7.1 -65.1] months). The RR of the first anti-TNF drug 2 years after initiation was 67.4% for ETA, 67.8% for ADA, and 55% for IFM. The hazard ratios (HR) for treatment cessation did not significantly differ between ETA and monoclonal antibodies. Inefficiencies were observed for 78 patients (70%), including 26 primary inefficiencies (33%) and 30% treatment discontinuations due to side-effects. Reasons for discontinuation did not significantly differ between the anti-TNF groups. IFM exhibited lower safety. Predictors of treatment discontinuation were older age, high activity disease, CRP, and rheumatoid nodules. In contrast, association with a DMARD significantly improved the median RT (17.5 *vs.* 60 months, 76 *vs* 29 months for MTX) for all anti-TNF drugs. Following treatment failure with the first anti-TNF therapy, a second anti-TNF was administered in 61 patients, while 44 were switched to a non-TNF-targeted biologic (22: rituximab; 8: abatacept; 10: tocilizumab; 4: anakinra). A second treatment failure was more common when using a second anti-TNF agent than with non-TNF-targeted biologics (77.1% *vs.* 9.1%, $p<0.001$). Loss of efficacy was the principal reason for discontinuing second anti-TNF drugs (46.8%). The median RT was 12 months [5–25] for second anti-TNF drugs and 10 months [6.5–14.5] for non-TNF-targeted agents. Treatment cessation did significantly differ between anti-TNF drugs and non-TNF-targeted agents (HR: 5.37 [51.92 -15.02]).

**Conclusions:** Our results showed near-identical retention levels recorded for anti-TNF, lower safety for infliximab, improvement of retention when anti-TNF were associated with a DMARD and better efficacy achieved with a non-TNF-targeted biologic following the failure of a first-line anti-TNF treatment.

## FRI0187 A RANDOMIZED CROSSOVER COMPARISON OF INJECTION SITE PAIN WITH 40 MG/0.8 ML AND 40 MG/0.4 ML FORMULATIONS OF ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Nash[1], J. Vanhoof[2], S. Hall[3], R. Tarzynski-Potempa[4], K. Unnebrink[5], A. Cividino[6]. *[1]University of Queensland Rheumatology Research Unit Sunshine Coast, Queensland, Australia; [2]ReumaClinic Genk, Genk, Belgium; [3]Monash University, CabriniHealth, Malvern, Australia; [4]AbbVie, North Chicago, IL, United States; [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany; [6]McMaster University, Ontario, Canada*

**Background:** A new 40 mg/0.4 mL formulation of adalimumab was developed that has fewer excipients, a smaller volume, and a delivery presentation with a smaller gauge needle than the current 40 mg/0.8 mL formulation.

**Objectives:** Evaluate injection site–related pain, safety, and tolerability of the new and current formulations of adalimumab in patients with rheumatoid arthritis (RA).

**Methods:** In 2 identically designed, phase 2, randomized, single-blind, 2-period

crossover studies, adults with RA (biologic-naive or current users of 40 mg/0.8 mL adalimumab with an average injection site–related pain rating ≥3 cm on a visual analog scale [VAS; 0–10 cm]) were randomized to receive 40 mg/0.8 mL or 40 mg/0.4 mL adalimumab at visit 1; after 1–2 weeks (depending on patient medication schedule), patients received the other formulation at visit 2. A pain VAS (McGill Pain Questionnaire [MPQ-SF]) and the Draize scale were evaluated immediately after injection and 15 minutes postinjection; the primary endpoint was immediate pain after injection.

**Results:** Sixty-four and 61 patients were randomized in Studies 1 and 2, respectively. Both studies found significantly lower immediate pain after injection for the 40 mg/0.4 mL versus the 40 mg/0.8 mL formulation (Table). The mean difference on the VAS for the pooled data (–2.48 cm) was statistically significant ($P<0.001$) and clinically relevant; the median percent reduction was –84%. Most other endpoints in both studies favored the 40 mg/0.4 mL formulation (Table), and its tolerability and safety profiles were consistent with 40 mg/0.8 mL adalimumab (data not shown).

Table. Pain Parameters After Injection

| Assessment, mean (SD) | Immediately After Injection | | | | 15 Minutes After Injection | | | |
|---|---|---|---|---|---|---|---|---|
| | 40 mg/0.8 mL Formulation | 40 mg/0.4 mL Formulation | Within-Patient Difference* (95% CI) | P Value† | 40 mg/0.8 mL Formulation | 40 mg/0.4 mL Formulation | Within-Patient Difference* (95% CI) | P Value† |
| Study 1 | N=61‡ | N=61‡ | | | N=61§ | N=61§ | | |
| Pain of injection | 3.3 (2.11) | 1.4 (2.00) | −1.79 (−2.33 to −1.24) | <0.001 | 1.8 (2.12) | 0.9 (1.64) | −0.89 (−1.41 to −0.37) | 0.001 |
| Present pain intensity | 1.3 (0.79) | 0.7 (0.84) | −0.6 (−0.84 to −0.35) | <0.001 | 0.3 (0.54) | 0.2 (0.48) | −0.05 (−0.17 to 0.07) | 0.564 |
| MPQ-SF pain experience total score | 4.4 (5.09) | 2.4 (3.33) | −2.03 (−3.13 to −0.94) | 0.009 | 0.9 (2.32) | 0.7 (2.64) | −0.16 (−0.91 to 0.61) | 0.678 |
| Study 2 | N=63‖ | N=63‖ | | | N=63‖ | N=63‖ | | |
| Pain of injection | 4.2 (2.72) | 0.9 (1.44) | −3.25 (−4.03 to −2.48) | <0.001 | 1.0 (1.41) | 0.4 (1.09) | −0.62 (−1.04 to −0.17) | 0.009 |
| Present pain intensity | 1.9 (1.12) | 0.5 (0.69) | −1.35 (−1.64 to −1.06) | <0.001 | 0.7 (0.84) | 0.2 (0.53) | −0.42 (−0.62 to −0.22) | <0.001 |
| MPQ-SF pain experience total score | 6.9 (7.36) | 1.1 (1.61) | −5.84 (−7.63 to −4.05) | <0.001 | 1.6 (2.69) | 0.5 (1.03) | −1.17 (−1.81 to −0.52) | 0.001 |

ANOVA, analysis of variance; MPQ-SF, short-form McGill Pain Questionnaire.
*Within-patient difference for 40 mg/0.4 mL adalimumab − 40 mg/0.8 mL adalimumab from the crossover ANOVA model with period, sequence, and treatment as fixed effects, and subject as a random effect.
†For differences between treatment groups from ANOVA with period, sequence, and treatment as fixed effects, and subject as a random effect.
‡2 patients discontinued from the study, 1 before receipt of study drug and 1 after the first dose of study drug (pharyngitis).
§1 patient discontinued from the study before receipt of study drug.

**Conclusions:** A 40 mg/0.4 mL adalimumab formulation was well tolerated and associated with less injection site–related pain than the 40 mg/0.8 mL adalimumab formulation.

## FRI0188 SAFETY, TOLERABILITY, AND PHARMACODYNAMICS OF ABT-122, A DUAL TNF- AND IL-17–TARGETED DUAL VARIABLE DOMAIN (DVD)-IG™ IN PATIENTS WITH RHEUMATOID ARTHRITIS

R.M. Fleischmann [1], F. Wagner [2], A.J. Kivitz [3], H.T. Mansikka [4], N. Khan [4], J. Liu [4], F. Hong [4], M. Ruzek [4], R.J. Padley [4]. *[1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, United States; [2]Charité Research Organisation GmbH, Berlin, Germany; [3]Altoona Center for Clinical Research, Duncansville, PA; [4]AbbVie Inc., North Chicago, IL, United States*

**Background:** TNF and IL-17 independently contribute to the pathophysiology of RA, synergistically inducing inflammatory mediators and joint destruction. Selective dual neutralization of TNF and IL-17 confers superior protection vs inhibition of either alone in mouse RA models. ABT-122 is a novel dual variable domain immunoglobulin (DVD-Ig™) targeting both human TNF and IL-17A and hypothesized to provide greater clinical responses in RA patients (pts).

**Objectives:** Investigate safety, tolerability, and exploratory pharmacodynamics of multiple doses of ABT-122 in pts with stable RA

**Methods:** Two phase 1, placebo (PBO)-controlled, multiple-dose studies randomized 43 pts with stable RA receiving stable methotrexate (7.5–25 mg/wk). Pts received subcutaneous PBO, ABT-122 1 mg/kg every other wk (4 doses), or ABT-122 0.5, 1.5, or 3 mg/kg weekly (8 doses), and were evaluated through 45 d after last dose. Serum for inflammation markers and chemokines, based on preclinical studies with dual TNF and IL-17 neutralization, was collected at baseline (BL) through d 92 and analyzed by multiplex assays.

**Results:** No clinically significant safety findings were observed. Rates of treatment-emergent AEs were similar in the ABT-122 and PBO groups, with no evidence of a dose response. There were no AE or serious AE trends, systemic hypersensitivity reactions, or dose-limiting toxicities with ABT-122. Infections were reported, as expected in RA, with no apparent patterns related to etiology, type, or dose with ABT-122 vs PBO, and no pt discontinued the study owing to infection. There were no clinically significant laboratory, vital sign, or ECG abnormalities. CXCL9 and CXCL10 decreased within 3 d of ABT-122 administration (–25% and –30% vs BL, respectively) relative to PBO. Maximal decreases occurred by d 15 (–60% and –45% for CXCL9 and CXCL10, respectively) and persisted through 14 d after last dose. CCL23 decreased following ABT-122, with maximal decreases (–30%) at d 64, and continued through d 92. Consistent with TNF inhibition, soluble E-selectin decreased following ABT-122, persisting through d 92 for the 3 mg/kg group.

**Conclusions:** ABT-122 demonstrated a well-tolerated safety profile in RA pts through 8 wk of dosing up to 3 mg/kg, consistent with the prior first-in-human study in healthy subjects. Because CXCL9, CXCL10, and CCL23 are involved in lymphocyte and myeloid cell recruitment into inflamed tissues, decreases in these chemokines indicate that ABT-122 rapidly modulates potential pathophysiologic pathways in RA pts, with evidence for persistent effects after cessation of dosing. These results suggest that dual neutralization of TNF and IL-17 may provide an opportunity to control inflammation and its clinical manifestations in RA and other immune-mediated inflammatory diseases.

**Acknowledgement:** The design, study conduct, analysis, and financial support of the clinical trials were provided by AbbVie. AbbVie participated in the interpretation of data, review, and approval of the content. All authors had access to all relevant data. Katherine Groschwitz and John Fincke of Complete Publication Solutions, LLC, provided medical writing support. ABT-122 is an investigational product.

## FRI0189 THE USE OF INTERFERON GAMMA RELEASE ASSAYS IN SCREENING FOR LATENT TB PRIOR TO BIOLOGICS IN PATIENTS WITH RHEUMATIC DISORDERS; VALIDATION OF NICE GUIDANCE

S. Sacks, N. Ahmad, A. Steuer, A. Zakari. *NHS - Wexham Park Hospital, London, United Kingdom*

**Background:** Patients with rheumatic disorders treated with TNF-α inhibitors have a 3–4 fold increased risk of developing TB. Our local population (Slough, UK) has a very high TB incidence with a rate of 58.5 per 100,000 population in 2012, approximately four times the national average. Latent TB in our population, many of whom are on immunomodulatory treatment, is thus likely to be several-fold higher. NICE guidance recommends that immunocompromised patients should be screened for latent TB using either an Interferon Gamma Release Assay (IGRA) alone or in combination with a tuberculin skin test.

Two currently available IGRAs are the TB-ELISPOT and QuantiFERON-TB Gold In Tube (QFT) test. The NICE guidelines do not distinguish between these two assays. Whilst they have enhanced our ability to diagnose latent TB their use in immunosuppressed patients has not been widely evaluated. Furthermore, there is limited evidence to support the superiority of either of the two assays.

**Objectives:** We aim to:

- Study the effectiveness and outcomes of our current TB screening programme prior to biologic therapy in our high risk immunosuppressed patients
- Compare two currently used IGRAs (ELISPOT and QFT) in this population of patients.

**Methods:** Retrospective data was obtained from our patient database. 246 consecutive patients (39% male and 61% female; age range 29 – 86 years; 78.5% Caucasian, 19.5% Asian and 2% other) were identified with inflammatory rheumatic disorders who had undergone clinical screening, a chest radiograph and an IGRA (either one or both of TB ELISPOT or QFT) prior to use of a biologic agent between 2008 and 2015.

**Results:** 16/246 (6.5%) patients had a positive IGRA. Of these 15 received chemoprophylaxis for latent TB. 12 (75%) of these patients were Caucasian and the remainder were Asian. 230/246 (93.5%) patients were IGRA negative. 190 patients were receiving immunosuppressant therapy at the time of screening and 245 patients screened were subsequently treated with TNF inhibitors. In this 7-year period there have been no cases of TB reactivation reported to date.

Of the patients screened with both IGRAs, the majority of patients tested negative for both (158/171, 92.4%). 13/171 (7.6%) patients had a positive result. Of these 6 tested positive for both ELISPOT and QFT, 4 had a positive ELISPOT only, and the remaining 3 had a positive QFT test only. The concordance of the two assays used was thus 95.9% (164/171 patients).

**Conclusions:**

- The absence of TB reactivation in our high risk immunosuppressed population receiving biologic therapy indicates the effectiveness of our current screening strategy.
- The current study demonstrates good concordance between the ELISPOT and QFT assays, suggesting that the use of either test on its own is sufficient for screening for latent TB in this population. This data supports current NICE guidance on diagnosing latent TB in the immunocompromised population.

## FRI0190 INDUCTION-MAINTENANCE IN EARLY RA: A META-ANALYSIS OF TRIALS USING MTX PLUS TNF-INHIBITOR AS INDUCTION THERAPY

S. Emamikia[1], E.V. Arkema[2], J. Detert[3], K. Chatzidionysiou[1], M. Dougados[4], G.R. Burmester[5], R.F. van Vollenhoven[1]. *[1]ClinTRID; [2]Clinical Epidemiology Unit, Karolinska Institute, Stockholm, Sweden; [3]Charité - Universitätsmedizin Berlin, Institute of Clinical Immunology and Rheumatology, Berlin, Germany; [4]Department of Rheumatology B, Cochin Hospital, Paris, France; [5]Charité - Universitätsmedizin Berlin, Institute of Clinical Immunology and Rheumatology, Berlin, Germany*

**Background:** The goal of rheumatoid arthritis (RA) treatment is remission or, when not achievable, low-disease-activity (LDA). Initial combined therapy with MTX + TNF-inhibitor (TNFi) achieves these goals more often than MTX alone, but at a high cost. Some trials have therefore used the combined treatment for a limited time only ("induction-maintenance").
**Objectives:** It has remained unclear if the benefits from the induction phase are sustained during maintenance, and individual trials may not have been sufficiently powered to resolve this issue. Therefore, we performed a meta-analysis of trials using the initial combination of MTX+ TNFi in DMARD-naïve early RA-patients.
**Methods:** A systematic literature search was performed for induction-maintenance randomized controlled trials where initial combination therapy was compared with MTX-monotherapy in patients with clinically active early RA. Our primary outcome was the proportion of patients who achieved LDA (DAS28<3.2) and/or remission (DAS28<2.6), at 12–76 weeks of follow-up comparing patients who started with MTX+TNFi to those who started with MTX alone. A random effects model was used to pool the risk ratio (RR) for LDA and clinical remission.
**Results:** The literature search identified 1269 studies that matched the predefined search terms. We identified six published randomized trials, four of them where MTX+ADA was given as initial therapy and where ADA was withdrawn in a subset of patients after LDA/remission had been achieved. For two of these trials (Guépard and Hit-Hard) original data were re-examined, for the other two (Optima and Opera) only published data were available. Two of the additional identified trials (T20 and BeST) used MTX+Infliximab as initial combination-therapy. For BeST, only LDA could be assessed. As expected, the RR of achieving LDA or clinical remission with combination therapy was significantly greater than with MTX monotherapy; 1.70 (95%CI 1.21–2.38) and 1.67 (95%CI 1.42–1.95), respectively. The pooled RRs for achieving LDA and clinical remission at follow-up after discontinuation of TNFi were 1.41 (95%CI 1.05–1.89) and 1.34 (95%CI 0.95–1.89), respectively, with significant heterogeneity between trials (Figure 1).

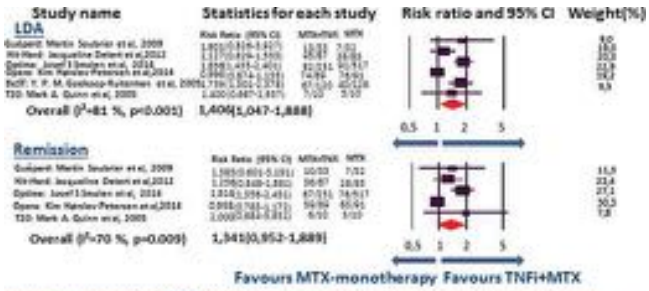

Figure 1A) Forest plot of the risk ratio of attaining LDA using combination therapy versus monotherapy at follow up. 1B) Forest plot of the risk ratio of attaining remission using combination therapy versus monotherapy at follow up. The $I^2$ and p-values for heterogeneity are shown. (Remission= disease activity score (DAS)28<2.6; LDA=low-disease activity(DAS28<3.2)

**Conclusions:** This meta-analysis supports the hypothesis that in early RA, initial therapy with MTX+TNFi is associated with a higher chance of retaining LDA and/or remission even after discontinuation of TNFi.

## FRI0191 BIOSIMILAR CANDIDATE ABP 501: ADDITIONAL EFFICACY ANALYSES FROM THE PHASE 3 STUDY

S. Cohen[1], N. Zhang[2], P. Kaur[2]. *[1]1Metroplex Clinical Research Center, dallas; [2]Amgen Inc., Thousand Oaks, United States*

**Background:** ABP 501 is being developed as a biosimilar candidate to adalimumab, a fully human recombinant monoclonal antibody. Evidence from analytical and pharmacokinetic comparisons indicates that ABP 501 is highly similar to adalimumab. Results of efficacy and safety from a phase 3 study comparing ABP 501 with adalimumab in subjects with rheumatoid arthritis (RA) have been previously presented.[1,2]
**Objectives:** To report descriptive results from additional efficacy analysis based on clinical disease activity index (CDAI) and simplified disease activity index (SDAI) composite indices as well as results for the ACR individual components. These analyses provide information on alternate methods for disease management.
**Methods:** This was a randomized, double-blind, active-controlled study in adult subjects with moderate to severe RA who had an inadequate response to methotrexate. Subjects were randomized in a 1:1 ratio (ABP 501: n=264; adalimumab: n=262) to receive either ABP 501 or adalimumab 40 mg subcutaneously every 2 weeks. Details of the study design have been previously reported.[1] For these analyses descriptive summaries of CDAI, SDAI and individual American College of Rheumatology response criteria (ACR) components were generated.
**Results:** Baseline characteristics were well balanced between groups. At week 24, the mean (SD) CDAI improvement from baseline was 25.94 (12.62) for ABP 501 and 25.06 (12.02) for adalimumab. At week 24, the mean (SD) SDAI improvement from baseline was 26.57 (12.97) for ABP 501 and 25.64 (12.31) for adalimumab. Results for CDAI, SDAI and individual ACR components at baseline and week 24 are shown in the Table. The overall safety and immunogenicity profile of ABP 501 was comparable to that of adalimumab and has been previously reported.[1,2]

Table 1. Results [mean (SD)] for individual ACR components at week 24

| Parameter | ABP 501 | | Adalimumab | |
|---|---|---|---|---|
| | Baseline | Week 24 | Baseline | Week 24 |
| CDAI | 39.1 (12.08) | 13.3 (11.67) | 38.7 (11.87) | 13.5 (11.20) |
| SDAI | 40.5 (12.54) | 14.0 (11.95) | 40.1 (12.28) | 14.3 (11.55) |
| ACR Component | | | | |
| Swollen Joint Count | 14.7 (9.05) | 4.0 (7.55) | 14.1 (7.98) | 3.7 (5.38) |
| Tender Joint Count | 24.3 (14.35) | 7.7 (9.99) | 23.9 (13.49) | 8.0 (10.67) |
| Subject's Global Health Assessment | 6.5 (1.92) | 3.4 (2.25) | 6.6 (1.86) | 3.4 (2.10) |
| Investigator's Global Health Assessment | 6.8 (1.29) | 2.4 (1.80) | 6.7 (1.59) | 2.5 (1.73) |
| Subject Assessment of Disease-related Pain | 58.3 (21.82) | 25.6 (23.25) | 60.6 (22.37) | 27.3 (23.50) |
| C-reactive Protein (mg/L) | 13.88 (20.69) | 7.30 (9.57) | 14.68 (19.38) | 7.48 (10.97) |
| Health Assessment Questionaire – Disability Index (HAQ-DI) Total Score | 1.48 (0.62) | 0.97 (0.69) | 1.50 (0.65) | 0.95 (0.68) |

**Conclusions:** These additional analyses confirm that the of efficacy ABP 501 is comparable to adalimumab in multiple clinical characterisitics providing further evidence that ABP 501 is similar to adalimumab.

## FRI0192 CLINICAL IMPORTANCE OF ANTI-DRUG AND SERUM DRUG LEVEL TESTING IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ETANERCEPT

S. Drynda, J. Kekow. *Clinic of Rheumatology, University of Magdeburg, Vogelsang, Germany*

**Background:** In the past two decades TNF inhibitors have proved especially effective in the treatment of chronic inflammatory diseases such as rheumatoid arthritis. However, despite a high responder rate there is a substantial number of patients showing a primary therapy failure or loss of efficacy after initial response. The presence of anti-drug antibodies and serum drug levels are considered as variables that influence therapy outcome.
**Objectives:** It was the aim of the study to analyse the clinical relevance of anti-drug antibodies and drug levels in the course of a long term treatment of rheumatoid arthritis (RA) patients with etanercept (ETN).
**Methods:** In this retrospective analysis, 508 serum samples from 104 RA patients (86 female/18 male, mean age 51.1±11.5 years (mean±SD), mean disease duration 10.8±8.3 years) were obtained after 6, 12, 24, 36, and 48 months

of treatment with ETN, and selected for determination of anti-ETN antibodies and drug levels. If available, serum samples obtained at least 2 weeks after discontinuation of ETN treatment (due to side effects, non-response, remission or surgery) were used for analysis to exclude any interference of high drug levels with the anti-drug antibody assay. For the determination of anti-ETN and ETN levels, Promonitor® - assays (Proteomika, Spain) were used according to the manufacturer's instructions.

**Results:** Mean baseline disease activity (DAS28) of 5.77±1.19 decreased to 3.69±1.35, 3.43±1.27, 3.39±1.27 and 3.16±1.19 after 6, 12, 24, and 48 months of ETN treatment. No anti-ETN antibodies were found at any time point, neither in the course of treatment nor in samples from 72 of these patients obtained at least two weeks after discontinuation of ETN treatment (mean 51±3.9 months, range 18–120 months).

Mean ETN serum levels for all patients were 3.58±0.17μg/ml, 4.33±0.24μg/ml, 4.22±0.29μg/ml, 4.21±0.27, and 4.66±0.42μg/ml after 6, 12, 24, 36, and 48 months, respectively.

In the course of treatment ETN levels remained stable in most patients, mean levels (calculated from up to 5 single values) between individual patients ranged between 0.9 and 9.91μg/ml. ETN serum levels were not associated with patient related variables such as age, disease duration, rheumatoid factor, ACPA reactivity, creatinine or estimated glomerular filtration rate. There was a slight trend that a higher body weight is associated with lower ETN levels without reaching statistical significance.

In the lower quartile of patients with mean ETN level ≤2.5μg/ml, the DAS28 decreased from 5.52±1.34 to 3.73±0.96 (-1.79, 3.81±1.62 (-1.71), and 3.54±1.54 (-1.98) after 6, 24, and 48 months. A stronger DAS28 improvement was found in the upper quartile >5.07μg/ml from 6.01±1.19 to 3.68±1.57 (-2.33), 3.19±1.14 (-2.82), and 3.08±0.88 (-2,93), respectively.

**Conclusions:** Our study confirms the lack of anti-drug antibodies in a large cohort of RA patients in the course of a long-term treatment with ETN.

ETN drug levels are characterized by a wide inter-individual variability with limited prognostic value for therapy outcome. Our findings do not explain the treatment failure in some patients indicating that other factors/mechanisms determine the lack or loss of efficacy.

## FRI0193 ETANERCEPT DOSE REDUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS – A PILOT STUDY IN SOUTH WALES

S. Duffill[1], S. Kia[2], N. Amos[1], E. Thomas[1] on behalf of Search Results Abertawe Bro Morgannwg University Health Board. *[1]Rheumatology, ABMU, Bridgend; [2]Rheumatology, ABMU, Swansea, United Kingdom*

**Background:** In the era of biologics,increasing numbers of patients achieve full remission.Although biological agents play an important role in reducing morbidity associated with long-term disease of rheumatoid arthritis (RA),they also present risks associated with side effects,increased risk of infection and a significant cost to the Healthcare Provider. There is an increasing body of evidence supporting dose reduction in RA patients[1] and, recently, European League Against Rheumatism (EULAR) updated their recommendations for the management of RA suggesting biologic dose reduction in stable patients[2].

**Objectives:** The aim of this study was to investigate the effect of Etanercept dose reduction on our symptom-stable RA patients. We wished to examine whether patients were receptive to the idea,what their preferred delivery timescales/dose would be and the outcome to the individual.

**Methods:** Suitable RA patients (on Etanercept for >1 year with 2 consecutive Disease Activity Score (DAS)<2.6 over at least 12 months and no steroid therapy in the preceding 6 months) were identified by clinicians and reviewed by a Clinical Nurse Specialist (CNS) for suitability. No limits were set for DMARD use. Informed consent was obtained; patients were offered 4 choices of reduced dose and could withdraw and return to standard dose at any time. A DAS score was performed at baseline and at each follow up visit planned at 3, 6 and 9 months before consultant review at 12 months. Patients also received a telephone consultation by our CNS 6 weeks after starting dose reduction.

**Results:** 50 patients met inclusion criteria and were invited to participate. Three patients (6%) declined due to concerns regarding potential flare. The most popular regime was 50mg fortnightly (n=24), followed by 50mg every 10 days (n=11), then 25mg weekly (n=10), and 50mg four weekly (n=2). In total, 9 (19%) patients discontinued dose reduction – 1 patient at 6 weeks and, by 3 months, a further 8 reported loss of symptom control. Of these 9 patients, 5 were on biologic monotherapy while 4 were taking concomitant DMARDs. On withdrawal, 7 resumed the full Etanercept dose while 2 elected to switch to the 10 day regime. All patients who reported loss of efficacy were in the 50 mg fortnightly group, demonstrating a 38% failure rate for this group.

**Conclusions:** Our pilot study suggests that biologic dose-reduction is mutually beneficial for patients and healthcare providers. Patients are open to the concept of dose-reduction, and were reassured by easy access and frequent review by our CNS. Nurse-led monitoring offers patients a longer and more cost effective assessment, and frees resources for consultant-led commitments. Outcomes from six- and twelve-month follow-up are awaited and larger studies are needed to determine the optimal regime for dose reduction.

## FRI0194 DRUG SURVIVAL ON TNF INHIBITORS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN FINLAND

K.J. Aaltonen[1], J. Joensuu[1], L. Pirilä[2], M. Kauppi[3], T. Uutela[4], T. Varjolahti-Lehtinen[5], T. Yli-Kerttula[6], P. Isomäki[7], D. Nordström[8], T. Sokka[9,10] on behalf of ROB-FIN. *[1]Faculty of Pharmacy/Division of Pharmacology and Pharmacotherapy, University of Helsinki, Helsinki; [2]Department of Medicine, Turku University Hospital, Turku; [3]Department of Medicine, Lahti Central Hospital, Lahti; [4]Department of Medicine, Rovaniemi Central Hospital, Rovaniemi; [5]Department of Medicine, Hatanpää Hospital, Tampere; [6]Department of Medicine, Rauma Central Hospital, Rauma; [7]Department of Medicine, Tampere University Hospital, Tampere; [8]Department of Medicine, Helsinki University Hospital, Helsinki; [9]Department of Medicine, Jyväskylä Central Hospital, Jyväskylä; [10]Faculty of Health Science, University of Eastern Finland, Kuopio, Finland*

**Background:** Previous studies have found that 26 to 34% of Rheumatoid Arthritis (RA) patients using Tumor Necrosis Factor (TNF)-inhibitors discontinue their treatment within one year [1,2]. Infliximab has been associated with poorer drug survival as compared to adalimumab and etanercept.

**Objectives:** The aim of this study was to assess the drug survival on TNF-inhibitors including golimumab and certolizumab pegol among patients with RA and the effect of co-medication on drug survival.

**Methods:** Patients were identified from the National Register for Biologic Treatment in Finland (ROB-FIN), which is a longitudinal cohort study established in 1999 to monitor the effectiveness and safety of Biologic Disease Modifying Anti-Rheumatic Drugs (bDMARDs) in rheumatic diseases. Inclusion was limited to TNF-inhibitor treatments started as the patients' first, second or third biologic treatment between 2004 and 2014. Missing baseline data was imputed by multiple imputation. Follow-up data was available until the end of 2015; however follow-up of individual treatment periods was truncated at 36 months. A Cox proportional hazards model with age as well as conventional synthetic DMARD (csDMARD) and glucocorticoid use as time-dependent confounders was carried out to compare the survival of individual TNF-inhibitors and to study the effect of co-medication. The results were reported as adjusted Hazard Ratios (HRs) with 95% Confidence Intervals (CI).

**Results:** Of the 4,067 TNF-inhibitor treatment periods identified from ROB-FIN, 3,345 periods from 2,641 patients met the inclusion criteria, accumulating a total of 5,620 patient years. Median baseline age and DAS28 score were 55 and 3.8, respectively while 74% of the included patients were women. Etanercept, adalimumab, infliximab, golimumab and certolizumab Pegol were used by 1320 (39%), 1306 (39%), 333 (10%), 195 (5.8%) and 191 (5.7%) patients, respectively. Infliximab (34%) and golimumab (20%) were associated with the highest and the lowest percentages of patients discontinuing their treatment within one year, respectively while the overall percentage was 23%. Infliximab (HR 2.2, 95% CI 1.6–3.1) and certolizumab pegol (HR 1.8, 95% CI 1.3–2.6) had lower drug survival when compared to golimumab. Similar although statistically non-significant trend was seen with adalimumab (HR 1.3, 95% CI 0.99–1.8) and etanercept (HR 1.4, 95% CI 0.99–1.8) as well. Concomitant use of methotrexate (MTX) with or without any additional csDMARDs was associated with improved drug survival (HR 0.78, 95% CI 0.66–0.92) in comparison with TNF-inhibitor monotherapy.

**Conclusions:** We found that golimumab was better in terms of drug survival than infliximab or certolizumab pegol and at least as good adalimumab and etanercept. Concomitant use of MTX improves drug survival on TNF-inhibitors.

## FRI0195 SWITCHING FROM ANTI-TNF TO NON ANTI-TNF THERAPY YIELD BETTER SURVIVAL IN RHEUMATOID ARTHRITIS (RA): RESULTS FROM BRAZILIAN REGISTER OF BIOLOGICAL AGENTS IN RHEUMATIC DISEASES – BIOBADABRASIL

J. Falcão[1,2], V. Valim[1,2], D. Titton[1], R. Ranza[1], H. Carvalho[1], W. Bianchi[1], B. Stadler[1], V. Fernandes[1], P. Louzada[1], M. Bertolo[1], A. Duarte[1], J. Macieira[1], J. Miranda[1], G. Castelar[1], M. Freire[1], R. Toledo[1], J. Moraes[1], I. Costa[1], I. Pereira[1], M. Sauma[1], G. Castro[1], C. Brenol[1], E. Zandonade[2], I. Laurindo[1], C. Baaklini[1]. *[1]Brazilian Register of Biological Agents in Rheumatic Diseases – BIOBADABRASIL, São Paulo; [2]Federal University of Espírito Santo, Vitória, Brazil*

**Background:** There are few studies evaluating switching strategies of biological therapy in RA[1]. Survival studies are indirect evidence of treatment efficacy and safety besides being an useful tool to evaluate switching options in the real life[2].
**Objectives:** To compare the survival of different strategies of switching to a second biological therapy.
**Methods:** Data from a population-based cohort including 1,109 RA patients biological therapy were analyzed at baseline (beginning of the first biologic therapy) up to 7 years (2009–2015). Sex, age, disease duration, DAS-28 and concomitant treatments at baseline were recorded. Kaplan-Meier estimates, Chi-square, Kruskal-Wallis and Wilcoxon-Mann-Whitney tests, Cox regression analysis were applied when appropriate. Results expressed in mean±SD, % (n). Small sample precluded golimumab (GOL) and certolizumab (CER) from the survival analysis.
**Results:** 85% of the patients were women; mean age=50.10±11.81yrs; 86,56% rheumatoid factor positive. At baseline, mean DAS28=5.36±1.35; 77% receiving methotrexate, 78% prednisone, and 40% leflunomide. Regarding biological therapy, 32.1% (356) started with infliximab (INF), 33.36% (370) with adalimumab (ADA), 23.26% (258) with etanercept (ETA), 4.33% (48) with rituximab (RTX), 3.15% (35) with tocilizumab (TOC), 1.26% (14) with abatacept (ABA), 1.70% (19) with GOL and 0.81% (09) with CER. 32.28% (358) switched to second biological therapy. Of those, 65.92% (236) switched from anti-TNF to anti-TNF (INF=33, ETA=105, ADA=83) vs 27.93% (100) from anti-TNF to non anti-TNF (RTX=38, TOC=32, ABA=30), 6.13% from non anti TNF to anti-TNF (n=15) or to non anti-TNF (n=7). Discontinuation of first anti-TNF therapy was due to inefficacy (57%, n=134), adverse effects (31%, n=73) or other (12%, n=29). Better switching strategy was from anti-TNF to non-anti-TNF: 50.72±3.00 (95%CI 44.84,56.60) vs 44.67± 2.46,(95%CI 39.85,49.49)months; p=0.010. Patients that switched to TOC were using less corticosteroid, had higher DAS28 at baseline, and yield better survival (55.80±4.74 95%CI 46.51,65.09 months, p=0.029) as second biological therapy compared to ETA (50.06±3.61 95%CI 42.99–57.14), RIT (47.75±4.93 95%CI 38.10,57.40), ABA (44.89±5.94 95%CI 33.25,56.53), ADA (39.45±3.89 95%CI 31.83,47.08), and INF (34.43±4.65 95%CI 25.31,43.55).

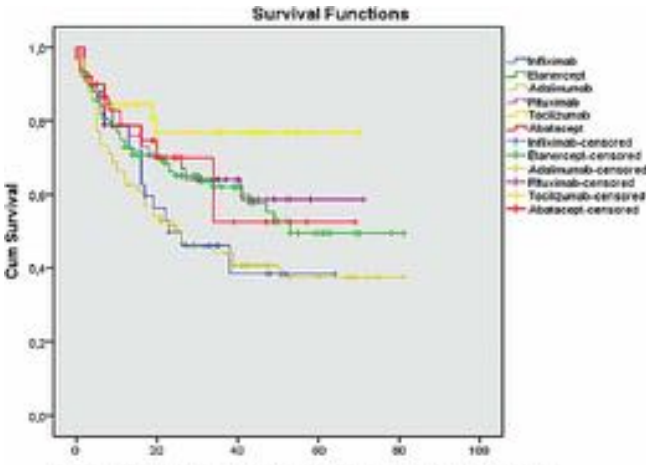

Figure 1. Survival of second biological therapy from baseline.

**Conclusions:** Switching from anti-TNF to non anti-TNF therapy seems to be a better option in the treatment of RA patients. Tocilizumab showed a better survival as second biological therapy, especially in severe disease.

## FRI0196 REAL-WORLD IMPACT OF TAIWAN HEALTH POLICY ON DOSE TAPERING AND WITHDRAWING BIOLOGICS IN RHEUMATOID ARTHRITIS PATIENTS: A RETROSPECTIVE CHART REVIEW STUDY

C. Chang[1], K. Chen[2], Y. Chen[3], T. Cheng[4], P. Hsu[5], N. Lai[6], J. Lan[7], C. Lee[8], S. Lee[9], H. Lin[10], G. Tsay[11], J. Yen[12], C. Tsai[13], Y. Bao[14], M. Skup[14], M. Yang[15], E.Q. Wu[15], V. Garg[14]. *[1]Taipei Medical University Hospital; [2]Cathay General Hospital; [3]National Yang-Ming University; [4]Chang Gung Memorial Hospital; [5]National Taiwan University, Taipei; [6]Tzu-Chi University, Hualien; [7]China Medical University Hospital, Taichung; [8]Mackay Memorial Hospital; [9]Cheng Hsin General Hospital; [10]Taipei Veterans General Hospital & National Yang-Ming University School of Medicine, Taipei; [11]Chung Shan Medical University, Taichung; [12]Kaohsiung Medical University Hospital, Kaohsiung; [13]AbbVie, Taipei, Taiwan, Province of China; [14]AbbVie, North Chicago; [15]Analysis Group, Boston, United States*

**Background:** The OuTcomes Associated with taPering biologics among patiEnts with Rheumatoid arthritis (TAPER) study is a multicenter retrospective chart review to assess real-world implication of the Taiwan National Health Insurance Administration policy on tapering and withdrawing biologics in stable rheumatoid arthritis (RA) patients.
**Objectives:** To assess the clinical and health resource utilization (HRU) outcomes associated with dose tapering and withdrawing of biologics among stable RA patients.
**Methods:** Medical chart data were collected from RA patients tapering adalimumab (ADA) or etanercept (ETN) who had been on the treatment for ≥2 years prior to tapering. RA disease flares and HRU were assessed for the 6-month pre-tapering period, and for the 6-month short-term and up to 18-month longer-term post-tapering periods. A flare was defined *a priori* as any of the following: 1) an increase in DAS28 ≥1.2; 2) an increase in the number of swollen/tender joints; or 3) use of injectable steroids during outpatient or emergency room (ER) visits.
**Results:** Data were collected from medical charts of 261 patients (ADA=106, 40.6%; ETN=155, 59.4%). The majority were female (76.2%), with a mean age of 57.2±13.0 years, and an average RA duration of 10.1±5.6 years. Hypertension (31.4%), osteoporosis (19.2%), other autoimmune diseases (16.9%), and dyslipidemia (14.2%) were the most common comorbidities. More than half of the patients had a longer-term follow-up between one year and18 months (58.6%: ADA=62, 40.5%; ETN=91, 59.5%). The majority of ADA patients were tapered to 40mg every three weeks (63.6%) or 40mg every four weeks (30.8%); most ETN patients were tapered to 25mg every 5 days (49.4%) or once a week (30.5%). Greater proportions of patients had an RA flare post-tapering (pre-tapering: 20.7%; post-tapering short-term: 44.1%; post-tapering longer-term: 73.9%). When compared to the pre-tapering period, the mean RA flare events per patient per year increased substantially post-tapering (pre-tapering: 0.5; post-tapering short-term: 1.2; post-tapering longer-term: 1.6, all $p<0.001$). Patients had increased office visits during the short-term (pre: 1.2 vs. post: 1.4 per patient per month, $p<0.001$).
**Conclusions:** Tapering biologic agents among stable RA patients may lead to an increase in RA flare and an increase in outpatient visits.

## FRI0197 TIME LAG OF IMPROVEMENT IN SYNOVIAL HYPERTROPHY COMPARED TO RAPID RESPONSE IN POWER DOPPLER SYNOVIAL VASCULARITY IN POST-ADALIMUMAB RHEUMATOID ARTHRITIS

Y.-C. Chen[1], J.-F. Chen[2], T.-T. Cheng[1]. *[1]Rheumatology; [2]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

**Background:** In previous studies, the patients achieved greater disease control by adalimumab at 24 weeks, this response was maintained over the next 24 weeks[1], however, we could not found the characteristic in image to confirm the clinical presentations.
**Objectives:** This study aimed to validate the use of power Doppler ultrasonography (PDUS) for evaluating synovial vascularity and synovial hypertrophy for synovitis in patients with rheumatoid arthritis (RA) treated with adalimumab.
**Methods:** The synovial disease activity and vascularity of RA on both wrists (radio-carpal joint) were assessed using GS and PDUS to derive the composite US scores based on abnormal counts and severity. The relationship between each measure was determined.
**Results:** The 71 patients who received adalimumab therapy had significantly decreased DAS28, ESR, and CRP. After one month, PD score decreased and then remained low for 12 months. Synovial hypertrophy did not change until 3–6 months after, when it started to improve ($p$=0.017). By multivariate analysis, sex,

age, BMI, and DAS28 did not lead to any difference between synovial hypertrophy and PDUS changes ($p$=0.498).
**Conclusions:** Composite US markers of synovial hypertrophy correlate significantly to the DAS28 score and ESR/CRP in adult RA. The time needed for synovial hypertrophy to decrease may be up to 3–6 months after adalimumab therapy. Using ultrasound Doppler measurements predict success of treatment with anti-TNF-alpha has been a trend in monitoring biological therapy in patients with RA

## Rheumatoid arthritis - other biologic treatment

### FRI0198 WHICH SERONEGATIVE RA PATIENTS RESPOND TO RITUXIMAB?

E.M. Vital[1,2], E.M. Hensor[1,2], P. Emery[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** RF-CCP- RA patients have inferior response to rituximab (RTX) but a subset respond as well as seropositive RA. RF-CCP- RA may have alternative markers of B cell dysfunction such as ANA or hypergammaglobulinaemia.
**Objectives:** To identify clinical predictors of response to rituximab in RF-CCP-RA as a means to select patients suitable for RTX.
**Methods:** Data from 7 clinical trials were pooled. Binary logistic regression models were used to test whether baseline factors affected odds of ACR20 at 24 weeks in patients negative for RF and CCP patients, controlling for trial. Non-response was imputed for patients who withdrew or were retreated prior to 24 weeks. Interaction terms were added to identify potential treatment effect modifiers ($p<0.2$ criterion).
**Results:** 396 patients had data available (mean age 52.3, 82% female, mean baseline DAS28CRP 5.5) of whom 155 (39%) achieved ACR20 at 24 weeks. Odds ratios are presented in Table 1. In addition to expected markers of therapy response, we found a relationship between higher IgG and increased odds of response with an interaction with rituximab dose. Overall, 2x1000mg was more effective than placebo, and the level of IgG did not influence the odds of response. In contrast, 2x500mg was increasingly effective compared to placebo with increasing IgG titre. Data on ANA status were more limited. We tested a model including ANA in a set of 301 patients. There was a trend to greater response in ANA positive patients (OR 1.49, CI 0.87 – 2.58). Controlling for ANA the interaction with IgG remained for rituximab 500mg (OR 1.1, CI 0.96 – 1.34)

Table 1. Odds of ACR20 response at 24 weeks according to variables at baseline, adjusted for all variables and data source (trial)

| Variable | Odds ratio (95% CI), *P* value | |
|---|---|---|
| | Main effects model | Interaction model |
| RTX dose 2x500mg | 1.4 (0.6, 2.9), p=0.442 | 1.3 (0.6, 2.8), p=0.507 |
| 2x1000mg | 2.5 (1.3, 5.0), p=0.009 | 2.4 (1.2, 4.8), p=0.010 |
| Number of previous DMARDs | 1.0 (0.8, 1.3), p=0.822 | 1.0 (0.8, 1.3), p=0.840 |
| Number of previous bDMARDs | 0.6 (0.4, 1.0), p=0.043 | 0.6 (0.4, 1.0), p=0.040 |
| Age, per 10 years | 1.23 (1.01, 1.50), p=0.036 | 1.23 (1.01, 1.50), p=0.038 |
| Female | 1.1 (0.6, 1.9), p=0.858 | 1.0 (0.6, 1.9), p=0.902 |
| BMI, per unit | 1.0 (0.9, 1.0), p=0.005 | 1.0 (0.9, 1.0), p=0.005 |
| Disease duration, per 5 years | 1.1 (0.9, 1.3), p=0.441 | 1.1 (0.9, 1.3), p=0.390 |
| Oral steroid use at baseline | 1.3 (0.8, 2.1), p=0.229 | 1.4 (0.8, 2.2), p=0.202 |
| DAS28CRP, per unit | 1.2 (0.9, 1.6), p=0.305 | 1.2 (0.9, 1.6), p=0.275 |
| HAQ, per unit | 0.8 (0.5, 1.2), p=0.343 | 0.8 (0.5, 1.2), p=0.295 |
| IGA, per g/L | 1.2 (1.0, 1.5), p=0.093 | 1.2 (1.0, 1.5), p=0.099 |
| IGG, per g/L | 1.1 (1.0, 1.1), p=0.021 | 1.0 (0.9, 1.2), p=0.867 |
| IGM, per g/L | 1.0 (0.7, 1.4), p=0.966 | 1.0 (0.7, 1.4), p=0.959 |
| IGG x RTX500 | | 1.1 (1.0, 1.3), p=0.140 |
| IGG x RTX1000 | | 1.0 (0.9, 1.2), p=0.614 |

**Conclusions:** The lower dose RTX appeared less effective in this group of patients overall. A subset of RF-CCP- patients with alternative markers of B cell mediated inflammation have more scope to respond to RTX. However, this effect is less relevant when the licensed dose is used. The efficacy of RTX in RF-CCP-ANA+ arthritis patients supports its efficacy in connective tissue diseases.

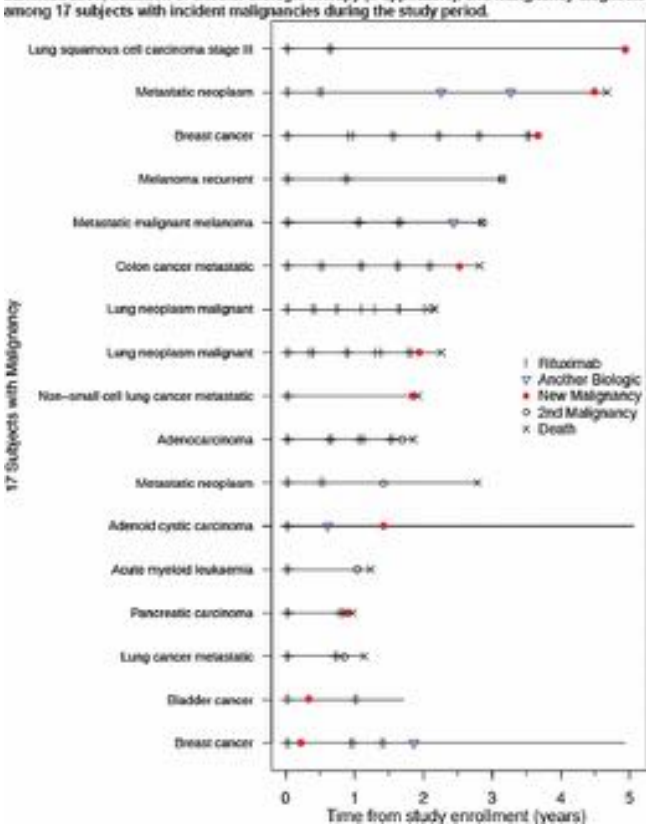
### FRI0199 RITUXIMAB IN COMBINATION WITH LEFLUNOMIDE: RESULTS FROM A MULTICENTER RANDOMIZED PLACEBO CONTROLLED INVESTIGATOR INITIATED CLINICAL TRIAL IN ACTIVE RHEUMATOID ARTHRITIS (AMARA-STUDY)

F. Behrens[1,2], T. Rossmanith[2], M. Köhm[1,2], R. Alten[3], M. Aringer[4], M. Backhaus[5], C. Baerwald[6], G. Burmester[7], E. Feist[8], H. Kellner[9], K. Krüger[10], U. Müller-Ladner[11], A. Rubbert-Roth[12], H.-P. Tony[13], S. Wassenberg[14], H. Burkhardt[1,2] on behalf of AMARA Study Group. *[1]Rheumatology, Goethe-University; [2]Clinical Research, Fraunhofer IME Project group TMP, Frankfurt; [3]Rheumatology, Schlosspark-Klinik, Berlin; [4]Medizinische Klinik und Poliklinik III, Universitätsklinik Dresden, Dresden; [5]Rheumatology, Park-Klinik Weissensee, Berlin; [6]Klinik für Gastroenterologie und Hepatologie, Universitätsklinik Leipzig, Leipzig; [7]Rheumatology; [8]Rheumtology, Charité Universitätsklinik Berlin, Berlin; [9]Rheumapraxis; [10]Praxiszentrum St. Bonifatius, München; [11]Rheumatology/Immunology, Kerckhoff-Klinik Bad Nauheim, Bad Nauheim; [12]Rheumatology, Universitätsklinik Köln, Köln; [13]Rheumatology/Immunology, Universitätsklinik Würzburg, Würzburg; [14]Evangelisches Fachkrankenhaus, Ratingen, Germany*

**Background:** Use of biologicals such as Rituximab (RTX) in Rheumatoid Arthritis (RA) is effective and often only licensed in combination with Methotrexate (MTX). In cases of contraindications to or intolerances, other cDMARDs are frequently used in routine care without data from RCTs.
**Objectives:** To demonstrate safety and efficacy of RTX in combination with Leflunomide (LEF) in a multicenter randomized placebo (PLA) controlled clinical trial in Germany.
**Methods:** A total of 189 patients with active RA (DAS28 >3.2 and at least 3 SJC and 3 TJC) despite stable LEF treatment were screened for a 52-weeks double-blind placebo controlled multicenter RCT. Patients were randomized to receive either two times 1000mg RTX i.v. or PLA, followed by a second course of RTX of either two times 500 or 1000 mg at week 24. The primary endpoint of the study was superiority of RTX in ACR20 and 50 responses vs. PLA during 24-weeks treatment period. Adult patients who had inadequate response to more than one antiTNF or failed more than three cDMARDs were excluded. Disease activity as well as patient reported outcomes were measured at each visit. For safety evaluation, frequency and severity of adverse events were documented.
**Results:** Of 189 screened patients 148 were randomized. The mean age was 56 years; the mean body weight 76 kg and 74% were female. The disease activity (DAS28) at baseline was 5.57 for RTX and 5.54 in the PLA group. All baseline-characteristics were well balanced between the treatment arms. RTX demonstrated significant superiority compared to PLA at week 16 in both, ACR 20 and ACR 50 response. ACR 20 response was significant superior for RTX treatment at weeks 12, 16 and 24 in both analyses, per protocol and modified intention to treat (see table). DAS28 levels in the RTX treatment-group decreased to 3.69 at week 24 (PLA 4.51) and to 3.01 at week 52. A total of 372 adverse events (AE) were observed during the one-year study period, only 14 were classified as severe (10 in RTX and 4 in PLA). 43 serious adverse events were reported, 28 of them in the RTX treatment group during the placebo controlled period.

Table 1

| | *Week 12* | | Week 16 | | Week 24 | |
|---|---|---|---|---|---|---|
| | RTX+LEF | PLA+LEF | RTX+LEF | PLA+LEF | RTX+LEF | PLA+LEF |
| ACR 20 (mITT) | 53.8* | 25.5 | 51.6* | 23.4 | 46.2* | 27.6 |
| ACR 50 (mITT) | 24.7* | 12.8 | 31.2* | 14.9 | 27.0 | 14.9 |
| ACR 20 (PPS) | 56.1* | 26.67 | 56.1* | 24.44 | 48.78* | 28.89 |
| ACR 50 (PPS) | 25.6 | 13.3 | 32.9* | 15.6 | 29.3 | 15.6 |



**Conclusions:** Here we report for the first time data of a RCT of combination of RTX with LEF. The treatment with RTX in combination with LEF demonstrated significant efficacy compared to the PLA for ACR20 response and for ACR50 response as well as reduction in DAS28. The highest level of response was seen at week 16. The combination of RTX and LEF demonstrated a reasonable safety profile.

## FRI0200 INCIDENT MALIGNANCIES FOLLOWING INITIATION OF RITUXIMAB FOR RHEUMATOID ARTHRITIS: ANALYSIS FROM THE SUNSTONE REGISTRY

M.D. Cascino[1], J. Pei[2], T. Haselkorn[2], A. John[2], A. Jahreis[2], D.E. Furst[3].
[1]*Division of Rheumatology, Department of Medicine, University of California, San Francisco, San Francisco;* [2]*Genentech, Inc., South San Francisco;* [3]*University of California, Los Angeles, Los Angeles, United States*

**Background:** Rheumatoid arthritis (RA) is associated with an increased incidence of malignancy compared to the general population. The long term safety of biologic therapies continues to be defined. Clinical trials of rituximab in the treatment of RA report an incident malignancy rate of 0.74 per 100 person years.[1]
**Objectives:** To describe the frequency and characteristics of incident malignancies in a real-world, observational cohort of rheumatoid arthritis (RA) patients initiating rituximab in the United States.
**Methods:** The Prospective Study of the Safety of Rituximab in Patients With Rheumatoid Arthritis After an Inadequate Response to Previous Anti-TNF Therapy (SUNSTONE) recruited patients from January 2007 to October 2008 from 173 private and academic practices across 38 states within the United States and Puerto Rico, with more than 350 rheumatologists contributing data. Included subjects were age 18 or greater with a diagnosis of RA and inadequate response to anti-tumor necrosis factor-$\alpha$ therapy (TNF-IR). Enrollment occurred at the time of treatment initiation with rituximab. Subjects were followed for 5 years or until death or loss to follow-up. Targeted safety events including malignancies were reported at follow up visits occurring at least every 6 months. Nonmelanoma skin cancers and non-malignant events were excluded. Standardized incidence rate (SIR) was calculated using the US National Cancer Institute Surveillance Epidemiology and End Results (SEER) reference population and matched for age and sex.
**Results:** 989 subjects were followed for a mean of 3.9 years and contributed 3844 person-years in total. There were 17 incident malignancies yielding an event rate of 0.44 per 100 person years (95% C.I. 0.27–0.71) and age- and sex-adjusted standardized incidence ratio (SIR) of 0.36 (95% C.I. 0.21–0.57). Malignancy diagnosis occurred a median of 22 months after rituximab initiation (range 2.6–59.3) and following a median of 2 treatment cycles (range 1–6). Lung cancer was the most common malignancy reported (n=5) followed by melanoma (n=2). Subjects diagnosed with malignancy were older (67.7 vs. 57.1 years, $P<0.001$) and more likely to report current or prior tobacco use (94% vs. 57%, P=0.002) than those not diagnosed with malignancy.

Schematic illustration of the temporal relationship between study enrollment, rituximab administration, initiation of another biologic therapy (if applicable), and malignancy diagnosis among 17 subjects with incident malignancies during the study period.

**Conclusions:** At five years' follow up, the observed rate of incident malignancies in this real-world cohort of RA patients treated with rituximab is not increased compared to the background population or clinical trials.

## FRI0201 RITUXIMAB TREATED NON RESPONDER RHEUMATOID ARTHRITIS PATIENTS ARE GENERATING A NEW AUTOANTIBODY REPERTOIRE

Z. Konthur[1], M.M. Wiemkes[2], T. Häupl[2], G.R. Burmester[2], K. Skriner[2].
[1]*Hennigsdorf, Germany, Drug Response Dx GmbH;* [2]*Department of Rheumatology and Clinical Immunology, Humboldt University and Free University, Berlin, Germany*

**Background:** Rituximab (RTX) has shown clinical efficacy but up to 40% of RTX treated rheumatoid arthritis (RA) patients are poor responders (ref:1) and the commonly used RA biomarkers (*RF/ACPA*) are poor predictors for therapy response. Others reported associations between BAFF/BLyS levels, Fcg RIII and IL-6 genotype, interferon type I signatures and Epstein-Barr virus genome in bone marrow and clinical outcome (ref:2).
**Objectives:** Analysis of the autoantibody repertoire from RA patients under RTX treatment on human genome protein macroarrays and it's correlation to clinical DAS28 response.
**Methods:** Screening of RA sera was conducted on 37.830 unique human expression clones with sera taken before and 24 weeks after treatment. The autoantibody response of different immunoglobulin classes IgD, IgA, and IgG was recorded and bioinformatically evaluated. Response was determined according to DAS28 criteria. DAS 28 scores in the responder group before treatment was from 5.4 – 7.8 and in the non-responder group 5,6 – 6,8. We analyzed 26 RA patient sera (9 responder, 7 non-responder and 10 patients with blinded response classification) investigated the data of found autoantigens *in silico* and by hierarchical clustering.
**Results:** In the cohort of 26 patients 1292 different autoantigens (IgD,IgA,IgG) were detected. Using protein array we investigated clusters of autoantigen responses that disappeared or developed during RTX treatment of RA patients. Post treatment developing responses against new autoantigens can be correlated to mRNA tissue expression data and were interestingly found organ-specifically expressed. RA autoantigenic patterns before and 6 month after RTX treatment were patient-specific and no relevant autoantigenic cluster was found that was shared between patients or associated with response. However, RTX reduced the repertoire of autoantibodies after 24 weeks of treatment in the tested RA patient cohort on average by 60%. RA patients which do not respond are generating on average 63% new autoantibodies. In good responders to RTX only 5,5% (±3%) new autoantibodies can be detected. The IgA and IgG autoantibody repertoire in the serum after 24 weeks of RTX treatment is reduced (IgA: 41%, IgG: 31%) in good responders whereas it is increased (IgA: 1,3%, IgG: 24%) in non responders to RTX.
**Conclusions:** RA patients present highly individual autoantibody profiles before and after RTX treatment, which do not reveal antigen-specific patterns for outcome prediction. However, after 6 month of RTX treatment the autoantibody repertoire in all good responding RA patients is reduced and non responders to RTX change their autoantibody repertoire directed against new but patient specific antigens. The fast rebuilding of functional B cells might be a underlying mechanistic difference between responders and non-responders to rituximab.

## FRI0202 SAFE AND EFFECTIVE TOCILIZUMAB THERAPY IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

C. Specker[1], J. Kaufmann[2], H. Kellner[3], P. Kästner[4], C. Volberg[5], V. Braunewell[6], A. Aringer[7], M. Sieburg[8], L. Meier[9], M.W. Hofmann[10], J.-P. Flacke[11], H.-P. Tony[12], G. Fliedner[13]. *[1]Klinik f. Rheumatologie u. **Background:** The single-arm non-interventional study ICHIBAN was set up to evaluate the effectiveness and safety of intravenously administered Tocilizumab (TCZ IV) in patients (pts) with moderate to severe rheumatoid arthritis (RA) in Germany. Clinical data were collected during routine medical consultations including concomitant therapies, co-morbidities, therapeutic responses and adverse events.

**Objectives:** This interim analysis assessed the effectiveness and safety of long-term TCZ IV treatment with respect to patients' age.

**Methods:** Since February 2010 ~250 German rheumatology study centres collected these prospective data. Pts were observed for a maximum period of 2 years (104 weeks). The present interim analysis included pts with complete baseline (BL) data before 03rd December 2015 (group total; n=2999). 902 pts have completed the maximal 104 week observation period (group W104). Subgroups according to age have been defined as <50 years, 50–65 years, >65 years.

**Results:** At BL the age distribution showed the following proportions: <50 years 28.9%, 50–65 years 48.6%, and >65 years 22.5%. The mean TCZ IV treatment duration was 1.7, 1.8, and 1.7 years, respectively, for the three age groups.

In comparison to younger pts, the elderly (>65 years) showed longer disease duration, higher inflammatory parameters, higher disease activity, and higher co-morbidity rates at BL. Nevertheless, TCZ IV showed comparable effectiveness in all age groups. At last visit, DAS28-BSG remission (<2.6) was reached by 55.2%, 51.6%, and 48.8% of pts aged <50, 50–65, and >65 years, respectively. The mean reduction from BL in DAS28-BSG was 2.6, 2.7, and 2.8, respectively.

Regarding co-medication, the mean glucocorticosteroid (GC) dose was reduced from 7.1 (BL) to 4.6 mg/d (last visit) and was similar in all subgroups. About 12% of pts stopped GC therapy completely, again similar in all subgroups. At baseline, the rate of TCZ monotherapy (without concomitant sDMARD) was highest in the elderly (53.2%) while combination therapy is more common in younger pts (47.1%). The rate of sDMARD discontinuation while receiving TCZ is comparable in all subgroups (11.5%, 12.1%, 12.3%).

**Table 1**

* Infections: All AEs/SAEs with a MedDRA Preferred Term indicating an infection

** In case of discontinuation of TCZ due to an AE, the last AE reported under TCZ administration was used

*** 5 Patients of this subgroup were older than 80 years. No serious infection, no gastrointestinal perforation nor a TCZ discontinuation due to an AE was observed within those 5 patients

# For both patients no history of gastrointestinal disease was documented

Despite slightly higher incidence rates of adverse events (AE) and serious adverse events (SAE) for the elderly, the rates of infections, serious infections and TCZ discontinuation rates due to an AE did not increase with age (Table 1). Gastrointestinal perforation was rarely observed.

**Conclusions:** TCZ IV treatment resulted in improvement of disease activity and reduction in concomitant GC dosing were observed. Despite higher disease burden at baseline, elderly RA patients (>65 years) benefited to the same extent as younger patients, without increased risk of infections. Considering natural age related risks, the low infection and gastrointestinal perforation rates of elderly patients seem to be attributable to the steroid sparing effect of TCZ therapy. Safety concerns should be no reason to argue against anti-IL-6 therapy in elderly patients.

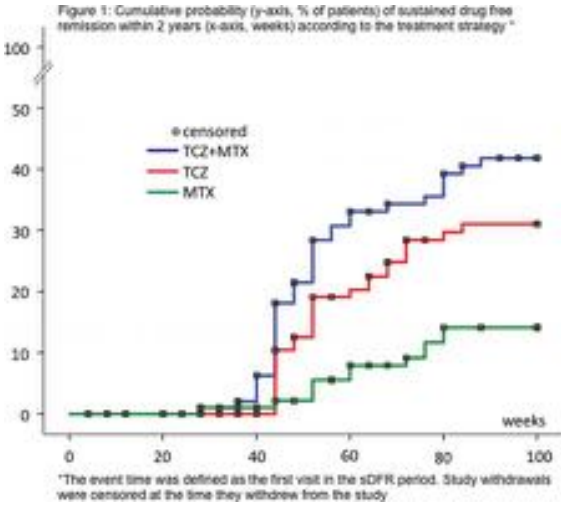
## FRI0203 SUSTAINED DRUG FREE REMISSION IN EARLY RA PATIENTS TREATED TO TARGET WITH TOCILIZUMAB, METHOTREXATE OR THEIR COMBINATION

X.M. Teitsma[1], J.W. Jacobs[1], P.M. Welsing[1], T.G. Woodworth[2], A. Pethö-Schramm[3], M.E. Borm[4], C. Bernasconi[5], F.P. Lafeber[1], J.W. Bijlsma[1]. *[1]Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands; [2]Rheumatology, David Geffen School of Medicine, UCLA; [3]Roche, Basel, United States; [4]Roche, Woerden, Netherlands; [5]Roche, Basel, Switzerland*

**Background:** The U-ACT EARLY study is a 2-year, randomized placebo-controlled, double blind study in which disease modifying antirheumatic disease (DMARD)-naive early RA patients were randomized to initiate tocilizumab (TCZ, n=103), methotrexate (MTX, n=108)) or their combination (n=106), and treated according to a step-up strategy. The primary endpoint, sustained remission (SR, defined as DAS28 <2.6 and <4 swollen joints for >24 weeks), was achieved by significantly more patients in the TCZ+MTX (86%) and TCZ (84%) groups, compared to MTX (44%). Here we report a post hoc analysis of sustained drug free remission (sDFR).

**Objectives:** To compare the number of patients achieving sDFR between the three treatment strategies.



**Methods:** We analyzed data of all 317 patients included in the study. TCZ was given intravenously (8 mg/kg 4 weekly) and MTX was increased over 3 months from 10 to 30 mg/week (or maximum tolerated dose) until remission. If remission was not reached after 20 weeks, hydroxychloroquine was added. Twelve weeks thereafter, if the target was not achieved, the placebo was substituted by TCZ/MTX. If SR was achieved, medication was tapered stepwise and stopped provided remission persisted. Differences in prevalence, time-to, and duration of sDFR (drug-free for >3 months with remission) were analyzed. To identify predictive factors for achieving sDFR, baseline data were analyzed using a backward selection procedure ($p \leq 0.10$).

**Results:** Table 1 shows baseline characteristics. The proportion of patients achieving sDFR was significantly higher in the TCZ+MTX (35%, $p<0.01$) and TCZ (27% $p<0.01$) strategy, compared to MTX (11%, Fig. 1). In patients achieving it, the median time (IQR) to achieve sDFR was shorter in the TCZ+MTX (48 (44–56) weeks; p=0.09) and TCZ strategy (52 (44–67) weeks; p=0.18) when compared to MTX (60 (52–76) weeks). The median duration (IQR) of sDFR within the study period was 44 (16–56), 32 (20–48) and 28 (20–44) weeks (p=0.15) in the TCZ+MTX, TCZ and MTX group, respectively. Baseline HAQ (OR 0.2 (95% CI: 0.1–0.4), any (RF and/or anti-CCP) seropositivity (OR 0.5 (95% CI: 0.2–0.8) and initiation with TCZ+MTX (OR 3.9 (95% CI: 1.9–8.3) or TCZ (OR 3.4 (95% CI: 1.5–7.3) were significant predictors for achieving sDFR. The Area Under the Curve (AUC-ROC) of the multivariable model was 0.73 (95% CI: 0.67–0.80), indicating fair discriminative ability. In our sample, a classifier with

Table 1. Characteristics of the 317 patients with early rheumatoid arthritis

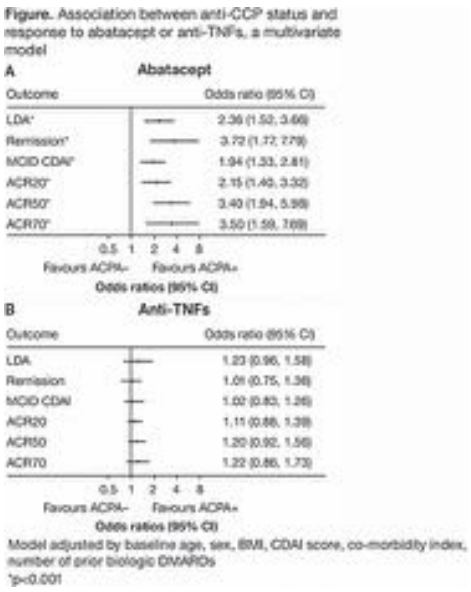
## FRI0204 EFFECT OF TOCILIZUMAB TREATMENT ON QTC INTERVAL IN PATIENTS WITH RHEUMATOID ARTHRITIS WITHOUT CARDIAC SYMPTOMS



I. Yokoe, H. Kobayashi, A. Nishiwaki, K. Sugiyama, Y. Nagasawa, H. Karasawa, M. Iwata, T. Nozaki, N. Ikumi, H. Inomata, H. Shiraiwa, N. Kitamura, M. Takei.
*Division of Hematology and Rheumatology, Nihon University School of Medicine, Tokyo, Japan*

**Background:** Individuals with rheumatoid arthritis (RA) are at a 2-fold increased risk of sudden death compared with age- and gender-matched controls without RA. Although mechanisms underlying the increased risk are yet unclear, evidence indicates effects of systemic inflammation on ventricular repolarization. Accordingly, corrected QT (QTc) interval prolongation is more frequent in patients with RA than in those without RA. A previous pilot study reported that tocilizumab (TCZ) normalizes the QTc interval by dampening systemic inflammation.
**Objectives:** Our study prospectively evaluates TCZ treatment effects on the QTc interval of patients with RA without cardiac symptoms and explores the association between this QTc interval and RA disease activity and severity measures.
**Methods:** This prospective interventional study was conducted between March 2012 and August 2015 at the Itabashi Chuo Medical center. Patients who fulfilled the American College of Rheumatology (ACR) RA classification criteria or the 2010 ACR/ European League against Rheumatism RA criteria were included. Exclusion criteria included diabetes, history of cardiovascular events, hypertension (systolic blood pressure (BP) >140 mm Hg and/or diastolic BP >90 mm Hg), dyslipidemia (LDL cholesterol levels >140 mg/dL, HDL cholesterol level <40 mg/dL, or triglyceride level >150 mg/dL), cardiomyopathy, renal disease, and current atrial fibrillation. Age- and gender-matched healthy controls without any cardiac symptoms were selected. Patients with active RA with inadequate clinical response to methotrexate (MTX) were administered tocilizumab (TCZ 8 mg/kg IV every 4 weeks or 162 mg SC biweekly). Electrocardiography and clinical and biological monitoring were performed at baseline and 24 weeks after TCZ treatment in patients with RA.
**Results:** Ninety patients with RA (mean age: 56.4±10.4 yers; 85% female) and 40 age and gender matched healthy controls (mean age 55.6±3.4 years; 86% female) were included, of which 20% and 13% of RA patients received antihypertensive and antihyperlipidemia therapy, respectively. No significant differences were observed in mean Framingham 10 scores between healthy controls and patients with RA at baseline. The 24-week Simplified Disease Activity Index scores were significantly lower than those at baseline. Using previously established cutoffs (440 ms), we identified 8 (10%) patients with abnormal QTc interval prolongation. However, QTc intervals at baseline were higher in patients with RA than in controls (mean SD 420.3 ± 35.8 msec, mean SD 411 ± 31.2 msec; p=0.04). The QTc interval decreased by 20.9 msec from baseline to 24 weeks (p=0.001) following TCZ treatment. QTc interval prolongation at baseline was significantly correlated with the anticyclic citrullinated peptide antibody (ACPA) at baseline (p=0.003). ACPA at baseline (p=0.001) was associated with %change in QTc interval. Furthermore, no significant associations between QTc interval and RA activity were observed.
**Conclusions:** Tocilizmab treatment in patients with RA decreases QTc interval. Furthermore, anti-arrhythmic potential of TCZ treatment may have beneficial effects in patients with RA. Our results provide further evidence regarding the close association between ACPA degree and QTc intervals.
**Disclosure of Interest:** None declared

## FRI0205 RELATIONSHIP BETWEEN ANTI-CITRULLINATED PROTEIN ANTIBODY STATUS AND RESPONSE TO ABATACEPT OR ANTI-TUMOUR NECROSIS FACTOR THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A US NATIONAL OBSERVATIONAL STUDY

L.R. Harrold[1], H.J. Litman[2], S.E. Connolly[3], S. Kelly[3], W. Hua[2], E. Alemao[3], L. Rosenblatt[3], S. Rebello[2], J. Kremer[4]. *[1]University of Massachusetts Medical School, Worcester; [2]Corrona, LLC, Southborough; [3]Bristol-Myers Squibb, Princeton; [4]Albany Medical College and The Center for Rheumatology, Albany, United States*

**Background:** Anti-citrullinated protein antibodies (ACPA) are associated with more severe, erosive rheumatoid arthritis (RA), but the extent to which ACPA status predicts response to therapy is not known.[1,2]
**Objectives:** To evaluate in a real-world, observational RA cohort whether baseline ACPA status is associated with response to biologics among patients with RA.
**Methods:** Using the Corrona RA registry, we identified patients with RA who initiated abatacept (ABA) or a tumour necrosis factor-alpha inhibitor (TNFi) between June 2002 and January 2015, had a follow-up visit 6 months (±3 months) after initiation and anti-cyclic citrullinated peptide (anti-CCP [a surrogate of ACPA]) measured at or prior to initiation. Anti-CCP positivity was defined as anti-CCP ≥20 U/mL. The primary outcome was mean change from baseline in Clinical Disease Activity Index (CDAI) at 6 months. Secondary outcomes at 6 months included: 1) achievement of low disease activity (LDA; CDAI ≤10) among those with moderate or high disease activity who initiated treatment; 2) achievement of remission (CDAI ≤2.8) in those with low, moderate or high disease activity who initiated treatment; 3) Minimally Important Clinical Difference (MCID) in CDAI; and 4) modified ACR20/50/70. Unadjusted and adjusted linear and logistic analyses were performed based on anti-CCP status (positive [+] vs negative [–]).
**Results:** 566 patients initiated ABA: 204 (36.0%) were anti-CCP– and 362 (64.0%) anti-CCP+. There were no differences by CCP status for age (mean 57–58 years), disease duration (median 7 years) or prior biologic use (0, 1 or ≥2 prior); however, median baseline CDAI was greater in anti-CCP– vs anti-CCP+ patients (21 vs 19, p=0.035). 1715 patients initiated a TNFi: 602 (35.1%) were anti-CCP– and 1113 (64.9%) anti-CCP+. There were no differences by CCP status for age (mean 55–56 years), prior biologic use or median baseline CDAI; however, median disease duration was greater in anti-CCP+ vs anti-CCP– patients (4 vs 3 years, p=0.021). In adjusted analyses, anti-CCP+ ABA initiators had a mean (SE) change in CDAI of –8.5 (0.6) vs –4.1 (0.8) for anti-CCP– (p<0.001); in TNFi initiators, this was –7.4 (0.3) vs –6.4 (0.4) (p=0.071). In the multivariate model for secondary outcomes, the magnitude of response was greater in anti-CCP+

vs anti-CCP– ABA initiators. Outcomes did not differ by anti-CCP status in TNFi initiators (Figure).

**Conclusions:** In a clinical practice setting, anti-CCP positivity was associated with a differential treatment response to abatacept, but not TNFis. These real-world data suggest that anti-CCP+ patients with RA show incremental improvements in response while receiving abatacept therapy compared with anti-CCP– patients.

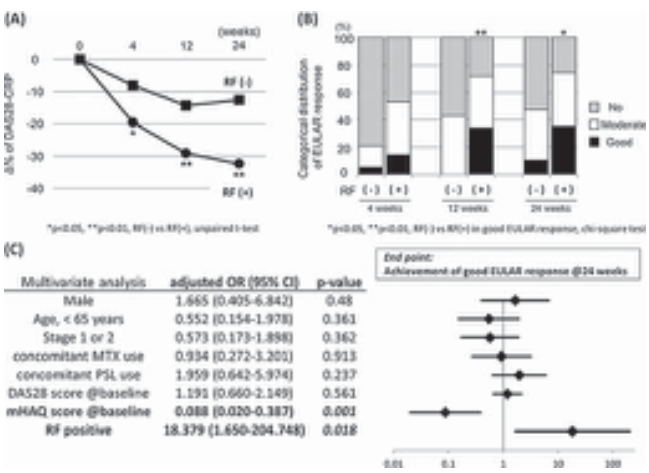
## FRI0206 SERO-POSITIVITY FOR RHEUMATOID FACTOR IS AN INDEPENDENT PREDICTOR FOR ACHIEVEMENT OF GOOD EULAR RESPONSE AT 24 WEEKS IN ACPA POSITIVE RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT: RESULTS FROM JAPANESE MULTICENTER REGISTRY



N. Takahashi, T. Kojima, K. Funahashi, N. Ishiguro on behalf of TBCR Study Group. *Orthopaedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** Abatacept is a new class of biologic agent for the treatment of rheumatoid arthritis (RA) that inhibits T cell activation by binding to CD80/86. Although some clinicians feel that the rapidity of treatment response of abatacept is slower than that of tumor necrosis factor (TNF)-inhibitors, some patients can respond to abatacept treatment quite rapidly. Recently, some reports have been published regarding the positive association between sero-positivity for anti-citrullinated protein antibody (ACPA) and clinical efficacy of abatacept in RA patients (1).

**Objectives:** The aim of this study was to demonstrate the effect of double-seropositivity for ACPA and rheumatoid factor (RF) on the rapidity of treatment response of abatacept using data from a Japanese multicenter registry system for RA patients treated with biologic agents.

**Methods:** Participants were selected from the consecutive 508 RA patients treated with abatacept who were registered in the Tsurumai Biologics Communication Registry (TBCR). We excluded the patients with previous biologic agent treatment history since it has been already reported as an independent factor affecting the clinical efficacy of abatacept (2). A total of 146 biologics-naïve and ACPA positive patients with baseline data of RF were included in this study. We compared the proportion of patients that achieved good EULAR response at 24 weeks between the RF negative and RF positive (>20 U/ml) group within the ACPA positive patients. We defined the ACPA positive as >13.5 U/ml of anti-CCP antibody (3 times cutoff value) to ensure that the positivity was reasonably sure.

**Results:** In the ACPA positive patients, the percent decreasing of DAS28-CRP scores in the RF positive group were significantly greater than those in the RF negative group at all time points (Figure A, e.g. -32.3 vs -12.6% at 24 weeks, $p<0.01$). The proportion of patients that achieved the good EULAR response was significantly higher in the RA positive group at 12 and 24 weeks (Figure B). Multivariate logistic regression analysis (adjusted with gender, age, Steinbrocker's stage, concomitant MTX and oral steroid usage, and DAS28-CRP score at baseline) revealed that the RF positivity, along with the modified HAQ score at baseline, was the independent predictor for the achievement of good EULAR response at 24 weeks (Figure C).

**Conclusions:** We clearly demonstrated that the positive association of the double-seropositivity for ACPA and RF with the rapid and good clinical response for abatacept in the biologics-naïve RA patients. This new clinical evidence regarding the effect of double-seropositivity is the valuable real-world data for the prediction of clinical efficacy of abatacept in daily clinical practice.

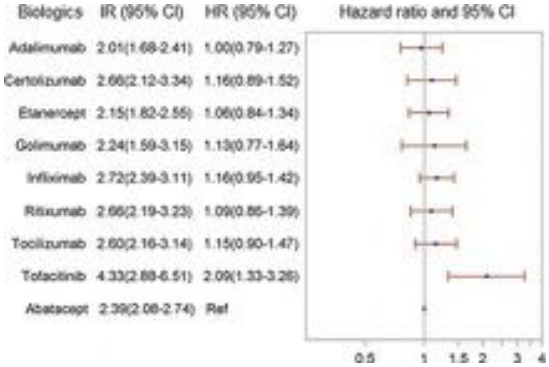
## FRI0207 REAL-WORLD COMPARATIVE RISKS OF HERPES VIRUS INFECTIONS IN TOFACITINIB AND BIOLOGIC-TREATED RHEUMATOID ARTHRITIS PATIENTS

J.R. Curtis[1,2], F. Xie[2], H. Yun[2], S. Bernatsky[3], K.L. Winthrop[4]. *[1]Epidemiology; [2]Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham; [3]Division of Gastroenterology, University of Pennsylvania, Philadelphia; [4]Infectious Diseases, Oregon Health & Science University, Portland, United States*



**Background:** While placebo-controlled clinical trials have suggested an increased rate of herpes zoster (shingles) with tofacitinib, the real-world risks of herpes zoster and herpes simplex associated with tofacitinib compared to other biologics for rheumatoid arthritis are largely unknown.

**Objectives:** To evaluate the risks of herpes zoster (HZ) and herpes simplex virus infection (HSV) associated with tofacitinib compared to biologic agents among patients with rheumatoid arthritis (RA).

**Methods:** Using health plan data, we identified RA patients without a history of HZ or HSV who initiated tofacitinib or biologics from 2010–2013. Among this cohort, new cases of HZ or HSV were found and incidence rates calculatedby drug. We used Cox proportional hazards models evaluated the adjusted association between tofacitinib and either HZ, and a composite outcome of HZ or HSV.

**Results:** A total of N=1,746 patients initiating tofacitinib were compared with initiations of other biologics including anti-TNF (n=38,871), abatacept (n=11,434), rituximab (n=4,785), and tocilizumab (n=6,266). Tofacitinib patients were somewhat younger (mean age 57 years) versus those on other biologics, and somewhat less likely to use concomitant MTX (39% vs. 44–56%, depending on drug).

Crude incidence of HZ associated with tofacitinib was 4.33/100py and after multivariable adjustment, was significantly elevated (hazard ratio, HR=2.09, 95% CI 1.33–3.26) compared to abatacept (referent). Rates and adjusted HRs for all other RA biologics were comparable to each other and abatacept. Older age, female sex, prednisone >7.5mg/day, prior outpatient infection, and greater number of hospitalizations were also associated with increased HZ risk Incidence rates for the combined outcome were greatest for tofacitinib (9.33/100py) and also significantly elevated after adjustment (HR=1.65, 95%CI 1.21–2.23).

**Conclusions:** Zoster infections were relatively common among RA patients. The

risk for zoster associated with tofacitinib was approximately double that observed in patients using biologics.

## FRI0208 ABATACEPT THERAPY COMBINED WITH TACROLIMUS FOR RHEUMATOID ARTHRITIS PATIENTS SHOWS SUPERIOR EFFICACY THAN ABATACEPT THERAPY WITHOUT TACROLIMUS

A. Nampei[1], Y. Nagayama[2], H. Tsuboi[2]. [1]*Orthopedic Surgery, Osaka Minami Medical Center, Kawachinagano;* [2]*Orthopedic Surgery, Osaka Rosai Hospital, Sakai, Japan*

**Background:** Abatacept (ABT) and tacrolimus (TAC) are similar at the point that both drugs block the T cell activation. ABT blocks co-stimulatory signaling from CD80/86 on the surface of antigen-presenting cell. TAC blocks the calcineurin activity in T cells. The each effectiveness of ABT and TAC respectively for the treatment of rheumatoid arthritis (RA) is apparent, however, the efficacy and safety at concomitant use of ABT and TAC was not unclear and there are few reports [1,2].

**Objectives:** The objective of this study is comparison between ABT therapy for RA patients with and without TAC.

**Methods:** Forty eight RA patients were included in this observational retrospective study, who were undertaken intravenous ABT therapy at Osaka Rosai Hospital after February 2011 and could be observed over 52 weeks. Patient background, efficacy, and safety were examined.

**Results:** Mean age was 67.4 years, disease duration was 10.8 years. Concomitant use of methotrexate was 58%, of prednisolone was 56% and prior biologics use was 48%. Concomitant use of TAC was 31%. Mean tacrolimus dose was 2.0g (1.0–3.0). The retension rate of ABT at 52 weeks was 80.8%. DAS28CRP was decreased significantly at 4 weeks (-16.5% from baseline, $p<0.001$), and gradually decreased until 24 weeks (-37.3%, $p<0.001$) and maintained until 52weeks (-39.3%, $p<0.001$) by Wilcoxon signed rank test. Patient background between ABT + TAC group (n=15) vs ABT group (n=33) were not significantly different (age, sex, disease duration, stage, class, concomitant use of prednisolone, MTX, prior biologics, baseline DAS28CRP, positivity of RF, ACPA) by chi-square test and Mann-Whitney U test. DAS28CRP of ABT + TAC group decreased significantly greater than ABT group at 16 weeks (-42.9% vs -30.3%, p=0.048), maintained until 52 weeks (-50.1% vs -34.5%, p=0.017) by Mann-Whitney U test. Adverse event between ABT + TAC and ABT group was not different. Predictive factor that achieve the low disease activity at 52weeks were Steinbrocker class1/2 (p=0.047), concomitant use of TAC (p=0.043) and DAS<3.3 at 12 weeks (p=0.005) by multivariate logistic regression analysis.

**Conclusions:** ABT therapy concomitant with TAC has the possibility to show higher effectiveness for RA patients than ABT therapy without TAC.

## FRI0209 MORAB-022, AN ANTI-GRANULOCYTE MACROPHAGE-COLONY STIMULATING FACTOR (GM-CSF) MONOCLONAL ANTIBODY (MAB): RESULTS OF THE FIRST STUDY IN PATIENTS WITH MILD-TO-MODERATE RHEUMATOID ARTHRITIS (RA)

A. Kivitz[1], L. Hazan[2], K. Hoffman[3], B.A. Wallin[3]. [1]*Altoona Center for Clinical Research, Altoona;* [2]*Axis Clinical Trials, Los Angeles;* [3]*Clinical Development, Morphotek, Inc., Exton, United States*

**Background:** GM-CSF plays a central role in the inflammatory immune response cascade. GM-CSF is expressed at higher levels in the synovial fluid of patients with RA. Therefore, neutralization of GM-CSF activity by specific mAbs could be beneficial in treating RA (Cornish, et al., 2009). MORAb-022 is an investigational monoclonal antibody with high affinity for GM-CSF.

**Objectives:** This Phase 1 study (NCT01357759) evaluated the safety and tolerability, pharmacokinetics/pharmacodynamics and preliminary evidence of activity of MORAb-022 in healthy subjects (HS) as well as in patients (Pts) with mild-to-moderate active RA.

**Methods:** This was a double-blind, placebo-controlled, randomised, dose-escalating study in HS as well as in Pts with mild-to-moderate RA (according to ACR 2010 criteria) receiving stable MTX doses for ≥12 weeks prior to randomisation. HS received a single intravenous (IV) infusion of MORAb-022 0.0085, 0.042, 0.12, or 0.36 mg/kg or placebo and Pts received 0.36, 0.7, 1, 3, or 10 mg/kg or placebo on Day 1 with 85 days' follow-up. Clinical efficacy was an exploratory endpoint measured by DAS28 (CRP), ACR20 and ACRn.

**Results:** 26 HS and 25 RA patients were enrolled (HS:77% male, mean age 41.1 years; Pts:56% females, mean age 55.4 years). Mean DAS28 (CRP) at baseline: placebo=4.1; MORAb-022, 0.36=3.6; MORAb-022, 0.7=4.5; MORAb-022, 1=3.8; MORAb-022, 3=3.8; MORAb-022, 10=4.8. MORAb-022 was generally well-tolerated. 14 treatment-emergent adverse events were observed in 25 Pts (56%). There was no evidence of immunogenicity. The mean $C_{max}$ and $AUC_{0\text{-}inf}$ for MORAb-022 increased approximately dose proportionally in both HS and Pts. The median half-life for MORAb-022 ranged from 9 to 13 days in both HS and Pts. All of the MORAb-022 dose cohorts demonstrated decreases in median DAS28 (CRP), however only the 10 mg/kg cohort showed a median decrease of more than 1.2 units by Day 2 (see Table). For Pts who received placebo, there was no discernable change in median DAS28 (CRP) results. 3/6 Pts who received placebo achieved an ACR20 response at any time as compared to 3/4 Pts in each of the 0.7 mg/kg, 3 mg/kg, and 10 mg/kg cohorts. 10 mg/kg dose cohort Pts demonstrated improvement in ACRn at Day 2, which was maintained through Day 29. The best mean (SD) ACRn for these Pts was 54.96 (40.52).

Table 1. DAS28 (CRP)

| Visit | Placebo | 0.36 | 0.7 | 1 | 3 | 10 |
|---|---|---|---|---|---|---|
| Baseline, n | 6 | 3 | 4 | 4 | 4 | 4 |
| Mean (SD) | 4.13 (0.4) | 3.76 (0.3) | 4.66 (0.9) | 3.94 (1.5) | 3.72 (1.3) | 4.62 ( 0.7) |
| Change from baseline | | | | | | |
| Day 2, n | 6 | 3 | 4 | 4 | 4 | 4 |
| Mean (SD) | 0.02 (0.7) | 0.49 (0.4) | –0.56 (0.60) | 0.07 (1.2) | –0.25 (1.2) | –1.34 (1.6) |
| Day 8, n | 6 | 3 | 4 | 4 | 4 | 4 |
| Mean (SD) | –0.28 (1.0) | –0.65 (0.7) | –0.29 (0.6) | –0.71 (0.6) | –0.52 (0.9) | –1.29 (1.0) |
| Day 15, n | 6 | 3 | 4 | 4 | 4 | 4 |
| Mean (SD) | –0.28 (1.3) | –0.48 (0.4) | –0.45 (0.6) | –0.78 (0.4) | –0.19 (1.1) | –1.02 (0.7) |
| Day 29, n | 6 | 3 | 4 | 4 | 4 | 3 |
| Mean (SD) | –0.56 (1.2) | –0.55 (0.5) | –0.46 (0.6) | –0.34 (0.8) | –0.04 (0.9) | –1.40 (1.6) |

**Conclusions:** MORAb-022 was generally well-tolerated in HS as well as in active RA Pts. Preliminary evidence of activity was observed but further evaluation is needed due to the small sample size in this study. PK was linear with a t1/2 =9–13 days.

## FRI0210 CD16+ NK CELLS ARE PERSISTENTLY INCREASED AFTER RITUXIMAB THERAPY IN RHEUMATOID ARTHRITIS PATIENTS

A. Giollo[1], O. Viapiana[1], A. Carletto[1], D. Gatti[1], R. Ortolani[2], S. Adami[1], M. Rossini[1]. [1]*Rheumatology Section, Department Medicine;* [2]*Immunology Section, Department Pathology, University of Verona, Verona, Italy*

**Background:** The clinical response of rituximab (RTX) is related to the degree of B cell depletion, although flow cytometry analysis of peripheral blood leukocytes after RTX therapy has shown some effects on other cell types in addition to B lymphocytes. Currently, however, data on NK cells changes after RTX are lacking.

**Objectives:** The primary objective was to investigate the changes in lymphocyte sub-populations in real-life rheumatoid arthritis (RA) patients treated with RTX, with particular attention to NK cells and their subpopulations. The secondary objective was to analyze the correlations between lymphocyte changes and the therapeutic response of RA patients treated with RTX.

**Methods:** In 33 RA patients diagnosed according the 1987 ACR criteria peripheral blood B and T lymphocytes and NK cells subtypes were counted by flow cytometry before and 3, 6 and 12 months after RTX administration. Patients received a 1,000-mg infusion of RTX preceded by a 100-mg methylprednisolone intravenous pulse, at baseline and at week 2. Twenty-two patients (67%) were treated with another course of RTX after 6 months from baseline. Clinical assessment was performed with the disease activity score in 28 joints (DAS28) with C-reactive protein (CRP) and the EULAR response criteria at each visit. Natural killer (NK) cells were counted using APC-CY7-conjugated anti-CD16 and PE-conjugated antiCD56.

**Results:** RTX significantly increased $CD56^+3^-$ and $CD56^{dim}CD16^+$ NK cells at 3 months (27% [interquartile range, IQR =46] and 33% [50] respectively, $p\leq0.001$). The punctual increase persisted both at month 6 and month 12 only for $CD56^{dim}CD16^+$ NK cells (24% [88], p=0.011 and 41% [80], p=0.002, respectively). The 22 patients who were treated with a second course of RTX showed an increase respect month 6 values in $CD56^{dim}CD16^+$ cell counts, at month 12 (nonretreatment vs retreatment: - 18% [21] vs 24% [41]; p=0.002). $CD56^{dim}CD16^+$ absolute counts were correlated with DAS28 values at baseline ($\rho$=0.355, p=0.043), month 3 ($\rho$=0.353, p=0.044) and month 6 ($\rho$=0.526, p=0.002), and were higher in nonresponders than in responders (n.s.). The $CD56^{bri}16^-$ NK cells were unaffected from RTX. No significant changes in $CD3^+$, $CD4^+$ and $CD8^+$ cells were observed during the whole study period.

**Conclusions:** In RA patients, RTX treatment is associated with a persistent increase in $CD56^{dim}CD16^{+}$ NK cells, although a trend to restoration to baseline values is seen after 12 months. A second course could mantain the initial increase. Therefore, homeostasis of $CD16^{+}$ cells is somehow influenced by anti-CD20 therapy. A correlation between $CD16^{+}$ NK cell changes and disease activity after RTX is probable, although the association with clinical response remains to be proved.

## FRI0211 TAPERING MTX VERSUS STEADY-STATE MTX IN COMBINATION WITH TOCILIZUMAB FOR TREATMENT OF RHEUMATOID ARTHRITIS (ACT-TAPER): A RANDOMISED, DOUBLE-BLIND, CONTROLLED PHASE 4 TRIAL

C.J. Edwards[1], P. Kiely[2], A. Ostor[3], B. Naisbett-Groet[4]. *[1]University Hospital Southampton, Southampton; [2]St George's Hospital, London; [3]Addenbrooke's Hospital, Cambridge; [4]Roche Products Ltd, Welwyn Garden City, United Kingdom*

**Background:** For most DMARD-IR patients (pts) with severe active RA, therapy with a biologic and methotrexate (MTX) is effective. However, nearly 1/3 discontinue or are non-compliant with MTX because of toxicity or preference[1–4]. Previous data showed tocilizumab (TCZ) was effective as monotherapy in MTX-intolerant pts or pts for whom MTX was ineffective or inappropriate[4,5]. In addition, the ACT-RAY study suggested tapering MTX may result in maintained efficacy and an improved safety profile.
**Objectives:** To explore if TCZ + tapering MTX has comparable efficacy and safety vs TCZ + stable MTX in pts with inadequate response to MTX [EudraCT 2011–005260–20].
**Methods:** ACT-TAPER was a randomised, placebo-controlled non-inferiority study investigating efficacy and safety of tapering MTX vs stable MTX in DMARD-IR pts with severe active RA (DAS28 $>$5.1) who had initiated TCZ + MTX at study start. At Week (Wk) 0, DMARDs except MTX were discontinued; pts started open-label TCZ (8 mg/kg IV 4 weekly) and open-label MTX. At Wk 24, pts achieving good/moderate EULAR response were randomised to Group A (double-blind MTX taper) or Group B (double-blind MTX maintenance). Both continued open-label TCZ. Pts achieving adequate improvement stayed in treatment groups to Week 72. Primary analysis: proportion of pts maintaining good/moderate EULAR from wks 24–60 in TCZ + MTX taper vs TCZ + stable MTX. Secondary analyses included safety outcome measures.
**Results:** The study stopped early due to low recruitment; 427 pts entered the initial open-label phase (IP) of the study and 272 pts were randomised (36% withdrew or were not eligible to be randomised; protocol required 494 pts to be randomised), 136 in each arm. Of the IP population, 64.4% achieved good/moderate EULAR at Wk 24, with 45.0% achieving DAS28 $\leq$3.2, 33.5% remission (DAS28 $<$2.6) and 64.2% with DAS28 change $\geq$1.2. After Wk 24 randomisation, the proportion of pts maintaining good/moderate EULAR to Week 60 was greater for MTX taper vs stable MTX (76.5% vs 65.4%). This allowed the pre-determined criteria for non-inferiority to be fulfilled despite the reduced recruitment. The proportion of pts achieving a change $\geq$1.2 DAS28 at Wk 60 did not differ significantly between groups; mean (SD) change from Wk 24–60 was -0.179 (1.1702) Group A and -0.233 (1.5156) Group B. The proportion of pts with DAS28 $\leq$3.2 at Wks 60 and 72 did not differ significantly between groups (59.6% and 61.0% for Group A; 62.5% and 60.3% for Group B). The proportion of pts in remission at Wks 60 and 72 did not differ significantly between treatments. Safety analysis revealed no unexpected TCZ safety signals.
**Conclusions:** Tapering MTX in RA pts using TCZ was non-inferior to continuing stable MTX in maintaining a good/moderate EULAR response. No significant change in DAS28 was observed between groups. There were no unexpected safety signals; TCZ and MTX therapy was generally well tolerated in both groups.

## FRI0212 COMPARISON STUDY OF TESTS AVAILABLE TO MONITOR TOCILIZUMAB THERAPY IN RHEUMATIC PATIENTS

S. Martín[1,2], A. Ruiz del Agua[1], N. Torres[1], D. Pascual-Salcedo[3], C. Plasencia[4], T. Jurado[4], A. Martínez[3], A. Balsa[4], B. Ruiz-Argüello[1], A. Martínez[1], R. Navarro[2], D. Nagore[1]. *[1]R&D, Progenika-Grifols, Derio; [2]Physiology, University of the Basque Country, Lejona; [3]Immunology; [4]Rheumatology, Hospital La Paz, Madrid, Spain*

**Background:** The options for treatment of rheumatic diseases is constantly growing. Tocilizumab (TCZ) is an anti-interleukin 6 receptor monoclonal antibody indicated for the treatment of severe active and progressive rheumatoid arthritis (RA) and active systemic juvenile idiopathic arthritis (sJIA). Monitoring of drug levels (DL) and anti-drug antibodies (ADA) in clinical practice is highly advisable in order to establish normal therapeutic ranges, complement clinical assessment and optimise patient treatment. As a consequence several tests and technologies have been developed. However, a common objection that limits implementation of biological drug monitoring in medical practice is the claim that the magnitude of measurements varies among assays and that assay standardisation is lacking.
**Objectives:** The purpose of this study was to evaluate the correlation and agreement between different commercially available tests to measure TCZ and antibodies to TCZ (ATT) in patients with rheumatic diseases.
**Methods:** Trough levels of TCZ and ATT were analyzed in a retrospective cohort of 26 rheumatic patients (42 serum samples, 88% RA and 12% sJIA) under maintenance therapy with TCZ for up to two years. Samples were assayed using Promonitor-TCZ and Promonitor-ANTI-TCZ ELISA kits (PR, Progenika, Spain), LISA-TRACKER Duo Tocilizumab ELISA kit (LT, Theradiag, France), and by Sanquin Blood Supply testing service (SQ, Amsterdam, The Netherlands) that uses ELISA and RIA technologies to measure TCZ and ATT levels, respectively. One-way analysis of variance (ANOVA) and Spearman's test was used to study correlation between the DL tests; the difference (bias) in values obtained with DL assays was also assessed with Bland-Altman analysis. Percentage of positive and negative agreement was used to study the association between the ADA assays.
**Results:** TCZ trough level in patients are much higher than other biological treatments like anti-TNF infliximab and adalimumab. ANOVA analysis showed that the differences in the median values among the three DL assays are not statistically different (median 4.4 vs 4.7 vs 5.4 $\mu$g/mL, IQR 0 – 8.7 $\mu$g/mL vs 0 – 7.8 $\mu$g/mL vs 0 – 9.4 $\mu$g/mL for Promonitor-TCZ, LISA-TRACKER and Sanquin ELISA tests, respectively, $p$=0.693). Spearman's coefficient showed a very high correlation between the each pair of assays ($r$=0.951, 0.935 and 0.944 for PR vs LT, PR vs SQ and LT vs SQ, respectively, p$<$0.0001). Bland-Altman analysis shows an excellent association between each pair of DL assays with no significant difference in bias (-0.3, -0.5 and -0.2 $\mu$g/mL for PR vs LT, PR vs SQ and LT vs SQ, p$>$0.05). Antibodies to TCZ were not detected with any of the assays in the patient cohort confirming the low immunogenicity of TCZ.
**Conclusions:** Despite different reagents, assay formats and technologies, all tests studied here provide exactly the same results and measure the same magnitude of TCZ in rheumatic patients. Assays can be safely exchanged in a clinical setting even in the absence of a gold standard test, and should lead to similar drug therapeutic ranges and actions.

## FRI0213 IDENTIFICATION OF SYNOVITIS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CLINICAL REMISSION DURING THERAPY WITH TOCILIZUMAB

E. Panasyuk, A. Smirnov, E. Fedorenko, T. Gavva, E. Gubar, E. Loginova, G. Lukina, E. Luchikhina, E. Tsvetkova, A. Avdeeva, E. Alexandrova, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The aim of therapy rheumatoid arthritis (RA) is the achievement of remission of the disease and slowing destruction of the joints. Tocilizumab (TCZ), anti-interleukin-6 receptor monoclonal antibody was used in treatment of active RA. TCZ has a rapid positive effect on the clinical manifestations and laboratory disoders, slowing destruction of joints in RA.
**Objectives:** To assess the effect of TCZ on synovitis on MRI of bilateral wrist and metacarpophalangeal joints in accordance with the OMERACT RA MRI scoring system (RAMRIS).
**Methods:** 43 adult patients with active RA were enrolled in the open label, phase IV trial to confirm the effectiveness and safety TCZ. Average age (median, interquartile range) 50,5 (43,0–55,0) years, duration of RA 56,5 (23,0–81,0) months, RF (+) 81%, ACCP (+) 77%. Patient had to be naive to biologics and have moderate to severe active RA (based on the 1987 ACR criteria). Patients remained on stable doses of disease-modifying antirheumatic drugs and received TCZ 8 mg/kg every 4 weeks for 24 weeks (total 6 infusions). Disease remission was assessed according to the criteria of EULAR and EULAR/ACR 2011. MRI performed at 0 and 24 weeks of observation.
**Results:** Before therapy indices DAS28 (6,4; 5,9–7,0), CDAI (41,5; 32,0–53,0) and SDAI (45,0; 36,2–57,0) corresponded to high activity of RA. The value of DAS28 to 24 weeks of treatment was 2,1; 1,3–2,8, p$<$0.05. Indicators SDAI and CDAI up to 24th week match the low activity of RA (4,4; 2,0–8,8 and 3,6; 1,4–7,6, respectively). Remission was achieved by 24 weeks of treatment on indices:

DAS28<2.6 for 30 patients (71%), CDAI<2.8 to 14 (33%), SDAI<3.3 to 13 (31%) and according to the criteria of ACR/EULAR 2011 (Boolean) – 10 (24%). MRI of the bilateral wrist and metacarpophalangeal joints was performed for patients who achieved remission according to the DAS28 criteria (n=27) and Boolean (n=10). Synovitis was detected in 81.5% and 80%, osteitis in 11.1% and 10% of patients, respectively.
**Conclusions:** Despite the pronounced clinical effect of TCZ in patients with RA and remission according to the criteria of DAS28 and ACR/EULAR, synovitis was detected in most patients. MRI examination allows to observe the patients during the therapy to achieve complete remission of the disease.

## FRI0214 SIX-YEAR RETENTION RATE OF ABATACEPT IN RHEUMATOID ARTHRITIS: A MULTICENTRIC RETROSPECTIVE ANALYSIS

E.G. Favalli[1], C. Botsios[2], C. Bazzani[3], B. Raffainer[4], G. Ciancio[5], A. Giollo[6], A. Marchesoni[1], R. Gorla[3], C. Caimmi[6], A. Becciolini[1], C. Crotti[7], S. Piantoni[3], M. Biggioggero[7], A. Carletto[6]. *[1]Department of Rheumatology, Gaetano Pini Institute, Milano; [2]Rheumatology Unit, Department of Medicine, University of Padova, Padova; [3]Rheumatology Unit and Chair, Spedali Civili and University of Brescia, Brescia; [4]Internal Medicine Division, Azienda Sanitaria dell'Alto Adige, Bolzano; [5]Rheumatology Unit, Department of Medical Sciences, Azienda Ospedaliera-Universitaria Sant'Anna, Ferrara; [6]Rheumatology Unit, Department of Medicine, University of Verona, Verona; [7]Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milan and Gaetano Pini Institute, Milano, Italy*

**Background:** Abatacept (ABT) short-term efficacy and safety profile in the treatment of rheumatoid arthritis (RA) is well established and supported by randomised controlled trials. However, data on ABT long-term effects are still lacking and reported drug survival analyses are often limited to no more than 2-year follow-up.
**Objectives:** The aim of the study is to evaluate in a real-life scenario the overall 6-year retention rate of ABT in the treatment of RA and to compare its survival rate as first or second line biotherapy.
**Methods:** Data were retrospectively extracted from six local registries including all RA patients treated with ABT between January 2008 and April 2015. The analysis was limited to patients treated with ABT as first or second line biologic agent. The 6-year retention rate was calculated by Kaplan-Meier method and the comparative risk for discontinuation between the two lines of treatment was compared by a stratified log-rank test.
**Results:** 236 RA patients (78.5% female, mean age [± standard deviation, SD] 57.6 [±12.7] years, mean disease duration 14.3 [±13.4] years, positive rheumatoid factor 82.2%, positive anti-citrullinated peptide antibodies 71.1%, mean DAS28 5.19 [±1.2]) were retrospectively enrolled. 83 patients were treated with ABT as first-line biotherapy, whereas 153 were second-line users. The overall retention rate was 63.7% at 3 years and 61.8% at 6 years. The 6-year retention rate was significantly higher in the first-line compared with the second-line therapy group (68% and 61.8%, respectively; p=0.04). Overall, ABT was discontinued in 69 (29.2%) patients. Twenty-one (8.9%) patients (4 first-line and 17 second-line users, p=0.15) withdrew ABT because of adverse events, whereas 41 (17.4%) patients (10 first-line and 31 second-line users, p=0.1508) stopped the therapy because of primary or secondary inefficacy. Seven (2.7%) patients discontinued ABT because of other reasons (i.e. lost at follow-up, pregnancy and remission) and were excluded from the retention analysis.
**Conclusions:** In our multicentric experience the 6-year retention rate of both first and second line ABT was about 60%. Used as first line ABT showed a significantly higher survival on treatment compared with the second line. Moreover, ABT demonstrated an overall favourable safety profile, with a very low occurrence of adverse events leading to discontinuation.

## FRI0215 SUBCUTANEOUS TOCILIZUMAB AS MONOTHERAPY OR IN COMBINATION WITH A CSDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS – INTERIM ANALYSIS OF A LARGE PHASE IV INTERNATIONAL UMBRELLA STUDY, "TOZURA"

E. Choy[1], R. Caporali[2], R. Xavier[3], B. Fautrel[4], R. Sanmarti[5], C. Bernasconi[6], A. Pethö-Schramm[6]. *[1]Cardiff University, Cardiff, United Kingdom; [2]University of Pavia, Pavia, Italy; [3]Universidade Federal do Rio Grande do Sul Porto Alegre, Rio Grande do Sul, Brazil; [4]Pierre and Marie Curie University, Paris, France; [5]Universitat de Barcelona, Barcelona, Spain; [6]F. Hoffmann-La Roche AG, Basel, Switzerland*

**Background:** Tocilizumab (TCZ), administered as intravenous (TCZ-IV) and subcutaneous (TCZ-SC) formulations, has been approved for treatment of patients (pts) with rheumatoid arthritis (RA) both as mono- and combination therapy.
**Objectives:** To evaluate the efficacy and safety of TCZ-SC 162 mg once weekly (qw) as monotherapy and in combination with conventional synthetic DMARDs (csDMARDs) over 24 weeks in adult pts with moderate to severe RA.
**Methods:** TOZURA is a multinational, open-label, single-arm umbrella study comprising 7 single-country and 4 regional multicountry protocols. It aimed to enroll ≈ 1,850 pts who were biological DMARD inadequate responders (IR; 8/11 protocols) and/or csDMARD-IR (11/11 protocols). Pts received TCZ-SC 162 mg qw for 24 weeks, administered at the investigator's discretion as monotherapy or in combination with a csDMARD. Stable oral NSAIDs and corticosteroids (CCS), ≤10 mg/day prednisone or equivalent, were allowed. Efficacy and safety were evaluated at weeks 1, 2, 4 and every 4 weeks thereafter.
**Results:** In this interim analysis, 1246 pts were included by end of 2014; 283 pts received monotherapy, 963 combination; 25% of pts were biologic DAMRD-IR (monotherapy: 36%, combination: 22%). Background characteristics: 80.5% female, mean age 54.5 years, mean RA disease duration 7.7 years and 81.4% seropositive – similar between treatment groups. Baseline oral CCS use was less frequent in the mono- group (42.8%) than in the combination group (51.2%); however, their mean dose was similar (6.673 vs 6.505 mg/day, respectively). Pts continuation of TCZ at week 24 based on Kaplan-Meier estimates (95% CI) were 0.784 (0.732, 0.828) for mono- and 0.855 (0.831, 0.875) for combination therapy. All pts had significant reductions in mean 28-joint Disease Activity (DAS28) scores by week 24 (mean decrease: monotherapy 3.41 and combination 3.44; $P$ <0.0001 for both) with no significant difference between groups ($P$ =0.788). Results were similar for the Clinical Disease Activity Index (CDAI), which does not include acute phase reactants (mean change by week 24: 24.03 and 23.28, $P$ <0.0001 for both groups: between groups $P$ =0.629). The proportion of pts who achieved DAS28 or CDAI-based remission and low disease activity and ACR20/50/70/90 responses was similar between the treatment groups (Figs 1A, 1B). Of the 231 pts (18.5%) who withdrew, 92 (7.4%) did so for safety reasons (29 [10.2%] monotherapy, 63 [6.5%] combination). Serious AEs (SAEs) occurred in 78 pts (6.3%; 11.5/100 PY) and rates of AEs and SAEs were similar between groups (Table 1). Serious infections and infestations occurred in 18 pts (1.4%; 2.2/100 PY), with similar rates between groups. Five deaths occurred, 1 in the monotherapy group (coronary artery disease) and 4 in the combination group (intestinal ischemia, myocardial infarction, pneumonia, septic shock).

**Figure 1: DAS28 and CDAI Disease Activity, and ACR Responses**

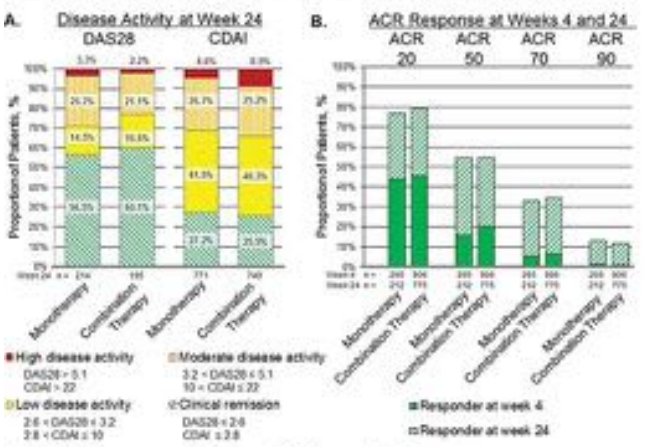

**Table 1: Summary of Relevant Adverse Events**

| | | Total Population (N = 1246; 892.4 PY) | Monotherapy (n = 283; 200.4 PY) | Combination Therapy (n = 963; 692.0 PY) |
|---|---|---|---|---|
| Adverse Events | Total patients with ≥ 1 AE, n (%) | 1058 (84.9%) | 228 (80.6%) | 830 (86.2%) |
| | Rate of AEs (per 100 PY) | 507.5 | 517.4 | 504.6 |
| Serious Adverse Events | Total patients with ≥ 1 SAE, n (%) | 78 (6.3%) | 23 (8.1%) | 55 (5.7%) |
| | Rate of SAEs (per 100 PY) | 11.5 | 16.0 | 10.2 |
| Serious Infections and infestations | Total patients with ≥ 1 SAE, n (%) | 18 (1.4%) | 6 (2.1%) | 12 (1.2%) |
| | Rate of SAEs (per 100 PY) | 2.2 | 3.0 | 2.0 |
| Withdrawals ≥ 1 reason, n (%) | Total patients with ≥ 1 reason, n (%) | 231 (18.5%) | 68 (24.0%) | 163 (16.9%) |
| Withdrawals due to safety reasons* | Patients, n (%) | 92 (7.4%) | 29 (10.2%) | 63 (6.5%) |
| Deaths | Number of deaths, n (%) | 5 (0.4%) | 1 (0.4%) | 4 (0.4%) |
| | Rate of deaths (per 100 PY) | 0.56 | 0.50 | 0.58 |

AE: adverse event; PY: patient-year; SAE: serious adverse event
*Includes AEs, deaths, withdrawals and abnormal laboratory findings. † Coronary artery disease. ‡Intestinal ischemia, myocardial infarction, pneumonia, septic shock.

**Conclusions:** TCZ-SC demonstrated convincing and comparable efficacy in mono- and combination therapy in pts with RA as previously observed with TCZ-IV. The safety profile of TCZ-SC is consistent with the known safety profile of TCZ as monotherapy and in combination with csDMARDs.

## FRI0216 LONG-TERM SAFETY AND EFFICACY OF MAVRILIMUMAB, A FULLY HUMAN GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR RECEPTOR-ALPHA MONOCLONAL ANTIBODY, IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Burmester[1], I. McInnes[2], J. Kremer[3], P. Miranda[4], J. Vencovský[5], A. Godwood[6], M. Albulescu[6], D. Close[6], M. Weinblatt[7]. *[1]Charité – University Medicine Berlin, Berlin, Germany; [2]University of Glasgow, Glasgow, United Kingdom; [3]The Albany Medical College, Albany, United States; [4]Centro de Estudios Reumatológicos, Santiago, Chile; [5]Institute of Rheumatology, Prague, Czech Republic; [6]MedImmune, Cambridge, United Kingdom; [7]Brigham and Women's Hospital, Boston, United States*

**Background:** Mavrilimumab, a fully human monoclonal antibody, which targets granulocyte-macrophage colony-stimulating factor receptor-α, has demonstrated efficacy and an acceptable safety profile in prior 12- and 24-week studies.[1,2]
**Objectives:** This analysis evaluated all long-term (LT) safety and efficacy, through 74 weeks of treatment, of mavrilimumab.
**Methods:** This open-label extension (OLE) study (NCT01712399) enrolled adult rheumatoid arthritis (RA) patients (pts) who had completed the EARTH EXPLORER 1[2] and 2 (NCT01715896) Phase IIb studies or were rescued as inadequate responders (from Week 12). Pts received subcutaneous mavrilimumab 100 mg every other week (eow), consistent with data from the Phase IIa study[1]. The primary objective was to assess the LT risk:benefit ratio of mavrilimumab via evaluation of i) Treatment emergent adverse events (TEAEs), TE serious AEs (TESAEs), and independently adjudicated pulmonary function tests (PFTs) ii) Exploratory LT efficacy endpoints (DAS28–CRP/ACR responses). AEs with onset date after start of mavrilimumab are presented. Change from baseline (BL) in modified Total Sharp Score (mTSS) was used to explore radiographic progression in EARTH EXPLORER 1 pts.
**Results:** At the 74 week (includes original study) cutoff, 391 pts had been enrolled in the OLE study. Of these, 329 (84.1%) continued on treatment, 62 (15.9%) discontinued (due to withdrawal of consent, 9 [2.3%]; adverse event, 7 [1.8%]; non study-related site closure, 20 [5.1%]; other, 24 [6.1%]; lost-to-follow-up, 1 [0.3%]; death [sudden cardiac arrest, preferred term cardiopulmonary failure], 1 [0.3%]), and 239 (61.1%) were assessed for efficacy at Week 74. Between the Phase IIb and OLE studies, 440 pts received mavrilimumab, with a safety exposure of 603 pt years (yr) and median duration of 1.6 yr. Most common TEAEs (n [/100 pt yr]) were nasopharyngitis (51 [8.45]), bronchitis (36 [5.97]) and hypertension (32 [5.30]); the serious infection rate was 1.82/100 pt yr. Pulmonary events/defined PFT changes occurred in a few pts and were generally transient with no signal identified (Table). Mavrilimumab demonstrated sustained efficacy (DAS28–CRP/ACR responses) (Table). After 74 weeks of treatment, 68% of pts showed no radiographic progression (<0.5 change in mTSS vs. BL) (Table).
**Conclusions:** Mavrilimumab continues to demonstrate a sustained efficacy and safety profile in pts with active RA, over the 74 week treatment duration reported. Although mavrilimumab 100 mg eow is suboptimal compared with 150 mg eow in DMARD-IR pts,[2] efficacy results are comparable with those of previous studies.[1,2]

## FRI0217 ANAPHYLACTIC-TYPE REACTIONS ASSOCIATED WITH ABATACEPT AND OTHER BIOLOGIC AGENTS: REVIEW OF SAFETY REPORTS FROM FAERS

H. Yu, A. Dominique, T.A. Simon, A. Gomez. *Bristol-Myers Squibb, Princeton, United States*

**Background:** The US Food and Drug Administration AE reporting system (FAERS) contains information for all marketed and investigational drugs in the US and provides sufficient safety data for disproportionality analysis for specific events associated with the use of drugs.
**Objectives:** To perform the disproportionality analysis of anaphylactic reactions among users of abatacept (ABA) and other biologics for the treatment of RA, utilizing data from FAERS.
**Methods:** The disproportionality of anaphylactic-type reactions associated with ABA and other biologics was analysed using cumulative safety data retrieved from the FAERS database up to 22 June 2015. The preferred terms in the Standardized Medical Dictionary for Regulatory Activities Queries (SMQ) for anaphylactic reactions (narrow terms) were used for the database search and included anaphylactic reaction, anaphylactic shock, anaphylactic transfusion reaction, anaphylactoid reaction, anaphylactoid shock, circulatory collapse, Kounis syndrome, shock and type I hypersensitivity. Biologics searched for included ABA, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. Penicillin was included as positive control due to its known association with anaphylactic-type reactions.[1] The disproportionality report is defined as a ratio of observed to expected frequencies of reports mentioning both the targeted drug (Y) and targeted AE (X). The observed frequency is calculated as the number of reports for event X with drug Y, and the expected frequency is the number of drug–event combinations of interest that would be expected if the event of interest (X) is reported independently of the drug of interest (Y). The disproportionality measure (i.e. observed/expected) referred to by empirical Bayesian geometric mean and the corresponding 90% CI (EB05, EB95) were calculated. The threshold of EB05 ≥2 for any drug–event pair identifies drug–event combinations that are reported at least twice as often as all other drug–event combinations.
**Results:** Among the evaluated drugs, the EB05 scores for anaphylactic reaction, anaphylactic shock and anaphylactoid reaction were the highest with penicillin use, as expected (Table). The EB05 scores for all drug–event pairs for ABA were

| Generic name | SMQ Anaphylactic Reaction (Narrow) | n | EBGM | EB05 | EB95 |
|---|---|---|---|---|---|
| Abatacept | Anaphylactic reaction | 53 | 1.45 | 1.16 | 1.81 |
| Abatacept | Anaphylactic shock | 11 | 0.59 | 0.36 | 0.92 |
| Abatacept | Anaphylactoid reaction | 5 | 1.12 | 0.56 | 2.04 |
| Abatacept | Circulatory collapse | 6 | 0.49 | 0.26 | 0.85 |
| Abatacept | Shock | 11 | 0.68 | 0.42 | 1.06 |
| Abatacept | Type I hypersensitivity | 1 | 0.86 | 0.27 | 2.17 |
| Infliximab | Anaphylactic reaction | 598 | 2.16 | **2.02** | 2.31 |
| Infliximab | Anaphylactoid reaction | 145 | 2.75 | **2.40** | 3.15 |
| Penicillin | Anaphylactic reaction | 54 | 3.96 | **3.16** | 4.91 |
| Penicillin | Anaphylactic shock | 42 | 4.86 | **3.76** | 6.20 |
| Penicillin | Anaphylactoid reaction | 169 | 3.68 | **3.24** | 4.16 |
| Tocilizumab | Anaphylactic reaction | 71 | 2.91 | **2.39** | 3.52 |

EBGM=empirical Bayesian geometric mean; SMQ=Standardized Medical Dictionary for Regulatory Activities Queries

<2. The EB05 scores for drug–event pairs for other biologics were <2 except anaphylactic reaction and anaphylactoid reaction for infliximab, and anaphylactic reaction for tocilizumab.
**Conclusions:** Overall, there were few signals of disproportionality for anaphylactic-type reactions with the use of abatacept and other biologics for RA, with the exceptions of anaphylactic reaction and anaphylactoid reaction for infliximab and anaphylactic reaction for tocilizumab. This observation is consistent with the results reported from clinical studies that were documented in the prescribing information for abatacept and other respective drugs for RA.[2–4]

## FRI0218 SAFETY OF NON ANTI-TNF BIOLOGIC AGENTS IN RHEUMATIC PATIENTS WITH PAST HEPATITIS B VIRUS INFECTION. A SINGLE-CENTER REAL-LIFE STUDY

I. Papalopoulos[1], N. Kougkas[1], N. Avgoustidis[1], A. Repa[1], A. Fanouriakis[1,2], P. Sidiropoulos[1]. *[1]Rheumatology, Clinical Immunology and Allergy, University Hospital of Heraklion, Heraklion, Crete; [2]Rheumatology and Clinical Immunology, 4th Department of Internal Medicine, Athens, Greece*

**Background:** The safety of newer non anti-TNF biologic agents [abatacept (ABA), tocilizumab (TCZ) and rituximab (RTX)] in patients with autoimmune rheumatic diseases and past HBV infection [defined as HBsAg(–), anti-HBc(+), anti-HBs(±)] has not been firmly established.
**Objectives:** To assess the safety [reactivation of hepatitis B virus (HBV)] of non anti-TNF biologic agents in patients with serologic evidence of past HBV infection in real-life clinical settings.
**Methods:** Retrospective chart review of patients followed in the Department of Rheumatology of the University Hospital of Crete. Patients who received ABA, TCZ or RTX during the period 2005–2015 and were HBsAg(–), anti-HBc(+), anti-HBs(±) at baseline were identified and reviewed for cases of HBV reactivation (defined as increased ALT accompanied by an increase of serum HBV DNA levels by >1 $\log_{10}$ compared with baseline or a switch in HBV DNA detection from negative to positive). Changes in anti-HBs titers during biologic therapy in patients who were anti-HBs(+) at baseline were also documented.
**Results:** 83 different cases of non anti-TNF biologic therapy (34 ABA, 26 RTX and 23 TCZ) from 58 patients (56 RA - 2 ANCA-associated vasculitis) were identified. 64 cases (77.1%) were anti-HBc(+) anti-HBs(+) and 19 (22.9%) were anti-HBc(+) anti-HBs(–). Mean (SD) age at disease diagnosis and at non anti-TNF initiation was 53.6 (13.1) and 63.4 (9.2) years, respectively. All cases with RA had received prior anti-TNF agents [mean (SD) number of anti-TNF agents 1.1 (0.8)]. During treatment with non anti-TNF, concomitant synthetic disease modifying drugs or glucocorticoids were received by 91.5% and 46.3% of cases, respectively. Only 7 cases (8.4%) received antiviral prophylaxis concomitant with non anti-TNF treatment (4 with lamivudine - 3 with entecavir). After a mean (SD) of 41.9 (24.6) months of follow-up and a mean (SD) of 18.0 (15.9) therapy cycles, one anti-HBc(+) anti-HBs(–) case experienced HBV reactivation 12 months after treatment with abatacept and was treated with tenofovir with good outcome. Of anti-HBs(+) patients at baseline, titers of anti-HBs antibodies did not show statistically significant delay from baseline to most recent follow-up (456.9 mIU/ml vs. 390.7 mIU/ml, respectively, p=0.08) (Figure 1).

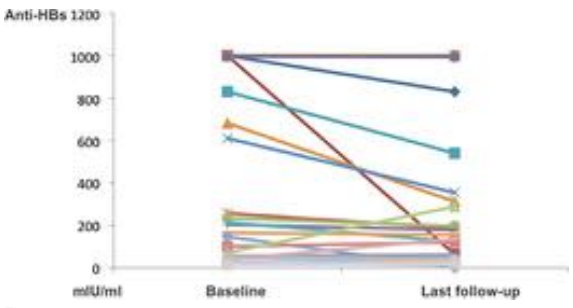

Figure 1

**Conclusions:** One case of HBV reactivation underlines the need for diligent monitoring in patients with serologic evidence of past HBV infection receiving non anti-TNF biologic agents. More data are needed to determine the need for universal prophylactic antiviral therapy in this subset of patients.
**Disclosure of Interest:** None declared

## FRI0219 RISK FACTORS OF SEVERE INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOCILIZUMAB IN THE FRENCH REGISTRY REGATE (REGISTRY –ROACTEMRA)

J. Morel[1], A. Constantin[2], E. Dernis[3], S. Rist[4], R.M. Flipo[5], T. Schaeverbeke[6], O. Vittecoq[7], M. Soubrier[8], A. Saraux[9], B. Combe[1], M. Dougados[10], A. Pinta[11], G. Baron[12], J.-E. Gottenberg[13], X. Mariette[14], P. Ravaud[12], J. Sibilia[13] on behalf of REGATE Working Group. *[1]Rheumatology, Teaching Hospital Lapeyronie and University of Montpellier, Montpellier; [2]Rheumatology, Teaching Hospital Purpan and University of Toulouse, Toulouse; [3]Rheumatology, Hospital of le Mans, le Mans; [4]Rheumatology, Hospital of Orléans, Orléans; [5]Rheumatology, Teaching Hospital Salengro and University of Lille, Lille; [6]Rheumatology, Teaching Hospital of Pellegrin and University of Bordeaux, Bordeaux; [7]Rheumatology, Teaching Hospital Bois-Guillaume and University of Rouen, Rouen; [8]Rheumatology, Teaching Hospital Montpied of and University of Clermont Ferrand, Clermont Ferrand; [9]Rheumatology, Teaching Hospital Cavale Blanche and University of Brest, Brest; [10]Rheumatology, Teaching Hospital Cochin and University Paris 5; [11]Roche Laboratory; [12]UMR 1153, Paris; [13]Rheumatology, Teaching Hospital Hautepierre and University of Strasbourg, Strasbourg; [14]Rheumatology, Teaching Hospital Kremlin Bicêtre and University of Paris Sud, Paris, France*

**Background:** Observational studies have already reported the risk of severe infections in rheumatoid arthritis (RA) treated with tocilizumab but in limited samples.
**Objectives:** The aim of this study was to investigate the predictive risk factors of severe infections in the largest European registry of patients treated with tocilizumab for RA.
**Methods:** 1491 RA patients included in the French REGistry –RoAcTEmra (REGATE) were analysed to calculate incidence rate of severe infections and to identify independent factors associated with severe infections.
Kaplan -Meier method was used to assess probability of remaining severe infection-free. Cox models were performed to identify independent factors associated with severe infections. Variables showing bivariate association with the dependent variable with a *P* value less than 0.15 were entered into the multivariate model. Multiple imputation was used to compensate missing data in some variables. A *P* value <0.05 was considered statistically significant.
**Results:** Exposure was 2,606 person-years (mean age±SD, 56.6±13.6). 125 serious infections occurred in 122 patients (4.7/100 patient-years). Most frequent infections were lung and respiratory tract and skin/soft tissue in 35 (28%) and 32 (26%) cases respectively. Three deaths were related to one septic chock secondary to pyelonephritis, one pneumocystosis, and one *Haemophilus influenzae* infection. Favourable outcome was observed in most cases. Four opportunistic infections were reported: 1 Pneumocystosis, 1 tuberculosis, 1 *Haemophilus influenzae* infection and 1 infection related to *Klebsiella pneumoniae*. A pathogen was identified in 41 cases. TCZ was definitively stopped for 35 patients. The incidence of serious infection was stable over the first 3 years of follow-up in the registry. Bivariate analysis identified initial ACPA positivity as the only factor associated with a lower risk of severe infection (HR 0.55 CI95% 0.35–0.86). Factors significantly associated with a risk of severe infections were DAS28-CRP, DAS28-ESR, and number of polymorphonuclear neutrophils (PMN) at baseline. Initial PMN above 4.5 G/L (HR 1.62 CI95% 1.06–2.5, p=0.02) and negative ACPA (HR 0.63 CI95% 0.41–0.95, p=0.03) remains significantly associated with severe infections in multivariate analysis after imputation for missing data.
**Conclusions:** The rate of severe infections in current practice is similar to that reported in clinical trials. High PMN above 4.5 G/L at baseline and negative ACPA are predictive factors of serious infection requiring in this case a tighter surveillance.

## FRI0220 PRESCRIPTION OF TOCILIZUMAB ALONE OR IN COMBINATION WITH DMARDS IN RHEUMATOID ARTHRITIS PATIENTS IN A REAL LIFE SETTING: THE ACT-SOLO STUDY 12 MONTHS RESULTS

J. Tebib[1], I. Idier[2], M. Coudert[3], J.-F. Maillefert[4], R.-M. Flipo[5]. *[1]Department of Rheumatology, Univesity Hospital, Lyon; [2]Medical, Chugai Pharma France, Paris la Defense; [3]Clinical Operations, Roche SAS, Boulogne; [4]Department of Rheumatology, University Hospital, Dijon; [5]Department of Rheumatology, University Hospital, Lille, France*

**Background:** Although the use of a biologic as monotherapy is not the standard in Rheumatoid Arthritis (RA), it concerns around a third of the patients. The objectives of the Act Solo study was to evaluate tocilizumab (TCZ) alone (Mono) or in combination (Combo) at 12 months in real life.
**Methods:** Prospective, multicenter, longitudinal, non-interventional 12-month study in RA pts requiring TCZ according to their physician. Besides drug retention rate, efficacy and safety, the effect of Mono when compared to Combo was evaluated using a propensity score. Efficacy population was pts fulfilling inclusion and non-inclusion criteria and with ≥1 TCZ infusion. Safety population was all pts with ≥1 TCZ infusion.
**Results:** 608 pts were recruited of whom 603 were analysed for safety and 577 (Total) for other endpoints. At baseline: mean age 57±13 years, 454 (79%) females, at least 1 co-morbidity: 409 (71%), mean RA duration 11±9 years, RF or ACPA positive: 478 (86%), erosive disease: 435 (77%), mean DAS28 5.2±1.3. Past RA treatments included DMARDs + biologics in 75%, only DMARDs in 24%. MTX was previously prescribed in 95% of pts and in 71% within the last 2 years. TCZ Mono was initiated in 228 (40%) pts and TCZ Combo in 349 (60%) pts of whom 80% received MTX (mean 16±5mg/w). Steroids (GCs) were used in 386 (67%) pts (mean 10±7mg/d). 337 pts completed M12 visit. 194 pts withdrew for: AE 53 pts, inefficacy 88, patients wish 12, lost to follow-up 23, other 18. At M12, drug retention rate was 69% in Total, 67% in Mono, 71% in Combo (Fig.). Mean number of TCZ infusions was 9.4±4.1; mean time between infusions was 31.8 ±12.6 days. 29% of the pts experienced at least 1 discontinuation, 25% and 33% in Mono and Combo groups respectively. DMARD was added in 20 Mono and definitely stopped in 25 Combo pts. 170 (50%) pts remained on GCs, 66 (51%) in Mono group and 104 (50%) in Combo group. At M12, mean DAS28 in Total, Mono and Combo were 2.4±1.3, 2.4±1.3 and 2.3±1.2 respectively. DAS28 remission was 35% in Total, 35% and 36% in Mono and Combo respectively (p=0.83). Using the propensity score, no effect of Mono was observed on drug retention HR=1.194 [0.852,1.673], p=0.30; DAS remission OR=1.111 [0.773,1.597], p=0.57; or GCs use OR=0.880 [0.558,1.387], p=0.58 at M12.
No new safety signal was reported. 325 (54%) patients had at least one AE, 74 (12%) had at least one serious AE with no differences between Mono and Combo.

Fig. : TCZ Drug retention rate at 12 months

**Conclusions:** The Act Solo study confirms, in real life, the clinical results of RCTs showing a comparable efficacy of TCZ as monotherapy when compared to combotherapy. No new safety signal occurred.

## FRI0221 OCCURRENCE OF SERIOUS INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICS AND DENOSUMAB OBSERVED IN A CLINICAL SETTING

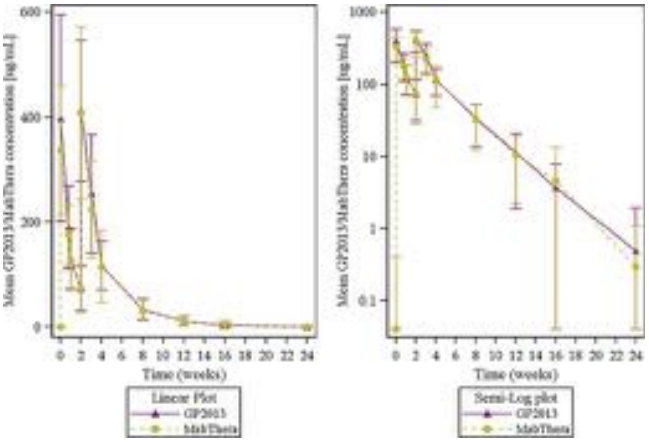
M. Wong-Pack[1], R. Rodjanapiches[1], A. Lau[1,2], G. Ioannidis[1,2], S. Wade[3], A. Balasubramanian[3], C.J. Lin[3], P. Roy-Gayos[1], W.G. Bensen[1,2], R. Bensen[2], J.D. Adachi[1,2]. *[1]McMaster University; [2]St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [3]Amgen Inc., Thousand Oaks, CA, United States*

**Background:** Studies combining immunosuppressive biologics have shown an increased risk of infections.
**Objectives:** Examine the occurrence of serious and opportunistic infections in RA patients treated concurrently with DMAb and an immunosuppressive biologic, and those treated with only an immunosuppressive biologic.
**Methods:** We reviewed RA patients from two rheumatology practices in Ontario (Canada) between 01July2010 and 31July2014. Eligible patients were ≥18 years of age with RA, registered in the practice ≥3 months before and after the index date, and received ≥1 injection/infusion or filled a prescription for an immunosuppressive biologic therapy for RA. Patients with HIV or AIDS, or who were receiving cancer treatment or immunosuppressive therapies for conditions other than RA or living in a nursing home were excluded. The incidence of serious infections was counted for two different groups: 1) those who had used DMAb and an immunosuppressive biologic concurrently and 2) those who had used an immunosuppressive biologic alone. Serious infection was defined as resulting in hospitalization or an emergency room (ER) visit with associated use of IV antibiotics and a primary diagnosis of infection. The observational period was from the index date to 31July2014 or loss to follow-up, whichever came first. For the concurrent group, index date was defined as their first DMAb injection. A frequency-matching technique utilizing the index date of the concurrent group was used to select the index date of the biologic-alone group.
**Results:** 308 patients met the eligibility criteria; patient characteristics (± 6 months of index event) are shown below. Three events of serious infection occurred in three patients in the concurrent group (all three were cases of pneumonia); four events of serious infection occurred in four patients in the biologic-alone group (three cases of pneumonia, one upper respiratory tract infection, all resulting in hospitalization). One event of opportunistic infection (*mycobacterium avium* complex and pleural infection) occurred in the biologic-alone group. All patients recovered, with no instances of death.

Patient characteristics

| | Concurrent (N=102) | Biologic-alone (N=206) |
|---|---|---|
| Women, n (%) | 90 (88) | 158 (77) |
| Age, years | 66.4 (10.8) | 57.4 (11.6) |
| Average follow-up time, years | 2.4 (1.2) | 2.5 (1.3) |
| History of fracture, n (%) | 8 (8) | 4 (3) |
| T-score ≤–2.5 at the spine or hip, n (%) | 45 (47) | 23 (13) |
| Chronic kidney disease, n (%) | 1 (1) | 4 (2) |
| Chronic obstructive pulmonary disease, n (%) | 4 (4) | 16 (8) |
| Cardiovascular disease, n (%) | 7 (7) | 19 (9) |
| Diabetes, n (%) | 8 (8) | 25 (12) |
| Liver disease, n (%) | 1 (1) | 1 (0.5) |
| Prednisone use, % (n) | 21 (21) | 15 (7) |
| C-reactive protein, mg/L | 4.6 (6.8) | 4.5 (8.0) |
| Erythrocyte sedimentation rate, mm/h | 19.0 (17.0) | 17.2 (15.2) |

Data are means (SD) unless otherwise noted.



**Conclusions:** RA patients may require treatment for bone loss due to intrinsic disease, steroid use, and advancing age. This study demonstrates a low occurrence of serious infections in biologically-treated RA patients, including patients with concurrent DMAb use.

## FRI0222 PHARMACOKINETICS, PHARMACODYNAMICS, SAFETY AND EFFICACY OF PROPOSED RITUXIMAB BIOSIMILAR (GP2013) VS. EU-APPROVED RITUXIMAB (RTX) IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL (GP13-201) OVER 52 WEEKS

J. Smolen[1], M. Scheinberg[2], H.-P. Tony[3], P. Zhu[4], T. Shisha[5]. *[1]Dept. of Rheumatology and Internal Medicine III, University Hospital, Wien, Austria; [2]Clinical Research Division, Hospital Abreu Sodre AACD, Sao Paulo, Brazil; [3]Department of Rheumatology, Medizinische Klinik and Poliklinik II (ZIM), University of Wuerzburg, Wuerzburg, Germany; [4]Pharmacology, Sandoz, a Novartis Company, Princeton, United States; [5]Biopharmaceutical Clinical Development, Sandoz, a Novartis Company, Holzkirchen, Germany*

**Background:** GP2013 has been developed as a proposed biosimilar to originator rituximab (RTX), by Sandoz, a Novartis Company. The stepwise development program is comprised of structural and functional characterization with highly sensitive analytical methods followed by nonclinical testing and clinical studies.
**Objectives:** The primary objective of the study was to demonstrate PK bioequivalence of GP2013 and EU-approved rituximab (RTX) in patients with RA, defined as equivalence of AUC(0–inf) up to week 24. Secondary endpoints included other PK and PD parameters and evaluation of safety and efficacy.

**Methods:** In this prospective, randomized, double blind study patients with active RA refractory or intolerant to standard DMARDs and TNF inhibitor(s) were randomized to GP2013 or RTX. Read-out of the primary analysis was performed at week 24. Efficacy and PD data were collected to week 52, while safety follow-up ended 24 weeks after the last infusion of study medication. For anti-drug antibody (ADA) assessment a validated in-house ELISA method for binding ADAs was applied.
**Results:** Of the 325 patients screened, 173 were randomized to either GP2013 or RTX. There were no relevant differences in baseline characteristics between the treatment arms. A similar number of patients received a second treatment course after week 24: 58 (67.4%) patients in the GP2013 and 56 (64.4%) patients in the RTX arm.
The study met its primary objective by demonstrating PK bioequivalence based on AUC0-inf. The ratio of the geometric means (GP2013/RTX) was 1.064, and the 90% confidence interval (CI) was maintained within the standard bioequivalence limits [0.8 to 1.25] (Figure 1).
For maximum serum concentration (Cmax) after the first infusion, the upper limit of the 90% CI of the ratio of the geometric means (1.262) was slightly above the upper bound of the bioequivalence limit (1.25) whereas for Cmax after the second infusion, the CI was fully within the 90% CI. This outcome was attributed to a higher variability in infusion rates and durations during the first infusion. The study met all other secondary PK endpoints.
Equivalence of GP2013 and RTX was also demonstrated in terms of peripheral B cell depletion. The ratio of the geometric means (GP2013/RTX) was 1.019 and the 95% CI was within the equivalence limits [0.8 to 1.25]. Non-inferiority to reference RTX was demonstrated for disease activity score DAS28(CRP) change from baseline at week 24. The LS mean difference between the groups was 0.07 and the 95% confidence interval was below the non-inferiority margin of 0.6. The number of adverse events, serious adverse events and potential infusion related reactions were similar between the treatment arms. Nine (11.0%) patients in the GP2013 vs. 18 (21.4%) patients in the RTX group developed anti-drug antibodies (ADAs).

**Conclusions:** The proposed biosimilar GP2013 met the primary endpoint demonstrating bioequivalence to originator EU-approved RTX. No clinically meaningful differences were found between GP2013 and the reference RTX in PD and safety, as well as efficacy and immunogenicity at week 24.

## FRI0223 THE BEST SELECTION OF SECOND BIOLOGICS FOR PATIENTS WITH RHEUMATOID ARTHRITIS IN DAILY CLINICAL PRACTICE

K. Saito, K. Nakano, S. Nakayamada, S. Kubo, I. Miyagawa, S. Hirata, Y. Tanaka.
*The First Department of Internal Medicine, University of Occupational & Environmental Health, School of Medicine, Kitakyushu, Japan*

**Background:** Since the approval of infliximab (IFX) in 2003, 8 biologics have been approved for rheumatoid arthritis (RA) in Japan. However, little is known regarding what to do when patients have an inadequate response to first biologics in daily clinical practice.
**Objectives:** This study aimed to evaluate the effectiveness of biologics as 2nd-line use in RA patients in daily clinical practice from our university cohort (FIRST registry).
**Methods:** We retrospectively examined 2553 patients who were treated with biologics in our institute between July 2003 and December 2015. We compared the effectiveness of TNF-inhibitors (TNFi), TCZ, ABA as 2nd-line use and efficacy of switching from 1st TNFi to 2nd TNFi, TCZ or ABA based on retention rates and change in disease activity such as CDAI at 1 year, ΔCDAI (0–52W), ΔDAS28-ESR (LOCF). Propensity score (PS) were generated using multinomial logistic regression and the study groups were matched regarding baseline variables including age, disease duration, disease activity, concomitant use of MTX and PSL. In addition, in order to find out the characteristic of 2nd biologics, we conducted comparison between the upper (1yCDAI-H; low response) and lower (1yCDAI-L; good response) quartiles in CDAI at 1 y after switching.
**Results:** In terms of switching of biologics, better treatment outcome of ΔCDAI was observed in order of TCZ (n=141) >2nd TNFi (n=186) >ABT (n=91) but was comparable after the adjustment by PS. Comparison between the upper (1yCDAI-H) and lower (1yCDAI-L) quartiles in CDAI at 1 y after switching revealed that disease activity might improve despite of a high disease activity at switching in the case of TCZ as shown in Figure. In addition, high CRP and MMP-3 at switching were higher in the 1y CDAI-L group only in the case of switching to TCZ.

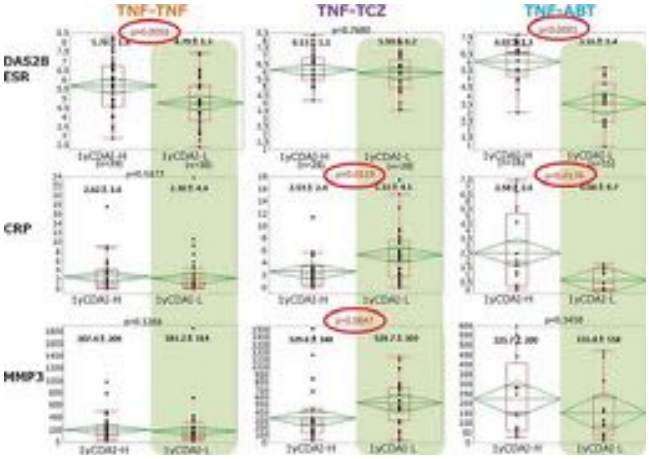

Figure 1. Comparison of DAS28, CRP and MMP3 at initiation of 2nd biologics between the upper (1yCDAI-H) and lower (1yCDAI-L) quartiles in CDAI at 1 y after switching.

**Conclusions:** After adjustment using PS-score, RA patients with prior anti-TNF exposures had similar outcomes if they switched to a new TNFi as compared with initiation of TCZ or ABA. Also our results imply us that TCZ might bring about good outcome despite of disease activity at switching. Furthermore, higher CRP or MMP-3, suggesting inadequate suppression of IL-6 by first biologics, might predict better outcome of TCZ.

## FRI0224 COMPARISON OF EFFICACY AND SAFETY OF RITUXIMAB BIOSIMILAR, BCD-020, AND INNOVATOR RITUXIMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS REFRACTORY TO TNFA INHIBITORS

A. Eremeeva[1], E. Chernyaeva[1], R. Ivanov[1], E. Nasonov[2], L. Knyazeva[3].
*[1]CJSC BIOCAD, Saint-Petersburg; [2]Nasonova State Institute of Rheumatology of Russian Academy of Medical Sciences, Moscow; [3]Kursk Clinical Hospital of Kursk Regional Healthcare Committee, Kursk, Russian Federation*

**Background:** BCD-020 is the first Russian rituximab (RTX) biosimilar which was approved for medical use in lymphoma patients in Russia and some CIS countries. Previous preclinical and clinical studies showed that BCD-020 is highly similar to innovator RTX. Since there are several differences in mechanism of action of RTX in NHL and RA it is recommended to conduct separate clinical studies in oncology and autoimmune indications to prove similar efficacy and safety of biosimilar and original medicine.
**Objectives:** The primary objective was to evaluate the efficacy and safety of BCD-020 used in combination with MTX in patients with RA with inadequate response or intolerance to other DMARDs including 1 or more TNF inhibitor. The secondary objectives included direct comparison of safety, efficacy, pharmacokinetics, pharmacodynamics and immunogenicity of RTX biosimilar and innovator RTX.
**Methods:** This international multicenter randomized double-blind phase 3 clinical study was conducted in patients with active RA despite DMARD therapy, which included 1 or more TNF inhibitor. After completion of screening all eligible patients were stratified by age (<40 years/40 years), ACCPA positive/ACCPA negative,

presence/absence of the need for oral steroids. Then patients were randomized in 1:1 ratio into 2 arms: patients from the main arm received BCD-020 1000 mg as an IV infusion on day 1 and day15, patients from the reference arm received innovator RTX by the same regimen. In this work results of the first 6-months period of observation are presented.

**Results:** A total of 160 patients were enrolled; 159 patients had data eligible for efficacy analysis. ACR20 at Week 24 was reported in 84.14% patients in BCD-020 arm and 87.01% in reference arm. The 95% CI for the difference in proportion of ACR20 between groups was [-13.95; 8.74%], where the limits of 95% CI lie within the pre-specified equivalence margin. Both drugs caused deep and sustained depletion of B-cells from peripheral blood without any toxicity to other cell populations. Favorable safety profiles were demonstrated in both groups without any significant differences: AEs have been reported in 59.34% patients from BCD-020 arm and 54.12% patients from reference arm. Treatment discontinuation caused by AE/SAE was reported only for 3 (3.30%) patients in BCD-020 arm and 4 (3.53%) patients in the reference arm (p=1.00). SAEs occurred only in the reference group (2.35%). Binding antibodies were revealed in 3 patients from BCD-020 arm and in 7 patients from reference arm (p=0.209). There were 2 events of neutralizing antibodies against RTX, both in the reference arm (p=0.232).

**Conclusions:** Equivalent efficacy of BCD-020 compared to innovator RTX in patients with active RA has been confirmed. Further clinical evaluation of BCD-020 is planned to confirm long-term efficacy and safety.

## FRI0225 SHORT COURSE OF TOCILIZUMAB INCREASES RISK OF HEPATITIS B VIRUS (HBV) REACTIVATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: A REAL-WORLD, PROSPECTIVE COHORT STUDY

L.-F. Chen, Y.-Q. Mo, J. Jing, J.-D. Ma, D.-H. Zheng, L. Dai. *Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

**Background:** Our previous study showed approximately 11% of Chinese RA patients combined with chronic Hepatitis B virus (HBV) infection and 32% with resolved HBV infection. HBV reactivation may occur as an adverse event of biologic DMARDs and TNFIs or abatacept have been categoried as moderate risk of HBV reactivation, rituximab as high risk [1]. However, tocilizumab (TCZ) is still unclassified due to few data. TCZ has been approved for RA patients in combination with csDMARDs by CFDA in November 2013 and most of Chinese RA patients can only afford short course of TCZ for self-paid and expensive price.

**Objectives:** To investigate the impact of short course of TCZ on HBV reactivation in RA patients.

**Methods:** RA patients with moderate or high disease activity were recruited. Three consecutive doses of intravenous TCZ were given combined with csDMARDs. RA disease activity, liver function and HBV infection status were evaluated at baseline, week 4, week 8 and week 12 during TCZ based therapy.

**Results:** Fifty-seven RA patients were recruited and 51 were qualified for statistics (Figure 1). They were divided into chronic HBV infection group (n=7, 13.7%), resolved HBV infection group (n=33, 64.7%) and non-HBV infection group (n=11, 21.6%). Three patients (6%) developed HBV reactivation after 1–3 doses of TCZ and all of them had chronic HBV infection without antiviral prophylaxis. All reactivation patients were asymptomatic along with normal aminotransferases and resolution of virological response after therapeutic antiviral therapy. None of patients with resolved HBV infection suffered from HBV reactivation. Aminotransferases elevated in 24% (12/51) of RA patients with 4% (2/51) exceeding 2-fold of ULN and returned to normal 4 weeks after adding hepatinica. Anti-HBs titer was positive (≥10 IU/L) in 82% (27/33) of patients with resolved HBV infection and reduced significantly after first dose of TCZ compared to baseline [426 (59–978) IU/L vs. 446 (78–000) IU/L, $P<0.05$], which was below protective level (<10 IU/L) in 19% (5/27) of patients and unable to recover in 7% (2/27) up to week 28–36. All patients were kept follow-up after 12 weeks. No additional HBV reactivation occurred during 4–80 weeks on extended period.

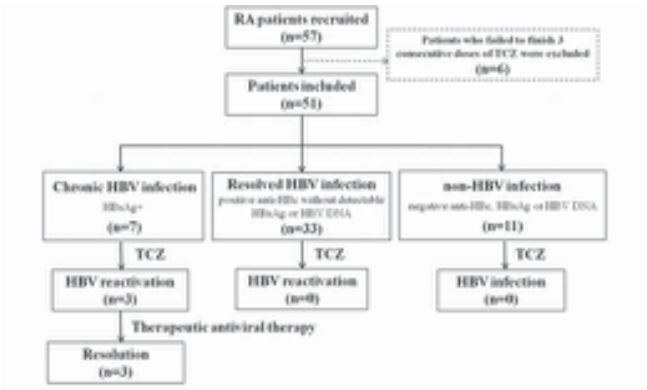

**Figure 1 Flow diagram illustrating cohort selection and the development of hepatitis B virus (HBV) reactivation/infection during 12 weeks of tocilizumab (TCZ) based therapy.**
**RA: rheumatoid arthritis; HBsAg: surface antigen of HBV; anti-HBc: antibody to core antigen of HBV.**

**Conclusions:** This real-world, prospective cohort study suggests that short course of TCZ has moderate risk of HBV reactivation in RA patients and high risk in RA patients with chronic HBV infection especially without antiviral prophylaxis, which indicate the importance of HBV screening and antiviral prophylaxis for patients with chronic HBV infection before starting TCZ therapy.

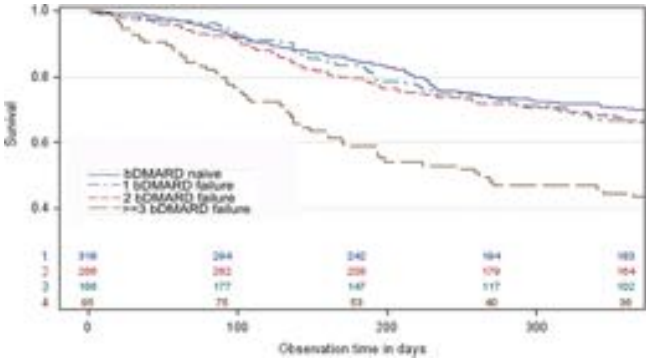
## FRI0226 TOCILIZUMAB IS SIMILARLY EFFECTIVE IN RA PATIENTS WITH NO OR UP TO TWO PRIOR BDMARD FAILURES: RESULTS FROM THE GERMAN PROSPECTIVE COHORT STUDY RABBIT

L. Baganz [1], A. Strangfeld [1], J. Kekow [2], A. Bussmann [3], A. Krause [4], C. Stille [5], J. Listing [1], A. Richter [1], A. Zink [1,6]. *[1]German Rheumatism Research Centre, Berlin; [2]Scientific Advisory Board, Magdeburg; [3]Rheumatologist, Geilenkirchen; [4]Rheumatologist, Berlin; [5]Rheumatologist, Hannover; [6]Charité University Medicine, Berlin, Germany*

**Background:** In Germany, Tocilizumab (TCZ) is used for the treatment of rheumatoid arthritis both in biologic-naïve patients and those with previous failures of biologic (b)DMARDs.



**Objectives:** To investigate effectiveness and retention rates of TCZ in patients with multiple bDMARD failures.

**Methods:** We included 885 RA patients enrolled with the start of TCZ treatment between 2009 and 2015 in the German biologics register RABBIT (Rheumatoid arthritis: Observation of biologic therapy). Patients were stratified according to the number of bDMARD failures prior to the initiation of TCZ: biologic naive (n=318), 1 bDMARD failure (n=286), 2 bDMARD failures (n=186), ≥3 bDMARD failures (n=95).

We used Kaplan-Meier survival methods to examine the retention rates within 12 months after the initiation. Discontinuation was defined as stopping TCZ therapy. Effectiveness regarding the control of disease activity (mean DAS28-ESR) over 3, 6 and 12 months was examined with linear mixed models.

**Results:** Compared to biologic naive patients those with prior bDMARD failures at start of TCZ were younger but had significantly longer disease duration (bio-naive: 8, 1 bDMARD failure: 11.6, 2 failures: 13.3 and ≥3 failures: 15.3 years; p<0.01). The DAS28 at baseline and loss of physical function were significantly higher in patients with ≥3 bDMARD failures. In the latter group patients with more than 2 comorbidities were also more frequent (21% (bio-naive), 31% (1), 24% (2), 38% (≥3 failures)). No differences were found regarding concomitant use of glucocorticoids and csDMARDs. All patients with ≥3 bDMARD failures had been exposed to TNF-inhibitors (TNFi), 60% had also been exposed to other bDMARD

classes. In contrast, only 5.9% (12.9%) of patients with 1 (2) bDMARD failures had been exposed to non-TNFi.
During follow-up in RABBIT, patients with ≤2 bDMARD failures reached low disease activity (DAS28) on average while those with ≥3 bDMARD failures remained in moderate disease activity. Treatment continuation on TCZ therapy was similar in biologic naive patients and in those with ≤2 bDMARD failures. Patients with ≥3 bDMARD failures had significantly lower continuation rates (Figure). Adverse events (AEs) were the most frequent reason for discontinuation in all strata; in patients with ≥3 bDMARD failures the withdrawal of TCZ due to AEs occurred in 52% of patients.

**Conclusions:** TCZ was similarly effective in biologic naive patients and in patients with up to 2 prior TNFi failures. The majority of those patients achieved low disease activity (DAS28<3.2). However, in patients with ≥3 bDMARD failures disease activity remained on a higher level and treatment continuity was significantly lower. It seems that despite all progress in the treatment of RA during the last decades a small patient group remains in which the disease is difficult to be controlled despite effective treatment.

## FRI0227 FIVE-YEAR SAFETY AND EFFICACY OF SUBCUTANEOUS ABATACEPT IN PATIENTS WITH MODERATE TO SEVERELY ACTIVE RA AND AN INADEQUATE RESPONSE TO MTX: LONG-TERM EXTENSION OF THE PHASE III, DOUBLE-BLIND, RANDOMIZED ACQUIRE STUDY

M.C. Genovese[1], C. Pacheco Tena[2], A. Covarrubias[3], G. Leon[4], E. Mysler[5], M. Keiserman[6], R. Valente[7], P. Nash[8], J.A. Simon-Campos[9], J. Box[10], C.W. Legerton III[11], E. Nasonov[12], P. Durez[13], A. Elegbe[14], R. Wong[14], X. Li[14], S. Banerjee[14], R. Alten[15]. *[1]Stanford University, Palo Alto, United States; [2]Universidad Autónoma de Chihuahua, Chihuahua; [3]Unidad Reumatológica Las Américas S.C.P, Mérida, Mexico; [4]Instituto de Ginecología y Reproducción, Lima, Peru; [5]Organización Médica de Investigación, Buenos Aires, Argentina; [6]Pontifical Catholic University, Porto Alegre, Brazil; [7]Arthritis Center of Nebraska, Lincoln, United States; [8]University of Queensland, Brisbane, Australia; [9]Köhler & Milstein Research, Mérida, Mexico; [10]Box Arthritis and Rheumatology of the Carolinas, Charlotte; [11]Low Country Rheumatology, Charleston, United States; [12]Russian Academy of Medical Sciences, Moscow, Russian Federation; [13]Université Catholique de Louvain, Brussels, Belgium; [14]Bristol-Myers Squibb, Princeton, United States; [15]Schlosspark-Klinik University Medicine, Berlin, Germany*

**Background:** The ACQUIRE study demonstrated non-inferiority of the SC to the IV formulation.[1]
**Objectives:** To assess the 5-yr safety and efficacy of SC ABA 125 mg/wk plus background MTX in the LT extension (LTE).
**Methods:** The 6-month, double-blind (DB) period was followed by an open-label LTE in which patients (pts) received SC ABA 125 mg/wk. Dose adjustments to MTX, corticosteroids and NSAIDs were permitted. Safety, efficacy and immunogenicity assessments were performed at 12-wk intervals. Safety and efficacy analyses included all pts who entered the LTE and received ≥1 dose of ABA.
**Results:** 1373/1385 pts who completed the DB period entered the LTE, 427 (31.1%) had discontinued by end of Yr 5 (due to AE: 100 [7.3%]; lack of efficacy: 89 [6.5%]; withdrawal of consent: 81 [5.9%]). In the LTE, 1240 pts (90.3%) had an AE (Table), most (79.8%) were mild/moderate; most frequent non-serious AEs were infections. Overall, 353 pts (25.7%) had an SAE. The incidence rate/100 pt-yrs (95% CI) for SAEs decreased from 9.02 (6.31, 12.90) in the DB period to 7.73 (6.96, 8.58) during the LTE (332.6 and 4566.2 pt-yrs of exposure, respectively). Efficacy in the LTE was consistent with the DB phase and was maintained to 5 yrs in pts who remained on study: at Day 1821, 356/421 (84.6%), 277/423 (65.5%) and 191/425 (44.9%) had an ACR20, 50 or 70 response, respectively. ABA trough concentrations were stable over the LTE. Immunogenicity was low over 5 yrs (4.6/100 pt-yrs); there was no association between immunogenicity and ABA efficacy, safety or PK.

| Adverse event | Adverse events in 5-yr LTE (n=1373) n (%) of pts |
|---|---|
| All AEs | 1240 (90.3) |
| AE related to study drug | 632 (46.0) |
| AE leading to discontinuation | 97 (7.1) |
| SAEs | 353 (25.7) |
| Death | 41 (3.0) |
| AEs of special interest | |
| Infections | 962 (70.1) |
| Serious infections | 85 (6.2) |
| Opportunistic infections* | 4 (0.3) |
| Systemic injection reactions | 161 (11.7) |
| Autoimmune disorders† | 67 (4.9) |
| Malignancies‡ | 56 (4.1) |
| Local injection-site reactions | 33 (2.4) |

*Peritoneal tuberculosis, fungal oesophagitis, fungal eye infection, fungal sinusitis (n=1 each); †Including psoriasis (n=13), chronic gastritis (n=11), Sjögren's syndrome (n=10), vasculitis (n=6); ‡Including basal cell carcinoma (CA) (n=15); breast cancer, squamous cell CA, squamous cell CA of skin (n=4 each); thyroid neoplasm (n=3); cervical CA Stage 0, invasive ductal breast CA, non-small cell lung cancer, prostate cancer (n=2 each).

**Conclusions:** During this 5-yr LTE of the ACQUIRE study, the safety and efficacy of SC abatacept were consistent with that seen in the initial DB phase, with no new safety signals.

## FRI0228 SARILUMAB DOSE REDUCTION TO MANAGE LABORATORY ABNORMALITIES IN AN OPEN-LABEL EXTENSION STUDY IN RA PATIENTS

M.C. Genovese[1], J. Fay[2], J. Parrino[2], A. Garg[3], H. van Hoogstraten[3], A. Boddy[3], R. Martincova[4], N. Graham[5], J. Simon[6], G.R. Burmester[7]. *[1]Stanford University Medical Center, Palo Alto; [2]Regeneron Pharmaceuticals, Inc., Tarrytown; [3]Sanofi, Bridgewater, United States; [4]Sanofi, Prague, Czech Republic; [5]Regeneron Pharmaceuticals, Tarrytown, United States; [6]Köhler & Milstein Research, Yucatan, Mexico; [7]Charité University Medicine, Berlin, Germany*

**Background:** The investigational agent sarilumab is a human monoclonal antibody directed against the interleukin 6 (IL-6) receptor. In the phase 3 MOBILITY (NCT01061736) and TARGET (NCT01709578) studies, sarilumab (150 or 200 mg subcutaneously every 2 weeks [q2w] + conventional synthetic disease-modifying antirheumatic drugs [csDMARDs]) demonstrated efficacy in adults with active, moderate-to-severe rheumatoid arthritis (RA).[1] Among the most common treatment-emergent adverse events in both studies were infections, neutropenia, injection site reactions, and increased transaminases. Laboratory changes were consistent with IL-6 signaling blockade.
**Objectives:** This analysis examined laboratory changes and treatment continuation after sarilumab dose reduction in EXTEND (NCT01146652), an open-label, follow-up study that evaluated long-term safety and efficacy of sarilumab with or without concomitant csDMARDs.
**Methods:** Adults with RA who previously participated in sarilumab studies were eligible. Patients who entered into EXTEND before dose selection for the phase 3 studies received sarilumab 150 mg every week. After dose selection for the phase 3 studies, patients were switched to or initiated on sarilumab 200 mg q2w. Per protocol, investigators could have reduced the dose of sarilumab to 150 mg q2w for absolute neutrophil count (ANC) ≥0.5 to 1.0 Giga/L, platelet count ≥50 to 100

Giga/L, or alanine aminotransferase (ALT) ≥3 to 5× upper limit of normal. Dose reductions to avoid laboratory changes were also performed at the investigator's discretion. Efficacy data from EXTEND were analyzed before and 24 weeks after dose reduction for patients entering from the MOBILITY (n=158) and TARGET (n=42) studies.

**Results:** As of the April 2015 interim analysis, dose reduction from sarilumab 200 to 150 mg q2w had occurred in 15% of patients. The most common reasons for dose reduction were decreases in ANC (9.5%) and elevations in ALT (3.3%) (Table). Infection was the most common non-laboratory reason for dose reduction (0.4%). At the time of analysis, 80.1% of patients who dose reduced were continuing treatment, with a mean treatment duration of 1.5 years after dose reduction. Improvements in ANC and ALT were observed over the 6 months after dose reduction. Efficacy of sarilumab was maintained in patients from MOBILITY and TARGET after dose reduction in EXTEND as assessed by ACR20 responses (83.3% and 77.4%, respectively) and HAQ-DI scores (-0.68 and -0.73, respectively).

Table. Reasons for Dose Reduction

| | Patients on 200 mg q2w (N=1843) n (%) |
|---|---|
| Patients who dose reduced from 200 mg q2w to 150 mg q2w | 276 (15%) |
| Decrease in ANC | 175 (9.5%) |
| ANC <1.0 Giga/L and ≥0.5 Giga/L | 92 (5.0%) |
| Precautionary measure to avoid ANC <1.0 Giga/L | 83 (4.5%) |
| Increase in ALT level | 61 (3.3%) |
| ALT increase >3 × ULN and ≤5 × ULN | 54 (2.9%) |
| Precautionary measure to avoid ALT increase >3 × ULN | 7 (0.4%) |
| Decrease in platelet count | 19 (1.0%) |
| Platelet count ≥50 Giga/L and <100 Giga/L | 8 (0.4%) |
| Precautionary measure to avoid platelet count <100 Giga/L | 11 (0.6%) |
| Other AE | 16 (0.9%) |
| Other reason | 5 (0.3%) |

AE, adverse event; ALT, alanine aminotransferase; ANC, absolute neutrophil count; q2w, every 2 weeks; ULN, upper limit of normal.

**Conclusions:** In patients whose sarilumab dose was decreased from 200 mg q2w to 150 mg q2w, there was an improvement in laboratory abnormalities and continuation of treatment for the majority of patients. Improvements in signs and symptoms of RA and physical function were maintained after dose reduction.

## FRI0229 RISK OF HOSPITALIZED INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING ABATACEPT AND OTHER BIOLOGICS: ANALYSIS OF A UNITED STATES CLAIMS DATABASE

N. Baker[1], M. Boers[2], M. Hochberg[3], H. Kawabata[1], N. Ray[4], T. Simon[1].
*[1]Bristol-Myers Squibb, Princeton, United States; [2]VU University Medical Center, Amsterdam, Netherlands; [3]University of Maryland, Baltimore, United States; [4]Mu Sigma, Bangalore, India*

**Background:** Some studies have shown an increased risk of serious infection in patients with RA on biologic therapy.[1,2] Abatacept, the first selective co-stimulation modulator for the treatment of RA, has a mechanism of action that is fundamentally different from that of other biologic agents.

**Objectives:** The purpose of this cohort study was to compare the risk of hospitalized infection between patients initiating abatacept and patients initiating other biologic treatments.

**Methods:** Adult patients diagnosed with RA in the MarketScan® Commercial and Supplemental Medicare database, who initiated treatment with abatacept or another biologic treatment between 1 July 2006 and 30 September 2014, were eligible for inclusion in the analysis. Patients were required to have at least 180 days of continuous health plan enrolment prior to, and ≥1 day following, initiation of the qualifying RA treatment. Patients were presumed to have initiated a treatment if there was no claim for that drug in the 180 days prior to the index date. Hence, patients initiating abatacept or another biologic may have been initiating a biologic for the first time or switching from one biologic to another. Hospitalized infections were identified by International Classification of Diseases, Ninth Revision (ICD-9) diagnosis codes indicating an infection in conjunction with a hospital stay. Patients were followed up from the date of initiation of abatacept or another biologic treatment until the event of interest, end of the initiated treatment (last treatment date plus days' supply, where the last treatment date was defined as no subsequent treatment within 90 days from last treatment date plus days' supply), end of enrolment in the database or end of data collection, whichever occurred first. Patients who were hospitalized for an infection in the 6 months prior to the date of initiation were excluded. Crude incidence rates were calculated for each cohort and a Cox regression analysis was conducted to compare patients, matched by propensity score, in the two groups.

**Results:** A total of 18,474 patients with RA initiating abatacept and 53,591 initiating another biologic were identified and eligible to be included in the analysis. There were 546 incident events among abatacept initiators and 1,716 events among other biologic initiators, resulting in crude incidence rates of 35 (95% CI: 32, 38) and 36 (34, 37) per 1000 person-years, respectively. A total of 17,517 patients initiating abatacept and 32,277 patients initiating another biologic were included in the matched analysis. After adjusting for prior biologic treatment, the hazard ratio comparing hospitalized infections in the abatacept cohort and the other biologic cohort was 0.97 (0.82, 1.14).

**Conclusions:** In this study, the risk of hospitalized infection was not significantly different in patients who initiated abatacept compared with patients who initiated other biologics.

## FRI0230 ASSESSMENT OF SAFETY, PHARMACOKINETICS AND PHARMACODYNAMICS OF A NOVEL ANTI-CD40 MONOCLONAL ANTIBODY, CFZ533, IN HEALTHY VOLUNTEERS AND IN RHEUMATOID ARTHRITIS PATIENTS

A. Slade[1], P. Koo[1], Y. He[2], P. Espie[3], A. Auger-Sarrazin[3], J. Rush[3], P. Gergely[3]. *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Novartis Pharmaceuticals Corporation, Cambridge, MA, United States; [3]Novartis Pharmaceuticals Corporation, Basel, Switzerland*

**Background:** Aberrant CD40-CD154 pathway signaling has been linked to pathology in autoimmune disease. Blocking the CD40-CD154 pathway prevents T cell-dependent antibody responses, germinal center formation and prolongs renal allograft survival in non-human primates. CFZ533 is a novel, fully human, non-agonistic Fc-silent, anti-CD40 monoclonal antibody being developed for treatment of autoimmune diseases and prevention of rejection in solid-organ transplantation.

**Objectives:** To assess the safety, pharmacokinetics (PK) and pharmacodynamics activity (PD) of CFZ533 in humans.

**Methods:** A double-blind, placebo controlled, ascending, single-dose study was conducted in 48 healthy volunteers (HV) receiving 0.03, 0.1, 0.3, 1.0, 3.0 mg/kg i.v., 3.0 mg/kg s.c. CFZ533 or matching placebo (3:1) as well as in 12 rheumatoid arthritis (RA) patients receiving 10.0 mg/kg i.v. CFZ533 or placebo (1:1). HVs were immunized with a single intramuscular dose of a T-cell dependent neo-antigen, Keyhole Limpet Hemocyanin (KLH) with alum adjuvant on Day 3 and again between Day 29–85 depending on predicted loss of CD40 receptor occupancy (RO) as a function of CFZ533 dose. Blood samples for PK, CD40 RO and anti-KLH IgG and IgM profiling were collected at multiple time points during the study. Anti-KLH antibodies were assessed using a validated human ELISA system with an LOQ of 0.7 (IgG) and 2.1 (IgM) μg/mL. RA patients were evaluated for safety, PK and RO.

**Results:** All doses of CFZ533 and KLH were safe and well tolerated. CFZ533 PK concentrations were quantifiable at all dose levels tested. Complete (≥90%) peripheral CD40 RO by 3 mg/kg i.v. CFZ533 in HVs was maintained for 28 days. During this period of full RO, full suppression of the primary humoral response to KLH was evident in all treated subjects (KLH administered 2 days after CFZ533 dosing). After complete CFZ533 washout in 3 mg/kg cohort, all subjects mounted a robust anti-KLH response following a re-challenge on Day 85. Full RO in RA patients who received 10 mg/kg i.v. CFZ533 was maintained for at least 6 weeks and up to 10 weeks.

**Conclusions:** The favorable safety and tolerability profile of CFZ533 coupled with a predictable concentration-CD40 receptor occupancy relationship and suppression of a primary T cell-dependent antibody response supports future clinical trials of CFZ533 in select autoimmune diseases and transplantation.

## FRI0231 TREATMENT WITH BI 655064 (ANTAGONISTIC ANTI-CD40 ANTIBODY) MODULATES BIOMARKERS ASSOCIATED WITH RHEUMATOID ARTHRITIS (RA)

S. Visvanathan[1], M. Ramanujam[2], C. Schoelch[3], R. Vinisko[4], U. Mueller-Ladner[5], S. Padula[6], J.S. Fine[7], J. Steffgen[8]. *[1]Translational Medicine and Clinical Pharmacology; [2]Discovery Research, Boehringer Ingelheim, Ridgefield, United States; [3]Translational Medicine and Clinical Pharmacology, Boehringer Ingelheim, Biberach, Germany; [4]Clinical Development, Boehringer Ingelheim, Ridgefield, United States; [5]Kerkhoffklinik, Bad-Nauheim; [6]Medicine, Boehringer Ingelheim, Ingelheim; [7]Discovery Research, Boehringer Ingelheim, Ridgefield; [8]Medicine, Boehringer Ingelheim, Biberach, Germany*

**Background:** Co-stimulation through the CD40- CD40L axis has been implicated in the pathogenesis of RA including T cell mediated responses, B cell driven autoantibodies, adhesion molecule expression, synovial hyperplasia, and pannus formation, in addition to the secretion of proinflammatory cytokines and MMPs. Circulating CD40L levels are elevated in RA patients versus healthy controls. BI 655064 is a humanized antagonistic anti-CD40 monoclonal antibody which blocks the CD40/ CD40L interaction in in vitro CD40L induced B cell and APC activation assays with IC50 of $<$1nM.
**Objectives:** To characterize the effect of BI 655064 on cellular and protein biomarkers in RA patients with prior inadequate response to a stable dose MTX $\geq$15 mg over a 12 wk period of treatment.
**Methods:** In this double-blinded, randomized trial RA patients were treated with either 120 mg BI 655064 or placebo q1w for 12 wks as add-on to MTX. Inclusion criteria were $\geq$6 swollen and $\geq$6 tender joints, CRP $>$8 mg/L or ESR$>$28 mm/1h. The primary efficacy endpoint was ACR20 response at wk 12.Select biomarkers were assessed in whole blood and serum pre and post treatment with BI 655064.
**Results:** Treatment with BI 655064 resulted in minimal changes in median %CD19+ B cell population but larger median decreases in select %CD95+ activated B cell subsets, specifically class switched (CD19+IgD-CD27+CD95+), pre-switched (CD19+IgD+CD27+CD95+) and double negative (CD19+IgD-CD27-CD95+) cells and decreases in autoantibodies (IgG-RF and IgA-RF), total IgG and IgM levels in RA patients vs placebo at 12 wks. Median decreases in IL-6 levels (important for B cell and monocyte differentiation) and select bone resorption biomarkers (MMP-3 and RANKL) were also observed in the BI 655064 treated patients vs placebo through 12 wks. Baseline levels of IgG RF, IgM RF, TNFa and COMP correlated with improvement in swollen joint counts at 12 wks and IgA RF levels correlated with improvement in DAS-28 CRP scores at 12 wks in patients treated with BI 655064.

Table 1. Median % or change from baseline to 12 wks in select biomarkers by treatment group

| | | N | BI 655064 | Placebo | p-value* |
|---|---|---|---|---|---|
| Change in | % CD19+CD27+IgD+CD95+ | 28/15 | –16.8 | –8.0 | 0.0831 |
| Change in | % CD19+CD27+IgD-CD95+ | 28/15 | –15.3 | +2.3 | 0.0765 |
| Change in | % CD19+CD27-IgD-CD95+ | 28/15 | –14.6 | +4.0 | 0.0097 |
| % change in | IgG ACPA | 35/19 | –19 | –11.9 | 0.2771 |
| % change in | IgG RF | 35/17 | –22.7 | +14.3 | 0.0018 |
| % change in | IgA RF | 35/17 | –13.9 | 0 | 0.0050 |
| % change in | Total IgG | 34/18 | –8.6 | –0.6 | 0.0082 |
| % change in | Total IgM | 34/18 | –12.3 | –0.3 | 0.0002 |
| % change in | CD40L | 34/17 | –47.2 | –59.6 | 0.9920 |
| % change in | IL-6 | 34/18 | –17.3 | +18.7 | 0.1001 |
| % change in | MMP-3 | 34/18 | –7.8 | +2.3 | 0.1574 |
| % change in | RANKL | 35/19 | –29.4 | 0 | 0.0041 |

*Wilcoxon 2-sample test.

**Conclusions:** These results demonstrate that treatment of RA patients with BI 655064 decreases activated B cell subsets, inhibits the production of pathogenic autoantibodies, and reduces the level of circulaiting inflammatory and bone resorption biomarkers at 12 wks. Baseline levels of select biomarkers significantly correlated with clinical response to treatment with BI 655064 at 12 wks.

## FRI0232 FACTORS INFLUENCING THE CHOICE OF FIRST AND SECOND LINE BIOLOGIC THERAPY FOR THE TREATMENT OF RHEUMATOID ARTHRITIS: REAL LIFE DATA FROM THE ITALIAN LORHEN REGISTRY

S. Monti[1], R. Gorla[2], P. Sarzi-Puttini[3], F. Atzeni[3], R. Pellerito[4], E. Fusaro[5], G. Paolazzi[6], P.A. Rocchetta[7], E.G. Favalli[8], A. Marchesoni[8], R. Caporali[1]. *[1]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, Pavia; [2]Rheumatology, Spedali Civili Brescia, Brescia; [3]Rheumatology, University Hospital Sacco, Milan, Milan; [4]Rheumatology, Ospedale Mauriziano; [5]Rheumatology, Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Torino; [6]Rheumatology, Santa Chiara Hospital, Trento, Trento; [7]Rheumatology, A.S.O. "SS. Antonio e Biagio e C.Arrigo", Alessandria, Alessandria; [8]Rheumatology, Gaetano Pini Institute, Milan, Milan, Italy*

**Background:** The therapeutic armamentarium for the treatment of rheumatoid arthritis (RA) has been significantly implemented with the use of biologic-disease modifying anti-rheumatic drugs (bDMARDs). TNF inhibitors (TNFi), abatacept (ABA) or tocilizumab (TCZ) are all approved as first-line biologic agents. International Recommendations (1) do not provide a preference on the mechanism of action (MoA) to be chosen first or after the failure of bDMARD therapy.
**Objectives:** To analyse the factors influencing the choice of the first-line bDMARD or the switching strategy in RA, focusing on the prescription of ABA or TCZ compared to TNFi.
**Methods:** Patients were selected from the Lombardy Rheumatology Network (LORHEN) Registry. The analysis was limited to patients enrolled after 2008, when all three different MoA were available. The study population was divided into "first-line" and "second-line" bDMARD.
**Results:** A total of 1910 patients were included. First line n=1264, second line n=646 patients. Both age at diagnosis and at bDMARD initiation were significantly lower in patients treated with first-line TNFi compared to ABA and TCZ ($p<0.0001$). A positive screening for latent tuberculosis was more represented in the group treated with first-line ABA compared to TCZ or TNFi (p=0.002). Combination therapy with methotrexate (MTX) was significantly lower in the TCZ group (50.77% of patients), compared to both ABA (86.70%) and TNFi (64.28%); p=0.02. The presence of dyslipidemia (p=0.018), hypertension (p=0.002) or concomitant pulmonary disease ($p<0.0001$) was significantly associated with the choice of ABA first-line. The presence of other comorbidities in general and of $\geq$2 comorbidities influenced the choice of the bDMARD towards ABA (p=0.01). When switching to a second line of treatment, patients with higher DAS28 were more frequently treated with TCZ compared to TNFi (p=0.005) or ABA (p=0.038). The presence of peripheral neuropathy also influenced the choice towards ABA Vs TNFi (p=0.005). TCZ, followed by ABA showed the lowest interruption rate compared to TNFi (p=0.002 and p=0.003, respectively). Multinomial logistic regression demonstrated that a second-line treatment, higher age, dyslipidemia, pulmonary disease, other comorbidities, and extra-articular RA manifestations such as vasculitis were all associated with the choice of ABA compared to TNFi. The choice of TCZ was associated with a second line of treatment, higher age and more severe disease activity.
**Conclusions:** According to International Guidelines, the selection of the first and second-line bDMARD is left to the clinician's preference. However, real-life data suggest that higher age and comorbidities influence the choice towards ABA and TCZ compared to TNFi. After failing a first-line TNFi, a strategy of swapping to a different MoA is more common.

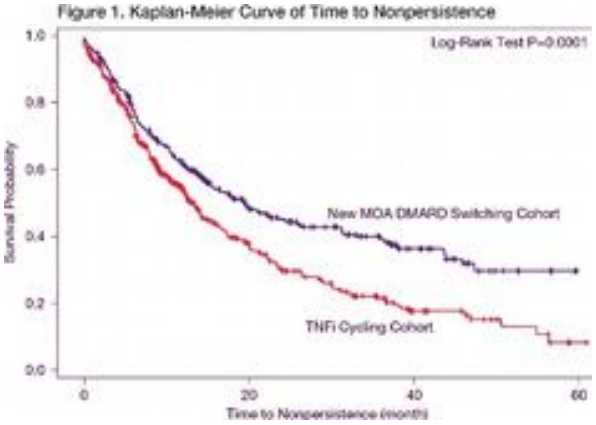
## FRI0233 REAL-WORLD TREATMENT PERSISTENCE AND CLINICAL OUTCOMES OF TNFI CYCLING VS SWITCHING TO NEW MECHANISM-OF-ACTION DMARDS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN THE UNITED STATES



W. Wei[1], K. Knapp[2], L. Wang[3], C. Chen[4], G. Craig[2], K. Ferguson[2], S. Schwartzman[5]. *[1]Sanofi, Bridgewater; [2]Discus Analytics, Inc., Spokane; [3]STATinMED Research, Plano; [4]Regeneron Pharmaceuticals, Inc., Tarrytown; [5]The Hospital for Special Surgery, New York, United States*

**Background:** Recent studies suggested that in rheumatoid arthritis (RA) patients discontinuing their prior tumor necrosis factor inhibitor (TNFi), treatment persistence was greater in those switching to a disease-modifying antirheumatic drug (DMARD) with a new mechanism-of-action (MOA) than in those cycling to a second TNFi.
**Objectives:** To evaluate in RA patients real-world treatment persistence and clinical outcomes associated with TNFi cycling vs switching to a new MOA DMARD.
**Methods:** This retrospective analysis of RA patients used the US clinical JointMan® database, an evidence-based rheumatology software application that

rheumatologists use to systematically document patient-level data in routine clinical practice. Adult RA patients were included if they had a physician prescription record of a TNFi from April 1, 2010 through March 31, 2015 *and* a subsequent DMARD that was a different TNFi (TNFi cycling cohort) or new MOA DMARD (new MOA DMARD switching cohort). Patients were indexed on the date of the subsequent TNFi or new MOA DMARD from a prior TNFi during the pre-index period. Treatment persistence was assessed, defined as neither discontinuing nor switching the drug post-index before the end of the observational period. Change in Clinical Disease Activity Index (CDAI) at 1 year post-index and its correlation with treatment persistence were evaluated. Kaplan-Meier survival analysis measured time to nonpersistence. Cox proportional hazards regression and ordinary least-squares regression were used to identify independent factors predicting time to nonpersistence and 1-year CDAI change, respectively.

**Results:** Included were 613 patients (mean age 56.5 years; 78.5% women; 82.9% white; baseline CDAI 22.7). After discontinuing a prior TNFi, 54.2% (n=332) of patients cycled to another TNFi and 45.8% (n=281) switched to a new MOA DMARD. During follow-up, 36.7% (n=225) of patients were persistent with their index drug, 34.1% (n=209) switched from their index drug to another drug, and 29.2% (n=179) discontinued their index drug. Compared with TNFi cyclers, new MOA DMARD switchers were more likely to be persistent at 1 year (45.2% vs 29.5%; $P<0.0001$) and to persist for a longer period of time (Figure 1). After adjusting for covariates, TNFi cyclers were more likely to be nonpersistent than new MOA DMARD switchers (adjusted hazard ratio 1.511; $P<0.001$). Reduction in CDAI at 1 year was lower in TNFi cyclers than in new MOA DMARD switchers (–4.73 vs –7.64; $P=0.027$); however, this effect was not statistically significant when baseline CDAI was controlled for in the regression model (–5.83 vs –6.39; $P=0.607$). Overall, treatment persistence was associated with a significantly higher reduction in CDAI (–8.69 vs –3.16; $P<0.001$).

Figure 1. Kaplan-Meier Curve of Time to Nonpersistence

**Conclusions:** This real-world study suggests that after discontinuing their prior TNFi, RA patients who switched to a new MOA DMARD demonstrated better treatment persistence than those cycling to another TNFi. Persistence with RA treatment was associated with better clinical outcome.

## FRI0234 PREDICTIVE FACTORS OF DISCONTINUATION OF THERAPY WITH ABATACEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Piantoni[1,2], E. Colombo[3], A. Tincani[4], P. Airò[3], M. Scarsi[3,5]. *[1]Rheumatology and Clinical Immunology, Department of Clinical and Experimental Sciences, Spedali Civili and University of Brescia, Brescia; [2]Rheumatology Chair, University of Pavia, Pavia; [3]Rheumatology and Clinical Immunology, Spedali Civili of Brescia; [4]Rheumatology and Clinical Immunology, Department of Clinical and Experimental Sciences, Spedali Civili and University of Brescia, Brescia; [5]Internal Medicine Unit, Esine-Vallecamonica Hospital, ASL Vallecamonica-Sebino, Esine, Italy*

**Background:** Biomarkers who facilitate clinicians in decision making regarding the drugs that could be more effective for their patients with rheumatoid arthritis (RA) are needed.

**Objectives:** To look for predictors of abatacept (ABA) therapy discontinuation in patients with RA.

**Methods:** Seventy-one consecutive patients with RA who received treatment with intravenous ABA from 2008 to 2014 were enrolled. Demographical, clinical and laboratory parameters were evaluated, including peripheral blood T- and B-cell populations, rheumatoid factor and anti-cyclic citrullinated peptide (autoantibodies ACPA) isotypes, and serum free light chains. To evaluate the predictors of therapy discontinuation by logistic multivariable analysis, both variables associated with $p<0.05$ in univariable analysis, and variables previously reported by literature as potential confounders were considered. Receiver-operating characteristic (ROC) analysis was used to verify the applicability of predictive biomarkers. The Kaplan-Meier method and the log-rank test were applied to compare the probability of discontinuing therapy in the different groups.

**Results:** Comparing patients who discontinued ABA (n:28) with those still in therapy (n:41) we observed: a higher proportion of smokers (51.9% vs 25.6%; p=0.03); a lower proportion of terminally-differentiated effector-memory cells (TDEM) among total CD8+ T-lymphocytes at baseline (22.0% (7.8–39.2) vs 38.7% (20.7–55.9); p=0.002). The proportion of patients with positivity for ACPA was lower among patients who discontinued ABA, but not significantly (76% vs 89.5%; p=0.13). Logistic multivariate analysis showed that only the proportion of CD8+TDEM T-cells was an independent predictive factor of therapy discontinuation (OR (95% IC)=6.2 (1.2 to 30.8); p=0.026). ROC analysis showed a significant performance of this biomarker for prediction of therapy discontinuation (using a cut-off of 30.6%: AUC: 0.760+0.07; p=0.002). Patients with a low proportion of CD8+TDEM at baseline had a higher probability of discontinuing the treatment during time (log-rank test: $p<0.01$).

**Conclusions:** A high number of circulating TDEM T-cells might be a marker of a stronger activation of costimulatory signals in the history of RA patients. It might be speculated that these patients may be particularly responsive to costimulation blockade by ABA. T-cell characterization for identification of TDEM CD8+ T-cells might be a useful test to predict discontinuation of ABA therapy.

## FRI0235 INCIDENCE OF PARADOXICAL REACTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS DURING TOCILIZUMAB THERAPY: DATA FROM THE FRENCH REGISTRY REGATE

W. Terreaux[1], J.-P. Eschard[1], D. Wendling[2], C. Marcelli[3], A. Perdriger[4], P. Collet[5], L. Le Dantec[6], A. Constantin[7], C. Scotto Di Fazano[8], T. Bardin[9], J. Sibilia[10], J. Morel[11], J.-H. Salmon[1]. *[1]Rheumatology department, CHU Reims, Reims; [2]Rheumatology, CHU Besançon, Besançon; [3]Rheumatology department, CHU Caen, Caen; [4]Rheumatology department, CHU Rennes, Rennes; [5]Rheumatology department, CHU Saint Etienne, Saint Etienne; [6]Rheumatology department, CH Riaumont, Liévin; [7]Rheumatology department, CHU Toulouse, Toulouse; [8]Rheumatology department, CH Perpignan, Perpignan; [9]Rheumatology department, CHU Lariboisière, Paris; [10]Rheumatology department, CHU Strasbourg, Strasbourg; [11]Rheumatology department, CHU Montpellier, Montpellier, France*

**Background:** Tocilizumab is a humanized monoclonal antibody specific to the alpha subunit of the receptor of interleukin-6 (IL-6) indicated in the management of some rheumatic diseases. The monitoring of patients under biotherapy has led to the discovery of particular side effects called paradoxical effects, that is to say, conditions that are supposed to be treated with the biotherapy itself [1–2]. To our knowledge, there is no clinical trial or "real life" data assessing the occurrence of paradoxical effects under tocilizumab therapy from a large cohort.

**Objectives:** To assess the frequency of paradoxical effects encountered in everyday practice under tocilizumab therapy, using the REGATE (Registry-RoActemra) registry [3]. The secondary objectives are to determine the type of paradoxical effect and the consequences of these effects.

**Methods:** The REGATE registry is an independent prospective registry, promoted by the French Society of Rheumatology, consisting of patients with rheumatoid arthritis treated by tocilizumab. For every paradoxical reaction, the data was validated by the clinician in charge of the patient. The paradoxical effect was noted if the induced pathology appeared after exposure to at least one tocilizumab infusion, and if tocilizumab was likely to treat the condition in question [4]. If patients had one of these conditions de novo while under tocilizumab therapy for another condition, we considered it as a paradoxical effect. The aggravation of a preexisting condition was also considered as a paradoxical effect [1].

**Results:** Among the 1499 patients included with at least one follow-up visit (3429 patient-years), a paradoxical reaction occurred in 14 patients (0.93% of patients; 4.08/1000 patient-years). These were 10 de novo pathologies (3 vasculitis, 3 uveitis, 2 psoriasis, 1 lupus, 1 ulcerative colitis) and 4 exacerbations

of pre-existing conditions (2 psoriasis, 1 vasculitis, 1 lupus). The average time between the initiation of tocilizumab and the appearance of the first manifestation of the paradoxical effect was 14.85 (±12.79) months. Permanent discontinuation of tocilizumab was chosen for 5 patients (35%), a transitional stop for 3 patients, a dosage adjustment for 1 patient. One paradoxical effect (psoriasis) recurred with continued tocilizumab.

**Conclusions:** Paradoxical reactions under tocilizumab are not frequent (less than 1%) but require an adaptation of treatment in over 50% of cases.

## FRI0236 SAFETY, PHARMACOKINETICS AND EFFICACY OF E6011, AN ANTI-FRACTALKINE MONOCLONAL ANTIBODY, IN A FIRST-IN-PATIENT PHASE 1/2 STUDY IN RHEUMATOID ARTHRITIS

Y. Tanaka[1], T. Takeuchi[2], H. Umehara[3], T. Nanki[4], H. Akama[5], N. Yasuda[5], F. Tago[5], M. Kawakubo[5], S. Hojo[5], T. Kawano[6], T. Imai[6]. *[1]University of Occupational and Environmental Health, Japan, Kitakyushu; [2]Keio University, Tokyo; [3]Kyoto University Graduate School of Medicine, Kyoto; [4]School of Medicine, Faculty of Medicine, Toho University; [5]EISAI Co. Ltd., Tokyo; [6]KAN Research Institute, Inc., Kobe, Japan*

**Background:** Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to dual actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1, during their migration. Accumulating evidence is telling that FKN-CX3CR1 axis plays a pivotal role in leukocyte/lymphocyte accumulation in inflamed tissues in RA[1]. We developed E6011, a novel humanized anti-FKN monoclonal antibody.

**Objectives:** To evaluate safety, pharmacokinetics and efficacy of E6011 in a Phase 1/2, open-label, multiple ascending dose study in RA patients for the first time (NCT02196558).

**Methods:** Active RA patients with inadequate response to MTX or TNF inhibitors were received 7 consecutive doses (subcutaneous: SC) of E6011 at week 0, 1, 2 and thereafter every 2 weeks up to week 10. A hundred and 200 mg of E6011 were chosen for the study as putatively appropriate doses for patients by the PK/PD modeling previously obtained in the Ph1 healthy volunteer study of E6011.

**Results:** Twelve subjects were enrolled in the cohort of 100 mg and subsequently 15 subjects were enrolled in the 200 mg cohort, in total, 27 subjects received repeated subcutaneous administrations of E6011. As a result, repeated dose of E6011 was found safe and well tolerated. The incidence of AE, treatment-related AE and SAE was 59.3%, 29.6% and 7.4%, respectively. There were no severe AE or deaths, and no significant differences were observed in the incidence or severity of AE between the 100 mg and 200 mg cohorts. After starting multiple SC injection of E6011, serum E6011 concentration reached steady-state at week 2, and its level was maintained up to week 12. Mean trough E6011 concentrations from week 2 through week 12 were 11.6 – 15.7 ug/mL and 29.2 – 38.8 ug/mL after dosing of 100 and 200 mg, respectively. Clinical outcome was also available in the study in which response rates of ACR20, 50 and 70 at week 12 were 75.0%, 33.3%, 8.3% and 80.0%, 26.7%, 20.0% in the cohort of 100 and 200 mg, respectively. At week 12, 33.3% of subjects achieved DAS28-CRP remission in both cohorts, 16.7% and 20.0% for SDAI remission and 8.3% and 26.7% for Boolean remission were observed in the 100 and 200 mg cohorts, respectively.

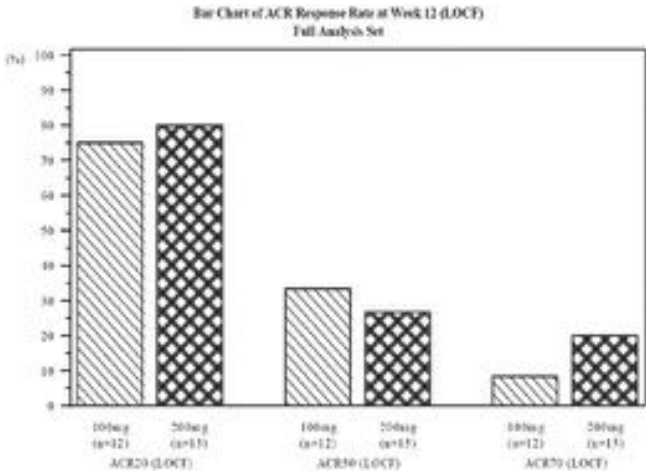

Figure 1

**Conclusions:** E6011 was safe and well tolerated, and demonstrated a promising efficacy in active RA patients with MTX or TNFi-IR. While further clinical studies are required, the results obtained indicate that a novel biological DMARD targeting FKN/CX3CR1 interaction will be clinically beneficial for active RA patients.

## FRI0237 TOCILIZUMAB IMPACT ON KINETICS OF TREATMENT TARGET PARAMETERS IN SYSEMIC NEPHROTIC TYPE AA-AMYLOIDOSIS, SECONDARY TO RA

A. Alexeeva, Y. Muraviev, S. Radenska-Lopovok, E. Aleksandrova, L. Kashnikova. *Federal State Scientific Institution "Research Institute of Rheumatology named V.A. Nasonova", Moscow, Russian Federation*

**Background:** Systemic AA-amyloidosis is a severe complication of RA occurring due to upregulated production of serum amyloid A (SAA), induced predominantly by IL-6.

**Objectives:** To assess Tocilizumab (humanized monoclonal antibody to IL-6 receptors) impact on kinetics of treatment target parameters in sysemic nephrotic type AA-amyloidosis, secondary to RA.

**Methods:** DAS28, SAA levels, CRP, ESR, 24-hour proteinuria, glomerular filtration (GFR), and gistomorphologic examination of biopsy samples were monitored in all participants to the study in addition to the standard clinical and lab parameters. Statistical processing covered the number of participating subjects, arithmetic mean (AM), standard deviation from AM (δ). Difefferces were considered statistically significant with $p$ values $<0,05$. Student's $t$-test was used. Data was processed with Statistica 7.0 for Windows ("StatSoft Inc.") software.

**Results:** The study included 10 pts (mean age 52±9,1 y.) with systemic AA amiloidosis and morphologically verified nephrotic syndrome (biosy samples of duodenal mucous), secondary to RA, meeting ACR 1987 criteria (average disease duration - 17,1±8,9 y). All poor responders to DMARDs, NSAIDs and GCs at a stable dose for at minimum 6 preceding mo (peroral $<10$ mg/day prednisolone or its equivalent) were administered Tocilizumab i/v by drop infusions each 4 weeks at 8 mg/kg during total 12 mo.

After 12 mo of therapy significant decrease was documented for mean SAA (from 46,7±28,1 mg/mL to 14,7±24,3 mg/mL; $p$=0,03), DAS28 score (from 5,5±1,4 to 3,3±1,15; $p$=0,003), 24-hour proteinuria (from 0,8±0,7 g/day to 0,08±0,6 g/day; $p$=0,04). At the same time no desiarable changes occurred in ESR (from 32,1±19,5 mm/hour to 17±26,5 mm/hour; $p$=0,1), GFR (from 62,2±42,9 mL/min to 54,2±31,9 mL/min; $p$=0,3). Although, second control biopsy& histomorphology did not reveal amiloid depositions in duodenal mucous in 2 pts.

**Conclusions:** 12-mo Tocilizumab therapy resulted in target decrease of RA activity, accompanied by simultaneous decrease in SAA and 24-hour proteinuria (although not all pts achieved the desired target levels), and complete disappearance of amiloid depositions in duodenal mucous in 2 pts.

## Scleroderma, myositis and related syndromes

### FRI0238 INCREASED SERUM FREE LIGHT CHAINS OF IMMUNOGLOBULINS IN SYSTEMIC SCLEROSIS PATIENTS: CORRELATION WITH LUNG INVOLVEMENT AND INFLAMMATORY MILIEU

S.L. Bosello[1], U. Basile[2], E. De Lorenzis[1], G. Canestrari[1], F. Parisi[1], M. Rucco[1], D. Birra[1], F. Gulli[2], C. Napodano[2], K. Pocino[2], F. Forni[2], B. Tolusso[1], G. Ferraccioli[1]. *[1]Institute of Rheumatology; [2]Department of Laboratory Medicine, Catholic University, Rome, Italy*

**Background:** Humoral immunity and B cells are thought to play an important role in the pathophysiology of the systemic sclerosis (SSc). The production of free light chains (FLC) of immunoglobulins is abnormally high in different pathological autoimmune conditions and reflects B cell activation. Furthermore FLCs demonstrated different biological activities including their capability to modulate the immune system, proteolytic activity, complement cascade activation, as well as FLC binding to antigens and chemotactic factors.
**Objectives:** To determine the FLC levels in patients with SSc and in healthy controls and to study their possible association with organ involvement and disease characteristics.
**Methods:** Sixty-five SSc patients (90.0% females; mean age 50.8±17.0 years; 27 (41.5%) with diffuse skin involvement-dcSSc) and 20 age and sex matched healthy controls (HC) were studied. Clinical and immunological inflammatory characteristics were assessed for all the SSc patients. FLC levels were quantified by nephelometry (Freelite TM Human Kappa and Lambda Free Kits, The Binding Site, UK). IL6 and BAFF levels were measured in SSc patients by ELISA.
**Results:** The mean serum FLC-κ level (SSc: 20.4±7.5 ng/ml *vs* HC 9.4±4.3 ng/ml, $p<0.001$) and FLC ratio (SSc: 1.6±0.6 *vs* HC 0.8±0.2, $p<0.001$) were significantly higher in patients with SSc compared to healthy controls, while the serum FLC-$_{\lambda}$ levels were comparable (SSc: 13.6±4.8 ng/ml *vs* HC 11.9±6.2 ng/ml, p=ns).
The levels of FLC were comparable in patients with diffuse skin disease and limited skin involvement, while FLC-κ levels were increased in patients with restrctive lung (FVC<79%) disease (SSc: 26.4±7.4 ng/ml) when compared to patients with FVC>79% (HC 19.6±7.3 ng/ml, p=0.009).
In SSc patients the levels of serum FLC-κ level directly correlate with the IL-6 levels (R=0.6, $p<0.001$), while no correlation was found with skin involvement and autoantibodies distribution.
**Conclusions:** Free light chains of immunoglobulins (sFLC) levels are elevated in systemic sclerosis. High levels of sFLC are associated with the fibrotic lung involvement and with an higher degree of inflammation, supporting the role of B cell activation in the pathophysiology of SSc.

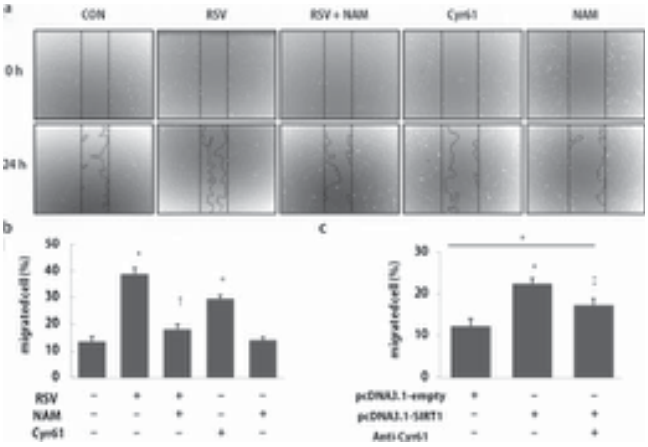
### FRI0239 COMPLEMENTARY VALUE OF ELF TEST AND NT-PROBNP IN REFLECTING FIBROSIS AND VASCULOPATHY IN SYSTEMIC SCLEROSIS

G. Abignano[1,2], J. Blagojevic[2,3], L.-A. Bissell[1,2], R.B. Dumitru[2], S. Eng[2], N. Calder[4], M. Messenger[4], M. Buch[1,2], P. Emery[1,2], F. Del Galdo[1,2]. *[1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine - University of Leeds, Leeds, United Kingdom; [3]Department of Experimental and Clinical Medicine, Division of Rheumatology, Florence, Italy; [4]NIHR Diagnostic Evidence Co-operative, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*



**Background:** The ELF test and its components (PIIINP, TIMP-1 and HA) have been shown to correlate with skin, lung and overall fibrosis and not with any vascular manifestation of Systemic Sclerosis (SSc)[1]. On the contrary, NT-proBNP has been suggested to be useful for stratification of SSc patients, especially to identify those at risk of pulmonary hypertension[2].
**Objectives:** Aims of this study were: a) to validate ELF score and its single analytes on an independent cohort of scleroderma patients; b) to evaluate whether NT-proBNP could provide additional value to the development of an SSc-specific algorithm.
**Methods:** 250 sera from SSc patients from a single UK centre were analysed employing a high-throughput in vitro diagnostic of a routine NHS pathology lab to measure ELF score, its analytes and NT-proBNP levels. All patients fulfilled 2013 ACR/EULAR classification criteria for SSc. Clinical, laboratory and instrumental data were collected at time of sampling. Statistical analysis was performed using SPSS. $P<0.05$ was considered statistically significant.
**Results:** Multivariate analysis of ELF score (including the variables found statistically significant in univariate analysis) identified age, mRSS and DLCO% as independently associated with ELF score ($p<0.0001$ for all), confirming results previously published on an independent Italian cohort. As previously shown, ELF score and single analytes were not associated with heart and vascular manifestations of the disease. On the contrary NT-proBNP significantly correlated with heart severity ($p<0.0001$) and peripheral vasculopathy (p=0.005). Its levels were higher in patients with current digital ulcers (p=0.001), digital pitting scars (p=0.01), telangiectasias (p=0.01), systemic arterial hypertension (p=0.004), pulmonary artery hypertension (PAH) (p=0.01), diastolic dysfuction (p=0.002), reduced ejection fraction (p=0.0002), arrhythmias ($p<0.0001$) and dyspnoea (p=0.003) compared to those without the manifestation. Multivariate analysis identified presence of arrhythmias ($p<0.0001$), age ($p<0.0001$), PAH ($p<0.001$) and DLCO% (p=0.006) as independently associated with NT-proBNP. All the biomarkers significantly correlated with total Medsger's severity scale and EScSGactivity index ($p<0.0001$).
**Conclusions:** Our findings validate the value of ELF score in a second independent cohort of 250 SSc sera and suggest that NT-proBNP has a complementary value correlating with other aspects of the disease such as PAH and heart severity. Longitudinal multicentres studies are warranted to determine the sensitivity to change and the predictive value of these biomarkers in SSc patients and to build up a new combined scleroderma specific algorithm including markers of fibrosis and vasculopathy.

## Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models

### FRI0240 SIRT-1 REGULATES TGF-β INDUCED DERMAL FIBROBLAST MIGRATION VIA MODULATION OF CYR61 EXPRESSION

W. Jeong[1], E.-J. Park[2], E.-J. Kwon[3], M. Cho[4], J. Kim[2]. *[1]Department of Medicine; [2]Dvision of Rheumatology, Department of Medicine, Jeju National University Hospital, Jeju National University School of Medicine; [3]Jeju National University School of Medicine, Jeju-si, Korea, Republic Of; [4]Department of Biochemistry, Jeju National University School of Medicine, Jeju-si, Korea, Republic Of*

**Background:** SIRT1 is a NAD-dependent protein deacetylase that participate in cellular regulation. The increased migration of fibroblast is important phenotype in fibroblast activation. The role of SIRT1 in cell migration remains controversial whether SIRT1 act as a activator or suppressor for cell migration.
**Objectives:** The aim of this study was to establish the role of SIRT1 in human dermal fibroblast migration and explore a target of SIRT1 for dermal fibroblast migration.
**Methods:** Levels of SIRT1 expression were analysed in human dermal fibroblast by RT-PCR and western blotting before and after stimulation with tumour gowth factor-β (TGF-β) and resveratol. Human dermal fibroblasts were transfected with active SIRT1 expression vectors or with siRNA targeting SIRT1 or were treated with nicotinamide. Cyr61 expression analysis was performed by western blotting to study the role of SIRT1 on cell migration. The wound healing assay was performed due to analyze migration of human dermal fibroblasts.
**Results:** SIRT1 and Cyr61 was expressed in human dermal fibroblasts and the stimulation of TGF-β further induced expression levels of SIRT1 and Cyr61 (figure a). Treatment of resveratol, SIRT1 agonist or overexpression of SIRT1 also promoted expression of SIRT1 and Cyr61 in human dermal fibroblasts, whereas inhibition of SIRT1 activity by nicotinamide or knock down of SIRT1 down-regulated Cyr61 basal level as well as TGF-β or resveratol-induced Cyr61expression. Blocking of ERK signaling by PD98509 reduced TGF-β or resveratol-induced Cyr61 expression. Resveratol increased migration and nicotinamide attenuated resveratol-induced migration of human dermal fibroblasts. Furthermore, SIRT1 overexpression promoted cell migration whereas blocking Cyr61 attenuated SIRT1-stimulated migration of human dermal fibroblasts (figure b and c).

**Conclusions:** We suggested a role of SIRT1 in human dermal fibroblast migration.

SIRT1 increased cell migration by stimulated Cyr61 expression for their target through the ERK signaling. SIRT1-induced Cyr61 production is very important for human dermal fibroblasts migration.

## FRI0241 HMGB1 INDUCES REACTIVE OXYGEN SPECIES (ROS)-DEPENDENT ACTIVATION OF THE ER STRESS PATHWAY IN C2C12 MYOTUBES

A.P. Lightfoot, R.S. Morgan, R.G. Cooper. *Dept of Musculoskeletal Biology, University of Liverpool, Liverpool, United Kingdom*

**Background:** The term myositis describes a heterogeneous spectrum of autoimmune diseases, which cause symmetrical proximal muscle weakness and atrophy, and resulting dysfunction. Infiltration of immune cells into muscle has long been regarded as the primary pathological event in myositis. However, the magnitude of inflammatory cell loads often correlates poorly with the levels of detected muscle weakness, so myositis patients often remain weak in the absence of inflammation; while in a murine myositis model muscle weakness may actually precede inflammatory cell infiltrations. Thus, non-immune cell mediated mechanisms, such as those related to ER stress pathway activation, likely play an important role in weakness and atrophy induction, [1]. High-mobility group box protein 1 (HMGB1) is a chromatin protein which is localised outside of the nucleus in myositis, and induces muscle dysfunction and fatigue, via TLR4 signalling, [2, 3]. Given the likely importance of ER stress pathology activation in myositis, and knowledge that HMGB1 can alter ER stress mechanisms and thus induce reactive oxygen species generation (ROS) in non-muscle systems; we wondered whether HMGB1 could induce ROS generation in muscle, and so contribute to ER stress pathway activation, [4].
**Objectives:** To determine whether antioxidant compounds can ameliorate *in vitro* HMGB1-induced activation of the ER stress pathway in skeletal muscle.
**Methods:** C2C12 myotubes were treated with rHMGB1 (10ng/ml) without and with (10nM) of the broad-spectrum antioxidant N-acetyl-L-cysteine (NAC) or (5uM) of the mitochondrial-targeted antioxidant SS-31, for a period of 24 hours. Cells were then harvested, RNA-isolated using TRIzol extraction, and cDNA synthesised. Changes in gene expression associated with ER stress pathway activation, mitochondrial function/dynamics and antioxidant defence mechanisms were examined using qPCR.
**Results:** HMGB1 exposure significantly unregulated the gene expression of the ER stress pathway components ATF4, ATF6 and IRE1. Treatment of cells with HMGB1 in the presence of NAC significantly inhibited this expected upregulation of expression of ATF4, ATF6 and IRE1 genes. Treatment with SS-31, a specific scavenger of mitochondria-derived ROS, similarly inhibited upregulation of expression of these genes, but where inhibition was clearly greater than that due to NAC exposure.
**Conclusions:** In myositis, ER stress has been widely implicated in the pathogenesis of non-immune cell mediated weakness and atrophy induction. Our *in vitro* findings here suggest that HMGB1 plays a role in ER stress pathway activation, and that both broad spectrum and targeted antioxidant interventions can ameliorate this effect. Thus, the development of therapies to selectively inhibit HMGB1 upregulation of ROS, and/or to selectively block pathogenic ROS effects, may represent worthwhile therapeutic avenues to explore to address issues of myositis-induced weakness and atrophy.

## FRI0242 ROLE OF MITOCHONDRIA- AND NADPH OXIDASE-DERIVED ROS IN FIBROBLASTS ISOLATED FROM PATIENTS AFFECTED BY SYSTEMIC SCLEROSIS

T. Spadoni, S. Svegliati, A. Gabrielli. *scienze mediche e chirurgiche, Università Politecnica delle Marche, ancona, Italy*

**Background:** Oxidative stress plays an important role in the development of fibrosis under various pathological conditions. Fibroblasts isolated from patients with Systemic Sclerosis (SSc) overproduce reactive oxygen species (ROS), overexpress type I collagen and α-smooth muscle actin (α-SMA) and show DNA damage and activation of checkpoint kinase ATM (1, 2). NADPH oxidase (NOX) is an important source of ROS, and its overactivity or overexpression are often associated with chronic diseases, characterized by tissue damage and fibrosis. Recently, we have demonstrated that NOX2 and NOX4 are critical components of NADPH oxidase complex in SSc fibroblasts and ROS generated by NOX play a primary role in the pathological activation of dermal fibroblasts (3). Since a recent study reported that NOX4 localizes to membranes and mitochondria and contributes to the generation of mitochondrial ROS (4), we wondered whether mitochondria also play a role in ROS production in SSc fibroblasts.
**Objectives:** The aim of this study was to investigate the contribution of mitochondrial ROS to oxidative stress in SSc.
**Methods:** ROS production was analysed by confocal microscopy using dihydroethidium (DHE, to assess all intracellular superoxide), or MitoSOX™ Red (to detect mitochondria superoxide), or using a microplate reader following Amplex® Red kit protocol (to measure $H_2O_2$). Mitochondria were purified using a mitochondria isolation kit. For protein expression, mitochondrial and cytosolic fractions were subjected to western blot with specific antibodies.
**Results:** SSc fibroblasts incubated with the mitochondria-targeted antioxidant MitoQ showed a reduced MitoSOX™ Red staining, and a partially decreased DHE fluorescence, suggesting that mitochondria contribute to the redox state in SSc fibroblasts. Mitochondria purified from SSc fibroblasts generated significantly higher levels of ROS compared to controls. Incubation of normal cells with PDGF, a profibrotic cytokine able to activate a SSc-like phenotype, led to a significant increase of total and mitochondrial ROS levels compared to unstimulated cells. Mitochondrial and cytosolic fractions from SSc and activated normal fibroblasts were also analyzed to evaluate different protein expression patterns.
**Conclusions:** In this study we demonstrated that mitochondria contribute to the abnormal redox state of SSc fibroblasts and activated normal cells. Further studies may clarify whether mitochondrial ROS are generated by a mitochondrial NOX isoform or are the result of the interplay between mitochondria and NOX enzymes located outside the organelles.

## FRI0243 IS THE BMP ANTAGONIST GREMLIN-1 A TARGET IN SYSTEMIC SCLEROSIS?

S. O'Reilly. *Life sciences, Northumbria University, Newcastle Upon Tyne, United Kingdom*

**Background:** Gremlin-1 is BMP antagonist that mediates its effects through negative regulation of BMP signalling. BMP signalling is important in development and has been found to be deregulated in various rheumatic diseases. It also has BMP-independant effects that are poorley described. Systemic sclerosis is an autoimmune disease that results in fibrosis of the skin and internal organs. We have previously found elevated levels of gremlin-1 in systemic sclerosis skin biopsies compared to controls. Gremlin-1 genetically reduced mice are protected from kidney fibrosis. It is suggested that fibrosis may be associated with reactivation of development programs.
**Objectives:** The aim of this work was to measure the levels of gremlin-1 and to determine its effects on dermal fibroblasts.
**Methods:** Skin biopsies were taken from systemic sclerosis patients and analysed by PCR for gremlin-1 and 18S as the housekeeing gene. Bleomycin was injected into mice and skin fibrosis developed, control mice received saline. Biopsies were taken and fixed and processed. Laser capture was used to dissect the tissue using a guided laser. Dissected tissue was processed for RNA and qPCR was performed for gremlin-1 and collagen-1. C-Myc tagged human Gremlin-1 was cloned into a vector and empty vector was transfected into human fibroblasts and HEKs. After transfection collagen and alpha-Smooth muscle actin was measured.
**Results:** Elevated levels of gremlin-1 was found in systemic sclerosis skin biopsies. We also found elevated levels of gremlin-1 in skin sections from an animal model of fibrosis, the bleomycin model. Laser capture microdissection found that this was in the dermal proportion of skin and not in the epithelial section. Overexpression of gremlin-1 in a vector system in dermal fibroblasts showed elevated levels of collagen, but not alpha-smooth muscle actin.
**Conclusions:** Gremlin-1 is dsyregulated in systemic sclerosis and in the bleomycin model of fibrosis. Overexpressing gremlin-1 induced higher levels of collagen. Targeting gremlin-1 may represent a novel target in systemic sclerosis.

## FRI0244 LYSYL OXIDASE AS A BIOMARKER IN SYSTEMIC SCLEROSIS– A MULTICENTER STUDY

D. Rimar[1], A. Balbir Gurman[2], P. Meroni[3], D. Farge[4], Y. Levy[5], I. Rosner[1], G. Slobodin[1], N. Jiries[1], M. Rozenbaum[1], L. Kaly[1], N. Boulman[1], K. Zilber[1], S. Ginsberg[1], A. Awisat[1], Z. Vadasz[6]. *[1]Rheumatology, Bnai Zion Medical Center; [2]Rheumatology, RAMBAM medical center, Haifa, Israel; [3]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [4]Internal Medicine and Vascular Disease Unit AP-HP, Hôpital Saint-Louis, Paris 7 University, Paris, France; [5]Department of Medicine E, Meir Medical Center, Kfar Saba; [6]Immunology, Bnai Zion Medical Center, Haifa, Israel*

**Background:** Fibrosis and vasculopathy are the major concerns in systemic sclerosis (SSc), the pathogenesis of which is not clear. Lysyl oxidase (LOX) is an extracellular copper enzyme that cross-links collagen and elastin, thus stabilizing collagen fibrils [1]. In a preliminary study, LOX was found to be overexpressed in SSc patients and was suggested to be related to diffuse disease [2]. We evaluated skin and lung biopsies from 11 SSc patients and were able to show LOX located in the epidermis in the skin and in the endothelium of blood vessels within the dermis and in lung tissue. It is not clear whether the source of elevated LOX levels in SSc is damaged vascular endothelium or fibrotic tissues.
**Objectives:** To evaluate LOX serum level of patients with SSc compared to patients with very early diagnosis of SSc (VEDOSS), patients with primary Raynaud's phenomena (PRP) and healthy controls in order to validate the elevated levels in SSc and to delineate its source.
**Methods:** We prospectively evaluated patients for demographics, clinical manifestations and laboratory results including blood count, chemistry, urine examination, autoantibodies and serum LOX concentration determined by ELISA. We further evaluated lung function tests, echocardiography, lung high resolution CT scans, as needed, and determined lung involvement, modified Rodnan skin score (mRSS), Medsger disease severity scale and Valentini activity index [3].
**Results:** 86 SSC patients (76 women and 10 men) at a mean age of 49±12.4 were evaluated and compared with 110 patients with VEDOSS, 86 patients with PRP, and 80 age and gender matched healthy controls. Of the SSc patients, 42 had diffuse disease- 23 of them with lung fibrosis, and 44 had limited disease. LOX concentration in SSc was higher than VEDOSS, PRP and healthy controls, 12.8±7.5 ng/ml vs. 9.7±7.4 ng/ml vs. 8.1±5.4 vs. 8.9±5.1 ng/ml, respectively ($p<0.0001$). LOX level correlated with Medsger disease severity scale, correlation coefficients 0.24 ($p=0.025$) and inversely correlated with DLCO in patients with diffuse disease, correlation coefficients -0.35 ($p=0.03$). Age, duration of disease, mRSS, activity score, capillaroscopy pattern and pulmonary hypertension, did not correlate with LOX concentration.
**Conclusions:** LOX level was found to be high in the serum of patients with SSc correlating with disease severity and inversely correlated with lung diffusion, suggesting a vascular source of LOX excretion in SSc. LOX was not elevated in patients with VEDOSS or PRP. Our study confirms our former observation of elevated LOX level in SSc and suggests LOX to be a possible biomarker of disease severity and vasculopathy in SSC.

## FRI0245 SCCA-IGM IS UP-REGULATED IN SCLERODERMA PATIENTS WITH REDUCED DLCO: A NEW BIOMARKER OF PULMONARY INVOLVEMENT?

E. Zanatta, A. Martini, A. Biasiolo, E. Pigatto, K. Bourji, M. Favaro, L. Punzi, P. Pontisso, F. Cozzi. *Department of Medicine DIMED, University of Padua, Padua, Italy*

**Background:** Systemic sclerosis (SSc) is a connective tissue disease characterized by diffuse fibrosis of skin and internal organs. The pulmonary involvement represents the first cause of death in these patients (1). The reduction of DLCO is the first functional alteration observed in interstitial lung disease (ILD). The detection of sera biomarkers predictive of ILD is still discussed in SSc.
Squamous Cell Carcinoma Antigen (SCCA) is a serin protease inhibitor typically expressed by dysplastic and neoplastic cells of epithelial origin, and in pulmonary tissue of patients with idiopathic ILD (2). SCCA is detectable in serum as free protein and as circulating immune complex coupled to IgM.
**Objectives:** The aim of this study was to evaluate the serum levels of free SCCA and SCCA-IgM in a group of scleroderma patients and to investigate the correlation with different SSc subsets.
**Methods:** Forty patients, 31 women and 9 men affected by SSc (according to ACR/EULAR 2013 criteria), with mean age of 55±2 years and mean disease duration of 14±8 years were recruited. Seventeen patients had the diffuse cutaneous form of SSc and 23 the limited one. ANA were positive in all subjects with specificity for ACA in 16 cases, anti-Scl70 in 14, anti-RNA polymerasis III in 3, without specific pattern in 7. We considered the avascular score (detected at nailfold capillaroscopy), the Rodnan skin score, the pulmonary function tests, the coronary flow reserve (CFR), EUSTAR score and the systolic pressure in pulmonary artery (PAPs) as clinical parameters.
SCCA-IgM (AU/ml) and free SCCA (ng/ml) serum levels were measured in all patients using a validated ELISA assay. SCCA-IgM positivity was considered for values >200 AU/ml, according to our laboratory.
**Results:** SCCA-IgM serum levels were found increased in 14 SSc patients (35%). We didn't find significant differences in patients with diffuse and limited cutaneous form of disease, and not even statistically significant correlations with skin score, avascular score, CFR and PAPS.
SCCA-IgM and free SCCA levels were found significantly increased in patients with reduced DLCO (<75%) at pulmonary functions test in comparison to those without ($p<0.05$). At multivariate analysis SCCA-IgM positivity (OR: 6.25; CI: 1.26–31.02) and EUSTAR score >3 (OR: 7.75; CI: 1.28–46.3) were independently associated with diagnosis of ILD.
**Conclusions:** Serum levels of SCCA-IgM and free SCCA were increased in a group of patients with SSc. Patients with reduced DLCO, the first functional alteration observed in ILD, showed a significant increase of SCCA-IgM. Futhermore this biomarker is independently associated with the diagnosis of ILD, suggesting a possible role of this molecule in the first phases of the pathogenesis of pulmonary involvement in systemic sclerosis.

## FRI0246 DYSREGULATION OF CCN PROTEINS IN SYSTEMIC SCLEROSIS PATIENTS WITH PIGMENTARY DISORDERS

P. Henrot[1,2], C. Pain[1], J. Seneschal[3], A. Taïeb[3], M.-E. Truchetet[2], M. Cario-André[1]. *[1]Inserm U1035, Biotherapies for genetic diseases and cancer; [2]Rheumatology, Hopital Pellegrin; [3]Dermatology, Hopital Saint-Andre, Bordeaux, France*

**Background:** Pathogenesis of Systemic Sclerosis (SSc) is complex and includes impaired communication between endothelial cells, epithelial cells and fibroblasts, leading to connective tissue fibrosis such as dermal fibrosis. About half of the patients present pigmentation patches. It is already known that CCN2 (CTGF) is increased in SSc and that polymorphism of its promoter is associated with the disease. More recently, it was shown that CCN2 is increased in the epidermis of SSc patients. CCN2 is part of a family of 6 members, including CCN3 (NOV), which often antagonizes CCN2. We have previously observed that CCN3 is modulated in non-segmental vitiligo, a hypopigmentary skin disorder, and that fibroblasts can regulate skin pigmentation. In SSc, CCN2 upregulation is sustained by an autocrine activating loop of endothelin 1 (ET-1). ET-1 is a well known pigmentary factor and its secretion by endothelial cells has recently been demonstrated as inducer of skin pigmentation.
**Objectives:** We hypothesize that in patients with pigmentary disorders, secretion of CCN by dermal cells is dysregulated (isoforms, levels). Thus, we plan to study the expression profile of CCNs, among other factors implicated both in fibrosis and pigmentation (ET-1, PPARγ, HIF1α) in SSc patients presenting or not skin pigmentary disorders.
**Methods:** Skin biopsies were obtained from 10 SSc patients, both in abnormally pigmented zones (hypo and/or hyperpigmented) and in non-lesional skin areas. Two patients with morphea were also included. Normal skin from healthy donors was used as control. Biopsies were used to culture fibroblasts, endothelial cells and keratinocytes and to perform histological and immunohistochemical analysis. We performed proteomic analysis, and immunocytochemistry regarding CCN2 and CCN3 on skin cells.
**Results:** Clinical examination of patients with SSc revealed two patterns of pigmentary troubles. Some patients have hypo and/or hyperpigmentary patches in non sun-exposed areas, whereas other patients have only hyperpigmentation in exposed areas which looks like photoaging. In most patients, it seems that pigmentary troubles appeared during the early development of the disease. Our preliminary datas revealed that level of expression of CCN3 observed by

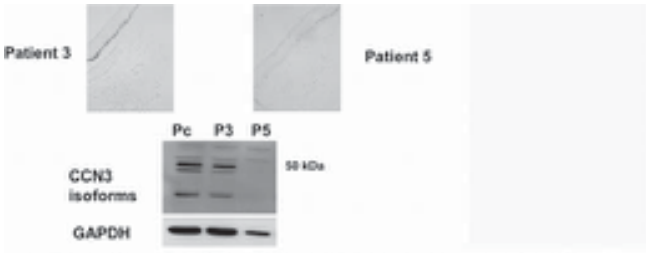

Figure 1: Top, Observation of degree of pigmentation (Fontana Masson staining) in lesional skin of two SSc patients : Patient 3 with hyperpigmented skin and Patient 5 without pigmentary disorder. Bottom, Study of CCN3 expression in lesional fibroblasts by Western Blot assay : marked decrease in CCN3 expression for Patient 5, as compared to fibroblasts from control donor (Pc).

immunohistochemistry or in fibroblasts protein extracts differed in lesional and non-lesional areas. Moreover, SSc patients presented various CCN3 isoforms according to pigmentary status. CCN2 examination also revealed variation of its expression as compared to healthy controls. Interestingly, these abnormalities could also be found in apparently non-lesional skin areas from SSc patients, which suggests that CCN2 and 3 expression is altered at early stages of the disease.

**Conclusions:** Differential level of expression and presence of various isoforms of CCNs have to be confirmed in fibroblasts and endothelial cells according to the pigmentary status of the fibrotic areas. This will allow us to verify our hypothesis of two different types of SSc, depending on time of apparition and localization of pigmentary patches. This could help to detect the disease early, which is essential for therapeutic issues. Moreover, if spatio-temporal variations of CCN are confirmed, it could open a specific therapeutic window for the use of CCNs modulators.

**Disclosure of Interest:** None declared

## FRI0247 THE INVOLVEMENT OF THE LONG NONCODING H19X IN TGFβ SIGNALING AND ITS PROFIBROTIC EFFECTS IN SYSTEMIC SCLEROSIS AND OTHER FIBROTIC DISEASES

E. Pachera[1], S. Assassi[2], G. Salazar[2], M. Frank-Bertoncelj[1], R. Dobrota[1], M. Brock[3], F. Kurreeman[4], J. de Vries-Bouwstra[5], T. Messemaker[6], C. Feghali-Bostwick[7], J. Distler[8], G. Kania[1], O. Distler[1]. *[1]Division of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Department of Internal Medicine, University of Texas, Houston, United States; [3]Department of Pulmonology, University Hospital Zurich, Zurich, Switzerland; [4]Division of Rheumatology; [5]Leiden University Medical Center, Leiden, Netherlands; [6]Leiden University Medical Center, Leiden, Switzerland; [7]Division of Rheumatology, University of South Carolina, Charleston, United States; [8]Department of Internal Medicine 3, University of Erlangen, Erlangen, Germany*

**Background:** Long noncoding RNAs (lncRNAs) are an emerging class of noncoding transcripts involved in the regulation of gene expression in health and disease. We have recently identified a novel lncRNA, H19X, which is strictly regulated by TGFβ in a dose and time dependent manner.

**Objectives:** To detail the differential expression of H19X in SSc and other fibrotic diseases and to characterize its function in fibrotic diseases.

**Methods:** Skin and lung biopsies from patients with SSc, idiopathic lung fibrosis (IPF), and healthy controls (HC) were obtained from cohorts at four different expert centers. Expression of H19X was analyzed by RNA Sequencing Ilumina HiSeq2000 and real-time PCR respectively. H19X was silenced in skin fibroblasts using locked nucleic acid antisense oligonucleotides (LNA GapmeRs), followed by qPCR analyses, immunofluorescence staining, SIRCOL assay, contraction assay and Western blot. In situ hybridization of H19X on SSc dermal fibroblast was performed using Stellaris FISH probes.

**Results:** H19X expression was consistently upregulated across all four cohorts (SSc n=34, HC n=26). Notably, the upregulation was also consistent across different subsets of patients. H19X showed a similar expression profile in clinically non-involved skin compared to established fibrotic skin. Moreover, expression of H19X was also significantly increased in SSc interstitial lung disease patients versus HC (n=11 each, $p<0.05$). A significant H19X overexpression was also detected in IPF samples indicating a broader role of H19X in fibrotic diseases (n=11 each, $p<0.05$). The knockdown of H19X by GapmeRs in skin fibroblasts led to a strong downregulation of collagen 1, fibronectin and αSMA mRNAs (n=5, $p<0.05$). Furthermore, H19X knockdown followed by SIRCOL assay and Western blot analysis confirmed the importance of this lncRNA in the regulation of extracellular matrix components such as collagens and fibronectin. Additionally, silencing of H19X significantly impaired αSMA fiber formation, stress fiber formation and cell contractility showing an important role of H19X in the development of the myofibroblast phenotype. Because the H19X gene hosts the sequence for two microRNAs, miR-424 and miR-503, it could exert its function acting as reservoir for these microRNAs. However, the effects of miR-503 and miR-424 loss and gain of function experiments on fibrosis measures were minimal compared to the effects after H19X silencing indicating that H19X employs another main molecular mechanism. Indeed, in situ hybridization showed that TGFβ-induced expression of H19X is localized to a defined spot in the nucleus indicating that H19X could influence gene expression by directly interacting with the chromatin.

**Conclusions:** H19X is a novel lncRNA which is a key factor in mediating the pro-fibrotic effects of TGFβ in systemic sclerosis and other fibrotic diseases.

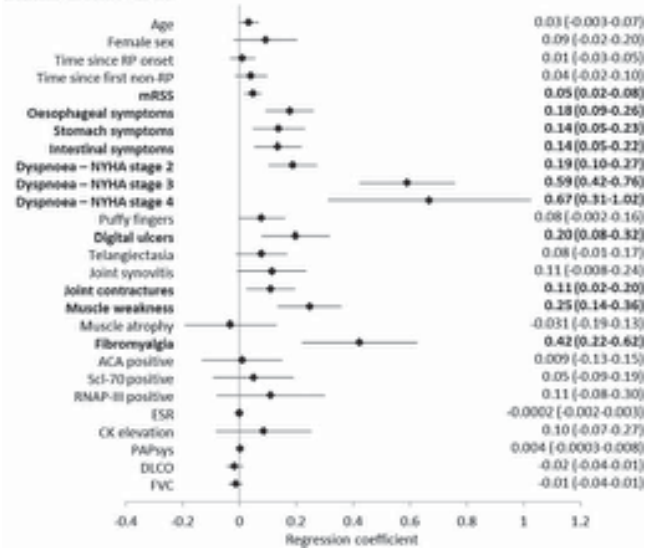
**Background:** Systemic sclerosis (SSc) can greatly impact the patients' quality of life due to the multisystem manifestations. The health assessment questionnaire (HAQ) is one of the most commonly used measures of disability in musculoskeletal disorders and was extended to form the scleroderma HAQ (SHAQ), a more disease-specific disability scale that incorporates the HAQ and the 5 SHAQ-visual analogue scales (VAS) into one score.

**Objectives:** This study aims to identify predictors of disability in SSc by means of the SHAQ.

**Methods:** Patients from the DeSScipher cohort were included in the analysis if they had at least one complete SHAQ recorded, fulfilled either the 1980 ACR or the 2013 ACR/EULAR criteria for SSc and were above 18 years of age.



Multiple linear regression analysis was used to assess the combined effect of factors possibly associated with disability. Variables included in the model were defined *a priori.*

**Results:** 813 patients had one complete SHAQ recorded between June 2013 and January 2016 (34.1% of all patients followed in the DeSScipher cohort). Of these, 12% fulfilled only the 2013 ACR/EULAR criteria, 2% fulfilled only the 1980 ACR criteria and 86% fulfilled both, the median age was 58 years (IQR 49–67) and 15% were male. 26% of the patients were in the diffuse SSc subset, 56% in the limited and 18% had SSc sine sclerosis.

The patients had a median SHAQ score of 0.79 (IQR 0.28–1.31) and a median HAQ score of 0.88 (IQR 0.25–1.5). The medians of the five VASs included in the SHAQ were (in order of the VAS magnitude): overall disease severity (30, IQR 10–51), Raynaud's phenomenon (21, IQR 3–50), pulmonary symptoms (10, IQR 1–40), gastrointestinal symptoms (6, IQR 1–31) and digital ulcers (2, IQR 1–30). 60% of the patients were in the lowest SHAQ category (score of 0 to 1) which is regarded as "mild to moderate difficulty", 34% in the category regarded as "moderate to severe disability" (score of 1 to 2) and 6% in the category regarded as "severe to very severe disability" (score of 2 to 3).

In multiple linear regression, the main factors associated with high SHAQ scores were dyspnoea (NYHA-stage 4 (β=0.67), 3 (β=0.59) and 2 (β=0.18; all

**Figure:** Multivariable regression coefficients with 95% confidence intervals for the composite SHAQ score (range 0 to 3).
RP, Raynaud's phenomenon; mRSS, modified Rodnan skin score; NYHA, New York Heart Association; DPS, digital pitting scars; DU, digital ulcers; ACA, anti-centromere autoantibodies; Scl-70, anti-topoisomerase-I autoantibodies; RNAP-III, anti-RNA-polymerase-III autoantibodies; ESR, erythrocyte sedimentation rate; CK, creatinine kinase; PAPsys, systolic pulmonary artery pressure as estimated by echocardiography; DLCO, single breath diffusing capacity for carbon monoxide; FVC, forced vital capacity.
Age, time since RP onset and first non-RP, increase per 10 year; mRSS, increase per 5 points; dyspnoea, vs NYHA stage 1; ESR, increase per mm/hr; PAPsys, increase per mmHg; DLCO and FVC, increase per 10% of predicted; all others, yes/no.

*vs.* stage 1), fibromyalgia (β=0.42), muscle weakness (β=0.25), current digital ulcers (β=0.20) and gastrointestinal symptoms (oesophageal symptoms, β=0.18; stomach symptoms, β=0.14; intestinal symptoms, β=0.14; figure).
**Conclusions:** Patients perceive dyspnoea, pain, digital ulcers, muscle weakness and gastrointestinal symptoms as the main factors driving their level of disability.

## FRI0249 RISK FACTORS FOR DEVELOPMENT OF PULMONARY ARTERIAL HYPERTENSION IN AUSTRALIAN SCLERODERMA PATIENTS

K. Morrisroe[1], M. Huq[2], W. Stevens[2], C. Rabusa[2], S. Proudman[3], M. Nikpour[4] on behalf of Australian Scleroderma Interest Group (ASIG). *[1]Rheumatology and Medicine, St Vincent's Hospital, Melbourne; [2]Rheumatology, St Vincent's Hospital, Melbourne; [3]Rheumatology, Royal Adelaide Hospital, Adelaide; [4]Rheumatology and Medicine, St Vincent's Hospital, Melbourne, Australia*

**Background:** Pulmonary arterial hypertension (PAH) is the leading cause of mortality in patients with scleroderma (SSc).
**Objectives:** To determine the incidence, prevalence and risk factors for PAH development in a large Australian SSc cohort.
**Methods:** PAH was diagnosed on right heart catheterization (mPAP >25 and PAWP <15 mmHg at rest). Patients with PH secondary to interstitial lung disease (ILD; defined as abnormal HRCT scan and FVC<60%) were excluded. Summary statistics, chi-square tests, univariate and multivariable logistic regression along with post-estimation diagnostics were used to determine the associations of different combinations of risk factors with PAH.
**Results:** Among 1579 SSc patients, 8.4% (132 patients) were diagnosed with PAH over a mean (±SD) follow-up of 3.2 (±2.5) years. The incidence of PAH in this cohort was 0.7% per annum. Of these, 68.9% had limited disease subtype (lcSSc). In multivariable regression analysis, the presence of anti-centromere antibody (ACA) (OR 1.6, 95%CI 1.1–2.5, p=0.03), oesphageal stricture (OR 2.0, 95%CI 1.2–3.3, p=0.006), calcinosis (OR 1.9, 95%CI 1.2–2.9, p=0.003), sicca symptoms (OR 1.6, 95%CI 1.1–2.5, p=0.03), mild ILD (OR 2.3, 95%CI 1.5–3.7, p<0.001) and digital ulcers (OR 1.6, 95%CI 1.0–2.4, p=0.03) were predictive of PAH. This model had an area under the curve of 0.7 and concordance of 91.8%. Risk factors for PAH were were analyzed by disease subtype and are presented in Table 1 and 2.

Table 1. Multivariable analysis of predictors of PAH in lcSSc

| Predictors of PAH | OR (95% CI) | *p* |
|---|---|---|
| Calcinosis | 2.24 (1.4–3.7) | 0.001 |
| Sicca | 2.63 (1.5–4.6) | 0.001 |
| ILD | 2.31 (1.4–3.8) | 0.001 |
| Digital Ulcers | 1.85 (1.2–3.7) | 0.01 |

Abbreviations: ILD, Interstitial lung disease; PAH, pulmonary arterial hypertension.

Table 2. Multivariable analysis of predictors of PAH in dcSSc

| Predictors of PAH | OR (95% CI) | *p* |
|---|---|---|
| Oesphageal stricture | 4.42 (1.9–10.5) | 0.001 |
| ILD | 2.83 (1.2–6.8) | 0.02 |
| ACA | 5.16 (1.8–14.8) | 0.002 |

Abbreviations: ILD, Interstitial lung disease; PAH, pulmonary arterial hypertension; ACA, anticentromere antibody.

**Conclusions:** The incidence and prevalence of PAH in this cohort are 0.7% per annum and 8.4%, respectively. The clinical-serologic risk factors for PAH differ based on disease subtype. In both subtypes, mild ILD is associated with PAH, suggesting the possibility of a common pathogenic mechanisms underlying both of these disease manifestations. This model identifies a subset of patients at an appreciably higher risk of developing PAH, who should be screened and would in future, benefit from preventative therapies.

## FRI0250 SELF REPORTED GASTROINTESTINAL TRACT SYMPTOMS IN SYSTEMIC SCLEROSIS: EXPERIENCE FROM A LARGE CONSECUTIVE COHORT

T. Garen, H. Andersson, Ø. Midtvedt, A.M. Hoffmann Vold, Ø. Palm, Ø. Molberg. *Department of Rheumatology, Dermatology and Infectious Diseases (RDI) Division of Cancer Medicine, Surgery & Transplant, Oslo University Hospital, Rikshospitalet, Oslo, Norway*

**Background:** Gastrointestinal tract (GIT) involvement in systemic sclerosis (SSc) is common, occurring in 50–90% of the patients (1). However, there is limited knowledge of self reported GIT symptoms affecting patients in daily life.
**Objectives:** To describe frequency and severity of self reported gastrointestinal symptoms in a large SSc cohort and evaluate possible correlations between special clinical characteristics and GIT-symptoms.
**Methods:** Patients from the The Norwegian Systemic Connective Tissue Disease and Vasculitis Registry (NOSVAR) who fulfilled the 2013 ACR/EULAR SSc criteria were included (N=245)). The patients completed the UCLA SCTC GIT 2.0 questionnaire which comprises seven clinical symptoms; Reflux, distention/bloating, diarrhea, fecal soilage, social functioning, emotional well-being and constipation. All variables are scored from better to worse in health related quality of life (HRQL) with a mean total score of 2.8. In addition we used the visual analogue scale on intestinal problems (VAS-GIT) of the Scleroderma Health Assessment Questionnaire (SHAQ) with a maximum score of 3. Disease duration was defined as time from diagnosis to the completion of the questionnaires. Possible correlations were tested by Spearman's correlation coefficient.
**Results:** Patient characteristics and frequencies of the different GIT symptoms are presented in Table 1. Distention bloating, reflux and diarrhea were the most frequent symptoms reported (80%, 69% and 61%, respectively. The least reported symptom was fecal soilage (16%) (Figure 1). Mean (SD) total GIT score was 0.42 (0.41), indicating mild symptoms. The seven subscales ranged from mean (SD) 0.22 (0.55) for fecal soilage to mean (SD) 0.95 (0.50) for distention/bloating. Mean (SD) VAS-GIT score was 0.33 (0.37) and correlated strongly with the mean total UCLA-GIT score (0.667, p<0.001). Female sex and disease duration correlated weakly with mean total UCLA-GIT score (r=-.234, r=199, respectively), as did positive anticentromere-antibody (r=.229).No correlation was found between mean total UCLA-GIT score and subset of SSc, interstitial lung disease, pulmonary hypertension, digital ulcers, Rodnan skin score or Raynaud.

Table 1

| Clinical characteristics | |
|---|---|
| Female sex, n (%) | 210 (86) |
| Age, yrs, mean (SD) | 53 (14) |
| Diffuse, n (%) | 57 (24) |
| Limited, n (%) | 178 (73) |
| Sine, n (%) | 10 (4) |
| Disease duration, yrs, median (25th, 75th centile) | 5.8 (2.1, 10.7) |
| Anti-SCL70 antibody, n (%) | 32/208 (15) |
| Anticentromere antibody, n (%) | 133/223 (60) |

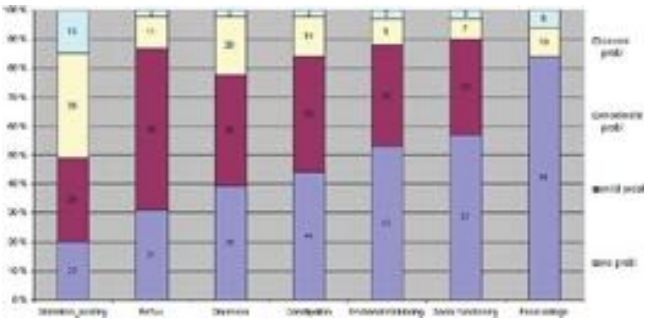

Figure 1

**Conclusions:** This study describes a high frequency of self-reported gastrointestinal symptoms in systemic sclerosis patients classified as mild to moderate symtoms. Positive anticentromere-antibody, disease duration and female sex had a minor impact on mean total UCLA-GIT score. The correlation between mean total UCLA-GIT score and the VAS-GIT score of the SHAQ was highly significant indicating a good conformity between the tests.

## FRI0251 ANTI-MDA5 AUTO-ANTIBODY: EXPANDING THE CLINICAL SPECTRUM IN PATIENTS WITH DERMATOMYOSITIS IN NORTH AMERICA

S. Moghadam-Kia[1], C.V. Oddis[1], S. Sato[2], M. Kuwana[3], R. Aggarwal[1].
*[1]University of Pittsburgh Medical Center, Pittsburgh, United States; [2]Tokai University, School of Medicine, Isehara; [3]Nippon Medical School Graduate School of Medicine, Tokyo, Japan*

**Background:** Clinically amyopathic dermatomyositis (CADM) is a subset of dermatomyositis (DM) presenting with the characteristic DM rash (es) without objective proximal muscle weakness. Asian studies report that anti-MDA5 autoantibody (autoAb) in CADM is associated with a unique clinical phenotype, which has not been well established in US.
**Objectives:** The goals of our study were to determine the clinical features associated with anti-MDA5 autoAb in CADM as compared to classic DM in US.
**Methods:** CADM patients were selected consecutively from the patients enrolled in the University of Pittsburgh Myositis Database from January 1985 to July 2013 (n=450). CADM was defined a typical DM rash without objective muscle weakness for at least 6 months after rash onset and no or minimal abnormalities of serum muscle enzymes [<3 x ULN], electromyography or muscle biopsy. The classic DM was defined as per probable and definite criteria of Bohan and Peter. DM patients were selected similarly and 1:1 matched (gender and age ±5 years) to CADM patients. The clinical features were assessed using our prospective myositis database, along with electronic medical record review when necessary.
**Results:** We identified 61 CADM patients and 61 matching DM controls. Demographics were similar in both groups. Anti-MDA5 frequency was similar in two cohorts (13.1% [8/61] vs. 13.1% [8/61]). Anti-MDA5 positivity was associated with a higher likelihood of abnormal capillary microscopy, vasculitic rash and digital tip ulceration (18.7% vs. 2.8%) and a lower frequency of Raynaud's as compared to anti-MDA5 negativity. The frequency of DM rashes (Gottron sign or papule, heliotrope, mechanics hands, etc were similar in both groups. However, puffy finger frequency was higher in the anti-MDA5+ patients as compared to anti-MDA5- patients (20% vs. 4.7%). Anti-MDA5 positivity was significantly associated with ILD (p=0.043), RPILD (p<0.001), and poor survival (p=0.007). Multivariate analysis suggested that anti-MDA5 positivity was predictive of survival even after controlling for diagnosis, age at diagnosis, gender, ethnicity, smoking, and ILD (p=0.001). ILD frequency was similar in CADM and DM (31.1% vs. 26.2%) as was RPILD (8.2% vs. 5%). CADM patients were more likely to have puffy fingers (9.8% vs. 4.9%) but less likely to have mechanic's hands (3.2% 9.8%) and heliotrope rash (36.1 vs. 19.7%) than DM patients. Rest of the clinical features were similar for both CADM and DM cohorts.

Table 1

| Clinical features | MDA5+ (N=16) | MDA-5– (N=106) | P value | CADM (N=61) | Classic DM (N=61) | P value |
|---|---|---|---|---|---|---|
| ILD | 50% | 25.5% | 0.04 | 31% | 26% | 0.46 |
| RPILD | 44% | 1% | <0.001 | 8% | 5% | 0.55 |
| Raynaud's | 12.5% | 26.4% | 0.35 | 22.9% | 26.2% | 0.67 |
| Vasculitic rash | 18.7% | 1.8% | 0.01 | 3.2% | 4.9% | 1 |
| Abnormal capillary microscopy | 43.7% | 26.4% | 0.15 | 29.5% | 27.8% | 0.8 |
| Digital tip ulceration | 18.7% | 2.8% | 0.02 | 4.9% | 4.9% | 1 |
| Heliotrope rash | 18.7% | 29.2% | 0.55 | 36% | 19.6% | 0.04 |
| Dysphagia | 31.2% | 10.3% | 0.03 | 24.5% | 1.6% | <0.001 |

**Conclusions:** Anti-MDA-5 autoAb is seen in similar frequency in CADM and DM patients in US. Anti-MDA-5 autoAb is associated with a unique clinical phenotype consisting of ILD, RPILD, abnormal nailfold capillary, vasculitic rash, and digital tip ulceration in U.S. patients. CADM patients were similar to DM apart from obvious disease defining features of muscle weakness and muscle enzyme. In addition there was more puffy fingers, less mechanics hands and heliotrope rash in CADM.

## FRI0252 EFFICACY OF MYCOPHENOLATE MOFETIL (MMF) VERSUS ORAL CYCLOPHOSPHAMIDE (CYC) ON SKIN THICKNESS IN THE SCLERODERMA LUNG STUDY II

D. Khanna[1], D. Tashkin[2], D.E. Furst[2], C.-H. Tseng[2], H. Wilhalme[2], M. Roth[2], S. Kafaja[2], E. Volkmann[2], R. Elashoff[2], P. Clements[2] on behalf of Scleroderma Lung Study II Investigators. *[1]University of Michigan, Ann Arbor; [2]UCLA, Los Angeles, United States*

**Background:** Mycophenolate mofetil (MMF) has been shown to improve skin thickness, as assessed by the modified Rodnan skin score (mRSS), in patients with diffuse cutaneous SSc (dcSSc) in retrospective analyses of different cohorts (1). In addition, oral cyclophosphamide (CYC) had a favorable impact on mRSS in SLS-I (2).
**Objectives:** Our objectives were to: 1. Assess the impact of MMF and CYC on the mRSS in a randomized controlled trial of MMF vs. oral CYC in patients with symptomatic scleroderma-related interstitial lung disease (SLS II) over 24 months, and 2. Compare the improvement in mRSS in the SLS I vs. SLS II cohorts at 6 and 12 months.
**Methods:** 142 patients with SSc-ILD were randomized in the SLS II. Patients received MMF (≤3 g daily) for two years or oral CYC (≤2 mg per kilogram of body weight) for one year followed by placebo twice daily for an additional year. In addition, we compared the change in mRSS in the dcSSc subset in the SLS-II vs. SLS-I oral CYC (≤2 mg per kilogram of body weight) and matching placebo prescribed for 1 year.
**Results:** The baseline (mean± SD) disease duration was 2.6±1.8 years and mRSS was 14.0±10.6 for CYC and 15.3±10.4 for MMF groups in the SLS II; 58.5% were classified as dcSSc and 42.5% were classified as limited cutaneous SSc (lcSSc). Both treatments were associated with improvement in mRSS over the period of 24 months but there was no statistically significant between 2 groups at any time points in the dcSSc and lcSSc subsets (p>0.05 for all comparisons). The mean improvement in the CYC group was 1.4 vs. 2.0 in the MMF group in the lcSSc subset and 8.0 vs. 6.3 in the dcSSc subset at 24 months.
For our second objective, there was no statistical difference in the baseline mRSS scores in the dcSSc in SLS-I (mean disease duration=3.1 years) and SLS-II (mean disease duration=2.5 years) trials (Table). In addition, the change in mRSS at 6- and 12-month period was similar in the SLS-II pooled (MMF+ CYC) and SLS-I CYC groups (Table; p>0.05). In contrast, SLS-II pooled and SLS-I CYC groups showed statistically significant improvement at 12-month period vs. SLS-1 placebo group (p<0.05).

Table 1. Mean change in mRSS in the dcSSc subset in the SLS-1 and SLS-2

| | SLS-2 pooled group | | SLS-1 CYC group | | SLS-2 pooled and SLS-1 CYC groups | | SLS-1 Placebo group | |
|---|---|---|---|---|---|---|---|---|
| | N | | N | | N | | N | |
| Baseline | 83 | 20.8 | 49 | 21.6 | 132 | 21.1 | 46 | 20.4 |
| 6 month | 69 | –2.4† | 45 | –2.7† | 114 | –2.6† | 43 | –2.6† |
| 12 month | 66 | –5.5† | 43 | –5.3† | 109 | –5.4*† | 37 | –1.7* |

†P<0.05 for for mRSS at follow up vs. baseline within each group. *P<0.05 for SLS-II pooled and SLS-I CYC groups compared to SLS-1 Placebo group.

**Conclusions:** In the SLS II, 2 years of daily MMF and 1-year of CYC were associated with clinically important improvements in mRSS in the dcSSc over 24 months. The change in mRSS in the SLS-II paralleled that in the SLS-I CYC group and was significantly superior to the SLS-I placebo group. These data support the use of MMF or CYC for management of skin fibrosis in early dcSSc.

## FRI0253 A 18 MONTH OBSERVATION IN PATIENTS WITH PROGRESSIVE SYSTEMIC SCLEROSIS TREATED WITH AN INTENSIFIED B-LYMPHOCYTE DEPLETION -CLINICAL AND IMMUNOLOGICAL RESPONSE

D. Rossi[1], M. Saracco[2], S. Sciascia[3], R. Pellerito[2], V. Modena[1], D. Roccatello[1].
*[1]Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare; [2]Rheumatology Unit, Mauriziano Hospital, Turin; [3]Center of Research of Immunopathology and Rare Diseases, University of Torino, Torino, Italy*

**Background:** B cells (BC) play a critical role in progressive systemic sclerosis (SS). BC depletion therapy is an attractive option.
**Objectives:** to evaluate the efficacy of an intensified B cell depletion therapy in patients with progressive SS
**Methods:** Eighteen patients with SS [2 males, mean age 58.33 yrs (46–82)] with severe multiorgan involvement including skin [16], lung, with pulmonary fibrosis (17 patients) and pulmonary hypertension (5), esophagous [9], with polyarthralgias [2] have been prospectively treated with an intensified B cell depletion therapy (IBCDT) protocol due to their resistance or intolerance to previous therapy (4 cases) or as a front line treatment in 14 patients with unsatisfactory therapeutic compliance. IBCDT included: Rituximab (RTX) 375mg/sm on days 1, 8, 15, 22, and 2 more doses after 1 and 2months, associated with 2 IV administrations of 10mg/kg of cyclophosphamide and 3 methylprednisolone pulses (15mg/kg) followed by oral prednisone (0.8mg/kg/day, rapidly tapered to 5mg/day by the end of the 3rd month after RTX). No further immunosuppressive maintenance therapy has been given.
**Results:** Patients had been followed-up for a mean of 21,67 ± ds 11,05 (06–43) months. Significant decreases (p<0.05) were found in Rodnan skin score (baseline: 12.28; end of follow-up: 11.67), visual activity score (baseline mean value: 6.8 mm; end of follow-up: 4.2. A significant increase (p<0.05) FVC (baseline: 92.35; end of follow-up: 95.44), FEV (baseline: 86.5; end of follow-up: 90.43), DLCO (baseline: 57.15; end of follow-up: 66.75), and NTpro BNP (baseline: 345.19; end of follow-up: 62.29). PAP values did not change during the observation (baseline: 29.77mmHg; end of follow-up: 26.57). During the follow-up, pulmonary fibrosis, as established on a radiological level, was found to be ameliorated in 2 out of the 14 evaluable patients, worsened in 3, and unchanged in 9.
**Conclusions:** A promising role of RTX in an intensified protocol of induction therapy can be envisaged in patients for whom avoiding prolonged immuno-

suppressive therapy particularly appealing. Our data confirm the opportunity to consider the regimens of BL depletion in the treatment of the most severe or refractory forms of SS.

## FRI0254 THE EFFECT OF CYCLOPHOSPHAMIDE ON LUNG FUNCTION IN DIFFERENT STAGES OF INTERSTITIAL LUNG DISEASE ASSOCIATED TO SYSTEMIC SCLEROSIS

W.M.T. Van Den Hombergh [1], E. Teesselink [1], H.K.A. Knaapen-Hans [1], S.O. Simons [2], F.H.J. van den Hoogen [1], J. Fransen [1], M.C. Vonk [1]. *[1]Department of Rheumatology; [2]Department of Pulmonary Medicine, Radboud University Medical Centre, Nijmegen, Netherlands*

**Background:** The primary cause of death in patients with systemic sclerosis (SSc) is interstitial lung disease (ILD). Several retrospective studies have shown some effect of cyclophosphamide (CYC) on ILD. In one randomized controlled trial a small but significant effect on pulmonary function was shown after oral CYC (Taskin,2006). Hoyles (2006) showed a trend towards improvement of forced vital capacity after monthly CYC infusions. In our centre, intravenous CYC pulses are the first choice of therapy in SSc-ILD.

**Objectives:** To analyze 1) the effects of iv CYC pulses (750mg/m$^2$) on pulmonary function in SSc-ILD in our cohort, and 2) whether this effect is dependent on the extent of ILD.

**Methods:** Patients with SSc-ILD receiving CYC pulses between 2003 to 2015 were classified by the Goh criteria (2008) in either limited or extensive ILD, using HRCT at baseline judged by two raters. Pulmonary function tests were performed at 0, 6 and 12 months. Missing outcome data due to drop-out, but not death, were replaced by last observation carried forward.

**Results:** 79 patients were included, 42 with limited ILD, 37 with extensive ILD. There were no differences in age, gender, SSc subtype classification, disease duration or autoantibody status between the two groups. Baseline FVC (median 80% vs. 91%) and DLCO (39% vs. 50%) were lower in extensive ILD ($p<0.05$). After 12 months, FVC (p=0.08)), and DLCO (p=0.62) did not worsen compared to baseline values. There were no differences in the degree of change in FVC and DLCO between limited and extensive ILD. Forty-eight patients completed 12 cycles of CYC. Per protocol analyses showed not significant differences between limited and extended ILD.

Table 1. Changes in pulmonary function test after 1 year

| | Limited ILD (n=42) | | | Extensive ILD (n=37) | | | Difference with 95%>CI | P-value† |
|---|---|---|---|---|---|---|---|---|
| | Baseline | 1 year | Δ* | Baseline | 1 year | Δ* | | |
| FVC | 91 (78–104) | 94 (82–109) | 2.9±13 | 80 (66–92) | 82 (63–95) | 2.0±9 | 0.9 (–4.7–6.4) | 0.76 |
| DLCO | 51 (39–60) | 47 (41–60) | –1.4±11 | 39 (31–51) | 41 (32–52) | 1.3±6 | –2.6 (–7.6–2.4) | 0.29 |
| *Last observation carried forward* | | | | | | | | |
| FVC | 88 (75–102) | 93 (81–108) | 2.4±13 | 80 (66–92) | 82 (65–93) | 0.8±9 | 1.6 (–3.8–7.0) | 0.56 |
| DLCO | 51 (39–60) | 48 (41–59) | –1.5±11 | 39 (31–51) | 39 (29–50) | 0.04±6 | –1.6 (–6.1–3.0) | 0.50 |
| *Per protocol analysis* | | | | | | | | |
| FVC | 83 (74–100) | 90 (80–106) | 2.3±13 | 83 (68–92) | 83 (66–98) | 3.0±9 | –0.7 (–7.5–6.1) | 0.83 |
| DLCO | 50 (40–60) | 48 (41–60) | 0.7±11 | 41 (32–55) | 40 (31–57) | 2.3±7 | –1.6 (–7.6–4.4) | 0.59 |

Values are the median of %> predicted (p25–75); *mean ± SD; Δ: difference between baseline and 1 year; CI: confidence interval. †Significance of the degree of change in the limited ILD group versus the extensive ILD group at 1 year; FVC: forced vital capacity; DLCO: diffusing capacity of the lung for carbon monoxide.

**Conclusions:** 1. CYC pulse therapy does not worsen pulmonary function in SSc-related ILD after 1 year. 2. The extent of ILD does not influence the effect of CYC.

**Disclosure of Interest:** None declared

## FRI0255 COMBINATION THERAPY WITH RITUXIMAB AND MYCOPHENOLATE MOFETIL IN SYSTEMIC SCLEROSIS. SAFETY AND EFFICACY FROM 12 MONTHS

P. Fraticelli [1], C. Fischetti [1], F. Salaffi [2], M. Carotti [3], G. Pomponio [1], A. Gabrielli [4]. *[1]Department of Internal Medicine, Ospedali Riuniti, Università Politecnica delle Marche, Ancona; [2]Clinic of Rheumatology, Ospedale Carlo Urbani Jesi, Università Politecnica delle Marche, Jesi (AN); [3]Department of Radiology, Ospedali Riuniti, Università Politecnica delle Marche; [4]Department of Clinical and Molecular Sciences, Università Politecnica delle Marche, Ancona, Italy*

**Background:** Systemic Sclerosis (SSc) is a chronic systemic disease characterized by immune abnormalities, microangiopathy and progressive fibrosis of skin and internal organs. Only few therapeutic options have shown a proved disease-modifying effect for skin thickening and SSc-associated interstitial lung disease. Rituximab (RTX) and Mycophenolate Mofetil (MMF) have separately proven some evidence of efficacy and safety in clinical trials or case series

**Objectives:** Assess efficacy and safety of a combination therapy, with RTX and MMF in a cohort of SSc patients with pulmonary and cutaneous involvement rapidly progressive or resistant to conventional therapy.

**Methods:** Eligible patients were treated with RTX in two different regimens (1000 mg fortnightly x 2 or 375 mg/m$^2$/week for 4 consecutive weeks) at baseline and after 6 months, associated with MMF 2000 mg/day. They received anti-infective prophylaxis with Valacyclovir 1000 mg and Cotrimoxazole 160/800 mg alternate days. Patients with previous malignancy or HBV, HCV or TB infection or connective overlap were excluded. Patients underwent clinical and laboratory evaluation every 3 months. Skin involvement was assessed by using the modified Rodnan Skin Score (mRSS) performed by the same physician at baseline and after 3, 6 and 12 months. Chest high-resolution computed tomography (HRCT) and pulmonary function tests (PFTs) and single-breath diffusing capacity were performed at baseline, after 6 and 12 months. The assessment of the extension of pulmonary fibrosis (PF) was analysed with the semiquantitative Warrick score and with the OsiriX quantitative computerized analysis. Data were analysed by Friedman test (GraphPadPrism V5).

**Results:** 18 SSc patients were enrolled (M/F: 8/10, median age 51y, median disease 1 y, diffuse SSc 9, limited SSc 9). Three patients withdrew from the study: one was lost to follow-up, one had a minor infusion reaction which led to RTX discontinuation and one died for different causes. The analysis includes all 15 of 18 patients who completed 12 months of follow-up. The mRSS showed a statistically significant improvement (p**=0,0036), more remarkable in patients with diffuse cutaneous SSc. Concerning PFTs there was a statistically significant increase of FVC (p**=0,0093), $FEV_1$ (p**=0,0061), with stable values of DLCO (p=0,3375). The HRCT scan showed an improvement statistically significant evaluated with analysis by OsiriX (p*=0,0331), while the Warrick score showed a not significant trend toward improvement. No serious adverse events were observed during the follow-up. In two patients the MMF dose was reduced for mild neutropenia.

**Conclusions:** Despite preliminary and limited to a small number of patients, our results suggest that combination therapy with RTX and MMF is well tolerated, safe, and potentially effective for cutaneous and pulmonary involvement in SSc patients.

**Disclosure of Interest:** None declared

## FRI0256 SIGNIFICANCE OF COGNITIVE IMPAIRMENT IN SYSTEMIC SCLEROSIS

L. Groseanu [1,2], T. Gudu [1], A. Balanescu [1,2], V. Bojinca [1,2], D. Opris [1,2], I. Saulescu [1,2], A. Borangiu [1,2], C. Constantinescu [1,2], D. Predeteanu [1,2], F. Berghea [1,2], M.M. Negru [1,2], V. Vlad [1], M. Abobului [1], R. Ionescu [1,2]. *[1]Internal Medicine and Rheumatology, Sf Maria Clinical Hospital; [2]Rheumatology, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

**Background:** There is an increased appreciation of the burden of cognitive impairment in people with autoimmune diseases (1). Recent studies have demonstrated that patients with systemic sclerosis (SSc) have a specific pattern of cognitive impairment: the dysexecutive syndrome (2).

**Objectives:** We evaluated the prevalence of cognitive impairment in SSc and assessed the association with the disease features and impact on daily living

**Methods:** Consecutive SSc from EUSTAR center 096 were examined. Montreal Cognitive Assessment (MoCA) was used to assess cognitive dysfunction and scores ≤26 were considered abnormal (3). SSc patients were assessed according tu MEDS evaluation sheets to determine organ involvement, autoantibody profile, disease activity (Valentine Activity Index) and disease severity (Medsger Severity Index). sHAQ (Scleroderma Health Assessment Questionnaire) has also been completed. Data were compared by difference tests according to the types of variables: t-test, Mann-Whitney or chi-square. To evaluate correlations between variables Pearson or Spearman correlations were used.

**Results:** A total of 70 SSc patients [36 (51.42%) limited SSc (lSSc) and 34 (48.57%) with diffuse SSc (dSSc), 60 female; mean age 54.5 (±11.62) years; mean disease duration 66 (±429.6) months] were included in the study. 47.14% of the patients had active disease, the mean Rodnan score was 7 (±4.17), the mean Medsger score was 5.5 (±2.89), 24.28% of the patients had lung involvement and 20% had pulmonary arterial hypertension. The mean HAQ was 1 (±0.59). Cognitive impairment was identified in 65.71% SSc patients; the mean MOCA score was 26 (±2.83).

Cognitive impairment of SSc patients was related to older age (r=-0.378, p=0.001), rural provenience (r=-0.351,p=0.003), severity of the disease evaluated by the Medsger score (r=–0.262,p=0.029) and poor quality of life evaluated by sHAQ (r=-0.323,p=0.003).Correlations were also identified with musculoarticular involvement (r=-0.330,p=0.006), advanced capillaroscopy patttern (r=-0.331, p=0.006). The diiffuse SSc patients were more likely to have cognitive dysfunction (likehood ratio 0.012) as were those with SCL70 positive (0.0.18). No relationship was identified between cognitive impairment and lung, heart or renal involvement, the presence of digital ulcers, the use of corticosteoids or immunosuppression.

**Conclusions:** An increased prevalence of cognitive impairment was observed in SSc and associated with age, rural provenience, more severe disease, muscle involvement and poor quality of life. Further studies are needed to be compared with healthy controls and to assess the role of microvascular damage or that of other confounders.

## FRI0257 AUGMENTED CONCENTRATIONS OF CX3CL1 ARE ASSOCIATED WITH PROGRESSIV INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS

A.-M. Hoffmann-Vold[1], R. Huynh[2], E. Volkmann[2], S. Palchevskiy[2], Ø. Midtvedt[1], T. Garen[1], A. Der Hovanessian[2], S. Weigt[2], M. Fishbein[2], A. Ardehali[2], D. Ross[2], R. Saggar[2], J.3. Lynch[2], P. Aukrust[1], T. Ueland[1], R. Elashoff[2], Ø. Molberg[1], J. Belperio[2]. *[1]Oslo University Hospital, Oslo, Norway; [2]University of California Los Angeles, Los Angeles, United States*

**Background:** Systemic sclerosis (SSc) is a complex, immune-mediated disorder that carries high risk for progressive interstitial lung disease (ILD). CX3CL1 (Fractalkine) is expressed in lungs; and has the ability to act as an adhesion molecule as well as a potent chemoattractant of mononuclear cells via its interaction with CX3CR1. Here, we hypothesized that the CX3CL1/CX3CR1 axis could play an important role in the immune pathogenesis of SSc associated ILD.
**Objectives:** (i) To explore CX3CL1 concentrations in lung homogenates from patients with SSc-ILD at the time of lung transplant (LT) compared to donor lung homogenates with no lung disease. (ii) To test whether CX3CL1 concentrations in serum differ between SSc patients and healthy controls. (iii) To assess associations between serum CX3CL1 and the development of SSc-ILD.
**Methods:** Lung tissue was collected at LT from SSc (n=12) and donor lungs (n=12) at the UCLA. Concentrations of CX3CL1 in lung homogenates were determined by Luminex technology. Cellular sources of CX3CL1were assessed by immunohistochemistry (IHC). Sera from the prospective Oslo University Hospital SSc cohort (n=240) and healthy controls (n=100) were analysed for CX3CL1 concentration by ELISA. Paired pulmonary function tests (PFTs) and HRCT images were obtained at baseline and follow-up. Non-parametric statistical analysis was performed via Kruskal-Wallis testing. Categorical data were analyzed by Chi-squared testing. Predictive values were analyzed by multivariate linear regression and cox regression.
**Results:** Concentrations of CX3CL1 in lung homogenates and serum were increased in SSc compared to healthy controls (Table 1). IHC demonstrated a CX3CL1 co-localization with reactive type II pneumocytes, airway epithelial cells, epithelial cells involved in bronchiolization, and infiltrating mononuclear cells. Serum CX3CL1 was significantly associated with anti-Topoisomerase I antibody and extensive ILD (Table 1). Linear regression analyses showed associations between CX3CL1 and extent of lung fibrosis at follow up (Regression coefficient (B): 0.86, SE 0.41, p=0.038) when adjusting for age and gender. Cox regression analysis showed predictive associations of CX3CL1 to extensive ILD (HR 1.43, 95% CI 1.02–1.26, p=0.017) and to ΔDLCO% decline >7.5% (HR 1.13, 95% CI 1.02–1.25, p=0.023). However, following further adjustment, including PFT parameters and autoantibodies, CX3CL1 was no longer significant.

Table 1: CX3CL1 concentrations in the SSc study cohorts and corresponding controls. Also shown are CX3CL1 in SSc subsets stratified by demographics and clinical characteristics.

| | OUH cohort (serum) | | | UCLA cohort (lung) | | |
|---|---|---|---|---|---|---|
| | No (%) | CX3CL1 ng/ml (SD) | p-value | No | CX3CL1 ng/ml (SD) | p-value |
| Total SSc cohort | 240 | 1.79 (2.25) | 0.010 | 12 | 0.892 (0.839) | 0.026 |
| Controls | 100 | 1.16 (1.36) | | 12 | 0.253 (0.271) | |
| SSc subsets | | | | | | |
| Male | 44 (13) | 1.80 (1.86) | 0.959 | 7 | 0.924 (0.961) | 0.845 |

| Deceased | 56 (16) | 1.89 (2.43) | 0.689 | 5 | 0.736 (0.646) | 0.434 |
| ATA | 36 (11) | 3.09 (4.07) | 0.030 | 3 | 1.335 (1.440) | 0.654 |
| PH | 45 (13) | 1.94 (2.43) | 0.612 | 8 | 1.176 (0.901) | 0.217 |
| Extensive lung disease* | 27 (8) | 2.80 (4.09) | 0.023 | | n.a. | |

OUH: Oslo University Hospital; UCLA: University of California Los Angeles; No: number; SD: standard deviation; SSc: systemic sclerosis; FVC: Forced vital capacity; DLCO: diffusing lung capacity for carbon monoxide; dcSSc: diffuse cutaneous systemic sclerosis; ATA: anti-topoisomerase I antibody; *defined as total lung fibrosis ≥20% and FVC <70%

**Conclusions:** We have demonstrated an association between elevated protein levels of CX3CL1 in SSc-ILD and have shown that within the lungs, CX3CL1 are predominately co-localized with epithelia and infiltrating mononuclear cells. Augmented concentrations in the serum of SSc patients may be predictive of ILD.

## FRI0258 VALIDATION OF BIOELECTRICAL IMPEDANCE ANALYSIS FOR THE ASSESSMENT OF BODY COMPOSITION IN PATIENTS WITH SYSTEMIC SCLEROSIS

M.J. Spanjer[1], I.E.M. Bultink[1], M.A.E. de van der Schueren[2], A.E. Voskuyl[1]. *[1]Department of Rheumatology, Amsterdam Rheumatology and Immunology Center, location VU University Medical Center; [2]Department of Nutrition and Dietetics, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Malnutrition is a frequently reported complication in patients with systemic sclerosis (SSc) [1]. Especially low fat free mass (FFM) has been identified a prognostic factor for morbidity and mortality. Different methods are available to assess body composition. Bioelectrical impedance analysis (BIA) is a bedside method that has not yet been validated in this patient group.
**Objectives:** To validate BIA against whole body dual-energy x-ray absorptiometry (DXA), for the assessment of body composition in patients with SSc.
**Methods:** Body composition was assessed in 72 patients with whole body DXA (Hologic, Discovery A) and BIA (Bodystat Quadscan 400). The Geneva equation [2] was used to estimate FFM. The agreement between BIA and whole body DXA was assessed with Bland-Altman analysis and intraclass correlation coefficients (ICCs). The occurrence of malnutrition was assessed and defined as fat free mass index (FFMI) $\leq$14.5 kg/m$^2$ for women or $\leq$16.6 kg/m$^2$ for men [3].
**Results:** No difference was found between BIA and whole body DXA for the assessment of FFM as predicted by the Geneva equation (mean difference 0.02 ± 2.4 kg). ICC was 0.97 (95% CI: 0.95–0.98). The 95% limits of agreement, as assessed by Bland-Altman analysis were -4.6 kg and 4.6 kg. Despite normal BMIs (24.6 ± 4.3 kg/m$^2$), malnutrition was found in 14 (19.4%) patients with SSc.

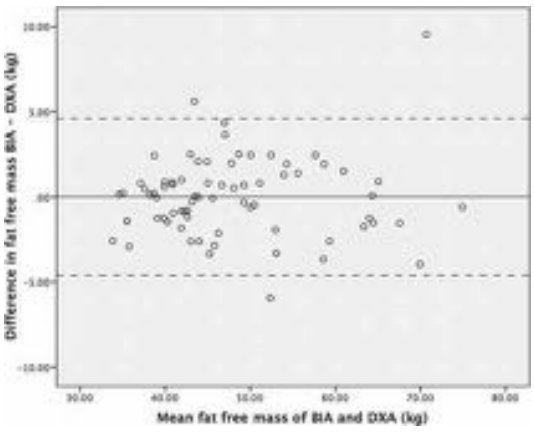

Figure 1. Bland-Altman plot comparing fat free mass measured by whole body DXA and fat free mass measured by BIA using the Geneva equation. The solid line represents the mean and the dotted lines represent the limits of agreement.

**Conclusions:** This study shows acceptable validity of BIA in determining FFM in patients with SSc on a group level, while on an individual level, FFM may vary by 4.6 kg. This study also demonstrated a high prevalence (19.4%) of malnutrition in patients with SSc, underlining the necessity of assessing body composition in this patient group.

## FRI0259 A RETROSPECTIVE STUDY: PREDICTIVE FACTORS FOR INSUFFICIENT IMPROVEMENT OF MUSCLE WEAKNESS AFTER TREATMENT AMONG PATIENTS WITH POLYMYOSITIS AND DERMATOMYOSITIS

A. Nishino, Y. Katsumata, H. Kawasumi, Y. Kawaguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** The severity of muscle involvement and the response to immunosuppressive drugs are highly variable among patients with polymyositis (PM) and dermatomyositis (DM). Although previous studies reported that some clinical and laboratory features were associated with a poorer prognosis, the results were not consistent through those studies. A decade ago, we reported that the height of the baseline serum creatine kinase (CK) elevation predict the course of disease among patients treated with glucocorticoids (GCs) alone. However, other groups reported conflicting results. In addition, we later changed our basic treatment strategy to combination therapy with another immunosuppressive agent to improve response and reduce the need for GCs.
**Objectives:** We aimed to identify predictive factors for insufficient improvement of muscle weakness after treatment among patients with PM/DM, focusing more recent patients than those included in our previous report.

**Methods:** Patients were included in this retrospective study when they met all these criteria: 1) fulfill the Bohan and Peter classification criteria for PM/DM; 2) were administered to our university hospital for the treatment of muscle manifestations of PM/DM from 2008 through 2015. In addition, these patients were excluded from the study: those with clinically amyopathic DM and those complicated with other overlapping systemic autoimmune diseases or cancer. Manual muscle testing (MMT) was assessed using traditional 5 point MMT scales (i.e. the Medical Research Council Scale.) The Total MMT score included 2 axial and 8 proximal muscle groups, with a maximum potential value of 50. The Total MMT score less than 48 at 6 to 8 weeks after initiation of GC treatment was defined as insufficient improvement of muscle weakness. Clinical and laboratory parameters were statistically compared between patients with sufficient and insufficient improvement of muscle weakness. Odds ratios (ORs) for insufficient improvement of muscle weakness were assessed by multiple logistic regression analysis.
**Results:** Ultimately, 45 patients, comprising 30 PM and 15 DM patients were included in the present study. Among these, 22 were positive for anti-aminoacyl-tRNA synthetase (anti-ARS) antibodies, the mean age was 55 years, and the mean CK level before treatment was 2,544 U/l. GCs (≥0.5 mg/kg/day) were administered in all the patients and another immunosuppressant were concomitantly used in 39 patients. By univariate analyses, age and CK levels before treatment were significantly higher in patients with insufficient improvement of muscle weakness than those with sufficient improvement ($p<0.05$). The cut off values were determined by receiver operating characteristic curve analyses as ≥65 years for age and ≥1,900 U/l for CK level. The patients with ≥65 years old, CK ≥1,900 U/l, or negative anti-ARS antibodies were more frequent in patients with insufficient improvement. By multivariate analyses, ORs (95% confidence interval) for ≥65 years old, CK ≥1,900 U/l, and negative anti-ARS antibodies were 16 (2 to 342), 22 (3 to 526), and 9 (1.3 to 104), respectively.
**Conclusions:** The present study suggested that ≥65 years old, CK ≥1,900 U/l before treatment, and negative anti-ARS antibodies were predictive factors for insufficient improvement of muscle weakness in patients with PM/DM.

## FRI0260 QUANTITATIVE CT INDEXES IN ILD-SSC PATIENTS WITH DIFFERENT AUTOANTIBODIES

A. Ariani[1], E. Bravi[2], M. Saracco[3], S. Parisi[4], F. De Gennaro[5], L. Idolazzi[6], M. Silva[7], V. Seletti[7], F. Lumetti[1], P. Caramaschi[6], C. Benini[6], F.C. Bodini[8], C.A. Scirè[9], G. Lucchini[1], D. Santilli[1], D. Imberti[2], E. Arrigoni[2], E. Michieletti[8], R. Pellerito[3], E. Fusaro[4], N. Sverzellati[7]. *[1]Dipartimento di Medicina, Unità di Medicina Interna e Reumatologia, Azienda Ospedaliero Universitaria di Parma, Parma; [2]Department of Medicine, Internal Medicine and Rheumatology Unit, Ospedale G. Da Saliceto, Piacenza; [3]Rheumatology Unit, Ospedale Mauriziano - Umberto I di Torino; [4]Rheumatology Department, Azienda Ospedaliera Cittá della Salute e della Scienza di Torino, Torino; [5]Rheumatology Unit, Azienda Ospedaliera "Istituti Ospitalieri" di Cremona, Cremona; [6]Rheumatology Section, Department of Medicine, University of Verona, Policlinico Borgo Roma, Verona; [7]Department of Clinical Sciences, Section of Radiology, University of Parma, Parma; [8]Radiology Unit, Ospedale G. Da Saliceto, Piacenza; [9]Epidemiology Unit, Italian Society for Rheumatology, Milano, Italy*

**Background:** Quantitative Computed Tomography (QCT) is an innovative method to assess the severity of interstitial lung disease (ILD) related to systemic sclerosis (SSc). QCT is correlated to semi-quantitative radiological scores (SQs) and functional outcomes (e.g. FVC, DLco, oxygen desaturation after exercise) in SSc patients. However, the autoimmune profile can deeply influence the respiratory system's involvement.
**Objectives:** The main aim of this study is to verify the correlation between SQs, FVC, DLco and QCT in SSc patients clustered according to their autoimmunity.
**Methods:** Three hundred three (303) SSc patients were enrolled and underwent functional and radiological assessment. Chest CTs of each patient were evaluated with both SQs and Horos (a software up to perform voxel-wise analysis) in order to obtain QCT indexes.
**Results:** Patients were divided in three groups (94 with ACA, 93 with antiScl70, 116 with other autoantibodies). QCT indexes taken into account were kurtosis (Kurt), skewness (Skew), Standard Deviation (SDev), Mean Lung Attenuation (MLA) and fibrosis ratio (FR). Except for the last one, all QCT indexes were assessed both in the parenchymal (pQCT) and in the whole lung (tQCT). The statistically significant ($p<0,05$) correlation coefficients between SQs, FVC and DLco vs QCT are listed in Table 1.
In ACA patients there are not correlations between DLco and QCT indexes.
**Conclusions:** Our results confirm that the majority of QCT indexes are correlated to SQS and functional outcomes. The strongest correlation coefficients were in the antiScl70 subgroup while the weakest ones were in ACA patients. This relevant difference, possibly due to the different prevalence of ILD and type of lung involvement in these two subgroups, should be taken into account when applying the QCT assessment to SSc patients.
**Disclosure of Interest:** None declared

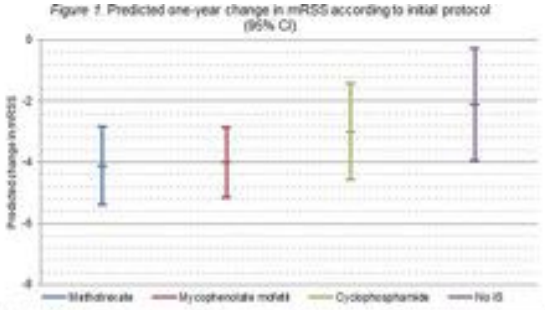
## FRI0261 OBSERVATIONAL STUDY OF OUTCOME IN PATIENTS WITH EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS TREATED WITH IMMUNOSUPPRESSIVE THERAPIES (ESOS STUDY)

A.L. Herrick[1], X. Pan[1], S. Peytrignet[1], R. Hesselstrand[2], L. Mouthon[3], E. Brown[1], L. Czirjak[4], J. Distler[5], O. Distler[6], K. Fligelstone[7], W. Gregory[1], R. Ochiel[7], A. Silman[8], M. Vonk[9], M. Lunt[1], C. Denton[7] on behalf of ESOS Investigators. *[1]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom; [2]Department of Clinical Sciences, Lund University, Lund, Sweden; [3]National Referral Center for Rare Autoimmune and Systemic Diseases, Université Paris Descartes, Hôpital Cochin, Paris, France; [4]Department of Rheumatology and Immunology, University of Pecs, Pecs, Hungary; [5]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany; [6]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [7]Centre for Rheumatology, Royal Free and University College Medical School, London; [8]Nuffield Department of Orthopaedics, University of Oxford, Oxford, United Kingdom; [9]Department of Rheumatology, Radboud University Nijmegen Medical Center, Nijmegen, Netherlands*



**Background:** Early diffuse cutaneous systemic sclerosis (dcSSc) has high morbidity and mortality, and there is currently no cure.
**Objectives:** The main objective of ESOS (European Scleroderma Observational Study) was to compare the effectiveness of currently used immunosuppressant treatments.
**Methods:** ESOS was a prospective observational cohort study, capturing entry and outcome data in a standard way. Four recommended treatment protocols were decided by the steering committee: methotrexate (MTX), mycophenolate mofetil (MMF), cyclophosphamide, and "no immunosuppressant". Patients were assessed at baseline, and then 3-monthly for 24 months or (for those entering the study subsequent to September 2013) at least 12 months. The primary outcome measure was the change in modified Rodnan skin score (mRSS – 17 sites) between 0 (baseline) and 12 months. Secondary endpoints largely reflected routine clinical practice and are not reported here. Effects of treatment on the skin score were assessed using linear regression with baseline treatments as predictors. Confounding by indication at baseline was accounted for using inverse probability of treatment (IPT) weights, while censoring weights adjust for bias due to patient attrition. Survival in each protocol was estimated using Kaplan-Meier curves and survival differences were tested based on the results of an IPT-weighted Cox regression model.
**Results:** Target recruitment was achieved, with 326 patients from 50 centres (median age 52.3 years, 72% female, median disease duration 11.1 months). Because this was not a randomized study, the number of patients starting on each treatment protocol differed: 65 MTX, 117 MMF, 87 cyclophosphamide, and 57 no immunosuppressant treatment. 273 patients (84%) completed 12 months follow-up and 179 (55%) 24 months follow-up. Median mRSS at baseline was 21.0 units. After 12 and 24 months, 153 (56%) and 139 (78%) of remaining patients had an improved skin score with respect to baseline. The mean change in mRSS after 12 and 24 months was -2.9 and -6.8 units. Predicted decreases in mRSS in each of the protocols are summarized in Figure 1. In both weighted and unadjusted models, the differences between the treatment groups are non-significant (p=0.27 and p=0.16).
At 24 months, Kaplan-Meier predicted survival rates (adjusted for confounding) are 94% (MTX), 90% (MMF), 91% (cyclophosphamide) and 87% (no immunosuppressant). However, differences are non-significant (p=0.42).
**Conclusions:** 1. All groups showed improvement in MRSS which was not

## FRI0262 PERIPHERAL BLOOD PERFUSION IS LOWER IN PRIMARY RAYNAUD'S PHENOMENON PATIENTS THAN IN THOSE WITH SYSTEMIC SCLEROSIS SHOWING THE "EARLY" PATTERN OF NAILFOLD MICROANGIOPATHY

B. Ruaro[1], A. Sulli[1], V. Smith[2], A.C. Trombetta[1], C. Pizzorni[1], M. Cutolo[1].
[1]*Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy;* [2]*Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium*

**Background:** Peripheral blood perfusion is reduced in patients with both primary (PRP) or secondary Raynaud's phenomenon (SRP) (1–2).
**Objectives:** To investigate blood perfusion (BP) in different skin areas of hands in patients with PRP, SRP to systemic sclerosis (SSc), and healthy subjects (CNT).
**Methods:** 70 SSc patients (ACR/EULAR criteria) (3) (mean age 63±12 years, mean disease duration 6±5 years), 31 PRP patients (LeRoy criteria) (4) (mean age 48±18 years, mean Raynaud duration 3±2 years) and 68 CNT (mean age 59±19 years) were enrolled during winter time, after informed consent. BP was assessed by Laser speckle contrast analysis (LASCA) at the level of fingertips, periungual areas, dorsal and palmar aspect of 3rd finger bilaterally, dorsum and palm of both hands, and the average BP calculated as perfusion units (PU) (1). Nailfold videocapillaroscopy (NVC) was also performed to distinguish between PRP and SRP, and to detect the proper pattern of nailfold microangiopathy ("early", "active" or "late") in SSc patients (5). Patients were not taking vasodilator drug since at least two weeks.
**Results:** Both PRP and SSc patients showed a statistically significant lower BP than CNT at the level of fingertips (median 86, 88, 186 PU, respectively, $p<0.0001$), periungual (median 75, 76, 142 PU, respectively, $p<0.0001$), palmar aspect of 3rd finger (median 71, 81, 134 PU, respectively, $p<0.0001$), and palm areas (median 61, 78, 112 PU, respectively, $p<0.0001$). On the contrary, the three groups displayed similar BP values at the level of other areas of hands. Of interest, PRP patients showed lower BP values than SSc patients in all areas of hand, even if BP was found statistically different only at the level of both palmar aspects of 3rd finger ($p=0.04$) and palm of hands ($p=0.008$). The gradients of BP fingertip-phalanx-palm and periungual-phalanx-dorsum were significantly lower in PRP than in SSc patients ($p<0.0001$), as well as significantly higher in CNT when compared with both PRP and SSc patients ($p<0.0001$). A statistically significant progressive decrease of BP was observed in SSc patients with progressive pattern of nailfold microangiopathy ("early", "active", and "late") at the level of fingertips, periungual, palmar aspect of 3rd fingers and palm areas ($p<0.05$). Moreover, BP was significantly lower in PRP than in SSc patients with the "early" pattern of microangiopathy in all areas ($p<0.04$), with the exception of dorsal phalanx and hand dorsum.
**Conclusions:** By considering a small cohort of patients, BP of hand was found lower in PRP than in SSc patients with the "early" NVC pattern of microangiopathy. Also the gradients of perfusion between distal and proximal areas of hand were significantly lower in PRP than in SSc patients. The clinical value of this new early finding is matter of further analysis.

## FRI0263 NODULAR REGENERATIVE HYPERPLASIA OF THE LIVER – A RARE VASCULAR COMPLICATION OF SSC

B. Maurer[1], L. Graf[1], Y. Allanore[2], R. Dobrota[1], S. Jordan[1], O. Distler[1].
[1]*UniversitätsSpital Zürich, Zürich, Switzerland;* [2]*Cochin Hospital, Paris, France*

**Background:** Nodular regenerative hyperplasia (NRH) is a rare liver disease causing non-cirrhotic intrahepatic portal hypertension (1). The knowledge of NRH is based mainly upon case reports. Although patients with NRH may remain asymptomatic, at least 50% develop life-threatening complications. Among the autoimmune diseases, SSc has been hypothesized to be associated with NRH. In SSc, microvascular injury is considered one of the earliest pathologic events, followed by inflammation and fibrosis. Similar mechanisms are supposed to be operative in NRH. Therefore, it might be hypothesized that NRH represents a yet unidentified vascular complication of SSc.
**Objectives:** To investigate the prevalence and clinical phenotype of NRH in SSc.
**Methods:** Published cases of SSc-NRH were identified by systematic literature review. Next, we screened the Zurich SSc cohort. In accordance with international guidelines, the diagnosis of NRH had to be established by liver biopsy showing a characteristic diffuse micronodular transformation without fibrous septa (2). SSc characteristics were derived from the EUSTAR database. Information on NRH was extracted from the patients' charts. The study was approved by the local institutional review board. For the statistical analysis, SPSS version 20 was used. Continues variables are presented as mean±SD or median+range. Categorical variables are given as absolute numbers and percentage.
**Results:** The Pubmed search review retrieved 9 cases of SSc-NRH. In the Zurich cohort, 5 out of 278 patients with established SSc were diagnosed with NRH resulting in a prevalence of 1.8%. The main characteristics of all 14 patients are provided in Fig.1. The majority of patients was female (69.2%) with an average age of 44.5±12.3 years at diagnosis of SSc. Mean disease duration of SSc was 8.2±7 years when NRH was diagnosed. NRH occurred in both diffuse and limited cutaneous SSc. ACR/EULAR criteria were fulfilled by all patients. Of note, in the majority of patients, vascular features of SSc were present at the time point of the diagnosis of NRH including digital ulcers (ever 100%, active 71.4%), an active pattern on nailfold capillaroscopy (100%), and pulmonary hypertension (50%). The most prevalent auto-antibodies were anti-centromere (40%) and anti-U1nRNP (33%), whereas no patient was positive for anti-Scl70 or anti-RNA-Polymerase III. In the majority of patients, an elevation of AP and GGT (75%, 60%) was observed, whereas transaminases were not

| Patients' characteristics (n=14) | |
|---|---|
| Age at time point of diagnosis of SSc (years) (n=12/14) | 44.5 ± 12.3 |
| Disease duration of SSc at time point of diagnosis of NRH (years) (n=13/14) | 8.2 ± 7 |
| Female gender | 9/13 (69.2%) |
| MRSS (n/51) at time point of diagnosis of NRH (n=4/14) | 10 ± 7 |
| **Skin involvement** | |
| Diffuse cutaneous SSc | 5/10 (50%) |
| Limited cutaneous SSc | 4/10 (40%) |
| None | 1/10 (1%) |
| **Peripheral vasculopathy** | |
| Raynaud's phenomenon | 14/14 /100%) |
| Digital ulcers ever | 7/7 (100%) |
| Active digital ulcers | 5/7 (71.4%) |

| Anti-U1nRNP | 2/6 (33.3%) |
| GOT elevated (n=8) | 2/10 (20%) |
| GPT elevated (n=6) | 3/9 (33.3%) |
| GGT elevated (n=9) | 6/10 (60%) |
| AP elevated (n=9) | 9/12 (75%) |
| Bilirubin elevated (n=7) | 0/10 (0%) |
| **Organ involvement** (most relevant findings) | |
| Lung | |
| Dyspnoea present | 8/8 (100%) |
| Pulmonary hypertension (on echocardiography) | 3/6 (50%) |
| Lung fibrosis (defined as FVC <60% or FVC <70% + presence of lung fibrosis on HRCT) | 5/8 (62.5%) |
| Gastrointestinal tract | |
| Esophageal symptoms | 9/9 (100%) |
| Intestinal symptoms | 4/6 (66.7%) |
| Stomach symptoms | 3/6 (50%) |
| Melaena | 4/6 (66.7%) |
| Haematemesis | 4/8 (50%) |
| **Ultrasound of the liver** | |
| Liver size normal | 6/8 (75%) |
| Surface smooth | 3/4 (75%) |
| Parenchyma homogeneous | 3/4 (75%) |
| Focal lesions | 0/5 (0%) |
| Portal vein flow normal | 4/5 (80%) |
| Ascites | 3/5 (60%) |
| Splenomegaly | 6/8 (75%) |
| **Fibroscan** | |
| Increased stiffness | 3/4 (75%) |
| **Complications** | |
| Portal hypertension (increased pressure) | 6/7 (86.7%) |
| Gastric varices (by gastroscopy) | 2/6 (33.3%) |
| Esophageal varices (by gastroscopy) | 7/10 (70%) |
| Variceal hemorrhage (by gastroscopy) | 4/9 (44.4%) |

increased. Melaena and hematemesis occurred in 66.7%, resp. 50% of patients. Ultrasound detected ascites (60%) and splenomegaly (75%), but no pathologic liver morphology, although an increased stiffness was diagnosed by fibroscan (75%). Portal hypertension was diagnosed in 85.7% with oesophageal varices (70%) and variceal haemorrhage (44.4%) as main complications.

**Conclusions:** NRH might represent a rare, yet clinically important, potentially life-threatening complication in SSc patients, especially in those with prominent vascular features and positivity for anti-centromere. Elevated levels of AP and GGT, ascites and splenomegaly by ultrasound and increased stiffness by fibroscan might alert to the presence of NRH. If suspected, the diagnosis should be confirmed by liver biopsy.

## FRI0264 PREVALENCE, RISK FACTORS AND ASSESSMENT OF DEPRESSIVE SYMPTOMS IN PATIENTS WITH SYSTEMIC SCLEROSIS

C. March[1], D. Huscher[2], A. Makowka[1], E. Preis[1], F. Buttgereit[1], G. Riemekasten[3], K. Norman[4], E. Siegert[1]. *[1]Division of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin; [2]German Rheumatism Center, Berlin; [3]Department of Rheumatology, University of Luebeck, Luebeck; [4]Research Group Geriatrics, Charité-Universitätsmedizin Berlin, Berlin, Germany*

**Background:** The development of depressive symptoms is very common among patients with Systemic Sclerosis (SSc).[1]

**Objectives:** Evaluation of the prevalence of depressive symptoms among German SSc patients at our centre, identification of possible risk factors and analysis of the current standard of care in clinical settings.

**Methods:** 94 of 134 patients (82 women (87.2%), age 58.3 ± 13.6 years, BMI 24.5 ± 5.4 kg/m$^2$) in our study met the inclusion criteria of matching the ACR/EULAR 2013 classification criteria, being at least 18 years old, able to consent and having completed the Major Depression Inventory (MDI), Short Form 36 (SF-36®), Scleroderma Health Assessment Questionnaire (SHAQ), Brief Fatigue Inventory (BFI) and Physical Activity Questionnaire (IPAQ). The prevalence of depressive symptoms was evaluated using the MDI. The identifying potential of patient questionnaires for the risk of an SSc patient to suffer from depressive symptoms was evaluated using the SF-36® for quality of life, the SHAQ for disability, the BFI for fatigue and the IPAQ for activity. Discharge letters of the time when the patients were included were analyzed regarding the assessment and treatment of depressive symptoms and mental health. Clinical and para clinical parameters were measured according to standardized procedures. The data were analyzed with IBM SPSS® Statistics by using Chi-Square/Fisher-, Mann-Whitney-U-test, correlation and regression analysis.

**Results:** The prevalence of depressive symptoms according to the MDI score ≥20 was 22.3%. In the analysis of risk factors between two subgroups (MDI Score <20 and MDI Score ≥20), underweight (BMI <18.5 kg/m$^2$) turned out to be a significant risk factor (p=0.002) (Image 1). Also, there was a significant correlation between general health (SHAQ) (r=0.508, p=0.01), quality of life (SF 36®) (r= -0.769, p=0.01), fatigue (BFI) (r=0.721, p=0.01) and physical activity (IPAQ MET/min) (r= -0.331, p=0.01) with the level of the MDI score. The analysis of the current standard of care showed that the majority of the patients 84 (89.4%) were not assessed for depressive symptoms or mental health, including 19 with an MDI score ≥20. Mood disorders were diagnosed in 5 (5.3%) patients, 13 (13.8%) were treated with antidepressants and in 6 (6.4%) cases psychological intervention was carried out or suggested.

| Variable | MDI < 20 | MDI ≥ 20 | p |
|---|---|---|---|
| n | 73 | 21 | |
| Woman, n (%) | 61 (83.6) | 21 (100.0) | **0.047** |
| Age in years, mean ± SD | 58.1 ± 13.5 | 58.9 ± 14.4 | n.s |
| Disease duration in years, mean ± SD | 7.8 ± 5.6 | 6.8 ± 6.8 | n.s |
| Body-Mass-Index, mean ± SD | 24.5 ± 4.3 | 24.7 ± 8.5 | n.s |
| Underweight, n (%) | 1 (1.4) | 5 (23.8) | **0.002** |
| MDI score, mean ±SD | 9.5 ± 5.2 | 28.7 ± 6.0 | |
| SHAQ score, mean ± SD | 0.85 ± 0.59 | 1.4 ± 0.67 | **0.003** |
| SF-36 score, mean ± SD | 59.9 ± 14.4 | 36.2 ± 13.3 | **0.000** |
| SF Mental Health total score, mean ± SD | 67.8 ± 15.7 | 38.7 ± 10.6 | **0.000** |
| IPAQ MET/min, mean ± SD | 3114 ± 2327 | 1760 ± 1954 | **0.048** |
| BFI score, mean ± SD | 3.4 ± 1.8 | 6.0 ± 1.7 | **0.000** |

**Table 1** Analysis of risk factors between two subgroups (MDI < 20; MDI ≥ 20)

**Conclusions:** There is a high prevalence of depressive symptoms, which should be kept in mind when treating patients with SSc. Special attention should be paid to weight loss and fatigue, results in the SF-36®, SHAQ and IPAQ. The mental health should be assessed during consultations on a regular basis. The questionnaires applied in this study could be used as indicators for the risk of an SSc patient to suffer from depressive symptoms with the BFI and SF-36 being the most sensitive ones.

## FRI0265 SELEXIPAG IN RAYNAUD'S PHENOMENON SECONDARY TO SYSTEMIC SCLEROSIS: A RANDOMISED, PLACEBO-CONTROLLED, PHASE II STUDY

C.P. Denton[1], É. Hachulla[2], G. Riemekasten[3,4], A. Schwarting[5], J.-M. Frenoux[6], A. Frey[6], F.-O. Le Brun[6], A. Herrick[7]. *[1]Royal Free Hospital, London, United Kingdom; [2]Hôpital Huriez, University of Lille, Lille, France; [3]Charité University of Medicine, Berlin; [4]University of Lübeck, Lübeck; [5]Johannes Gutenberg University, Mainz, Germany; [6]Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; [7]University of Manchester, Salford Royal NHS Foundation Trust, Manchester, United Kingdom*

**Background:** Raynaud's phenomenon (RP) occurs in >95% of patients (pts) with systemic sclerosis (SSc) and contributes to digital ischaemia that may lead to digital ulcers (DUs) and gangrene.[1,2] Empirical treatment of SSc-associated RP includes oral vasodilators, particularly calcium channel blockers and intermittent intravenous prostacyclin analogues.[3,4] However, there is a need to identify oral therapies that are more efficacious than those currently available.

**Objectives:** To determine the activity of selexipag, an oral, selective, prostacyclin receptor agonist, on RP attack frequency in pts with SSc.

**Methods:** The study comprised a placebo single-blind run-in phase of 2–4-weeks followed by an 8-week double-blind treatment phase. Pts (≥18 years) with definite SSc and ≥7 RP attacks on ≥5 days in the week before randomisation were assigned 1:1 to selexipag or placebo. Study drug was titrated to an individual highest tolerated dose (200–1600 μg BID). The primary efficacy endpoint was the number of RP attacks per week in the maintenance phase (5 weeks) as determined from the pt's daily entries in the eDiary, and was analysed using a negative binomial model adjusted for the baseline number of RP attacks. Other outcomes included Raynaud Condition Score (RCS),[5] RP attack duration, new DU frequency, and treatment-emergent adverse events (AEs).

**Results:** Baseline (BL) characteristics were comparable between the groups (selexipag n=36, placebo n=38). No significant difference in effect was demonstrated for selexipag vs placebo (observed average number of RP attacks per week during the maintenance phase: 18.0 [vs 22.4 at BL, selexipag, n=27], 14.2 [vs 21.5 at BL, placebo, n=32]), adjusted mean treatment difference 3.43 in favour of placebo. During the maintenance phase, 63.0% (selexipag) and 81.3% (placebo) of pts had an improvement in the average number of RP attacks per week vs BL. No significant treatment effect was observed on RCS, RP attack duration and new DU frequency. At least one AE occurred in 100% (selexipag) and 86.8% (placebo) of pts; ≥1 prostacyclin-associated AE occurred in 91.7% (selexipag) and 55.3% (placebo) of pts. AEs were mostly reported as mild (16.7% selexipag pts, 34.2% placebo pts) or moderate (61.1% selexipag pts, 44.7% placebo pts) in intensity.

**Conclusions:** The primary efficacy endpoint was not met (no reduction in number of RP attacks per week for selexipag vs placebo). The robust study design may nevertheless provide a template for future studies in RP. The marked reduction in attack frequency on placebo may underlie failure to show additional potential benefit with selexipag, which should be considered when designing future studies in RP. The safety profile of selexipag was similar to previous studies,[6] with no new safety signals identified.

## FRI0266 LONG-TERM EFFICACY AND TOLERABILITY OF MYCOPHENOLATE MOFETIL THERAPY IN DIFFUSE SCLERODERMA SKIN DISEASE

D. Boulos[1], A. Rajadurai[1], G.S. Ngian[1], K. Elford[1], W. Stevens[2], S. Proudman[3], J. Roddy[4], M. Nikpour[5], P. Youssef[6], C. Hill[7], J. Sahhar[1].
*[1]Rheumatology, Monash Health; [2]Rheumatology, St Vincent's Helath, Melbourne; [3]Rheumatology, Royal Adelaide Hospital, Adelaide; [4]Rheumatology, Royal Perth Hospital, Perth; [5]Rheumatology, St Vincent's Health, Melbourne; [6]Rheumatology, Royal Prince Alfred Hospital, Camperdown; [7]Rheumatology, Queen Elizabeth Hospital, Woodville, Australia*

**Background:** Skin involvement in diffuse systemic sclerosis (dSSc) is progressive and can be extremely debilitating, however, treatment options remain limited. Although many disease modifying agents have been examined in dSSc, only cyclophosphamide has randomised controlled data suggesting efficacy in the treatment of skin thickening.[1] Several observational studies suggest benefit in skin disease with mycophenolate mofetil (MMF) therapy;[2] which, given its more favourable side effect profile, would be a preferable alternative to cyclophosphamide.
**Objectives:** To assess the long-term efficacy and tolerability of MMF in patients with dSSc in the Australian Scleroderma Cohort Study.
**Methods:** The Australian Scleroderma Cohort Study is a longitudinal study of disease outcomes in patients with SSc. Patients with dSSc and baseline modified Rodnan skin score (mRSS) $\geq$12 who were treated for a minimum twelve months with MMF for the primary indication of skin disease were included, and their prospectively collected data were retrieved. The proportion with clinically significant improvement in skin scores (defined as reduction in mRSS$\geq$4 from baseline) and stable disease (change in mRSS $<$4) were compared to those with clinical deterioration (increase in mRSS$\geq$4) as well as adverse effects resultant of therapy.
**Results:** 74 participants were identified and of these, 44 met inclusion criteria. The mean age of participants was 53±12 years and 36 (82%) were female. The mean duration of disease at MMF commencement was 4.9±4.3 years, with 23 participants (52%) commencing MMF within 2.5 years. The mean duration of therapy was 2.7±1.7 years. The mean mRSS at baseline was 25.3 with a reduction of 3.7 (p-value $<$0.01) after one year of therapy and a mean total reduction in mRSS of 8.0 (p-value $<$0.01). Response to treatment was not affected by disease duration at onset of MMF therapy as expected. Over the first year of therapy, 24 participants (48%) demonstrated clinically significant improvement in skin scores, increasing to 92% clinically improved after four years of therapy. MMF was well tolerated, with two participants (5%) ceasing the drug due to adverse effects.
**Conclusions:** MMF was associated with improved skin scores and was well tolerated in the treatment of dSSc. Given the natural history of dSSc where skin involvement can spontaneously improve, placebo-controlled studies are required to confirm whether improvement can be attributed to MMF therapy.

## FRI0267 MYCOPHENOLATE MOFETIL VERSUS ORAL CYCLOPHOSPHAMIDE IN SCLERODERMA-RELATED INTERSTITIAL LUNG DISEASE: SCLERODERMA LUNG STUDY II

D. Khanna[1], M. Roth[2], P. Clements[2], D. Furst[2], C.-H. Tseng[2], R. Elashoff[2], E. Volkmann[2], S. Kafaja[2], J. Goldin[2], D. Tashkin[2] on behalf of Scleroderma Lung Study II. *[1]University of Michigan, Ann Arbor; [2]UCLA, Los Angeles, United States*

**Background:** Progressive Interstitial lung disease (ILD) occurs in $\sim$ 40% of scleroderma (SSc) patients and is the leading cause of death. Oral CYC for 1 year in SSc-ILD led to modest but significant improvements in lung function and dyspnea vs. placebo (Tashkin, NEJM, 2006) but the benefits were lost over the ensuing year and drug therapy was not extended due to the known toxicity profile of CYC. (Tashkin AJRCCM 2007). Preliminary data from uncontrolled clinical studies suggest that MMF may be an effective and safer immunosuppressive therapy than CYC for SSc-ILD.
**Objectives:** A randomized controlled trial was performed to determine the efficacy, safety and tolerability of mycophenolate mofetil (MMF) administered for two years compared with CYC administered for one year followed by matching placebo for SSc-ILD.
**Methods:** 142 patients with pulmonary function and high-resolution computed tomography (HRCT) defined SSc-ILD were randomized at 14 centers to receive MMF or CYC. The primary endpoint, change in forced vital capacity (FVC%$>$predicted) over 24 months, was assessed using a joint longitudinal model (Elashoff, Statist Med 2006).
**Results:** 126 patients (63 MMF; 63 CYC) had $\geq$3 months of outcome data and were included in the primary analysis. A greater number of patients on CYC than on MMF prematurely withdrew from (32 vs 20) and failed treatment (2 vs 0), and the time to stopping treatment was significantly shorter in the CYC arm (p=0.019). At 24-months, the adjusted FVC%$>$predicted had improved by 2.17 in the MMF arm (95% CI, 0.53–3.84; p$<$0.01) and 2.86 in the CYC arm (95% confidence interval 1.19–4.58; p$<$0.001) with no significant between-treatment difference (p=0.24). Significant within- (but not between-) treatment improvements in skin score, dyspnea and whole-lung HRCT scores were also observed. Leukopenia and thrombocytopenia occurred more often with CYC (p$<$0.05). Sixteen deaths occurred (11 CYC; 5 MMF) with most due to underlying disease.
**Conclusions:** In this first RCT comparing MMF with CYC in SSc-ILD, both agents appeared to have comparable efficacy but MMF was better tolerated with significantly fewer premature withdrawals from treatment and fewer adverse events. These findings support the increasingly common clinical practice of prescribing MMF for this disease.

## FRI0268 SAFETY AND EFFICACY OF SUBCUTANEOUS TOCILIZUMAB IN EARLY SYSTEMIC SCLEROSIS: RESULTS FROM THE OPEN-LABEL PERIOD OF THE FASSCINATE TRIAL

D. Khanna[1], C.P. Denton[2], A. Jahreis[3], J.M. van Laar[4], L. Burke[5], H. Spotswood[5], C.J. Lin[3], J.E. Pope[6], Y. Allanore[7], U. Müller-Ladner[8], J. Siegel[3], D.E. Furst[9] on behalf of faSScinate Clinical Trial Investigators.
*[1]University of Michigan, Ann Arbor, United States; [2]University College London Medical School, London, United Kingdom; [3]Genentech, South San Francisco, United States; [4]University Medical Center Utrecht, Utrecht, Netherlands; [5]Roche Products Ltd., Welwyn Garden City, United Kingdom; [6]University of Western Ontario, London, Canada; [7]Paris Descartes University, Paris, France; [8]Justus-Liebig University Giessen, Bad Nauheim, Germany; [9]University of California, Los Angeles, United States*

**Background:** Systemic sclerosis (SSc) is a debilitating disease with few treatment options. Interleukin-6 (IL-6) appears to play a role in SSc pathogenesis.[1,2] Data from the 48-week, double-blind (DB), placebo (PBO)-controlled period of the faSScinate trial were previously presented,[3] and open-label (OL) data are presented herein.
**Objectives:** To assess safety and efficacy of tocilizumab (TCZ) in SSc patients during 48 weeks of OL TCZ treatment.
**Methods:** Patients $\geq$18 y with active SSc ($\leq$5-year duration, modified Rodnan skin score [mRSS] 15–40, and elevated acute-phase reactants) received OL TCZ 162 mg SC weekly from week 48 to week 96. Change from baseline in mRSS, patient-reported outcomes (PROs), and FVC at week 96 were exploratory measures. Observed means used all available data.
**Results:** In total, 27/43 (63%) TCZ and 24/44 (55%) PBO patients completed week 96. Baseline (BL) characteristics were similar at BL and at entry into the OL period. Patients who switched from PBO→OL TCZ showed improvement in observed mean change from BL in mRSS at week 96 (–9.4) relative to the end of the 48-week DB period (–3.1). In patients initially randomized to TCZ (TCZ→OL TCZ), mean change in mRSS was –5.6 at week 48 and –9.1 at week 96. In the OL period, improvements in PROs were noted at week 96 vs week 48 in the PBO→OL TCZ group (mean [SD] change from BL at week 96 vs week 48 in HAQ-DI: –0.3 [0.4] vs 0.2 [0.4]; Patient Global VAS: –23.8 [36.0] vs –4.0 [24.0]; FACIT-Fatigue:11.3 [12.8] vs 1.4 [7.6]). In patients who completed the study, none experienced a $>$10% decline in % predicted FVC during the OL period on TCZ therapy. Rates (95% CI) of serious adverse events/100 patient-years (PY) in the DB period were 76.1 (50.6, 110.0) in PBO patients and 66.7 (42.3, 100.1) in TCZ patients and were 36.0 (18.0, 64.4) in PBO→OL TCZ patients and 16.5 (5.4, 38.5) in TCZ→OL TCZ patients in the OL period. Rates (95% CI)/100PY of serious infections in the DB period were 10.9 (3.0, 27.9) in PBO patients and 34.8 (18.0, 60.8) in TCZ patients. In the OL period they were 19.6 (7.2, 42.7) in PBO→OL TCZ patients and 0.0 (0.0, 12.2) in TCZ→OL TCZ patients. No deaths occurred in the OL period (deaths in DB period: 3 TCZ, 1 PBO).
**Conclusions:** Although OL data have to be interpreted with caution, efficacy and safety in PBO-treated patients who switched to OL TCZ were generally similar to those observed in patients randomized to TCZ in the DB period. Results over 96 weeks of TCZ treatment suggest maintenance of the clinical response for mRSS in SSc patients. Serious infection rates increased in PBO patients after they switched to OL TCZ. Long-term safety was consistent with the natural history of SSc and the safety profile of TCZ.

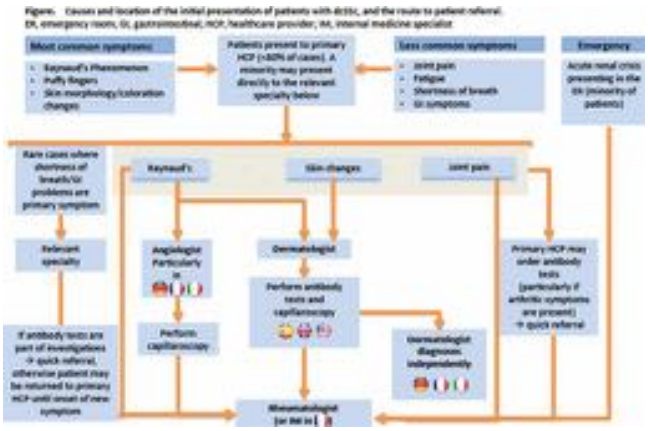
## FRI0269 DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (DCSSC) REFERRAL AND DIAGNOSIS: RESULTS OF A SURVEY OF HEALTHCARE PROVIDERS



D. Khanna[1], Y. Allanore[2], C. Denton[3], M. Matucci-Cerinic[4], J. Pope[5], B. Hinzmann[6], S. Briody[7], J. de Oliveira Pena[8], O. Distler[9]. *[1]Division of Rheumatology, University of Michigan, Ann Arbor, United States; [2]Immunogenetics, Cochin Institute, Paris, France; [3]University College London, London, United Kingdom; [4]Division of Medicine and Rheumatology, University of Florence, Florence, Italy; [5]University of Western Ontario, London, Canada; [6]Bayer Pharma AG, Berlin, Germany; [7]Blueprint Partnership, Manchester, United Kingdom; [8]Bayer Healthcare Pharmaceuticals Inc., Whippany, United States; [9]Center of Experimental Rheumatology, Research of Systemic Autoimmune Diseases, University Hospital Zurich, Zurich, Switzerland*

**Background:** Diffuse cutaneous systemic sclerosis (dcSSc) is a severe subset of SSc, a chronic rare autoimmune connective tissue disease associated with high morbidity and mortality, and reduced quality of life. There are few treatments approved for dcSSc. Using semi-structured discussions, our objective was to gain better insight into clinical practice regarding referral and diagnosis of patients with dcSSc in different geographic regions.
**Methods:** Physicians participated in 60- or 30-minute interviews, following a discussion outline, to determine how dcSSc patient care is structured in the USA and EU. Physicians were asked to identify key steps in the patient pathway, typical patient presentation, and the diagnostic, treatment, and follow-up processes used, and those responsible for their implementation.
**Results:** Physicians in six countries (France, Germany, Italy, Spain, UK, and USA) were interviewed; 84 60-minute interviews with rheumatologists (or internal medicine specialists in France), and 40 30-minute interviews with dermatologists were conducted. Patient care was coordinated mostly by rheumatologists (except in France, where internal medicine specialists can be responsible), or to a lesser degree by dermatologists (in Germany, France, Italy) (Figure). Specialist centers are not well defined, and do not exist in all countries; therefore, most patients continued their treatment in the hospital where first diagnosed. Patients were slow to present to primary healthcare providers (HCPs), with presentation taking on average 6 months to 1 year, as they considered very early dcSSc symptoms to be trivial. Once referred to a rheumatologist, clinical evaluation and antibody testing led to quick diagnosis; however, dcSSc awareness among primary HCPs is variable, and delayed referral to a rheumatologist is common. Use of the 2013 ACR/EULAR updated classification of SSc, and the modified Rodnan skin score (mRSS) were limited to specialist centers and clinical trials, rather than daily practice, although physicians follow a similar diagnostic process. Where mRSS was measured (n=46 in this survey, predominantly by rheumatologists), patients had an mRSS of 10–22 at diagnosis, and >50% of diagnosed patients had an mRSS of ≥15. Physicians were vigilant for signs of organ involvement, but the priority given to skin changes differed according to specialty.
**Conclusions:** Improved patient and primary HCP awareness of dcSSc could lead to earlier referral to a rheumatologist or dermatologist and the avoidance of delayed diagnosis. Specialized centers need better definition in most countries. Use of the mRSS at diagnosis and follow-up may help to monitor disease progression.

## FRI0270 PATIENT PERCEPTION OF DISEASE BURDEN IN DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (DCSSC)

D. Khanna[1], Y. Allanore[2], C. Denton[3], M. Matucci-Cerinic[4], J. Pope[5], B. Hinzmann[6], S. Briody[7], J. de Oliveira Pena[8], O. Distler[9]. *[1]Division of Rheumatology, University of Michigan, Ann Arbor, United States; [2]Immunogenetics, Cochin Institute, Paris, France; [3]University College London, London, United Kingdom; [4]Division of Medicine and Rheumatology, University of Florence, Florence, Italy; [5]University of Western Ontario, London, Canada; [6]Bayer Pharma AG, Berlin, Germany; [7]Blueprint Partnership, Manchester, United Kingdom; [8]Bayer HealthCare Pharmaceuticals Inc., Whippany, United States; [9]Center of Experimental Rheumatology, Research of Systemic Autoimmune Diseases, University Hospital Zurich, Zurich, Switzerland*

**Background:** DcSSc is associated with high morbidity and mortality, and reduced quality of life. Patient priorities are rarely discussed, with physicians focusing on organ involvement. Using discursive approaches and ethnography, we evaluated the impact of dcSSc on patients' daily lives, and examined how disease burden shapes patient outlook.
**Methods:** Patients were recruited via healthcare professionals (HCPs) or patient associations. In France, Italy, the UK and USA, patients filmed short (~15-minute) daily video diaries about their lives over 7 days. On Days 1 and 7, patients participated in a moderator-led discussion of their experiences, and an observation session. In Germany and Spain, patients participated in 60-minute telephone interviews. Video footage and transcribed discussions were reviewed, and the data were categorized and assessed for themes, patterns, and indicators of emotion, ambivalence, and conflict.
**Results:** Twenty-three patients (mean age 54 years; 83% women) participated. Of these, 17 made video diaries, and 6 took part in telephone interviews. The majority of video diaries and interviews took place in patients' homes; on average 5.25 hours of video footage were collected per patient.

Results show that time to diagnosis was often delayed, as patients trivialized symptoms and HCPs attributed symptoms to other causes. Patients had a poor understanding of their diagnosis, and rarely received patient information. DcSSc patients had a high treatment burden; on average this patient sample received 10 tablets of prescribed drugs daily. Importantly, while patients were aware of the seriousness of organ involvement, they reported that skin changes, pain, and fatigue had a dominant effect on daily life, impairing their ability to perform routine tasks. Skin tightening in the lower limbs and feet lead to deformity and loss of mobility, while Raynaud's phenomenon, calcinosis, and digital ulcers caused significant pain and loss of function. Changes in appearance lead to embarrassment, social withdrawal, and depression. Patients experienced dcSSc as a series of losses, including independence and self-esteem, and the unpredictability of the disease made acceptance of the condition difficult (Figure 1). Moreover, patients tended to have small support networks and support services were not offered as part of standard care.

**Conclusions:** Patients with dcSSc had high treatment and emotional burdens, with skin complications, pain, and fatigue profoundly affecting their lives. Patients placed the greatest emphasis on these issues rather than the possibility of organ involvement. There is an unmet need for patient information at the time of diagnosis, and for emotional support services throughout their journey with dcSSc. Directing patients to websites such as SSc patient organizations may be helpful.

## FRI0271 PERFORMANCE OF MODIFIED RODNAN SKIN SCORE IN EARLY DIFFUSE CUTANEOUS SCLERODERMA–ANALYSIS FROM 4 COHORTS

D. Khanna[1], S. Produman[2], T. Frech[3], S. Nihtyanova[4], R. Domsic[5], V. Berrocal[1], W. Stevens[6], M. Nikpour[6], C. Denton[4] on behalf of ASIG, CRISS and PRESS collaborators. *[1]University of Michigan, Ann Arbor, United States; [2]Royal Adelaide Hospital and University of Adelaide, Adelaide, Australia; [3]Univ. of Utah, Utah, United States; [4]UCL, London, United Kingdom; [5]Univ of Pittsburgh, Pittsburgh, United States; [6]St Vincent's Hospital Melbourne, Melbourne, Australia*

**Background:** The modified Rodnan skin score (mRSS) is used as a primary outcome measure in clinical trials of dcSSc. EUSTAR analysis has proposed that a lower mRSS and earlier disease duration are associated with progressive disease, as defined by worsening mRSS [1].

**Objectives:** 1. To find an optimal cut off for worsening mRSS in 4 cohorts of dcSSc, and 2. To assess if presence of anti-RNA polymerase III [RNAP] vs. anticentromere /or anti-SCL-70 is associated with different mRSS cut off for worsening disease.

**Methods:** We used 4 cohorts with early dcSSc (defined as $\leq$60 months from 1st non-RP sign or symptom) – 2 US cohorts [Combined Response Index in Systemic Sclerosis [CRISS] and Prospective Registry in Early Systemic Sclerosis [PRESS]], the UK Royal Free Hospital [RFH] cohort, and the Australian Scleroderma Interest Group [ASIG] cohort. Inclusion criteria included dcSSc diagnosed by a scleroderma physician, mRSS data at 2 time points (12±3 months apart), and availability of disease duration (defined as 1st non Raynaud phenomenon sign or symptom). Worsening of skin fibrosis was defined as increase in mRSS $>$5 points and $\geq$25% from baseline to 2nd visit.

To identify the optimal cut point of baseline MRSS that yields the highest sensitivity for worsening disease, we developed the ROC curves. For worsening of mRSS, we fitted logistic regression model with worsening as outcome variable and a binary variable of baseline mRSS cut point as predictor. We also explore the differences between the proportion of patients with worsening of mRSS among the patients with presence of RNAP vs. anticentromere /or anti-SCL-70 and tested using proportion z-test.

**Results:** There were 235 patients with early dcSSc included in the analysis. Mean (SD) disease duration was 26.61 (14.67) months, median=23.67 months. We evaluated 3 cut points for disease duration based on inclusion criterion from recent clinical trials: $\leq$24, 36, and 60 months. For all disease durations, approximately 10.5% of patients had mRSS worsening at 1-year period. A mRSS cut off of 26 had the highest probability of worsening (Table). mRSS of $\leq$26 was able to enrich worsening mRSS from 10.5% to 15.0% for different cut points but excluded 33–35% of patients with early dcSSc. 64 patients (27.23%) had RNAP and 48 (20.43%) had anti-centromere and anti-SCL-70 and there was no difference in cut off for worsening of mRSS at 1-year.

**Conclusions:** In this preliminary analysis, a mRSS$\leq$26 was the optimal cut point for worsening disease in 4 cohorts with dcSSc. This threshold gained an additional 5% of patients who worsened but excluded 33–35% of patients with early dcSSc.

## FRI0272 EVALUATION OF BLEOMYCIN INDUCED RAYNAUD'S PHENOMENON AND SYSTEMIC SCLEROSIS VASCULOPATHY IN GERM CELL TUMOUR PATIENTS

D. Faulkner[1], J. Britton[2], S. Eng[3], F. Del Galdo[2], D. Stark[4], M. Buch[3]. *[1]University of Leeds; [2]Leeds Musculoskeletal Biomedical Research Unit; [3]Leeds Institute of Rheumatic & Musculoskeletal Medicine; [4]Leeds Institute of Cancer & Pathology, Leeds, United Kingdom*

**Background:** Bleomycin forms part of the chemotherapy regimen ("BEP") for germ cell testicular cancer (1). The drug is known to cause Raynaud's phenomenon (RP) in up to 25% of men who receive the BEP regime (2). RP is also a feature of systemic sclerosis (SSc), a connective tissue disease that is studied in a mouse model using bleomycin as the agent to induce pulmonary fibrosis (3,4). There have been isolated cases where patients, treated for lymphoma with bleomycin containing regimens, have developed SSc (5,6) thus evaluation of RP and SSc is warranted in testicular cancer patients.

**Objectives:** In men with germ cell testicular cancer who have received BEP in Leeds: 1) Evaluate the prevalence, nature, and onset of RP. 2) Compare the characteristics of those that developed RP with those that did not. 3) Determine whether those reporting RP have microvascular features of SSc.

**Methods:** A patient questionnaire completed retrospectively by men receiving follow up post BEP treatment was used to collect data on the prevalence, nature, and onset of RP. A subset of patients reporting RP then underwent capillaroscopy and thermography.

**Results:** 24 eligible men completed the questionnaire. RP was prevalent in 13 of the men (54% CI 0.34–0.74), usually bilaterally (92%) and accompanied by sensory disturbance (92%). Onset was most commonly reported to be following chemotherapy completion (77%). There was no association between RP and marital status, smoking status, tumour type or total bleomycin dose (p values $>$0.05). No evidence was found to suggest SSc in the patients who underwent capillaroscopy and thermography. Hallmark capillary changes indicative of SSc were absent at the nailbed. The mean (SD) recovery of the fingers back to baseline temperature was 93.8 (14.57)% at ten minutes post cold challenge and the mean (SD) re-warming rate of the fingers was 0.925 (0.17) ℃/minute.

**Conclusions:** The prevalence of RP in this patient group was higher than expected. The absence of SSc vasculopathy was reassuring, however not all of the men reporting RP underwent Rheumatology assessment. The retrospective nature and small sample size of this study are key limitations but our findings justify further prospective evaluation of the prevalence and the basis for bleomycin-associated RP.

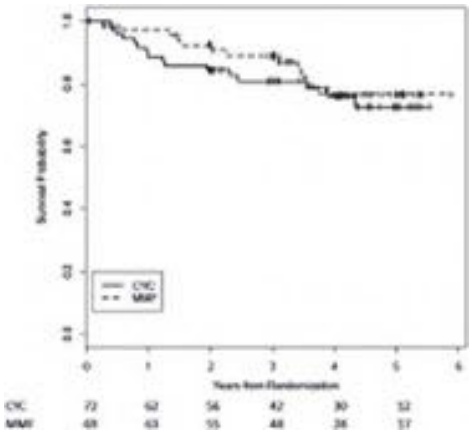
## FRI0273 SLOW RECOVERY OF MUSCLE STRENGTH IN YOUNG ANTI-HMG-COA REDUCTASE POSITIVE MYOPATHY PATIENTS

E. Tiniakou[1], I. Pinal Fernandez[2], L. Christopher-Stine[3], J. Werner[4], T. Lloyd[5], J. Paik[1], J. Albayda[1], S. Danoff[6], A. Mammen[2,5]. *[1]Rheumatology, Johns Hopkins University, Baltimore; [2]NIAMS, NIH, Bethesda; [3]Rheumatology, Johns Hopkins Univeristy; [4]Medicine, University of Maryland; [5]Neurology; [6]Pulmonary, Johns Hopkins University, Baltimore, United States*

**Background:** Anti-HMG-CoA reductase (HMGCR) myopathy is characterized by proximal muscle weakness, necrosis of muscle fibers on biopsy, elevated serum creatine kinase (CK) levels, and anti-HMGCR autoantibodies[1]. Although statins are associated with anti-HMGCR myopathy in patients over 50 years old, some patients have no history of statin exposure. In a previous longitudinal analysis including 17 patients with anti-HMGCR myopathy followed over a mean of 26 months, we found that only statin-exposed subjects had improvements in strength and CK with treatment during the observed time period[2].
**Objectives:** Here, we studied factors influencing disease progression in an expanded cohort of anti-HMGCR patients treated with immunosuppressive therapy.
**Methods:** A retrospective cohort study was conducted with all anti-HMGCR positive patients enrolled in the Johns Hopkins Myositis Cohort between May 2002 and June 2015. Anti-HMGCR antibodies were screened for by ELISA and verified by immunoprecipitating in vitro-transcribed and translated HMGCR protein. Anti-HMGCR levels, CK levels, and proximal muscle strength (on a 0–10 scale) were assessed. A multilevel linear regression model was used to identify clinical factors that influence recovery of strength over time.
**Results:** We identified 104 anti-HMGCR positive patients, 77 (74%) of whom were exposed to statins. The clinical characteristics for each of three age groups divided into tertiles (<51, 51–61 and >61 years old) were similar except statin exposure, which was 97% for the older group compared to 37% for the younger group of patients. There was no statistical significant difference of the CK, anti-HMGCR antibody titers and muscle strength between the different groups.
We analyzed factors that might influence recovery of muscle strength in 81 patients with more than one visit (mean follow-up time of 2.7 years; SD 2.6, 0–12 years). Older age at onset and greater weakness at first clinic visit were associated with faster recovery times in univariate and multivariate analyses, whereas statin exposure had no statistically significant effect.
We identified a subgroup of young, African American, statin naive women who were refractory to treatment, compared to older patients of both races.

Kaplan-Meier survival estimates show that a higher proportion of older patients recover 10/10 muscle strength (Figure 1A) and at least 8/10 muscle strength (Figure 1B) after 4 years of treatment:



**Conclusions:** The current study suggests that older age, rather than statin exposure, predicts faster recovery after initiating immunosuppressive treatment for anti-HMGCR myopathy. Four years after disease onset, ~50% of patients older than 61, but only ~25% less than age 51, had recovered full strength. We also found that a subset of young, African American women were refractory to treatment. Some of these had progressive weakness despite aggressive immunosuppressive therapy.

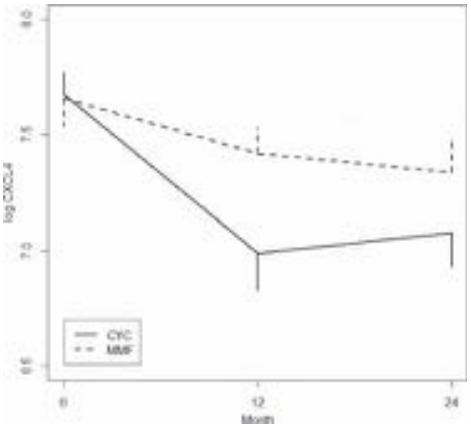
## FRI0274 PREDICTORS OF SURVIVAL IN PATIENTS WITH SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE ENROLLED IN THE SCLERODERMA LUNG STUDY II

E. Volkmann[1], D. Tashkin[1], A. Fischer[2], A.-M. Hoffmann-Vold[3], C.-H. Tseng[1], H. LeClair[1], D. Khanna[4], P. Clements[1], M. Roth[1], R. Elashoff[1] on behalf of Scleroderma Lung Study II Working Group. *[1]University of California, Los Angeles, Los Angeles; [2]University of Colorado, Denver, Denver, United States; [3]Oslo University Hospital, Oslo, Norway; [4]University of Michigan, Ann Arbor, United States*

**Background:** The results of the first randomized controlled trial comparing cyclophosphamide (CYC) and mycophenolate (MMF) for systemic sclerosis-related interstitial lung disease (SSc-ILD) demonstrated that MMF had improved safety and tolerability profiles compared with CYC over 2 years (Tashkin ACR Abstract 2015); however, the comparative long-term effects of these agents are unknown.
**Objectives:** To compare survival of patients randomized to MMF versus CYC in Scleroderma Lung Study (SLS) II and to determine which baseline factors predict survival.
**Methods:** All SSc-ILD patients in SLS II (Comparing 2 years of MMF versus 1 year of CYC followed by 1 year of placebo) were eligible for inclusion. During the 2-year trial, mortality outcomes were collected by the individual study sites and sent to the SLS II morbidity and mortality committee for adjudication. Following the trial, deaths were ascertained from reports by the next of kin or the coordinator/principal investigator at the study site, as well as reports from online obituaries and the National Death Index. Kaplan Meier curves were generated and the log-rank test was used to compare survival rates. Cox proportional hazards modeling was used to determine which baseline demographic and disease features, as well as which molecular markers predict survival.
**Results:** Of the 142 patients in SLS II, contact was established (or mortality was confirmed) with 88%. The median follow up was 3.3 years from randomization. 16 deaths occurred during the 2-year trial (5 MMF; 11 CYC), and an additional 11 deaths occurred after the trial (6 MMF; 5 CYC). One patient underwent lung transplantation (CYC). The majority of deaths were deemed to be due to respiratory failure (44%), followed by congestive heart failure (7%) and lung cancer (7%). Patients assigned to MMF had a trend for improved survival at 1- (HR 3.8; $P$=0.09), 2- (HR 2.1; $P$=0.1), and 3-years (HR 1.9; $P$=0.1) post-randomization. However, by 3.5 years, there was no difference in survival between treatment arms (Figure 1). In univariate analysis, male gender (HR 2.2; $P$=0.04), age (HR 1.1; $P$<0.001), disease duration (HR 0.7; $P$=0.02), and baseline DLCO (HR 0.9; $P$=0.02), were associated with increased risk of death. Of the molecular markers, higher baseline level of the chemokine CCL18 was associated with increased mortality (HR=1.003; $P$=0.05). In the multivariate analysis, the best 1-variable model for predicting survival was age (HR 1.1; $P$<0.001). The best 2-variable model for predicting survival was age (HR 1.1; $P$<0.001) and disease duration (HR 0.7; $P$=0.02), and the best 3-variable model for predicting survival was age (HR 1.1; $P$<0.001), disease duration <3 years from the onset of the first non-Raynaud's symptom (HR 4.6; $P$=0.008), and baseline FVC (HR 0.9; $P$=0.004).



**Conclusions:** Treatment with MMF for SSc-ILD appears to be associated with improved survival during the first 3 years following treatment initiation; however, beyond this time frame, there is no clear MMF survival advantage. Of the factors associated with SSc-ILD survival in prior observational cohorts, increased age, shorter disease duration, and lower baseline FVC were the most important predictors of mortality in SLS II participants.

FRI0275 **CHANGE IN CXCL4 LEVELS MAY PREDICT TREATMENT RESPONSE IN SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE (SSC-ILD)**

E. Volkmann[1], D. Tashkin[1], R. Elashoff[1], C.-H. Tseng[1], D. Khanna[2], M. Mayes[3], J. Charles[3], P. Clements[1], M. Roth[1], D. Furst[1], S. Assassi[3] on behalf of Scleroderma Lung Study II Working Group. *[1]University of California, Los Angeles, Los Angeles; [2]University of Michigan, Ann Arbor; [3]University of Texas, Houston, Houston, United States*

**Background:** Baseline circulatory levels of the chemokine CXCL4 have been associated with both extent and progression of SSc-ILD[1]. No studies have examined whether changes in CXCL4 levels may predict progression of SSc-ILD.
**Objectives:** To determine whether CXCL4 levels change in response to treatment for SSc-ILD and to explore whether these changes predict future progression of SSc-ILD.
**Methods:** All SSc-ILD patients enrolled in the Scleroderma Lung Study (SLS) II (Comparing 2 years of mycophenolate [MMF] versus 1 year of cyclophosphamide [CYC] followed by 1 year of placebo) were included. CXCL4 levels were measured at baseline, 12 and 24 months using validated, commercially available ELISA kits (Human CXCL4/PF4 Quantikine Kit - R&D Systems). CXCL4 levels were log-transformed. Spearman's correlations were performed to examine the relationship between the change in CXCL4 levels from baseline to 12 months and the change in the FVC from baseline to 18, 21, and 24 months. A mixed effects model was created to determine whether the change in CXCL4 from baseline to 12 months predicted the course of the FVC from 12 to 24 months, while controlling for treatment arm and baseline ILD severity. A T-test was used to compare the change in CXCL4 from baseline to 12 months between patients who experienced a clinically meaningful improvement in FVC at 24 months (defined as a $\geq$5% increase in FVC from baseline) and those who did not.
**Results:** Of the 142 patients in SLS II, 136 had CXCL4 levels measurements performed. The mean FVC% predicted for this cohort was 66.5 and the mean disease duration was 2.5 years. CXCL4 levels decreased significantly in both treatment arms at 12 months (Mean difference: CYC -0.71 [1.4], $P<0.001$; MMF -0.32 [0.86], $P=0.006$) and at 24 months (Mean difference: CYC -0.53 [1.3], $P<0.001$; MMF -0.43 [1.1], $P=0.01$). There was no significant difference in the change in CXCL4 levels between treatment groups at 12 ($P=0.12$) or 24 months ($P=0.38$) (Figure 1). There was a trend for a significant relationship between the change in CXCL4 level at 12 months and the change in the FVC from baseline to 18 months (r= -0.2; $p=0.06$), 21 months (r= -0.21; $p=0.06$), and 24 months (r=-0.18; $p=0.08$). In the mixed effects model, the change in CXCL4 level at 12 months significantly predicted the course of the FVC from 12 to 24 months (Estimate -1.2; Std Err 0.6; $p=0.04$). Patients with a $\geq$5% increase in FVC at 24 months had a greater decrease in CXCL4 levels compared with patients with a $<$5% increase in FVC at 24 months (-0.83 [1.46] vs. -0.24 [0.94]; $P=0.03$).

**Conclusions:** Treatment with immunosuppression led to significant decreases in CXCL4 levels in patients with SSc-ILD. Patients who experienced the greatest decrease in CXCL4 from baseline to 12 months had improved course of FVC from 12 to 24 months, suggesting that short-term change in CXCL4 may be a potential biomarker for predicting long-term treatment response in SSc-ILD.

FRI0276 **PERIPHERAL STRUCTURAL EVALUATION (RADIOGRAPHIC) AND AXIAL (SCAN) IN A POPULATION OF 77 PATIENTS WITH SYSTEMIC SCLEROSIS**

E. Bauer[1], D. Mandry[2], O. Huttin[3], I. Chary-Valckenaere[1], D. Loeuille[1]. *[1]Rhumatologie; [2]Radiologie; [3]Cardiologie, Nancy, France*

**Objectives:** The objective of this study was to describe for the first time the prevalence and characteristics of radiographic lesions of the hands and calcifications of the spine visible on CT scans (thoracic, thoracic-abdominal pelvic (TAP), and lumbar), in a population of patients with systemic sclerosis (SSc) (n=77) treated at the Nancy University Hospital (CHU) and to determine the relationships of these with the clinical and biological expression of the disease and its prognosis.
**Methods:** This was a single centre, retrospective, descriptive and analytical study involving 77 patients treated in the CHU for limited cutaneous SSc (lcSSc) or diffuse cutaneous SSc (dcSSc) complying with the ACR/EULAR 2013 classification criteria and having had an X-ray examination of the hands and a thoracic, TAP or lumbar CT scan within the same year. The X-ray evaluation of the hands was performed as described by Erre G.L et al. The morphological and topographical evaluation of the calcifications was performed on 3 spinal segments: discovertebral, intracanal and posterior. The prognostic factors were interstitial pulmonary lesions on the CT scan, pulmonary arterial hypertension (PAH) and death.
**Results:** Of the 77 patients of mean age 56.9 years (88.3% females), 55 (71%) suffered from lcSSc and 22 (29%) from dcSSc. There were statistically significantly more patients with interstitial disease on the CT scan and restrictive syndrome in the dcSSc group than in the lcSSc group. Study of the radiographic lesions revealed the following prevalences: calcinosis 26%, acro-osteolysis 20.8%, periarticular calcifications 28.6%, erosions 24.7%, narrowing 42.9%, subluxations 19.9% and flexion 27.3% of cases. Calcinosis, acro-osteolysis and periarticular calcifications were related to the duration of progression of the disease and to the onset of digital ulcers (DU) ($p=0.002$; $p<0.001$ and $p=0.014$). On the CT scan, the presence of calcifications was observed in the anterior segment in 62 patients (80.5%), in the canal segment in 21 patients (27.3%) (9 of which were foraminal) and in the posterior segment in 27 patients (35.1%). There was a relationship between the presence of axial calcifications and the existence of peripheral periarticular calcifications ($p=0.012$). From a prognostic viewpoint, the presence of calcinosis was associated with PAH ($p=0.02$), the existence of calcifications in the posterior segment ($p=0.029$) and foraminal calcifications ($p=0.041$) were associated with interstitial lung disease (ILD). The presence of foraminal calcifications was the only factor related to death ($p=0.001$).

**Conclusions:** This study shows for the first time, a link between peripheral periarticular calcifications and spinal calcifications detected on the CT scan. These results suggest that spinal calcifications could provide an indicator of severity and predict mortality in patients suffering from SSc.

FRI0277 **SIX-MINUTE WALK TEST IN SYSTEMIC SCLEROSIS PATIENTS WITHOUT INTERSTITIAL LUNG DISEASE AND PULMONARY ARTERIAL HYPERTENSION**

E. Vandecasteele[1], K. Melsens[2], F. De Keyser[2], M. De Pauw[1], E. Deschepper[3], S. Decuman[2], Y. Piette[4], G. Brusselle[5], V. Smith[4]. *[1]Department of Cardiology, Ghent University Hospital; [2]Department of Internal Medicine; [3]Biostatistics Unit, Dep of Public Health, Ghent University; [4]Department of Rheumatology; [5]Department of Respiratory Medicine, Ghent University Hospital, Ghent, Belgium*

**Background:** Interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH) are the leading causes of death in Systemic Sclerosis (SSc). Although the six-minute walk test (6MWT) is used for evaluating ILD and PAH in clinical practice, no data are available on six-minute walk distance (6MWD) in SSc without ILD and PAH.
**Objectives:** This study wants to evaluate the 6MWT at baseline and 6-month follow-up in a cohort of unselected SSc patients without ILD and PAH.
**Methods:** Prospectively collected data of the 6MWTs at baseline and 6-month

follow-up of 300 consecutive SSc patients, included in the Ghent University Hospital Systemic Sclerosis Cohort between May 2006 and April 2015 were analysed.
**Results:** 98% (286/292) of the SSc patients performed a 6MWT at baseline or 6-month visit, after exclusion of 8 of the 300 SSc patients due to logistic problems. Two patients were unable to perform a 6MWT due to leg amputation and 4 due to immobility. 76% of the patients were female with a mean age of 51±14 years. Six patients had PAH, five had ILD and four were not evaluated with HRCT.
Eventually 271 SSc patients without ILD and PAH performed a 6MWT at baseline or 6-month visit and 193 at both moments. The mean 6MWD of those 271 SSc patients was 460±108m. Patients in the diffuse cutaneous (DcSSc) subgroup (422±118m) walked less than in the limited (LSSc) subgroup (476±109m, p=0.02) and tended to walk less than in the limited cutaneous (LcSSc) subgroup (463±101m, p=0.06). In 193 SSc patients without ILD and PAH who walked at both moments, there was no significant difference between the 6MWDs (mean difference 2.11m 95%CI [-6.75m; 10.98m], p=0.64).

Table 1. 6MWD during the first 6MWT and the evolution of the 6MWD from baseline to 6-month visit in different subgroups of SSc patients without ILD and PAH

| | N | First 6MWD mean ± SD | P | N | 6MWD T0 mean ± SD | 6MWD T6 mean ± SD | r | Mean Diff (95% CI) | P |
|---|---|---|---|---|---|---|---|---|---|
| SSc | 271 | 460±108 | *0.02 | 193 | 466±100 | 468±95 | 0.80 | 2 (–7; 11) | 0.64 |
| LSSc | 70 | 476±109*#† | #0.67 | 53 | 471±115 | 466±104 | 0.83 | –5 (–23; 13) | 0.58 |
| LcSSc | 156 | 463±101*#‡ | †0.02 | 109 | 474±87 | 477±80 | 0.72 | 3 (–8; 15) | 0.57 |
| DcSSc | 45 | 422±118*†‡ | ‡0.06 | 31 | 432±111 | 441±121 | 0.87 | 10 (–12; 32) | 0.38 |

N: number of patients, T0: baseline visit, T6: 6-month visit, 6MWD and mean difference expressed in meter, r: Pearson's correlation coefficient, Diff: difference.

**Conclusions:** In SSc, execution of the 6MWT is feasible, as 98% of the SSc patients were able to perform a test. The baseline mean 6MWD of 271 SSc patients without ILD and PAH is 460±108m and is clinically stable over a 6 months period. The DcSSc subgroup walks less than the LSSc subgroup and the LcSSc subgroup.

## FRI0278 MACROVASCULAR DYSFUNCTION OF UPPER AND LOWER LIMBS CORRELATES WITH DIGITAL ULCERATIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS

E. Moradkhan[1], S. Ale-Saeidi[2], F. Gharibdoost[3]. *[1]Internal medicine, Rheumatology, Shahid Beheshti university of medical sciences; [2]Internal medicine, Rheumatology; [3]Rheumatology/ Rheumatology Research Center, Tehran university of medical sciences, Tehran, Iran, Islamic Republic Of*

**Background:** Systemic sclerosis (SSc) is a chronic connective tissue disorder of unknown etiology characterized by tissue fibrosis and vascular damage [1]. Digital ulcerations (DUs) are common manifestations of vascular involvement [2]. Althoughthe vascular dysfunction of SSc has been considered mainly to affect microvasculature [3], there is recent evidence showing that SSc is associated with the prevalence of large vessel disease [4]. However, only a few studies investigated the relationship between macrovascular disease and its role in the clinical manifestations of SSc such as ulcers.
**Objectives:** To assess the relationship between the Macrovascular dysfunction of upper and lower limbs with digital ulceratioins (DUs) in patients with systemic sclerosis and identification of the other possible factors that correlate with DUs.
**Methods:** Ninety patients with SSc (45 cases with DUs and 45 cases without DUs) enrolled in this study. Patients with other rheumatologic diseases and diabetics patients were excluded from the study. Data which were collected from the patients, included, age, past medical history of cardiovascular disease and dyslipidemia, SSc disease duration, type of SSc (lcSSc or dcSSc), Raynaud's phenomenon (RP), RP duration and digital ulcerations (DUs), Body weight (BW), Height, Waist circumference (WC), Body mass index (BMI), Blood pressure (BP), serum levels of SCL-70 antibody and Anti β2 microglobulin antibody. Then Doppler sonographies were performed. The outcome variables were the peak systolic velocity (PSV) and resistance index (RI) of ulnar, radial, popliteal, dorsalis pedis and tibia artery.
**Results:** The SSc patients with DUs have significantly lower PSV and higher RI in the ulnar (PSV:52.1±7.9 vs 55.7±4.1, p=0.006 and RI: 0.58±0.15 vs 0.52±0.06, p=0.003), dorsalis pedis (PSV: 33.9±1.9 vs 34.5±0.4, p=0.027 and RI: 0.54±0.11 vs 0.50±0.04, p=0.045) and tibial artery (PSV: 32.6±3.1 vs 34.4±0.9, p<0.001 and RI: 0.62±0.16 vs 0.51±0.07, p<0.001) in comparison to SSc patients without DUs. PSV and RI of ulnar artery were significantly correlated with age (p=0.012 and p=0.019), disease duration (p=0.001and p=0.001) and Raynaud's phenomenon (RP) duration (p=0.048 and p=0.028). PSV and RI of tibial artery had significant correlation with age (p=0.038 and p=0.009), systolic blood pressure (p=0.022 and p=0.037) and diastolic blood pressure (p=0.015 and p=0.010).
**Conclusions:** We concluded that digital ulceration in patients with SSc might be frequently related to the macrovascular dysfunction in below the elbow and knee.

## FRI0279 CURRENT IMMUNOSUPPRESSIVE DRUGS ARE NOT ENOUGH TO TREAT THE PULMONARY INVOLVEMENT OF CONNECTIVE TISSUE DISEASES

V. Yazisiz[1], S. Oygen[1], F. Erbasan[1], G. Arslan[2], E. Gökalp[1], G. Tazegül[1], A.B. Avci[1], E. Terzioğlu[1]. *[1]Rheumatology; [2]Radiology, Akdeniz University, Antalya, Turkey*

**Background:** Interstitial lung diseases (ILDs) may occur secondary to connective tissue diseases (CTDs) and increase morbidity and mortality due to ventilation impairment.
**Objectives:** To reveal clinical, laboratory and imaging features of CTD -ILDs and to analyze treatment approaches.
**Methods:** One hundred thirty two consecutive patients were included in this cohort. Demographic characteristics, laboratory and HRCT results and treatment results were analyzed. More than 10% increase of pulmonary function tests were categorized as improvement, >10% decrease were categorized as deterioration and ±10% changes were categorized as stable disease.
**Results:** There were 111 ILD patients (86.5% CTD-ILD) with follow-up time for more than 6 months. Median follow up time was 48 (Min-Max:6–260) months and mean age was 54.5±11.9 years. HRCT scan was repeated in median 3 (1–10) times per patients, with median 12.5 month intervals. The most frequent HRCT findings were ground-glass opacities, interlobular septal thickening and honeycomb patterns. 89.6% of CTD-ILD patients recieved corticosteroids and 44.8% recieved hydroxylchloroquine sulphate. Azathioprine and cyclophosphamide were the most common used immunosupresive drugs. Eighty four patients recieved at least one immunosuppressive agent. There were only 2 patients treated with four different immunosuppressive drugs. After treatment, mean pulmonary function tests did not significanty differ from baseline (p>0.05) (Table). 35% of the patients improved *forced vital capacity*(FVC >%10 increase) by treatment whereas 31% had decreased and 34% were stable.

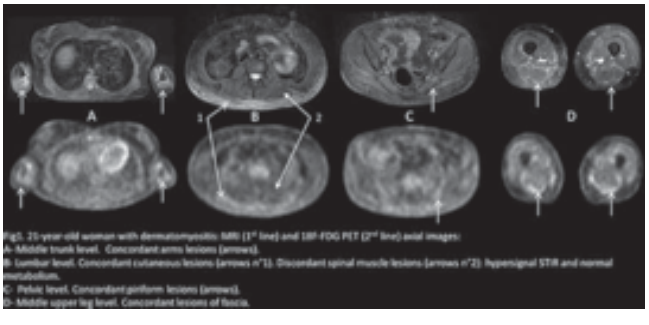
FRI0280 **USEFULNESS OF THE EUSTAR PRELIMINARY CRITERIA FOR VERY EARLY SYSTEMIC SCLEROSIS AND LE ROY CRITERIA FOR EARLY-SYSTEMIC SCLEROSIS IN IDENTIFYING PATIENTS AT RISK OF DEVELOPMENT OF SYSTEMIC SCLEROSIS**



F.M. Ortiz Sanjuan, J. Ivorra Cortés, L. González Puig, I. Chalmeta Verdejo, E. Grau Garcia, C. Feced Olmos, E. Labrador Sánchez, K. Arévalo Ruales, R. Negueroles Albuixech, J. Fragio Gil, I. Martínez Cordellat, J. Valero Sanz, C. Alcañiz Escandell, C. Nájera Herranz, G. Poveda Marín, J. Román Ivorra. *Rheumatology Department, HUP la Fe, Valencia, Spain*

**Background:** Previously, Early Systemic Sclerosis (Early-SSc) patients were defined as patients with Raynaud phenomenon (RP) and either a scleroderma marker autoantibody or typical capillaroscopy abnormalities or both.
Since 2013 the definition of Early-SSc has been updated: Patients should not meet the new 2013 ACR/EULAR criteria for the classification of Systemic Sclerosis (SSc). EUSTAR group also proposed preliminary criteria for the very early diagnosis of SSc which have not yet been validated.
**Objectives:** Our aim was to revise the usefulness of Le Roy criteria and Very Early EUSTAR criteria in identifying patients at risk of development of SSc.
**Methods:** Retrospective study of a wide and unselected series of patients with Early-SSc and SSc from a single university hospital from June 2012 to August 2015. We excluded patients who fulfilled 2013 ACR/EULAR criteria at first visit. Patients were classified as Early-SSc following Le Roy criteria and classified as SSc according to the 2013 ACR/EULAR criteria during follow-up. We reviewed EUSTAR criteria in both groups.
**Results:** We included a total of 56 patients with a mean age of 55±15 years (94.6% women; 5.4% men). At first visit, 15 (26.8%) of our patients fulfilled 2013 ACR/EULAR criteria and were excluded of the final analysis. 37 (66.1%) of our patients fulfilled Le Roy criteria at first visit. The remaining 4 patients (7.1%) did not meet any of these criteria in the first visit. During the follow-up of this group of 41 patients, 37 (90.2%) presented RP and 9 (22%) presented puffy fingers. Antinuclear antibodies (ANA) were present in 34 (82.9%) of the patients, Anti-centromere antibodies in 24 (58.5%) patients and 29 (70.7%) patients presented pathologic capillaroscopic exam.
After a mean follow-up period of 26.1±16.6 months, 20 (48.8%) patients fulfilled 2013 ACR/EULAR criteria. The remaining 21 patients remaining classified as Early-SSc following Le Roy criteria. Of the following EUSTAR criteria, only significant positivity of ANA was observed more frequently in patients that fulfilled 2013 ACR/EULAR criteria: ANA (100%vs63.6%;p=0.005), anti-centromere antibodies (65%vs50%;p=0.41), raynaud phenomenon (95%vs85.7%;p=0.31), abnormal capillaroscopic exam (65%vs76.2%;p=0.8), presence of puffy fingers (25%vs19%;p=0.65).
**Conclusions:** In our study, over the half of the patients initially classified as Early-SSc progressed to SSc during follow-up. EUSTAR preliminary criteria were more frequent in patients who during follow-up fulfilled 2013 ACR/EULAR criteria for SSc, although only the positivity of ANA was statistically significant. Further studies are needed to better characterize the patients with Early-SSc and Very Early-SSc.

FRI0281 **MRI VERSUS 18F-FDG PET IN INFLAMMATORY MYOPATHIES AND FASCIITIS**

H. Petit[1], A. Meyer[1], F. Hubele[2], G. Bierry[3]. *[1]Rheumatology; [2]Nuclear Medicine; [3]Radiology, Strasbourg University Hospital, Strasbourg, France*

**Background:** Idiopathic inflammatory myopathies (IIM) and eosinophilic fasciitis (EF) are defined as idiopathic inflammation of muscle or fascia. In patients clinically suspected of having those entities, Magnetic Resonance Imaging (MRI) is performed to assess muscle involvement, and 18F- Fluorodeoxyglucose Positron Emission Tomography (PET) to exclude a paraneoplastic origin of the symptoms.
**Objectives:** In this study, we aimed to compare the relative performance of MRI and PET in the detection of muscle and/or fascia inflammation.
**Methods:** This retrospective board – approved study included 18 patients suspected of MII (12) or EF (6) in which both MRI and an $^{18}$F-FDG PET were available and performed within a interval ≤3 months, and in which no therapeutic changes occurred between the two exams. The mean interval between MR and PET was 7 days [range -62 (PET performed between MRI) to +91].
For each subject, muscular involvement was independently evaluated on MRI and PET in up to 17 possible predefined muscular groups, subdivided on 3 categories: upper limbs, lower limbs and trunk. A total of 220 corresponding muscular groups were analyzed. A group was considered abnormal on MR when a high signal was seen on fat saturated T2w images (either in muscle or fascia) and, on PET, when high uptake was present. The Kappa statistics between the two imaging modalities were calculated.

**Results:** MRI detected significantly more lesions than $^{18}$F-FDG PET in the 3 categories (upper limbs, lower limbs and trunk) ($p<0.001$). The overall agreement between MRI and $^{18}$F-FDG PET was 0.67 (95% confidence interval 0.57 to 0.77); it was 0.81 (CI 95 0.70–0.93), 0.50 (CI 95 0.31–0.68) and 0.65 (CI 95 0.34–0.97) for upper limbs, lower limbs and trunk, respectively.
**Conclusions:** MRI seems more accurate to detect inflammatory changes of muscle or fascia than 18FDG PET when myositis or fasciitis is clinically suspected.
**Disclosure of Interest:** None declared

FRI0282 **POST-TREATMENT SHORT-TERM CHANGES IN NEEDLE ELECTROMYOGRAPHY AMONG PATIENTS WITH POLYMYOSITIS AND DERMATOMYOSITIS AND THEIR CLINICAL USEFULNESS: A RETROSPECTIVE STUDY**

H. Kawasumi[1], Y. Katsumata[1], E. Ito[2], A. Nishino[1], Y. Kawaguchi[1], H. Yamanaka[1]. *[1]Institute of Rheumatology, Tokyo Women's Medical University, Tokyo; [2]Department of Neurology, School of Medicine, Fukushima Medical University, Fukushima, Japan*

**Background:** There is no established single outcome measure of muscle manifestations in polymyositis (PM) and dermatomyositis (DM) although there are partially validated preliminary definitions of improvement by the International Myositis Assessment & Clinical Studies Group (IMACS). They are core set measures including Manual Muscle Testing (MMT), muscle-associated enzymes such as creatine kinase (CK), and so on. Needle electromyography (EMG) is useful in the diagnosis of PM/DM. However, the degree and time course of changes in its findings after treatment and their associations with other measures remain elusive.
**Objectives:** We aimed to study post-treatment short-term changes in needle EMG among patients with PM/DM and their clinical usefulness.
**Methods:** Patients were included in the present study when they met all these criteria: 1) fulfill the Bohan and Peter classification criteria for PM/DM; 2) were administered to our university hospital for the treatment of muscle manifestations of PM/DM from 2008 through 2015; 3) received needle EMG before and after treatment. Needle EMG was performed by a single experienced electromyographer/neurologist in all the patients. The data of findings of needle EMG, MMT, serum CK levels, and other demographic and clinical information were retrospectively collected. The following findings of needle EMG were transformed into semiquantified relative frequencies on 0–7 point scale: fibrillation potential (Fib), positive sharp wave (Pos), low-amplitude motor unit potential (MUP) (Low), short-duration MUP (Short). MMT was assessed in 10 muscles on 0–5 point scale and their sum scores with maximum of 50 were used. Treatment was determined by physician preference in each individual.
**Results:** Ultimately, 24 patients were included in the present study, and 17 and 10 patients received needle EMG at 4 and 8 weeks after treatment, respectively: 3 patients received at both 4 and 8 weeks after treatment. Fib was detected in 23 patients, and Pos, Low, and Short were detected in all the patients before treatment. Fib, Pos, Low, and Short improved in 59%, 65%, 29%, and 24% of the patients at 4 weeks, and in 90%, 90%, 100%, and 90% of the patients at 8 weeks, respectively. When assessed by Wilcoxon signed-rank tests, Fib and Pos significantly improved at 4 weeks, and all of the needle EMG findings improved at 8 weeks ($p<0.05$ in each comparison). Although MMT scores and CK levels also significantly improved, their improvement did not significantly agree with the improvement of needle EMG findings except for Fib and Pos and CK levels at 8 weeks.
**Conclusions:** The present study showed that electrical activity in muscle recorded at rest (Fib and Pos) and during voluntary movement (Low and Short) significantly improved at as early as 4 and 8 weeks after treatment, respectively. It is also suggested that needle EMG findings can serve as different outcome measure from MMT and CK in PM/DM.
**Disclosure of Interest:** None declared

FRI0283 **ARE PATIENTS WITH EXTENDED INTERSTITIAL LUNG DISEASE BETTER TARGET FOR THE TREATMENT IN SSC?**

H. Takei, H. Yasuoka, K. Yamaoka, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University, Tokyo, Japan*

**Background:** Systemic sclerosis (SSc) is characterized by systemic excessive fibrosis, and interstitial lung disease (ILD) is an important organ involvement strongly associated with morbidity and mortality[1)]. Recent report showed that

extent of ILD could predict prognosis of patients with SSc-ILD, and 70% as %FVC or 20% involvement determined by HRCT were reported as thresholds for the differentiation of patients into limited (LD) or extended (ED) ILD[2]. On that note, adequate target for the introduction of the treatment is still unclear.
**Objectives:** To elucidate the better target for the treatment of patients with SSc-ILD.
**Methods:** This was a single-center study. Patient with SSc-ILD treated with cyclophosphamide during 2008 to 2015 in our hospital were consecutively involved. SSc patients were fulfilled 1980 American College of Rheumatology (ACR) classification criteria[3] or 2013 ACR/EULAR classification criteria[4]. Patients were stratified into 2 groups, extensive or limited lung disease, based on the disease extent over 20% or less using CT scan[2], respectively. Baseline data of pulmonary function tests and other clinical parameters were retrospectively collected from medical records, and response at 6 months after the treatment was evaluated by the change of data of pulmonary function tests before and after the treatment. Each parameter was compared between ED and LD groups.
**Results:** Sixteen patients with SSc-ILD who were treated with cyclophosphamide were involved. Mean age was 57.3±15.1 years and ratio of female patients and diffuse cutaneous SSc were 81%, 50%, respectively. Autoantibody profiles were 2 with anticentromere antibodies (13%), 8 with anti-topoisomerase I antibodies (50%), 1 with anti-U1 ribonucleoprotein antibody (6%) and 5 with antinuclear antibody positive without SSc-specific antibodies (31%). Disease duration at diagnosis of ILD was 26.4±31.9 months. Based on the criteria, 9 (56%) were stratified as ED and 7 (44%) as LD. At baseline, %FVC was higher (86.1±14.2 vs 67.2±16.8%, $p<0.05$) and disease duration was shorter in LD (12.6±24.8 vs 37.2±33.8 months, $p<0.05$) but other clinical parameters including age, sex, smoking, autoantibody profiles, mean cumulative dose of prednisolone or cyclophosphamide and serum KL-6 levels were comparable between 2 groups. Response to treatment was better in patients with LD compared to ED; improvement of %FVC (6.80±5.59 vs 0.04±3.92%, $p<0.05$), favorable outcome of %DLCO but not significant (3.37±12.77 vs 0.70±6.18%).
**Conclusions:** SSc patients with LD, who had earlier and milder disease, showed better short-term response to treatment compared to those with ED. These results suggest that earlier intervention could lead to better prognosis in patients with SSc.

## FRI0284 ANTI-SRP-ASSOCIATED AUTOIMMUNE MYOPATHY: YOUNGER AGE AT ONSET IS ASSOCIATED WITH MORE SEVERE DISEASE AND WORSE OUTCOME

I. Pinal-Fernandez[1], C. Parks[1], E. Tiniakou[2], M. Albayda[2], J. Paik[2], A. Lahouti[2], M. Casal-Dominguez[2], K. Pak[1], W. Huang[1], T.E. Lloyd[3], S. Danoff[4], L. Casciola-Rosen[2], L. Christopher-Stine[2], A.L. Mammen[1]. *[1]Muscle Disease Unit, NIAMS/NIH, Bethesda; [2]Division of Rheumatology; [3]Division of Neurology; [4]Division of Pulmonology, Johns Hopkins University School of Medicine, Baltimore, United States*

**Background:** Anti-SRP autoantibodies are associated with an immune-mediated necrotizing myopathy. Although some anti-SRP-positive patients respond well to therapy, others continue to have active disease and persistent weakness despite treatment[1,2].
**Objectives:** Here, we studied a large cohort of anti-SRP-positive patients to identify factors associated with disease severity and clinical improvement.
**Methods:** All anti-SRP positive patients in the Johns Hopkins Myositis Cohort from 2002 to 2015 were included in the study. Longitudinal information regarding proximal muscle strength, creatine kinase levels, and immunosuppressive therapy were recorded at each visit. Univariate and multivariate analyses using multilevel regression models were used to assess prognostic factors influencing the recovery of strength over time.
**Results:** Thirty-seven anti-SRP-positive patients (78% female) were included. Older age at onset was associated with greater strength at the first visit (p=0.02) and at all subsequent visits (p=0.002) independent of sex, race, disease duration and immunosuppressive treatment. Younger patients had worse outcomes, with less strength at the last visit (p=0.003) independent of disease duration, sex, and race. Although we could not definitively study response to treatment in this longitudinal cohort, rituximab appeared to be effective in 13 of 17 patients who received it (76%, 95%CI: 53% 90%). Younger patients often required continuous and intensive therapy with multiple immunosuppressive drugs to sustain full strength even two years after the onset of the disease.
**Conclusions:** In anti-SRP-associated myositis, a younger age at disease onset is associated with more severe weakness and worse outcomes. Rituximab may be an effective treatment in both young and old patients.

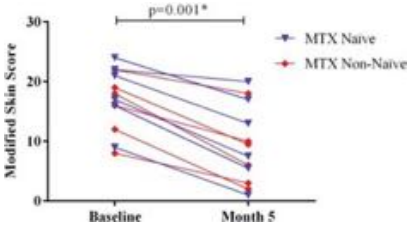
## FRI0285 SENSITIVITY TO CHANGE OF NAILFOLD VIDEOCAPILLAROSCOPY AND RELATIONSHIP WITH DISEASE PROGRESSION

J. Avouac, E. Toniolo, G. Lepri, C. Hurabielle, A. Vallet, Y. Allanore.
*Rheumatology A, Paris Descartes University, Cochin Hospital, Paris, France*



**Background:** Nailfold videocapillaroscopy (NVC) is a simple, non-invasive and inexpensive imaging technique that allows a detailed assessment of skin microcirculation. Although NVC has face and content validity for the detection of microvascular damages related to systemic sclerosis (SSc), its sensitivity to change has not been assessed in detail.
**Objectives:** Our aim was to determine in a prospective cohort the merit of NVC to detect meaningful changes over time and whether these changes are associated with disease progression.
**Methods:** A prospective cohort of 140 SSc patients was recruited over a 12-month period and was followed up on an annual basis for 3 years. NVC was performed at inclusion and repeated once a year by four investigators (ET, GL, CH and AV) according to a standardized procedure. NVC pictures were analysed by one investigator (JA) and classified as early, active and late patterns. Organ progression was defined according to validated definitions. The worsening of the Medsger severity scale (from category 1–2 to category 3–4) was considered as a marker of disease progression.
**Results:** 140 SSc patients were included (111 women, 56±11 year-old, disease duration of 9±8 years). A change of NVC pattern was observed in 29 SSc patients (21%) during the follow-up period.At least 3 annual NVC evaluations were available for each patient.
A progression from a normal or early NVC pattern to an active NVC pattern was detected in 15 patients (10%). Patients who progressed to the active NVC pattern were significantly less at risk to develop ischemic digital ulcers (DU) during follow-up (hazard ratio, HR: 0.78, 95% Confidence Interval, CI 0.17–0.95). A progression to a late NVC pattern was observed in 14 patients (10%). Progression to a late NVC pattern was associated with the occurrence of new ischemic DU (HR: 4.51, 95% CI 1.68–12.14), lung vascular progression (HR: 5.12 95% CI 1.23–21.27), progression of skin fibrosis (HR: 3.70, 95% CI 1.14–11.94) and the worsening of Medsger disease severity scale (HR: 4.47, 95% CI 1.63–12.26).
**Conclusions:** Change of the NVC pattern was observed in 21% of patient with SSc during a follow-up of 3 years. NVC has the ability to detect meaningful changes over time associated with markers of disease progression. Our results support the use of NVC for the routine follow-up of SSc patients in order to improve their risk stratification. NVC might be used in the future to select high-risk patients and change to a late NVC pattern might be regarded as potential surrogate marker for disease severity.

## FRI0286 HIGH-DOSE INTRAVENOUS PULSE METHOTREXATE IN PATIENTS WITH EOSINOPHILIC FASCIITIS: AN OPEN PROSPECTIVE STUDY

J.S. Mertens[1,2], M.C. Zweers[1], W. Kievit[3], H.K. Knaapen[4], M. Gerritsen[5], T.R. Radstake[2,6], F.H. van den Hoogen[4,7], M.C. Creemers[8], E.M. Jong[1]. *[1]Dermatology, Radboud University Medical Center, Nijmegen; [2]Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht; [3]Epidemiology, Health evidence; [4]Rheumatology, Radboud University Medical Center, Nijmegen; [5]Rheumatology, Westfries Gasthuis, Hoorn; [6]Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht; [7]Rheumatology, Sint Maartenskliniek, Nijmegen; [8]Rheumatology, Jeroen Bosch Hospital, 's-Hertogenbosch, Netherlands*

**Background:** Eosinophilic Fasciitis is a rare scleroderma-like connective tissue disorder. No treatment has shown to be effective in randomized trials. The treatment most often reported is combination of moderate to high-dose glucocorticoids (1–1,5mg/kg/day) with weekly methotrexate (MTX), up to 25mg, but often with disappointing results.[1,2]
**Objectives:** To examine the effect and safety of monthly intravenous (IV) high dose MTX in patients wtih eosinophilic fasciits.
**Methods:** Patients with biopsy proven eosinophilic fasciits and progression of skin involvement, who were either treatment naïve or not responsive to glucocorticoids and MTX were included in this open prospective study. Treatment consisted of IV pulse MTX 4 mg/kg/month for 6 doses in 5 consecutive months. Twenty-four hours after the administration of MTX, 5mg folinic acid was orally taken every six hours, to a maximum of 25 mg/day. Patients were evaluated monthly, prior to every infusion. Primary outcome measure was the absolute improvement at month 5 compared to baseline of the modified skin score (mSS), according to Zachariae.[3] Secondary outcome measures were durometer scores, Range of Motion (RoM) and Visual Analogue Scale (VAS) scores for disease activity by physician and patient and Short-Form-36.

**Results:** Between 2006 and 2009, 12 patients were included and the median monthly MTX dose was 288mg (range 252–336). The median mSS improved from 17.5 [range 8.0–24.0] at baseline to 8.5 [range 1.0–20.0] at 5 months (p=0.001) (Fig 1). Compared to baseline, secondary outcome measures improved significantly, except for durometer scores and the range of motion of the elbows. There was no significant difference in skin improvement between the treatment naïve and non-naïve patients (p=0.968). After the last dose of IV MTX, EF flared in six patients after a median of 2 months (range 2–5). A second cycle with IV MTX (3 pulses) was administered to these 6 patients, with a favourable response in all patients. One patient was withdrawn due to increased liver enzymes (2 – times upper limit of normal) after 5 administrations, which normalized after MTX withdrawal. Gastro-intestinal symptoms were present in the majority of the patients (n=9), but manageable with anti-emetics.

**Conclusions:** High dose IV MTX could be an effective and safe treatment option in patients with eosinophilic fasciitis.

## FRI0287 THE USE OF A DORSAL APPROACH FOR THE INJECTION OF BOTULINUM TOXIN A IN THE TREATMENT OF RAYNAUDS PHENOMENON SECONDARY TO SCLERODERMA

K. Dhaliwal[1], M. Griffin[1], S. Salinas[1], K. Howell[2], C. Denton[2], P. Butler[1].
*[1]Division of Surgery and Interventional Science, Royal Free NHS Trust; [2]UCL Institute of Immunity and Transplantation, UCL, London, United Kingdom*

**Background:** Raynaud's phenomenon (RP) is common in scleroderma patients and causes pain, paraesthesia, ulceration, and gangrene. Botulinum toxin A (Btx-A), injected via a palmar approach, has been shown to be effective in the treatment of severe RP. However, hand weakness is a common complication, with rates as high as 27% and can last for up to 6 months (1–5).
**Objectives:** This study aimed to determine the effect of Btx-A injected via a dorsal approach, on hand function and improvement in symptoms, in patients with RP secondary to Scleroderma.
**Methods:** Twenty one patients diagnosed with RP secondary to scleroderma were included. All patients met the criteria for systemic sclerosis of the American College of Rheumatology.
They were treated with 10 units of Btx-A, injected into the hand via a dorsal approach. Each patient had a baseline hand assessment and thermographic image (FLIR E60bx). Hand assessment included pinch and power grip strength measurements (Jammar plus digital pinch gauge and dynameter), range of movement of each joint in the hands using a goniometer, Kapandji thumb opposition test and a pain score using the 0–10 visual analogue scale. Patients were asked to report any symptoms of pain, colour change, cold intolerance and complete a Disabilities of the Arm, Shoulder and Hand (DASH) score. Post injection, the hand assessment and thermography was performed at 15 minutes and at 6 weeks in a temperature controlled room at 23.7±2°C.
Patients were followed up for 6 weeks and filled out a daily Raynaud's attack diary.
**Results:** 89% of patient reported an overall improvement in symptoms. There was a reduction in the overall number and severity of Raynaud's attacks. There was a significant improvement in both the DASH score value (P=0.008) and Kapandji score value (p=0.007). Pain score decreased by 1 point on average, from 4.9 to 3.9.
No patients reported hand weakness as a complication. One patient reported pain at the site of injection for 3 days and 1 patient reported itching for the first 2 days. The effect on range of movement and blood flow was variable.
**Conclusions:** Btx-A injected via a dorsal approach improves symptoms reduces number of attacks in patients with RP secondary to scleroderma. This approach has lower rates of Btx-A related complications compared to the palmar approach.

## FRI0288 IS IMMUNOSUPPRESSION EFFICIENT IN DIGITAL ULCER PREVENTION? A EUSTAR CENTER EXPERIENCE

L. Groseanu[1,2], T. Gudu[1], A. Balanescu[1,2], V. Bojinca[1,2], D. Opris[1,2], I. Saulescu[1,2], A. Borangiu[1,2], C. Constantinescu[1,2], F. Berghea[1,2], V. Vlad[1], M. Negru[1,2], M. Abobului[1,2], D. Predeteanu[1,2], R. Ionescu[1,2]. *[1]Internal Medicine and Rheumatology, Sf Maria Hospital; [2]Rheumatology, Carol Davila University of Medicine and Pharmacy, bucharest, Romania*

**Background:** Digital ulcers are frequent in patients with systemic sclerosis and have a high morbidity. No previous studies have evaluated the efficacy of immunosuppression on digital ulcers risk. Current treatment guidelines do not include the use of immunosuppressants as routine treatment for digital ulcers.
**Objectives:** To asses the efficacy of imunosuppresive therapy on the digital ulcer prevention in patients with systemic sclerosis
**Methods:** Prospective study on EUSTAR cohort 096 during september 2005-september 2015. Patients with systemic sclerosis (SSc) without previous digital ulcers at their first presentation in the clinic were selected. Immunosupression was started based on current recommandations according to specific organ involvement. Patients were evaluated every 6 month according to MEDS evaluation sheets and a special evaluation form for digital ulcer (number, type of ulcer, date of onset).
**Results:** 116 systemic sclerosis (SSc) patients were evaluated, but only those without previous ulcers at their first presentation in the clinic were selected – 60 patients; 12 of them were lost to follow-up.
There were 40 females, 8 males, 23 diffuse and 25 limited SSc. 26 out of the 48 patients received immunosupressants. The mean (±SD) interval of follow up was 72.67 (±60.75) months. No significant statistical difference was identified between patients with immunosuppression and those without regarding the age, the disease duration, the visceral involvement and the follow-up period. 69.23% received Methotrexate, 3,84% received Mycophenolate and 26.92% received monthly pulses of Cyclophosphamide. The use of immunosupresants was related to diffuse subset (R=0.631,p=0.001), antiSCL70 positivity (R=0.624, p=0.001) and lung involvement (R=0.331, p=0.034). There was no difference of the immunosuppressants efficacy regarding the new digital ulcers onset. The incidence of digital ulcers was 15.38% in patients receiving immunosuppression and 68.18% in patients without immunosuppression (p=0.001). The mean (±SD) number of ulcers in the follow-up period was 0.85 (±1.4) in immunosuppresed patients and 6.18 (±4.79) in the other group, p=0.001. The onset of new digital ulcers was also correlated with advanced age (R=0.392, p=0.032) and longer follow-up interval (R=0.036, p=0.049). The mean (±SD) interval from first visit of the patient until the appearence of the first digital ulcer was 7.3 (±5.43) month in patients with immunosuppression and 30 (±11.78) months in patients without immunosuppression.
**Conclusions:** Immunosupression might decrease the risk and the number of digital ulcers of patients with SSc, but they do not seem to extend the interval until their first appearance. More prospective, multicentric studies on larger cohorts with longer follow-up interval are needed in order to aasses the efficacy of immunosuppression on digital ulcers onset, number, rate and time to healing.

## FRI0289 MULTICENTER REGISTRY ON INFLAMMATORY MYOPATHIES IN MADRID (REMICAM): MORTALITY ANALYSIS

L. Nuño[1], M.J. García[2], B. Joven[3], V. Maldonado[4], I. Llorente[5], C. Barbadillo[6], P. García de la Peña[7], L. Ruiz[8], H. Moruno[9], T. Cobo[10], R. Almodovar[11], L. Lojo[12], F.J. López Longo[13] on behalf of REMICAM Study Group. *[1]H.La Paz; [2]Instituto de Salud Musculoesquelética; [3]H.Doce de Octubre; [4]H.Ramón y Cajal; [5]H.La Princesa; [6]H.Puerta de Hierro; [7]H.Madrid Norte Sanchinarro; [8]H.Niño Jesús, Madrid; [9]H.Príncipe de Asturias, Alcalá de Henares; [10]H.Infanta Sofía, San Sebastián de los Reyes; [11]H.F.Alcorcón, Alcorcón; [12]H.Infanta Leonor; [13]H.Gregorio Marañón, Madrid, Spain*

**Background:** Classically the prognosis of idiopathic inflammatory myopathies (IIM) has improved in recent decades, but can still be poor in certain subgroups or in the presence of some clinical factors.
**Objectives:** To analyze survival, causes of death and poor prognosis factors in a cohort of patients diagnosed with IIM.

**Methods:** A multicenter retrospective study from REMICAM[1] myositis study group was performed. All patients were diagnosed with IIM according to Bohan and Peter[2] criteria and were classified into 5 different clinical subgroups: primary dermatomyositis (DM), primary polymyositis (PM), juvenile dermatomyositis (JuvM), cancer associated myositis (CAM) and overlap myositis (OM).
**Results:** 478 IIM cases were included. 74% of the cases were women, with an age at diagnosis of 43.7±22.6 ys. and a mean follow-up of 9.7±8.3 ys. During the follow-up period there were a total of 114 deaths (24%), the main causes were infections (24%), cancer (24%), and cardiovascular events (22%). Factors associated with poor prognosis were CAM (HR 15.4) and OM subgroups (HR 4.55), older age at diagnosis (HR 1.05), shorter time of disease (HR 1.30), serious infections (HR 4.57), cancer (HR 3.07), systemic symptoms (HR 1.64), heart (HR 2.52) and haematological manifestations (HR 1.53), ESR/CRP elevation at baseline (HR 3.05) and chronic renal failure (HR 2.41). The clinical characteristics that showed a protective effect were arthralgia (HR 0.68), typical skin lesions (HR 0.62), drug use (HR 0.53) and female sex (HR 0.5). In multivariate analysis the independent variables associated with mortality were CAM (HR 8.83) and OM (HR 5.17) subgroups, severe infections (HR 3.42), older age at diagnosis (HR 1.03), shorter course of the disease (HR 1.34), thrombocytopenia (HR 2.93) and elevated ESR/CRP (HR 2.47).
**Conclusions:** In our REMICAM registry on inflammatory myopathies 24% of patients died, mainly due to infections, cancer and cardiovascular events. The independent predictors of mortality were belonging to the subgroups of paraneoplastic myopathies or overlap syndrome, the presence of severe infections, thrombocytopenia, elevated ESR/CRP at baseline, shorter course of the disease and older age at onset.

## FRI0290 IDENTIFICATION OF AT RISK PATIENTS FOR CARDIAC MRI DETERMINED SUB-CLINICAL SSC-CARDIOMYOPATHY (CM)

L.-A. Bissell[1,2], B. Erhayiem[3], E. Hensor[1,2], G. Fent[3], J.P. Greenwood[3], S. Plein[3], J. Andrews[1,2], M.H. Buch[1,2]. *[1]LIRMM, University of Leeds; [2]NIHR LMBRU; [3]LIGHT, University of Leeds, Leeds, United Kingdom*

**Background:** SSc-CM carries a poor prognosis once clinically evident. No clear management algorithm to guide screening & investigation for SSc-CM exists.
**Objectives:** To describe cardiac MR (CMR) abnormalities in SSc pts free of CM/CVD & their association with disease (dis.) phenotype to identify the "at risk" pt.
**Methods:** We compared 35 pts with ACR/EULAR criteria SSc & no diabetes/clinical CVD who received SSc/cardiovascular (CV) profile & pulse wave velocity (PWV) assessment & 3T delayed enhancement-CMR reported by CMR-cardiologists to 30 healthy controls (HC). Univariate analysis variables (var.): CV traditional risk factors (TRF), waist/hip ratio (WHR), dis. duration, prev. digital ulceration (DU), known ILD, palpitations hx, dis. subtype, ACA, Scl70, MRSS, NFC, prev. use of cyclophosphamide, SHAQ, FVC, PASP & PWV.
**Results:** Mean (SD) age (yrs) SSc pts 55 (13), 74% female; HC 50 (15), 63% female. Median (IQR) yrs from 1st non-RP symptom 9.5 (2.3, 19.6); 43% dcSSc, 31% ACA+ve, 34% Scl70+ve, 43% known ILD, 37% DU, 0% pulmonary hypertension, 29% prev. use of cyclophosphamide. CMR markers of fibrosis were increased in SSc: ECV (31% SSc vs 25% HC, p<0.001 after adj. for age/sex/TRFs); late gadolinium enhancement (LGE) in 9 SSc vs 1 HC. In SSc, diastolic dysfunction was evident (reduced torsion p0.038), there was a trend for reduced LV mass & RVEF was unexpectedly increased (p=0.028) vs HC. Higher ECV in SSc was associated (ass.) with DU (r0.397 p0.22), decreasing WHR (r-0.510 p0.004) & decreasing TC/HDL (r-0.376 p0.037); none significantly ass. in multi-variable analysis with age/sex. LGE was significantly ass. with ILD (78% vs 33%, p0.047), absence of ACA (0% vs 42%, p0.032), reduced sysBP (mean diff. (95%CI) -14 (27, -1)mmHg p0.034) & lower BMI (mean diff. (95%CI) -4.13 (-8.24, -0.02), p0.049). Other SSc LGE observations: male gender (56% vs 17% LGE-ve), 56% (vs 38% LGE-ve) dcSSc, 56% (vs 29%) Scl70+ve & shorter dis. duration (median (IQR) 7.4 (1.2, 15.8) vs 10.9 (2.5, 19.7) yrs).

Table 1. CMR measures in SSc & HC

| Variable | SSc pts (n=35) | HC (n=30) | Mean difference (95% CI), p adj. for age/sex/ever smoked/sys. BP |
|---|---|---|---|
| LVEF, % | 61.5 (4.6) | 61.8 (4.6) | –0.51 (–2.78, 1.75), 0.652 |

| LGE +ve | 9 (25.0)* (n=33) | 1 (3)* | 8.71 (0.74, 102.17), 0.085** |
| Distensibility, $10^{-3}$mmHg$^{-1}$ | 3.78 (2.25) | 4.70 (1.95) | –0.61 (–1.48, 0.26), 0.163 |

Values = mean (SD). *n (%), **OR (95% CI) p.

**Conclusions:** This study reports CMR detected sub-clinical SSc-CM with detailed SSc phenotype, associating with poor prognostic factors. These data indicate an at risk group for further evaluation that would justify more intensive monitoring for SSc-CM & its complications. The association of ECV with lower lipids/WHR, & LGE with lower BMI/sysBP is new & we postulate may reflect cachexia/medication use in severe disease.

Gutenberg, Mainz, Germany; [10]ILD and Rheumatology Units, Instituto Nacional de Enfermedades Respiratorias, Tlalpan, Mexico; [11]Rheumatology, University Hospital Ramón y Cajal, Madrid, Spain; [12]Rheumatology, University of Marche and C. Urbani Hospital, Jesi; [13]Rheumatology, University of Bari, Bari, Italy; [14]Rheumatology, Hospital Universitario La Paz, Madrid, Spain; [15]Interstitial and Rare Lung Disease Unit, Ruhrlandklinik, University Hospital, University of Duisburg-Essen, Essen, Germany; [16]Rheumatology, Città della Salute e della Scienza, Torino; [17]Rheumatology, Humanitas Research Hospital, Rozzano; [18]Epidemiology Unit, Italian Society for Rheumatology, Milan; [19]Rheumatology, Nuovo Osp. S Giovanni di Dio, Florence; [20]Rheumatology, University of Padua, Padova; [21]Rheumatology, University of Padua, Padua, Italy*

**Background:** The clinical phenotype of the antisynthetase syndrome (AS) has been related with the underlying autoantibody specificity. The typical disease triad (arthritis, myositis, and interstitial lung disease -ILD) is common in anti Jo-1 + AS, whereas isolated ILD is associated with anti PL-7 and PL-12 Ab. The majority of anti Jo-1 + patients without all triad findings at the onset (incomplete ASSD) will develop lacking features during the followup
**Objectives:** To assess the triad clinical spectrum time course in non anti Jo-1 + AS
**Methods:** The study cohort included patients + for anti-EJ, OJ, PL-7, or PL-12 Ab with at least 1 triad finding. Clinical features were retrospectively collected and analyzed
**Results:** we included 65 non anti Jo-1 + AS (7 anti EJ, 4 anti OJ, 30 anti PL-12, 24 anti PL-7; 49 females, 16 males). In median, age at disease onset was 53 years (IQR 42–64), diagnostic delay 9 months (IQR 3–23.5), followup 60 months (IQR 20.5–113). Patients' characteristics are reported in Table 1. During the followup, 22/61 patients with incomplete AS developed new triad findings, in median 12 months (IQR 6–27) after disease onset. The frequency of incomplete AS developing new triad findings and the length of followup were significantly reduced in non anti Jo-1 + patients with respect to our corresponding anti Jo-1 + cohort (respectively: 22/61 vs 138/220, p<0.001; median 60 months, IQR 18.5–113 vs median 75 months, IQR 39–134; p=0.002)

Table 1

| | Characteristics | | p† |
|---|---|---|---|
| | At disease onset | At last follow-up | |
| Arthritis (% of total) | 23 (37) | 31 (48) | 0.016 |
| Myositis (% of total) | 26 (40) | 34 (52) | 0.008 |
| Interstitial lung disease (ILD) (% of total) | 38 (58) | 54 (83) | 0.001 |
| Isolated arthritis (% of total) | 10 (15.5) | 2 (3) | 0.008 |
| Isolated ILD (% of total) | 21 (32.5) | 17 (26) | 0.125 |
| Isolated myositis (% of total) | 15 (23) | 8 (12) | 0.016 |
| Arthritis and myositis (% of total) | 2 (3) | 1 (2) | 1.000 |
| Arthritis and ILD (% of total) | 8 (12) | 12 (18) | 0.219 |
| Myositis and ILD (% of total) | 5 (8) | 9 (14) | 0.219 |
| Arthritis, myositis and ILD (% of total) | 4 (6) | 16 (25) | 0.001 |
| Fever/patients assessed* (%) | 16/59 (27) | 18/59 (30.5) | 0.500 |
| Mechanic's hands/patients assessed* (%) | 14/63 (22) | 17/63 (27) | 0.250 |
| Raynaud's phenomenon/patients assessed* (%) | 23/58 (43) | 26/58 (45) | 0.250 |

†McNemar test; *only patients with the complete timing of features.

**Conclusions:** In non anti Jo-1 + patients the ex novo occurrence of classic triad

finding is common, but less frequent than in anti Jo-1 + patients. The different length of followup may explain at least partly this difference

## FRI0292 RISK FACTORS FOR RECURRENCE OF POLYMYOSITIS/DERMATOMYOSITIS ASSOCIATED INTERSTITIAL LUNG DISEASE

M. Nakazawa, Y. Kaneko, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, School of Medicine, Keio University, Tokyo, Japan*

**Background:** Polymyositis (PM)/dermatomyositis (DM) are characterized by a systemic inflammation of a proximal skeletal muscles and/or a skin. Interstitial lung disease (ILD) is a common but life-threatening complication with PM/DM and often recurs despite intensive induction therapy. However, risk factors for the ILD flare are not determined.
**Objectives:** To identify risk factors of the recurrence of PM/DM-ILD.
**Methods:** Consecutive patients with PM/DM-ILD treated in our institution from 2002 to 2015 were enrolled in the study. The patients were divided into two groups according to the presence or absence of recurrence of ILD after the improvement by induction therapy; the recurrence group and the non-recurrence group. The patients were observed until the recurrence or the last visit to our clinic. The patients' characteristics and treatment between the two groups were compared.
**Results:** A total of forty four patients with PM/DM-ILD underwent induction therapy. After excluding 1 deceased patient (induction failure) and 1 lost to follow-up, forty five PM/DM-ILD cases who had been treated with predonisolone (PSL) and/or immunosuppressive agents as induction therapy were included in the analysis. Recurrence occurred in 17 cases (37.8%). The mean duration from the time of induction therapy to the recurrence was 124 (42.5–241.0) weeks. The following period was 338.5 (166.3–777.5) weeks in the non-recurrence group. At the time of induction therapy, no difference was found between the recurrence group and the non-recurrence group in the mean age (47.6±14.3 vs 47.8±11.9 years, P=0.95), the male ratio (23.5% vs 30.8%, P=0.54), and the proportion of DM (64.7% vs 78.6%, P=0.31), respectively. The levels of C-reactive protein, lactate dehydrogenase and KL-6 were also not different. The percentage of vital capacity (%VC) in the recurrence group was lower than that of the non- recurrence group (59.6% vs 78.3%, P=0.004). The induction therapy regimen was not different between the 2 groups; glucocorticoid pulse, 17.6% vs 21.4% (P=0.84), the initial PSL dose, 0.87 mg/kg vs 0.89 mg/kg (P=0.17), the concomitant use of immunosuppressive agents including cyclophosphamide and/or calcineurine inhibitor with PSL, 47.1% vs 50.0% (P=0.85), in the recurrence and the non-recurrence group, respectively. The PSL dose was 8.3 mg at the recurrence in the recurrence group, and 7.9 mg at the last observation in the non-recurrence group (P=0.40). Immunosuppressive agent was more frequently used as maintenance therapy in the non-recurrence group than the recurrence group (89.3% vs 64.7%, P=0.047).
**Conclusions:** PM/DM-ILD patients with low %VC at the induction therapy are inclined to recur. The concomitant use of immunosuppressive agent as maintenance after induction is important to prevent the recurrence of PM/DM-ILD. The study can improve the management of the PM/DM-ILD.

## FRI0293 SCREENING FOR MALIGNANCIES IN SYSTEMIC SCLEROSIS PATIENTS POSITIVE FOR ANTI-RNA POLYMERASE III ANTIBODIES: A DELPHI EXERCISE AMONG EUSTAR EXPERTS

M.G. Lazzaroni [1], I. Cavazzana [2], P. Airo' [2] on behalf of EUSTAR co-authors.
[1] *Spedali Civili and University of Brescia;* [2] *Spedali Civili of Brescia, Brescia, Italy*

**Background:** A temporal relationship between the onset of systemic sclerosis (SSc) and malignancies has been described in patients with anti-RNA polymerase III antibodies (anti-RNAP). Our analysis of the EUSTAR cohort (1) provided further information, highlighting the relationship of anti-RNAP with malignancies synchronous (±2 years) to the onset of SSc (OR 3.85, 95%CI 1.3–10.9). In particular, an increased rate of synchronous breast cancer was found (OR 20.2, 95%CI 1.4–355). These results suggest the possible need of a cancer screening program for these patients.
**Objectives:** To draw up a possible list of recommendations to guide the clinicians in every-day practice to screen anti-RNAP+ SSc patients for cancer.
**Methods:** A web-based Delphi approach was used to address the questions concerning possible screening for malignancies in anti-RNAP+ SSc patients. Prior to the first stage of Delphi exercise, the number of anti- RNAP+ patients needed to screen to find one synchronous malignancy was calculated using the results of the EUSTAR cohort. All EUSTAR centres were contacted: information on the analysis of the EUSTAR cohort was presented and centres were asked to participate to the exercise, voting on the opportunity of a screening for malignancies in anti-RNAP+ patients and its modality. In the second stage, questions that remained unsolved at the first step, and new suggestions from experts were re-proposed. Finally, possible recommendations were draft, and participants were asked to vote on them in stage 3 of the Delphi exercise. The level of agreement with each statement was voted using a 10-point visual analogue scale (10: fully agree).
**Results:** The number needed to screen to detect one synchronous malignancy in anti-RNAP+ patients in the EUSTAR cohort was 15; the number needed to screen to detect synchronous breast cancer was 22 (or 17, considering only female patients). Eighty-two experts from EUSTAR centers participated to the third stage of the Delphi exercise voting on possible recommendations on screening for synchronous cancer in anti-RNAP+ SSc patients: the results are shown in Table 1.

**Table 1. Levels of agreement among 82 EUSTAR experts**

Degree of agreement with the some statements about a screening for synchronous cancer in SSc anti-RNA Polymerase III positive patients (1-10; 10: fully agree)

| Statement | Mean | SD |
|---|---|---|
| A screening for synchronous malignancies is recommended | 8.73 | 1.70 |
| A screening for synchronous breast cancer in female patients is recommended with the execution of mammography (or US/MRI when needed) | 9.02 | 1.35 |
| Screening for other malignancies should be guided by clinical suspicion and patient age. Non invasive tests (e.g. fecal occult blood, gynecological evaluation, prostatic specific antigen) may be considered in all patients | 8.63 | 1.48 |
| Serum tumoral markers are NOT useful for screening in every patients | 8.59 | 2.18 |
| A period of 2-5 years of tight surveillance for cancer is recommended | 8.26 | 2.01 |
| If the screening tests for cancer performed at the diagnosis of scleroderma are negative, tests for breast cancers should be repeated (e.g. annually); other tests should be repeated in case of clinical suspicion | 7.90 | 2.14 |
| PET/CT may be considered when aspecific systemic signs suggest the possible presence of neoplasms | 8.00 | 2.02 |
| Further tight surveillance for cancer is not recommended after a period of 2-5 years | 7.10 | 2.27 |
| Prospective studies are needed to clarify how long should the tight surveillance lasts and which exams are most indicated for a screening of cancer in these patients | 9.56 | 1.04 |

**Conclusions:** Most EUSTAR experts who participated to the Delphi exercise would recommend screening for synchronous malignancies at the moment of diagnosis in anti-RNAP+ SSc patients. In particular, screening for synchronous breast cancer in female patients, and for other malignancies, guided by clinical suspicion and patient age, would be recommended. Non-invasive tests may be considered in all patients. Although most experts agreed on the proposed statements, some degree of discordance was found on the use of PET/CT and the program of follow-up in subsequent years: in particular on how long should the tight surveillance lasts, and which exams are most indicated to be repeated. The experts agreed that prospective studies are needed to clarify these issues.

## FRI0294 THE PROGNOSIS INTERVALS FOR PTS WITH SSC-ILD USING DISCRIMINANT ANALYSIS

O.B. Ovsyannikova [1], S. Glukhova [2], O. Koneva [1], V. Lesnyak [2], L. Ananieva [1].
[1] *Department of Vascular Pathology;* [2] *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Pulmonary alterations are the major cause of mortality in SSc. The most pts develop some degree of lung injury over the course of the disease.
**Objectives:** to assess predictors of poor prognosis in a single center cohort of SSc pts with interstitial lung disease (ILD) and to build a predictive model of prognosis disease SSc-ILD.
**Methods:** 77 pts with SSc-ILD were involved in a longitudinal study over a five-year period. We used discriminant analysis and our selection involved missing value. So discriminant analysis was held at 58 pts (4 were men). The mean age was 47±13 years. Pts. were divided into 3 subgroups based on HRCT changes estimated at the entry of the study and at last visit. The mean time between two evaluations was 57±10 months. The 1st group included 13pts with improvement (n=13), 2nd –pts without any changes (n=30) and 3rd – pts with deterioration negative dynamics (n=15). ROC analysis was used for determination of prognostic intervals.
**Results:** We got the discrimination function that included: ground glass opacities (GGO) (1 – the absents of GGO; 2 – the presents of GGO); index EScSG (the digital value); FVC (FVC $\geq$75 = 0, FVC $<$75 = 1); the maximum daily dose of glucocorticoids (the digital value, mg); Gamma globulins (the digital value, %); cyclophosphamide (CYC) (the absence of CYC =0, the treatment of CYC =1); DLco (DLco $<$52% =0, DLco $\geq$52 =1). We assessed all parameters at the entry in the study except DLco evaluated after one year of follow up. Based on this analysis the equation was developed.
The equation of prognosis is 3.14 GGO + 0,70 index EScSG – 1,326 FVC - 0,1 the maximum daily dose of glucocorticoids + 0,136 Gamma globulins + 1.066 CYC – 1.075 DLCO $\leq$ 5,8.
Value of equation of prognosis to 5.8 corresponds to stabilization or good prognosis and value after 5.8 corresponds to poor prognosis. The equation of prognosis had 86% sensitivity and 56% specificity. The cut-off point 4.7 was

represented 65% sensitivity and 67% specificity. The prognosis intervals were following: value of equetion to 4.7 corresponds to good prognosis; value from 4.8 to 5.8 corresponds to stabilization and vaule after 5.8 corresponds to poor prognosis.
The mean value of discrimination function for each group is shown in table.

| Groups | N | The mean value |
|---|---|---|
| Group 1 | 13 | 3,6±1.3* |
| Group 2 | 30 | 4,7±1.4** |
| Group 3 | 15 | 6,7±2.5* ** |

* **p<0.001.

**Conclusions:** using discrimination analysis we got the prognosis intervals for the pts with SSc. It can give an opportunity to determine the prognosis of SSc-ILD.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3948

## FRI0295 DLCO /VA: A POSSIBLE PREDICTOR OF PULMONARY VASCULAR DISEASE IN SYSTEMIC SCLEROSIS

P. Corzo[1], A. Pros[1], L. Polino[1], D. Marques[1], E. Balcells[2]. *[1]Rheumatology Department; [2]Respiratory Department, Hospital de Mar, Barcelona, Spain*

**Background:** Pulmonary function tests (PFTs) are used for screening of pulmonary involvement in systemic sclerosis (SS). Decreased DLCO is the earliest and most sensitive alteration detected. It has been seen that there are some SS patients with reduced values of DLCO (<80%) who have no demonstrable ILD by HRCT or pulmonary arterial hypertension (PAH) criteria by screening methods (pulmonary artery pressure (PAP) and tricuspid regurgitation (TR), by echocardiography). DLCO divided by the alveolar volume (DLCO/VA) is usually normal or moderately low in the ILD; its drop suggests an alveolar-capillary membrane dysfunction, thus might suggest the presence of a possible pulmonary vascular disease (no-PAH) related to SS, like in other locations, or could be a predictor of PAH presence
**Objectives:** To describe and compare the clinical, immunological, echocardiographic and spirometric data of two patients groups with SS and decreased DLCO; differentiating those with unknown causes for the DLCO and DLCO/VA decrease, suggestive of alveolar-capillary membrane disease, from those with ILD, PAH or other pulmonary disease associated which could justify this finding
**Methods:** Retrospective review of a hospital cohort of 115 SS patients. All patients with DLCO <80% were included. We defined: "Cases", patients with DLCO/VA decreased without known causes for DLCO decrease, and "controls", patients with a known cause of decreased DLCO: PAH (PAP>36mmHg by echocardiogram), ILD by HRCT, two groups were compared FVC <80%, FEV <80% or other known lung disease
**Results:** 75 patients with SS and DLCO <80%, 20 cases and 55 controls, were compared. We found statistically significant differences in the pattern disease, with a greater proportion of cases with limited SS (LSS) and anticentromere Ab positive whereas predominance of diffuse SS (DSS) and antiScl70 positive in controls. Esophageal involvement was higher in controls and tricuspid regurgitation (TR) higher in cases (p<0.005). "Cases" had mean values: DLCO: 65.60%, DLCO/VA: 62.65%, PAP: 26.29mmHg, right atrial diameter: 12.10cm$^2$ and max. tricuspid speed: 2.23m/s. There were no differences in sex, evolution time, the presence of digital ulcers, telangiectasia, Raynaud's phenomenon, ischemic heart disease, smoking, or in the capillaroscopic pattern.

| | Cases (%) | Controls (%) | p |

**Conclusions:** There are a group of patients with SS, LSS and anticentromere Ab positive predominantly, without respiratory symptoms and decreased DLCO/VA with no justifiable cause. The decrease in DLCO/VA suggest the existence of an alveolar-capillary membrane dysfunction.These patients often present TR without PAH by echocardiographic criteria, so there might be some alteration of the lungs microvasculature suggesting a "pre-PAH" pattern.We should consider a subgroup of patients who would be candidates, in clinical practice, to the application of the DETECT algorithm, cardiorespiratory response to exercise testing and/or cardiac hemodynamic study, despite the absence of symptoms and PAH criteria by ultrasound

## FRI0296 THE OPTIMAL MODIFIED RODNAN SKIN SCORE TO PREDICT SKIN PROGRESSION OVER ONE YEAR DIFFERS BETWEEN AUTOANTIBODY SUBSETS

R.T. Domsic[1], M. Lucas[1], V. Steen[2], R.L. Lafyatis[1], T.A. Medsger[1]. *[1]Rheumatology and Clinical Immunology, University of Pittsburgh, Pittsburgh; [2]Rheumatology, Georgetown University, Washington D.C., United States*

**Background:** There are muliple potential therapeutic a gents under development for sstemic sclerosis (SSc). Given that SSc is uncommon, there is interest in cohort enrichment to maximize the potential of identifying a drug effect, One area of interest is a modified Rodnan skin score (mRSS) cut-off as an inclusion criterion in early diffuse SSc trials. Autoantibody profiles of SSc patients vary by geographical region. Given that the mRSS differs between autoantibody groups and that many trials are multinational, it is important to understand the differences in mRSS patterns between autoantibodies to choose optimal mRSS cut-off points that facilitates enrichment for patients likely to develop skin progression.
**Objectives:** We sought to determine the baseline mRSS to maximally predict progressive skin involvement over one year in US patients with early diffuse SSc, and assess if this differed by autoantibody.
**Methods:** We examined a US single-center cohort of prospectively followed early diffuse SSc patients seen for an initial visit between 1980 and 2014. To reflect modern early diffuse SSc clinical trial design, early was defined as <3 years of symptoms and diffuse SSc as proximal skin thickening. Eligible patients had ≥2 mRSS within one year of the first SSc center visit, for a minimum of 3 mRSS over one year. The outcome of interest was mRSS progression at any time over that year, defined as an increase of 5 points or more and a 25% increase in the mRSS from baseline. Autoantibodies were confirmed by immunodiffusion for Scl-70, immunofluorescence for anti-centromere and immunoprecipitation for RNA polymerase III (RNAP) and all other SSc-associated antibodies. Descriptive statistics using Receiver Operating Curve (ROC) analysis were used with mRSS progression as the state variable to determine cut-off points for mRSS.
**Results:** Among 317 eligible patients the mean age was 50.8±13.5 years, 74% were female and 92% Caucasian. The median disease duration was 0.90 years (IQR 0.63, 1.46). The mean baseline mRSS was 23±11. 25% (n=79) were scl-70 positive, 56% n=178) RNAP positive, 54 (17%) other SSc-associated antibody and 2% (n=6) missing. The median baseline mRSS (IQR) for RNAP was 24 (17,33), compared to 18 (13,25) for Scl-70 and 20 (13,28) for other antibodies (p=0.0004). In total, 163 patients (51%) developed progressive skin disease over one year. 59% of RNAP positive patients progressed, versus 48% of Scl-70 and 33% of other antibody positive patients (p=0.004). The mean time to peak mRSS was 0.51±0.23 years overall. The baseline mRSS below which there was the maximal likelihood of predicting progressive skin disease, with the greatest area under the curve (AUC) in Scl-70 positive patients was ≤24 (AUC 0.72; 95%CI 0.64, 0.80). This contrasted with RNAP patients, for which the maximal AUC occurred at ≤29 (AUC 0.74;95% CI 0.67, 0.80). Patients with other autoantibodies had a much lower baseline mRSS of ≤17 for optimal prediction (AUC 0.67; 95%CI 0.53, 0.80).
**Conclusions:** The mRSS cut-off that predicted skin progression over one year was different between RNAP, Scl-70 and other SSc antibodies. his supports the concept that cohort enrichment in clinical trials may be enhanced by modifying the mRSS cut-off point for the major autoantibody groups. A lower cut-off point will exclude some US patients who are likely to progress.

## FRI0297 A QUANTITATIVE VIDEOCAPILLAROSCOPIC STUDY ABOUT THE MAIN CATEGORIES OF THE "SCLERODERMA PATTERN" AND THEIR CORRELATION WITH THE CLINICAL FEATURES OF SYSTEMIC SCLEROSIS (SSC)

R. De Angelis, E. Di Donato, W. Grassi. *Clinica Reumatologica, Università Politecnica delle Marche, Ancona, Italy*

**Background:** Many studies have been carried out in systemic sclerosis (SSc) in order to correlate the microvascular damage with the clinical features and/or organ involvement, most of them through qualitative assessment of the morphological abnormalities forming the so-called "scleroderma pattern" (SP). Quantitative studies about the SP are currently scarce, rarely addressing the relationship with the disease characteristics.
**Objectives:** To evaluate in a series of SSc patients the association between the types and extent of the SP with the clinical features and the disease severity.
**Methods:** Fifty-four patients (47 women and 7 men, mean age 59.5 years, median disease duration 13.0 years) consecutively enrolled, underwent nailfold videocapillaroscopy. For each patient, a total of 32 images were collected (4 images for the II, III, IV, V finger of both hands). All images were classified according to the following patterns: normal, non-specific, SP (with no reduction of the capillary density and with avascular areas). The patterns were correlated with such features as sex, age, disease duration, Raynaud's phenomenon and/or digital ulcers (DU). Moreover, skin, muscle, gastrointestinal, pulmonary, heart and renal involvement were considered. Statistical analysis was performed using MedCalc version 12.0 (MedCalc Software, Mariakerke, Belgium).

**Results:** A total of 1728 images were analyzed and patients were divided into 4 subsets, on the basis of the extent of the SP. In subset 1 (6 patients, 11.2%) the extent was less than 25%, in subset 2 (5 patients, 9.2%) the extent was between 25–50%, in subset 3 (16 patients, 29.6%) between 50–75%, in subset 4 (27 patients, 50%) was more than 75%. Subsets 1 and 2 showed no significant relationship with any of the variables considered. Patients of subset 3 had a significant correlation with the presence of DU (p=0.007). The subset 4 showed a significant correlation with disease severity (p=0.03), history of DU (p=0.04) and the presence of DU ($p \leq 0.0001$). SP without reduction of the capillary density was correlated with the presence of lung fibrosis (p=0.04). The SP with avascular areas showed a significant relationship with disease severity (p=0.001), lung fibrosis (p=0.01), gastrointestinal involvement (p=0.01), skin involvement (p=0.03), history of DU (p=0.04), and DU (p=0.001). No association was found between patterns and disease duration.
**Conclusions:** The correlation observed between the presence of DU and/or history of DU both with the extent of the SP and the avascular areas represent a relevant data, confirming the hypothesis of a strong relationship between the fingertip blood perfusion and the integrity of the nailfold microvasculature. Unexpectedly, lung fibrosis showed a significant association both with the SP without reduction in capillary density and with the avascular areas. This fact leads us to consider the possibility of the multifactorial nature of pulmonary involvement, not only determined by a reduced number of capillaries. The lack of correlation between type and extent of the scleroderma pattern with the disease duration supports the concept that the severity of microangiopathy is not a characteristic of the late stages of the SSc.

## FRI0298 TREATMENT PATTERNS AMONG ADULT SYSTEMIC SCLEROSIS PATIENTS IN A US HEALTHCARE CLAIMS POPULATION

S. Gale, N. Mathew, C.J. Lin, A. Jahreis, K. Sarsour. *Genentech, South San Francisco, United States*

**Background:** In the United States, systemic sclerosis (SSc) develops in adults at an annual estimated incidence rate of 20 cases per million, and the estimated prevalence is 240 cases per million.[1] Published research on the epidemiology of SSc and common treatments for US SSc patient cohorts is limited. In general, SSc patients are treated based on their specific organ involvement; patients with diffuse skin involvement or severe organ involvement, or both, are treated with systemic immunosuppressive therapy.
**Objectives:** To understand the treatment patterns for and the real-world use of immunosuppressive drugs in adults with SSc using data from a large US healthcare claims database.
**Methods:** The analysis is a retrospective cohort study of patients with SSc diagnosed from 2006 to 2012 using data from Truven Health MarketScan® Research Databases, a medical insurance claims database of insured active employees and their dependents, early retirees, Medicare-eligible retirees, and Medicaid recipients. An SSc diagnosis was determined by $\geq$1 inpatient claim for an SSc diagnosis (*ICD-9* 710.1) or $\geq$2 outpatient claims for an SSc diagnosis. During the study time period, patients were allowed enrollment gaps of $\leq$30 days but had to have enrollment data 6 months before and 12 months after the SSc diagnosis.
**Results:** The prevalence of SSc in the MarketScan database from 2006 to 2013 ranged from 204 to 247 cases per million adults who were actively enrolled in health insurance plans. There were 6872 patients $\geq$18 years of age diagnosed with and treated for SSc during the study time period. Eighty-six percent of the treated SSc population were female, and the average age of the cohort was 54 years. The most common medication claims among patients in the first year after an SSc diagnosis were for antibiotics (54%), opioids (44%), corticosteroids (40%), and proton pump inhibitors (PPIs) (31%). Approximately 30% of SSc patients initiated $\geq$1 of the following disease-modifying antirheumatic drugs (DMARDs), alone or in combination, in the first year after the SSc index, with a median time to initiation of 70 days: methotrexate (21%), mycophenolate mofetil (17%), biologics (3%), cyclophosphamide (2%), or other DMARDs (62% of which included azathioprine, chloroquine, cyclosporine, hydroxychloroquine, penicillamine, quinacrine, and sulfasalazine). Among patients who filled a DMARD prescription in the first year, 15% switched to a second type of DMARD. Of the 70% of patients who did not fill a prescription for DMARD in the first year after the SSc index, 63% filled prescriptions for antibiotics, 56% opioids, 33% corticosteroids, 26% PPIs, 20% NSAIDs, 10% ACE inhibitors, 10% calcium antagonists, 5% prokinetics, 1% ERA, and $<$1% prostacyclin.
**Conclusions:** These data show that the prevalence of SSc among adults in a US healthcare claims population is consistent with the estimated US prevalence. Most SSc patients do not initiate DMARD treatment in the first year after diagnosis, and most SSc patients have received antibiotics, opioids, and systemic corticosteroids.

**Background:** Occurrence of pulmonary arterial hypertension (PAH) in idiopathic inflammatory myopathies (IIM) without extensive interstitial lung disease (ILD) has been rarely described.
**Objectives:** This study aimed to report all cases with association of PAH and IIM in the French Pulmonary Hypertension (PH) Registry, to identify IIM features associated with PAH, and to describe treatment modalities of these patients.
**Methods:** All cases of IIM-PAH were retrieved from the French PH Registry, which gathers PAH patients prospectively enrolled by 21 referral centers across France. Patients were excluded if they had an extensive ILD or overlap syndrome. Characteristics of IIM-PAH patients were compared to a control group of IIM patients without PH.
**Results:** Among the 5223 PAH patients in the Registry, 34 had a diagnosis of IIM. Among them, 3 IIM-PAH patients had no sign of extensive ILD or overlap syndrome, and were included in this study. In these patients, dermatomyositis (DM) was the only identified IIM. Two of them had a myopathic DM, confirmed by electromyography and biopsy. The last patient had an amyopathic DM, associated with anti-Ku antibodies. Pre-capillary PH was hemodynamically proven in all patients. PAH always developed after IIM onset, was severe in all cases, and led to a marked functional impairment.
By pooling our cases with 6 previously reported patients, and comparing them to a control cohort of 35 IIM patients without PH, we identify several IIM characteristics possibly associated with PAH occurrence, including DM subtype (78% vs. 46%, $p$=0.02), skin involvement ($p$=0.04), anti-SSA antibodies ($p$=0.05) and peripheral microangiopathy ($p$=0.06).
Overall, IIM-PAH patients were managed by corticosteroids and/or immunosuppressants, either alone or combined with PAH therapy. Patients that did not receive PAH therapy did not seem to respond to IIM treatment alone.
**Conclusions:** Our study reports for the first time the rare but possible association of PAH and IIM in a large prospective PH Registry. In that setting, PAH seems associated with DM, skin involvement, peripheral microangiopathy and anti-SSA positivity. The best therapeutic strategy for IIM-PAH remains to be defined.

## FRI0300 CORRELATIONS OF Δ HIGH-RESOLUTION COMPUTED TOMOGRAPHY (HRCT) SCORE WITH Δ CLINICAL VARIABLES IN EARLY SYSTEMIC SCLEROSIS (SSC) PATIENTS

S. Wangkaew[1], J. Euathrongchit[2], P. Watanawittawas[1], N. Kasitanon[1], W. Louthrenoo[1]. *[1]Internal Medicine, Division of Rheumatology, Chiang Mai University; [2]Division of Diagnostic Radiology, Chiang Mai University, Chiang Mai, Thailand*

**Background:** The high-resolution computed tomography (HRCT) score showed correlation with % predicted Forced Vital Capacity (%pFVC) in our previous study[1]. However, the correlations of the delta (Δ) HRCT scores with Δ %pFVC and Δ clinical variables have not been reported.
**Objectives:** To evaluate the correlation of the Δ HRCT scores with Δ %pFVC, Δ

Modified Rodnan Skin Score (MRSS) and Δ ESR in patients with early SSc.
**Methods:** We used an inception cohort of early SSc patients seen at the Rheumatology clinic, Chiang Mai University, between January 2010 and June 2014. All patients underwent HRCT at study entry and every 12 months thereafter. The extent of ground glass (GG), lung fibrosis (Fib), bronchiectasis (B) and honeycombing (HC) was scored and then were aggregated to produce a total (t) HRCT score[1]. Thirty-one SSc patients who underwent pulmonary function test within 12 weeks of their corresponding HRCT were identified. The Δ HRCT score (the difference between the last visit and the baseline HRCT score) along with their corresponding clinical variables were used for analysis. Data abstracted include the HRCT scores: total (t)-GG, t-Fib, t-B, t-HC and t-HRCT; %pFVC; MRSS; and ESR.
**Results:** Mean±SD age and disease duration (from non-Raynaud's phenomenon to undergo first HRCT) were 52.2 ± 8.8 years and 11.7 ± 7.1 months, respectively. Seventeen (54.8%) patients were female and 20 (64.5%) were classified as diffuse cutaneous SSc. Mean±SD interval between the two HRCT tests was 16.0 ± 7.2 months. The mean±SD baseline t-GG, t-Fib, t-B, t-HC and t-HRCT scores were 3.2± 3.3, 4.0±3.5, 2.4±3.3, 0.7 ±2.2 and 10.3±10.3, respectively. The mean ±SD baseline %pFVC, MRSS and ESR were 69.0±15.9, 15.4±9.9 and 34.0±25.3, respectively. The mean ±SD absolute Δ HRCT scores were: t-GG, -0.5±2.1 (range -6.0 to 3.0); t-Fib, 0.3±1.9 (range -7.0 to 5.0); t-B, 0.5±1.2 (range -2.0 to 4.0); t-HC, 0.3±0.8 (range 0 to 3.0); t-HRCT, 0.7±3.8 (range-9.0 to 10.0). The mean ±SD absolute Δ clinical variables were: % of predicted FVC, 4.8 ±12.8 (range -33 to 26); MRSS, 4.9± 6.5 (range -17.0 to 8.0); ESR, -5.8 ±22.3 (range -60 to 58). Spearman rank correlations coefficient between the mean absolute ΔHRCT scores and the other variables were (N=31):

| | Δt-GG | Δt-Fib | Δt-B | Δt-HC | Δt-HRCT |
|---|---|---|---|---|---|
| Δ%pFVC | −0.09 | −0.16 | 0.05 | −0.15 | −0.05 |
| ΔMRSS | 0.05 | −0.08 | 0.01 | −0.02 | −0.01 |
| ΔESR | −0.02 | −0.09 | −0.29 | −0.44* | −0.33 |

*p<0.05.

**Conclusions:** In this study, the HRCT scores were fairly stable over the first two years of patients with early SSc; while %pFVC, MRSS and ESR showed relatively more change over the times. We found significantly negative correlation between Δ t-HC and Δ ESR. However, no significant correlations of Δ HRCT scores with Δ %pFVC and Δ MRSS were observed. Further longer study duration with larger study population is needed to confirm our findings.

## FRI0301 PROGNOSIS OF THE IDIOPATHIC INFLAMMATORY MYOPATHIES ASSOCIATED WITH INTERSTITIAL LUNG DISEASE: PRELIMINARY ANALYSIS OF THE REGISTRY REMICAM

T. Cobo-Ibáñez[1], L. Nuño[2], M.J. García[3], B. Joven[4], V. Maldonado[5], I. Llorente[6], C. Barbadillo[7], P. Garcia De La Peña[8], L. Ruiz[9], H. Moruno[10], R. Almodóvar[11], L. Lojo[12], F.J. López-Longo[13] on behalf of REMICAM. *[1]H. Infanta Sofía; [2]H. La Paz; [3]Instituto de Salud Musculoesquelética; [4]H. Doce de Octubre; [5]H. Ramón y Cajal; [6]H. la Princesa; [7]H. Puerta de Hierro; [8]H. Madrid Norte San Chinarro; [9]H. Niño Jesús; [10]H. Príncipe de Asturias; [11]H.F. Alcorcón; [12]H. Infanta Leonor; [13]H. Gregorio Marañón, Madrid, Spain*

**Background:** Some studies suggest that clinical subgroups of idiopathic inflammatory myopathies (IIM) and several myositis-specific antibodies (MSAs) could influence the prognosis of IIM with interstitial lung disease (ILD).
**Objectives:** To investigate the prognosis value of different clinical subgroups and of MSAs in a cohort of patients with IIM -associated ILD.
**Methods:** We analyzed patients with IIM-associated ILD included in the multicenter registry REMICAM (1980–2014). We compared prognosis between a) subgroups of IIM: dermatomyositis (DM) vs. polymiosytis (PM) (primary, juvenile, cancer-associated myositis or overlap myositis); and b) absence (–) or presence (+) of anti-Jo1 vs. anti-RO vs. anti-Jo1 and anti-RO. In this preliminary analysis, outcomes were mortality and change between final and initial visit in FVC and DLCO.
**Results:** 478 patients were included in the registry, of which 143 had ILD, 66% PM and 34% DM. The distribution by MSAs was: 56% anti-Jo1-/RO-, 20% anti-Jo1+, 9% anti-RO+ and 15% anti-Jo1+/RO+. There were 52 deaths; the main causes were 32.6% cardiovascular events and 22.4% infections without difference between subgroups of IIM. The probability of survival was 50% to 18.8 years and the mortality rate was 37.7/1000 patient-ys. We did not find differences when we compared survival between subgroups of IIM or we compared by MSAs. FVC seemed to improve more in DM than in PM patients (1.2±5.2vs. 0.5±4.7;p=0.059), but there were no significant changes in DLCO of DM patients or in FVC and DLCO according to MSAs.
**Conclusions:** We did not find prognostic differences in the causes of mortality, mortality rate between subgroups of IIM, or in mortality rate according to MSAs in patients with ILD. In DM patients there was a trend towards a greater improvement of FVC than in PM patients.
**Disclosure of Interest:** None declared

## FRI0302 SCREENING FOR PULMONARY HYPERTENSION IN SYSTEMIC SCLEROSIS USING THE DETECT PROTOCOL IN SECONDARY CARE

T. Gill[1], M. Mouyis[1], M. Saeidinejad[1], G. Balaji[2], H. Carneiro[1], H. Penn[1], S. Hamdulay[1]. *[1]Department of Rheumatology; [2]Department of Acute Medicine, Northwick Park Hospital, HARROW, United Kingdom*

**Background:** Pulmonary arterial hypertension (PAH) may occur in 20% of patients with systemic sclerosis (SS) which has a poor prognosis with survival approaching 50% at 2 years following diagnosis [(1)]. Early diagnosis of PAH may enable prompt pharmacological intervention, retard disease progression and improve long term outcomes[(2)]. It is recognised that proactive screening for SS-PAH with lung function testing and echocardiography (ECHO) is superior to investigations after PAH symptoms are established. In the UK, screening is based on the ESC/ESR guidelines, which includes annual ECHO and lung function testing. Although not widely utilised, screening with the DETECT protocol[(3)], an evidence based 2 step algorithm which includes serum urate, N-terminal pro-brain natriuretic peptide (BNP) and lung function testing may assist with earlier identification of patients with SS-PAH.
**Objectives:** To evaluate the utility of the DETECT protocol in identifying SS associated PAH in a secondary care connective tissue disease service.
**Methods:** A retrospective review of 74 patients with Systemic Sclerosis (Limited, Diffuse and Mixed CTD) attending a secondary care connective tissue disease clinic in Northwest London. All patients were analysed for general demographics, autoantibody profiles and parameters required for a DETECT 1 and DETECT 2 score within a 12 month period. Each score was correlated with diagnosis of PAH made at the regional PAH centre.
**Results:** 90% (68) of patients were female, mean age 56 years (range 27–85). Limited Systemic Sclerosis (LSSc) accounted for 53% of patients (Diffuse 24%, Mixed CTD 23%) and 43% (32) of all patients were anti-centromere positive (RNP- 24%, Scl-70 20%, PM-Scl 9%). DETECT 1&2 parameters were available for 26–100% of variables (Table 1). A full set of parameters to calculate DETECT 1 was achievable in 32/74 (43%) patients. 21/32 patients had a detect score >300 recommending ECHO with LSSc accounting for a majority of this group (LSSc 14, Diffuse 4, Mixed CTD 3). DETECT 2 parameters were complete in 15/21 patients. 7 of these patients had a score >35 recommending right heart catheterisation (RHC). 1 patient had RHC and a diagnosis of PAH was made in 3 patients (3/32) consistent with respective DETECT scores. Conversely, 7 patients with a DETECT 1 score<300 had echocardiography, against protocol recommendations.

Table 1. DETECT scores and parameters

| DETECT Score Variable (N=74) | N | % |
|---|---|---|
| FVC:TLCO | 49 | 66% |
| BNP | 46 | 62% |
| Serum Urate | 34 | 46% |
| ECG | 31 | 42% |
| Anti-centromere | 74 | 100% |
| Telangectasia | 74 | 100% |
| ECHO | 50 | 68% |
| TRV | 43 | 58% |
| RAA | 19 | 26% |
| PAP | 28 | 38% |
| | | |
| DETECT 1 | 32 | 43% |
| ECHO recommended (DETECT 1>300) | 21/32 | |
| ECHO performed | 19/21 | |
| PAP > 25 mmHg | 19/21 | |
| | | |
| DETECT 2 | 15 | |
| Referral & RHC recommended (DETECT 2 >35) | 7/15 | |
| Referred to Tertiary service | 5/15 | |
| RHC performed | 1/15 | |
| PAH diagnosed | 3/15 | |
| PAP > 25 mmHg | 7/15 | |

**Conclusions:** This small study indicates that the DETECT screening protocol for SS-PAH may be effective in secondary care connective tissue disease services enabling earlier diagnosis and a more prudent approach to using ECHO and rationalising tertiary service referrals. Limitations of this screening tool include the timely collection of clinical parameters required for calculation of DETECT scores, as was evident in our attrition rate.

FRI0303 **AUTOIMMUNE DISEASES ASSOCIATED WITH ANTI-KU ANTIBODIES: A RETROSPECTIVE CASE SERIES**

W.A. Sifuentes Giraldo[1], C. Bouruncle Alaluna[1], G. Roy Ariño[2], M.J. García Villanueva[1], C. de La Puente Bujidos[1], M.L. Gámir Gámir[1]. *[1]Rheumatology; [2]Immunology, University Hospital Ramon y Cajal, Madrid, Spain*

**Background:** The anti-Ku antibodies are directed against a DNA-binding nuclear protein complex composed of 2 polypeptides of 86 and 70 kDa in a 1:1 ratio. These autoantibodies were originally described in 1981 by Mimori et al. in patients with systemic sclerosis (SSc)-polymyositis (PM) overlap syndromes, but further studies have associated anti-Ku antibodies with a wide variety of autoimmune diseases (AD) including systemic lupus erythematosus, Sjögren's syndrome, SSc, mixed connective tissue disease (MCTD) and idiopathic lung fibrosis (ILF).
**Objectives:** To describe the clinical and immunological features of patients with positive anti-Ku antibodies treated in a Spanish tertiary center.
**Methods:** We performed a retrospective study of anti-Ku-positive patients seen in our center during the period 2007–2015. Positivity for anti-Ku was detected through line immunoassay and confirmed by indirect immunofluorescence. Demographic, clinical, therapeutic and outcome data were obtained through review of their medical records.
**Results:** During the study period 14 anti-Ku-positive patients were found, 10 of them women (71.4%), mostly Caucasian (85.7%) with a mean age of 53.2 years (range: 14–79). Three patients had ES-PM overlap syndrome, 3 dermatomyositis (1 paraneoplastic), 2 unspecified myositis, 1 diffuse cutaneous SSc, 1 limited cutaneous SSc, 1 SSc sine scleroderma, 1 MCTD, 1 ILF and 1 IgM mesangial glomerulonephritis. The most frequent clinical manifestations were: arthralgia 50%, Raynaud 42.8%, muscular weakness 42.8%, hand edema 42.8%, sclerodactyly 35.7%, dyspnea 35.7%, myalgia 28.5% and Gottron papules 28.5%. Interstitial lung disease (ILD) was detected in 6 cases (42.8%), 3 with radiological pattern of usual interstitial pneumonia, 2 nonspecific interstitial pneumonia and 1 without a characteristic pattern. The acute phase reactants were elevated in 5 cases and muscle enzymes in 9 (creatine kinase mean value 1096 IU/L, range: 309–2256), 3 showed lymphopenia and 4 polyclonal hypergammaglobulinemia. Myositis (demonstrated by electromyography and muscle biopsy) was present in 4 cases (29.5%). Antinuclear antibodies were positive in 12 cases (85.7%), anti-Ro/SSA antibodies in 3 (21.4%) and anti-centromere, anti-RNP, anti-DNA, anti-PM/Scl75 and anti-MDA5 in 1 case each (7.1%). After a mean follow-up of 35.2 months 4 patients with ILD developed impairment of respiratory function tests despite treatment with corticosteroids and immunosuppressants, but not worsening of myositis or mortality.
**Conclusions:** The features of anti-Ku-positive patients in our series are comparable to those reported in other series published. These antibodies are not specific markers of any AD but are more common in overlap syndromes, so that should be considered in these disorders, especially when myositis is present. ILD frequency was relatively high and the outcome was unfavorable in most cases. Anti-Ku antibodies have been associated with severe and corticoresistant ILD but not with a significant risk of malignancy.

FRI0304 **THE CHANGE OF THE FREQUENCY OF RIGHT HEART CATHETERIZATION FOR THE DIAGNOSIS OF PULMONARY HYPERTENSION AMONG PATIENTS WITH CONNECTIVE TISSUE DISEASES IN A HOSPITAL IN OSAKA, JAPAN – COMPARISON OF THE FIRST 5 YEARS AND THE LATTER 5 YEARS**

Y. Hara[1], K. Maeda[1], S. Higa[1], K. Kawamoto[1], N. Nishikawa[2], Y. Okazaki[2], M. Hiramatsu[1], H. Nakahara[1], Y. Manabe[1], T. Wibowo[1], T. Igarashi[1], A. Ogata[1]. *[1]Division of Allergy, Rheumatology and Connective Tissue Diseases, Department of Internal Medicine; [2]Department of Cardiovascular Disease, NTT West Osaka Hospital, Osaka, Japan*

**Background:** Pulmonary hypertension (PH) is defined as an increase in mean pulmonary arterial pressure (PAPm) greater than or equal to 25 mmHg at rest as assessed by right heart catheterization (RHC), but RHC is not routinely performed for the diagnosis of PH in a "real world" setting in Japan.
**Objectives:** The aim of this study is to assess the change of frequency of RHC for the diagnosis of PH among patients with connective tissue diseases in our hospital, and to know if the decision to prescribe pulmonary hypertension drugs is affected by whether we perform RHC.
**Methods:** Clinical records of admitted patients describe both the main diseases which were constantly followed by physicians and the actual diseases which were the reasons for admission. We analyzed the clinical records retrospectively of who was admitted to the wards of our rheumatology section for 10 years from Aug 1, 2005 to July 31, 2015. These 10 years were divided into two periods: the first half is from Aug 1, 2005 to July 31, 2010 (period A) and the latter half is from Aug 1, 2010 to July 31, 2015 (period B). We checked echocardiography, RHC and prescription for PH drugs. PH drugs include prostacyclin pathway agonists, endothelin receptor antagonists, and nitric oxide-cGMP enhancers.
**Results:** We reviewed clinical records of 5,428 patients for ten years and we found 57 patients with the diagnosis of PH either in the section of main diseases or actual diseases. We used the label "tentative pulmonary hypertension (tentative PH)" for patients who showed peak tricuspid regurgitation gradient in thoracic echocardiography of more than or equal to 30 mmHg. Among the tentative PH patients, those whose PAPm were confirmed by RHC were labeled "true pulmonary hypertension (true PH)". Forty patients among the 57 selected patients were categorized as having tentative PH and their original diseases were 20 with systemic sclerosis, 4 with Sjögren's syndrome, 3 with mixed connective tissue disease, and 2 with systemic lupus erythematosus, and so on. Among these 40 patients, 25 belonged to period A and 15 belonged to period B. RHC was performed for 9 patients (36.0%) in period A and true PH was diagnosed in 5 of those 9 patients (55.6%). Also RHC was performed for 12 patients (80.0%) in period B and 7 patients were found to have true PH (58.3%). In period A, 60% of true PH patients (3/5) and 60% of tentative PH patients (12/20) took PH drugs, and in period B, 71.4% of true PH patients (5/7) and 37.5% of tentative PH patients (3/8) took PH drugs.
**Conclusions:** The frequency of RHC increased from 36% in the first half period to 80% in the latter half period in our hospital. In addition, the use of PH drugs did not depend on the confirmation of PH by RHC, particularly in the first half period. In Japan rheumatologists, including doctors at our hospital have a tendency to prescribe PH drugs without RHC data, but recently this tendency is changing. This tendency to not always perform RHC may be partly explained by the content of the guidelines from the Ministry of Health, Welfare and Labor in Japan.

## SLE, Sjögren's and APS - clinical aspects (other than treatment)

FRI0305 **FACTORS DETERMINING HYDROXYCHLOROQUINE SERUM LEVELS IN A COHORT OF CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

C.C. Mok[1], K.L. Chan[1], P. Jannetto[2]. *[1]Medicine, Tuen Mun Hospital, HK, Hong Kong; [2]Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, United States*

**Objectives:** To study the factors determining the hydroxychloroquine (HCQ) serum concentration in a cohort of Chinese patients with systemic lupus erythematosus (SLE).
**Methods:** Consecutive patients who fulfilled $\geq$4 of the 1997 ACR criteria for SLE and had received HCQ for 6 months or more were recruited from our lupus clinic and hospital admissions in a 9-month period starting from November 2011. Patients were prescribed HCQ at fixed daily dosages of 400 mg, 300 mg, 200mg or less than 200mg (eg. 200mg 3 or 5 times per week) at the discretion of their attending doctors according to disease activity, organ manifestations and risk factors for HCQ toxicities. Blood was assayed for the serum levels of HCQ by an in-house technique using the tandem mass spectrometry (SPE-MS/MS). Factors affecting HCQ serum concentrations were studied by univariate and multivariate linear regression analyses. Covariates being tested in the regression models included age, sex, body mass index (BMI), prescribed dosage of HCQ, SLE disease activity score (SLEDAI), ever smoking, estimated glomerular filtration rate (eGFR) and concomitant prednisolone.
**Results:** 276 SLE patients were studied (94% women; mean age 41.0±13.8 years; SLE duration 8.7±6.6 years). HCQ was primarily used for the treatment of mucocutaneous or musculoskeletal manifestations, or both, in 73%, 78% and 93% of the patients, respectively. Patients were stratified into 3 groups according to the HCQ levels: (1) Total non-compliance ($<$10 ng/ml); (2) Sub-therapeutic (10–500 ng/ml); and (3) Therapeutic ($\geq$500 ng/ml). The proportion of patients with HCQ levels of $<$10, 10–500, $\geq$500 ng/ml was 11%, 77% and 12%, respectively. Patients with total non-compliance to HCQ were more likely to be in clinical and serological remission when compared to the remaining patients (42% vs 24%; p=0.04). However, no difference in the clinical manifestations could be observed between patients with total non-compliance and other patients. After excluding patients with total non-compliance to HCQ therapy, the mean and median HCQ serum concentration of the remaining 245 patients was 300±87ng/ml and 276ng/ml (interquartile range 167–401), respectively. Univariate linear regression revealed that the prescribed HCQ dosage (beta 0.47; $p<0.001$) and the SLEDAI score at the time of recruitment (beta 0.16; p=0.02) were the significant factors associated with the HCQ serum concentrations. Multivariate linear regression with all the factors being considered in the model showed that the prescribed HCQ dosage (beta 0.50; $p<0.001$) and eGFR (beta -0.14; p=0.02) were independent factors

associated with HCQ serum levels. Age, sex, BMI, smoking, SLEDAI score and concomitant prednisolone were not significantly associated with the HCQ serum concentrations.
**Conclusions:** Non-compliance and sub-therapeutic HCQ serum levels were frequent in our cohort of SLE patients, which was related to the low prescribed dosage for maintenance treatment in those with clinical and serological remission. Patients with lower eGFR or receiving higher doses of HCQ were more likely to achieve higher HCQ serum concentrations. Thus, HCQ level monitoring and dosage adjustment may be helpful in SLE patients with impaired renal function to reduce the risk of toxicities.

## FRI0306 SERUM ANTI-MÜLLERIAN HORMONE LEVELS IN SLE PATIENTS: INFLUENCE OF DISEASE SEVERITY AND THERAPY ON THE OVARIAN RESERVE

C. Di Mario[1], L. Petricca[2], M.R. Gigante[2], G. Marino[2], V. Varriano[2], A. Barini[3], S. Canestri[2], A. Barini[3], B. Tolusso[2], G. Ferraccioli[2], E. Gremese[2]. *[1]Institute of General Pathology; [2]Institute of Rheumatology; [3]Institute of Biochemical and Clinical Biochemic, Catholic University of the Sacred Heart, Rome, Italy*

**Background:** Systemic lupus erythematosus (SLE) predominantly affects women of reproductive age and may negatively affect their fertility due to severe organ involvement and the prolonged immunosuppressive therapy used. The Anti-Müllerian Hormone (AMH) is secreted from granulosa ovary cells and serum levels of Anti-Müllerian Hormone are used as a measure of ovarian reserve, reflecting the number of primary follicles. Systemic lupus erythematosus (SLE) predominantly affects women of reproductive age and may negatively affect their fertility due to severe organ involvement and the prolonged immunosuppressive therapy used. The Anti-Müllerian Hormone (AMH) is secreted from granulosa ovary cells and serum levels of Anti-Müllerian Hormone are used as a measure of ovarian reserve, reflecting the number of primary follicles.
**Objectives:** To compare serum levels of AMH in a cohort of patients with SLE and healthy controls and to assess whether the presence of the disease, the treatments used and/or other clinical parameters may affect the ovarian reserve.
**Methods:** Eighty-six consecutive female patients with SLE of childbearing age, aged between 18 and 42 years and with regular menses and 44 healthy controls age-matched were evaluated. Anti-Müllerian Hormone levels were measured in peripheral blood samples (kit AMH Gen II ELISA, Beckman Coulter). Clinical and demographic characteristics, disease duration, pattern of organ involvement and previous and current therapies were collected at the time of sampling. Fourteen patients (16.3%) had been treated with cyclophosphamide (CTX, cumulative dose 8.3 ± 5.4 g), and of the remaining, 39 (45.3%) with other DMARDs (methotrexate-MTX, azathioprine, mycophenolate mofetil, cyclosporine) and 33 (38.4%) with anti-malarials only.
**Results:** Patients with SLE had a mean age of 30.4±6.3 years, a disease duration of 7.7±5.1 years and 25 patients (33.3%) had a severe organ involvement (mainly renal and neurological, 14 were treated with cyclophosphamide, 11 with other DMARDs). Serum levels of AMH were comparable between patients and controls (4.2±3.3 vs 5.0±3.1 ng/ml, respectively, p=0.2). Considering patients on the basis of organ involvement, patients with major organ involvement had AMH levels (3.6±2.8 ng/ml) significantly lower than control subjects (p=0.03); no difference was found between patients with minor organ involvement (AMH 4.4±3.4 ng/ml) and control subjects (p=0.4). Considering the treatments used, patients with major organ involvement treated with cyclophosphamide showed serum AMH levels lower than controls (2.9±3.3 ng/ml, p=0.04). Moreover, patients previously exposed both to CTX and MTX, showed the lower AMH levels with respect to other groups (1.1±1.9 ng/ml, p=0.01). There were no associations between the use of other DMARDs than cyclophosphamide and lower AMH levels in SLE patients compared to controls.
**Conclusions:** In the whole cohort of SLE patients, the ovarian reserve was overall comparable to that of healthy controls, whereas a reduction of the ovarian reserve was associated with the use of cyclophosphamide and the severity of the disease.
**Disclosure of Interest:** None declared

## FRI0307 CHANGES IN URINARY BIOMARKER LEVELS CAN PREDICT TREATMENT RESPONSES IN LUPUS NEPHRITIS

J. Wither[1], S. Prokopec[2], B. Noamani[1], D. Bonilla[1], Z. Touma[1], C. Avila-Casado[1], H. Reich[1], J. Scholey[1], P. Boutros[2], P. Fortin[3], C. Landolt-Marticorena[1]. *[1]University Health Network; [2]Ontario Institute for Cancer Research, Toronto; [3]CHU de Quebec Universite Laval, Quebec City, Canada*

**Background:** The relapsing and remitting nature of lupus nephritis (LN) poses a challenge to clinicians who must balance the risk of long term kidney damage with the side effects of treatment. Management of this condition would be greatly aided by the identification of biomarkers that accurately reflect and predict treatment responses. We previously identified and validated a panel of urinary biomarkers that are specifically elevated in SLE patients with active LN as compared to active patients without LN or LN patients in remission.
**Objectives:** To determine whether changes in the levels of these urinary biomarkers predict treatment responses.
**Methods:** 21 SLE patients with biopsy-proven LN were followed longitudinally for a minimum of 2 years after treatment. Levels of 15 urinary biomarkers including Clusterin, Cystatin C, NGAL, PF4, vWF,sVCAM-1, GM-CSF, GRO, IL-15, IL-6, MCP-1, Adiponectin, PAI-1, MMP-7, and TIMP-1, were measured by Luminex. Patients were classified as having a complete response (n=12), partial response (n=4), or treatment (Tx) failure (n=5) at 2 years following initiation of treatment, based upon previously established criteria. Urinary biomarker levels were considered abnormal if they were >2 SD above the mean for 24 healthy controls. Data were analyzed using non-parametric statistics.
**Results:** At 3–6 months following treatment, the changes in biomarker levels from the first visit were not significantly different between complete responders and partial responders or Tx failures. However, at 1 year (11–16 months) following treatment, 5 urinary biomarkers, sVCAM-1, Adiponectin, IL-15, vWF, and MCP-1, demonstrated significantly different changes from baseline in complete responders as compared to Tx failures, with the majority of responders demonstrating improvement and the majority of Tx failures demonstrating worsening. As urinary biomarker levels not corrected for urinary osmolality correlated best with clinical outcomes, subsequent analyses were done with the uncorrected values. Normalization of urinary Adiponectin by 11–16 months was the best predictor of a complete response, with 11 of 12 patients who normalized being complete responders and 1 a partial responder. Similar but slightly less discriminative results were obtained for the other 4 urinary biomarkers. Conversely, the presence of an abnormal urinary vWF at 11–16 months was the strongest predictor of an adverse outcome with 4 of 6 patients with abnormal levels being Tx failures. Notably, all patients that were Tx failures that had normal levels of urinary biomarkers at 11–16 months subsequently developed abnormal levels, whereas patients who were complete responders eventually normalized the majority of these 5 biomarkers. Partial responders demonstrated normalization with delayed kinetics.
**Conclusions:** Measurement of urinary biomarkers can provide valuable insight into treatment responses in lupus nephritis.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5818

## FRI0308 SURFACE TETHERIN IS A NOVEL CELL-SPECIFIC BIOMARKER FOR INTERFERON RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOSUS

Y. El-Sherbiny[1,2], M.Y. Md Yusof[1,2], E. Hensor[1,2], M. Wittmann[1,2], P. Emery[1,2], E. Vital[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Type I interferons (IFN-I) have diverse effects on immune cell populations in SLE, Measuring IFN-I response using PBMCs or whole blood interferon-stimulated gene (ISG) expression does not completely explain clinical features of SLE and IFN blocking therapy. Furthermore, the proportions of cell populations in blood altered with disease activity. Bone marrow stromal antigen 2/Tetherin (BST2), is a cell surface protein eminent in viral immunology as interferon-induced viral restricting molecule expressed on most circulating leucocytes.
**Objectives:** To develop a cell-specific IFN-I assay
**Methods:** PBMCs were collected from 133 SLE patients and 19 healthy controls. Disease activity was measured using BILAG-2004. PBMCs were analysed by flow cytometry for cell surface BST2 protein on each immune cell subset. Cells were FACS-sorted into naïve and memory B-cells, plasmablasts, CD3+ T-cells, NK-cells and monocytes in 12 SLE patients and 16 healthy controls. Expression of *BST2,* as well as 32 other ISGs, were measured using qPCR and a 33-gene IFN score calculated.
**Results:** Analysis of sorted cells confirmed that surface BST2 is a valid cell-specific IFN assay. *BST2* expression correlated with BST2 surface protein within each immune subset: naïve B-cells (r=0.63, p=0.009); memory B-cells (r=0.78, p<0.001); plasmablasts (r=0.58, p=0.018); NK cells (0.63, p=0.008); T-cells (r=0.61, p=0.012); monocytes (r=0.47, p=0.064).
We next used surface BST2 to compare IFN activity of each subset with clinical features in 133 patients. A strong correlation between the PBMC 33-gene IFN score and surface BST2 was found for each cell subset (all p<0.001) confirming validity of BST2 as a biomarker.
BST2 was significantly higher in SLE than HC on naïve and memory B-cells (p=0.004, p=0.003), plasmablasts (p=0.047), T cells (p=0.043), but not different on monocytes (p=0.406).
Association of total BILAG score with BST2 on naïve and memory B-cells (Tau-a =0.23 and 0.22 respectively) was substantive and approximately twice as strong as monocytes and T-cells (Tau-a =0.12 and 0.14). A similar pattern was seen for anti-dsDNA titre, with no association with monocyte BST-2 (Tau-a =0.07) but a substantive association for memory B cell BST-2 (Tau-a =0.18).
**Conclusions:** IFN-I response differs in cell subsets. This can be measured in a fast, cost-effective, convenient assay using flow cytometric analysis of surface BST2. Our results show that IFN activity measured on B cells is more clinically relevant than on other cell populations.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6052

## FRI0309 TYPE I INTERFERON ACTIVITY IS ASSOCIATED WITH MUCOCUTANEOUS BUT NOT MUSCULOSKELETAL DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

A.A.A. Mohamed[1,2,3], Y. El-Sherbiny[1,2], E.M. Hensor[1,2], M.Y. Md Yusof[1,2], S.H. Goma[4], E.A. Abda[4], F.M. Abd-Allah[4], P. Emery[1,2], E. Vital[1,2]. *[1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [3]Rheumatology and Rehabilitation Department; [4]Assiut University, Assiut, Egypt*

**Background:** SLE is clinically and immunologically heterogeneous. Type I interferons (IFN-I) are pathogenic but expression of IFN-I stimulated genes varies. Many existing reports on clinical phenotype and IFN-I were limited by using categorical measures of IFN-I and disease activity scores that were not organ-specific. IFN-I targeted therapies are in development.
**Objectives:** To define the clinical phenotype of IFN-I mediated SLE.
**Methods:** 108 SLE patients and 20 age and sex matched healthy controls were studied. Activity was measured using BILAG-2004. PBMCs were collected for gene expression analysis using TaqMan. Relative expression of 7 interferon stimulated genes was ln-transformed, normalized to healthy control and summed to derive a 7-gene IFN-I score.
**Results:** The most common activity was mucocutaneous and musculoskeletal, which were analysed in detail (Table 1). The relationship between activity and IFN-I score differed between these domains. Overall, IFN-I scores were higher in active mucocutaneous disease. Scores were more variable for BILAG B: this was explained by subtype of BILAG B disease. IFN-I score was increased in subacute and discoid forms (25.3 (16.8–32.9), n=7) compared to acute forms (18.4 (4.9–31), n=15). Score was also higher in patients with anti-Ro60. In contrast, there was no relationship between musculoskeletal disease activity and IFN-I score.
Numbers of patients with renal, haematological and neuropsychiatric activity were limited but there was a trend to higher IFN-I scores with disease activity.

| BILAG domain score (n) | IFN score median (IQR) | P value vs. D+E | P value vs. E |
|---|---|---|---|
| Mucocutaneous | | | |
| A (6) | 27.2 (26.3–31.5) | 0.027 | 0.005 |
| B (22) | 20.5 (9.1–32) | 0.255 | 0.181 |
| C (18) | 30.7 (11.7–38.2) | 0.025 | 0.042 |
| D (46) | 19.3 (3.7–28.1) | NA | 0.469 |
| E (16) | 14 (4.2–22.6) | NA | NA |
| D+E (62) | 17.6 (3.7–27.6) | NA | NA |
| Musculoskeletal | | | |
| A (6) | 24.9 (5–31) | 0.846 | 0.662 |
| B (15) | 19.8 (6.5–28.4) | 0.652 | 0.925 |
| C (37) | 17.2 (3.5–30.7) | 0.445 | 0.965 |
| D (42) | 24.2 (6.2–31.8) | NA | 0.746 |
| E (8) | 19.4 (10.8–26.3) | NA | NA |
| D+E (50) | 23.5 (6.2–31.4) | NA | NA |

**Conclusions:** We identify a relationship between clinical presentation of SLE and IFN-I. High IFN-I activity is linked to anti-Ro60 and non-acute forms of skin disease. We previously reported a worse response to rituximab in this subgroup, whilst response in musculoskeletal disease was consistently good. Measurement of B cell and interferon biomarkers may therefore be important in the selection of the most appropriate targeted therapy for SLE.

## FRI0310 SERUM INSULIN-LIKE GROWTH FACTOR-BINDING PROTEIN 2 (IGFBP2) AS A BIOMARKER OF CLINICAL AND HISTOPATHOLOGICAL TREATMENT RESPONSE IN LUPUS NEPHRITIS

I. Parodis[1], H. Ding[2], A. Zickert[1], L. Arnaud[1], C. Mohan[2], I. Gunnarsson[1]. *[1]Department of Medicine, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [2]Department of Bioengineering, University of Houston, Houston, United States*

**Background:** Lupus nephritis (LN) is a severe manifestation of Systemic Lupus Erythematosus (SLE). Renal biopsy is the gold standard for evaluation of renal activity and damage in LN. Evaluation of new biomarkers for non-invasive assessment of renal pathology is warranted. Insulin-like growth factor-binding protein 2 (IGFBP2) has been found to be a robust diagnostic and prognostic biomarker in malignancies. In animal models, IGFBP2 expression was increased in anti-glomerular basement membrane (anti-GBM) glomerulonephritis and MRL/lpr lupus mice.
**Objectives:** We aimed to investigate the role of IGFBP2 in LN.
**Methods:** Serum levels of IGFBP2 were assessed by ELISA (R&D Systems) in 64 patients with biopsy-proven active LN (52 proliferative, 12 membranous), before and after completion of induction treatment. Post-treatment renal biopsies were performed after a median time of 7.7 months. Clinical responders (CR) were defined by $\geq$50% reduced proteinuria, normal or $\geq$25% improved estimated glomerular filtration rate (eGFR), and inactive urinary sediment. Histopathological responders (HR) were defined by $\geq$50% improvement of renal Activity Index (AI) in post-treatment biopsies. Long-term renal outcome after a median time of 11.3 years (range: 3.3–18.8) was determined by the last eGFR.
**Results:** Serum IGFBP2 levels decreased following induction therapy ($p<0.001$). Serum IGFBP2 levels decreased in both CR ($p<0.001$) and HR ($p<0.001$), but remained unchanged in clinical non-responders (CNR; p=0.44) and histopathological non-responders (HNR; p=0.16). Post-treatment, but not baseline, IGFBP2 levels were higher in CNR compared to CR (p=0.004). Serum IGFBP2 levels correlated with proteinuria, both at baseline (r=0.34, p=0.006) and post-treatment (r=0.48, $p<0.001$). Post-treatment, but not baseline, IGFBP2 levels correlated with Activity Index (r=0.31, p=0.015) and Chronicity Index (CI) scores (r=0.35, p=0.006) in post-treatment renal biopsies, as well as with post-treatment SLE disease activity index 2000 (SLEDAI-2K) scores (r=0.32, p=0.009). Baseline IGFBP2 levels were associated with decreases in eGFR following treatment (p=0.028); no other association was found between baseline IGFBP2 and changes in proteinuria (p=0.14), SLEDAI-2K (p=0.97), AI scores (p=0.54) or CI scores (p=0.07). Following induction treatment, patients showed improvements in eGFR ($p<0.001$). No correlation was found between IGFBP2 and eGFR at either baseline or post-treatment, and there was no association between baseline (p=0.48) or post-treatment (p=0.91) serum IGFBP2 levels and changes in eGFR during long-term follow-up.
**Conclusions:** The decreases in serum IGFBP2 levels following induction therapy in responding, but not in non-responding, patients suggest serum IGFBP2 as a marker of disease activity and response to treatment in LN. Interestingly, baseline IGFBP2 levels were associated with renal function deterioration following treatment, despite an overall improvement in eGFR. Post-treatment, but not baseline, levels mirrored both global SLE activity and histopathological findings, which together with the observed correlation with proteinuria levels suggests IGFBP2 as a marker of activity in patients with history of LN and no or low-grade proteinuria.

## FRI0311 NEUROPSYCHIATRIC LUPUS: COMBINING ADVANCED MORPHOMETRIC METHODS, DIFFUSION TENSOR IMAGING AND CONVENTIONAL MRI LEADS TO THE PATHWAYS OF BRAIN ABNORMALITIES. CORRELATION WITH CLINICAL AND LABORATORY DATA

M.I. Sarbu[1], P. Toledano[2], A. Calvo[3], N. Sarbu[4], E. Roura[5], G. Espinosa[6], X. Lladó[5], R. Cervera[6], N. Bargalló[7]. *[1]Departament of Rheumatology, CHU Saint Pierre and Erasme University Hospital, ULB, Bruxelles, Belgium; [2]Departament of Autoimmune Diseases, Hospital Clinic, Barcelona, Spain; [3]Magnetic Resonance Image Core Facility, Institut d'Investigacions Biomèdiques August Pi I Sunyer (IDIBAPS), Barcelona, Spain; [4]Neuroadiology, Erasme University Hospital, ULB, Bruxelles, Belgium; [5]Departament of Computer Architecture and Technology, University of Girona, Girona; [6]Departament of Autoimmune Diseases, IDIBAPS, Hospital Clinic, Barcelona, Spain; [7]Magnetic Resonance Image Core Facility, IDIBAPS, Department of Radiology, Neuroradiology Section, Hospital Clinic, Barcelona, Spain*

**Objectives:** To combine conventional and advanced magnetic resonance imaging (MRI) to describe brain abnormalities in neuropsychiatric (NP) systemic lupus erythematosus (SLE), and to correlate them with clinical data.
**Methods:** Prospective study including patients presenting central primary NPSLE, non-NPSLE and healthy controls (HC) undergoing brain MRI at 3T in 2014–2015. Conventional MRI data using visual scales for atrophy and white matter (WM) lesions, brain volumetry (voxel-based morphometry and Freesurfer), and diffusion-tensor imaging (DTI) were analyzed. Group differences were correlated with clinical, laboratory and treatment data.
**Results:** Twenty-eight females with NPSLE, 22 non-NPSLE and 20 HC, mean age around 40 years, were recruited. Conventional MRI showed brain atrophy in NPSLE (p=0.005). Total cortical volume was reduced in NPSLE compared to HC (p=0,042). Non-NPSLE had a reduction of left temporal gray-matter (GM) volume compared to HC (p=0.028). NPSLE had a decrease of left frontal WM volume compared with HC (p=0.002). Corpus callosum was reduced in NPSLE compared to HC (p=0.033) and non-NPSLE (p=0.043). DTI showed increased diffusivity (mean, axial and radial: MD, AD, RD) in bilateral temporal WM ($p<0,010$) and reduced fractional anisotropy (FA) in right frontal WM (p=0.018) in NPSLE versus HC.
SLEDAI score was correlated with atrophy (p=0.046); negatively with left temporal cortex volume (p=0.029) and with FA in WM hippocampal regions (p=0.002 left, p=0.048 right). SLICC score was correlated with diffusivity in bilateral temporal WM (MD:p=0.033; AD:p=0.039; RD:p=0.016) and right frontal WM (p=0.005); and negatively with FA in left WM hippocampal regions ($p<0.001$). SLE duration was correlated with diffusivity in temporal WM (MD:p=0.007; AD:p=0.007 and RD:p=0.007); and negatively with FA in right frontal and left temporo-occipital WM ($p<0.0005$ and p=0.014) and with right frontal cortex volume (p=0.028). Low C4 and CH50 were inversely correlated with left temporal cortex volume (p=0.003 and 0.002).
Antimalarials were negatively correlated with atrophy on conventional MRI (p=0.004), total GM volume (p=0.021) and subcortical GM volume (p=0.020); specifically with right and left frontal cortex (p=0.029 and 0.015) and right and left thalamus (p=0.009 and 0.047). Antimalarials were correlated with lower diffusivity in multiple WM clusters (right and left temporal: decreased MD, p=0.006 and

0.004; AD, p=0.007 bilaterally; RD, p=0.005 bilaterally; and right frontal: decreased RD, p=0.010).
**Conclusions:** Atrophy and DTI changes indicating microstructural damage in frontal and temporal white and gray matter are the most important radiological findings in NPSLE. Assessing them should become the milestone of monitoring this disease. This changes correlates with the severity, activity and duration of the disease. Antimalarial treatment could produce some protective effect on the brain in SLE patients.

## FRI0312 PREDICTORS OF INCIDENT EPISODES OF PROTEINURIA AMONG PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L.S. Magder[1], A. Duarte-Garcia[2], E. Barr[1], M. Petri[3]. *[1]Epidemiology and Public Health, University of Maryland, Baltimore, Baltimore; [2]Medicine, Tufts Medical Center, Boston; [3]Medicine, Johns Hopkins University, Baltimore, United States*

**Background:** Lupus nephritis remains one of the most devastating SLE complications, occurring in over 50% of the patients. It is important to identify clinical conditions that precede nephritis for the purposes of patient care and to identify preventive strategies. Most previous studies of predictors of incident nephritis in SLE are cross-sectional or do not incorporate time-varying predictors.
**Objectives:** We leveraged a large clinical cohort which evaluated patients quarterly to identify fixed and time-varying predictors of lupus nephritis.
**Methods:** Since 2006, the urine protein/creatinine ratio was measured quarterly in patients in our SLE cohort. This analysis was based on cohort follow-up after 2006 in patients who did not have a history of diabetes and who did not have a prior episode of sustained elevated proteinuria, nor a history of nephritis, renal insufficiency, or failure. Among these patients, we defined an incident case of proteinuria as two or more measures of urine protein/creatinine (or 24-hour protein measure) greater than 0.5 in two visits separated by more than 30 days and less than 180 days, among patients with no prior episodes of proteinuria. We estimated rates of incident proteinuria in subgroups of patients defined by time-invariant and time-varying predictors.
**Results:** Among 895 patients included in the analysis, 840 (94%) were female, and 518 (58%) were Caucasian, 304 (34%) African-American, with mean age of 42 at the start of follow-up. We observed 58 incident cases of proteinura over a span of 4669 person-years of cohort follow-up. The overall rate of incident proteinuria was 12.4 per 1000 person-years. The Table shows the association between select predictors and the rate incident proteinuria. The rate was significantly lower among those of older age, and significantly higher among those who were not Caucasian. Among those with a history of low C3, the rate was 8 times higher, and highest among those with a recent measure of low C3. The rate among those prescribed hydroxychloroquine was similar to those not prescribed hydroxychloroquine. Among those taking medicine for hypertension, the rate among those prescribed ACE inhibitor or ARB was similar to the rate among those prescribed other treatments.

Table 1: Rates of incident proteinuria by patient characteristics.

| Subgroup | Observed Number of new cases of proteinuria | Person-years of follow-up | Rate of events per 1000 py's | Rate Ratios | P-value |
|---|---|---|---|---|---|
| Everyone | 58 | 4669 | 12.4 | | |
| Age | | | | | |

| Yes | 46 | 3783 | 12.2 | 0.8(0.4, 1.5) | 0.44 |
| Currently on ACE/ARB | | | | | |
| No | 10 | 628 | 15.9 | 1.0 (Ref) | |
| Yes | 24 | 1592 | 15.1 | 0.9 (0.5, 2.0) | 0.89 |

**Conclusions:** Older SLE patients who have not previously had renal involvement are at low risk for developing proteinuria. The highest rates of incident proteinuria were among those with recent low complement. There was not strong evidence that hydroxychloroquine or ACE inhibitor's reduced the risk of proteinuria.

**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5500

## FRI0313 EVALUATION OF THROMBOTIC RISK IN PATIENTS WITH POSITIVE ANTIPHOSPHOLIPID ANTIBODIES WITHOUT CLINICAL CRITERIA OF THE DISEASE

R. Demetrio Pablo[1], P. Muñoz[2], V. Calvo-Río[3], L. Riancho-Zarrabeitia[3], M. López-Hoyos[4], V.M. Martínez-Taboada[3]. *[1]Ophtalmology; [2]Primary Care Management; [3]Rheumatlogy; [4]Immunology, Hospital Universitario Marqués de Valdecilla. IDIVAL. Facultad Medicina. UC, Santander, Spain*

**Background:** The prevalence of thrombosis in antiphospholipid syndrome (APS) and the factors vary depending on the population studied. Although aPL have a strong relationship with thrombosis and pregnancy morbidity, the value of each type of aPL as a marker to develop APS it is not fully clarified.
**Objectives:** To analyze the incidence of thrombosis in patients with positive aPL that do not meet clinical criteria for disease. To identify potential risk factors for thrombosis. To analyze the possible protective role of primary thromboprophylaxis.
**Methods:** Retrospective study of patients with positive aPL on at least 2 times, separated by a minimum of 12 weeks in medium or high titers without fulfilling clinical criteria for APS. The patients were selected from the database of the Department of Immunology of a tertiary hospital (1999- 2004). The presence of vascular event was confirmed through imaging tests. Cases of ischemic optic neuropathy (ION) were diagnosed by clinical and electrophysiological testing.
**Results:** After a mean follow-up of 146±60.3 months, of the 138 patients included in the study, 13 (9.4%) developed thrombosis. The mean time to thrombotic episode was 81.4±41.7 months. Several classic cardiovascular risk factors (CVRF) such as tobacco (61.5% in thrombosis group vs 23.2% in the group without thrombosis;p=0.003), hypertension (53.8% vs 15.3%;p=0.001) and dyslipidemia (DLP) (38.5% vs 5.6%;p=0.001) were more frequent in patients with thrombosis. These 3 classic CVRF were independent risk factors for thrombosis in the univariate analysis, with an OR of 6.5 (95%CI 2.0–21.3) for hypertension, 5.3 (95%CI 1.6–17.5) for tobacco and 10.5 (95%CI 2.7–40.8) for DLP. Regarding the different antibodies, only the lupus anticoagulant (LA) (p=0.062) and anticardiolipin antibodies (aCL) IgM (p=0.14) tended to be more frequent in patients with thrombosis. Positivity to the 3 types of antibodies (AL, aCL, AB2GPI) was associated with increased risk of thrombosis (OR 7 [95%CI 1.9–28.5]; p=0.004). Multivariate analysis showed as independent risk factors for thrombosis: smoking (OR 8.3 [95%CI 1.3–52.5]; p=0.024), hypertension (OR 15.9 [95%CI 1.8–138.7]; p=0.012), DLP (OR 16.9 [95%CI 1.4–108.3]; p=0.027) and IgM aCL (OR 18.7 [95%CI 12–277.7]; p=0.033). Of the 13 thrombotic events, 10 were arterial: 4 acute myocardial infarctions, 2 thrombosis of central retinal artery, 2 OIN 1 transient ischemic attack and 1 stroke. Three thrombosis occurred in venous territory as deep venous thrombosis of lower extremities, with secondary pulmonary thromboembolism in 2 patients. Regarding treatment, 102 patients received prophylaxis with ASA 100 mg, showing a tendency towards protection (OR 0.774 [95%CI 0.2–2.7]; p=0.686).
**Conclusions:** The incidence of thrombosis in patients with positive aPL that do not meet clinical criteria for the disease is about 10%. The tobacco, DLP, hypertension and IgM aCL are independent risk factors. Autoantibodies load increases the risk of thrombosis. The protective role of aspirin in this population seems limited and may raise primary thromboprophylaxis with oral anticoagulation in patients considered as high risk.

## FRI0314 ANTIPHOSPHOLIPID SYNDROME ALLIANCE FOR CLINICAL TRIALS AND INTERNATIONAL NETWORKING (APS ACTION) CLINICAL DATABASE AND REPOSITORY ANALYSIS: THE IMPACT OF SYSTEMIC LUPUS ERYTHEMATOSUS ON THE CLINICAL PHENOTYPE OF ANTIPHOSPHOLIPID ANTIBODY-POSITIVE PATIENTS

S. Zuily[1], D. Andrade[2], D. Erkan[3], M. Tektonidou[4] on behalf of APS ACTION. *[1]Vascular Medicine Division and Inserm U1116, Nancy University Hospital, Vandoeuvre les Nancy Cedex, France; [2]Dept. of Rheumatology, Sao Paulo, Brazil; [3]Hospital for Special Surgery, New York City, United States; [4]First Dept. of Propeudeutic and Internal Medicine, University of Athens, Athens, Greece*

**Background:** APS ACTION International Clinical Database and Repository ("Registry") was created to study the natural course of persistently antiphospholipid antibodies (aPL)-positive patients with or without autoimmune disorders over 10 years. The main autoimmune disease associated with aPL is Systemic Lupus Erythematosus (SLE); limited data exist on the impact of SLE on the clinical phenotype of persistently aPL-positive patients.
**Objectives:** Our objective was to compare the prevalence of clinical and laboratory characteristics of aPL-positive patients with or without SLE.
**Methods:** A secure web-based data capture system is used to store patient demographics, pertinent aPL history, and aPL profile. The inclusion criteria include aPL positivity according to the Updated Sapporo Classification Criteria. Only patients fulfilling the ACR SLE Classification Criteria and those with no other autoimmune diseases were included in this cross sectional analysis to study the

impact of SLE on aPL-positive patients. Baseline clinical characteristics were compared using $\chi^2$ or t-tests accordingly.
**Results:** As of June 2015, 573 aPL-positive patients recruited from 24 centers; 130 (22.7%) were excluded due to other or overlapping autoimmune diseases, SLE-like disease (fulfilling 3/11 ACR SLE Classification Criteria), or missing data. The mean ages (± SD) of individuals with persistently positive aPL but without other autoimmune diseases ("aPL only") (female: 218, 73%), and of those with SLE ("aPL with SLE") (female: 110, 77%) were 44±13 and 49±77, respectively. The majority of patients were Caucasians in both groups (62% and 65%, respectively), followed by Latin Americans (19.3% and 10.5%). Table shows the distribution of the clinical and laboratory characteristics (historically and/or at registry entry). The frequency of criteria and non-criteria APS manifestations was not different between two groups except persistent thrombocytopenia and autoimmune hemolytic anemia, which were more common in the "aPL with SLE" group (14% vs 28% and 2% vs 12%, respectively; both $p \leq 0.001$). Nephrotic syndrome, chronic or end-stage renal disease, and hypocomplementemia were also more common in the "apL with SLE" group.

## FRI0315 A PROSPECTIVE STUDY TO ASSESS RESPONSIVENESS OF CLINICAL AND ULTRASOUND OUTCOME MEASURES FOR MUSCULOSKELETAL SLE

A.S. Zayat[1,2], K. Mahmoud[1,2], M.Y. Md Yusof[1,2], H. Cassamoali[1,2], M. D'Agostino[1,2], P. Emery[1,2], E.M. Vital[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Musculoskeletal manifestations affect up to 95% of SLE patients. Assessment can be problematic as not all patients have swelling. There is a clinical need to better select SLE patients with musculoskeletal symptoms who may respond to therapy and assess their response. We previously analysed 100 patients with MSK symptoms and showed that ultrasound (US) detects synovitis in patients with no clinical swelling.
**Objectives:** To assess the responsiveness of clinical assessment tools and US in musculoskeletal SLE.
**Methods:** 107 patients fulfilling ACR/SLICC criteria for SLE with musculoskeletal involvement were analysed in a cross-sectional study. 16 of these with current inflammatory symptoms entered a pilot study of US before and after intramuscular injection of depomedrone 120mg. These 16 patients were followed up and assessed clinically using BILAG, SLEDAI, patient VAS, physician VAS, tender joint count, swollen joint count) and US of hand (joints and tendon sheath) at 0, 2 and 4 weeks.
**Results:** Of 107 patients only 35 (32.7%) had swelling clinically at baseline but 53 (49.5%) had US synovitis. Response in US and clinical parameters for the 16 longitudinal patients is shown in Table1.

Table 1

| | Week 0 | Week 2 | P* | Week 4 | P |
|---|---|---|---|---|---|
| BILAG-MSK n (%) | | | | | |
| A | 6/16 (37.5) | 3/16 (18.7) | | 1/16 (0.06) | |
| B | 6/16 (37.5) | 3/16 (18.7 | | 2/16 (12.5) | |
| C | 4/16 (25) | 5/16 (31.2) | | 6/16 (37.5) | |
| D | 0/16 (0) | 5/16 (31.2) | | 6/16 (37.5) | |
| BILAG improved, n (%) | N/A | 10/16 (62.5) | | 13/16 (81) | |
| SLEDAI MSK Criterion = 4 points, n (%) | 14/16 (87.5) | 10 /16 (62.5) | | 9 /16 (56) | |
| SLEDAI improved, n (%) | | 4/14 (28.5) | | 5/14 (36) | |
| TJC (0–28), median (IQR) | 8 (4.3–12.3) | 4 (1.0 –13.5) | 0.228 | 4 (1–14.8) | 0.197 |
| SJC (0–28), median (IQR) | 3 (0.3–5) | 0 (0–1) | 0.059 | 0 (0–0) | 0.003 |
| Symptomatic joints, median (IQR) | 15 (5.8–21.5) | 2 (0–13) | 0.047 | 3.5 (1–14.8) | 0.066 |
| Patient VAS (0–100), median (IQR) | 55 (30–78.5) | 30 (8.8–40) | 0.016 | 35 (10–48.8) | 0.059 |
| Physician VAS (0–100), median (IQR) | 31 (13–65.5) | 23 (5–50) | 0.001 | 21 (3.8–43.5) | 0.001 |
| US- total PD, median (IQR) | 8.5 (4.8–34.8) | 1 (0–6.3) | 0.002 | 1 (0–1) | 0.001 |
| US-total GS, median (IQR) | 24 (17–46) | 12.5 (5.3–23.8) | 0.002 | 10.5 (7–13.8) | 0.001 |
| No. joints with synovitis, median (IQR) | 8 (5–19.3) | 3 (0.8–7.5) | 0.004 | 2 (1–4) | 0.001 |

P values compare 2 and 4 weeks with baseline. Value under 0.05 considered as trend, values under 0.025 considered significant.

**Conclusions:** Although swollen joint count was responsive to change with therapy, US was more sensitive in detecting active joints disease at baseline and showed greater and more significant change with therapy. The responsiveness of swollen joints likely explains the responsiveness in BILAG musculoskeletal system index and physician VAS. However, tender and symptomatic joint counts, as well as SLEDAI, were poorly responsive to therapy. Overall, US is the tool most responsive to change for monitoring musculoskeletal disease activity in SLE.

## FRI0316 ASSESSING ATTRIBUTION OF NEUROPSYCHIATRIC EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS. PERFORMANCE OF A NEW ALGORITHM IN AN INTERNATIONAL MULTICENTER COHORT

A. Bortoluzzi[1], A. Fanouriakis[2], L.T. Costallat[3], S. Appenzeller[3], M. Padovan[1], E. Murphy[4], G. Bertsias[2], J.G. Hanly[4], M. Govoni[1]. *[1]Department of Medical Science, Rheumatology Unit, University of Ferrara, Cona (Ferrara), Italy; [2]Department of Rheumatology, Clinical Immunology and Allergy, University of Crete, Heraklion, Greece; [3]Medicine, State University of Campinas, Campinas, Brazil; [4]Dalhousie University and Nova Scotia Health Authority, Halifax, Nova Scotia, Canada*

**Background:** In a recent study of a large cohort of systemic lupus erythematosus (SLE) patients, we evaluated a new algorithm to determine the attribution of neuropsychiatric (NP) events to SLE or other causes [1].
**Objectives:** In the present study, we tested the performance of the algorithm in a new international multicenter cohort of patients, all of whom had one or more NP events as per the 1999 ACR case definitions.
**Methods:** A similar methodology to that used in the first study, was adopted. A dedicated electronic chart was created, including the core set of items for classification. Four factors were considered for each NP event (i) the time of onset of the NP event; (ii) the presence of concurrent or confounding non-SLE factors (i.e. "associations" suggested in the glossary for the 1999 ACR case definition); (iii) the type of NP event (major vs minor or common according to what has been proposed by Ainiala *et al.* [2]; (iv) the presence of "favouring factors" (i.e. supporting attribution). Patients from each center satisfied classification criteria for SLE and had one or more NP events. To maintain blinding, thus avoiding circular thinking, all events were evaluated by two independent assessors from each center, each assigned different tasks: the first assessor provided an attribution diagnosis (related/uncertain/not related to SLE) on the basis of their clinical judgement utilizing all of the information available in the patient record; the second assessor applied the attribution algorithm using the same available information and provided an attribution score. The performance of the attribution score was compared to the attribution determined by clinical judgement, which was taken as the "gold standard". Receiver Operating Curve (ROC) analysis was used to determine the area under the curve (AUC) and the calculation of sensitivity, specificity, positive and negative predictive values [PPV and NPV (CI 95%)] using dichotomous outcomes (related *vs* uncertain/not related to SLE).
**Results:** There were 243 SLE patients (23 M, 220 F; mean (SD) age 47 (12.7) years with 336 NP events. Using a pre-defined attribution score cut-off $\geq 7$ (derived by our previous national validation study of NP events related vs uncertain/not related to SLE) the AUC was 0.89 for NP events attributed to SLE with sensitivity of 88.5% (95% CI 77.7, 87.5), specificity of 74.6% (95% CI 67.9, 80.53), a PPV of 81.8% (95% CI 75.8, 86.8) and a NPV of 83.4% (95% CI 75.9, 89.3).
**Conclusions:** The attribution algorithm for evaluating NP events in SLE patients compared favourably to the judgement of experienced clinicians for the majority of NP events. It is a valid tool and provides a standardized approach to determining the attribution of NP events in future studies of NPSLE.

## FRI0317 CIRCULATING LEVELS OF IC3B & C3 PREDICTS SLE DISEASE ACTIVITY: THE CASTLE (COMPLEMENT ACTIVATION SIGNATURES IN SYSTEMIC LUPUS ERYTHEMATOSUS) STUDY

A.H. Kim[1], D. Sen[1], V. Strand[2], Q.J. Fu[3], R. Bruchas[4], N. Staten[4], M. Schmidt[4], J. Atkinson[1]. *[1]Rheumatology, Washington University School of Medicine, Saint Louis, MO; [2]Immunology/Rheumatology, Stanford University School of Medicine, Palo Alto, CA; [3]Biostatistics, Saint Louis University; [4]Kypha, Inc., Saint Louis, MO, United States*

**Background:** A major unmet need in SLE is identifying a biomarker that consistently tracks with disease activity. One approach is measuring complement activation by evaluating consumption of serum C3 and C4. However, since they are acute phase reactants (1), interpretation of these levels is challenging as serum levels may not decrease until late in a disease flare (2). iC3b is a proteolytically derived molecule of C3b, and increases with complement activation. iC3b/C3 ratio measures complement consumption relative to production, which may provide for a more accurate assessment of complement activation.
**Objectives:** We hypothesize that blood iC3b and iC3b/C3 levels will provide a more specific and reliable marker of complement activation and disease activity in SLE.
**Methods:** 137 adult SLE patients were enrolled in this prospective observational study. The number of patient visits varied from 1 to 7 times during the study period, encompassing 376 visits. C3 and C4 were measured by nephelometry; iC3b using an investigational lateral flow assay test (Kypha, Inc, St. Louis, MO). SLE disease activity was measured using the SLEDAI 2K Responder Index-50 (S2K RI-50) instrument. Patients with active disease are considered to have a S2K RI-50 score $>4$. Clinically meaningful improvement is defined as a decrease in S2K RI-50 score $\geq 4$ from prior visit, while clinically meaningful worsening is defined as an increase in S2K RI-50 score $\geq 4$ from prior visit. Multilevel regression models were performed to examine associations with disease activity. Ordinal logistic regression models with the generalized estimating equation modeling (GEE) were used to examine associations for clinically meaningful changes since the outcome variable is ordinal (i.e. clinical deterioration, stability, and improvement). Odds ratios and 95% confidence intervals for iC3b, C3, C4, ESR, CRP, dsDNA values, prednisone usage, and race were estimated using Proc GLIMMIX and Proc GENMOD (SAS v9.4).
**Results:** Blood levels of iC3b, C3, iC3b/C3 ratio, C4, dsDNA, ESR, and prednisone use each correlated with SLE disease activity. Multilevel multiple logistic regression analysis revealed only iC3b/C3 ratio, dsDNA levels, and prednisone use were significant predictors of disease activity (Table 1). To determine whether iC3b/C3 ratio can predict clinically meaningful changes in SLE disease activity, we evaluated the interpatient association between clinical deterioration, stability, and improvement and iC3b/C3 ratios. Multiple ordinal logistic regression with GEE showed that iC3b/C3 ratio, dsDNA levels, and prednisone use significantly predicted both clinically meaningful improvement and deterioration in disease activity.

**Table 1. Univariate and multivariate logistical regression analysis of variables predictive of active SLE.**

| | Univariate | | | Multivariate | | |
|---|---|---|---|---|---|---|
| Predictor Variable | Odds Ratio | Lower 95% CI | Upper 95% CI | Predictor Variable | Odds Ratio | Lower 95% CI | Upper 95% CI |
| iC3b (Δ1 µg/mL) | 1.27 | 1.08 | 1.47 | iC3b/C3 ratio (Δ0.01 units) | 1.28 | 1.11 | 1.47 |
| iC3b/C3 ratio (Δ0.01 units) | 1.34 | 1.18 | 1.52 | dsDNA Ab (Δ10 IU/mL) | 1.04 | 1.01 | 1.06 |
| C3 (Δ10 mg/mL) | 0.82 | 0.72 | 0.93 | Prednisone (Yes vs No) | 3.44 | 1.73 | 6.84 |
| C4 (Δ10 mg/mL) | 0.57 | 0.36 | 0.85 | | | | |
| dsDNA Ab (Δ10 IU/mL) | 1.05 | 1.02 | 1.07 | | | | |
| ESR (Δ10 mm/hr) | 1.18 | 1.01 | 1.37 | | | | |
| CRP (Δ10 mg/L) | 1.27 | 0.95 | 1.70 | | | | |
| Prednisone (Yes vs No) | 4.03 | 1.87 | 8.68 | | | | |
| Race (White vs AA) | 0.96 | 0.40 | 2.31 | | | | |

**Conclusions:** In this prospective study, blood iC3b/C3 ratios were predictive of active SLE disease. Furthermore, iC3b/C3 ratio was predictive of clinical meaningful changes in disease activity. These data warrant further investigation of iC3b/C3 ratio as a potential biomarker for disease activity in SLE.

## FRI0318 SERUM ADIPOCYTE FATTY ACID-BINDING PROTEIN LEVEL IS ELEVATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) BUT NOT ASSOCIATED WITH BIOPHYSICAL MARKERS OF CARDIOVASCULAR DISEASE

A. Mak[1], H. Schwarz[2], N.Y. Kow[1], S.H. Tay[1], L.H. Ling[1]. *[1]Medicine; [2]Physiology, National University of Singapore, Singapore, Singapore*

**Background:** Adipocyte fatty acid-binding protein (aFABP) is an intracellular lipid-binding protein expressed in adipocytes and macrophages, particularly in inflammatory conditions. Recently, high circulating serum aFABP levels have been shown to predict the development of carotid atherosclerosis, metabolic syndrome and ischaemic stroke. As an inflammatory disease, circulating aFABP level is expected to be raised in patients with SLE. However, a recent study failed to demonstrate higher aFABP levels in SLE patients than in healthy controls (HC), likely due to the lack of power of study and an optimally matched HC group.
**Objectives:** We aimed to address if serum aFABP level is indeed higher in SLE patients by comparing a larger number of SLE patients with HC stringently matched for age, sex and BMI. In addition, potential associations between serum aFABP levels and clinical and disease-related factors, as well as biophysical markers of cardiovascular (CVS) disease were explored in SLE patients.
**Methods:** Patients with SLE and HC matched for age, gender and BMI were recruited. Subjects with a history of hypertension, diabetes mellitus, renal impairment, CVS and cerebrovascular diseases, and those who were on statins were excluded. Clinical parameters including daily prednisolone dose, SLEDAI, SLICC/ACR DI, and serum C3, C4, anti-dsDNA, total cholesterol (TC) and HDL-c levels were obtained. Serum aFABP levels were determined by commercially available ELISA kit. Endothelial function, arterial stiffness and carotid atherosclerosis were assessed by brachial artery flow-mediated dilation (FMD), pulse-wave velocity (PWV) and carotid intima-media thickness (cIMT) respectively using the Prosound Alpha-10 ultrasound system. Relationships between serum aFABP levels and disease-related factors, FMD, PWV and cIMT were explored by bivariate correlations.
**Results:** Seventy one SLE patients and 71 matched HC (6 men in each group) were studied. The mean±SD age (year), BMI and atherogenic index (TC/HDL-c) of SLE patients and HC were 39.21±13.4 and 40.37±12.9, 22.06±4.3 and 22.86±4.2 and 3.09±1.6 and 3.22±1.4 ($p=0.611$) respectively. In SLE patients, the mean±SD daily prednisolone dose, SLEDAI and SLICC were 13.43±14.4mg, 6.52±5.4 and 0.17±0.4 respectively. SLE patients had significantly lower FMD than HC (3.82±2.9% vs 4.76±3.0%, $p=0.027$). PWV and cIMT did not differ between both groups ($p=0.739$ and $p=0.762$ respectively). Serum aFABP was significantly higher in SLE patients than that in HC (14.82±3.3ng/ml vs. 13.69±4.6ng/ml, $p<0.001$). However, no association between serum aFABP levels and serum C3, C4 and anti-dsDNA levels, SLEDAI, SLICC, atherogenic index, daily prednisolone dose, FMD, PWV and cIMT was found in the SLE group. In HC, no association was noted between serum aFABP levels and BMI, FMD, PWV, cIMT and atherogenic index.
**Conclusions:** While we confirmed that SLE patients had significantly higher aFABP levels and lower FMD than age-, sex-, and BMI-matched HC, no association between aFABP and various biophysical markers of CVS disease was found. Prospective studies addressing the CVS impact of aFABP by evaluating adjusted mean aFABP levels over time and CVS events in SLE patients are warranted.

## FRI0319 THE RISK OF PULMONARY EMBOLISM AND DEEP VENOUS THROMBOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS IN THE UNITED KINGDOM: A POPULATION-BASED STUDY

A. Jorge, L. Lu, H. Choi. *Rheumatology Unit, Massachusetts General Hospital, Boston, United States*

**Background:** Many studies have found that patients with SLE have a substantially increased risk of cardiovascular complications. However, the magnitude of the risk for venous thromboembolism (VTE) has not been well quantified in this patient group, particularly within the general population context.
**Objectives:** Our objective was to determine magnitude and temporal trend of the risk of venous thromboembolism (VTE), pulmonary embolism (PE), and deep vein thrombosis (DVT) in individuals with incident systemic lupus erythematosus (SLE) in the general population.
**Methods:** Using the Health Information Network (THIN) database, a population database that includes 11.1 million patients, 6.2% of the population of the United Kingdom, we conducted a cohort study of all patients with incident SLE and up to 10 age-, sex-, and entry time-matched individuals from the general population. SLE patients were identified by read codes for systemic involvement of lupus,

excluding cutaneous-only disease. We compared incidence rates of PE, DVT, and VTE between the two groups and within the SLE group according to SLE disease duration. We calculated hazard ratios (HRs), adjusting for confounders.
**Results:** Among 1494 individuals with SLE (87.1% female, mean age 50 years), there were 13 cases of DVT and 14 of PE. Among the 10,473 individuals without SLE, there were 38 cases of DVT and 33 of PE. The incidence rates of PE, DVT, and VTE were 1.6, 1.4, and 2.9 per 1000 person-years in the SLE group, whereas the corresponding rates were 0.5, 0.6, and 1.1 per 1000 person-years among individuals without SLE. Compared with non-SLE individuals, the multivariable HRs among SLE patients were 3.17 (95% CI, 1.65–6.10), 3.42 (95% CI, 1.72–6.81), and 3.14 (95% CI, 1.94, 5.07) for PE, DVT and VTE, respectively. The age-, sex-, BMI-, and entry time-matched incidence ratios for PE, DVT, and VTE were highest during the first year after SLE diagnosis 14.30 (95% CI, 4.02–50.82), 8.70 (95% CI, 1.74–43.40), and 10.82 (95% CI, 3.91–29.90), respectively. HRs remained similar after adjusting for covariates including BMI, smoking, relevant comorbidities, and use of pertinent medications.

Table 1. Age and sex adjusted risk for PE, DVT, or both (VTE) in SLE according to follow-up period

| Time after diagnosis | PE IRR (95% CI) | DVT IRR (95% CI) | VTE IRR (95% CI) |
|---|---|---|---|
| 1 year | 11.24 (3.47–36.97) | 11.48 (2.56–51.59) | 10.44 (4.02–27.12) |
| 3 years | 6.03 (2.97–12.25) | 4.65 (1.93–11.17) | 5.21 (2.97–9.11) |
| 5 years | 3.74 (1.92–7.28) | 3.48 (1.62–7.46) | 2.56 (2.12–5.93) |
| Total follow-up | 2.40 (1.33–4.33) | 3.31 (1.84–5.94) | 2.76 (1.82–4.21) |

IRR = age-, sex-, and BMI and entry time-matched Incidence Rate Ratio.

**Conclusions:** These findings provide population-based evidence that patients with SLE are at a considerably increased risk of VTE, especially within the first year after SLE diagnosis. Increased vigilance for this potentially fatal outcome and its modifiable risk factors appears warranted in this patient population, particularly early after disease onset.

## FRI0320 DISEASE SEVERITY IN PATIENTS WITH DISCOID LUPUS ERYTHEMATOSUS FROM A REAL-WORLD SETTING

B. Hoskin[1], S. Lobosco[1], D. Bell[1], A. Kao[2], S. Hall[3], S.-Y. Chen[4]. *[1]Adelphi Real World, Cheshire, United Kingdom; [2]Immunology Clinical Development; [3]Epidemiology; [4]HEOR, Global Market Access, Biogen, Cambridge, MA, United States*

**Background:** Real-world data on the severity of discoid lupus erythematosus (DLE) are scarce, limiting our understanding of the clinical course of this chronic disease that disproportionately affects minorities.
**Objectives:** To assess the clinical burden and unmet need by disease severity in DLE patients.
**Methods:** Data were drawn from a 2013 multinational survey of clinical practice that included 101 dermatologists across the US and EU (France, Germany, Italy, Spain & UK). Dermatologists completed the patient record (PRFs) for their next five consulting patients with cutaneous lupus erythematosus. The present analyses were a subset of patients with DLE, categorized by dermatologists into two groups based on their severity at the current visit: 1) mild, and 2) moderate/severe. The two groups were compared in bivariate analyses, using Mann-Whitney-U tests and Fisher's exact tests.
**Results:** Final analyses included 315 DLE patients; 72% were female; mean age at diagnosis=39.7 years; mean disease duration=4.4 years. At diagnosis, 74% of DLE patients had moderate-to-severe DLE, and 10% had joints affected; at the current visit, the corresponding proportions were 27% and 11%. Among DLE patients currently presenting as moderate-to-severe, achieving remission was less common (14% vs. 60% among mild DLE patients; $p \leq 0.0001$). Patients moderate-to-severe during the present visit were more likely to be currently flaring (18% vs. 4%; $p \leq 0.0001$) or have flared in the last 12 months (37% vs. 16%; p=0.0001). Finally, dermatologist satisfaction with the level of control from treatment was also significantly lower amongst currently moderate/severe DLE patients (39% satisfied vs. 91% mild; $p \leq 0.0001$), with dermatologists reporting that better control can be achieved in over a quarter of moderate/severe DLE patients (27% vs. 3% mild; $p \leq 0.0001$).
**Conclusions:** Across regions and despite an average of 4 years since diagnosis, a sizeable proportion of DLE patients (nearly one-third) in clinical care were moderate-to-severe at their current visit, indicating persistence, relapse or worsening. Results suggest an unmet need for better disease control. This study contributes to the scant literature on DLE by informing our understanding of the disease in real-world settings of clinical care, and may help development of appropriate new interventions amongst those not currently controlled under standard therapies.

## FRI0321 ASSOCIATION BETWEEN DISEASE SEVERITY AND PATIENT-REPORTED OUTCOMES IN PATIENTS WITH DISCOID LUPUS ERYTHEMATOSUS IN REAL-WORLD CLINICAL PRACTICE

B. Hoskin[1], S. Lobosco[1], D. Bell[1], A. Kao[2], S. Hall[3], S.-Y. Chen[4]. *[1]Adelphi Real World, Cheshire, United Kingdom; [2]Immunology Clinical Development; [3]Epidemiology; [4]HEOR, Global market access, Biogen, Cambridge, MA, United States*

**Background:** Cutaneous diseases are often associated with high humanistic burden. Current understanding of the patient perspective among those with discoid lupus erythematous (DLE), a chronic disease disproportionately affecting minorities, is particularly lacking. We undertook this analysis to gain insight into the patient perspective on the impact of DLE, and how impact might vary across severity levels.
**Objectives:** To assess the patient's self-reported burden associated with disease severity and perceived unmet need amongst moderate-to-severe vs. mild DLE patients from a real-world setting.
**Methods:** Data were drawn from a multinational survey of 101 dermatologists across the US and EU (France, Germany, Italy, Spain & UK) conducted in 2013. Dermatologists completed patient record forms (PRFs) for their next five prospectively consulting patients with cutaneous lupus erythematosus and patients provided data via self-completion forms (PSCs). Patient-reported outcomes (PROs) collected in the PSC included the EuroQol 5D (EQ5D), visual analog scores, work and activity impairment indices, and the functional assessment of chronic illness therapy scale (FACIT-Fatigue). For the current visit, patients were categorized by dermatologists into moderate/severe vs. mild groups. PRO measures by severity status were compared in bivariate analyses, using Mann-Whitney-U tests and Fisher's exact tests.
**Results:** A total of 180 DLE patients in the EU and US provided PSC data and were included in the analyses (mean age 39.5, disease duration 3.9 years, majority female [69%])
At the current visit, 25% of DLE patients were categorized as having moderate-to-severe disease. These patients self-reported a significantly and clinically lower EQ5D score compared to mild patients (0.86 vs. 0.94; p=0.0004), whilst also reporting a lower visual analog score (66.0 vs. 76.8; p=0.0005) indicating worse health-related quality of life. The reported impact of fatigue was also significantly greater amongst moderate-to-severe patients (FACIT-Fatigue score 36.0 vs. 43.4 among mild; p=0.0004). Moreover, moderate-to-severe DLE patients reported a greater degree of overall work impairment (30.0% vs. 18.0%; p=0.0612) and activity impairment (30.0% vs. 17.9%; p=0.0178). Finally, self-reported satisfaction with disease control was also significantly lower amongst these moderate-to-severe DLE patients (55% satisfied vs. 84%; $p < 0.0001$).
**Conclusions:** As reported by patients from a multinational sample in clinical care and compared to having a mild disease, having moderate-to-severe DLE was associated with a negative impact on quality of life, the ability to work and the ability to participate in activities, and satisfaction with disease control. Our research using PROs in a real-world setting, rather than in a clinical trial, adds to our limited understanding of the humanistic impact of DLE.

## FRI0322 DIAGNOSTIC UTILITY OF THE MINIMALLY INVASIVE BIOPSY OF THE MINOR SALIVARY GLAND

C. Galisteo, M. Garcia Manrique, J. Calvet, C. Orellana, N. Navarro, M. Moreno, M. Larrosa. *Rheumatology, Parc Tauli Sabadell Hospital Universitari, Sabadell, Spain*

**Background:** Sjögren's syndrome (SS) is a disease with a wide spectrum of clinical manifestations which can make diagnosis difficult. Due to difficult diagnosis the Americo-European classification criteria (AECC) are used. The positivity of antibodies or histology are essential to comply with these criteria, forcing in certain situations, especially in cases with negative immunology, to carry out a lip biopsy.
**Objectives:** To evaluate the diagnostic utility of the minimally invasive biopsy of the minor salivary gland.
**Methods:** Transversal study of 159 biopsies of the minor salivary gland. *Inclusion Criteria:* patients with dry syndrome. *Biopsy Technique:* vertical incision ($\leq$5 mm) of the internal surface of the lower lip whithout suturing. *Variables studied:* 1) Clinical: age, sex, presence and duration of the symptoms. 2) Diagnostic: The necessary examinations were performed to fulfill the AECC: Schirmer, salivary scintigraphy, ANA, RF, Ab-SSA and Ab-SSB. 3) Histological: a) degree of atrophy: absent, mild, moderate and severe; b) Chisholm-Mason scale (I-IV) considering as positive biopsy grade III or IV; c) degree of lymphocyte infiltration: absent, mild, moderate, severe; d) histological patterns: normal, nonspecific chronic sialadenitis (NSCS), sclerosing chronic sialadenitis (SCS), focal lymphocytic sialadenitis (FLS)
**Results:** The characteristics of the sample group were; age 59.9 ±12.43 years,

91% women, 88% xerostomia, 89% xerophthalmia for a period of 49±37 months, 45% positive salivary scintigraphy, 54% positive Schirmer, 54% AAN, RF 22%, Ab-Ro and Ab-La of 28% and 6.2% respectively. Appropriate material was obtained for histological study in 92.5%, being more frequent in older patients (60 ± 53 vs 12.2 ± 12.8; $p<0.05$). Analyzing the data after the biopsy, 16% (n=22) of patients met diagnostic criteria. Depending on the number of previous classificatory criteria 22% and 26% of patients met 3 and 4 criteria, respectively, were diagnosed of SS. Glandular atrophy was observed in 65% (n=95) with the following distribution: mild 38%, moderate 23%, severe 4%. The histological degree of atrophy was related to patient age ($r=0.38$; $p<0.0001$). Chisholm-Mason scale classified biopsies as normal (n=22; 15%), grade I (n=73; 50%), grade II (n=15; 10%), grade III (n=22; 15%) and grade IV (n=15; 10%), being biopsies positive in 25%. The most frequent histopathological pattern was NSCS (n=83; 57%), followed by FLS (n=37; 25%), normal (n=22; 15%) and SCS (n=5; 3%). Lymphocytic sialadenitis was observed in 85% (n=125; 47% mild, moderate 18%, severe 20%) but only 25% (n=37) presented the focal lymphocytic infiltration characteristic of SS. The positive biopsy was related to the positivity of Ab-Ro (40% vs. 22%; $p<0.0352$), Ab -La (10% vs 1%, $p<0.0002$), RF (35% vs. 18%; $p<0.03$) and ANA (70% vs 46%;. $p<0.01$) There was no difference between age and the different histological patterns, but SCS was more likely in patients with more advanced age

**Conclusions:** The minimally invasive biopsy of the minor salivary gland, could be currently considered essential for the diagnosis of SS, especially in patients who meet $\geq$3 criteria.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.4697

## FRI0323 A "COMPOSITE-INDEX" APPROACH FOR DEFINING SALIVARY GLAND INFLAMMATION, DYSFUNCTION AND ITS IMPACT ON PATIENT-REPORTED OUTCOMES: A ROLE FOR SALIVARY GLAND ULTRASONOGRAPHY?

C. Baldini, N. Luciano, F. Ferro, S. Bombardieri, M. Mosca. *Rheumatology Unit, University of Pisa, Pisa, Italy*

**Objectives:** To investigate the role of salivary gland ultrasonography (SGUS) in a composite index for the assessment of glandular involvement in primary Sjögren's syndrome (pSS), exploring whether SGUS may correlate with minor salivary gland focus score (MSG-FS), unstimulated salivary flow (USFR), patients' glandular symptoms, laboratory abnormalities, and physician global assessment (PhGA).

**Methods:** Consecutive patients with pSS (AECG criteria) were included in this cross-sectional study and systematically evaluated. SGUS was carried out by the same radiologist recording: size, parenchymal echogenicity and inhomogeneity, number of hypo/anechoic area, presence of lymph nodes and calcifications. A modified version of the De Vita score was adopted. All patients underwent sialometry and completed the ESSPRI, the VAS for xerostomia and the oral health impact profile (OHIP). The same physician assessed the ESSDAI and provided a PhGA score based on patients symptoms and laboratory abnormalities to quantify salivary gland activity according to a four grade scale (inactive, mild, moderate and severe glandular activity).

**Results:** We included 156 (152F:4 M) patients with pSS; out of them, 37 (23.7%) presented a small glandular swelling and 6 (3.8%) a major glandular swelling as defined according to the ESSDAI. MSG-FS was available for 125/156 (80%) patients. The median (IQR) USFR was 1,9 (0.2,3) ml/15'. Abnormal findings at SGUS examination were detected in 85/156 (55.5%) pSS patients. Forty-four (28.2%) pSS patients presented abnormal sonographic findings in both parotid and submandibular glands, whereas isolated pathological findings in either parotid glands or in submandibular glands were found in 22 (14.1%) and 19 (12.2%) patients, respectively. Age or disease duration did not influence the SGUS result. Higher SGUS scores were significantly more common in patients with glandular swelling with a direct correlation between the "glandular" domain of the ESSDAI and the SGUS score ($r=0.390$, $p=0.000$). A good correlation was also observed between PhGA and the SGUS score ($r=0.566$, $p=0.000$). A positive correlation was found between MSGB-FS and the total SGUS score ($r=0.431$, $p=0.000$) as well as between MSGB-FS and the single SGUS scores assigned to both parotid glands ($r=0.366$, $p=0.001$) and submandibular glands ($r=0.431$, $p=0.000$). The USFR and the SGUS score were inversely correlated ($r=-0.309$, $p=0.001$). VAS Dryness, ESSPRI and the OHIP index did not differ between normal or abnormal SGUS and were not correlated to the scores assigned to the ESSDAI "glandular" domain, to the MSGB-FS and to the USFR impairment. Finally, we confirmed that higher SGUS scores were significantly more common in patients with a higher total ESSDAI, lower C3/C4 levels, leukopenia, hypergammaglobulinemia, antiRo/SSA, antiLa/SSB, Rheumatoid Factor positivity and cryoglobulins ($p<0.01$).

**Conclusions:** This results highlight that to capture SS glandular activity a "composite index" would be the best choice. SGUS findings, significantly correlated with histopathology, salivary gland dysfunction, and both the ESSDAI "glandular" domain and the PhGA thus appearing as a complementary, promising tool for an integrate assessment of pSS salivary gland involvement in clinical practice and in clinical trials.

## FRI0324 WORK PRODUCTIVITY IN PRIMARY SJÖGREN'S SYNDROME: A CROSS-SECTIONAL MULTICENTER STUDY

C. Baldini[1], E. Bartoloni[2], R. Priori[3], F. Carubbi[4], A. Alunno[2], L. Quartuccio[5] on behalf of GRISS Group. *[1]Rheumatology Unit, University of Pisa, Pisa; [2]University of Perugia, Perugia; [3]Sapienza, University of Rome, Roma; [4]University of L'Aquila, L'Aquila; [5]University of Udine, Udine, Italy*

**Background:** Sjögren's syndrome (pSS) is generally considered a benign disease; however, given the high frequency of fatigue, articular and musculoskeletal pain and/or peripheral neurological disorders among pSS patients, the disease represents a potentially disabling disorder negatively affecting patient quality of life and work productivity. However, only limited information is available regarding the work ability of pSS patients.

**Objectives:** To assess work participation in a multicenter cohort of patients with pSS, and to explore whether work productivity differed across groups of patients when stratified according to disease activity and damage.

**Methods:** Consecutive pSS patients (AECG 2002) were recruited in 5 referral centers. Data collection included clinical examination, patient reported outcome measures (i.e. EULAR SS Patient Reported Index (ESSPRI), oral health impact profile questionnaire (OHIP), ocular surface disease index questionnaire (OSDI), Work Productivity and Activity Impairment Questionnaire (WPAI)) and laboratory assessment. The EULAR SS Disease Activity Index (ESSDAI) and the Sjögren's syndrome disease damage index (SSDDI) were used to assess disease activity and damage. We used data from WPAI and additional information on work participation to assess absenteeism (work time missed), presenteeism (impairment while at work) and overall work productivity loss (absenteeism plus presenteeism) due to pSS. We then compared work participation across patient groups stratified according to disease manifestations by Mann-Whitney U-test or chi-square test as appropriate.

**Results:** A total of 223 patients were included with median (IQR) age 62.5 (53, 69.5) years, median follow-up 5 (3, 11) years, 98% female gender and 56.2% anti-Ro/SSA positivity. Seventy-two patients (32.2%) reported current employment. Patients not reporting employment were retired (29.5%), or unemployed for other reasons (42.9%). On average, employed pSS patients reported a 9% (20%) mean (SD) absenteeism rate, a 35% (23%) mean (SD) presenteeism rate and a 38% (26%) mean (SD) overall work impairment rate due to health. In the entire cohort the mean (SD) activity impairment (AI) was 47,5% (27%). Primary SS patients with more aggressive disease manifestations, requiring steroids and immunosuppressive drugs, presented the highest rates of absenteeism and disability as assessed by AI. Additional determinants of AI were presence of arthritis ($p=0.02$) and fibromyalgia ($p=0.005$). Similarly, patients presenting arthritis reported significantly higher rates of absenteeism ($p=0.04$). Moreover, higher rates of presenteeism ($p=0.02$) and work productivity loss ($p=0.01$) were detected in patients showing a SSDDI$\geq$1. Finally, positive correlations were found between the ESSPRI, the VAS score for pain and fatigue, and the absenteeism rates, presenteeism rates, work productivity loss and AI, respectively ($p<0.01$).

**Conclusions:** Employment rates were particularly low among pSS patients. Determinants of work disability were fatigue, articular involvement and comorbidities, including fibromyalgia.

## FRI0325 CLINICAL AND SEROLOGICAL FEATURES ACCORDING TO AGE AT DIAGNOSIS OF PRIMARY SJÖGREN'S SYNDROME

C. Bohórquez Heras[1], C. Sanchez-Piedra[2], M. Fernandez Castro[3], J.L. Andreu[4], V. Martinez Taboada[5], A. Olivé[6], J. Rosas[7] on behalf of Sjögren-Ser Project (GEAS-SER). *[1]Immune System Diseases-Rheumatology Service, Príncipe de Asturias Hospital, Alcalá de Henares; [2]SER Research Unit; [3]Rheumatology Department, Infanta Sofía Hospital; [4]Rheumatology Department, Puerta de Hierro Hospital, Madrid; [5]Rheumatology Department, Marqués de Valdecilla Hospital, Santander; [6]Rheumatology Department, Germans Trias i Pujol Hospital, Barcelona; [7]Rheumatology Department, Marina Baixa Hospital, Alicante, Spain*

**Background:** Primary Sjögren's syndrome (pSS) is a chronic systemic autoimmune disease that usually affects middle age women. It is characterized mainly by the involvement of the exocrine glands; However, patients with pSS presents a broad spectrum of systemic involvement and serologic characteristics.

**Objectives:** The aim of this study is to analyze clinical and serological differences in different age at diagnosis groups in a pSS Spanish cohort.

**Methods:** This is a multicenter transversal study of pSS patients whose fulfilled European-American consensus criteria from thirty-three Rheumatology Units. The patients were randomized into the following age groups: $<$35 years, 35–50 years, 50–65 years and$>$65 years. Epidemiological, clinical and serological data were collected. All patients signed an informed consent, and the study was approved by the local ethics committees. Qualitative data were compared using the Chi-square tests. Quantitative variables were analyzed with a Kruskal-Wallis test. A value of $p<0.05$ was considered as significant.

**Results:** Four hundred and thirty-seven patients were included. The median age of the cohort was 58 years. Ninety-five percent of them were women.There were no statistically significant differences in the men and women percentage.The disease symptoms were initiated more frequently in 35–50 years group (38.5%).There

were no statistically significant differences in the time to disease progression in the four age at diagnosis groups. No statistically significant differences were found in sicca syndrome among age groups. Ocular and oral symptoms were present in 95% of patients. The glandular involvement (46.7%), central nervous system (14.13%) and Raynaud's phenomenon (29.3%) showed significantly more often in patients under 35 years. Genital involvement (54.5%) and asthenia (72.4%) showed significantly more often in the group of 35–50 years. The gastrointestinal involvement (20%) occurred significantly more frequently in the group of 50–65 years. Splenomegaly and cardiac involvement were less frequent manifestations in all four groups of patients (<4%). Rheumatoid factor (RF) positive was significantly higher in those under 35 years (77.1%). The anti-anti-SSA and SSB antibodies tended to be more frequently positive in groups <35 years (96.7% and 79.3% respectively) and>65 years (100% and 75% respectively). There were no significant differences in the ANA, anti-DNA, anti-Sm, anti-RNP, cryoglobulins and antiphospholipid antibodies values between groups.
**Conclusions:** Patients under 65 years old have an increased degree of systemic involvement. There are no differences in the presence of sicca syndrome. The FR is significantly more common in patients younger than 35-year-old, while the anti-Ro and anti-La antibodies tend to be it in more extreme age groups.

## FRI0326 PERIPHERAL LYMPHADENOPATHY IN PRIMARY SJÖGREN'S SYNDROME: FREQUENCY, PATTERN OF DISTRIBUTION AND CLINICAL SIGNIFICANCE - A SINGLE CENTER EXPERIENCE

E. Elefante, A. Parma, F. Ferro, N. Luciano, M. Mosca, S. Bombardieri, C. Baldini. *Rheumatology Unit, University of Pisa, Pisa, Italy*

**Objectives:** To analyze frequency and clinical determinants of SLN-US prescription in clinical practice; to explore patterns of nodal size/location and their clinical significance in Sjögren's syndrome (pSS)
**Methods:** In this retrospective, single center study we included patients with a diagnosis of pSS, regularly followed at our University Hospital in the time frame 2010–2015. Demographic, clinical and serological data were recalled from clinical charts. Patients with lymphadenopathy secondary to infections, malignancy, NHLs were excluded from the study. Variables analyzed included: clinical determinants of SLN-US, number of US evaluation/time, frequency, size and nodal locations of the SLN (axillary, inguinal, cervical, supraclavicular, other).
**Results:** We enrolled in this study 229 (224 F: 5M) patients with pSS (AECG 2002), mean age at diagnosis (DS) 49 yrs (14) and mean follow-up 5.6 yrs (6.6). All the patients included in the study underwent a SLN-US at least once in the time frame 2010–2015. Peripheral lymphoadenopathy was documented in 136/229 (59.4%) patients. The most common site for peripheral lymphadenopathy was the cervical region with the most affected LN groups at this level being the lateral – cervical lymph groups (55.5%). Inguinal LN were involved in the 11.4% of the cases and axillary LN in the 10.9%. In 29 (12.7%) patients, pSS affected simultaneously the LN groups located in several segments. On average, pSS patients underwent an US of SLN every 18 (12) months (mean (SD)) with a negative correlation between the frequency of SLN-US and the duration of follow-up (r=-0.742 p=0.000). Patients underwent a SLN-US either to characterize peripheral LN, palpable at physical examination, or as a routine screening test during the assessment of the disease activity in asymptomatic patients. On the basis of the SLN-US results we distinguished different patient groups: a) 26 patients with palpable LN and pathological SLN-US, b) 110 patients without palpable LN and subcentimer lymphadenopathy at SLN-US and c) 93 patients without palpable LN and normal SLN-US. Patients included in group a) were significantly younger at the diagnosis (p=0.003), more frequently male (p=0.001), had a significantly higher disease activity (p=0.001) and presented more often salivary gland swelling (p=0.007), low C3 levels (p=0.008), hypergammaglobulinemia (p=0.006), anti-Ro/SSA (p=0.000), anti-La/SSB (0.02), Rheumatoid Factor positivity (p=0.003) and cryoglobulins (p=0.02). No significant differences were detected when patients included in the group b) and c) were compared one to each other. No specific association was observed between LN location and disease related clinical and serological manifestations. However, patients with pathological LN located in several segments presented a significantly higher disease activity and a more complex serological profile (p<0.01).
**Conclusions:** Peripheral lymphadenopathy is quite common in pSS patients. However, only patients with palpable lymphadenopathy at clinical examinations or LN located simultaneously in several segments presented a distinguished more severe phenotype. Subcentimer lymphadenopathy tends to remain stable over the time and does not seem to represent a poor prognosis factor in pSS patients.

## FRI0327 SERUM ANTI-PHOSPHOLIPID ANTIBODY PREVALENCE AND CARDIOVASCULAR SIGNIFICANCE IN THE GENERAL POPULATION OF THE CAMELIA STUDY

C. Selmi[1,2], E. Generali[1], P.M. Battezzati[3,4], M. De Santis[1], A. Ceribelli[1,2], P.L. Meroni[4], M. Zuin[3,4]. *[1]Rheumatology and Clinical Immunology Unit, Humanitas Research Hospital, Rozzano (MI); [2]BIOMETRA Department, University of Milan; [3]Gastroenterology and Liver Unit, San Paolo Research Hospital; [4]University of Milan, Milan, Italy*

**Background:** The serum anti-phospholipid antibody (aPLs) prevalence in the general population and the association with cardiovascular disease and risk factors remain unclear.
**Objectives:** To test serum samples from a population study for aPLs and determine the presence of cardiovascular and metabolic comorbidities in a Northern Italian city.
**Methods:** We performed a cross-sectional study on 1712 adult subjects (median age 47 year-old, interquartile range 37–61, 49.8% women), randomly enrolled in 2010 from the voting lists of a 32.000-population city in the Lombardia region. All subjects completed a questionnaire for medical history and ongoing/past medications and underwent physical examination and abdomen and carotid ultrasound. Anti-cardiolipin (aCL), anti-beta2 glycoprotein I (aGPI), anti-phosphatidylserine-prothrombin (aSP) IgG, IgM, and IgA antibodies were tested in all subjects by ELISA.
**Results:** At least one aPL was positive in 258 (15.1%), at high titer in 56 (3.3%) subjects; 35 (2%) were positive for two or more aPL, 15 (0.9%) at high titer. Serum aCL were positive in 26 (1.5%) subjects, at high titer in 17 (1%), without additional aPL in 2; IgG in 15 (0.9%; at high titer in 11), IgM in 18 (1.1%, at high titer in 10), IgA at high titer in 4 (0.2%). Serum aGPI were positive in 73 (4.3%) subjects, at high titer in 48 (2.8%), without additional aPL in 4; IgG in 20 (1.2%; at high titer in 3), IgM in 28 (1.6%, at high titer in 6), IgA in 35 (2%, at high titer in 12). Serum aSP were positive in 201 (11.7%) subjects, at high titer in 29 (1.7%), without additional aPL in 167; IgG in 157 (9.2%, at high titer in 19), IgM in 65 (3.8%, at high titer in 12). Women represented 53.1% of aPL positive subjects, with higher incidence for aGPI, especially IgA, and aSP. Among aPL positive subjects, there were 10 cases of acute myocardial infarction, 7 strokes, 17 peripheral arteriopathy and 22 increased intimal-medial-thickness. Positivity for aPL was associated with older age, particularly for aGPI and aSP, while high-titer aCL IgG and aSP IgG were associated with tobacco smoking. Hypertension and hypercholesterolemia were significantly associated to aGPI IgG and IgM positivity, respectively. Hyperhomocystinemia was significantly associated with high titer multiple aPLs. Hyperuricemia was associated with aSP IgG positivity. Subjects with positive aPL had significantly higher frequency of thyroid disease (p=0.02 for high titer), peripheral arteriopathy (crude odds ratio –OR- 2; 95% confidence interval –CI- 1.2–3.6; isolated aCL crude OR 25.1; 95% CI 1.6–405.4), myocardial infarction (isolated aCL crude OR 28.5; 95%CI 1.8–460.5). Importantly, adjusted ORs for cardiovascular risk factors were not statistically significant.
**Conclusions:** We confirm that serum aPL are common in the general population, particularly at older age and possibly in association with smoking. Serum aPL is associated with common cardiovascular risk factors and specific events, however this latter effect needs to be clarified in the follow-up study to determine the real impact of aPL on the risk of cardiovascular events.

## FRI0328 A COMPLETE REMISSION LASTING AT LEAST ONE YEAR INFLUENCES THE OUTCOME IN PATIENTS AFFECTED BY SLE: RESULTS FROM A LARGE MONOCENTRIC COHORT

F. Ceccarelli, E. Cipriano, C. Perricone, I. Leccese, L. Massaro, F. Miranda, F. Morello, V. Pacucci, V. Orefice, M. Pendolino, C. Pirone, F.R. Spinelli, S. Truglia, C. Alessandri, G. Valesini, F. Conti. *Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome, Italy*

**Background:** The achievement of complete remission is one of the most important goal in the management of patients with Systemic Lupus Erythematosus (SLE). Even though a definition of remission has been proposed (complete absence of any clinical and serological sign or symptom of activity) and the concomitant acceptable treatment (including antimalarial drugs only) has been identified, however the minimum lapse of time is still controversial. This issue is of primary importance in a disease characterized by a relapsing-remitting course. Several cut-off have been suggested, ranging from 1 to 5 years.
**Objectives:** The primary end-point of the present study was to analyze the frequency of complete remission lasting at least 1 year in a large monocentric SLE cohort. Furthermore, we aimed at evaluating its association with different clinical and serological parameters and its impact on the chronic damage accrual.
**Methods:** Data on Caucasian SLE patients, diagnosed according to the ACR Classification Criteria for SLE, were collected. We included in the present analysis SLE patients evaluated at least twice per year during the last 5 years. The frequency of complete remission, defined as an SLE Disease Activity Index 2000 (SLEDAI-2k) =0, was assessed in glucocorticoid-free and immunosuppressant-free patients. Antimalarial drugs were the only SLE-related acceptable treatment.
**Results:** Our database includes 658 SLE patients evaluated at least once. From these patients non-Caucasian were excluded, resulting in 622 patients. Among

these, 179 (M/F 13/166, mean age 46.3±12.7 years, mean disease duration 173.9±101.9 months) fulfilled the above-reported selection criteria. During the 5-year follow-up, 27 patients (15.1%) experienced a complete remission lasting for at least 1 year, with a mean duration of 37.5±15.8 months. Notably, six patients experienced a prolonged complete remission lasting 5 years (4.6%). There were no significant differences in terms of demographic characteristics between patients achieving and those not achieving remission. Patients in remission showed a significantly lower frequency of renal involvement (29.0 vs 18.4, P=0.04) and low C3 and C4 (14.8% vs 36.8%, P=0.0005; 14.8% vs 33.5%, P=0.0002, respectively). There were no other differences in terms of clinical and laboratory features. The frequency and the severity of chronic damage, evaluated by SLICC Damage Index (SDI), resulted significantly lower in patients achieving remission (11.1% vs 51.9%, P<0.000001; 0.48±0.8 vs 0.8±1.2, P=0.03, respectively). The length of the remission status did not influence the chronic damage. At the multivariate analysis, no independent factors were associated with remission; conversely, low C3 resulted a risk factor for absence of remission (OR=0.15, 95% CI 0.03–0.06).

**Conclusions:** In the present SLE cohort, a complete remission lasting at least 1 year has been identified in 15% of patients. The remission status, regardless of its duration, is associated with a lower chronic damage, in terms of frequency and severity. These results suggest that the achievement of a state of remission lasting at least one year may represent a favorable prognostic factor in patients with SLE.

## FRI0329 BONE EROSIVE DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS IS ASSOCIATED WITH LOCAL HYPERVASCULARIZATION INDEPENDENTLY FROM ACPA POSITIVITY

F. Ceccarelli, C. Perricone, E. Cipriano, L. Massaro, M. Pendolino, G. Capalbo, F.R. Spinelli, C. Alessandri, F. Conti, G. Valesini. *Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome, Italy*

**Background:** Joint involvement is one of the most frequent manifestations in patients affected by Systemic Lupus Erythematosus (SLE). It is characterized by a wide heterogeneity ranging from arthralgia to a severe erosive disease. The presence of local hypervascularization, evaluated by power Doppler (pD), is a well-established risk factor for the development of erosive damage in patients affected by Rheumatoid Arthritis (RA), together with the positivity for anti-citrullinated peptide antibodies (ACPA). To date, these data are not confirmed in SLE patients.

**Objectives:** The aim of the present study was to estimate whether pD-evaluated local hypervascularization and the presence of ACPA represent risk factors for the development of erosive damage, assessed by ultrasonography, in SLE patients.

**Methods:** One hundred two SLE patients with joint involvement were enrolled (M/F 1/101; mean age 44.5±11.6 years; mean disease duration 144.6±103.2 months). The ACPA presence was evaluated in 64 patients (ELISA, Euroimmun Italia, Italy). Ultrasonographic assessment of metacarpophalangeal (MCP), proximal interphalangeal (PIP) and metatarsophalangeal (MTP) was performed in all patients. The presence of pD and erosive damage were recorded by a dichotomic (present/absent) and a semiquantitative (0–3) score. A total score was obtained by the sum of modifications observed in every single joint.

**Results:** Hypervascularization in at least one joint was identified in 25/102 (24.5%) patients (median score 4, range 1–23). This feature was more frequent at level of II and III MCP (12.7% and 8.8% respectively). Erosive damage was detected in 19 patients (18.7%). The presence of pD signal was significantly associated with the presence of erosive damage. Indeed, 13 pD-positive patients showed erosions (13/25, 52.1%) in at least one joint, compared with 6/77 (8.4%) pD-negative patients (median 1, range 0–9 *vs* median 0, range 0–7, P<0.0001). 21.8% of patients tested ACPA positive. However, there was no association between erosive damage and ACPA positivity. The erosive damage was reported in 21.4% of ACPA-positive patients and in 22.0% of ACPA-negative (P=NS).

**Conclusions:** In the present study, we described for the first time the association between the presence of local hypervascularization, identified by pD ultrasonography, and erosive damage in a cohort of SLE patients with joint involvement. These results, similarly to RA, suggest the role of pD signal as a negative prognostic factor for erosive bone damage. This could help in the choice of a more aggressive therapeutic strategy. Conversely, the presence of ACPA does not seem to be associated with erosive damage, suggesting the presence of an alternative pathogenetic mechanism underlying the erosive damage in SLE patients.

## FRI0330 PREDICTIVITY OF OCULAR SURFACE PARAMETERS AND TEAR PROTEIN EXPRESSION IN THE DIAGNOSIS OF SJÖGREN SYNDROME VERSUS DRY EYE

G. Vukatana[1], P. Versura[2], M. Trevisani[1], P. Giannaccare[2], A. Buffa[1], R. Mulè[1], S. Corvaglia[1], E. Rossi[1], N. Malavolta[1]. *[1]Rheumatology Unit, Alma Mater Studiorum, S.Orsola-Malpighi Teaching Hospital; [2]Ophtamology Unit, DIMES, Alma Master Studiorum, S.Orsola-Malpighi Teaching Hospital, Bologna, Italy*

**Background:** Several studies report alterations of protein expression profiles of inflammatory cytokines in the tears of patients with dry eye syndrome. Futhermore several non cytokine proteins such as lysozyme, lactoferrin, lipocalin, etc were found to be altereted too (1). The minimal invasiveness of the methods of sample collection using glass microcapillary tubes makes tear fluid very interesting option for proteomic studies, although analysis may be challenging because of the small volume of tear fluid (>5nl) that can be collected (2).

**Objectives:** to discriminate the difference between ocular surface parameters and protein expression in tears of patients with dry eye syndrome and patients affected by Sjögren syndrome.

**Methods:** 80 patients (female 77) with sicca syndrome arrived in a period included from September 2010 to May 2015, in our Rheumatologic Unit were evaluated. Break Up time (BUT), Schirmer and Jones test, fluorescin and green lisamin coloration, citologic analysis of conjuctive for scraping/impression was done in each patients to evaluate the ocular surface parameters. 5 nl of tear fluid, was collected on external angle by using a glass microcapillary tube. The tear fluid sample was then analysed by Agilent 2100 Bioanalyzer system to detect non cytokine protein patterns. Scintigrafic parameters for salivary gland impairment, ANA, ENA, rheumatoid factor and albumin was researched too. The sensibility, the specificity and the predictive value (PV+ and PV -) was calculated for each protein evaluated. Statistic analysis was performed by using SPSS 20.0 IBM, Mann-Whitney test for indipendent samply and ROC curve.

**Results:** 25/80 patients was affected by Sjögren syndrome according to Vitali Criteria of 2002. Demografic and laboratoristic data of both groups were calculated. Significant reduction of BUT, fluorescin and green lisamin coloration value were observed in patients with Sjögren syndrome versus patients with dry eye. Significant reduction of lipocalin and lysozyme concentration were evaluated in patients affected by Sjogren syndrome versus the dry eye group. Lipocalin and fluorescin coloration risult having a high predictive value to discreminate patiens affected by Sjogren syndrome from patient with dry eye.

**Conclusions:** Protein pattern alterations in tears represent a high potential to generate biomarkers for disease state determination and provide sources for new diagnostic procedures and treatment response. In this study the observed reduction of lipocalin concentration and fluorescin coloration value was determinant to distinguish patients affected by Sjögren syndrome from patients with dry eye.

## FRI0331 PREVALENCE OF COMORBIDITIES IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS: A COMPARATIVE, REGISTRY-BASED STUDY WITH EMPHASIS IN CARDIOVASCULAR DISEASE

I. Rúa-Figueroa[1], M. Fernández de Castro[2], J.L. Andreu[3], C. Sanchez-Piedra[4], V. Martínez-Taboada[5], A. Olivé[6], J. López-Longo[7], J. Rosas[8], M. Galindo[9], J. Calvo-Alén[10], A. Fernández-Nebro[11], B. Rodríguez-Lozano[12], J.M. Pego-Reigosa[13] on behalf of SJÖGREN-SER and RELES-SER Researchers and EAS-SER Group. *[1]Rheumatology, Hospital Dr. Negrin, Las Palmas GC; [2]Rheumatology, Infanta Sofía Hospital; [3]Rheumatology, Puerta de Hierro Hospital; [4]Research Unit, Spanish Society of Rheumatology, Madrid; [5]Rheumatology, Marqués de Valdecilla Hospital, Santander; [6]Rheumatology, Germans T. i Pujol Hospital, Barcelona; [7]Rheumatology, Gregorio Marañón Hospital, Madrid; [8]Rheumatology, Marina Baixa Hospital, Villajoyosa; [9]Rheumatology, 12 Octubre Hospital, Madrid; [10]Rheumatology, Araba Hospital, Vitoria; [11]Rheumatology, Carlos Haya Hospital, Málaga; [12]Rheumatology, University Hospital of Canarias, Tenerife; [13]Rheumatology, Hospital Complex of Vigo, Vigo, Spain*

**Background:** Reliable data regarding the prevalence of specific medical comorbidities among patients with PrimarySjögren's Syndrome (pSS) remain sparse and there are not comparative studies among patients with pSS and patients with Systemic Lupus Erythematosus (SLE).

**Objectives:** To compare the prevalence of the main comorbidities of two large cohorts of patients with pSS and SLE, with focus in cardiovascular (CV) diseases.

**Methods:** Cross-sectional multicenter study comparing cumulative prevalence of the most relevant comorbidities, with identical definition in both cohorts. Patients on follow-up from SJOGRENSER (Spanish Register of pSS) and RELESSER (Spanish Register of SLE), fulfilling AECG-2002 and ACR-97 classification criteria, were included. Binomial logistic regression analysis was carried out to explore

potential differences, adjusting for age, sex and disease duration with further specific adjustments for each variable, including CV risk factors and treatments, when it was considered convenient.
**Results:** 437 pSS (95.2% female) and 2,960 SLE (89.5% female) patients were included. Mean age: 58.6 (p55-p75: 50.0–69.9) and 46.4years (22.4–41.6) respectively ($p<0.001$). Disease duration 10,4 (6.0–16.7) and 13.3 years (8.80–20.04) respectively ($p<0.001$).
Patients with pSS were hospitalized by the disease activity lesser than SLE: 17% vs 53%, $p<0.001$; OR 0.18 (95%CI:0.14–0.24). Moreover, the use of GC or IS were less prevalent in pSS [GC: 49.4% in pSS vs 88.2% in SLE; OR:0.13 (0.10–0.16); azathioprine: 10.1% vs 32.4%; OR: 0.24 (0.17–0.33); mycophenolate: 3.9% vs 16.2%; OR:0.21 (0.13–0.35); cyclophosphamide: 3.0% vs 22.6%; OR: 0.11 (0.06–0.18)].
The following comorbidities were less prevalent in pSS: Smoking [25.3% vs 48.2%, $p<0.001$, OR:0.50 (95%CI:0.40–0.64)], hypertension [25.3%vs 27.3%, $p<0.001$, OR: 0.44 (0.33–0.58)] and life-threatening CV events [(6.8% vs 8.5%, OR:0.53 (0.32–0.87)]. Severe infections were also more frequent in SLE [17.7% vs 10.1%, $p<0.001$, OR: 0.52 (0.37–0.72)], but this difference lost statistical significance when adjusted for glucocorticoid (GC) and immunosupressors (IS) use. Conversely, fibromyalgia and lymphoma were more frequent in pSS [14.6 vs 5.2%, $p<0.001$, OR: 2.70 (1.93–3.80)] and [1.6 vs 0.3%, $p=0.002$; OR: 5.71 (1.83–17.79)] respectively.
**Conclusions:** pSS patients have consistently less serious comorbidity burden compared with SLE patients, namely less CV diseases and less infections. In contrast, the risk of lymphoma exceeds that seen in SLE patients. The higher prevalence of CV events in SLE does not seem to be explained only by traditional CV risk factors, suggesting that SLE derived factors could be involved.

## FRI0332 FACTORS AFFECTING THE ATTITUDES OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS REGARDING POTENTIAL CLINICAL TRIAL PARTICIPATION

J. Braverman[1], S. Lops[2], E. Felicione[2], C. Wagner[2]. *[1]PatientsLikeMe, Inc, Boston; [2]Janssen Research and Development, LLC, Spring House, United States*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disorder affecting skin, joints, kidneys, brain, and other organs[1]. Recruiting participants for SLE clinical trials may be challenging for several reasons including patients' concerns that medications may exacerbate their condition or cause side effects[2].
**Objectives:** To address challenges of recruiting patients with SLE into clinical trials, we conducted a survey study to: (1) explore patients' satisfaction with their current treatment; (2) assess participants' motivations to switch to a new treatment; and (3) identify the characteristics of patient who indicated a willingness to participate in a clinical trial.
**Methods:** 259 members of an online patient network aged 18–77 (mean age = 47; 96% female, 78% white) with SLE completed an online survey about their experience and attitudes. The data was collected within 7 days. We used the Chi-square test to analyze the distribution of categorical variables; two sample t-tests to compare group means and Pearson r correlation to identify the association between continuous variables.
**Results:** 60% of SLE patients report being at least "somewhat satisfied" with their current treatment; 74% name worsening symptoms as an important factor for changing medications. Those patients (36%) who said they were motivated to change to a new treatment reported a slightly more severe daily impact of SLE (mean = 3.6 on a scale 1: not at all – 5 very much) than patients who did not see new treatment availability as a reason to change their current medication (SLE impact mean = 3.3; $t(258)=2.49$; $p<0.01$). 29% say knowing that a trial drug has never been tested before will increase the likelihood of their participation in the trial. The correlation analyses revealed slight, but statistically significant association between this favorable view of novel drug trials and higher number of treatments, frequency of healthcare utilization, and lupus daily impact (r ranged 0.13–0.22, $p<0.03$). The disease-related factors positively associated with likelihood of clinical trial participation are SLE daily impact ($r=0.26$, $p<0.03$), headaches ($\chi^2=14.06$, $p<0.01$), and pain ($\chi^2=8.8$, $p<0.05$); the treatment-related factors are burden of treatment, frequency of flares, frequency of healthcare utilization, number of medications (r ranged 0.14–0.18, $p<0.03$), and use of pain medications ($\chi^2=12.6$, $p<0.05$).
**Conclusions:** Investigators and clinical trial coordinators may achieve a higher recruitment and retention rate by targeting: 1) patients whose SLE symptoms are under poor control and who therefore frequently utilize the healthcare system rather than patients with low disease activity or stable disease; and 2) those patients who are experiencing more pain and headaches and more frequently using pain medications.

## FRI0333 HEMOGLOBIN, COMPLEMENT 3 AND CAROTID IMT ARE ASSOCIATED WITH LOW FREE PROTEIN S IN SLE

J.-Y. Jung, H.-A. Kim, C.-H. Suh. *Rheumatology, Ajou University of medical school, Suwon, Korea, Republic Of*

**Background:** Protein S plays a role as a cofactor not only in coagulation pathway, but also in the removal of apoptotic remnants. Free protein S was investigated whether it could represent as a disease related marker in systemic lupus erythematosus (SLE), which has a defect in clearance of apoptotic debris[1,2]. In SLE, cardiovascular diseases including myocardial infarction and stroke develop more frequently and earlier than healthy population. It has become important to find underline mechanisms about the advanced atherosclerosis in SLE[3].
**Objectives:** We measured free protein S and carotid atherosclerosis using Doppler sonography among SLE patients, and analyzed their associations with clinical features including disease activity markers.
**Methods:** Total of 110 female patients with SLE were recruited and serum free protein S level was evaluated by enzyme-linked immunosorbent assay. The carotid artery intima media thickness (cIMT) and plague were measured by Doppler ultrasound and the clinical characteristics were collected.
**Results:** Mean level of free protein S was 67.4±19.7%, and 21 patients had low level of free protein S, defined as less than 50%. Hemoglobin and lymphocyte count were significantly lower (11.4±1.4 vs 12.5±1.4, $p$=0.002 and 1, 221±609 vs 1,720±1,097, $p$=0.047), and erythrocyte sedimentation rate (ESR) was significantly higher (30.1±20.6 vs 20.8 ± 17.8, $p$=0.033), complement 3 (C3) and complement4 (C4) were significantly lower (80.8±27.6 vs 103.4±25.8, $p$=0.001 and 15.6±10.4 vs 21.5±7.6, $p$=0.005) in SLE patients with low free proteins S level compared to those not. Carotid IMT levels were different (3.78±0.69 vs 4.13±0.87, $p$=0.051) while plaque index was not different between two groups. On univariate logistic analysis, hemoglobin (OR 0.6, $p$=0.003), lymphocyte (OR 1.0, $p$=0.03), ESR (OR 1.03, $p$=0.041), C3 (OR 0.96, $p$=0.001), and C4 (OR 0.91, $p$=0.007) were related with free protein S. With adjustments, hemoglobin (OR 0.57, $p$=0.023), C3 (OR 0.94, $p$=0.017) and cIMT (OR 0.51, $p$=0.046) were associated with low free protein S.
**Conclusions:** Hemoglobin, complement 3 and cIMT were independently associated with low free protein S in SLE patients. Moreover, cIMT showed negative influence to low free protein S. From this clinical data, endothelial thickness might contribute free protein S rise in SLE patients.

## FRI0334 ALTERED CUTANEOUS MICROVASCULAR FUNCTION IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

K. Perdan Pirkmajer[1], E. Blokar[1,2], M. Čepar[1,2], Ž. Melik[2], A. Ambrožič[1], K. Cankar[2]. *[1]Department of Rheumatology, University Medical Centre Ljubljana; [2]Institute of Physiology, Medical faculty, University of Ljubljana, Ljubljana, Slovenia*

**Background:** Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterized by thrombotic events and/or pregnancy morbidity in the persistent presence of antiphospholipid antibodies (aPL). The mechanisms by which aPLs cause thrombosis have not been completely elucidated. Recent studies suggest that thrombosis may be linked to diminished production of nitric oxide (NO) in endothelial cells. Endothelium-derived NO normally exerts anti-thrombotic and vasodilator effects. Diminished NO production in APS patients may therefore result not only in thrombosis but also blunted vasodilator responses. Whether patients with APS display blunted NO-stimulated vasodilation has not been directly determined.
**Objectives:** We determined endothelium-dependent and endothelium-independent vasodilator response in cutaneous microvasculature of APS patients and healthy controls.
**Methods:** Patients with primary or secondary APS (all positive for at least two different aPL) and healthy controls were enrolled between May 2014 and May 2015. Participants were asked to avoid coffee, tea or energy drinks on the day the measurements were performed. During the 2-hour measurement protocol electrocardiogram, arterial blood pressure and laser Doppler flux of cutaneous

microvessels were monitored. Iontophoresis of acetylcholine, which stimulates NO production in endothelial cells, was used to assess endothelium-dependent vasodilation. Iontophoresis of sodium nitroprusside, a direct NO donor, was used to assess endothelium-independent vasodilation. Finally, local warming (42°C) of skin on the left forearm skin was used to assess heat-stimulated vasodilator response. Data were analyzed using independent samples t-test or repeated measures ANOVA followed by Dunnett's test.
**Results:** Thirty four APS patients and 34 healthy age and sex-matched controls completed the study (24 female and 10 male in each group, age range 22–74). Participants were divided into three age groups, 22–38 years (12 female per group), 39–49 (5 female, 6 male per group) and ≥50 (7 female, 4 male per group). Acetylcholine iontophoresis, sodium nitroprusside iontophoresis or local heating stimulated vasodilation in all participants. Endothelium-dependent vasodilator response to acetylcholine was blunted in APS patients aged ≥50 ($P<0.050$ vs. healthy controls), but remained unaltered in younger participants. Conversely, vasodilator response to local heating was blunted in APS patients from the 22–38 age group ($P<0.050$ vs. healthy controls). Endothelium-independent vasodilation stimulated by NO donor sodium nitroprusside was similar in all groups.
**Conclusions:** Here we show that endothelium-dependent vasodilator response in cutaneous microvasculature is diminished in older APS patients, while changes in vasodilator response to local heating affect mainly younger APS female patients. Our results indicate that cutaneous microvasculature in APS is functionally altered. This study supports diminished endothelial NO production in patients with APS.

## FRI0335 AN EVALUATION OF CLINICAL OUTCOME MEASURES FOR MUSCULOSKELETAL LUPUS USING ULTRASOUND AS A GOLD STANDARD

K. Mahmoud[1,2], A. Zayat[1,2], C.J. Edwards[3], M.Y. Md Yusof[1,2], H. Cassamoali[1,2], M. D'Agostino[1,2], P. Emery[1,2], E.M. Vital[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Biomedical Research Unit, Leeds Teaching Hospitals, Leeds; [3]Musculoskeletal Research Unit, NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton, Southampton, United Kingdom*

**Background:** Musculoskeletal symptoms in SLE patients are common, but difficult to assess clinically. Ultrasound (US) is an objective measure of synovitis.
**Objectives:** To test clinical tools currently used for musculoskeletal lupus against US as a gold standard.
**Methods:** A multicentre cross-sectional study recruited 107 patients in Leeds and Southampton fulfilling ACR/SLICC criteria for SLE, all had history of musculoskeletal symptoms and 79% had pain at the time of evaluation. Patients with positive CCP or RF were excluded. Patients were clinically assessed using BILAG, SLEDAI, tender joint count (TJC), swollen joint count (SJC), physician and patient VAS (both 0–100, for MSK symptoms). US hand was used to examine joints and tendon sheaths.
**Results:** There was disagreement between US and clinical joint swelling in 26% of patients. In the 40% with clinical joint swelling, US confirmed this in 83%. 20% of all patients had US synovitis that was not detected clinically. Overall, objective synovitis was found in 40% of patients using clinical swelling and 53% using US. US was correlated with SJC (R=0.389, P≤0.001), MSK-BILAG numeric score (R=0.503, P≤0.001), and physician VAS (R=0.5, P≤0.001), but not with TJC, SLEDAI, or patient VAS. We then looked for clinical appearance of patients with US-proven synovitis: see table 1. We identified significant associations in the whole cohort. In multivariate analysis only physician-VAS was significant (p=0.018). However, in 50 patients with no joint swelling, 15 had US synovitis, but no clinical variable could identify this.

Table 1

| | US+ve, median (IQR) | US–ve, median (IQR) | p |
|---|---|---|---|
| MSK- BILAG | 2 (2) | 3 (1) | <0.001 |
| SLEDAI | 4 (6) | 2 (4) | 0.006 |
| Physician VAS | 41 (50) | 8 (20) | <0.001 |
| Patient VAS | 55 (33) | 45 (70) | 0.085 |
| ESR | 21 (45) | 12.5 (24) | 0.086 |
| TJC | 6.5 (10) | 3 (9) | 0.034 |
| SJC | 1.5 (4) | 0 (0) | <0.001 |

**Conclusions:** Swollen Joint Count, Physician VAS, and MSK-BILAG all correlate with true synovitis as defined by US. However, these variables are all based on the clinical detection of joint swelling and 50% of this cohort did not have joint swelling. In the latter group, no clinical variable was helpful in identifying the 30% of patients with US-proven synovitis. US should be used to evaluate MSK-SLE patients who do not have clinical synovitis.
**Disclosure of Interest:** None declared

## FRI0336 HYPOCOMPLEMENTEMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS; ESTABLISHING THE IMPORTANCE OF LOW C3 AND C4 IN A LONGITUDINAL COHORT

L. Durcan[1,2], W. Fu[2], M. Petri[2]. *[1]Rheumatology, University of Washington, Seattle; [2]Rheumatology, Johns Hopkins, Baltimore, United States*

**Background:** Despite inclusion in systemic lupus erythematosus (SLE) disease activity indices and classification criteria, the relationship between hypocomplementemia, disease manifestations and cumulative organ damage has not been systematically investigated. It is also unknown whether there is a particular disease phenotype associated with chronic, unresolving hypocomplementemia.
**Objectives:** To evaluate SLE patients with a history of hypocomplementemia, to establish the relationship between clinical manifestations and organ damage. To compare low C3 to low C4 and establish relative importance for manifestations and damage parameters. To assess SLE patients with persistent hypocomplementemia to ascertain whether these patients have unique clinical characteristics.
**Methods:** As part of a lupus cohort, C3 and C4 were measured quarterly. Using univariate and multivariate methods, those with and without a history of low C3, low C4 and both were compared and an odds ratio calculated and compared using generalized linear hypothesis testing. We then considered those who had persistent hypocomplementemia (i.e. complement never normalized, on a minimum of 3 evaluations) and compared them to patients with a similar number of assessments.
**Results:** 2399 patients were included in the analysis; 47% had a history of low C4 and low C3 in 55%. Persistently low C3 was found in 83 (4.0%) and C4 in 65 (3.2%). A history of low C3 associated strongly with nephritis and with renal damage parameters. Low C4, in isolation, associated only with false positive RPR and the presence of arthritis. With unresolving hypocomplementemia (Table 1), strong associations were demonstrated between low C3, low C4 and both in combination and hematologic, serologic and antiphospholipid-related parameters. No associations were found for cutaneous disease. Persistently low C3 associated with nephritis.

Table 1

| Manifestation | | Persistent low C3 OR | P value | Persistent low C4 OR | P value | Persistent low C3+C4 OR | P value |
|---|---|---|---|---|---|---|---|
| Arthritis | | 1.48 | 0.2266 | 0.87 | 0.6787 | 1.59 | 0.3639 |
| Serositis | Pleurisy | 1.15 | 0.6116 | 1.22 | 0.5334 | 0.94 | 0.8786 |
| | Pericarditis | 1.76 | 0.0647 | 1.52 | 0.2597 | 0.45 | 0.2837 |
| Renal | | 3.40 | 0.0030 | 0.53 | 0.5407 | 1.89 | 0.3978 |
| Neurologic | Seizures | 1.14 | 0.7664 | 0.80 | 0.7089 | 0.44 | 0.4224 |
| | ACS | 1.21 | 0.8014 | 0.86 | 0.8834 | 1.49 | 0.6992 |
| Hematologic | Hemolytic anemia | 1.68 | 0.2536 | 4.56 | 0.0001 | 0.62 | 0.6453 |
| | Leukopenia | 3.78 | <0.0001 | 2.35 | 0.0079 | 2.58 | 0.0240 |
| | Lymphopenia | 1.99 | 0.0114 | 2.78 | 0.0019 | 1.11 | 0.8009 |
| | Thrombocytopenia | 2.44 | 0.0032 | 2.44 | 0.0122 | 1.64 | 0.3375 |
| Immunologic | Anti-dsDNA | 10.71 | <0.0001 | 2.93 | 0.0021 | 8.48 | 0.0006 |
| | Anti Sm | 6.8 | <0.0001 | 3.31 | 0.0013 | 2.98 | 0.0252 |
| Anti-phospholipid | Anti-cardiolipin | 1.49 | 0.1467 | 2.39 | 0.0089 | 1.44 | 0.4020 |
| | Anti-B2 GP | 4.48 | 0.0001 | 2.42 | 0.1264 | 2.59 | 0.1462 |
| | FP RPR | 2.83 | 0.0041 | 2.87 | 0.0119 | 3.65 | 0.0300 |
| | LAC | 1.98 | 0.0159 | 2.1 | 0.0255 | 1.38 | 0.4858 |

**Conclusions:** A history of, and chronically low C3 associates uniquely with renal disease whilst a history of low C4, associated only with arthritis and a false positive RPR.
Persistent hypocomplementemia associated strongly with other hematological and serological abnormalities. While a history of low C4 was not strongly associated with other disease activity parameters, chronically low C4 appears to be a more important marker.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3767

## FRI0337 ANTI-C1Q AUTOANTIBODIES, C1Q CIRCULATING IMMUNE COMPLEXES AND COMPLEMENT LEVELS IN PATIENTS WITH NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

C. Magro-Checa, R.A. Schaarenburg, H.J.L. Beaart, T.W. Huizinga, G.M. Steup-Beekman, L.A. Trouw. *Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Experimental SLE-models show that complement activation may be a key part of lupus cerebritis and lupus-thrombosis. It is also known that complement factors contribute to the pathology of inflammatory central nervous system (CNS) and neurodegenerative diseases
**Objectives:** To analyse serum levels of anti-C1q, C1q circulating immune complexes (CIC), complement activation and complement components in systemic lupus erythematosus (SLE) patients during the first CNS neuropsychiatric (NP) event and to define the possible association between these results and clinical and laboratory characteristics
**Methods:** Patients suspected of having NP involvement due to SLE were recruited in the Leiden NPSLE-clinic. All SLE patients were classified according to the ACR 1982 revised criteria for the classification of SLE. The clinical disease activity was measured by the SLE Disease Activity Index 2000 (SLEDAI-2K) and NP diagnoses were classified according to the 1999 ACR case definitions for NPSLE.

We measured in serum of all patients anti-C1q and C1q CIC levels using ELISA, the activation capacity of complement (CH50 and AP50) using functional assays and different complement components (C1q, C3, C4) using laser nephelometry. Two-hundred healthy controls (HC) were also included for comparison

**Results:** A total of 280 patients were included. In 92 patients the symptoms were attributed to SLE. NPSLE patients consisted of 63 patients with focal NPSLE and 34 patients with diffuse NPSLE. Anti-C1q antibodies were significantly higher and CH50, AP50 and C3 were significantly lower in NPSLE patients compared to SLE and HC. This association was specially marked for diffuse NPSLE (SLE: 20.8 versus 8.7; HC: 20,8 versus 7,04; both comparisons $P<0.05$). No differences in antibody titters were found for C1q CIC when SLE and NPSLE patients where compared. Low C4 was significantly associated with focal NPSLE after using potential predictors, but we lost this association when antiphospholipid antibodies (aPL) were excluded from the model. Low C3, AP50 and CH50 were independently associated with diffuse NPSLE ($P<0.001$). When SLEDAI-2K was included in the model we did not find any association. When individual NPSLE syndromes were analysed, psychosis and cognitive dysfunction showed significantly lower values of AP50 and CH50 ($P<0.001$ for psychosis and $P<0.05$ or cognitive dysfunction). Furthermore, patients with lupus psychosis showed higher prevalence of low C1q (OR=5, 95% CI 1.5–15.8, $P<0.05$), low C3 (OR=28.6, 95% CI 3.5–230.4, $P<0.001$) and low C4 (OR=3.8, 95% CI 1.1–13.3, $P<0.05$) and cognitive dysfunction showed a higher prevalence of low C1q (OR=5, 95% CI 1.5–15.8, $P<0.05$), low C3 (OR=4.4, 95% CI 1.8–10.5, $P<0.001$) and low C4 (OR=3.6, 95% CI 1.5–8.6, $P<0.05$) when compared with SLE. No significant associations were seen with other individual NPSLE syndromes

**Conclusions:** No association was found between anti-C1q, C1q CIC and NPSLE. The associations between diffuse NPSLE and low C3/AP50 and focal NPSLE and low C4 may be explained by disease activity and the presence of aPL respectively. The role of complement activation and complement components in lupus psychosis and cognitive dysfunction merits further research

## FRI0338 EVALUATION OF THE SENSITIVITY AND SPECIFICITY OF THE SJÖ® DIAGNOSTIC TEST

L. Shen[1], L. Suresh[1], Y. Sun[2], G. Shi[2]. *[1]R&D, Immco Diagnostics, Buffalo, United States; [2]Rheumatology, The First Hospital of Xiamen University, Xiamen, China*

**Background:** An early and accurate diagnosis of Sjögren's Syndrome is an important factor in limiting complications of the disease. Achieving this diagnosis has historically proved challenging, requiring a number of diagnostic tests including serology [1]. The utility of the traditional serological markers (SSA/Ro, SSB/La, Antinuclear Antibody, Rheumatoid Factor) have several limitations, including a combined sensitivity and specificity of approximately 40–60%, lack of detectability in approximately 20–30% of cases, lack of detectability early in the disease process, and lack of target-organ specificity [1,2].

Sjö™ is an advanced diagnostic panel for the early detection of Sjögren's Syndrome. It includes the traditional biomarkers as well as three novel, proprietary biomarkers (SP-1, CA6, PSP) that provide high sensitivity and specificity for Sjögren's Syndrome, are target-organ specific and appear early in the disease process [3,4].

**Objectives:** To Evaluate the sensitivity and specificity of the advance Sjö panel in comparison to the traditional serological markers.

**Methods:** Antibodies to the traditional markers (SSA [Ro], SSB [La], antinuclear antibody [ANA], and rheumatoid factor [RF]) and the novel biomarkers (salivary protein-1 [SP1], carbonic anhydrase-6 [CA6] and parotid secretory protein [PSP]) in patient sera samples were detected using the Sjö panel. To assess sensitivity, sera samples from 267 confirmed SS patients across 3 clinical studies were analyzed with Sjö. To assess specificity, sera samples from 125 age- and sex-matched controls, as well as 64 pediatric controls, were analyzed with Sjö.

**Results:** Overall, the cumulative sensitivity of the complete Sjö panel was 91.4% (244/267); sensitivity of SSA/SSB alone was 74.9% (200/267), while sensitivity for the novel biomarkers alone was 49.8% (133/267). The cumulative specificity for the complete Sjö panel was 79.8% (151/189), and the cumulative specificity for the novel biomarkers was 83.5% (158/189).

**Conclusions:** An early and accurate diagnosis of SS is an important factor in limiting complications of the disease. The Sjö panel incorporates traditional and novel markers and increases the sensitivity in the diagnosis of SS by over 25% without compromising specificity. Patients who may have SS would benefit from screening with the Sjö panel to facilitate early diagnosis and contribute to better management of dry eye symptoms and other systemic manifestations.

## FRI0339 ADHERENCE TO VACCINATION AND OSTEOPOROSIS PREVENTION IN A FRENCH SYSTEMIC LUPUS ERYTHEMATOSUS COHORT

M. Scherlinger[1,2], A. Hourdillé[1,2], C. Pichon[1,2], T. Schaeverbeke[1,2], J.-F. Viallard[2,3], J.-L. Pellegrin[2,3], E. Lazaro[2,3,4], C. Richez[1,2,4]. *[1]Rheumatology, hopitaux universitaires Bordeaux; [2]Bordeaux University; [3]Internal medicine, hopitaux universitaires Bordeaux; [4]CIRID, CNRS UMR 5164, Bordeaux, France*

**Background:** Systemic lupus erythematosus (SLE) is a chronic inflammatory disease in which improvements in treatments have led to new challenges in patient care. Longer survival and patients aging come with long-term complications that the rheumatologists should work to recognize and prevent effectively. In fact, osteoporosis and infections bear a great importance in disease-related morbidity, mortality and care-related costs of SLE patients.

**Objectives:** Evaluate adherence to influenza and pneumococcal vaccination as well as to osteoporosis prevention in regard of the 2003 french recommendations, in a SLE patient cohort. Describe the factors associated with osteoporosis as well as with adherence to adequate vaccinal prevention.

**Methods:** We included all SLE patients (fulfilling the American College of Rheumatology criteria), seen from May 2014 to November 2014, in Rheumatology or Internal medicine department from Bordeaux teaching hospital, France. Using 2 questionnaires and medical records, informations concerning patients, disease-related characteristics and adherence to preventions were collected. Statistical analyze was made with appropriate tests regarding the type of data and a p-value $<0,05$ was considered of statistical significance.

**Results:** One hundred and nine patients were included. There was 100 women (92%), mean disease duration was 9,9 years. Renal and neurologic involvement were present in 20 and 9% of patients respectively. At the time of the study 76% were receiving hydroxychloroquine, 57% corticoids with 34% of them on a dose $\geq$7,5mg prednisone/day and 57% had received an immunosuppressant.

Twenty-one (19%) patients had an indication for anti-osteoporotic treatment. These patients were older (mean 54 versus 42 years, $p<8.10^{-4}$), had a longer use of corticosteroid (103.7 versus 62,5 months, $p<0.01$) and a greater use of immunosuppressant (81% versus 51%, $p<0.01$). Lombar and femoral head T-score were negatively correlated with SLICC-ACR damage index after excluding fractures from the score (b = -0,35 and -0,27; $p<0,006$ and $p<0,03$ respectively). Only 12/21 (57%) patients received the indicated anti-osteoporotic treatment, mainly by lack of prescription by the attending physician.

Only 11 patients (10%) received both influenza and pneumococcal vaccines, 35% received influenza vaccination at least once and 18% received pneumococcal vaccination. Reasons for non-vaccination were: lack of recommendation by general practitioner or rheumatologist (51%), fear of side effects (29%), contraindication with lupus (14%), inefficiency (2%). Predictive factors for an appropriate vaccination for both vaccines were: higher SLICC-ACR damage index ($p<0,03$) and past or current treatment with rituximab ($p<0,02$). Longer disease duration was associated with a better vaccination against influenza ($p<0,02$), and contact with elderly for pneumococcal vaccine ($p<0,04$).

**Conclusions:** Osteoporosis treatment and infection prevention with influenza and pneumococcal vaccination remains low among SLE patients. Rheumatologists need to better implement these aspects in the global care of their SLE patients.

**Disclosure of Interest:** None declared

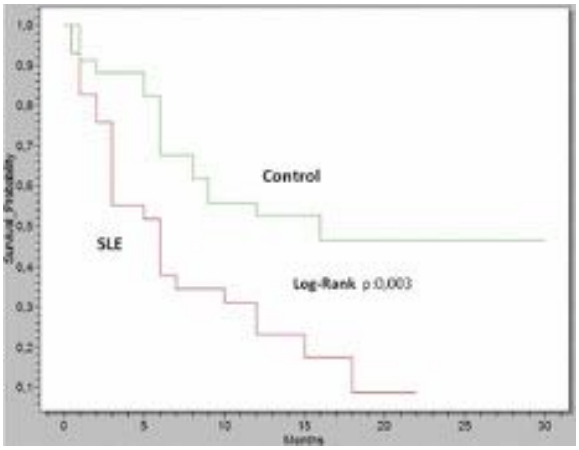
## FRI0340 BREASTFEEDING IN SYSTEMIC LUPUS ERITHEMATOSUS



M. Acevedo, J. Pretini, M. Micelli, G. Sequeira, E.M. Kerzberg. *Servicio de Reumatologia, Hospital J. M. Ramos Mejia, Ciudad Autonoma de Buenos Aires, Argentina*

**Background:** Breastfeeding is the optimal source of nourishment for newborns and infants during their first year of life.Both short and long benefits accrue to mothers who breastfeed (1,2). The clinical condition of patients with systemic lupus erythematosus (SLE) may have an impact on breastfeeding onset and duration.

**Objectives:** Assess breastfeeding in patients with SLE.

**Methods:** Retrospective case-control study. Patients who had got pregnant after being diagnosed with SLE (4 or more SLICC ACR/EULAR criteria) and whose pregnancies had been followed up in the hospital were interviewed. The control group consisted of patients approached in the waiting-room of the paediatrics service. The data collected included epidemiological information, main features of their pregnancies and newborns, breastfeeding duration, and reasons for

weaning. This study was approved by the Bioethics Committee of the Ramos Mejia Hospital, and both patients and controls signed the informed consent form.
**Results:** Thirty-six pregnancies in 31 patients with SLE and the same number of controls were studied. The following features were similar in both groups: current age, age at the time of delivery, level of education, average number of children, number of patients that breastfed for the first time, and preterm birth rates.
Patients with SLE had planned their pregnancies ahead less frequently than controls (16.7% vs 44.4%, p 0.02), they had experienced a greater number of complications during the pregnancies (33.6% vs 5.6%; p 0.007), and their newborns showed a higher trend to minor complications (25% vs 11.1%; p 0.2).
Twenty-five percent of the patients with SLE presented some kind of complication during puerperium, mainly related to disease activity, versus none in the controls (p 0.001). Also, a higher number of patients with SLE did not even initiate breastfeeding (19.4% vs 5.6% in the controls; p 0.07). Breastfeeding average duration in patients with SLE was 6 months (SD 6 months) versus 12 months (SD 8 months) in the controls (Log Rank p: 0.003).
Fifty-two percent of the controls mentioned that there had been no reason for weaning and considered that they had nursed their children a suitable amount of time. Conversely, patients with SLE frequently set weaning in motion on the grounds that they had been placed on medication (42%). However, when the medication was analysed, in 6 of 11 cases (55%), it consisted of low doses of corticoids or Hydroxychloroquine.

**Conclusions:** In this retrospective case-control study it was observed that patients with SLE show a lower trend to initiate breastfeeding, and they sustain it for less time than controls (6 months vs 12 months respectively). Although the most common reason for weaning is the administration of medication, breastfeeding duration could be optimised by improving the level of information provided to patients.

## FRI0341 DO PATIENTS WITH SLE AT ONSET DIFFER FROM MIMICKERS? A COMPARISON OF CLINICAL AND SEROLOGICAL MANIFESTATIONS IN A MULTICENTER COHORT TO INFORM THE DEVELOPMENT OF NEW CLASSIFICATION CRITERIA FOR SLE

Z. Touma[1], K.H. Costenbader[2], S. Johnson[1], M. Mosca[3], B.F. Hoyer[4], S. Navara[5], E. Bonfa[6], R. Ramsey-Goldman[7], J. Medina-Rosas[1], C. Tani[3], A. Fine[8], S. Tedeschi[2], V. Lorenzoni[9], G.D. Sebastiani[10], T. Dorner[4], M. Aringer[11] on behalf of the ACR/EULAR Group. *[1]University of Toronto, Toronto, Canada; [2]Harvard Medical School, Boston, United States; [3]University of Pisa, Pisa, Italy; [4]Charité University Medicine, Berlin, Germany; [5]University of Santo Tomas, Manila, Philippines; [6]Universidade de São Paulo, São Paulo, Brazil; [7]Case Western Reserve University, Chicago; [8]Brigham and Women's Hospital, Boston, United States; [9]SSSUP, Pisa; [10]Osp. San Camillo, Roma, Italy; [11]Universitätsklinikum Carl Gustav Carus, Dresden, Germany*

**Background:** Current SLE classification criteria may not classify patients with early SLE well. SLE mimickers can have an initial presentation similar to SLE and need to be distinguished from early SLE patients by classification criteria.
**Objectives:** To describe the clinical and serological presenting manifestations of SLE at disease onset and those of SLE mimickers.
**Methods:** We collected clinical and laboratory data on patients newly presenting with potential SLE (symptoms <12 months) within the past 3 years at centers in Europe (2), North America (3), South America (1) and Asia (1). Patients were diagnosed as SLE or mimicking conditions by clinical experts. We compared the presenting manifestations in SLE vs. mimickers. We examined combinations of autoantibodies, clinical and laboratory manifestations for their association with SLE vs. SLE mimickers in multivariable analyses.
**Results:** Of 616 patients, 389 were diagnosed with SLE (89% female) and 227 were given other diagnoses (97% female). A smaller proportion of SLE patients than patients with mimicking conditions were White (55% vs. 90%). Mimickers included UCTD, Sjögren's syndrome, rheumatoid arthritis, scleroderma, and fibromyalgia. Clinical and autoantibodes presenting manifestations in new onset SLE and mimickers are represented in table 1. In univariable analyses, the following autoantibodies profiles were associated with SLE vs. mimickers: Profile 1 (ANA, anti-Sm, anti-Ro and anti-RNP; OR 3.49, 95% confidence interval [CI] 2.29–5.31) and Profile 2 (ANA, anti-cardiolipin IgG/IgM, Beta2 and lupus anticoagulant; OR 2.82, 95% CI 1.75–4.55). In multivariable analyses, the following autoantibodies profiles were associated with SLE vs. mimickers: Profile 1 (OR 3.02, 95% CI 1.90–4.80) and Profile 2 (OR 3.11, 95% CI 1.80–5.36). Adding hypocomplementemia to Profile 1 and 2 showed a high association with SLE [OR 3.40, 95%CI 2.21–5.22 and OR 2.41, 95%CI 1.53–3.80] respectively.

Table 1

| | SLE (N=389) | Mimickers (N=227) | P-value |
|---|---|---|---|
| Fever | 134 (34.5%) | 31 (13.7%) | <0.001 |
| Fatigue | 110 (28.3%) | 84 (37.0%) | 0.024 |
| Malar rash | 193 (49.6%) | 14 (6.2%) | <0.001 |
| Oral ulcers | 84 (21.6%) | 12 (5.3%) | <0.001 |
| Alopecia | 119 (30.6%) | 27 (11.9%) | <0.001 |
| Inflammatory arthritis | 224 (57.6%) | 60 (26.4%) | <0.001 |
| Pleuritis | 87 (22.4%) | 6 (2.6%) | <0.001 |
| Kidney | 51 (13.1%) | 0 | <0.001 |
| Seizures | 11 (2.8%) | 0 | 0.009 |
| Dry eyes | 15 (3.9%) | 63 (27.8%) | <0.001 |
| Raynaud's | 86 (22.1%) | 110 (48.5%) | <0.001 |
| ANA | 387 (99.5) | 216 (95.1%) | <0.001 |
| anti-dsDNA | 251 (71.7%) | 14 (6.9%) | <0.001 |
| Anti-Sm | 90 (30.2%) | 5 (2.6%) | <0.001 |
| Anti-Ro | 98 (33.2%) | 53 (25.6%) | 0.067 |
| Anti-RNP | 85 (28.5%) | 12 (5.9%) | <0.001 |
| Low complement | 243 (73.4%) | 104 (48.4%) | <0.001 |
| Leucopenia | 61 (74.4%) | 315 (61.9%) | 0.029 |

**Conclusions:** We identified clinical manifestations and autoantibodies more commonly associated with SLE than with mimickers at initial presentation. Autoantibody profiles particularly including ANA and especially in the presence of hypocomplementemia, showed associations with SLE.
**Acknowledgement:** New SLE classification criteria for clinical research are being developed, sponsored by EULAR and ACR.

## FRI0342 VULVAR HISTOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL CHANGES IN PATIENTS WITH PRIMARY SJÖGREN SYNDROME

M. Orlandi[1], A. De Magnis[1], A. Fanchi[1], S. Maddali Bongi[2]. *[1]Università degli Studi di Firenze; [2]Università di Firenze, Firenze, Italy*

**Background:** Primary Sjogren Syndrome (pSS) is an autoimmune disease mostly affecting women, characterized by a lymphocyte-mediated infiltration and destruction of several exocrine glands, which causes mucosal dryness. Genital involvement is frequent and characterized by vulvar and vaginal dryness, dyspareunia and pruritus, that significantly impairs sexual function. However, despite the high frequency of genital involvement, few data were published about the histopathology of external genitalia in pSS. The studies performed until now show that vaginal and vulvar dryness are due to the presence of a vulvar inflammatory infiltrate and to the atrophy of minor and major vestibular glands, whose secretions are important for the sexual function.
**Objectives:** To evaluate the presence and the characteristics of histopathological and immunohistochemical changes in vulvar tissues in women with pSS.
**Methods:** Women with pSS (21 patients) underwent vulvar biopsies that have been evaluated for histopathological and immunohistochemical changes and finally compared with those obtained from 26 patients with lichen sclerosus.
**Results:** An inflammatory infiltrate (composed predominantly by T lymphocytes (CD3+), sparse CD20+ B cells and mean CD4:CD8 T-cell ratio of 1.5) was evidenced in all 21 biopsies and classified in mild (10), moderate (11) and severe (0). No correlation was shown between vulvar inflammatory infiltrate score and salivary Chisholm e Mason score.
No differences were found neither in gynecological symptoms neither in clinical and demographical characteristics between patients with mild and those with moderate vulvar inflammatory score.
A higher prevalence of moderate inflammatory infiltrate was observed in biopsies from women with lichen sclerosus than in pSS.
**Conclusions:** Women with pSS show high prevalence of vulvar inflammation that could explicate the high frequency of gynaecological symptoms, but the severity don't correlate with the grade of histological changes.

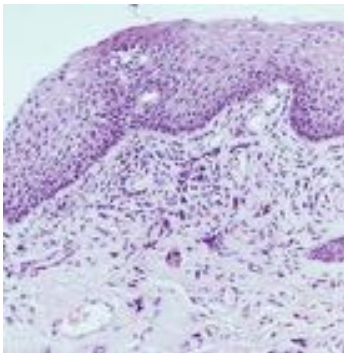

Figure 1

The gynaecological evaluation is mandatory in pSS to assess genital involvement and, eventually, to address a therapy targeted to genital symptoms.

## FRI0343 SLEEP DISORDERS IN PATIENTS AFFECTED BY SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) WITH PROLONGED INACTIVE DISEASE

M. Iudici, S. Fasano, I. Pantano, L. Pierro, G. Valentini. *Rheumatology Section, Department of Clinical and Experimental Medicine, Second University of Naples, Naples, Italy*

**Background:** Sleep disturbances are frequently observed in systemic lupus erythematosus (SLE) patients, but the relationship with disease activity has not been unequivocally established.
**Objectives:** To assess the prevalence of and factors associated with sleep disorders in a cohort of SLE patients with persistent complete (no clinical activity, no serological activity and no treatment other than antimalarials) or clinical remission (only serological activity; stable immunosuppressive therapy with or without corticosteroids allowed) (1).
**Methods:** Consecutive adult SLE patients attending the outpatient clinic of the Second University of Naples were enrolled in a cross-sectional study. A complete clinical and laboratory assessment was carried out. Moreover, the Pittsburgh Sleep Quality Index (PSQI), Health Assessment Questionnaire – Disability Index (HAQ-DI), Short-Form 36 (SF-36), VAS pain, VAS fatigue, VAS global health, were administered.
**Results:** Ninety SLE patients (86 females) with a mean±SD age of 43±18 and a median disease duration of 17 years (range 2–38) were enrolled in the study. A poor sleep quality (i.e. PSQI score>5) was observed in 38 (42.2%) patients, with no difference between patients in complete remission (13/30) and those in clinical remission with or without GCs (25/51; p=0.651). PSQI score was found to be significantly correlated with physical component score of SF-36 (rho -0.467, 95% CI -0.632 to -0.262; p<0.0001), mental component score of SF-36 (rho -0.501, 95% CI -0.657 to -0.303; p<0.0001), HAQ-DI (rho 0.497, 95% CI 0.303 to 0.651; p<0.0001), VAS pain (rho 0.480, 95% CI 0.283 to 0.639; p<0.0001), VAS fatigue (rho 0.491, 95% CI 0.296 to 0.697; p<0.0001). No correlation was found between the physician assessment of disease activity and sleep disturbance (rho 0.113, 95% CI -0.114 to 0.128; p=0.329).
**Conclusions:** Sleep disorders are frequent in SLE patients with persistent complete or clinical remission. An impaired mental and physical quality of life, disability, fatigue and pain represent the main features associated with a low quality of sleep.

## FRI0344 EXTRA-GLANDULAR MANIFESTATIONS OF PRIMARY SJÖGREN SYNDROME EXCLUDED FROM DISEASE ACTIVITY INDEXES

M. Fernandez Castro[1], J.L. Andreu[2], C. Sanchez-Piedra[3], A. Olive[4], J. Rosas[5], V. Martinez Taboada[6] on behalf of members of the Sjogren-SER study group (EAS-SER). *[1]H. Infanta Sofía; [2]H. Puerta de Hierro; [3]Unidad de Investigacion de la SER, Madrid; [4]H. Germans Trias i Pujol, Barcelona; [5]H. Marina Baixa, Alicante; [6]H. Marqués de Valdecilla, Santander, Spain*

**Background:** Primary Sjögren syndrome (pSS) is a systemic autoimmune disease characterized by lymphocyte infiltration of the exocrine glands. Nevertheless, it can affect any organ and develop extra-glandular manifestations that even can precede the typical glandular manifestations and delay the diagnosis.
**Objectives:** The aim of our study was to evaluate the extra-glandular manifestations not included in disease activity indexes (Sjogren's Syndrome Disease Activity Index and EULAR Sjogren's Syndrome Disease Activity Index).
**Methods:** We conducted a multicenter descriptive transversal study of pSS patients fulfilling European/American criteria, from 33 Spanish rheumatology departments. Patients were selected by randomization. Every patient was interviewed for data collection and signed an informed consent. Data were also collected by reviewing medical records. Local ethics committees approved the study. Variables were analysed by descriptive statistical methods, using means, medians and rates. Chi-square was used to establish the statistical associations. A p<0.05 was considered significant.
**Results:** Four hundred and thirty-seven patients were included. Ninety-five percent of them were women. The median age of the cohort was 58 years. Nineteen percent of the patients referred involvement of the trachea or upper airway. Twenty-one percent of the patients developed Raynaud phenomenon. Twelve (2.7%) patients suffered cardiac impairment (6 pericarditis and 6 cardiac conduction disorders). Thirteen percent of the patients referred digestive involvement, being chronic atrophic gastritis the most frequent condition (21 patients), followed by esophageal motility alteration (12 patients), followed by lymphocytic colitis (3 patients). Seven percent of the patients developed hepatic involvement: primary biliary cirrhosis and autoimmune hepatitis were the most frequent (15 and 14 patients, respectively), followed by autoimmune cholangitis in 3 patients; 55 patients (13%) had anti-LKM antibodies, 15 patients anti-mitochondrial antibodies, and 5 patients anti-smooth muscle antibodies. Seven patients had pancreatic involvement. Seventy-eight patients (18%) had thyroid involvement: anti-thyroid peroxidase (anti-TPO) hypothyroidism was the most frequent (41 patients), followed by subclinical hypothyroidism in 23 patients, negative anti-TPO hypothyroidism in 12 patients, anti-TPO+ hyperthyroidism in one patient and anti-TPO- hyperthyroidism in one patient. Thyroid involvement was significantly more frequently in patients with anti-Ro+. Raynaud phenomenon was significantly more frequent in patients with anti-La antibodies. Digestive involvement was significantly more frequent in patients with low C3. Pancreatic involvement was significantly more frequent in patients with low C3 and C4. Hepatic and trachea involvement were significantly more frequent in patients with hypergammaglobulinemia.
**Conclusions:** Twenty percent of the patients with primary Sjögren syndrome developed extra-glandular manifestations not included in disease activity indexes. Serological characteristics may be helpful in identifying this subgroup of patients.

**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3865

## FRI0345 NEUROLOGICAL MANIFESTATIONS OF PRIMARY SJÖGREN SYNDROME

M. Fernandez Castro[1], J.L. Andreu[2], C. Sanchez-Piedra[3], J. Rosas[4], V. Martinez Taboada[5], A. Olive[6] on behalf of members of the Sjogren-SER study group (EAS-SER). *[1]H. Infanta Sofía; [2]H. Puerta de Hierro; [3]Unidad de Investigacion de la SER, Madrid; [4]H. Marina Baixa, Alicante; [5]H. Marqués de Valdecilla, Santander; [6]H. Germans Trias i Pujol, Barcelona, Spain*

**Background:** Primary Sjögren syndrome (pSS) is a chronic systemic autoimmune disease with a relevant impact in patients' quality of life. Neurological manifestations of pSS could have an important impact on morbidity and mortality.
**Objectives:** The aim of our study was to evaluate central and peripheral neurological manifestations of a pSS cohort of patients assisted in Spanish Reumathology Departments.
**Methods:** This is a multicentre descriptive transversal study of pSS patients from thirty-three rheumatology departments. Patients fulfilling European/American consensus criteria were included after randomisation. By reviewing clinical records and interviewing the patients, we collected epidemiological, clinical, serologic, therapeutic, and disease activity indexes data. Informed consent was obtained and local ethics committees approved the study. Variables were analysed by descriptive statistical methods, using means, medians, and rates. Chi-square was used to establish the statistical associations, being considered a p<0.05 as significant.
**Results:** Four hundred and thirty-seven patients were included. Ninety five percent of them were women. The median age of the cohort was 58 years. Thirty-four (7.8%) patients developed central nervous system (CNS) involvement. Interestingly, 15 patients developed CNS manifestations before the diagnosis of pSS. Fourteen patients referred headache, 11 patients some psychiatric disorder, 6 patients cerebral ischemic attack, 5 patients cognitive impairment, 5 patients

multiple sclerosis, 3 patients cranial nerve involvement of central origin, 3 patients cerebral vasculitis, 2 patients optic neuritis, a patient aseptic meningitis and a patient myelopathy. ESSDAI index was significantly higher in patients with CNS involvement. Systemic treatments (glucocorticoids, bolus of glucocorticoids, azathioprine, methotrexate and cyclophosphamide) and biological treatments (anti-TNF, abatacept and tocilizumab) were used significantly more frequently in patients with CNS impairment. Thirty-nine (8.9%) patients developed peripheral nervous system (PNS) involvement, 14 of them, before the diagnosis of pSS. Thirteen patients had mixed polyneuropathy, 2 patients motor polyneuropathy, 8 patients sensitive polyneuropathy, 3 patients small fiber neuropathy, a patient developed mononeuritis multiplex and 8 patients focal mononeuropathy. Three patients had trigeminal sensory neuropathy, a patient III cranial neuropathy and 3 patients VII cranial neuropathy. SSDAI and ESSDAI indexes were significantly higher in patients with PNS involvement. Systemic therapies (glucocorticoids, bolus of glucocorticoids, methotrexate, mycophenolate mofetil and cyclophosphamide), biological treatments (rituximab) and intravenous immunoglobulins were used significantly more frequently in patients with PNS impairment.

**Conclusions:** More than 7% of pSS patients with pSS of our cohort developed nervous system manifestations. The CNS and PNS involvement led to a significantly higher disease activity, scored by formal activity indexes. The use of systemic and biological treatment was significantly higher in patients with nervous system involvement.

**Disclosure of Interest:** None declared

## FRI0346 EVALUATING DIFFERENCES IN THE ENROLLED POPULATIONS OF RANDOMIZED CLINICAL TRIALS OF SYSTEMIC LUPUS ERYTHEMATOSUS

N. Goel[1,2], B. Barrett[3], A. Duncan[4], M.-B. Gallagher[1], M. Mackey[3]. *[1]Quintiles Inc; [2]Duke University School of Medicine, Durham, NC; [3]Quintiles Inc., Rockville, MD, United States; [4]Quintiles Inc., Reading, Berkshire, United Kingdom*

**Background:** Most randomized controlled trials (RCTs) in systemic lupus erythematosus (SLE) specify specific populations of interest for eligibility, but still vary in the populations included. These differences include the level of baseline disease activity, the relative contribution of clinical vs laboratory disease manifestations, baseline corticosteroid dosage, the presence and number of specific immunosuppressant therapy, antimalarials and racial/ethnic mix. Data have been presented previously highlighting regional differences in SLE populations potentially influencing treatment responses.[1]

**Objectives:** Evaluate the demographics and baseline disease characteristics of randomized SLE patients across three different clinical trials conducted through our organization.

**Methods:** We evaluated combined screening demographic and disease-specific data from three recently conducted SLE studies post hoc. Eligibility criteria were targeted at the enrollment of patients with moderate to severe active SLE (SELENA-SLEDAI $\geq$8 for two studies of approximately 700 and 850 patients each, and SLEDAI-2K $\geq$6 for the third study of approx. 300 patients). Two studies were globally recruited, one was regional. Patients with varying degrees of severely active lupus nephritis or neuropsychiatric SLE were excluded. Differences between each combination of two study populations were evaluated via a two-tailed t-test for disease duration, corticosteroid use, immunosuppressant use, C3/C4 and anti-dsDNA status.

**Results:** Of the 1857 randomized patients, 39.3% were white and 93.4% were female. Details regarding treatment medications (corticosteroids, immunosuppressant use and antimalarials), SLEDAI scores (total and clinical); anti-dsDNA, ANA, and C3 and C4 status are presented in the table for the overall population. Mycophenolate (20.0%) was the most common immunosuppressant used, followed by azathioprine (15.8%) and then methotrexate (9.5%). Differences were determined to exist between each study population at the $p<0.001$ level for the percentage of subjects on corticosteroids, on immunosuppressants (except for a nonsignificant difference in the proportions using concomitant immunosuppressants between the two global studies); with hypocomplementemia, with elevated anti-dsDNA titers or with both.

| Screening Characteristics of All Randomized SLE Subjects | Results (N=1857) |
|---|---|
| Age, years, mean (SD) | 36.1 (11.7) |
| Disease duration, years, mean (SD) | 6.2 (6.2) |
| Positive ANA (≥1:80 titer or equivalent), % | 97.3 |
| Elevated anti-dsDNA ≥30 IU/mL, % | 70.8 |
| Hypocomplementemia (low C3 and/or C4), % | 55.5 |
| Elevated anti-dsDNA and hypocomplementemia, % | 47.4 |
| Corticosteroids, % | 90.3 |
| Corticosteroids ≥10 mg prednisone equivalent, % | 57.9 |
| Corticosteroid dose, mg, mean (SD) in subjects using corticosteroids (prednisone equivalent) | 14.19 (9.34) |
| Antimalarials, % | 70.0 |
| Immunosuppressants, % | 54.3 |
| Corticosteroids and immunosuppressants, % | 50.8 |
| Corticosteroids, antimalarials and immunosuppressants, % | 33.0 |
| No corticosteroids, antimalarials or immunosuppressants, % | 1.2 |
| SLEDAI score ≥8, % | 95.2 |
| Clinical SLEDAI score ≥6, % | 84.7 |
| SLEDAI ≥8 and Clinical SLEDAI score ≥6, % | 83.6 |
| Proteinuria >1g/day, % | 18.2 |

ANA=antinuclear antibody; anti-dsDNA=double-stranded deoxyribonucleic acid antibody; SD=standard deviation; SLE=Systemic Lupus Erythematosus; SLEDAI=Systemic Lupus Erythematosus Disease Activity Index.

**Conclusions:** SLE patients enrolled in RCTs, despite having similar levels of disease required by SLEDAI scores, had differences in critical baseline laboratory characteristics as well as in standard of care medications. These differences may have been impacted by regional differences, e.g., treatment standards of care as well as culturally driven behaviors, and study size; and may impact evaluation of the treatment response. Further differences in regional levels of disease activity are being evaluated as a next step. Understanding such differences may influence the design of SLE trials moving forward.

## FRI0347 PHENOTYPIC CHANGES OF LYMPHOCYTES IN PATIENTS WITH SEVERE SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH AN INTENSIFIED B-CELL DEPLETION THERAPY WITH RITUXIMAB

S. Sciascia, S. Baldovino, E. Menegatti, L. Solfietti, D. Di Simone, D. Rossi, D. Roccatello. *Centro di Ricerche di Immunologia Clinica ed Immunopatologia e Documentazione su Malattie Rare, Torino, Italy*

**Background:** B cells (BC) play a critical role in systemic lupus erythematosus (SLE). BC depletion therapy still remains an attractive option, despite the disappointing results of randomized controlled trials. However, the effects of rituximab treatment on T –cells including regulatory T cells (Treg) in SLE have not been fully determined.

**Objectives:** We prospectively investigated the differentiation and phenotypic changes of peripheral B cells and T regulatory lymphocytes (Treg) in patients with SLE after an intensified B-Cell depletion therapy with Rituximab

**Methods:** Ten patients with sever SLE [2males, mean age 41.6 yrs (25–57)] with severe multiorgan involvement have been prospectively treated with IBCDT protocol due to their resistance or intolerance to previous therapy. Protocol: Rituximab (RTX) 375 mg/sm on days 1, 8, 15, 22, and 2 more doses after 1 and 2 months, associated with 2 IV administrations of 10 mg/kg of cyclophosphamide and 3 methylprednisolone pulses (15 mg/kg) followed by oral prednisone (0.8 mg/kg/day, rapidly tapered to 5mg/day by the end of the 3rd month after RTX). No further immunosuppressive maintenance therapy has been given. Circulating B cells and Treg in the peripheral blood were investigated by flow-cytometry at baseline, month 1, month 2, and every other month thereafter up to 1 year. Whole blood samples obtained in the morning, in EDTA, were stained with monoclonal antibodies against CD45, CD3, CD4 CD19, CD20, CD25 and FOXP3. Response was evaluated by assessing the changes in clinical signs and symptoms, laboratory parameters and SLEDAI score.

**Results:** All patients had complete peripheral blood-B cell depletion after IBCDT and the CD20+ B cells were not detectable in the circulation by the 12th month (detection limit of $0.005 \times 10^9$/l). Upon detection of B cell depletion, we observed in 12 months a 4-fold increase in the circulating Treg (CD4+CD25+FOXP3+) (2% at baseline, 3% after 1 month, 4,5% at 6 month, 8% at 12 months). All patients achieved clinical remission after IBCTD and no flare were observed during the one-year follow-up. IBCDT resulted in a decrease of median global SLEDAI from 14.6 [11–23] to 4 [1–5] at 12 months ($p<0.01$)

**Conclusions:** Our results suggest a phenotypic change of peripheral T lymphocytes as a result of B cells depletion obtained with IBCTD. Treg considered being essential in the maintenance of peripheral self-tolerance, progressively increased after B cell depletion. Such immunological re-assessment was observed in association with clinical remission in the absence of further disease flare.

## FRI0348 FEASIBILITY AND VALIDITY OF PATIENT REPORTED OUTCOME MEASUREMENT INFORMATION SYSTEM (PROMIS) IN SYSTEMIC LUPUS ERYTHEMATOSUS

S. Kasturi[1], J.C. Burket[2], J. Berman[1], K. Kirou[1], A.B. Levine[1], L.R. Sammaritano[1], L.A. Mandl[1]. *[1]Medicine/Rheumatology; [2]Healthcare Research Institute, Hospital for Special Surgery, New York, United States*

**Background:** Accurate measurement of patient reported outcomes (PROs) is important in systemic lupus erythematosus (SLE), a heterogeneous disease in which similar symptoms can have disparate impact across patients. PROMIS

offers dynamic computer adaptive tests (CATs) to precisely and efficiently measure PROs in a variety of relevant domains.
**Objectives:** The aims of this study were to: 1) assess the feasibility of administering PROMIS CATS serially to SLE outpatients 2) correlate PROMIS CATs with legacy PRO measures, SLE disease activity and organ damage 3) assess retest reliability of PROMIS CATs.
**Methods:** Adults meeting American College of Rheumatology SLE classification criteria were recruited from a SLE Center of Excellence. Subjects completed the Short Form-36 (SF-36), LupusQoL-US, and selected PROMIS CATs. SLE disease activity, flare, and damage were evaluated with the SELENA-SLEDAI and SLICC-ACR damage index. PROMIS domains were compared with disease activity, damage, and similar domains in legacy instruments using Spearman correlations. Retest reliability was evaluated among subjects reporting stable SLE activity at two assessments one week apart using intraclass correlation coefficients (ICC).
**Results:** Of 198 patients approached, 163 (82%) completed at least one assessment, 130 (80%) completing it remotely. 138 (85%) completed a retest. Most PROMIS domains showed moderate to strong correlations with similar domains in both legacy instruments (Figure 1). However, correlations between PROMIS and the physician global assessment, SELENA-SLEDAI, and SLICC-ACR damage index were generally weak and statistically insignificant. PROMIS CAT retest ICCs ranged from 0.74 to 0.89.

Bold correlations indicate p < 0.0001.

**Conclusions:** To our knowledge, these data are the first to show that PROMIS CATs can be successfully administered to a diverse cohort of SLE patients at the point of care or remotely, and are valid and reliable for many SLE relevant domains. Importantly, PROMIS scores did not correlate well with physician-derived measures. This disconnect between objective signs and symptoms and the subjective patient disease experience underscores the crucial need to integrate PROs into clinical care to ensure optimal disease management.

## FRI0349 A SURVIVAL ANALYSIS OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

V. Yazisiz[1], M. Göçer[2], S. Oygen[1], A.B. Avci[1], E. Gökalp[1], E. Terzioğlu[1].
*[1]Rheumatology; [2]Internal Medicine, Akdeniz University, Antalya, Turkey*

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease with unknown aetiology and involves mainly salivary and lacrimal glands. It is an autoimmune disease with a broad range of systemic manifestations. Mortality rate might reduce in pSS patients with treated new medications. There is no information on survival of pSS patients in our country.
**Objectives:** This study was conducted to determine clinical features and survival in pSS patients
**Methods:** All pSS patients who diagnosed betwen 2004–2014 years were included in this study. The clinical and laboratory features and mortality rates were reevaluated
**Results:** There were 718 patients with suspected pSS at 10 years. 372 patients were classified as pSS according to 2012 American Collage of Rheumatology Classification Criteria for Sjögren's Syndrome. Women/men ratio was 11/1. The mean age at the time of diagnosis was 50.3±11.81 years. 14 patients (3.8%) were diagnosed different malignancy and 18 patients died (4.8%). The rate of 10-year survival was 95.6% (%96.6 for women, %86.6 for men, p:0.004). 10-year survival rate was % 98.7 in patients without pulmonary involvement, but 79.2% in patients with pulmonary involvement. Multivariate Cox analysis showed that pulmonary involvement (OR:12.8, %95 CI: 4.52–44.8, $p<0.001$) and male gender (OR:1.7%95, CI: 1.17–4.53, p=0.004) were independent mortality risk factors
**Conclusions:** Our data revealed that cumulative survival was 95.6% at 10 years in pSS patients. Pulmonary involvement represented the main cause of death. pSS patients with pulmoner involvement have greater risk of death.
**Disclosure of Interest:** None declared

## FRI0350 THE IFN BIOMARKER SIGLEC1 INDICATES EXTRAGLANDULAR MANIFESTATION IN PRIMARY SJÖGREN'S SYNDROME

T. Rose, F. Szelinski, G. Burmester, F. Hiepe, R. Biesen, T. Dörner.
*Rheumatologie Und Klinische Immunologie, Charité Universitätsmedizin Berlin, Berlin, Germany*

**Background:** Over the last decades evidence of an activated type I interferon (IFN) system in the pathogenesis of different autoimmune diseases such as Sjögren's Syndrome (pSS) (1,2) has emerged to an extent, that anti-IFN therapies are tested in clinical trials.(3) On the other hand, IFN biomarkers are missing in clinical practice, although those biomarkers might be useful to guide clinical decision making or as pharmacodynamic marker.(4)
**Objectives:** To investigate the IFN biomarkers Sialic acid-binding Ig-like lectin 1 (SIGLEC1) and IFN$\gamma$-inducible protein-10 (IP-10) in patients with pSS.
**Methods:** 23 patients with pSS were included. Disease activity was obtained by EULAR Sjögren's syndrome disease activity index (ESSDAI). SIGLEC1 expression on monocytes was analyzed by flow cytometry. IP-10 was determined by Bioplex human Cytokine 27-plex kit. The correlation analysis was performed by Spearman rank test (SRT) and MannWhitney U (MWU) test was used to delineate differences between glandular and extraglandular manifestations.
**Results:** Increased SIGLEC1 expression was found in 60% of our cohort. In a subsequent analysis, SIGLEC1 was up-regulated in all patients with extraglandular manifestation, with an observed significant difference in SIGLEC1 expression (p=0.02, MWU) between glandular and extraglandular manifestation. SIGLEC1 expression correlated with the disease activity (p=0.002, r=0.6, SRT). Elevated levels of IP-10 levels were found in patients with pSS but did not show a difference between glandular and extraglandular manifestation nor did it correlate with the disease activity.
**Conclusions:** SIGLEC1 is up-regulated in pSS patients with a known higher mortality and morbidity (5,6), which therefore may be of value for a risk stratification, differential therapeutic approaches and guiding clinical decision making in pSS.

## FRI0351 INFLUENCES OF HYDROXYCHLOROQUINE USE ON THE RISK OF CANCERS IN PATIENTS WITH SJÖGREN'S SYNDROME: PROPENSITY SCORE MATCHED LANDMARK ANALYSIS

T.-T. Chuang, C.-F. Kuo. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

**Background:** Hydroxychloroquine is a disease-modifying anti-rheumatic drug for patients with Sjögren's syndrome who have an increased risk of malignancies, particularly lymphoma. Inhibition of systemic inflammation and autophagy by hydroxychloroquine has been linked to antineoplastic effects but there is a lack of evidence on the effect of hydroxychloroquine on the risk of cancers in patients with Sjögren's syndrome.
**Objectives:** This study aimed to explore the effect of hydroxychloroquine on the risk of cancers in patients with Sjögren's syndrome.
**Methods:** We compared cancer incidence in incident patients with Sjögren's syndrome who received hydroxychloroquine for at least 6 months within one year or three years to those did not using the Taiwan National Health Insurance Research Database. Landmark analysis was used to account for immortal time bias and propensity score matching was used to control for potential effects of known confounders.
**Results:** Of 4,262 Sjögren's syndrome patients was identified between 2000 to 2005, we included 4,175 patients who were alive and did not have cancer at one year from initial diagnosis of Sjögren's syndrome. The propensity score matched 1,141 patients who exposed to 6 months of hydroxychloroquine prescription on the date 1 year from the initial diagnosis and 1,141 patients who was not exposed to hydroxychloroquine. The median follow year was 6 years from one-year landmark. There were 71 hydroxychloroquine users and 56 non-hydroxychloroquine users had cancer during the follow-up. The hazard ratio for cancer was 1.31 (95% confidence interval [CI], 0.92–1.86) in the one year landmark analysis. We further conducted three-year landmark analysis and 6-month hydroxychloroquine exposure was associated with a hazard ratio of 1.33 (95% CI, 0.98–1.81) in the three-year landmark analysis between hydroxychloroquine users and non-hydroxychloroquine users, was 1.31 (0.92–1.86) in the one landmark analysis. There was no difference in overall survival based on Kaplan-Meier estimates between hydroxychloroquine user and non-users in both the one-year (log-rank test p=0.15) and three-year landmark analysis (log-rank test p=0.09).
**Conclusions:** This propensity score matched landmark analysis in a population of incident patients with Sjögren's syndrome in Taiwan found a neutral effect of 6-month hydroxychloroquine treatment early in the clinical course on the risk of cancer, but whether a higher dose or an longer exposure to hydroxychloroquine could influence the risk of cancer remains to be determined.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4477

## FRI0352 SMALL FIBRE NEUROPATHY AND GANGLIONOPATHY IN PRIMARY SJOGREN'S SYNDROME (PSS)

V. Gupta[1], J. Peters[1], M. Bombardieri[1], A. Radunovic[2], N. Sutcliffe[1]. *[1]Department of Rheumatology; [2]Department of Neurology, Barts Health NHS Trust, London, United Kingdom*

**Background:** Neuropathy occurs in 5–15% of cases with Sjogren's syndrome. Small fibre neuropathy and ganglionopathy are said to be the commonest types of neuropathy in pSS[1]. Small fibre neuropathy is under-recognised since physical examination is often normal and nerve conduction studies show no abnormalities. The increased use of skin biopsy has improved our diagnostic sensitivity.
**Objectives:** To estimate the frequency of small fibre neuropathy and ganglionopathy in pSS patients with neuropathic symptoms using skin biopsy, and to describe the clinical characteristics of these patients.
**Methods:** We identified 25 patients with pSS who were investigated for symptoms of small fibre neuropathy and/or ganglionopathy between January 2010 and December 2015. Patients were assessed by neurological examination, nerve conduction studies, skin biopsy and imaging where appropriate.
**Results:** 13/25 patients had conclusive evidence of small fibre neuropathy (n=12) or ganglionopathy (n=1) on skin biopsy. A further 2/25 patients had borderline skin biopsies suggestive of small fibre neuropathy. 12/13 patients with clear evidence of small fibre neuropathy/ganglionopathy were female. Median age at time of neuropathy diagnosis was 60 years (range 42 – 84, interquartile range 56 – 63). 2 presented initially to a neurologist, and the remainder to a rheumatologist. At least one autoantibody was detected in 11/13. Autoantibody frequencies were ANA 62%, RF 31%, anti-Ro 46%, and anti-La 23%. 7/13 patients met the American-European Consensus Group (AECG) criteria for the diagnosis of definite pSS. 4 of the 6 who did not meet the AECG criteria had a positive ANA or RF. Of these four, 2 had a salivary gland ultrasound (US) characteristic of pSS, and 1 was anti-Ro antibody positive. Both patients with borderline skin biopsies had anti-Ro antibodies and one also had antibodies to La. Median time from diagnosis of pSS to diagnosis of small fibre neuropathy or ganglionopathy was 16 months. In a quarter of patients, the diagnosis of neuropathy was made within 6 months of the diagnosis of pSS. Nerve conduction studies (NCS) did not show a neuropathy in 8/13. In the remaining 5 patients, NCS showed sensory axonal neuropathy in 4 patients, one of whom had diabetes mellitus, and ganglionopathy in 1. In the 2 patients with borderline skin biopsies, NCS suggested a mild sensory axonal neuropathy in one and a mild sensorimotor abnormality in the other.
**Conclusions:** Small fibre neuropathy is an under-recognised complication of pSS in clinical practice. In over half of our pSS patients who presented with neuropathic symptoms, a diagnosis of small fibre neuropathy or ganglionopathy was confirmed. Rheumatologists should consider the possibility of small fibre neuropathy in pSS, and not be falsely reassured by normal clinical examination or nerve conduction studies. 2 patients presented initially to a neurologist. Neurologists should consider Sjogren's syndrome in patients presenting with small fibre neuropathy.

## FRI0353 A LONGITUDINAL ANALYSIS OF CHANGE IN LUPUS DISEASE ACTIVITY PATTERN IN HOPKINS LUPUS COHORT USING A MULTISTATE MARKOV MODEL APPROACH

W. Fu, M. Petri. *Rheumatology, Johns Hopkins University, Baltimore, United States*

**Background:** Systemic Lupus Erythematosus (SLE) is a multi-systemic inflammatory disease with extreme variability of its activity over time. We have described three main patterns: long quiescence (LQ), chronic activity (CA) and relapsing-remitting (RR). Patients may move through a series of these activity states over time. To capture these complex fluctuations, we used a Multistate Markov model to evaluate SLE disease activity patterns over time in a longitudinal lupus cohort.
**Objectives:** To describe burden of disease activity patterns over time among patients with SLE. To estimate the probability of transition between disease activity patterns and survival at 1, 2 and 5 years after SLE diagnosis. To identify predictors of change in disease activity patterns.
**Methods:** SLE patients were followed up quarterly in Hopkins Lupus Cohort for 1–28 years. Medication, disease activity (by Physician Global Assessment (PGA) and SLE Disease Activity Index (SLEDAI)), C3, C4, anti-dsDNA, antiphospholipid antibodies and urine protein/creatinine ratio were recorded at each visit.
For each patient, visits were divided into 1-year blocks. Any 1-year block with only one visit or patients followed for only 1 year were excluded. SLE disease activity patterns were defined using PGA and SLEDAI. LQ: SLEDAI/PGA=0 for all visits within 1-year blocks; RR: periods of disease activity (SLEDAI/PGA>0) interspersed with periods of disease inactivity (SLEDAI/PGA=0) within 1-year block; CA: SLEDAI/PGA>0 for all visits within 1-year block. Multistate Markov models were used to provide estimates of relative transition rates and identify predictors of change in disease activity patterns.
**Results:** 1735 SLE patients were included in this analysis. 92.3% were females, mean ± SD age 32.8±13.1 years at diagnosis. 52.9% were Caucasian and 40.3% African American, the remainders were mostly Asian. 127 patients died during follow up.
Likelihood of deterioration (LQ to RR; RR to CA; LQ to CA) was greater than improvement (RR to LQ; CA to RR; CA to LQ). At year 1, 63.6% remained in LQ, while at year 2 and year 5, 58.2% and 84.1% had deteriorated from LQ pattern to either RR or CA pattern. From the RR pattern, the estimated probability for deterioration (to CA pattern) was higher than improvement (to LQ pattern), regardless of years since SLE diagnosis.
Multivariate analysis (see table 1) identified that race/ethnicity (African American), low C3, low C4, ESR >20, taking prednisone, plaquenil or anti-hypertension drug were predictors for deterioration. Plaquenil improved survival.

Table 1. Hazard ratio and 95% confidence interval of predictors of transitions

| | RR → CA | RR → LQ | RR → Death |
|---|---|---|---|
| African American vs. Caucasian | 1.81 (1.59,2.06)* | 0.72 (0.58,0.89) | 1.57 (0.93,2.64) |
| Urine protein creatine ratio | 1.11 (0.96,1.28) | 0.48 (0.34,0.68)* | 1.79 (1.11,2.89) |
| Low C3 | 1.75 (1.51,2.03)* | 0.38 (0.24,0.59)* | 1.46 (0.82,2.59) |
| Low C4 | 1.56 (1.32,1.83)* | 0.2 (0.1,0.4)* | 1.69 (0.88,3.26) |
| ESR.c | 1.28 (1.13,1.45)* | 0.68 (0.56,0.81)* | 2.4 (1.34,4.29) |
| Prednisone | 1.06 (0.94,1.19) | 0.65 (0.54,0.78)* | 3.83 (1.99,7.38)* |
| Plaquenil | 1.28 (1.12,1.45)* | 0.98 (0.81,1.18) | 0.37 (0.23,0.59)* |
| Anti hypertension drug | 1.08 (0.96,1.21) | 1.1 (0.92,1.31) | 2.99 (1.7,5.26)* |

*P value <0.0006, accounting for multiple comparison.

**Conclusions:** 1 year after SLE diagnosis, more than half of patient with LQ deteriorated. Patients in RR were more likely to deteriorate than improve. Plaquenil showed great promise in improving survival.
**Disclosure of Interest:** None declared

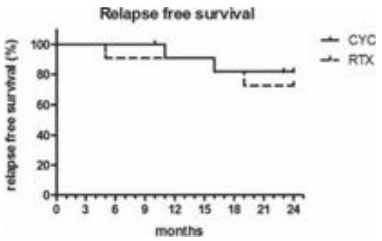
## Vasculitis

### FRI0354 CARDIOPULMONARY INVOLVEMENT IN TAKAYASU ARTERITIS



D. Brennan[1], K.J. Warrington[1], J. Schmidt[2], C. Crowson[3], M.J. Koster[1]. *[1]Rheumatology, Mayo Clinic, Rochester, United States; [2]Department of Internal Medicine and RECIF, Amiens University Hospital and INSERM U-1088, Jules Verne University of Picardy, Amiens, France; [3]Health Sciences Research, Mayo Clinic, Rochester, United States*

**Background:** Takayasu arteritis (TAK) is an inflammatory large-vessel vasculitis of unknown etiology affecting the proximal aorta and its primary branches. Heart disease is a major cause of death in patients with TAK but studies evaluating coronary/pulmonary artery involvement and myocardial dysfunction in this population have been limited.
**Objectives:** To evaluate cardiopulmonary (CP) involvement in patients with TAK and assess the impact on disease outcomes.
**Methods:** A retrospective cohort of patients with newly diagnosed TAK from 1984 to 2009 was assembled. All patients included met 1990 American College of Rheumatology classification criteria for TAK. Demographics, baseline disease characteristics, relapse events, surgeries and mortality were abstracted from direct medical record review. Angiograms (invasive and non-invasive), echocardiograms, nuclear medicine scans, and electrocardiograms (ECG) were reviewed for evidence of CP involvement. For the purpose of this study, CP abnormalities were defined as coronary or pulmonary artery vasculitis, left ventricular (LV) dysfunction, left atrial (LA) enlargement, moderate-severe valvular disease, pulmonary arterial hypertension (PAH), regional wall hypokinesis/akinesis, LV hypertrophy or persistent ECG axis deviation. Cox models with time-dependent covariates were used to assess the association between CP involvement and outcomes.
**Results:** A total of 117 patients with TAK were identified. The mean (±SD) age at diagnosis was 31.8 (±10.5) years. Fifty-four (46%) patients had at least one objective CP abnormality observed during the course of follow-up. No difference in age, sex, inflammatory markers or Hata classification were seen between those with and those without CP involvement. Baseline characteristics and symptoms were similar, except shortness of breath, which was more frequently observed at TAK diagnosis in patients with CP involvement compared to those without (54% vs 33%, respectively; p=0.035). PAH was identified in 8, pulmonary arteritis in 9, coronary arteritis in 3, aortic valve insufficiency in 10 (6 moderate, 4 severe), LV systolic heart failure in 5, LV enlargement in 19, and LA atrial enlargement in 21 patients.
Seventy-nine patients had at least 1 year of follow-up [median (IQR): 5.5 (2.9–10.1) years]. Of these 79 patients, 46 had at least one vascular or valvular surgery during the follow-up period. Composite CP involvement was not associated with risk of first surgery [Hazard ratio (95% CI): 1.40 (0.75–2.59); p=0.29]. However, PAH on echocardiogram was significantly associated with risk of first surgery [HR (95% CI): 14.2 (2.1–96.9); p=0.007]. During follow-up 6 patients died. CP involvement was not significantly associated with mortality [HR (95% CI): 1.81 (0.30–10.98); p=0.52].
**Conclusions:** Cardiopulmonary abnormalities in TAK are common. In this population, the presence of PAH predicted a 14-fold increased risk for vascular or valvular surgery. In this cohort, the presence of CP involvement did not increase mortality.
**Disclosure of Interest:** None declared

### FRI0355 COMPARISON OF RITUXIMAB WITH CYCLOPHOSPHAMIDE AS INDUCTION THERAPY IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (CHURG-STRAUSS SYNDROME): A 24 MONTHS FOLLOW-UP ANALYSIS

N. Venhoff, K. Halmschlag, M. Rizzi, R. Voll, J. Thiel. *Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany*

**Background:** Eosinophilic granulomatosis with polyangiitis (EGPA) forms part of the ANCA associated vasculitides (AAV) and is associated with eosinophilia and asthma. To date no consensus exists on induction and maintenance therapy and refractory patients still represent a considerable therapeutic challenge. We recently reported on the efficacy of rituximab (RTX) as induction therapy in EGPA. So far there are no data on RTX in comparison with cyclophosphamide (CYC) in this disease.
**Objectives:** To investigate the potential of RTX compared with CYC in EGPA as induction therapy and during long-term follow-up.
**Methods:** Retrospective analysis in a single-center cohort of 46 EGPA patients. Remission and disease activity were determined by BVAS. Laboratory follow-up included C-reactive protein, eosinophils, IgE, IgG, IgA, IgM, ANCA, and peripheral $CD19^+$ B-cell count.
**Results:** Eleven patients treated with RTX for relapsing or refractory disease were compared with twelve age- and sex-matched patients treated with CYC for remission induction. Median disease duration was longer in RTX patients (49 months, IQR 7–66 vs. 8.5 months, IQR 0–7; p=0.0025). Prior to induction therapy there was no significant difference in median BVAS (14 vs. 12.5) and in FFS (1 vs. 0.75). Median eosinophil percentages were increased in both RTX (18.4%) and CYC (6.75%) treatment groups (n.s.). 73% of the RTX-treated patients were ANCA-positive compared to only 23% of the CYC-treated patients. Median prednisolone dose per day at induction was significantly higher in CYC-treated patients (35 mg/day, IQR 26–138) than in RTX-treated patients (17.5 mg/day, IQR 10–30). After 3 months all patients in both treatment groups were in partial or complete remission. For maintenance therapy all but two patients per group received standard immunosuppressive treatment with a predominance of azathioprine (AZA) (n=7 per group). Median cumulative prednisolone doses during the first treatment year including high doses for remission induction were 3.6 g in RTX- and 3.8 g in CYC-treated patients (p=0.725). Within an observation period of 24 months after remission induction 3 patients in the RTX group and 2 patients in the CYC group had major relapses (n.s.). In two of the 3 relapsing patients after RTX treatment peripheral B-cell counts were evaluated showing a beginning repopulation of the peripheral B-cell compartment. Serum concentrations of IgG, IgA, and IgM remained stable in both treatment groups during follow-up.

**Conclusions:** RTX was effective in remission induction in EGPA patients. Remarkably this was the fact even in patients refractory to prior CYC treatment and in ANCA negative patients. During follow up the number of major relapses was comparable in both treatment groups. Prior to relapse the peripheral B cell compartment showed beginning repopulation in RTX-treated patients.

### FRI0356 PRIMARY CENTRAL NERVOUS SYSTEM VASCULITIS ASSOCIATED WITH LYMPHOMAS

C. Salvarani[1], R.D. Brown[2], T.J. Christianson[2], C. Giannini[2], J. Huston III[2], S. Ansell[2], G.G. Hunder[2]. *[1]Rheumatology, Azienda-Ospedaliera IRCCS di RE, Reggio Emilia, Italy; [2]Mayo Clinic, Rochester, United States*

**Background:** Vasculitis as a complication of lymphoproliferative diseases is relatively uncommon. Some cases of primary central nervous system vasculitis (PCNSV) have been described in association with lymphoma, particularly Hodgkin's lymphoma (HL).
**Objectives:** The aim of this study is to report the presenting clinical, laboratory, and imaging features of patients with PCNSV associated with lymphoma and compare them with the characteristics of patients with PCNSV without lymphoma.
**Methods:** We reviewed all patients diagnosed with vasculitis and lymphoma seen at the Mayo Clinic, Rochester, MN over the 32 year period of 1982–2014. 10 patients had PCNSV in association with lymphoma. We also used our updated cohort of 158 consecutive patients with PCNSV without lymphoma who were examined at Mayo Clinic over a 29-year period from 1983 to 2011. The diagnosis of PCNSV was based on brain/spinal cord biopsy or cerebral angiography, or both. Clinical data were collected.
**Results:** 10/168 (5.9%) patients had PCNSV associated with lymphoma: 6 with HL and 4 with non-HL. PCNSV diagnosis was established by cerebral biopsy in 8 patients, and by cerebral arteriogram in 2. Two patients had spinal cord involvement. A granulomatous inflammatory histologic pattern was found in all 8 patients, accompanied by vascular deposits of β-amyloid peptide in 2. In 7 patients (5HL and 2NHL) neurologic symptoms preceded lymphoma diagnosis and subsequent medical workup revealed lymphoma.The 10 patients with lymphoma were compared with the 158 patients with PCNSV without lymphoma. The patients with lymphoma were more frequently males (80% vs 44%, p=0.04). No significant differences in the clinical manifestations at presentation and CSF findings were observed in the two groups, although cognitive dysfunction was more frequent in patients with lymphoma (80% vs 53%), while visual field deficit and intracranial hemorrhage less frequent (0% vs 19%, and 0% vs 10%, respectively). Systemic manifestations were infrequent in both groups (10% vs 9.5%). More patients with lymphoma showed meningeal gadolinium enhancing lesions at MRI (50% vs 19%, p=0.03). The frequencies of PCNSV relapse (20% vs 28.4%) and patients not requiring therapy at last follow-up (30% vs 25.5%) were similar in both groups. Patients with lymphoma had a higher frequency of poor outcome (modified Rankin disability score $\geq$4) at last followup (60% vs 21.5%, p=0.01). Considering all 168 patients, univariate Cox proportional hazards modeling showed an increased mortality rate in those with increasing age [hazard

ratio (HR) 1.3], lymphoma (HR 3.9), cerebral infarction on MRI (HR 3.4), and angiographic large vessel involvement (HR 3.9), while mortality rate was lower in those with gadolinium–enhanced lesions on MRI (HR 0.3).
**Conclusions:** PCNSV is associated with a diagnosis of lymphoma in 5.9% of PCNSV cases. Neurological manifestations of PCNSV may precede the diagnosis of lymphoma. Clinical characteristics of those with lymphoma were similar to those without lymphoma, however they had a more severe cerebral vasculitis with increased neurological disability and mortality.

## FRI0357 INCIDENCE AND PREDICTORS OF THORACIC AORTIC DAMAGE IN BIOPSY-PROVEN GIANT CELL ARTERITIS: A SINGLE-INSTITUTION COHORT STUDY

M.J. Koster[1], C. Labarca[2], C. Crowson[3], E.L. Matteson[1], K.J. Warrington[1]. *[1]Rheumatology, Mayo Clinic, Rochester, United States; [2]Rheumatology, Clinica Alemana de Santiago, Santiago, Chile; [3]Health Sciences Research, Mayo Clinic, Rochester, United States*

**Background:** Patients with giant cell arteritis (GCA) are at an increased risk for aortic structural damage; however, the timing and predisposing characteristics for development of aortic aneurysm is poorly understood.
**Objectives:** The aim of this study was to evaluate the incidence and predictors of thoracic aortic aneurysm in a large single-institution cohort of patients with biopsy-proven GCA.
**Methods:** A retrospective review was performed to identify all patients with biopsy-proven GCA from 1998 through 2013. Demographic, clinical, laboratory, radiographic, and treatment data at baseline and subsequent followup visits were collected. Kaplan-Meier methods were used to estimate cumulative incidence and Cox models were used to examine potential predictors of development of aneurysm/dilatation of the thoracic aorta.
**Results:** The cohort included 286 patients with biopsy-proven GCA (213 females and 73 males, mean [±SD] age 75 [±7.6] years) with a mean (±SD) follow up of 6 (±3.9) years.
130 patients had 280 imaging studies (41% magnetic resonance angiography [MRA], 55% computed tomographic angiography [CTA] and 4% conventional angiography). The median time from diagnosis to first imaging study was 0.2 [interquartile range (IQR) 0.0, 2.7] years. Of the 130 patients, 48% underwent follow up imaging studies.
At the first imaging study, 14 (11%) patients had evidence of aneurysm or dilatation of the thoracic aorta and 28 (22%) patients had thoracic aorta thickening. Excluding prevalent cases, the cumulative incidence (±SE) for aneurysm/dilatation of the thoracic aorta during followup was 0% at both 1-yr and 2-yrs but increased to 9% (±0.4) at 5-years. Among all patients with GCA evaluated with vascular imaging, thoracic aortic aneurysm/dilatation was detected in 11% (±3) at 1-yr, 11% (±3) at 2-yrs, and 15% (±3) at 5-yrs.
Patient baseline demographics, cardiovascular risk, clinical presentation, laboratory values, and initial treatment were assessed to predict incidence of thoracic aortic damage. Baseline thickening of the thoracic aorta was not a risk factor for subsequent aneurysm/dilatation (p=0.99). Neither the presence of relapse (p=0.99) nor the number of relapses (p=0.65) were associated with development of thoracic aortic damage [HR (95% CI): 0.88 (0.50, 1.54); p=0.65]. Furthermore, there was no difference in initial prednisone dose between patients who did and did not develop aortic damage. The sole predictor for development of thoracic aortic aneurysm/dilatation was a history of smoking [HR (95% CI) 28.1: (1.59, 495.71); p=0.023].
**Conclusions:** In our cohort, thoracic aortic aneurysm/dilatation was seen in 11% of patients at baseline evaluation and increased to 15% at 5-yrs after diagnosis. Former smokers were at a 28-fold increased risk for developing thoracic aortic damage. Surveillance for aortic damage should be pursued in all patients with GCA, particularly those with a smoking history. Prospective investigations into screening methods and optimal frequency are warranted.

## FRI0358 SHORT TERM PROGNOSIS OF A PROSPECTIVELY FOLLOWED COHORT OF UNSELECTED ADULT IGA VASCULITIS CASES – A SINGLE RHEUMATOLOGY CENTRE EXPERIENCE

J. Ostrovršnik, A. Hočevar, Ž. Rotar, M. Tomšič. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** The acute phase of adult IgA vasculitis (IgAV) is well characterized. Data of even short-term prognosis of adult IgAV is scarce, mostly retrospective and usually limited to patients with significant renal disease.
**Objectives:** Our aim was to examine the short-term prognosis in a cohort of unselected adult IgAV cases.
**Methods:** We analysed medical records of newly diagnosed, histologically proven cases of IgAV at our department of rheumatology between 1 January 2010 and 30 June 2015, that were followed until 31 December 2015.
**Results:** We identified 139 IgAV cases during the observation period. The clinical characteristics at presentation and the initial treatment are shown in Table 1. During the acute phase of the disease 3/139 patients died (2 due to active vasculitis, 1 due to generalized CMV infection and heart failure). Twenty patients were lost to follow-up. The clinical characteristics of the remaining 116 patients who were followed for a median 8.9 (IQR 5.5 – 22.7) months at follow-up are shown in Table 2. During the follow-up new malignancy was diagnosed in 6/116 (5.2%) patients and 8/116 (6.9%) patients died. All deaths were due to causes unrelated to IgAV.

Table 1. Clinical characteristics at presentation and initial treatment of IgAV

| | |
|---|---|
| Male, % | 57.6 |
| Median age (IQR), years | 65.4 (41.3–77.4) |
| Purpura, # (%) | 139 (100) |
| necrotic, # (%) | 61 (43.9) |
| generalized, # (%) | 63 (45.3) |
| Joint involvement, # (%) | 62 (44.6) |
| GI tract involvement, # (%) | 49 (35.3) |
| severe GI, # (%) | 13 (9.4) |
| Renal involvement, # (%) | 69 (49.6) |
| severe, # (%) | 19 (13.7) |
| Median BVAS-3 (IQR) | 10 (5–16) |
| Malignancy, # (%) | 3 (2.2%) |

Legend: # – number of patients; IQR – interquartile range; GI – gastrointestinal tract; severe GI tract involvement- - bloody diarrhoea or ileus or surgical intervention; severe renal involvement – acute renal failure or nephrotic syndrome; BVAS-3 – Birmingham vasculitis activity score; Malignancy – concurrently diagnosed malignancy.

Table 2. Clinical characteristics at last follow-up visit

| | Patients, n (%) |
|---|---|
| Relapse | 17 (14.7) |
| once; twice; three times | 14 (12.1); 2 (1.7); 1 (0.9) |
| skin limited | 15 (12.9) |
| skin + renal; skin + GI | 1 (0.9);1 (0.9) |
| Urinary abnormalities | 42 (36.2) |
| microhematuria | 33 (28.4) |
| proteinuria – $<$1g/day; $\geq$1g/day | 10 (8.6); 5 (4.3) |
| Renal function worsening | 10 (8.6) |
| Treatment, # (%) | 107 (77.0) |
| local GC, # (%) | 9 (6.5) |
| systemic GC, # (%) | 98 (70.5) |
| cyclophosphamide, # (%) | 11 (7.9) |
| IVIG, # (%) | 4 (2.9) |

Legend: GC – glucocorticoids; IVIG – intravenous immunoglobulin.

**Conclusions:** Contrary to the experience in children, IgAV in adults does not seem to be a benign disease even in the short-term. Admittedly, it is impossible to conclude whether this is due to the nature of the adult IgAV or because adults have more comorbidities than children.

## FRI0359 ASSESSMENT OF THE FREQUENCY OF CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH TAKAYASU'S ARTERITIS

F. Alibaz-Oner[1], M.J. Koster[1], A.U. Unal[2], H.G. Yıldırım[2], C. Çıkıkçı[2], C.S. Crowson[3], A. Makol[1], S.R. Ytterberg[1], E.L. Matteson[1], K.J. Warrington[1]. *[1]Rheumatology, Mayo Clinic, Rochester/MN, United States; [2]Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey; [3]Health Sciences Research, Mayo Clinic, Rochester/MN, United States*

**Background:** Accelerated atherosclerosis associated with chronic inflammation is one of the major complications of systemic inflammatory diseases. Takayasu arteritis (TAK) is a rare, systemic large-vessel vasculitis predominantly affecting the aorta and its major branches. The prevalence of atherosclerotic risk factors and cardiovascular (CV) disease in patients with TAK has not been well defined.
**Objectives:** The purpose of this study was to assess the frequency of CV risk factors and the incidence of CV events (CVE) in patients with TAK.
**Methods:** Patients fullfilling the American College of Rheumatology criteria for TAK from Mayo Clinic, Rochester, USA and Marmara University, Istanbul, Turkey were included in this retrospective cohort study. Data on cardiovascular risk factors at the time of TAK diagnosis and incident CVE during follow-up were abstracted from the medical records. Patients with TAK were compared to age, sex and calendar year–matched controls from the same geographic region without TAK. The 2008 Framingham 10-year general cardiovascular risk score (FRS) was used for the evaluation of CV risk at the time of TAK incidence/index date. For patients without lipid profiles, the office-based FRS, which does not require lipid values, was computed according to previously published algorithms.
**Results:** A total of 175 patients with TAK and 175 non-TAK controls were included in the study (115 from Mayo Clinic, 60 from Marmara University for each group). Among patients age $\geq$30 years at index date (107 TAK,109 non-TAK), complete data to calculate FRS were available in 93 (87%) TAK and 91 (83%) non-TAK subjects. Hypertension diagnosis and lipid lowering treatment were significantly more frequent in the TAK group compared to non-TAK). Prior to the incidence/index date, the occurrence of CVE was significantly higher in the TAK group The overall Framingham 10-year CV risk score was significantly higher in the TAK group compared to non-TAK at incidence/index date (Table 1).)After

excluding patients with prevalent CVE, 18 TAK and 3 non-TAK patients developed CVE during a mean follow-up of 7.4 years in TAK and 7.9 years in non-TAK groups. The cumulative incidence of CVE was 16.4% at 10 years in TAK group vs. 6.0% in non-TAK group and the risk of CVE was increased among patients with TAK (hazard ratio: 4.52; 95% CI: 1.29, 15.78 adjusted for age, sex and country).

**Table 1:** Baseline characteristics of TAK and non-TAK cohorts in index dates.

| | TAK (n=175) | Non-TAK (n=175) | P value |
|---|---|---|---|
| Age (Years)* | 34.1±32.7 | 34.9±32.9 | 0.70 |
| Sex (female/male) | 157 / 18 | 160 / 15 | 0.58 |
| Hypertension, n (%) | 69 (40%) | 22 (13%) | **<0.001** |
| Diabetes mellitus, n (%) | 12 (7%) | 8 (5%) | 0.35 |
| Lipid profile (mg/dl)* | | | |
| Total cholesterol, mg/dL | 200±50 (n=113) | 190±37 (n=60) | 0.23 |
| Low density lipoprotein, mg/dL | 119±42 (n=101) | 108±35 (n=51) | 0.12 |
| High density lipoprotein, mg/dL | 52±17 (n=103) | 54±15 (n=53) | 0.50 |
| Triglycerides, mg/dL | 137±90 (n=108) | 126±90 (n=60) | 0.13 |
| Lipid lowering treatment, n (%) | 22 (13%) | 7 (4%) | **0.004** |
| Chronic kidney disease (physician diagnosis), n (%) | 3 (2%) | 4 (2%) | 0.71 |
| BMI (kg/m$^2$)* | 26±6.7 | 26± 6.4 | 0.94 |
| Obesity (BMI >30 kg/m$^2$), n, (%) | 52 (22%) | 37 (25%) | 0.78 |
| Smoking status, ever, n, (%) | 80 (47%) | 70 (41%) | 0.36 |
| Framingham risk score, %† | 3.6 (2.2-10) | 2 (1.2-5) | **0.001** |
| Any prior atherosclerotic vascular event | 37 (21%) | 6 (3%) | **<0.001** |

*Mean ±SD †Median (Interquartile range); BMI, body mass index; n = number; SD = standard deviation; TAK = Takayasu arteritis; bolded p-values statistically significant at <0.05

**Conclusions:** CV risk factors are more common in patients with TAK, and the Framingham 10-year cardiovascular risk score is higher in patients with TAK at the time diagnosis compared to non-TAK subjects of similar age and sex. The cumulative incidence of CVE was also significantly higher during follow-up in the TAK group. Patients with TAK should undergo careful assessment of CV risk factors, and an aggressive risk modification approach is warranted.

**Disclosure of Interest:** None declared

## FRI0360 AORTITIS DIAGNOSIS BY PET. A REPORT OF 33 PET FROM A UNIVERSITY HOSPITAL IN A 3 YEAR PERIOD

O. Fernandez Berrizbeitia[1], I. Calvo Zorrilla[1], M.L. Garcia Vivar[1], E. Ruiz Lucea[1], J. Garcia Llorente[1], I. Torre Salaberri[1], E. Ucar Angulo[1], J. Gorordo Olaizola[1], C. Gomez Arango[1], C. Perez Velasquez[1], J.M. Blanco Madrigal[1], E. Guerrero Basterretxea[1], A. Santander Bilbao[2], E. Galindez Agirregoikoa[1]. *[1]Rheumatology; [2]Internal Medicine, Basurto University Hospital, Bilbao, Spain*

**Background:** Early diagnosis and treatment of aortitis are important to prevent possible serious complications such us aneurysm, aneurismal ruptured or aortic dissection. Aortitis may present with non-specific symptoms. Positron emission tomography (PET) is useful in diagnosing aortitis. However, PET is an expensive technique.
**Objectives:** Our aim was to evaluate those PET performed by suspected aortitis in order to find some predictive factors for positive PET for aortitis.
**Methods:** Study of PET performed by suspected aortitis in a University Hospital (from January 2013 to December 2015). The main epidemiological, clinical and laboratory data of these patients were extracted from clinical records according to a specifically designed protocol, reviewed for confirmation of the diagnosis, and stored in a computerized file. To minimize entry error all data were double checked.
A comparative study was made between positive and negative PET to identify red flags of an underlaying aortitis.
Quantitative variable results were expressed as mean±standard deviation (SD) or median [IQR] and were analyzed by Mann-Whitney U test. Qualitative variable results were expressed as percentages and frequency and were analyzed by Fisher's exact test. Statistic analysis was performed with the SAS System for Windows V 9.2.
**Results:** In last 3 year period 33 PET were requested to confirm aortitis (5 of them in 2013, 7 in 2014 and 21 in 2015). We had 3 positive results of 5 (60%) in 2013, 3 of 7 (42.85%) in 2014 and 7 of 21 (33.33%) in 2015. The mean age of the 33 (22 female/11 male) patients was 70.30±14.16 years (range, 31–89).
The underlying diseases associated to these patients were: giant cell arteritis (GCA) (n=12), polymyalgia rheumatic (PmR) (n=8), connective tissue diseases (Sjögren syndrome, dermatomyositis, undifferentiated connective pathology) (n=5), seronegative polyarthritis (n=3), relapsing polychondritis (n=2), idiophatic (n=2), hiper-IgG syndrome (n=1).
Comparative study between positive and negative PET is summarized in TABLE. Inflammatory back pain and irradiated lower limb pain conditions were more common among patients with positive PET. They were the unique variables with statistically significant difference. The rest of both epidemiologic, clinical, laboratory or the possible influence of treatment with steroids and/or immunosuppressants at the time of conducting PET did not differ between groups.
**Conclusions:** In this estudy we observed an increasing in demand for PET for suspected aortitis every year and more cases were diagnosed in recent years. However, positive test percentage progressively decreased. The presence of inflammatory back pain and pain radiating to the lower extremities may have clinical relevance to suspect aortitis and a positive PET result. Prospective studies are needed with larger numbers of patients to establish a predictive model for aortitis.

## FRI0361 THE EXTENSION OF INFLAMMATORY INFILTRATES OR INTIMAL HYPERPLASIA IN TEMPORAL ARTERIES DO NOT SIGNIFICANTLY PREDICT CTA-DETECTION OF AORTIC THICKENING IN NEWLY-DIAGNOSED PATIENTS WITH BIOPSY-PROVEN GIANT-CELL ARTERITIS

G. Murgia[1], J. Hernández-Rodríguez[1], S. Prieto-González[1], A. García-Martínez[1], G. Espigol-Frigole[1], M.A. Alba[1], I. Villar[1], E. Campo[2], P. Arguis[3], R. Gilabert[3], J.M. Grau[4], M.C. Cid[1]. *[1]Vasculitis Research Unit, Dept. Autoimmune Diseases; [2]Dept. Pathology; [3]Dept. Diagnostic Imaging; [4]Dept. Internal Medicine, Hospital Clínic, University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*

**Background:** Giant cell arteritis (GCA) is a granulomatous vasculitis preferentially targeting the carotid and vertebral artery branches. Aortic involvement is common and may lead to severe complications such as aortic dilatation/aneurysm or dissection[1]. While small necropsy studies detected histopathologically-proven aortic inflammation in more than 90% of patients, aortic wall thickening suggesting aortitis is detected in 65% of patients using CTA at diagnosis [2]. We hypothesized that histological features underlying arterial wall thickening (transmural inflammatory infiltrate or intimal hyperplasia) observed in temporal artery biopsies might predict CTA-detection of aortic wall involvement.
**Objectives:** To assess whether the extension of inflammatory infiltrates and/or the degree of intimal hyperplasia in temporal artery biopsies (TAB) from GCA patients correlate with CTA detection of aortitis at the time of diagnosis.
**Methods:** TABs from biopsy-proven GCA included in an ongoing prospective study for detection of large vessel vasculitis (LVV) at diagnosis[1] were scored for the extent of inflammatory infiltrates or intimal hyperplasia as described[3]. Aortitis was defined by CTA as concentric thickening of the aortic wall $\geq$2mm. TABs were categorized according to the extent of inflammatory infiltrates (inflammation limited to adventitia vs transmural inflammation) and the degree of intimal hyperplasia. The latter was considered mild/moderate or severe depending on the ratio between the maximal thickness of the intima layer and the distance between the center of the lumen and the internal elastic lamina ($<$75%vs$>$75%). Fisher exact test was used for statistical analysis.
**Results:** Between November 2006 and June 2013, 51 patients diagnosed with biopsy-proven GCA were included in a CTA-based screening protocol for LVV. Overall, aortitis was detected by CTA in 34 (66.7%) of cases. Inflammation limited to the adventitia was observed in 10 (19.6%) of cases and transmural inflammation in 41 (80.4%). Mild/moderate intimal hyperplasia was observed in 17 (33.3%) biopsies and severe intimal hyperplasia in 34 (66.7%). CTA-detected aortitis was observed in 27 (79.4%) of patients with transmural inflammation compared with 7 (70%) of patients with inflammation limited to the adventitia (p=1.00). Aortitis was seen in 23 (67.6%) of patients with severe intimal hyperplasia compared to 11 (64.7%)of patients with mild/moderate neointima formation (p=1.00).
**Conclusions:** Although the limited size of this cohort prevents definitive conclusions, the extension of inflammatory infiltrates or intimal hyperplasia in temporal

arteries do not significantly predict CTA-detection of aortic thickening in GCA. Variability in the distribution of lesions along the vascular tree may account for these findings. Supported by Marato TV3 2014/201507.

## FRI0362 PRONOSTIC FACTORS OF SURVIVAL IN ANCA-ASSOCIATED VASCULITIS (AAV). CHANGES IN THE NEW CENTURY

M. Rodriguez-Carballeira[1], G. Fraile[2], F. Martinez-valle[3], L. Saez[4], J.J. Rios[5], X. Solanich[6], F. Pasquau[7], E. Fonseca[8], M. Zamora[9], J.L. Calleja[10], J. Oristrell[11], B. Frutos[12], M. Abdilla[13], M.J. Castillo[14], L. Caminal[15], P. Fanlo[16], I. Garcia-Sanchez[17], B. Sopeña[18], M. Lopez-Dupla[19], A. Perez[20], R. Solans-Laqué[3] on behalf of REVAS Study from GEAS-SEMI. *[1]Internal Medicine, H Mutua Terrassa, Terrassa; [2]Internal Medicine, H Ramon y Cajal, Madrid; [3]Internal Medicine, H Vall Hebron, Barcelona; [4]Internal Medicine, H Miguel Servet, Zaragoza; [5]Internal Medicine, H La Paz, Madrid; [6]Internal Medicine, H Bellvitge, Barcelona; [7]Internal Medicine, H Marina Baixa, Alicante; [8]Internal Medicine, H Cabueñes, Asturias; [9]Internal Medicine, H Virgen Nieves; [10]Internal Medicine, H San Cecilio, Granada; [11]Internal Medicine, H Parc Tauli, Sabadell; [12]Internal Medicine, H Fuenlabrada, Madrid; [13]Internal Medicine, H Alzira, Valencia; [14]Internal Medicine, H Virgen Rocio, Sevilla; [15]Internal Medicine, HUCA, Asturias; [16]Internal Medicine, Clinica Navarro, Navarra; [17]Internal Medicine, H Infanta Leonor, Madrid; [18]Internal Medicine, CHUVI, Vigo; [19]I Medicine, H Joan XXIII, Tarragona; [20]I Medicine, H Orense, Orense, Spain*

**Background:** AAV are still related to a high morbidity and mortality in spite of new available therapies. To recognize factors associated with a worse prognosis is essential to tailor the treatment

**Objectives:** To identify survival prognostic factors in a large cohort of patients with AAV from Spain and analyze changes in the new century

**Methods:** multicenter retrospective-longitudinal study that included patients diagnosed with AAV between Jan95 and Nov14 in 20 Hospitals from Spain (REVAS Study). Statistical analysis was done using SPSS vs21

**Results:** 455 patients were included: 188 (41.3%) GPA, 167 (36.7%) MPA, 100 (22%) EGPA. Mean age at diagnosis was 55.7±17.2 y. ANCA were positive in 86.8% of cases:35.8% C-ANCA and 51% P-ANCA. Median time to diagnosis was 4 weeks (IQR 10). Median follow-up was 80 months (IQR 105). Renal, lung, neurological and cardiac involvement were present in 56.7, 54.7%, 34.5% and 12.7% of cases,respectively. Pulmonary-renal syndrome was observed in 17%, ENT in 44.8% and eye involvement in 13.4%. Mean BVAS at diagnosis was 17.7±7.7. All patients received oral glucocorticoids; 342 (75%) cyclophosphamide (50.3% oral), and 6.6% biological therapy. Dialysis was required in 16.4% of cases and plasma exchange in 7%. During follow-up, 22.2% of patients suffered leucopenia, 39% bacterial infections, 12.7% opportunistic infections and 5.3% neoplasms. One hundred thirty (28.6%) patients died: 74 (44.3%) with PAM, 42 (22.3%) with GPA and 14 (14%) with EGPA ($p<0.001$). Median time to death was 57.5 months (IQR 105): significantly higher for EGPA (94m vs 69m for GPA and 50m for PAM;LogRank=0.01). Comparing diagnostic century, the percentage of deaths was higher in the XXth than in XXIth (48% vs 21%, $p<0.001$). No differences were found in clinical manifestations, but yes in treatment and rate of infections: in the actual century more plasma exchange is used (9% vs 2.2%, p=0.008), more biological therapy (9% vs 0.7%, $p<0.001$), less oral CF (29% vs 57.8%, $p<0.001$) and more CF IV pulses (52% vs 35.6%, p=0.001). Multifactorial Cox regression analysis showed that prognostic factors associated with survival were age>65y (HR 4.6), cardiac (HR 3.9) and renal involvement (HR 2.0). ENT involvement was a protector factor (HR 0.4). Bacterial infections during follow-up were also independent predictor of poor prognosis (HR 2.0)

**Conclusions:** survival rate in AAV has significantly improved in the new century probably due to new treatment strategies, including less CF and biological therapy. Poor prognostic factors are age>65y, cardiac and renal involvement at diagnosis,and bacterial infections, while ENT involvement is protective.

## FRI0363 TRIGGERS OF BEHÇET'S DISEASE-RELATED ORAL ULCER RECURRENCES

G. Volle[1], J.-B. Fraison[2], A. Thuillier[3], R. Dhote[4], D. Gobert[5], T. Goulenok[6], F. Lhote[7], S. Rivière[8], A. Mahr[1]. *[1]Internal Medicine, Hospital Saint-Louis, Paris; [2]Hospital Jean-Verdier, Bondy; [3]Dietetics, Hospital Saint-Louis, Paris; [4]Hospital Avicenne, Bobigny; [5]Hospital Saint-Antoine; [6]Hospital Bichat, Paris; [7]Hospital Delafontaine, Saint-Denis; [8]Hospital Saint-Eloi, Montpellier, France*

**Background:** Recurrent oral ulcers (ROU) are an almost constant feature of Behçet's disease (BD) but its pathophysiology is not well understood. It is widely admitted that certain foods or other external factors play a role in BD-related ROU. Thus, the proportion of patients with BD able to identify a specific triggering factor of their ROU and the nature of these factors remain unknown.

**Objectives:** To study the role of dietary and non-dietary factors as triggers of BD-related ROU.

**Methods:** A 23-item self-report questionnaire was given to consecutive in- and outpatients with BD who attended 7 French hospital departments for internal medicine over a 12-month period. Patients were enrolled if they consented to participate in the study and if they had a history of ROU that had not become definitively extinct to ensure patients' ability to provide accurate information. The questionnaire consisted of 13 items collecting general information, e.g., demographic characteristics, dietary habits, age at onset and severity of ROU. Six additional open-ended, dichotomous ("Yes" or "No") or scaled questions ("Yes, I am sure", "Yes, that's possible", "No, that's highly unlikely", or "I don't know") collected information on potential triggering factors of ROU. In particular, the questionnaire evaluated the influences of 6 general triggering situations (i.e., fatigue/stress, dental care, tooth brushing, menstruation, infection, and food/drinks), 24 selected food and drink items, 8 physicochemical properties of food (i.e., salty, sweet, bitter, acid, astringent, hard, hot, cold), and the effect of fast eating. The results were described as percentages of positive responses; for scaled questions, the combined responses of "Yes, I am sure" or "Yes, that's possible" were considered positive.

**Results:** Of the 100 questionnaires distributed, 87 were returned and 80 could be used for the analyses. Among those 80 patients (mean age: 41 years, men: 63%), 96% fulfilled the International criteria for BD, 75% had non-French origins and 81% consumed European-style food. The mean time since ROU onset was 19 years and the ROU was judged by 53% as "very discomforting" or "discomforting" over the previous 12 months. Among the 6 general situations suggested, 91% recognized at least 1 of them as "surely" or "possibly" related to their ROU: fatigue/stress (75%) and food/drinks (70%) were the most frequently cited triggering factors. Among the 24 food/drinks items suggested, the most frequently reported items were: walnuts (49%), pineapple (43%), peanuts (33%), Emmental cheese (30%), lemon (25%), almonds (24%), and other cheeses (21%). Acidity was the most frequently reported physicochemical food characteristic triggering ROU (58%).

**Conclusions:** Fatigue/stress and food are frequently recognized triggering factors of BD-related ROU. This implies the need to take into account such external factors in the management of ROU. The fact that most food items identified as common triggers of ROU are histamine-rich or histamine-releasing could suggest a role of histamine in the pathophysiology of BD-related ROU. Hormonal and traumatic components seemed to be of lesser importance in ROU.

## FRI0364 DOES AN ELEVATED SERUM IMMUNOGLOBULIN A LEVEL PREDICT THE COURSE OF ADULT IGA VASCULITIS?

A. Hočevar, J. Ostrovršnik, Ž. Rotar, M. Tomšič. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Objectives:** Our objective was to evaluate the impact of serum IgA level on the clinical presentation and severity of adult IgA vasculitis (IgAV).

**Methods:** We prospectively collected data on newly diagnosed histologically proven adult IgAV cases between January 2013 and December 2015 at our at our secondary/tertiary rheumatology centre. Patients were stratified according to the serum level of IgA into two groups (elevated IgA (>4.10 g/l) vs. normal IgA (0.7–4.10 g/l)).

**Results:** During the 36 month observation period, 92 new adult IgAV cases (54% male) were identified. The median age was 65.8 (interquartile range (IQR) 48.7–77.3, range 19–88) years and the median disease duration (IQR, range) 7 (6–21, 2–120) days. The serum level of IgA was elevated in 39 (42.4%) cases.

Table 1. Clinical characteristics

| | Normal serum IgA level (N=53) | Elevated serum IgA level (N=39) | P value |
|---|---|---|---|
| M : F ratio | 1.1 | 1.2 | 0.83 |
| Age (years; median (IQR)) | 60.7 (41.3–76.9) | 72.4 (51.6–78.0) | 0.13 |
| Disease duration (days; median (IQR)) | 8 (6–21) | 7 (5–19) | 0.50 |
| Prior infection (%) | 39.6 | 20.5 | *0.07* |
| History of cancer (%) | 9.4 | 15.4 | 0.52 |
| General symptoms (%) | 20.8 | 10.3 | 0.26 |
| Generalized purpura (%) | 49.1 | 46.2 | 0.84 |
| Skin necroses (%) | 41.5 | 43.6 | 1.0 |
| Isolated skin involvement (%) | 26.4 | 25.6 | 1.0 |
| Joint involvement (%) | 47.2 | 30.8 | 0.14 |
| Arthritis (%) | 18.9 | 10.3 | 0.38 |
| GI tract involvement (%) | 39.6 | 25.6 | 0.19 |
| Severe GI tract involvement (%) | 11.3 | 2.6 | 0.23 |
| Renal involvement (%) | 28.3 | 43.6 | 0.18 |
| Severe renal involvement (%) | 11.3 | 23.1 | 0.16 |
| BVAS (median (IQR)) | 8 (3–14) | 6 (2–16) | 0.57 |
| IgAV relapses (%) | 14.3 | 16.7 | 1.0 |
| Persistent urinary abnormalities (%) | 53.6 | 57.1 | 1.0 |
| Newly diagnosed cancer (%) | 0 | 12% | *0.06* |

Legend: M – Male; F – Female; Severe GI tract involvement – bloody diarrhea or ileus or surgical intervention; Severe renal involvement – acute renal failure or nephrotic syndrome; BVAS – Birmingham Vasculitis Activity Score.

The characteristics of IgAV groups with increased and with normal serum IgA level at presentation and at follow-up are presented in Table 1. Follow-up data were available for 59 (24 had elevated IgA) patients, with a median (IQR) follow-up of 7.2 (5.0–14.5) months.

**Conclusions:** Elevated IgA serum level does not seem to have any significant impact on the disease manifestations and severity of adult IgAV. However, there was a trend toward less frequent antecedent infections and more frequent malignancy development in the group with high serum IgA.

## FRI0365 LIMITED EVIDENCE OF ACTIVE VARICELLA ZOSTER VIRUS (VZV) INFECTION IN A COHORT OF ACUTE GIANT CELL ARTERITIS (GCA) PATIENTS

A.M. Sammel[1,2], K. Rosettenstein[2], J.J. Post[1,3], J.V. Bertouch[2]. *[1]Prince of Wales Clinical School, University of New South Wales; [2]Rheumatology; [3]Infectious Diseases, Prince of Wales Hospital, Randwick, Australia*

**Background:** Recent studies have identified a high prevalence of VZV antigen in temporal artery biopsy specimens from patients with GCA. The clinical implication of this finding is uncertain. Some researchers have proposed that reactivation of VZV infection may have a role in inducing arteritis and have promoted antiviral therapy as adjunctive therapy to corticosteroids in cases of biopsy negative and positive GCA. While not currently recommended in GCA, antiviral therapy is used in the clinically distinct condition of VZV vasculopathy which is associated with angiographic abnormalities in the anterior and middle cerebral arteries.

**Objectives:** We aimed to assess if there was clinical, serological or imaging evidence of active VZV in patients with acute GCA. Positive findings may have supported a role for antiviral therapy.

**Methods:** We prospectively assessed the clinical, serological and angiographic profile of all 13 patients referred for assessment of acute GCA to our tertiary referral rheumatology service from June to December 2015 to identify evidence of active VZV infection.

**Results:** 10 patients with an average age of 77 years (range 66 to 87 years) were ultimately diagnosed with GCA. Nine met the American College of Rheumatology 1990 criteria for the classification of GCA, three had positive and one had an equivocal biopsy. Eight were female. All ten had visual disturbance and three had evidence of acute ischaemic optic neuropathy on fundoscopy.

One patient had an episode of cutaneous herpes zoster affecting the right sixth thoracic dermatome two months after onset of GCA headache. This was treated with a five day course of valaciclovir and resolved three weeks before referral to our service. GCA symptoms progressed despite valaciclovir. Seven patients recalled an episode of primary VZV infection in childhood but no other patients had a history of herpes zoster.

VZV serology was performed in all ten patients within 24 days of referral. Time from GCA symptom onset to serology ranged from 15 days to five months. All patients had positive VZV IgG indicating past exposure to the virus. Nine had negative IgM serology. IgM was equivocally elevated in the patient with recent herpes zoster.

Six patients underwent magnetic resonance imaging or computer tomographic cererbral angiography and there was no evidence of VZV vasculopathy of the anterior or middle cerebral arteries.

Patients were treated with pulse intravenous methylprednisolone 500 mg to 1000 mg for three days plus an antiplatelet agent with subsequent oral prednisone. We did not add antiviral therapy. All demonstrated rapid clinical improvement with normalization of inflammatory markers and no progression of visual loss.

**Conclusions:** We did not find clinical, serological or imaging evidence of active VZV infection contributing to acute GCA to support routine adjunctive antiviral therapy.

## FRI0366 COCAINE-LEVAMISOLE INDUCED VASCULITIS: A SERIES OF 11 CASES

C.H. Munoz[1,2], A.L. Vanegas[1,3], A. Arbelaez[1,4], M. Restrepo[1,3], G.M. Vasquez[1,3], L.A. Correa[1,5], L.F. Arias[1,6], L.A. Gonzalez[1,3]. *[1]Hospital Universitario de San Vicente Fundacion, Medellín, Colombia; [2]On behalf of Section of Rheumatology, Universidad de Antioquia, Medellín, Colombia and IPS Universitaria, Medellín, Colombia; [3]On behalf of Section of Rheumatology, Universidad de Antioquia, Medellín, Colombia; [4]On behalf of Clínica de Artritis Temprana, Cali, Colombia; [5]On behalf of Section of Dermatology, Universidad de Antioquia, Medellín, Colombia; [6]On behalf of Department of Pathology, Universidad de Antioquia, Medellín, Colombia*

**Background:** Levamisole, an antihelmintic and immunomodulatory agent currently used as a cocaine adulterant; is related with levamisole-induced vasculopathy (LIVEN), characterized by necrosis of ears, retiform purpura, cytopenias and positive anti-neutrophilic cytoplasmic antibody (ANCA)[1].

**Objectives:** To describe the clinical features and laboratory findings of 11 patients with LIVEN.

**Methods:** We describe 11 consecutive patients with LIVEN, evaluated at 3 Colombian hospitals from December 2010 to May 2015.

**Results:** Hispanic patients with a median age of 35 years (IR 31–39), 82% were male, had a history of more than 2 years of cocaine abuse, and 1 year of symptoms (IR 10–24). All had necrosis of ears, 91% retiform purpura (limbs, buttocks, face and abdomen), 45% fever, 27% genital necrosis and 9% digital necrosis (image). Skin biopsy (n=9) reported thrombotic vasculopathy (78%), pseudo-vasculitis (33%), and leukocytoclastic vasculitis (33%). Fifty five percent of patients had arthralgia/arthritis, 55% glomerulonephritis, 18% pulmonary disease, serositis or lymphadenopathy, 9% hepatosplenomegaly; 64% chronic disease anemia, 27% leucopenia, 73% lymphopenia, 9% neutropenia, 100% raised acute phase reactants. ANCA were positive in 91%, with perinuclear pattern (IIF) and anti-MPO positive (ELISA) or double positivity (anti-MPO and anti-PR3). Forty five percent exhibit ANA (homogeneous pattern), 29% anti-dsDNA and anti-Ro, 55% hypocomplementemia, 73% lupus anticoagulant, 20% anticardiolipin antibodies and cryoglobulins. Most patients received prednisolone (median dose 50 mg/d, IR 35–60). Lesions resolved in all patients with treatment and cocaine suspension; relapses were associated with resuming consumption.

**Conclusions:** LIVEN cases had increased due to the use of levamisole-adulterated cocaine[1]. Besides the typical skin lesions, there are hematological, renal, joint and lung manifestations. Main laboratory findings are high ESR and CRP levels, positive ANCA and lupus anticoagulant, although other autoantibodies could be present (aCL, ANA and anti-dsDNA). The differential diagnosis includes systemic vasculitis, systemic lupus erythematosus and antiphospholipid syndrome. The characteristic skin lesions, the relationship with the consumption and the improvement at suspension are diagnostic clues. In this series the clinical and laboratory features were similar to those described in the literature but we found higher renal involvement[2]. LIVEN should be considered in patients with retiform purpura, ear involvement and multiple autoantibodies posivity.

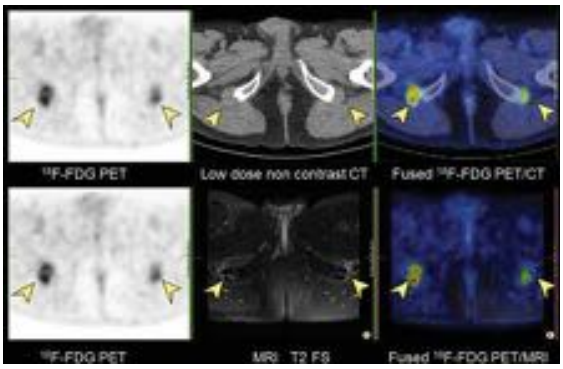
## FRI0367 PET/MRI FUSION DEMONSTRATES HAMSTRING PERI TENDONITIS IN PATIENTS WITH POLYMYALGIA RHEUMATICA

C.E. Owen[1,2], A.M. Poon[3,4], S.-T. Lee[2,3,4], L.-P. Yap[5], R.B. Zwar[5], C. McMenamin[1], K. Pathmaraj[3], A. Kemp[5], A.M. Scott[2,3,4], R.R. Buchanan[1,2]. *[1]Rheumatology, Austin Health, Heidelberg VIC; [2]Medicine, University of Melbourne, Parkville VIC; [3]Molecular Imaging and Therapy, Austin Health; [4]Olivia Newton-John Cancer Research Centre; [5]Radiology, Austin Health, Heidelberg VIC, Australia*



**Background:** Positron emission tomography/computed tomography (PET/CT) possesses the unique potential to document whole body inflammation in polymyalgia rheumatica (PMR), however the precise anatomical structures involved have not been well characterised.

**Objectives:** To characterise the pattern of $^{18}$F-fluorodeoxyglucose ($^{18}$F-FDG) uptake on whole body PET/CT in patients with newly diagnosed PMR, and to precisely identify anatomic correlates of $^{18}$F-FDG uptake with magnetic resonance imaging (MRI).

**Methods:** Patients with newly diagnosed PMR according to the 2012 EULAR/ACR classification criteria (1) were prospectively recruited. Participants with symptoms suggestive of giant cell arteritis were excluded. A whole body $^{18}$F-FDG PET/CT scan was performed at baseline in all untreated patients. Qualitative and semi-quantitative (standardised uptake value maximum [$SUV_{max}$]) scoring of $^{18}$F-FDG

uptake was undertaken, with statistical analyses completed using Stata 13.0 (Statcorp, College Station, TX, USA). MRI of the pelvis, knee and hand/wrist was then performed in three patients with representative $^{18}$F-FDG PET/CT findings using a 1.5 Tesla magnet. Medview fusion software was utilised to anatomically correlate sites of $^{18}$F-FDG uptake.

**Results:** Nineteen patients were recruited. Mean age was 67.52±6.36 years and there was a slight male predominance (63.16%). On whole body PET/CT, adjacent to the ischial tuberosities was the most common site of abnormal $^{18}$F-FDG uptake (18/19 patients [94.74%]) and showed the highest mean $SUV_{max}$ value (3.95 ± 1.81). Eleven patients (11/18 [61.11%]) were found to have knee involvement, with intense $^{18}$F-FDG uptake in posteromedial knee structures in ten participants. $^{18}$F-FDG uptake was similarly appreciated at the hand/wrist in twelve patients (63.16%). At the hand/wrist, a volar distribution was typical. MRI of the pelvis demonstrated bilateral and symmetric high T2 signal surrounding the proximal hamstring tendon origins of semimembranosus and the conjoint tendon of semitendinosus and biceps femoris. At the knee, peri tendinous oedema surrounding the distal insertion of semimembranosus was similarly visualised. Hand/wrist MRI revealed synovial thickening and enhancement in the flexor compartment, in keeping with tenosynovitis. PET/MRI fusion at the pelvis and knee confirmed semimembranosus peri tendonitis as the anatomical correlate of $^{18}$F-FDG uptake adjacent to the ischial tuberosities and of posteromedial knee structures on whole body PET/CT.

**Conclusions:** PET/MRI fusion demonstrates that hamstring peri tendonitis is a distinctive manifestation of PMR. This further characterise the imaging phenotype of PMR and highlights a predilection for tendon involvement in this condition.

## FRI0368 THE USE OF ULTRASOUND IN THE DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH GIANT CELL ARTERITIS: EXPERIENCE OF A SINGLE CENTRE

C.B. Ponte[1,2], A. Floris[1,3], S. Vaggers[1], N. Goodfellow[1], J. Sznajd[1], L. O'Neill[1], J. Piper[1], J. Gunn[1], K. Mankia[1], R.A. Luqmani[1]. [1]*Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom;* [2]*Rheumatology Department, Hospital de Santa Maria – CHLN, Lisbon Academic Medical Centre, Lisbon, Portugal;* [3]*Rheumatology Unit, University Clinic of Cagliari, Cagliari, Italy*

**Background:** Giant cell arteritis (GCA), the most common primary vasculitis, can cause irreversible blindness in 20–30% of untreated cases, but glucocorticoid therapy leads to significant toxicity in >80% of patients. Ultrasound has proven to be effective in diagnosing giant cell arteritis (GCA) and has the potential to monitor disease activity.

**Objectives:** We reviewed data on all patients referred to a single university hospital between August 2014 and December 2015 who were seen in a "fast-track" service established to diagnose and evaluate suspected GCA or a suspected flare.

**Methods:** All patients underwent rapid evaluation by a combination of standard clinical assessment and ultrasound of the temporal and axillary arteries. The ultrasound scan was considered positive when we identified the presence of a dark halo around the temporal artery wall or a homogeneous hypoechoic wall thickness >1.5 mm in the axillary arteries. We performed a retrospective analysis and comparison of the ultrasound findings with the clinical features, temporal artery biopsy (TAB) results and decision to treat patients with suspected or established GCA.

**Results:** We performed 206 scans in 169 patients (71% females, mean [SD] age 72 ± 11 years). In 123 cases, patients were referred for suspected GCA: 63% were already receiving high-doses of steroids (mean of 12 ± 10 days); 78% had headache; 60% high inflammatory markers; 33% abnormal vascular examination (e.g. diminished/absent pulse or bruits); 31% scalp tenderness; 28% jaw claudication; 26% polymyalgia rheumatica and 26% visual symptoms. In 39 cases the scan was positive: 9 also had a TAB (4 positive) and all were treated as GCA. In 77 cases the scan was negative: 27 also had a TAB (1 positive) and 9 were treated as GCA. In 7 cases the scan was inconclusive requiring further investigations (e.g. TAB). Patients with a positive scan had a mean CRP of 17.6 ± 30.1 g/dl and a mean ESR of 41.3 ± 43.3 mm/hour; patients with a negative scan had a mean CRP of 13.8 ± 17.9 g/dl and a mean ESR of 16.3 ± 17.6 mm/hour (p=0.979 and p=0.048, respectively). We scanned 83 patients with an established diagnosis of GCA to assess for flare or monitor disease activity: 29 had a positive scan (21 increased medication; 8 were follow-ups with improvement from baseline) and 54 had a negative scan (4 increased medication; 50 allowed a safer taper or withdrawal of glucocorticoids). Patients with a positive scan had a mean CRP of 8.0 ± 10.1 g/dl and a mean ESR of 15.6 ± 17.3 mm/hour; patients with a negative scan had a mean CRP of 9.6 ± 16.9 g/dl and a mean ESR of 20.5 ± 19.3 mm/hour (p=0.970 and p=0.190, respectively).

**Conclusions:** The combination of rapid clinical evaluation and ultrasound were key elements in diagnosis and monitoring of GCA, allowing more flexible use of glucocorticoid dose regimens and reducing the number of TABs required. The only patient with a negative scan but a positive TAB had already received 20 days of glucocorticoids, suggesting that delay in investigation after starting therapy could affect the results of the scan.

## FRI0369 PATTERN OF CLINICAL PRESENTATION AND DISEASE SEVERITY IN PATIENTS WITH POLYMYALGIA RHEUMATICA

D. Camellino, A. Sobrero, V. Tomatis, S. Paolino, M. Cutolo, M.A. Cimmino. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

**Background:** Polymyalgia rheumatica (PMR) is an inflammatory disorder of the elderly characterized by girdle pain and stiffness, constitutional symptoms and elevation of inflammatory indexes. In its classical form, the shoulder girdle is affected, associated or not with pelvic and spinal pain. The latter two locations can occasionally precede shoulder involvement. It is not known if the pattern of clinical presentation is related to disease severity at onset.

**Objectives:** In this study, disease severity of PMR has been correlated with clinical characteristics at presentation.

**Methods:** 394 patients (251 women, median age 73 yrs, range 47–92 yrs) with PMR diagnosed according to Bird's criteria, visited between 1990 and 2014 by the same clinician were studied. Clinical features recorded at disease presentation included initial involvement of: i) the shoulder girdle; ii) the pelvic girdle; iii) the column; iv) two or more of the previous locations; v) presence of giant cell arteritis (GCA); vi) acute onset, defined as completion of full symptoms and signs in ≤72h; or vii) peripheral arthritis. Disease severity of PMR was evaluated by considering: i) weight loss; ii) fever; iii) morning stiffness (MS); iv) ESR; v) CRP; and vi) initial dose of prednisone.

**Results:** Acute onset and classical involvement of the shoulder girdle were not associated with our indicators of PMR severity. By contrast, onset in the pelvic girdle (p=0.002), simultaneous onset in multiple locations (p=0.006), peripheral arthritis (p=0.045) and GCA (p=0.0004) were associated with a higher initial dose of prednisone; multiple locations onset correlated also with MS (p=0.044).

**Conclusions:** The presentation with multiple locations, including column and pelvic girdle, peripheral arthritis, and GCA resulted in a more severe onset at least in the perception of the clinician who used a higher initial dose of prednisone. Clinicians should consider the pattern of disease presentation when evaluating the burden of PMR.

## FRI0370 TWO SUBSETS OF GIANT CELL ARTERITIS CHARACTERIZED BY THE ABSENCE OR PRESENCE OF SPONDYLOARTHRITIS OR ITS ASSOCIATED DISEASES

D. Ernst, N. Baerlecken, R. Schmidt, T. Witte. *Medizinische Hochschule Hannover, Hannover, Germany*

**Background:** Whilst large vessel vasculitis (LVV) predominantly occurs in isolation, associations with other infectious and non-infectious diseases have been reported. Limited data describing associations with various autoimmune diseases, including spondyloarthritis exists. The aim of this study was to characterize the association of LVV and spondyloarthritis or its associated diseases (SpAD).

**Methods:** A single centre, retrospective study of patients ≥50yrs with first presentation LVV between 01.06.2008–01.06.2015 was performed. Patients were categorized according to SpA or associated disease, other autoimmune disease or controls. Clinical, laboratory and imaging findings were compared. Kaplan-Meyer survival analysis, with relapse taken as the primary end-point, was performed.
**Results:** LVV was confirmed in 62 pts, of who 16/62 (26%) had SpA or associated disease. In these patients, LVV presented earlier (59.2 SpAD vs. 68.1 AI and 70.3yrs Controls; p=0.01) and occurred predominantly in spring compared to autumn and winter in non-SpA patients, was associated with more centralised pattern of distribution (p=0.05) and was more likely to exhibit a refractory course (p=0.05). Overall relapse rates were similar across groups. Smoking-status influenced age of onset in all groups, being associated with earlier onset.
**Conclusions:** A clear association between LVV and SpAD exists. LVV associated with SpAD has a particular phenotype characterised by earlier onset, thorax-limited disease and increased risk of a refractory course. Given on-going LVV treatment trials further genetic and pathophysiological characterization appears warranted, to evaluate potential variation in treatment response and optimize future care.

## FRI0371 THE CLINICAL SPECTRUM OF MEDIUM-SIZED VESSEL VASCULITIS

F. Alibaz-Oner[1], M.J. Koster[2], C.S. Crowson[3], A. Makol[1], S.R. Ytterberg[1], E.L. Matteson[1], K.J. Warrington[1]. *[1]Rheumatology; [2]Mayo Clinic, Rochester/MN, United States; [3]Health Sciences Research, Mayo Clinic, Rochester/MN, United States*

**Background:** Polyarteritis nodosa (PAN) is a systemic necrotizing vasculitis of medium sized visceral vessels. The 2012 Chapel Hill Consensus Conference Nomenclature of vasculitides defined vasculitis affecting any size of vessel in a single organ without systemic manifestations as single organ vasculitis (SOV). However, cutaneous arteritis (CA) and Gastrointestinal (GI) vasculitis are forms of SOV having indistinguishable histopathological findings from PAN.
**Objectives:** In this study, we aimed to evaluate and compare the demographics, clinical characteristics, treatment, and outcomes of patients with systemic PAN, CA and GI vasculitis.
**Methods:** We assembled retrospective cohorts of patients with PAN, CA and GI vasculitis between 1980 and 2014. The demographics, clinical characteristics, treatment and outcomes of patients were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS), prognostic Five Factor Score (FFS) and vasculitis damage index (VDI) were calculated.
**Results:** The study included 48 patients with PAN, 41 patients with CA, and 19 patients with GI vasculitis. Only 1 patient presenting as CA evolved to systemic PAN during the disease course. Most cases of PAN were idiopathic, while only 7 patients had hepatitis B and 2 patients had hepatitis C positivity. Constitutional and musculoskeletal manifestations were the most common clinical manifestations in the PAN group and were less frequent in CA and GI vasculitis. At diagnosis, 94% of patients with PAN, 93% of patients with CA and 67% of patients with GI vasculitis were treated with glucocorticoids. Additional immune-suppressive agents were used in 67% of PAN, 37% of GI vasculitis and 32% of CA. Twenty-seven patients with PAN, 18 patients with CA and 9 patients with GI vasculitis had mean follow-up of about 6 years. The five year cumulative relapse rate was 45.2% in CA, and only 9.6% in PAN. VDI was comparable in PAN and GI vasculitis, but was lower in CA. While no deaths were observed in the CA group, survival at 10-years was 66% in the PAN and 61% in GI vasculitis group.
**Conclusions:** CA and GI vasculitis appear to be distinct diseases rather than a limited expression of systemic PAN. Progression of CA to systemic PAN is very rare. Relapse risk is very low during follow-up in PAN. Patients with CA have a higher relapse rate compared to those with systemic PAN, possibly due to lower use of immunosuppressive therapy in the former group.
**Disclosure of Interest:** None declared

## FRI0372 RITUXIMAB FOR ANCA ASSOCIATED VASCULITIS REFRACTORY TO CONVENTIONAL TREATMENT: A RETROSPECTIVE STUDY ON 25 PATIENTS

G. Ayan, S. Ugurlu, G. Hatemi, E. Seyahi, M. Melikoglu, I. Fresko, H. Ozdogan, S. Yurdakul, V. Hamuryudan. *Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey*

**Background:** The efficacy of rituximab (RTX) in ANCA associated vasculitis (AAV) has been shown in controlled trials. Observational data reflecting its real life use in AAV is limited.
**Objectives:** Here we present our experience with RTX therapy in AAV patients refractory to conventional treatment.
**Methods:** We retrospectively reviewed the records of 25 AAV patients (11 men, 14 women; mean age 42.8±14.2 SD years; mean disease duration 45.5 ± 47.5 SD months) treated with RTX between 2011 and 2015 due to inadequate response or relapse under conventional treatment modalities. Among these 25 patiens the main types of involvement at baseline were renal involvement in 14 patients, pulmonary involvement in 16, upper respiratory system in 10, ocular in 2, peripheral nervous system in 2, CNS in 1, skin in 1 patient and ear in 2 patients. We assessed treatment response with disease activity using BVAS scores, decrease in corticosteroid dose, improvement in renal functions and other organ manifestations.
**Results:** RTX was given for a median of 2 courses (range 1–5, courses given at fixed intervals in 21 patients) during a mean follow-up of 17.4±13.9 SD months. The reasons for RTX treatment were active renal disease in 11 patients, pulmonary involvement in 9, upper respiratory system involvement in 4, and CNS involvement in 1 patient. In addition to RTX, corticosteroids were used in 13 patients, azathioprine + corticosteroids in 7 patients, methotrexate + corticosteriods in 2 patients, solo azathioprine in 2 patients and RTX was given solo in 1 patient. At final assessment 22 patients were under follow-up, 1 was lost to follow-up after 7 months and 2 had died, due to renal failure in one and respiratory failure in the other patient. 17/25 (68%) patients were in remission (BVAS score 0) at the final assessment. 3/25 patients (12%) had experienced relapses during follow-up. The mean BVAS score during the final assessment was 1.6 ± 4.1. Mean corticosteroid dose was reduced from 42±21.9 mg/day to 15.5±21.0 mg/day ($p<0.001$).The last evaluation of patients with renal involvement showed stable disease in 6 improvement in 6 and worsening in 2 patients. Mean creatinine level had slightly improved from 2.1 ± 1.2 mg/day to 1.9 ± 1.4 mg/day (p=0.36). Proteinuria had decreased from 1686±1466 mg/day to 1010±1100 mg/day (p=0.02). RTX treatment was terminated in 2 patients because of infusion reaction. Four patients were hospitalized while being on RTX. The first had pneumonia and responded to antibiotics. The second patient with diffuse lung involvement had died. The third died due to renal failure and the last patient developed end stage renal disease.
**Conclusions:** Our retrospective study showed that RTX is an effective treatment modality that enables corticosteroids tapering and remission in majority of AAV patients refractory to conventional treatment modalities. It was generally well tolerated with few serious adverse events.

Kalyoncu[2]. *[1]Rheumatology, Koç University Hospital, Istanbul; [2]Hacettepe University; [3]Yıldırım Beyazit University, Ankara; [4]Gaziantep University, Gaziantep; [5]Uludağ University, Bursa; [6]Erciyes University, Kayseri; [7]Süleyman Demirel University, Isparta; [8]Acıbadem University, Istanbul; [9]Ondokuz Mayıs University, Samsun; [10]Antalya Education and Research Hospital, Antalya; [11]Gulhane Military Medical Academy, Ankara; [12]Trakya University, Edirne; [13]Kocaeli University, Kocaeli; [14]Bilim University, Istanbul; [15]Gazi University; [16]Ankara University, Ankara, Turkey*

**Background:** Relapsing polychondritis (RP) is a rare systemic and inflammatory disease.
**Objectives:** to assess clinical features, management and prognosis in RP.
**Methods:** Retrospective medical records were collected from 16 centers for 37 patients with RP diagnosed by Michet criteria. Data included patients' demographics, clinical features, laboratory findings and outcome.
**Results:** A total of 37 patients, (Male/female=19/18) with a mean disease onset of 45.7±11.8 years and median follow up period is 20 (1–360) months were enrolled. The most common initial complaints and organs involved were showed in table 1. Mean lead time to diagnose was 28.6±54.3 (0–228) months. Four patients had a known history of cartilage injury before the RP diagnosis (Three goiter operation and 1 resuscitation due to a drowning). Twelve of the patients (32.4%) had also various autoimmune or hematologic diseases. After the diagnosis, moderate or high dose prednisone (n=37, 100%), plus methotrexate (n=15, 40.5%) or azathioprine (AZA) (n=11, 29.7%) or hydroxychloroquine (HQ) (n=3, 8.1%) or cyclophosphamide (CYP) (n=2, 5.4%), or (AZA+ HQ n=3, 8.1%) treatments were initiated. In the case of resistant disease, CYP (n=6, %16.2), tocilizumab (n=2, 5.4%), etanercept (n=1, 2.7%), infliximab (n=1, 2.7%) and bevacizumab (n=1, 2.7%) treatments were given. Due to tracheal stenosis surgery applied to 2 patients, one patient died due to respiratory collapse, 21 patients on remission without any complications, 13 (35.1%) patients had developed tracheal stenosis

Table 1. Clinical features at diagnosis

| Complaints | n (%) | Organ involvement | n (%) |
|---|---|---|---|
| Pain and redness in the auricular area | 32 (86.4) | Auricular chondritis | 32 (86.4) |
| Constitutional symptoms | 30 (81.8) | Arthritis | 22 (59.4) |
| Arthralgia | 28 (75.7) | Eye | 19 (51.3) |
| Swollen joints | 22 (59.4) | Skin lesions | 14 (37.8) |
| Myalgia | 21 (56.8) | Nasal chondritis | 11 (29.7) |
| Red eye and pain | 20 (54.1) | Major airway | 10 (27) |
| Erythema and pain in the nose | 16 (43.2) | Costochondritis | 9 (24.3) |
| Dyspnea | 13 (35.1) | Hearing loss | 7 (18.9) |

(n=5, 13.5%), major airway cartilage loss (n=5, 13.5%), auricular collapse (n=2, 5.4%), nasal collapse (n=3, 8.1%), subglottic stenosis (n=2, 5.4%), hearing loss (n=5, 13.5%), vision loss (n=1, 2.7%) and deforming arthritis (n=1, 2.7%). In the univariate analysis, only major airway involvement had a relationship with complication development. (OR 12, 95% CI 1.97–72.8, p=0.007)

**Conclusions:** RP is a rare disease which diagnosis is commonly delayed and lead to cartilage loss. RP developed after trauma in 4 patients, possibly trauma can be blamed as an etiologic factor. Awareness and early diagnosis results with better prognosis

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.2775

## FRI0374 THE DIAGNOSTIC VALUE OF ALPHA-1-ANTITRYPSIN PHENOTYPE IN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS (WEGENER'S GRANULOMATOSIS)

I. Belyaeva[1], M. Pervakova[1], S. Lapin[2], V. Mazurov[1], A. Chudinov[1].
*[1]North-West Medical University Named by Ii Mechnikov; [2]First Pavlov State Medical University of St. Peterburg, Russia, St.Petersburg, Russian Federation*

**Background:** Deficiency of alpha-1 protease inhibitor, or alpha-1-antitrypsin (A1AT), predisposes to chronic lung diseases and some extra-pulmonary pathology. Besides classical implications, such as pulmonary emphysema and other associated lung diseases, A1AD is also known to be associated with granulomatosis with polyangiitis (GPA, or Wegener's).

**Objectives:** The aim of our study was to evaluate the frequency of mutated A1AT forms and its clinical significance among GPA patients.

**Methods:** We analysed 38 samples of sera, collected from GPA patients. Detailed clinical data, including Birmingham Vasculitis Activity Score (BVAS), incidence of lung involvement, anti-(Pr3) antibodies concentrations and other laboratory data were collected. We also studied control group of 46 healthy donors. All collected samples underwent A1AT phenotyping by isoelectrofocusing (IEF) and turbidimetric A1AT measurement.

**Results:** Mutated A1AT variants were revealed in 18.4% (7/38) cases and included following phenotypes: 1ZZ, 4MZ and 2MF. The mean A1AT concentration in samples with pathological genetic A1AT forms was significantly lower (P=0,0038), than in normal A1AT phenotype. According to reference values, only 2 of 7 pathological samples demonstrated decreased A1AT concentration. Comparing BVAS activity, we found that patients with mutated A1AT phenotype had significantly higher vasculitis activity, as well as anti-PR3 antibodies concentration. When analysis of nonspecific systemic inflammation markers was performed, the significant difference ($P<0.05$) was found only between means of erythrocyte sedimentation rate (ESR)

**Conclusions:** Laboratory testing to find pathological A1AT forms are not usually ordered for patients with systemic vasculitides. During medical examination of GPA patients the possibility of A1AT deficiency should be considered and may be verificated by IEF.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3593

## FRI0375 CLINICAL IMPROVEMENT ACCORDING TO PATIENT REPORTED OUTCOMES IN PATIENTS WITH POLYMYALGIA RHEUMATICA: A LONGITUDINAL ANALYSIS FROM ROUTINE CARE

I. Castrejon, S.L. Everakes, A. Nika, W. Sequeira, T. Pincus. *Rheumatology, Rush University Medical Center, Chicago, United States*

**Background:** Several outcomes and clinical response measures have been used in patients with polymyalgia rheumatica (PMR), but there is no consensus about the optimal endpoint for evaluating response to treatment. A PMR activity score has been proposed which includes three patient reported outcomes (PROs)[1]. RAPID3 is an index found on a multidimensional health assessment questionnaire (MDHAQ) only including PROs, which is effective to document improvement not only in RA but also in other rheumatic diseases[2]

**Objectives:** To prospectively evaluate the performance of RAPID3 and other PROs included on the MDHAQ to document improvement in clinical status over time in patients with PMR.

**Methods:** This study was conducted at an academic rheumatology center at which all patients complete a MDHAQ, which includes 0–10 scores for physical function (FN), pain (PN), and patient global estimate (PATGL), compiled into a 0–30 RAPID3. The MDHAQ also scores fatigue, morning stiffness, self-reported joint counts and demographic data. Data collection included MDHAQ, acute-phase reactants, and prednisone dose. PMR patients with complete data seen between 2010 and 2014 were included. A baseline visit and the most recent visit were compared using paired t-test and McNemar's test. Spearman correlation analysis for non-normally distributed variables was performed between RAPID3 and ESR and CRP.

**Results:** 34 PMR patients seen in routine care were included: 59% were females, 71% Caucasian, and mean age was 71.6 years. The mean duration from a baseline visit to most recent visit was 15.5 months. At initial presentation, RAPID3 was 12.2, FN 2.2, pain 5.3, and PATGL 4.7, fatigue 3.9, and morning stiffness 63.1 minutes; 64.7% of the patients had painful hips, 79.4% had painful shoulders, 73.5% had abnormal ESR, and 70.6% had abnormal CRP. Significant improvement was seen between baseline and last visit in mean level of RAPID3 and all other MDHAQ measures, except fatigue ($p<0.05$), as well as ESR and CRP (Table). The mean dose of prednisone was decreased from 12.2 mg at first visit to 4.3 mg at most recent visit. The RAPID3 was significantly correlated with ESR (rho=0.52), and with CRP (rho=0.50).

Table 1

| | PMR patients (n=34) | | | Mean change | % Improvement |
|---|---|---|---|---|---|
| | Baseline | Most recent visit | P value | | |
| MDHAQ: patient self-reported measures | | | | | |
| RAPID3, mean (SD) | 12.2 (7.0) | 8.5 (7.2) | 0.02 | 3.7 | 30.7% |
| MDHAQ – Function, mean (SD) | 2.2 (2.1) | 1.5 (1.7) | 0.03 | 0.6 | 27.2% |
| MDHAQ – Pain, mean (SD) | 5.3 (2.9) | 3.4 (3.4) | 0.002 | 1.9 | 35.8% |
| MDHAQ – PATGL, mean (SD) | 4.7 (2.9) | 3.1 (3.1) | 0.01 | 1.6 | 34.0% |
| RADAI – painful hip, n (%) | 22 (64.7%) | 12 (35.3%) | 0.02 | 29.4 | 45.4% |
| RADAI – painful shoulder, n (%) | 27 (79.4%) | 17 (50%) | 0.005 | 10 | 37.0% |
| MDHAQ – Fatigue, mean (SD) | 3.9 (3.6) | 3.5 (3.3) | 0.54 | 0.4 | 10.5% |
| Morning stiffness duration, minutes, mean (SD) | 63.1 (97.7) | 19.1 (34.1) | 0.05 | 43.9 | 69.5% |
| Laboratory measures | | | | | |
| Abnormal ESR, n (%) | 25 (73.5%) | 14 (41.1%) | 0.002 | 32 | 43.5% |
| Abnormal CRP, n (%) | 24 (70.6%) | 13 (38.2%) | 0.01 | 32 | 45.3% |
| Medication | | | | | |
| Prednisone dosage, mg, mean (SD) | 12.2 (6.8) | 4.3 (3.5) | <0.001 | 7.9 | 64.7% |

**Conclusions:** In patients with PMR, improvement was seen according to PROs included on a self-reported MDHAQ questionnaire in a similar range to ESR and CRP, documenting effective response to prednisone.

## FRI0376 COMPARISON OF CLINICAL CHARACTERISTICS OF PATIENTS WITH TAKAYASU'S ARTERITIS BY AGE AND GENDER

J. Wan, T. Wang. *Rheumatology, Beijing An Zhen Hospital Affiliated to Capital Medical University, Beijing, China*

**Background:** Takayasu's arteritis (TA) is a rare and heterogeneous disease that can be difficult to diagnose.

**Objectives:** In this study we distinguish clinical characteristics in the different groups with TA and aimed to improve the diagnosis ability of this disease in different people.

**Methods:** We retrospectively analyzed the clinical manifestations and laboratory and angiographic findings of 53 TA patients divided into groups by age and by gender.

**Results:** Ratio of incidence in males and females was 1:4; mean age at onset was (35 ± 11) years in males and (28 ± 11) years in females. In 17% of patients, at onset was over the age of 40. The most common symptom at onset was chest pain and reduced glomerular filtration rate (GFR) in males [7 (63.6%) *vs.* 12 (28.6%), *P*=0.031; 8 (72.7%) *vs.* 14 (33.3%), *P*=0.034], especially in young males [age≤40 years, 5 (62.5%) *vs.* 8 (22.2%), *P*=0.024; 7 (87.5%) *vs.* 12 (33.3%), *P*=0.006]. Significantly more male patients, especially males over the age of 40, had multi-vessel involvement [10 (90.9%) *vs.* 24 (57.1%), *P*=0.038; 2 (66.7%) *vs.* 0, *P*=0.033]. Significantly more young males had aortic insufficiency [5 (62.5%) *vs.* 8 (22.2%), *P*=0.024]. Pulselessness [2 (66.7%) *vs.* 0, *P*=0.03] and radial artery weakening [2 (66.7%) *vs.* 0, *P*=0.03] were found in more males over 40 years of age at onset. There were no differences in laboratory data between males and females. Chest pain [13 (29.5%) *vs.* 6 (66.7%), *P*=0.031] and fever [0 *vs.* 1 (11.1%), *P*=0.027]occurred significantly more often in patients over the age of 40., and patients over 40 years of age at onset had significantly less renal artery [1 (11.1%) *vs.* 21 (47.7%), *P*=0.042], abdominal aortic [0 *vs.* 16 (38.1%), *P*=0.030], and multi-vessel involvement [2 (22.2%) *vs.* 32 (72.7%), *P*=0.004]. Patients over 40 years of age were rarer in type V [1 (11.1%) *vs.* 22 (50%), *P*=0.032)] while more common in type IIa [3 (33/3%) *vs.* 4 (9.1%), *P*=0.050] than young ones. Multivariate analysis showed that thoracic aortic involvement was an independent risk factor for developing hypertension (OR =3.918, 95% confidence interval [CI] 1.616–1566.185, *P* =0.026), and ascending aortic involvement was an independent risk factor for both aortic insufficiency (OR =3.674, 95% CI 2.734–567.621, *P* =0.007) and aneurysm formation (OR =7.255, 95% CI 7.255 ~ 1,628,614; *P* =0.044).

**Conclusions:** Patients with disease at onset after age 40 are more likely to present with chest pain and fever and only rarely have renal artery, abdominal aortic or multi-vessel involvement. Males are likely to present with multi-vessel involvement and reduced GFR, and these differences are more prominent in young males, who are more likely to develop aortic insufficiency. Aortic stenosis was an independent risk factor for hypertension, while ascending aortic involvement was an independent risk factor for aortic valvular insufficiency and aneurysm formation. Aortic valve lesion and ascending aorta involvement may play reciprocal role to aggravates destructions of each other and induce chest pain.

## FRI0377 CLASSIFICATION CRITERIA FOR GIANT CELL ARTERITIS: DATA FROM GIACTA INFORMING THE NEED FOR REVISION

K. Tuckwell[1], N. Collinson[1], M. Klearman[2], S. Dimonaco[1], J.H. Stone[3] on behalf of GiACTA Investigators. *[1]Roche Products Ltd., Welwyn Garden City, United Kingdom; [2]Genentech, South San Francisco; [3]Harvard Medical School, Boston, United States*

**Background:** Classification criteria are often used to standardize the enrollment of patients (pts) in clinical studies. American College of Rheumatology (ACR) classification criteria for giant cell arteritis (GCA)[1] are >25 years old. Advances in diagnosis and clinical understanding of GCA make their relevance to current studies questionable.
**Objectives:** To compare inclusion criteria for the GiACTA (tocilizumab for GCA) study[2] with 1990 ACR GCA classification criteria.
**Methods:** Pts were enrolled into GiACTA according to study inclusion criteria and were evaluated as to whether they met the 1990 ACR classification criteria (Table). Data are from a live database.
**Results:** Of the 251 pts enrolled into GiACTA, 198 (79%) pts met the 1990 ACR classification criteria. The 53 pts who did not fulfill ACR criteria were eligible for GiACTA based on cross-sectional imaging studies and/or polymyalgia rheumatica (PMR) symptoms. In total, 156 (62%) pts had positive temporal artery biopsies (TAB); of these, 24 also had positive imaging findings. The remaining 95 (38%) pts had no TAB or negative TAB; diagnosis of GCA was confirmed by positive findings from large-vessel imaging studies. Positron emission tomography (PET), often coupled with computed tomography (CT), was important in diagnosis. Positive PET/CT findings contributed to GCA diagnosis in 97 (39%) GiACTA pts. CT angiography and magnetic resonance angiography contributed to diagnosis in 14 (6%) and 8 (3%) pts, respectively. New-onset headache, the only GCA symptom in the ACR criteria, was absent in 33% of GiACTA pts. However, other symptoms that often accompany GCA (PMR, scalp tenderness, jaw claudication, ischemia-related vision loss) were present in 62%, 36%, 34%, and 10% of pts, respectively.

| GiACTA Entry Criteria for the Classification of GCA | ACR Criteria for the Classification of Giant Cell (Temporal) Arteritis[a] |
|---|---|
| Age ≥50 y | Age at disease onset ≥50 y |
| History of ESR ≥50 mm/h (or CRP ≥2.45 mg/dL if ESR unavailable) | Elevated ESR ≥50 mm/h |
| At least one of the following:<br>– Unequivocal cranial symptoms of GCA (new-onset localized headache, scalp or temporal artery tenderness or decreased pulsation, ischemia-related vision loss, or otherwise unexplained mouth or jaw pain on mastication)<br>– Unequivocal symptoms of PMR, defined as shoulder and/or hip girdle pain associated with inflammatory stiffness | New-onset headache |
| | Temporal artery abnormality (tenderness to palpation or decreased pulsation) |
| At least one of the following:<br>– TAB revealing features of GCA<br>– Evidence of large-vessel vasculitis by angiography or cross-sectional imaging study such as MRA, CTA, or PET-CT | Positive TAB |

CRP, C-reactive protein; CTA, computed tomography angiography; ESR, erythrocyte sedimentation rate; MRA, magnetic resonance angiography. [a]The presence of ≥3 criteria classifies a patient as having GCA.

**Conclusions:** The 1990 ACR classification criteria for GCA require updating. Cross-sectional imaging, particularly PET/CT, now plays a major role in establishing the diagnosis of GCA. Symptoms in addition to headache merit consideration as part of revised classification criteria.

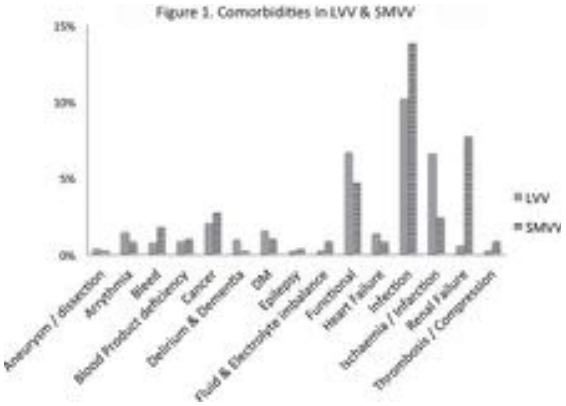
## FRI0378 NATIONAL AUDIT OF VASCULITIS INPATIENT COMORBIDITIES AND MORTALITY FROM 2005-14



L. Harty, S. Burns, D. Jayne. *Vasculitis, Addenbrookes Hospital, Cambridge, United Kingdom*

**Background:** Incidence of inpatient (inpt) events, comorbidities and age of death for Irish vasculitis patients is currently unknown
**Objectives:** Establish mortalitity & comorbidities in Irish vasculitis inpts
**Methods:** The HIPE system was evaluated from 57 Irish hospitals between 2005–2014 for vasculitis inpt episodes (not individual patients) based on ICD10. Age, length of stay (LOS), gender and admitting indication and mortality were recorded. Results are shown as totals, % & median (IQR). The Mann–Whitney U test and $\chi^2$ were employed
**Results:** 5,841 vasculitis inpt records were reviewed with median annual admissions of 601 (601–622). 2,229 inpt admissions had large vessel vasculitis (LVV – Takayasu's & GCA) whose median age was 75yrs (66–81), LOS 6 days (3–13) and 68% were female. 3612 inpt admissions had small & medium vessel vasculitis (SMVV –GPA, eGPA, MPA, PAN, Behcet's, Goodpastures, Necrotizing & Juvenile Vasculitis) with a median age 58yrs (42–70), LOS 6 days (2–13) and 48% were female. MPA, eGPA and GPA admissions were more common for men whereas GCA, Takayasu's and Behcets admissions were more common for women (*table 1)*. 58% LVV inpts & 50% SMVV inpts were admitted for systemic inflammation ($p<0.001$). Infection was the next most common cause for admission (14% SMVV & 10% LVV, $p<0.001$). Ischaemic events were the 3rd most common reason for admission in LVV (7% v 3%, $p<0.001$) whereas renal failure was for SMVV (8% v 1%, $p<0.001$). Symptoms without a diagnosis were the 4th most common reason for admission (7% LVV & 5% SMVV, p=0.002). *Figure 1.* Admission for cancer occurred in mean 2.5% and all other diagnoses accounted for <2% each. A greater percentage of SMVV inpts died than LVV inpts (4.1% v 2.7%, p=0.006) and they died younger (71yr (61–79) v 82 (76–86), $p<0.001$). Infection accounted for 28% of all deaths without difference between LVV and SMVV (p=0.5). More SMVV inpts died due to disease activity than LVV inpts (19% v 6%; p=0.03) and from renal failure (12% v 1%, p=0.05). More LVV inpts died from vascular infarction than SMVV (19% LVV v 6% SMVV; $p<0.001$). Male GPA inpts died younger than female (69yrs (62–78) v 79yrs (68–82); p=0.02).

Table 1. Admission and mortality data of specific vasculitides

| | n | Age | Male | % Died | Age at death |
|---|---|---|---|---|---|
| Behcets disease | 437 | 36 (29–48) | 36%* | 2% | 63 (42–72) |
| Eosinophilic granulomatosis polyangiitis | 257 | 59 (51–65) | 57%* | 2% | 70 (59–78) |
| Giant cell arteritis | 2187 | 75 (67–81) | 33%* | 3% | 82 (76–86) |
| Goodpasture's syndrome | 432 | 60 (45–73) | 53% | 7% | 70 (60–78) |
| Granulomatosis polyangiitis (GPA) | 1806 | 60 (48–70) | 55%* | 4%* | 72 (63–80) |
| Juvenile polyarteritis | 29 | 10 (8–12) | 3%* | 0% | – |
| Microscopic polyarteritis | 125 | 66 (59–76) | 64%* | 2% | 72 (66–77) |
| Necrotising vasculopathy | 236 | 64 (49–73) | 53% | 7% | 71 55–80) |
| Polyarteritis nodosa | 220 | 51 (39–69) | 52% | 7% | 71 (56–80) |
| Takayasu's arteritis | 112 | 38 (23–54) | 8%* | 0% | – |

Values are whole numbers, percentage and medians (IQR). *Indicates significant gender difference.

**Conclusions:** Around 600 vasculitis admissions occurred each year across the 57 hospitals directing the need for a concentrated number of centres of excellence to facilitate expert care, research and education. Small vessel vasculitis admissions were more common for men and large vessel and Behcet's for women. Despite advances in therapy systemic autoimmune disease and infection prevailed as causes for admission and death in vasculitis inpts, with greater mortality in SMVV from disease activity and renal failure and from vascular infarction in LVV. There is a need for improved diagnostic tests.
**Disclosure of Interest:** None declared

## FRI0379 SURVIVAL ANALYSIS IN ANTINEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

L. Petelytska, O. Iaremenko. *O. Bogomolets National Medical University, Kyiv, Ukraine*

**Background:** The mortality of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis is generally greater than for other types of vasculitis. The long-term survival of patients (pts) with ANCA-associated vasculitis in Ukraine is uncertain.

**Objectives:** To determine predictors of survival of pts with ANCA-associated vasculitis.
**Methods:** Outcome data was collected for 49 pts who had been diagnosed with ANCA-associated vasculitis (27 pts with granulomatosis with polyangiitis (GPA), 10 pts with microscopic polyangiitis (MPA) and 12 pts with eosinophilic granulomatosis with polyangiitis) according to the ACR 1990 criteria or the CHCC diagnostic criteria in the two city hospitals in Kyiv between 1972 and 2013. There were 15 males and 34 women aged from 20 to 77 years (median age 48.5±13.8). The duration of disease at time of diagnosis was from 1 to 156 months (mean 22.5±34.3 months). All pts received glucocorticoids, 37 - cytotoxic drugs and 3 – rituximab according to local treatment protocols. Survival was evaluated as a function of the main demographics, clinical and laboratory parameters and Birmingham Vasculitis Activity Score (BVAS) assessed at diagnosis. Statistical analyses used the Kaplan-Meier method and the multivariate Cox proportional hazards regression model.
**Results:** The median duration of follow-up was 62 months and 6 deaths (12.2%) were recorded (4 pts with MPA and 2 pts with GPA). The predominant causes of deaths were renal failure and disease activity. Cumulative survival rates at 1, 3, 5 and 10 years was 91.8, 87.6, 87.6 and 76.7%, respectively. Comparison survival of pts with ANCA-associated vasculitis according to age at onset of the disease and sex revealed that gender and age cumulative survival function didn't differ significantly. According to univariate analysis, a poor prognostic value was attributed to serum creatinine more than 176 umol/l (p=0.0001) and hemorrhagic alveolitis (p=0.01). Other factors (including ear, nose and throat, joints, skin, heart and nervous system involvement, increased ESR, leukocytosis, anemia, ANCA positivity, etc) didn't have influence on the survival curves. Survival curves of groups of pts with different disease activity determined by BVAS were not significantly different (p=0.88). Multivariate analysis showed that presence of increased creatinine levels more than 176 umol/l (HR=3.04, p=0.0001) and hemorrhagic alveolitis (HR=1.94, p=0.02) were independent predictors of poor outcome in pts with GPA and MPA.
**Conclusions:** Cumulative survival of pts with ANCA-associated vasculitis at 1, 3, 5 and 10 years of observation is 92, 88, 88 and 77%, respectively. The increased creatinine levels more than 176 umol/l and presence of hemorrhagic alveolitis are independent predictors of poor survival of pts with GPA and MPA. Vasculitis activity detected by BVAS and other clinical and laboratory parameters no effect on mortality.

## FRI0380 IL-6 RECEPTOR POLYMORPHISM IN POLYMYALGIA RHEUMATICA; RELATIONSHIP BETWEEN ASP358ALA (T/G) POLYMORPHISM OF THE INTERLEUKIN 6 RECEPTOR (IL6R) GENE AND SUSCEPTIBILITY AND SEVERITY OF THE DISEASE

L. Boiardi[1], P. Macchioni[1], E. Farnetti[2], G. Restuccia[1], L. Pulsatelli[3], R. Meliconi[4], C. Salvarani[1]. *[1]Rheumatology Unit; [2]Molecolar Biology Unit, Arcispedale S Maria Nuova IRCCS, Reggio Emilia; [3]Immunorheumatology Laboratory; [4]Rheumatology Unit, Istituto Ortopedico Rizzoli, Bologna, Italy*

**Background:** In previous study, we found in Polymyalgia rheumatica (PMR) patients a significant correlation between the number of relapses and serum soluble interleukin-6 receptors (sIL-6R) concentrations at baseline and after 1, 3, and 12 months of therapy (1). The Asp358Ala (T/G) polymorphism of the interleukin 6 receptor (IL6R) was related with high levels of ser1um sIL-6R.
**Objectives:** The Aim of our study was to evaluate the relationship between Asp358Ala (T/G) polymorphism of IL6R gene and susceptibility and severity of the PMR
**Methods:** We studied 104 patients with pure PMR and 94 healthy controls. Serum levels of s-IL6R were evaluated using highly sensitive, commercial sandwich enzyme-linked immunosorbent assay kits (R&D Systems, Minneapolis, MN) according to the manufacturer's instructions. The IL6R Asp358Ala polymorphism (rs8192284) were molecularly genotyped
**Results:** The distribution of allele and genotype frequencies did not differ significantly between PMR patients and healthy controls. Carriers of the Asp358Ala T allele (TT+GT) in PMR patients was 58.7% and in Healthy controls was 60.6% (p=0.78).
Homozygosity for the T allele in PMR patients was 16.3% and in healthy control was 12.8% (p=0.48). However the patients and controls with this polymorphism presented higher level of serum s-IL6R. Finally, PMR patients with relapses/recurrences showed more frequently homozygosity for the T allele, but the difference with patients without relapses/recurrences was not statistically significant (p=0.07).
**Conclusions:** Asp358Ala (T/G) polymorphism of the IL6R was related with high serum levels of s-IL6R; however, no correlation existed between this polymorphism and PMR susceptibily. Moreover, a bordeline correlation existed between TT homozygosity and relapses/recurrences in these patients.

## FRI0381 PATTERN OF CLINICAL PRESENTATION AND OUTCOME OF POLYMYALGIA RHEUMATICA

A. Sobrero, D. Camellino, C. Cosso, C. Pizzorni, M. Cutolo, M.A. Cimmino. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

**Background:** Polymyalgia rheumatica (PMR) is an inflammatory disorder of the elderly characterized by girdle pain and stiffness, constitutional symptoms and elevation of inflammatory indexes. Glucocorticoid (GC) treatment is effective but often prolonged, with associated side effects. Data on risk factors of poor prognosis are scanty: in particular it is not known if the pattern of clinical presentation can influence PMR outcome.
**Objectives:** To test the hypothesis that clinical presentation of PMR can predict its outcome.
**Methods:** 394 patients (251 women, median age 73 yrs, range 47–92 yrs) with PMR diagnosed according to Bird's criteria, visited between 1990 and 2014 by the same clinician were studied. Median follow up was 13.8 months (range 1–250 months). Clinical features recorded at disease presentation included involvement of: i) the shoulder girdle; ii) the pelvic girdle; iii) the column; vi) two or more of the previous locations; v) with giant cell arteritis (GCA); or vi) with acute onset, defined as completion of full symptoms and signs in $\leq$72h. PMR outcome was evaluated by considering: i) duration of follow-up; ii) appearance of peripheral arthritis; iii) appearance of GCA; iv) number of exacerbations/ relapses; v) cumulative dosage of GC; vi) use of methotrexate (MTX); and vii) death.
**Results:** At multivariate analysis, acute onset predicted a longer follow-up duration (p=0.007) and death (p=0.037); involvement of the spine predicted longer follow up duration (p=0.001) and use of MTX (p=0.018); presentation at the pelvic girdle predicted a high number of exacerbations/relapses (p=0.034) and association therapy with MTX (p=0.009); onset in multiple locations predicted a high number of exacerbations/relapses (p=0.03); presentation with GCA predicted a higher cumulative dosage of GC (p=0.0001) and use of MTX (p=0.027).
**Conclusions:** Apart from the obvious association between concomitant GCA and negative prognosis of PMR, other clinical characteristics at disease onset influence outcome. In particular, the initial presentation with multiple locations, including spine and pelvic girdle, resulted in longer follow-up, more relapses, and need of MTX treatment, whereas the classic one with only shoulder girdle involvement was associated with a milder disease. An acute onset was also a negative prognostic factor. Clinicians should consider the pattern of disease presentation when evaluating the burden of PMR.
**Disclosure of Interest:** None declared

## FRI0382 LARGE VESSEL VASCULITIS AND PERIVASCULAR DISORDERS UNDERGOING IMMUNOSUPPRESSIVE THERAPY: THE USE OF PERFUSION-CT FOR RESPONSE MONITORING

M.S. Marius[1], J. Henes[2], T. Xenitidis[2], K. Nikolaou[1], G. Bier[1]. *[1]Department of Radiology; [2]Department of Internal Medicine II, Eberhard-Karls-University Tuebingen, Tuebingen, Germany*

**Background:** Inflammatory disorders of the large vessel walls (aortitis-A) or such arising around large vessels (periaortitis-P) are rare and generally difficult to diagnose. Acute phase inflammatory markers are used for monitoring these entities, but they knowingly fail in up to 20% of cases, in particular in patients with periaortitis. Moreover, these follow-up markers rapidly turn normal after onset of some novel therapeutic agents like biologicals (e.g. anti-IL6)[1]. Therefore, functional imaging techniques have advanced to the methods of choice in A/PA diagnosis, and even therapy monitoring [2].
**Objectives:** To evaluate the role of perfusion-based CT for monitoring inflammatory activity in patients with aortitis and chronic periaortitis (A/PA) undergoing immunosuppressive therapy (IST).
**Methods:** A retrospective database search at our institution between January 2010 and March 2015 identified 17 patients (8 female; median age 68.5 years) with A/PA that underwent combined anatomical and functional CT, including CT perfusion-based monitoring for assessment of disease activity. Institutional review board approval was obtained for data analysis. All patients were symptomatic at the time of 1st CT-imaging. Patients first underwent segmental volume perfusion-CT (VPCT) for assessment of the degree of vascularization of A/PA as a surrogate marker for inflammatory activity. Blood flow (BF) and blood volume (BV) were determined. The thickness of the increased perivascular connective tissue formation was measured. Perfusion data was correlated with C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR).
**Results:** In all patients, perfusion parameters dropped at FU under IST, this reduction was significant for BF and BV ($p<0.05$). 15 patients had elevated ESR and CRP at the time of the 1st perfusion-CT; 2 patients had normal values. In aortitis patients, CRP dropped from 3.86±5.31 to 0.9±1.37 and in periaortitis patients from 1.78±2.25 to 0.79 ±1.55, whereas ESR dropped from 45.71±37.59 to 8.57 ±3.1 and 36.78±34.67 to 17.22±21.82, in aortitis and in periaortitis, respectively. Correlation between serologic data and perfusion parameters was very good. Clinical symptoms were resolved in 12 patients at FU. At follow-up, the mean thickness of aortic or perivascular tissue formation decreased by 41.7±25.63% (range, 0–87.5%). The response was more vigorous in PA-patients (47.7±27.0%; range: 9–87.5%) than in A-patients (35.4±23.88%;

range: 0–62.5%). The difference between baseline and follow-up imaging was significant for both disease entities ($p<0.001$).

**Conclusions:** The course of perfusion-CT parameters in A/PA undergoing IST correlated well with that of serological markers with respect to disease activity assessment. In cases with bland serological data, perfusion-CT was the sole reliable monitoring parameter.

## FRI0383 PREDICTORS OF FRAGILITY FRACTURES IN PATIENTS WITH POLYMYALGIA RHEUMATICA ON STEROIDS: AN OBSERVATIONAL STUDY

M. Bukhari. *Rheumatology, Royal Lancaster Infirmary, Lancaster, United Kingdom*

**Background:** Fragility fractures are a consequence of poor bone health, this is especially seen in patients on corticosteroids. Polymyalgia rheumatica (PMR) is usually treated with corticosteroids for a median of two years (1). The predictors of fragility fractures in this cohort have not been explored in a large observational cohort. Furthermore it is unknown which other risk factors for Osteoporosis contribute to the risk of fractures in this cohort The FRAX™ tool uses the BMD in the femoral neck as a predictor for fracture, the ability of the lumbar spine bone mineral density (BMD) to increase prediction of fragility fracture has not been explored.

**Objectives:** To explore the further predictors of fragility fractures in patients with PMR on corticosteroids and to explore the added predictive value of lumbar spine BMD.

**Methods:** Patients referred for BMD estimation using a dual X-ray absorptiometry (DEXA) machine to a scanner in the North West of England between 2004 and 2014 were included in the study. Patients with a history of PMR on steroids were extracted. Initially those that sustained a fracture were compared to those that had not sustained a fracture using the chi squared test for categorical variables and Students T test for continuous variables. The predictors of fracture in that cohort were explored using a logistic model, initially in a univariate manner, and subsequently in a stepwise logistic model. Predictors included age at scan in years, gender, smoking, excess alcohol consumption, the presence of rheumatoid arthritis, body mass index (BMI) and family history of fragility fracture in addition to BMD in the lumbar spine and femoral neck.

**Results:** 703 patients were included in the analysis, 525 (74.7%) were female. Mean age was 70.4 years (SD 8.9 years). 154 (21.9%) had sustained a fracture. Comparing the patients who had and who had not sustained a fracture showed that they were more likely to be female 138/525 (26%) vs 16/178 (9%) ($p<0.001$), older 72.5 years (SD9.0) vs 70.0 (SD8.8) p=0.002 and have a lower BMD in the lumbar spine and the femoral neck. The results of the logistic models unadjusted and adjusted for age are shown in table 1 below with significant values denoted with an asterisk (*)

Table 1

| Variable | Unadjusted OR (95%CI) | Adjusted OR (95%CI) |
|---|---|---|
| Age at scan in decades | 1.39 (1.131.71)* | – |
| Female gender | 3.61 (2.08,6.25)* | 3.90 (2.24,6.80)* |
| Smoking | 1.07 (0.74,1.55) | 1.09 (0.75,1.59) |
| Alcohol excess | 0.40 (0.14,1.16) | 0.44 (0.15,1.28) |
| Rheumatoid arthritis | 0.37 (0.08,1.59) | 0.38 (0.09,1.65) |
| Body mass index (kg/m$^2$) | 1.00 (0.97,1.03) | 1.01 (0.98,1.05) |
| Family history of fracture | 1.32 (0.67,2.62) | 1.57 (0.78,3.15) |
| L1-L4 BMD | 0.07 (0.03,0.19)* | 0.08 (0.03,0.21)* |
| Femoral neck BMD | 0.03 (0.01,0.11)* | 0.04 (0.01,0.15)* |

In the multivariate model aside from age, female gender (OR 2.010 95%CI 1.11,3.99) and femoral neck but not lumbar spine BMD remained in the model (OR 0.07 95%CI 0.01,0.59), surprisingly family history of fracture (OR 2.21 95%CI 1.01,4.84) and a higher BMI (OR 1.06 95%CI 1.01,1.10) also were significant predictors.

**Conclusions:** In this cohort of patients the females, older patients and low BMD in the femoral neck were all associated with fractures, which is not unexpected, however added risks were identified which are not necessarily clinically obvious. BMD in the lumbar spine did not add to the predictive value of sustaining a fracture. Further prospective work is needed to validate these findings.

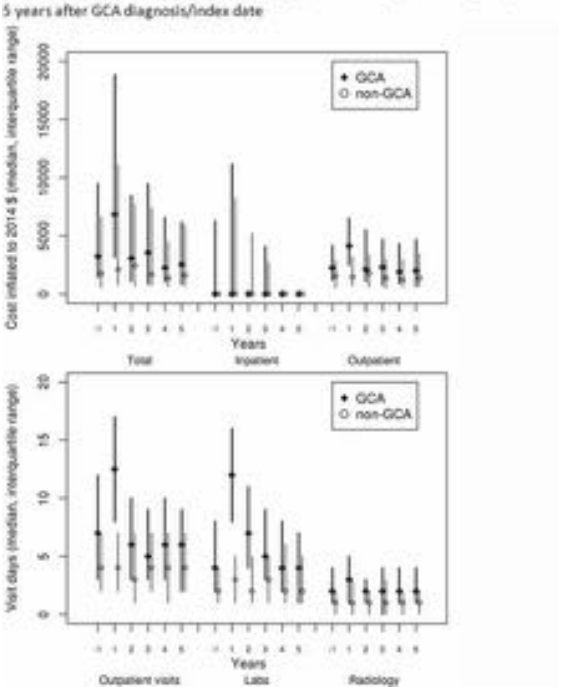
## FRI0384 HEALTHCARE UTILIZATION AND DIRECT MEDICAL COSTS OF GIANT CELL ARTERITIS

M.J. Koster[1], S. Achenbach[2], C.S. Crowson[2], H. Maradit-Kremers[2], E.L. Matteson[1], K.J. Warrington[1]. *[1]Rheumatology; [2]Health Sciences Research, Mayo Clinic, Rochester, United States*

**Background:** Giant cell arteritis (GCA) is the most common systemic vasculitis in patients aged ≥50 years. Few studies have evaluated the economic impact of this condition and have been limited to inpatient-only data sources. Although the majority of healthcare for patients with GCA is provided as an outpatient, utilization and costs from this healthcare sector is largely unknown.

**Objectives:** To determine the health care utilization and direct medical cost of GCA in a population-based cohort.



**Methods:** This study utilized a retrospective, population-based cohort of patients diagnosed with GCA, as defined by 1990 ACR criteria, in 1982–2009 and a reference cohort of patients without GCA matched on age, sex, and calendar year from the same population. Standardized cost data (inflation-adjusted to 2014 dollars) for 1987–2014 and outpatient utilization data for 1995–2014 were obtained from the Mayo Clinic Cost Data Warehouse and analyzed from one year before and up to five years after the GCA diagnosis/index date. Utilization and costs were compared between GCA and non-GCA cohorts using signed rank two-tailed paired analyses.

**Results:** The GCA cohort consisted of 147 patients (118 female, 29 male) with a mean (±SD) age of 77.2 (±8.2). The non-GCA cohort comprised 147 patients with a mean (±SD) age of 76.9 (±8.5) years.

During the year preceding diagnosis, excess healthcare cost related to GCA was only significantly increased in the month immediately preceding GCA diagnosis [mean (±SD) excess cost $1127 (±5154)]. Following diagnosis, significant annual excess outpatient cost was observed for patients with GCA in each of the first four years [mean excess cost (±SD): 0–1 yrs $1307 (±15581), $p<0.001$; 1–2yrs $908 (±5917), p=0.009; 2–3 yrs $1324 (±4648), p=0.007; 3–4 yrs $609 (±4596), p=0.04] but was similar between GCA and non-GCA subjects in the 5th year. There were no significant differences in inpatient costs between GCA and non-GCA subjects.

Patients with GCA had higher utilization of laboratory visit days annually for each of the first 3 years following diagnosis, as well as increased outpatient physician visits and combined radiology for years 0–1, 1–2, and 3–4 years (figure). Ophthalmologic procedures/surgery were increased for years 0–1, 1–2, and 4–5. Emergency medicine visits, musculoskeletal and cardiovascular procedures/surgery were similar between GCA and non-GCA groups throughout the study period.

Figure. Costs (upper panel) and utilization of health care resources (lower panel) in patients with GCA and non-GCA subjects by year of followup from one year prior to 5 years after GCA diagnosis/index date

**Conclusions:** Direct medical costs were increased in the month preceding and outpatient costs were increased in the first 4 years following GCA diagnosis and then return to levels similar to non-GCA subjects. A higher utilization of outpatient physician, laboratory and radiology visits, as well as ophthalmologic procedures among these patients accounts for the observed increased cost of care.

## FRI0385 CLINICAL CHARACTERISTC OF VALVULAR INVOLVEMENT IN TAKAYASU'S ARTERITIS

N. Gao, T. Wang, W. Ci, J. Du, Z. Zhou. *Anzhen Hospital, Capital Medical University, Beijing, China*

**Background:** Takayasu's arteritis (TKA) is a chronic large-vessel vasculitis that predominantly affects aorta and its major branches. Cardiac lesion in TKA could reach up to 8.6%, involving valve, myocardium and coronary artery or secondary to hypertension or pulmonary hypertension due to TKA [1]. The valvular involvement is one of the causes for the unfavorable prognosis of TKA [2]. Limited data about TKA with valvular involvement in Chinese patients have been reported yet.
**Objectives:** To investigate the clinical features of valvular lesions in TKA.
**Methods:** We retrospectively analyzed 22 medical records of TKA with valvular lesions from a total of 116 TKA admitted patients in Anzhen Hospital, Capital Medical University from January 2012 to January 2015.
**Results:** The spectrum of valvular involvements were aortic regurgitation (11,50%,), mitral regurgitation (1,4.5%), aortic stenosis (1,4.5%), mitral stenosis (1,4.5%) and multiple valvular disease (7,36.5%). 64.7% of the aortic regurgitation patients had aortic root dilation. Heart failure was the commonest manifestation (63.6%). Patients with aortic regurgitation were more likely to be positive for elevated erythrocyte sedimentation rate than those without aortic regurgitation (i58.8% vs. 0, P=0.04). Glucocorticoid and/or immunosuppression were administered on 11 (50%) patients. One (4.5%) patient received Tocilizumab injection. Surgeries were performed on 12 (54.5%) patients with cardiac architecture changing reversibly within one week after operation ($P<0.05$, Table 1). Three patients had aortic valve detachment or perivalvular leakage 6–36 months after primary valvular surgery. Three patients died during 10–46 month follow-up, with none of whom taking any anti-inflammatory treatments.

Table 1. Comparison of echocardiogram before and after cardiac operation in 12 Takayasu's arteritis patients with valvular lesion (x ± SD)

| | Pre-operation | Post-operation | P value |
|---|---|---|---|
| Aortic root (mm) | 41.64±8.79 | 26.50±5.84 | 0.004 |
| Ascending aorta (mm) | 44.17±7.89 | 28.33±5.05 | 0.017 |
| Interventricular septum (mm) | 9.88±1.28 | 10.58±1.57 | 0.102 |
| Main pulmonary artery (mm) | 25.09±2.39 | 24.18±3.97 | 0.356 |
| Left atrium (mm) | 47.08±14.98 | 35.17±10.18 | 0.014 |
| Left ventricular end-diastolic diameter (mm) | 58.50±5.92 | 48.50±10.03 | 0.001 |
| Left ventricular end-systolic diameter (mm) | 41.75±7.85 | 36.00±11.01 | 0.006 |
| Posterior wall of left ventricle (mm) | 9.40±1.46 | 10.41±1.62 | 0.096 |
| Posterior wall motion of left ventricle (mm) | 9.87±1.92 | 8.97±2.70 | 0.296 |
| Right ventricular (mm) | 19.91±3.83 | 18.55±3.50 | 0.236 |
| Ourflow tract of right ventricular (mm) | 26.80±5.27 | 21.80±4.49 | 0.004 |
| Ejection fraction (%) | 53.42±9.88 | 53.75±12.13 | 0.841 |

**Conclusions:** Aortic regurgitation is the prominent valvular lesion in TKA, mainly secondary to aortic root dilation. Operation could cut off the myocardium reconstruction promptly. The early surgical complication is rare, while perivalvular leakage may occur during longstanding follow-up. Poor inflammatory control might lead to adverse prognosis.

## FRI0386 IMMUNOGENICITY OF 13-VALENT PNEUMOCOCCAL CONJUGATE VACCINE IN PATIENTS WITH VASCULITIS RECEIVING STANDARD OF CARE THERAPY AND CONTROLS

P. Nived, J. Nagel, T. Saxne, P. Geborek, G. Jönsson, L. Skattum, M.C. Kapetanovic. *Lund university, Lund, Sweden*

**Objectives:** To study the effect of standard of care therapy on antibody (Ab) response and functionality of Abs following pneumococcal vaccination using 13-valent conjugate vaccine (PCV13) in patients with systemic vasculitis compared to healthy controls.
**Methods:** In total 49 patients with vasculitis (granulomatosis with polyangiitis=21, Churg-Strauss vasculitis=8, giant cell vasculitis=13; Takayasu=4 and other vasculitis=3) and 49 controls were immunized with a single dose (0.5 ml) PCV13 intramuscularly. Vasculitis patients were treated with azathioprine (n=11), cyclophosphamide +prednisolone (n=6), MTX (n=9), prednisolone without DMARD (n=16), rituximab+DMARDs (3); anti-TNF (n=2), mycophenolate mofetil (n=1) and no active treatment (n=1). Only patients with unchanged dose of DMARDs for at least 4 weeks before vaccination were eligible for the study. Blood samples were taken immediately before and 4–6 weeks after vaccination. Standard ELISA was used to determine pre- and post-PCV13 serotype-specific Ab concentrations for serotypes 6B and 23F. The measurement of functional Abs against one of serotypes (23F) was performed using opsonophagocytic (OPA) assay. Proportions of individuals with postvaccination Ab concentrations $\geq$1.0 μg/mL (i.e. putative protective levels) for both serotypes were determined, and groups were compared using Chi2 test. Proportion of individuals with positive Ab response (i.e. $\geq$2-fold increase from pre-PCV13 concentrations) for both serotypes was calculated. Geometric mean Ab concentrations (GMCs) were calculated. Pre- and post-PCV13 Ab levels were compared using paired T-test. Controls were younger (mean age 50.6 years vs 61.5 years) at vaccination and a larger proportion were women (63% vs 51%). Mean disease duration in vasculitis patients was 5.2 years.
**Results:** Pre- to post-PCV13 Ab concentrations increased significantly for 6B and 23F in both patient and control groups ($p<0.001$). Compared to controls, patients with vasculitis had lower pre- and postvaccination Ab levels for serotype 23F (p=0.012 and p=0.033, respectively) and numerically but not statistically significant lower pre- and post-PCV13 levels for 6B (Table). OPA shows significant increase after vaccination in both patients and controls ($p<0.001$) although this was numerically more pronounced in controls. Patients receiving any DMARD had significantly lower proportion of subjects reaching protective Ab concentrations ($\geq$1.0 μg/mL) for both serotypes (p=0.04) compared to controls. In addition, patients on DMARDs had lower proportion of responders for both serotypes which was most pronounced for azathioprine and rituximab+DMARD. Prednisolone without DMARD was not associated with impaired Ab responses.

| | Patients with vasculitis | Controls |
|---|---|---|
| Pre PCV13 GMC Pn6B (95% CI) | 0.5 (0.3–0.9) | 0.8 (0.5–1.3) |
| Post PCV13 GMC Pn6B (95% CI) | **1.7 (0.9–2.9)** | 3.**1 (1.9–5.0)** |
| Pre PCV13 GMC Pn23F (95% CI) | 0.3 (0.2–0.4) | 0.6 (0.4–1.0) |
| Post PCV13 GMC Pn23F (95% CI) | **1.8 (1.2–2.8)** | **3.3 (2.0–5.5)** |

**Conclusions:** PCV13 was immunogenic in patients with established vasculitis. Functionality of serotype specific antibodies was confirmed in both patients and controls although the opsonophagocytotic activity was more pronounced in controls. Treatment with DMARDs, mostly azathioprine or rituximab combined with DMARD but not systemic prednisolone lead to impaired antibody response.

## FRI0387 PERIPHERAL NEUROPATHY IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS (EGPA). INCAT DISABILITY SCORE TO EVALUATE DAMAGE AND TO PREDICT LONG TERM OUTCOME IN 50 PATIENTS

R. Padoan[1], M. Felicetti[1], M. Marconato[2], F. Cinetto[2], C. Agostini[2], L. Punzi[1], F. Schiavon[1]. *[1]Reumatologia; [2]Immunologia Clinica, Azienda Ospedaliera Padova, Padova, Italy*

**Background:** Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare necrotizing vasculitis characterized by bronchial asthma, hypereosinophilia and extrapulmonary granulomatous inflammation. One of the most frequently involved organ is the peripheral nervous system (PNS), followed by the lung and the skin. PNS involvement is usually characterized by mononeuritis multiplex or symmetrical peripheral neuropathy. Administration of corticosteroids and immunosuppressive agents typically achieves remission and results in good survival rates. However, patients may suffer from chronic residual functional deficits caused by neuropathy even after remission has been achieved. Although such deficits may disrupt the day-to-day functioning and quality of life, studies to target the residual neuropathy are still poor.
**Objectives:** VDI can't precisely indentify the severity of peripheral neurologic damage, so we propose the INCAT (Inflammatory Neuropathy Cause and Treatment) disability score, to evaluate long term outcome and damage in this patients.
**Methods:** We selected retrospectively patients affected by EGPA, satisfying ACR criteria, followed up by Rheumatology and Clinical Immunology Units, from 2005 through 2015. Basic demographic, duration of disease, clinical and serological features, treatments of each patient were routinely monitored at baseline, six, twelve months and last visit. Disease activity, relapses, damage and neurological involvement were also evaluated with Birmingham Vasculitis Activity Score (BVAS v3), Vasculitis Damage Index (VDI) and INCAT disability score. The INCAT score ranges from 0 (no signs of disability) to 10 (most severe disability). Statistical analyses were done using Mann Whitney test, Spearman correlation and Fisher's exact test.
**Results:** 50 patients were included, middle aged (49.9±13.8 years), mainly women (31:19). Twentyfive patients (50%) presented with peripheral neurological involvement; this patients were older (56.3±13.4 yrs, p=0.0009) and mostly ANCA positive (48%, p=0.015). Patients who presented with an INCAT score $\geq$3, compared to those with a lower score, at baseline (52%, 13/25), had also at the end of follow up (6.3±3.8 yrs) a higher INCAT score (2.7±1.2, $p<0.0001$), higher VDI (2.70±1.48, p=0.0046) and mostly relapses with a peripheral neurological flare (46%, 6/13). These patients were also treated more frequently with cyclophosphamide (76.9%, p=0.034). In all patients INCAT score was also significantly correlated to VDI (p=0.0046), but not to BVAS.
**Conclusions:** INCAT disability score measures daily activities limitation and it's used frequently as a primary end point in inflammatory polyneuropathy clinical trials. It's easy to administer and can be completed quickly, imposing a minimal burden on the administrator and the responder. It appears to be a valid tool, able

to evaluate peripheral neurological damage, treatment response and to predict long term outcome. Further studies in a larger patients cohorts are needed.

Perez-Iglesias[20] on behalf of REVAS Group from GEAS-SEMI. *[1]Internal Medicine, Vall Hebron University Hospital, Barcelona; [2]Internal Medicine, H Mutua Terrassa, Terrassa; [3]Internal Medicine, H La Paz, Madrid; [4]Internal Medicine, H Miguel Servet, Zaragoza; [5]Internal Medicine, H Ramon y Cajal, Madrid; [6]Internal Medicine, H Bellvitge, Barcelona; [7]Internal Medicine, H Marina Baixa, Alicante; [8]Internal Medicine, H Parc Tauli, Sabadell; [9]Internal Medicine, H Cabueñes, Asturias; [10]Internal Medicine, H San Cecilio; [11]Internal Medicine, H Virgen Nieves, Granada; [12]Internal Medicine, H Virgen del Rocio, Sevilla; [13]Internal Medicine, H Fuenlabrada, Madrid; [14]Internal Medicine, HUCA, Oviedo; [15]Internal Medicine, H la Rivera, Valencia; [16]Internal Medicine, H Clinica Navarra, Navarra; [17]Internal Medicine, H Infanta Leonor, Madrid; [18]Internal Medicine, CHUVI, Vigo; [19]Internal Medicine, H Joan XXIII, Tarragona; [20]Internal Medicine, H Orense, Orense, Spain*

**Background:** The Birmingham Vasculitis Activity Score (BVAS), and the Five Factor Score (FFS) at the time of diagnosis have been shown useful to asses prognosis in AAV (1,2), but few studies have been done comparing these tools to predict survival

**Objectives:** To compare the usefulness of BVAS vs 3, 1996 FFS and 2009 FFS at the time of diagnosis, to predict survival in a large cohort of patients with AAV from Spain

**Methods:** multicenter retrospective-longitudinal study that included patients diagnosed with AAV between Jan1995 and Nov13 in 20 Hospitals from Spain (REVAS Study). Patient survival was assessed by life-table analysis using the Kaplan-Meier method. Statistical analysis was done using SPSS vs21

**Results:** 455 patients were included: 188 (41.3%) GPA, 167 (36.7%) MPA and 100 (22%) EGPA; 50.8% were men. Mean age at diagnosis was 55.7±17.2 y. ANCA were positive in 86.8% of cases: 35.8% C-ANCA and 51% P-ANCA. Median time to diagnosis was 4 weeks (IQR 10). Median follow-up time was 80 months (IQR 105) for global population. Renal involvement was present in 61.5% of cases, lung involvement in 54.7%, pulmonary-renal syndrome in 16.9%, neurological involvement in 34.5%, and cardiac involvement in 12.7%. ENT was observed in 44.8% of cases and eye involvement in 18.9%. Mean BVAS at diagnosis was 17.7±7.7; 1996FFS was $\leq$1 in 390 (85.8%) patients, and 2009FFS was $\leq$2 in 361 (79.4%). All patients received oral corticoids, 342 (75.1%) cyclophosphamide (49.7% IV and 50.3% oral), and 6.6% biological therapy. Dialysis was required in 16.4% of cases. During the follow-up, 39.1% of patients suffered bacterial infections, 9.2% sepsis,12.7% opportunistic infections and 5.3% neoplasms. One hundred thirty (28.6%) died:74 (44.3%) with PAM, 42 (22.3%) with GPA and 14 (14%) with EGPA ($p<0.001$). Univariate analysis showed that BVAS, 1996FFS and 2009FFS at diagnosis were significantly related to death ($p<0.001$). A multifactorial Cox regression analysis including the three activity scores confirmed that all of them were statistically related to survival rate but the stronger predictor of poor prognosis was the 2009FFS with a HR 2.7. This result was confirmed by curve ROC: 2009FFS showed the greater area under the curve (75%), in front of 1996FFS (66%) and BVAS (62%)

**Conclusions:** BVAS and FFS at diagnosis are signifivantly related to survival in AAV, but the stronger predictor of survival is the 2009 FFS.

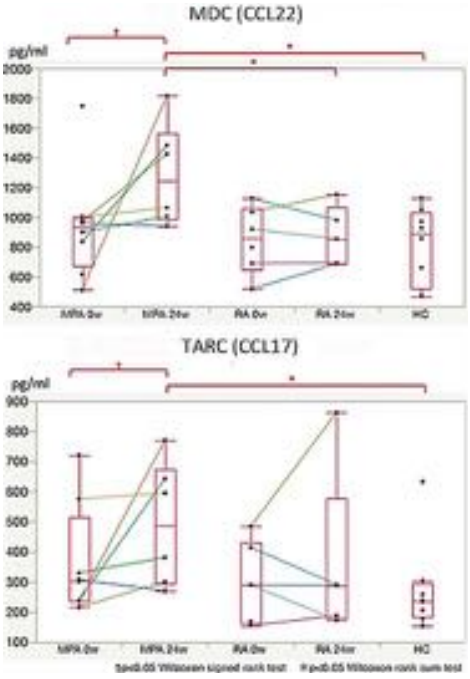
## FRI0389 AN INCREASE IN TREG- AND TH2-ASSOCIATED SERUM CHEMOKINES, MDC (CCL22) AND TARC (CCL17) DURING TOCILIZUMAB MONOTHERAPY IN PATIENTS WITH MICROSCOPIC POLYANGIITIS



R. Sakai[1], K. Yoshimoto[2], T. Kondo[1], T. Kurasawa[2], A. Shibata[1], J. Kikuchi[1], K. Chino[1], A. Okuyama[1], H. Takei[1], K. Suzuki[2], T. Takeuchi[2], K. Amano[1]. *[1]Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Kawagoe; [2]Division of Rheumatology, Department of Internal Medicine, Keio University, Tokyo, Japan*

**Background:** We have recently reported a case series that tocilizumab (TCZ) monotherapy without corticosteroids (CSs) may be an alternative treatment strategy in patients with microscopic polyangiitis (MPA). We found that four of six patients (66.7%) could be maintained drug-free after TCZ cessation for 6–15 months [1]; however, the mechanism remains unclear.

**Objectives:** To elucidate the TCZ efficacy mechanism in patients with MPA, we examined multiple serum levels of cytokines and chemokines in patients with MPA at 0 (baseline), 4, and 24 weeks after initiating TCZ monotherapy and compared the outcomes with those of healthy controls (HC) and patients with rheumatoid arthritis (RA).

**Methods:** The patients employed in this study were newly diagnosed with MPA (n=8; 71.0 ± 7.4 years) according to the Watts' classification algorithm, RA (n=6; 54.5 ± 13.0 years) according to the 2010 RA classification criteria, and HC (n=8, 65.1 ± 9.5 years). All MPA and RA patients received 8 mg/kg of intravenous TCZ monthly for 1 year without any CS or disease-modifying antirheumatic drugs, except for six out of eight patients with MPA who fortnightly received TCZ for the first 2 months, and then monthly for the next 10 months [1]. Multiple cyto- and chemokines in the serum of patients at 0, 4 and 24 weeks of the treatment of TCZ were analyzed by micro-spot-based multiplex assays using electrochemiluminescence. Complete remission (CR) was defined as the Birmingham Vasculitis Activity Score (BVAS) of 0 at two consecutive visits made at least a month apart, and partial response (PR) was defined as a 50% reduction of BVAS from the baseline.

**Results:** CR/PR was achieved in six out of eight patients with MPA at 6 months (75%, LOCF). MPA at baseline showed elevated levels of various cyto- and chemokines compared with HC, such as IL-10, IL-12/IL-23p40, IL-15, IL-16, IL-17A, IL-1$\alpha$, IL-4, IL-5, IL-6, IL-7, TNF$\alpha$, VEGF-A, IL-8 (CXCL8), IP-10 (CXCL10), MCP-1 (CCL2), MIP-1$\alpha$ (CCL3), MIP-1$\beta$ (CCL4), MCP-4 (CCL13), and eotaxin-3 (CCL26) ($p<0.05$). Conversely, RA at baseline showed elevated levels of cyto- and chemokines compared with HC, such as IL-6, IL-7, IL-16, TNF$\alpha$, VEGF-A, MIP-1$\beta$, eotaxin-3 ($p<0.05$). Moreover, serum levels of MDC (CCL22), TARC (CCL17), GM-CSF, IL-12p70 were not significantly different among these groups. Most of enhanced levels of serum cyto- and chemokines in MPA significantly decreased during the 24 weeks with TCZ monotherapy except IL-12/IL-23p40, IL-4, IL-13, and IL-1$\beta$, whereas only VEGF-A level was significantly decreased in RA under TCZ treatment. Interestingly, only the levels of MDC and TARC in MPA, the Th2 and Treg related chemokines, significantly increased after TCZ monotherapy, but not in RA (baseline vs 24 weeks: $p<0.05$) (Figure 1), even though other Th2 related cyto- and chemokines significantly decreased or remained unchanged.

**Conclusions:** Our study suggest that TCZ monotherapy provides a new insight into the treatment strategy for MPA and TCZ may suppress the disease activities of

MPA by increasing chemokines, such as MDC and TARC while other inflammatory cyto- and chemokines decreased.

## FRI0390 USE OF MUSCLE BIOPSIES FOR THE DIAGNOSIS OF SYSTEMIC VASCULITIS IN A RHEUMATOLOGY SERVICE

S. Rodríguez-Muguruza[1], J. Sanint[1], X. Saenz-Sarda[2], A. Prior-Español[1], Y. García-Mira[1], S. Holgado[1], L. Mateo[1], J. Cañellas[1], M. Martinez-Morillo[1], X. Tena[1], I. Casas[3], J.L. Mate[2], A. Olive[1]. *[1]Rheumatology; [2]Pathology; [3]Epidemiology, Germans Trias i Pujol Hospital, Barcelona, Spain*

**Background:** Systemic vasculitis (SV) comprises a group of diseases characterized by inflammation of vessels in various organs. Histopathological confirmation is required for the diagnosis. The biopsy of an involved organ is invasive and carries the risk of complications. By contrast, gastrocnemius muscle biopsy is simple and minimally invasive technique that may be performed by a rheumatologist.

**Objectives:** To evaluate the diagnostic use of muscle biopsies for the diagnosis of SV.

**Methods:** Retrospective study 1984 - 2015. Center: tertiary academic hospital, referral area 850.000 inhabitants. We analyzed the database of all muscular biopsies performed at our hospital. We selected patients undergoing a muscular biopsy for possible diagnosis of SV and we analyzed the clinical, laboratory, neurophysiological and pathologic data. Biopsies were classified as positive (presence of necrotizing vasculitis or non necrotizing vasculitis seen by optical microscopy) or negative for vasculitis. Muscular biopsy was performed in all cases at the medial gastrocnemius muscle ("open" and unilateral) by a rheumatologist. The diagnosis of SV was based on clinical, serological and histological data.

**Results:** A total of 619 muscular biopsies were performed, 55 were indicated with suspicion of SV, 52.7% female, 47.3% male, median age 64.4 years (DS 15.22); 47 (85.4%) were positive (sensitivity of 85%) and 8 (14.6%) were negative. The positive biopsy group showed more electromiographic alterations (p=0.01) than negative group. Furthermore, the positive biopsy group showed more frequently systemic manifestations such as: weight loss, myalgia, paresthesias, purpura and testicular pain but these differences were not statistically significant. No complications were encountered in the procedure.

| Features | Biopsy-positive | Biopsy-negative | p-value |
|---|---|---|---|
| ANCA positive/negative | 20 (54.1%)/17 (45.9%) (n=37) | 4 (50%)/4 (50%) | 0,8 |
| Serum VSG (mm), mean (sd) | 58.2 (35.6%) | 64.7 (36.3%) | 0.6 |
| Hemoglobine (g/dL), mean (sd) | 11.2 (1.4%) | 10,25 (1.3%) | 0.8 |
| Weight loss (≥2 kg) | 13 (27.7%) | 2 (25%) | 0,8 |
| Fever | 20 (42.5%) | 5 (62.5%) | 0.3 |
| Myalgia/arthralgia | 18 (38.3%)/12 (25,5%) | 3 (37,5/ 2 (25%) | 0.9 |
| Paresthesias | 20 (42.6%) | 2 (25%) | 0,3 |
| Purpura | 7 (14.9%) | 1 (12.5%) | 0.8 |
| Testicular pain | 3 (6.4%) | 0 | 0.4 |
| Legs ulcers | 5 (10.6%) | 2 (25%) | 0,3 |
| Abdominal/calf pain | 3 (6.4%)/12 (25.5%) | 1 (12.5%)/ 3 (37.5%) | 0,5 |
| Patologic EMG | 36 (76.6%) | 2 (25%) | 0.01 |

**Conclusions:** Our results suggest that muscle biopsy is a simple, clinically useful, safe and minimally invasive procedure for the diagnosis of SV with high sensitivity. No significant differences were observed in clinical or analytical features between patients with positive or negative biopsy, except in electromyography patients with positive biopsy had more a frequent pathological pattern.

## FRI0391 ANKLE BRACHIAL INDEX, PULSE WAVE VELOCITY AND ECHOCARDIOGRAPHIC STUDY IN 81 PATIENTS WITH BEHÇET'S DISEASE

S.-J. Yoo, S.W. Kang, S.C. Shim, I.S. Yoo, Y. Kim. *Internal Medicine, CHUngnam National University School of Medicine, Daejeon, Korea, Republic Of*

**Background:** Behçet's disease (BD) is a multisystemic vasculitis of unknown etiology. Cardiovascular (CV) involvement has been reported in 1–6% of BD patients. In case of CV involvement, prognosis is poor. The incidence of the CV involvement in Korean patients with BD is not clearly documented.

**Objectives:** The aim of this study is to evaluate the CV findings in Korean patients with BD and to prevent or lower mortality and morbidity through early diagnosis and early treatment.

**Methods:** We performed Ankle Brachial Index (ABI), Pulse wave velocity (PWV) and Echocardiographic screening in 81 patients with BD who fulfilled the International Study Group criteria. PWV was calculated as the brachial-ankle path length divided by the brachial-ankle transit time (baPWV). We compared the result between two groups of patients with BD. Two groups are patients who have been treated with immunosuppressant agent and without immunosuppressant agent. The patients of former group are patients who have been suffered from severe complication or refractory disease.

**Results:** Fifty-nine (72.8%) patients were female. Mean age was 50.6 ± 2.5 years old. Mean age at diagnosis was 40.5 ± 2.3 years old and disease duration was 10.2 ± 1.5 years. Mean ABI was 1.10 ± 0.03. There was no significant difference between with and without immunosuppressant agent treated group. (1.11 ± 0.03 vs. 1.09 ± 0.03, P=0.167). The number of patients with abnormal ABI was 7 (17.5%) vs. 6 (14.6%), P=0.781. Mean PWV (m/sec) was 14.0 ± 0.67. There was no significant difference between two groups (13.8 ± 1.09 vs. 14.2 ± 0.83, P=0.144). But the immunosuppressant treated group had more patients with elevated levels of PWV (>12.0 m/sec) compared to non-immunosuppressant treated group [n =34 (82.9%) vs. n=25 (62.5%), P=0.024]. Echocardiography was done. Left ventricular ejection fraction (%) (64.9 ± 1.5 vs. 63.7 ± 1.7, P=0.254), Left ventricular mass index ($g/m^2$) (74.9 ± 5.0 vs 74.1 ± 5.7, P=0.970), E/E' ratio (8.35 ± 0.9 vs 9.17 ± 1.0, P=0.228), Tricuspid regurgitating velocity (TRV) max (m/sec) (2.35 ± 0.09 vs 2.39 ± 0.11, P=0.572) were similar in both groups. We detected 39 minimal mitral, aortic and tricuspid valve insufficiencies. One patient showed suspiciously resting pulmonary hypertension (TRVmax – 3.3m/sec). In two patients, dilatation of ascending aorta was showed. There was aortic arch mass in one patient.

**Conclusions:** The CV involvement in BD can be a cause of death. In this screening study, asymptomatic patients showed many CV manifestations. And in 59 (72.8%) patients, PWV was elevated. Arterial stiffness can be a surrogate marker of CV disease. Larger study about CV manifestations in BD must be planned. And during treatment of patients with BD, CV screening study needs to be considered.

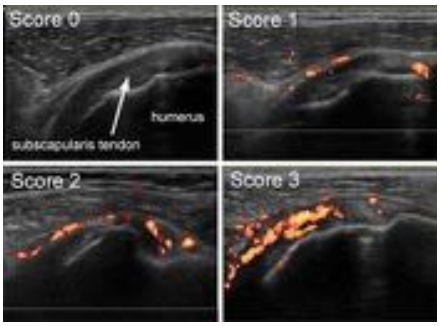
## FRI0392 ULTRASONOGRAPHIC SCORING REVEALED THAT THE RATIO OF EXTRA-SYNOVIAL INFLAMMATION TO SYNOVIAL INFLAMMATION IN THE SHOULDER IS HIGHER IN PMR PATIENTS THAN THAT IN ELDERLY-ONSET RA PATIENTS WITH PMR-LIKE ONSET



T. Suzuki, R. Yoshida, Y. Seri. *Division of Allergy and Rheumatology, Japanese Red Cross Medical Center, Tokyo, Japan*

**Background:** We previously reported that shoulder synovitis in polymyalgia rheumatica (PMR) is milder than that in elderly-onset rheumatoid arthritis (EORA) patients with PMR-like onset (polymyalgic-EORA) by using semi-quantitative ultrasound (US) scoring of the synovial components in the shoulder in spite of the higher serum CRP (1).

**Objectives:** We aimed to evaluate the contribution of the extra-synovial inflammation in PMR patients by power Doppler (PD) US.

**Methods:** We analyzed US records of 14 untreated PMR patients and 14 untreated polymyalgic-EORA patients using a semi-quantitative four-point scale (0 = absent, 1 = mild, 2 = moderate or 3 = severe). For the comprehensive evaluation of shoulder synovitis, the severity of the biceps tenosynovitis, subacromial/subdeltoid bursitis and glenohumeral joint synovitis were subjectively scored on a gray scale and by PD on a 4-point scale (0–3). The sum of six scores (0–18) for one shoulder was defined as shoulder synovitis score (SSS). For the evaluation of extra-synovial inflammation in the shoulder, the hyperemia adjacent to the anterior

aspect of the subscapularis tendon (SubST) was analyzed in the horizontal long axis view. The severity of PD-signals on SubST was subjectively scored on a 4-point scale (0–3) as exemplified in the figure, and the score was defined as the extra-synovial hyperemia score (ESHS).
**Results:** The ESHS/SSS ratio was significantly higher in PMR shoulders than in polymyalgic-EORA shoulders (0.447 ±0.251 vs 0.303 ±0.277, p=0.0138). The bilateral ESHS/bilateral SSS ratio was significantly higher in PMR patients than in polymyalgic-EORA patients (0.475 ±0.269 vs 0.236 ±0.182, p=0.00776).

**Conclusions:** Semi-quantitative US scoring of the synovial and the extra-synovial components in the shoulder revealed the larger involvement of the extra-synovial soft tissue inflammation in PMR patients than in EORA patients with PMR-like onset.

FRI0393 **CUT-OFF VALUES FOR INTIMA-MEDIA THICKNESS OF TEMPORAL, FACIAL AND AXILLARY ARTERIES IN GIANT CELL ARTERITIS**

V.S. Schäfer[1], A. Juche[1], S. Ramiro[2], A. Krause[1], W.A. Schmidt[1]. *[1]Medical Center for Rheumatology and Clinical Immunology Berlin-Buch, Immanuel Krankenhaus Berlin, Berlin, Germany; [2]Department of Rheumatology, LUMC, Leiden, Netherlands*

**Background:** Ultrasound (US) is increasingly used in the diagnosis of giant cell arteritis (GCA). US findings mainly rely on morphology ("halo-sign" and "compression sign"). Increasing resolution of modern US probes allows exact intima-media thickness (IMT) measurement of normal and vasculitic temporal arteries. No data have yet been published on IMT of temporal, facial and axillary arteries in GCA patients compared to healthy controls.
**Objectives:** To evaluate the mean IMT thickness of arteries commonly involved in GCA in GCA patients and controls, and to determine if cut-off values can define pathology.
**Methods:** Fourty newly diagnosed GCA patients of a fast-track GCA clinic and 40 age- and sex-matched controls were included between October 2014 and December 2015. The diagnosis of GCA was established by two very experienced rheumatologists (WAS or AJ) on the basis of clinical presentation, laboratory tests and US results. The diagnosis was confirmed after 6 months in patients who were included until July 2015. IMT measurement was performed at or within 24 hours after the first visit. The common superficial temporal arteries with their frontal and parietal branches and the facial arteries were bilaterally examined with a 10–22 MHz probe (Esaote MyLab Twice). A 6–18 MHz probe was used for both axillary arteries. In total, IMT measurement was performed at 800 sites. The mean IMT values of the different arteries were compared between controls and patients with active vasculitis of the corresponding artery by means of a Mann-Whitney test. ROC analysis was performed to determine the best cut-off value, balancing sensitivity and specificity, to discriminate between a normal and a vasculitic artery.
**Results:** Both groups of 40 participants, each, included 27 females. The mean age was 72 years (SD 9).
Of the 40 GCA patients, 22 (55%) had indurated temporal arteries on clinical examination, 16 (40%) had symptoms of polymyalgia rheumatica. The mean duration of symptoms was 15 weeks (SD 19). Five patients (13%) had visual impairment (anterior ischaemic optic neuropathy, 3; amaurosis fugax, 1; diplopia, 1). Twenty-eight patients (70%) described headache; and 17 (43%) had jaw claudication. The mean ESR was 82 mm/h (SD ± 28); and the mean CRP was 107 mg/dL (SD 79). In 26 patients (65%) the axillary arteries were involved of whom 9 had no involvement of temporal arteries.
Table 1 shows IMT of affected arteries in GCA patients compared to controls and cut-off values for distinguishing normal from inflamed arteries.
Maximum IMT of controls and minimum IMT of vasculitic segments in GCA was 0.34 mm/0.42 mm for the common superficial temporal arteries, 0.32 mm/0.34 mm for the frontal branch, 0.31 mm/0.24 mm for the parietal branch, 0.42 mm/0.31 mm for the facial artery and 0.86 mm/1.0 mm in the axillary arteries, i.e. no overlap occurred in the common superficial temporal arteries, the frontal branch and the facial arteries.

*Table 1: Measurements and cut-off values for each artery*

| Artery | N | IMT in mm | Cut-off in mm | Sensitivity | Specificity | Correctly classified |
|---|---|---|---|---|---|---|
| Common superficial temporal artery | 40 | C: r. 0.23 (SD 0.03) l. 0.23 (SD 0.04) | r. 0.42 l. 0.45 | 100 % 100 % | 100 % 100 % | 100 % 100 % |

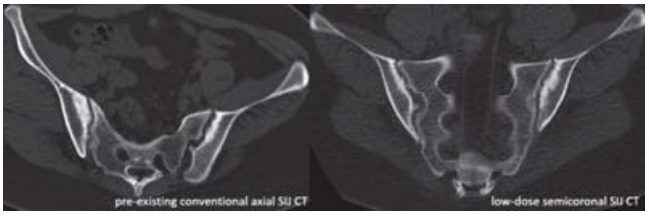
## Spondyloarthritis - clinical aspects (other than treatment)

FRI0394 **ASSESSMENT OF CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH SPONDYLOARTHRITIS AND THEIR ASSOCIATION WITH DISEASE FEATURES AND ITS ACTIVITY. A COMPARISON BETWEEN TWO POPULATION GROUPS FROM ASAS-COMOSPA**

C. López-Medina, P. Font-Ugalde, J. Calvo-Gutiérrez, M.C. Castro-Villegas, R. Ortega-Castro, A. Escudero-Contreras, E. Collantes-Estévez. *Reumatología, Hospital Universitario Reina Sofía de Córdoba/ Imibic/ Universidad de Córdoba, Córdoba, Spain*



**Background:** Data from epidemiologic studies suggest that patients with Spondyloarthritis (SpA) have an increased risk of developing cardiovascular disease[1] (CVD). In healthy people this risk is different depending on the country, ambient factors and lifestyle. However, in SpA patients these differences have not been studied yet, so it is unknown whether they are attributable to the socio-demographic factors or to the disease itself and its activity.
**Objectives:** To assess the prevalence of cardiovascular risk factors in SpA patients by making a comparison between two population groups which have socio-demographic differences, and to recognize the items which define the variability of the Framingham risk score.
**Methods:** An observational, cross-sectional and multicenter study which included 1982 patients with SpA selected from the ASAS-COMOSPA register and belonging to two groups of countries: Northern Europe (UK, Germany, Belgium and Netherland) and Mediterranean Basin countries (Spain, France, Italy, Morocco, Turkey and Egypt).
Univariate logistic regressions, stratified by sex and disease duration (with a cut-off of 10 years) were performed to contrast the two groups of countries and the cardiovascular risk factors (smoking, BMI, dyslipidemia, diabetes, renal deficiency, family history, ischemic heart disease and stroke).
A multiple linear regression was performed in order to determine the variability in Framingham risk score attributable to different items (socio-demographics, disease related factors and disease activity).
**Results:** There were 1336 (67.40%) patients from Mediterranean basin countries and 646 (32.60) from Northern Europe; 797 (40.21%) were women and 1185 (59.78%) were men.
Men and women from Northern Europe have a higher frequency in smoking (OR 1.85 and OR 1.37 respectively). However, for both sex, HTA (OR 0.48 and OR 0.45) and ischemic heart disease (OR 0.25 and OR 0.29) is less frequent than in those from Mediterranean countries.
It is less frequent obesity (OR 0.70 and OR 0.50), HTA (OR 0.49 and OR 0.59) and ischemic heart disease (OR 0.21 and OR 0.47) in patients from Northern Europe countries, both in a disease duration of $<10$ and $\geq 10$ years respectively,

than in patients from Southern countries. In patients with a disease duration of <10 years, it is also less usual dyslipidemia (OR 0.66) and renal deficiency (OR 0.24).
In the overall population, 70.5% of Framingham risk score was explained by sex, age, disease duration, belonging to Northern countries, current smoking, number of tender joints, physician's global assessment (all of them $p<0.001$) and erythrocyte sedimentation rate (being the latter one a confounding factor, p=0.091).
**Conclusions:** Northern Europe patients with SpA have a lower cardiovascular risk than those from Mediterranean basin countries, both women and men. However these differences can't be only attributable to socio-demographic characteristics, because disease related factors and disease activity are contributory causes in the appearance of cardiovascular risk.

## FRI0395 LOW-DOSE SEMI-CORONAL CT OF THE SACROILIAC JOINTS IN THE EARLY DIAGNOSIS OF ANKYLOSING SPONDYLITIS

D. Gao, K. Li, Y. Wang, Q. Wen, J. Zhu, J. Zhang, F. Huang. *Department of Rheumatology, Chinese People's Liberation Army General Hospital, Beijing, China*

**Background:** Imaging modalities are essential for the diagnosis of ankylosing spondylitis (AS). Radiographic sacroiliitis is the requirement of 1984 modified New York (mNY) criteria for AS but with the disadvantage of low sensitivity. MRI has the advantage of detecting active inflammatory lesions but was criticized for low specificity. Computerized tomography (CT) has higher diagnostic accuracy than radiography in detecting structural changes, but its application has been limited for high radiation dose. The reduction of radiation dose can be achieved by decreasing the tube current[1] and previous study has demonstrated that effective dose (ED) of semi-coronal sacroiliac joint (SIJ) CT is at least six times lower in female or nearly four times lower in male than that of axial SIJ CT[2].
**Objectives:** To evaluate the value of low-dose semi-coronal SIJ CT in the early diagnosis of AS.
**Methods:** Thirty-three patients diagnosed by mNY criteria who had pre-existing axial SIJ CT in past two years with visible structural damage were enrolled. These patients underwent low-dose semi-coronal SIJ CT examination which was obtained at 3-mm slices, 140 kV and 120 mAs, with the gantry tilted 20–25° cranially. The ED of the low-dose semi-coronal CT and the pre-existing conventional axial CT were compared. Image qualities of the low-dose semi-coronal CT were blind-graded separately by 2 rheumatologists into poor, fair, good or excellent. And the correlation between image quality and body mass index (BMI) was analyzed. The CT scans were read in a blinded manner by 2 rheumatologists who had been trained by radiologists. CT scans of the two groups were graded respectively by mNY criteria, the criteria established by Lee[3] and the Innsbruck criteria[4]. The kappa coefficient was used to assess the consistency of grading between the two groups.
**Results:** Thirty-three patients received low-dose semi-coronal CT examination with an average ED of 3.37 mSv, which meant a 49% reduction in radiation compared to the pre-existing CT. The quality of images of male patients with BMI<25 kg/m$^2$ and all female patients were good or excellent. Image qualities were assessed as poor or fair in 58% (7/12) male patients whose BMI>25 kg/m$^2$. There was a significant negative correlation between image quality and BMI (r=-0.784,*P*=0.000). The grading of low-dose semi-coronal CT showed no differences as compared with the pre-existing CT by mNY criteria (see below). For the other two classification criteria, the consistency of grading between the two groups were satisfactory (kappa=0.897 by Lee criteria; kappa=0.814 by Innsbruck criteria; $P>0.05$).

**Conclusions:** The radiation dose of low-dose semi-coronal SIJ CT was reduced significantly compared with the conventional axial SIJ CT with acceptable diagnostic efficacy.

## FRI0396 WHICH IS THE MOST RELIABLE IMAGING METHOD FOR DETECTION OF STRUCTURAL CHANGES IN THE SACROILIAC JOINTS OF PATIENTS WITH ANKYLOSING SPONDYLITIS? A CROSS-SECTIONAL STUDY COMPARING MRI, CT AND CONVENTIONAL RADIOGRAPHS

X. Baraliakos[1], F. Hoffmann[1], X. Deng[2], Y. Wang[2], F. Huang[2], J. Braun[1]. *[1]Rheumazentrum Ruhrgebiet, Herne, Germany; [2]Department of Rheumatology, Chinese PLA General Hospital, Beijing, China*

**Background:** Magnetic resonance imaging (MRI) is the gold standard for detection of inflammation and fat metaplasia in the sacroiliac joints (SIJ) and the spine of patients with axial spondyloarthritis (axSpA). Structural changes (erosions, sclerosis and ankylosis) assessed by conventional radiographs (CR) or computed tomography (CT) are characteristic for ankylosing spondylitis (AS). Direct comparisons of these imaging techniques have not been performed to date.
**Objectives:** Compare the reliability of CR and MRI as compared to CT for detection of structural changes in SIJs of AS patients.
**Methods:** Complete sets of MRI, CT and CR of SIJs of 69 AS patients and 49 age- and gender-matched controls in whom CTs had been performed for other reasons than back pain were analyzed. Two readers evaluated the images independently and blinded to diagnosis and clinical characteristics in random order. Assessment of lesions was performed based on SIJ-quadrants (SQ). Only definite erosions, sclerosis and ankylosis were recorded, and only SQ changes for which readers agreed on were used for analysis.
**Results:** The mean age of AS patients was 44.6 years, 72.5% were male, 85.5% were HLA-B27 positive, the mean time since diagnosis was 4.8±5.8 years (range 1 14 years), the mean BASDAI was 4.9±1.8 and the mean CRP was 1.9±2.3mg/dl. In total, 552 SQ (276 pairs) were analyzed. *Erosions* were found in 131 (23.7%) SQ by CR, 141 (25.5%) by CT and in 167 (30.3%) SQ on T1-MRI. Agreement for erosions was seen for 64 SQ assessed by CR/CT, 100 SQ by CT/MRI and 70 SQ by CR/MRI, with 48.9% of SQ detected by CR also seen on CT and 45.4% detected on CT also seen by CR. The corresponding numbers for CT/MRI were 70.9% and 59.9% and for CR/MRI 53.5% and 41.9%, respectively. Disagreement for erosions was found in 144 (26.1%), 108 (19.6%) and 158 (28.6%) SQ, respectively. *Sclerosis* was seen in 86 SQ on CR (15.6%), 91 SQ on CT (16.5%) and 63 on T1-MRI (11.4%). Agreement was found in 31 SQ on CR/CT, 22 SQ on CT/MRI and 45 SQ on CR/MRI, with 36.0% SQ detected on CR also seen on CT and 34.1% detected on CT also seen by CR. The corresponding numbers for CT/MRI were 24.2% and 34.9% and for CR/MRI 52.3% and 71.4%. Disagreement for sclerosis was found in 95 (17.2%), 72 (13.0%) and 66 (12.0%) SQ, respectively. *Ankylosis* was seen in 91 SQ pairs on CR (33,3%), 130 SQ pairs on CT (47,1%) and 106 SQ pairs on MRI (38,4%). Agreement was found in 87 SQ pairs on CR/CT, 94 SQ pairs on CR/MRI and 72 SQ pairs on CT/MRI, with 95.6% SQ detected on CR also seen on CT and 66.9% detected on CT also seen by CR. The corresponding numbers for CT/MRI were 72.3% and 88.7% and for CR/MRI 79.1% and 67.9%. Disagreement for ankylosis was seen in 47 (17.0%), 48 (17.4%) and 53 (19.2%) SQ pairs, respectively.In controls, 392 SQ were analyzed. Erosions were found in only 19 (4.8%) SQ and sclerosis in 23 (5.9%) SQ, while no patient showed ankylosis.
**Conclusions:** Erosions and ankylosis are more common than sclerosis in SIJs of AS patients and rarely seen in controls. The agreement between methods was rather limited. Compared to CT, less erosions were detected by MRI and CR when only erosions agreed on were counted. CT and MRI were more reliable than CR for the detection of ankylosis.

## FRI0397 THE DIAGNOSTIC VALUE OF THE SYMPTOM OF INFLAMMATORY BACK PAIN IN AXIAL SPONDYLOARTHRITIS IN THE RHEUMATOLOGY SETTING

D. Poddubnyy[1], I. Spiller[1], J. Listing[2], J. Braun[3], J. Sieper[1], M. Rudwaleit[4]. *[1]Charité Universitätsmedizin Berlin; [2]German Rheumatism Research Centre, Berlin; [3]Rheumazentrum Ruhrgebiet, Herne; [4]Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany*

**Background:** Inflammatory back pain (IBP) as a symptom has been shown to perform effectively for selecting patients in primary care/orthopaedic settings for referral of chronic back pain patients to the rheumatologist for further diagnostic work-up. IBP is also being used as a diagnostic test of axial spondyloarthritis (axSpA) by rheumatologists, but no validations studies have been performed so far with IBP as a diagnostic tool.
**Objectives:** The aim of the DIVERS study was to evaluate the diagnostic value of the IBP symptom in axSpA in the rheumatology setting.

**Methods:** A total of 405 consecutive patients referred to a rheumatologist because of chronic back pain starting at an age <45 years and suspicion of axSpA were included in this multicentre study. A questionnaire containing all relevant IBP parameters was first answered by the patient, followed by a rheumatologist blinded for presence or absence of other SpA features and for the diagnosis, and finally by the rheumatologist responsible for the diagnosis. A global evaluation of IBP by rheumatologists, and IBP according to the previously published Calin's, Berlin and ASAS criteria as well as single items of IBP were compared regarding their diagnostic performance.
**Results:** The diagnosis of definite axSpA was made in 180 (44.4%) patients (88 with ankylosing spondylitis and 92 with non-radiographic axSpA). The sensitivity, specificity and the positive likelihood ratio of IPB for the axSpA diagnosis was 81%, 44%, and 1.5, respectively, if globally assessed by the blinded rheumatologist, and 90%, 58% and 2.2, respectively, if globally assessed by the diagnosing rheumatologist - table. There was no clear superiority of any of the three criteria sets regarding sensitivity for the axSpA diagnosis with an overall sensitivity of about 80% and specificity between 25% and 45% if symptoms were assessed by a rheumatologist - table. The performance of the criteria sets based on patient's own evaluation of IBP symptoms was generally lower. No single IBP parameter showed superiority regarding sensitivity or specificity in comparison to the criteria sets.

Table. Sensitivity, specificity, a positive and a negative predictive value (PPV and NPV) of inflammatory back pain (IBP) for the diagnosis of axSpA.

| Assessor | IBP according to... | Sensitivity, % (95% CI) | Specificity, % (95% CI) | PPV (95% CI) | NPV (95% CI) | LR+ | LR- |
|---|---|---|---|---|---|---|---|
| Blinded rheumatologist | Global evaluation | 81.3 (75.4-86.3) | 44.0 (37.6-50.5) | 53.9 (48.0-59.8) | 74.2 (66.8-81.7) | 1.5 | 0.4 |
| | Calin's criteria | 79.4 (73.5-85.4) | 24.9 (19.2-30.5) | 45.8 (40.3-51.4) | 60.2 (50.3-70.2) | 1.1 | 0.8 |
| | Berlin Criteria | 81.1 (75.4-86.8) | 32.4 (26.3-38.6) | 49.6 (43.5-54.7) | 68.2 (59.6-77.1) | 1.2 | 0.6 |
| | ASAS criteria | 76.4 (68.1-83.8) | 39.6 (31.2-45.9) | 49.4 (43.7-55.4) | 65.9 (57.9-73.6) | 1.2 | 0.7 |
| Diagnosing rheumatologist | Global evaluation | 90.8 (83.4-94.4) | 58.2 (51.8-64.7) | 65.3 (57.4-69.2) | 87.9 (82.6-93.2) | 2.2 | 0.2 |
| | Calin's criteria | 85.8 (79.8-90.2) | 26.7 (20.9-32.6) | 48.1 (42.6-53.6) | 69.0 (59.2-78.7) | 1.2 | 0.6 |
| | Berlin Criteria | 81.9 (75.5-88.3) | 44.0 (38.4-51.6) | 54.9 (49.0-60.8) | 77.3 (70.3-84.9) | 1.5 | 0.4 |
| | ASAS criteria | 83.3 (78.5-88.3) | 35.6 (29.3-41.8) | 51.8 (45.3-56.7) | 73.4 (65.1-81.7) | 1.3 | 0.5 |
| Patient | Calin's criteria | 75.3 (68.8-81.3) | 39.4 (33.1-25.7) | 46.8 (37.5-48.6) | 58.8 (49.2-61.0) | 0.9 | 1.2 |
| | Berlin Criteria | 86.4 (82.4-91.3) | 18.6 (12.9-23.7) | 46.8 (42.6-51.3) | 69.3 (51.3-74.8) | 1.1 | 0.7 |
| | ASAS criteria | 76.8 (67.3-80.3) | 35.2 (29.1-37.2) | 46.3 (40.5-52.1) | 68.0 (51.1-69.0) | 1.3 | 0.8 |

**Conclusions:** IBP demonstrated high sensitivity but rather modest specificity for the diagnosis of axSpA among patients with chronic back pain referred to a rheumatologist. A resulting moderate diagnostic value of IBP in the rheumatology setting is likely to be counterbalanced by increase in the pre-test probability of axSpA in this patients population.
**Disclosure of Interest:** None declared

## FRI0398 PHARMACOLOGIC THERAPY AND RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS: A GROWING CONTROVERSY

L. Gensler[1], J.D. Reveille[2], M.M. Ward[3], M.A. Brown[4], M. Rahbar[5], M. Lee[6], M.H. Weisman[7]. *[1]Medicine/Rheumatology, University of California, San Francisco, San Francisco; [2]Medicine/Rheumatology, The University of Texas Health Science Center at Houston, Houston; [3]NIAMS, NIH, Bethesda; [4]Medicine/Rheumatology, University of Queensland, Brisbane; [5]Medicine; [6]Medicine/ Biostastics, The University of Texas School of Public Health at Houston, Houston; [7]Medicine/ Rheumatology, Cedar Sinai Medical Center, Los Angeles, United States*

**Background:** Pharmacologic therapies in Ankylosing Spondylitis (AS) have informed debatable effects on radiographic progression. Two-year studies using Tumor Necrosis Factor inhibitors (TNFi) showed no benefit, yet longer-term studies reported less radiographic progression. Similarly, NSAID effects have been controversial.
**Objectives:** To determine the relationship between pharmacologic therapies and radiographic progression in AS.
**Methods:** This is a prospective cohort of 505 AS patients meeting the modified New York criteria with at least 2 years of radiographic follow up. Using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS), progressors were defined with at least one mSASSS unit increase per year of follow up or patients who rapidly progressed at any time point (2 new syndesmophytes in 2 years). Patients with an mSASSS=72 at baseline (n=17) were excluded. TNFi use was defined at each 6-month study visit and adjusted for baseline use and total duration of use. High NSAID use was defined if the patient was taking NSAIDs at least 50% of the study period. We grouped patients according to their follow-up period (interval between baseline and last visit) and used progressor status (progressor vs. non-progressor) as a dichotomized outcome in univariable and multivariable mixed effects logistic regression models.
**Results:** The progressors made up 35.45% of the cohort (n=179). We found that TNFi use was related to a lower likelihood of radiographic progression and this association appeared to be strongest for patients with 2.1–3.5 years of follow-up (OR=0.25, 95% CI 0.07,0.92; p=0.0376). Although not statistically significant, in patients who were followed up for 3.6 years or longer, the odds of progression for the TNFi user group was 46% lower in the 3.6–5.9 year group (OR=0.54) and 23% lower in the 6+ year group (OR=0.77) than in TNFi non-users. Patients exposed to NSAIDs (≥50% exposure) also had a lower likelihood of radiographic progression (OR=0.47, 95% CI 0.22,0.99); p=0.046) [Table 1]. The probability of progression by years of follow up per TNFi user group is shown in Figure 1.

| Label | Odds Ratio | p-value |
|---|---|---|
| *TNFi* follow-up (FU) year group* | | |
| TNFi user vs. no for patients with FU year 2 | 1.10 (0.34, 3.60) | 0.87 |
| **TNFi user vs. no for patients with FU year 2.1–3.5** | **0.25 (0.07, 0.92)** | **0.04** |
| TNFi user vs. no for patients with FU year 3.6–5.9 | 0.54 (0.17, 1.72) | 0.29 |
| TNFi user vs. no for patients with FU year 6– | 0.77 (0.23, 2.59) | 0.67 |
| **High NSAID user vs. no** | **0.47 (0.22, 0.99)** | **0.04** |
| **Baseline mSASSS** | **1.03 (1.02, 1.05)** | **<0.0001** |
| **Disease duration >10 years** | **1.97 (1.15, 3.39)** | **0.01** |
| **Male gender** | **1.95 (1.06, 3.60)** | **0.03** |
| Education > college | 1.11 (0.58, 2.14) | 0.74 |
| **Current smoking** | **2.52 (1.23, 5.16)** | **0.01** |
| # Comorbidity ≥1 | 1.17 (0.69, 1.97) | 0.56 |
| Baseline BASDAI ≥40 | 1.04 (0.60, 1.81) | 0.88 |
| Baseline BASFI ≥40 | 0.94 (0.49, 1.78) | 0.84 |
| **Baseline CRP (high)** | **1.69 (1.03, 2.78)** | **0.03** |

**Figure 1. Probability of progression in patients exposed to vs. not exposed to TNFi**

**Conclusions:** TNFi use is associated with a lower likelihood of radiographic progression in AS with the most significant effect after longer than 2 years of follow up. Use of NSAIDs was also associated with less radiographic progression.

## FRI0399 BACKFILL IS MORE IMPORTANT THAN EROSION AND FAT DEPOSITION IN DIAGNOSING AXIAL SPONDYLOARTHRITIS AS SEEN ON MRI

Z. Hu, P. Zhang, M. Qiu, J. Qi, X. Guo, J. Gu. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-Sen Universit, Guangzhou, China*

**Background:** The structural lesions in patients with axial spondyloarthritis (SpA) seen on magnetic resonance imaging (MRI) include erosion, fat deposition, backfill and ankylosis. Backfill is the new tissue fills in the excavated bone in the sacroiliac joint (SIJ) which can be seen on T1SE MRI. Recent studies have shown that backfill is a key intermediary step in the development of ankylosis in patients with axial SpA. But data comparing the diagnostic value of backfill and other lesions is rare.
**Objectives:** To record erosion, fat deposition and backfill seen on T1SE MRI and to evaluate whether backfill is more important than other lesions in diagnosing axial SpA.
**Methods:** Three readers investigated erosion, fat deposition and backfill seen on T1SE MRI scans from 423 patients with axial SpA and 224 subjects with non-specific back pain (NSBP) or healthy (classified as control group). The SPARCC SIJ Structural Score (SSS) method was used to assess these three kinds of lesion. The sensitivity, specificity and positive likelihood ratio (LR) of three kinds of lesion for diagnosing axial SpA were calculated.
**Results:** 246 axial SpA patients (58.2%) were recorded with backfill, 343 (81.1%) were recorded with erosion, and 372 (88.0%) were recorded with fat deposition. While in healthy controls, only 4 (1.8%) were seen with backfill, 26 (11.6%) were with erosion, and 43 (19.2%) were with fat deposition. The SSS score of backfill, erosion, and fat deposition were all much higher in axial SpA patients than in control group (backfill: 2.8 ± 1.6 vs. 0.1± 0.7; erosion: 18.4 ± 9.7 vs. 4.5 ± 6.3; fat deposition: 25.8 ±17.2 vs. 16.4 ± 18.1; all p<0.01). The sensitivity and specificity of backfill, erosion, and fat deposition for diagnosing axial SpA were (0.58, 0.98),

(0.81, 0.88), and (0.88, 0.81), respectively. The positive LR of using backfill to diagnose axial SpA was quite high (32.6), while it was moderate for erosion (7.0) and fat deposition (4.6).
**Conclusions:** Backfill is more important than erosion and fat deposition in diagnosing axial spondyloarthritis as seen on MRI.

## FRI0400 A FIVE YEAR PROSPECTIVE STUDY OF SPINAL RADIOGRAPHIC PROGRESSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Deminger[1], E. Klingberg[1], M. Geijer[2], J. Göthlin[3], M. Hedberg[4], E. Rehnberg[5], H. Carlsten[1], L.T. Jacobsson[1], H. Forsblad-d'Elia[1,6].
*[1]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Göteborg; [2]Department of Radiology, Örebro University Hospital, Örebro; [3]Department of Radiology, Sahlgrenska University Hospital, Mölndal; [4]Section of Rheumatology, Södra Älvsborg Hospital, Borås; [5]Section of Rheumatology, Alingsås Hospital, Alingsås; [6]Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden*

**Background:** The knowledge about what predicts progress of syndesmophytes that characterize patients with ankylosing spondylitis (AS) is limited. The strongest known predictor for radiographic progression in the spine is existing syndesmophytes at baseline.
**Objectives:** To study the radiographic progression in the spine in AS patients in total and by gender and search for predictors for the changes.
**Methods:** 204 patients with AS, all meeting the New York criteria, from three rheumatology departments in western Sweden were included in a longitudinal study. At baseline and after five years lateral radiographs of the cervical and lumbar spine were obtained and graded according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). All radiographs were assessed by the same experienced radiologist (MG). Predictors were assessed through questionnaires, back mobility tests and blood samples.
**Results:** Of the 204 patients included at baseline, 169 (83%) patients were re-examined at the five year follow-up, 92 (54%) men and 77 (46%) women. At baseline, the median age (IQR) of the 169 patients was 49 (40 to 61.5) years old and the median duration of symptoms (IQR) was 22 (12 to 34) years, no significant difference in age or duration of symptoms between gender. Baseline mean mSASSS was 14.9±20.0 with progression to 16.4±20.8 at follow-up, an increase with 1.5±3.0 units ($p<0.001$). In men, mean baseline mSASSS was 22.0±23.5 and at follow-up 23.8±23.8, an increase of 1.8±2.8 units ($p<0.001$). In women, mean baseline mSASSS was 6.4±9.6 and 7.6±11.7 at follow-up, an increase of 1.2±3.3 ($p=0.002$). The mSASSS score at both baseline and at follow-up differed significantly between gender ($p<0.001$), whereas the progression of mSASSS did not differ significantly ($p=0.2$) between the groups. The presence of syndesmophytes at baseline was 47% in the whole group, 59.0% for men and 32.5% for women (p-value difference gender $<0.001$). In the total group 18.9% had had significant progression ($\geq$4 mSASSS units over five years), 23.9% of the men and 13.0% of the women ($p=0.11$). Such rapid progression of mSASSS was in age-adjusted logistic regression models significantly predicted by baseline syndesmophyte and mean CRP during follow-up in men and baseline BASMI in women (table).
**Conclusions:** The progression rate was 1.5±3.0 mSASSS units over five years and did not differ significantly between men and women, although being much higher in men at baseline in this cohort of AS patients with longstanding disease. Presence of existing syndesmophytes and persistent elevated CRP during follow-up were significant predictors for a change in $\geq$4 mSASSS units over five years in men whereas in women instead high BASMI was a significant predictor.

Table. Univariate logistic regression analyses adjusted for age, with increase of ≥4 mSASSS units during 5 years as dependent variable. Covariates are baseline values, except for CRP and treatment (mean during follow-up).

| | Men (N=92) | Women (N=77) |
|---|---|---|
| **Covariates** | **OR (95% CI)** | **OR (95% CI)** |
| Pack years (per year) | 1.03 (0.99 to 1.08) | 0.76 (0.53 to 1.10) |
| History of anterior uveitis | 1.77 (0.63 to 4.97) | 0.90 (0.22 to 3.63) |
| **BASMI, score (0-10, per unit)** | 1.10 (0.79 to 1.53) | **2.60 (1.27 to 5.32)** |
| **Presence of syndesmophyte** | **7.26 (1.75 to 30.18)** | 3.29 (0.82 to 13.26) |
| **Mean CRP during follow-up >10 mg/L** | **5.23 (1.69 to 16.18)** | 0.86 (0.09 to 8.13) |
| NSAID-index, 0-100 (per unit) | 1.00 (0.99 to 1.01) | 1.00 (0.98 to 1.02) |
| Part of time TNFi during follow-up, 0-1 (per unit) | 1.29 (0.39 to 4.30) | 2.46 (0.40 to 15.20) |
| Part of time bisphosphonate during follow-up, 0-1 (per unit) | 2.96 (0.52 to 16.76) | 4.12 (0.58 to 29.47) |

BASMI, Bath Ankylosing Spondylitis Metrology Index, CRP, C-reactive protein, NSAID, non-steroidal anti-inflammatory drug; TNFi, tumor necrosis factor inhibitor. For dichotomous variables, no was coded 0, yes 1.

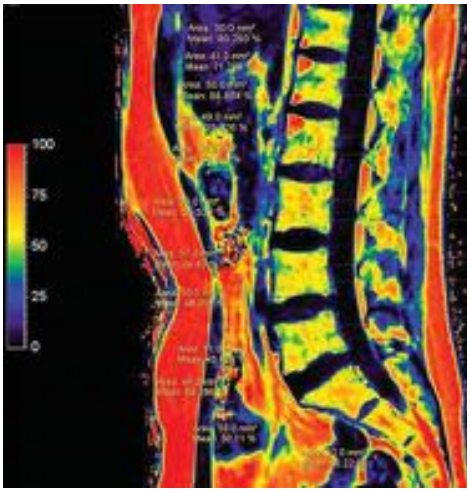
## FRI0401 SAFETY OF RESUMING TUMOR NECROSIS FACTOR INHIBITORS IN ANKYLOSING SPONDYLITIS PATIENTS CONCOMITANT WITH THE TREATMENT OF ACTIVE TUBERCULOSIS: A RETROSPECTIVE NATIONWIDE REGISTRY OF THE KOREAN SOCIETY OF SPONDYLOARTHRITIS RESEARCH

H.W. Kim[1], S.-H. Lee[2], H.J. Baek[3], T.-H. Kim[4], Y.-G. Kim[5] on behalf of Korean Society of Spondyloarthritis Research. *[1]Internal Medicine, Division of Rheumatology, Eulji General Hospital; [2]Internal Medicine, Division of Rheumatology, Center of Arthritis and Rheumatism, Kyung Hee University Hospital at Gangdong; [3]Internal Medicine, Division of Rheumatology, Gachon University Gil Hospital; [4]Internal Medicine, Division of Rheumatology, Hanyang University Hospital for Rheumatic Diseases; [5]Internal Medicine, Division of Rheumatology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of*

**Background:** Patients who develop an active tuberculosis infection (TI) during tumor necrosis factor (TNF) inhibitor treatment typically discontinue TNF inhibitor and receive standard anti-tuberculosis treatment. However, there is currently insufficient information on patient outcomes following resumption of TNF inhibitor treatment during ongoing anti- tuberculosis treatment.
**Objectives:** Our study designed to investigate the safety of resuming TNF inhibitors in ankylosing spondylitis (AS) patients who developed TI as a complication of the use of TNF inhibitors.
**Methods:** Through the nationwide registry of the Korean Society of Spondyloarthritis Research, 3929 AS patients were recruited who were prescribed TNF inhibitors between June 2003 and June 2014 at fourteen referral hospitals. Clinical information about the patients who experienced TI after exposure to TNF inhibitors was analyzed. The clinical features of resumers and non-resumers of TNF inhibitor were compared and the outcome of TI was surveyed individually.
**Results:** Fifty-six AS patients were treated for TI associated with TNF inhibitors. Among them, 23 patients resumed TNF inhibitors and these patients were found to be exposed to TNF inhibitors for a longer period of time and experienced more frequent disease flare up after discontinuation of TNF inhibitors compared with those who did not resume. Fifteen patients resumed TNF inhibitors during anti-tuberculosis treatment (early resumers) and 8 after completion of TI treatment (late resumers). Median time to resuming TNF inhibitor from TI was 3.3 and 9.0 months in the early and late resumers, respectively. TI was treated successfully in all resumers and did not relapse in any of them during follow-up (median 33.8 (IQR; 20.8–66.7) months).

| | Total patients (n = 56) | Resumers (n = 23) | Non-resumers (n = 33) | *P* |
|---|---|---|---|---|
| Age, yr (median, IQR) | 43.0 (32.9-55.8) | 43.3 (32.8 - 47.7) | 39.3 (33.3 – 61.9) | 0.16 |
| Male sex, n (%) | 50 (89.3) | 22 (95.7) | 28 (84.8) | 0.19 |
| Disease duration, yr (median, IQR) | 8.9 (5.9-13.4) | 9.3 (6.1 – 13.4) | 8.5 (5.9 – 13.9) | 0.54 |
| LTBI, n (%) | 15 (26.8) | 6 (26.0) | 9 (27.3) | 0.94 |
| Previous TI history, n (%) | 10 (17.8) | 5 (21.7) | 5 (15.2) | 0.53 |
| Type of TNFi at TI infection | | | | 0.07 |
| Infliximab, n (%) | 23 (41.7) | 13 (56.5) | 10 (30.3) | |
| Adalimumab, n (%) | 21 (37.5) | 8 (34.8) | 13 (39.4) | |
| Etanercept, n (%) | 12 (21.4) | 2 (8.7) | 10 (30.3) | |
| Duration of total TNFi exposure, mon (median, IQR) | 27.8 (11.2-64.0) | 42.8 (19.1-72.0) | 24.1 (7.0-36.7) | 0.03 |
| Increased AS activity after stopping TNFi, n (%) | 36 (64.3) | 21 (91.3) | 15 (45.5) | <0.001 |



**Conclusions:** TI were treated successful in our AS patients, even when given

concomitantly with TNF inhibitors. We suggest that early resuming TNF inhibitors in AS patients could be safe under effective coverage of the TI.
**Disclosure of Interest:** None declared

## FRI0402 QUANTIFICATION OF FAT FRACTION OF VERTEBRAL BONE MARROW IN PATIENTS WITH ANKYLOSING SPONDYLITIS

S. Lee[1], Y. Song[1], B.S. Koo[2], T.-H. Kim[3]. *[1]Radiology, Hanyang University Hospital for Rheumatic Disease, Seoul; [2]Rheumatology, Department of Internal Medicine, Konkuk University College of Medicine, Chungju; [3]Rheumatology, Hanyang University Hospital for Rheumatic Disease, Seoul, Korea, Republic Of*

**Background:** Focal fat deposition is frequently seen on magnetic resonance imaging (MRI) of the spine in patients with ankylosing spondylitis (AS)[1]. Fat metaplasia in bone marrow is known as one of disease progression in AS[2].
**Objectives:** To evaluate clinical characteristics and the correlation between bone marrow fat-signal fraction (FF), Bath AnkylosingSpondylitis Disease Activity Index (BASDAI), Bath AnkylosingSpondylitis Functional Index (BASFI) and modified Stoke Ankylosing Spondylitis Spine Score (mSASSS).
**Methods:** A total of 55 patients with AS who underwent a spine MRI at our institution from March 2015 to December 2015 were retrospectively evaluated. Quantification of vertebral bone marrow was assessed on the FF maps using the three-point Dixon technique[3]. FF was quantified after measuring the signal intensity within the region of interest (ROI) over anterosuperior and anteroinferior corner of bone marrow where there was no contamination from the bony cortex or syndesmophyte. The ROIs were drawn twice in sagittal FF map and average was used. mSASSSs were independently recorded by two musculoskeletal radiologists. Correlation, univariate and multivariate regression analyses were done for identifying significant predictors of FF.
**Results:** Patients had a mean age of 35.6±10.5 years, and 43 were male (78.2%). A significant correlation was found between FF, mSASSS, BASDAI, and BASFI (p=0.005, p=0.021, and p=0.050)in Pearson correlation analysis. Multivariate regression analysis showed that decrease total BASDAI associated with to increase FF (p=0.005). Measurements of mSASSS had excellent intraobserver (mean intraclass correlation coefficient [ICC] = 0.997 [95% confidence interval (CI): 0.994–0.999] and interobserver agreement (mean ICC =0.941–0.995).However, erythrocyte sedimentation rate (ESR) and C reactive protein (CRP) did not correlated with FF.

**Conclusions:** The quantitative assessment of FF using MRI might be another useful novel imaging technique to correlateactivity index of AS.

## FRI0403 EXPLORING THE NATURAL HISTORY OF BONE MARROW OEDEMA LESIONS IN AXIAL SPONDYLOARTHRITIS: WHEN TO REPEAT AN MRI?

R. Sengupta[1], H. Marzo Ortega[2], D. McGonagle[2], A.N. Bennett[3]. *[1]Royal National Hospital for Rheumatic Diseases, Bath; [2]Rheumatology, NIHR LMBRU, Leeds; [3]Academic Dept Military Rehabilitation, Defence Medical Rehabilitation Centre, Epsom, United Kingdom*

**Background:** MRI determined bone marrow oedema (BMO) lesions in the sacroiliac joints (SIJ) and spine have both diagnostic and prognostic value in axial spondyloarthritis (axSpA). It is unclear how quickly BMO may change on MRI and MRI scans are often normal in early axSpA. There is no clear evidence to guide the role of repeat MRI in the early diagnosis of axSpA.
**Objectives:** To identify:1. If negative MRI scans in patients with clinically suspected axSpA may become positive within a 12-week period. 2. The natural change in BMO MRI lesions over 12-weeks in patients with IBP
**Methods:** 29 patients, <40yrs, fulfilling ASAS Inflammatory Back Pain (IBP)criteria, with normal SIJ x-rays were recruited from 2 sites in the UK. Participants had MRI scans at baseline, 4, 8, and 12 weeks (total 109 scans). The MRI protocol included sagittal T1 and STIR cervico-thoracic and thoraco-lumbar spine and coronal oblique T1 and STIR sequences of the SIJs. NSAIDs were allowed if either continued at stable doses or discontinued throughout the study. Scans were read by consensus by 2 experienced readers unaware of clinical details or date sequence using the Leeds MRI Scoring system. In addition, each scan was scored as either positive or negative according to the ASAS definitions for the SIJ and spine.
**Results:** 28 patients completed the study. Male n=18 (66%), HLA-B27+ve n=21 (75%), mean symptom duration 5 (±2.1) years. Regular NSAIDs were used by n=13 (46%) of patients. Mean baseline BASDAI 4.8 (±0.7) and mean baseline CRP 2.7 mg/dl (±1.7). 10 (36%) met the ASAS clinical criteria for axSpA prior to any imaging. 64% (n=18) of the patients were ASAS (spine and SIJ) negative at baseline and remained so during the entire study. 25% (7) were ASAS SIJ positive, 0.04% (1) were ASAS spine positive and 7% (2) were ASAS (spine and SIJ) positive. A total of 4 (14%) patients changed from ASAS axSpA imaging classification criteria negative to positive (spine (n=3) or SIJ (n=1)) during the study. All of these met ASAS clinical arm classification criteria at baseline.
At any time point, 15 patients had 212 lesions in the spine: 185 vertebral corners (98 inflammatory and 87 fatty), 15 inflammatory endplates (3 patients over all time points) and 12 inflammatory posterior elements (3 patients over all time points).
At baseline, there were 22 inflammatory and 18 fatty corner lesions in the spine. 12 inflammatory corner lesions resolved between any 2 time points. 26 new spinal inflammatory corner lesions appeared at any time point when the baseline MRI was normal.
At baseline, BMO was present in 38 (33%) SIJ quadrants. Between any 2 time points, 16 (14%) BMO quadrant lesions resolved and new BMO lesions appeared in 6 (5%) SIJ quadrants.

Table 1. Change in ASAS status between any 2 time points

| | Spine | SIJ |
|---|---|---|
| Negative ASAS status to positive ASAS status | 3 | 1 |
| Positive ASAS status to negative ASAS status | 1 | 0 |
| Unchanged ASAS status | 77 | 82 |
| Total number of repeat scans | 81 | 83 |

**Conclusions:** These findings do not support the routine use of rescanning in new onset IBP cases suspected of having SpA. In a patient with severe IBP and high BASDAI with an initial negative MRI scan, a repeat scan has a 14% chance of changing the diagnosis which would thus make an otherwise ineligible patient suitable for potentially effective therapy

## FRI0404 ILLNESS PERCEPTIONS AND HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND OTHER FORMS OF CHRONIC BACK PAIN IN THE SPACE-COHORT

M. Van Lunteren[1], P. Bakker[1], M. Scharloo[2], A. Kaptein[2], Z. Ez-Zaitouni[1], C. Fongen[3], R. Landewé[4], M. van Oosterhout[5], M. Lorenzin[6], F. van Gaalen[1], D. van der Heijde[1]. *[1]Rheumatology; [2]Medical Psychology, LUMC, Leiden, Netherlands; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Rheumatology, AMC, Amsterdam; [5]Rheumatology, GHZ, Gouda, Netherlands; [6]Rheumatology, University of Padova, Padova, Italy*

**Background:** Knowledge about the impact of illness perceptions on Health-Related Quality of Life (HRQoL) in patients (pts) with axial Spondyloarthritis (axSpA) and other forms of chronic back pain (CBP) is lacking.
**Objectives:** To explore the association between illness perceptions and HRQoL in pts with short symptom duration of axSpA and other forms of CBP at baseline.
**Methods:** The Spondyloarthritis Caught Early (SPACE) study includes pts with CBP (≥3 months, ≤2 years, onset <45 years) recruited from 5 European centres. The Revised Illness Perception Questionnaire (IPQ-R) was completed at baseline. In the illness identity dimension, pts reported if they have experienced

and believed that a certain symptom is CBP related. Other illness perceptions and causal dimensions used 5-point Likert scales (1 strongly disagree, 5 strongly agree). HRQoL was assessed by 36-item Short-Form (SF-36). Scale scores ranged from 0 (worst) to 100 (best). Physical (PCS) and Mental Component Summary (MCS) scores were calculated. Univariable regression models were built for each IPQ-R subscale as independent and PCS or MCS as dependent variable. The models were adjusted for age and gender and stratified in case of effect modification by gender ($p<0.10$).

**Results:** 315 pts were included; 123 fulfilled axSpA ASAS criteria and 192 did not fulfil the criteria. Mean age was 31.3 (SD 8.3) years, mean duration of CBP was 13.2 (SD 7.2) months and 36.5% was male. Mean PCS was 28.0 (SD 16.3) for axSpA pts and 24.9 (SD 14.4) for CBP. As the MCS was only slightly decreased compared to the general population (48.0 (SD 13.3) axSpA and 49.7 (SD 11.5) CBP pts), analyses focused on PCS. Pts reported a mean of 4.3 (axSpA) and 4.8 (CBP) symptoms to be associated with back pain. Most reported symptoms were pain and joint stiffness. All other subscales showed a mean of approximately 3, except psychological attributions, risk factors, immunity and accident (mean approximately 2). All pts attributed their complaints mostly to genetic factors. In both pts groups attribution of multiple symptoms to CBP (Figure 1;-1.8 axSpA, -2.1 CBP) was associated with lower PCS. However more dimensions showed association with PCS in axSpA (8) than CBP pts (6). In male axSpA pts belief in severe consequences (-12.1), more negative emotions towards their complaints (-9.3), and stronger belief of psychological attributions as a cause (-8.8) were associated with lower PCS. Whereas in male CBP pts stronger belief in risk factors (-8.1) and immunity as a cause (-10.0) were associated with lower PCS. More illness coherence was associated with higher PCS in male axSpA (6.2) and all CBP pts (2.8). In women consequences (-6.3, axSpA) and strong emotional representations (-4.0, CBP) were statistically significant. No gender differences were found for risk factors (-6.0) or immunity (-5.7) in axSpA and consequences (-7.9) in CBP pts.

**Figure 1:** Linear regression models of Physical Component Scale (PCS) of Health-Related Quality of Life (HRQoL) and subscales of the Revised Illness Perception Questionnaire (IPQ-R) at baseline adjusted for age and gender (n=315)

| Scale | Range | axSpA | Coefficient (SE) | p-value | CBP | Coefficient (SE) | p-value |
|---|---|---|---|---|---|---|---|
| *Illness identity* | | *(n=119)* | | | *(n=175)* | | |
| Identity | 0-15 | | *-1.8 (0.6)* | *0.003* | | *-2.1 (0.5)* | *<0.001* |
| *Illness perceptions* | | *(n=123)* | | | *(n=190)* | | |
| Consequences | 1-5 | Men | *-12.1 (2.7)* | *<0.001* | | *-7.9 (1.1)* | *<0.001* |

## FRI0405 EXTRAARTICULAR MANIFESTATIONS IN PATIENTS WITH SPONDYLOARTHRITIS UNDER BIOLOGIC TREATMENT

A. Pieren, D. Peiteado, E. de Miguel, M. Espinel, E. Moral, I. Monjo, M.B. Paredes, C. Tornero, G. Bonilla, C. Plasencia, L. Nuño, A. Villalba, A. Balsa, E. Martin-Mola. *Rheumatology, Hospital Universitario La Paz, Madrid, Spain*

**Background:** The spondyloarthritides are a heterogeneous group of interrelated and overlapping chronic inflammatory arthropathies. The increasingly use of DMARDs and biologic treatments has led to a change in the profile of the spondyloarthritis patients as well as in the extraarticular manifestations.

**Objectives:** Analyze the extraarticular involvement in patients with Spondyloarthritis under biologic therapy.

**Methods:** A retrospective observational study was conducted in all the patients diagnosed of spondyloarthritis under biologic treatment in our Day-Care Hospital. We analyzed socialdemographic, serological (HLA-B27, ASCAS, IgA, urate levels), clinical aspects and extraarticular manifestations such as cardiological, mucocutaneous, pulmonary, ophthalmological and renal involvement. The association between subgroup diseases, risk factors and extraarticular manifestations was performed with linear regression analysis SPSS.

**Results:** 394 patients were analyzed. 58.8% were male with median age 51 years. We included 173 (43.96%) Ankylosing Spondylitis (AS), 71 (18.2%) non radiographic spondyloartritis (axial and peripheral Spa), 25 (6.35%) Spondyloarthritis associated with inflammatory bowel disease (IBD), 102 (25.9%) Psoriatic Arthritis (PsA), 18 (4.57%) juvenile idiopathic arthritis (JIA) and 5 (1.27%) reactive arthritis. All the patients had received at least one Anti TNF drug and 31.2%, more than one. Infliximab (38.1%) was the most employed drug, followed by Etanercept (31.2%). 69.6% were HLA-B27 positive and 10.4% had high IgA levels.

57.6% presented extraarticular manifestations. By subgroups, the extraarticular involvement was up to 48% in AS, 19.7% in Spa and 27.8% in JIA. Excluding the mucocutaneous and digestive symptoms, we found nonarticular activity in 31.4% PsA and 31.1% IBD. (See Table bellow).

12.4% had uveitis. Despite the biologic therapy, 6% had ophthalmological flares, 1/3 of which was under optimization strategy. The mucocutaneous involvement was shaped as psoriasis (nail, plaque, inverse and pustular psoriasis), erythema multiforme and erythema nodosum. Only one patient developed psoriasis during treatment. The most common nephrologic manifestations was hematuria (58.9%). 9.6% presented hyperuricemia which incidence was higher in AS than in PsA (55.3% Vs 34.2%). Only 8% of those patients had renal insufficiency. Finally, we would like to highlight the development of cancer in 11 patients (2.79%). 5 patients presented renal cancer (1.27% being all of them diagnosed of HLA-B27 positive AS with axial involvement.

The risk factors statistically associated with the extraarticular activity found were the positivity of HLA-B27 and the hyperuricemia ($p=0.000$, $p<0.002$). We found no correlation with age, sex and hyperIgA. In the development of uveitis, only the HLA-B27 positive was significantly associated.

| Manifestation | Total population | Subtypes |
|---|---|---|
| Uveitis | 12.4% | Acute Anterior 34.3%<br>Recidivating AA 55.1%<br>Chronic 2.05%<br>Posterior 4.1%<br>Non determinate 24.5% |
| Cutaneous | 28.7% | PsA 88.44%<br>Non PsA 9.8%<br>Rest of the cutaneous involvement 1.8% |
| Hyperuricemia | 9.6% | EA 55.3%<br>Spa 2.6%<br>APs 34.2%<br>EII 7.9% |
| Digestive | 10.4% | EII 73.2%<br>Chronic Diarrhea 26.8% |
| Renal | 9.89% | Hematuria 61.5%<br>Renal insufficiency 23.1%<br>Amiloidosis 5.13%<br>TIN 5.13%<br>Proteinuria 5.13% |
| Aortic insufficiency | 2.5% | |
| Pulmonary | 3.8% | EPID 21.4%<br>HTP 28.6%<br>Bronchiectasis 42.9%<br>Nodules 7.14% |

**Conclusions:** We observed a high prevalence of extraarticular manifestations in our sample of patients with Spondyloarthritis under biologic treatment. Nonetheless, the presence of serious manifestations was still low. The hyperuricemia, cutaneous psoriasis and anterior uveitis were the most frequent extraarticular manifestations. The risk factors associated were HLA-B27 positive and the high levels of urate.

## FRI0406 PREVALENCE AND SIGNIFICANCE OF RADIOGRAPHIC SACROILIITIS IN A LARGE INFLAMMATORY BOWEL DISEASE POPULATION

A. Nangit[1], D. Scaramangas[1], G. Dejesus[2], D. Karayev[1], C. Williams[3], D. Li[3], X. Yan[3], S. Targan[3], T. Learch[2], D. McGovern[3], M. Weisman[1]. *[1]Rheumatology; [2]Radiology, Cedars Sinai Medical Center; [3]F. Widjaja Foundation Inflammatory Bowel and Immunobiology Research Institute, Los Angeles, United States*

**Background:** Inflammatory bowel disease (IBD) is associated with a myriad of extra-intestinal manifestations (EIMs). Musculoskeletal EIMs are the most common EIM in IBD. Previous studies of sacroiliitis (SI) in IBD have a broad prevalence range of 2%>45%[1–3]. In these patients, HLA-B27 positivity ranged anywhere from 0–50%[1,2,4].

**Objectives:** To determine the prevalence of radiographic SI in a large IBD population, and identify risk factors associated with the development of SI.

**Methods:** 1,247 consecutive patients from our IBD clinic, 350 with ulcerative colitis (UC), and 897 with Crohn's disease (CD) were investigated as long as they had a pre-existing computed tomography (CT) of the abdomen and pelvis. These CTs were re-interpreted for evidence of SI. Each sacroiliac joint was graded

based on the modified New York Criteria[5]. Each patient was classified as having no disease, suspected disease, or definite disease. Definite SI was defined as bilateral grade 2, or unilateral grade 3 or 4. Suspicious SI was defined as unilateral or bilateral grade 1 or unilateral grade 2. Gender, age, type of IBD, HLA-B27 status (by next generation sequencing), and IBD serologies (ASCA, antiCBir1, anti-OMPc, ANCA) were also analyzed.
**Results:** Prevalence of either definite or suspicious SI was found in 16.1% and 19.4% in CD and UC respectively. The prevalence of definite SI was 8.7% and 8.1% in CD and UC respectively. In patients with SI (definite and suspicious), 57% were male and 43% were female. When looking only at the definite group, there 68% males and 32% females (p=0.002). This is in contrast to the suspicious SI group, where there were 48% males and 52% females. Of significance, 16% of patients in the definite SI group were positive for HLA-B27, while only 6% of the patients in the negative group were positive for HLA-B27 (OR 4.36, p=0.006). In the suspicious group, 8% of patients were positive for HLAB27. Definite SI was associated with: anti-Cbir1 (p=0.002) in CD, and ASCA (p=0.05) in UC.
**Conclusions:** In this study, the largest of its kind, we observed an overall SI prevalence of 17% in our IBD cohort. The prevalence of SI seen on CT was similar between UC and CD. Historically, UC and CD occur evenly between genders. However, when gender and SI in IBD were compared, there were more males in the definite group, while in the suspicious group there was a greater predominance of females. It remains unclear if the suspicious group represents a subtle phenotype of SI that has not yet progressed. Significant associations with clinically relevant subsets of IBD defined by serological markers were observed. The observed HLAB27 positivity is at the lower end of what has previously been reported, and is not as strong as is seen in ankylosing spondylitis without IBD. This further suggests that SI and spondylitis in the IBD population are different pathologic entities, with unique genetic risks, compared with the pure AS population.

## FRI0407 ELECTROPHYSIOLOGICAL CARDIAC REMODELING IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Nigmatzyanova[1], M. Mangusheva[1,2], S. Lapshina[1,2], D. Abdulganieva[1,2], M. Afanasieva[2], L. Myasoutova[1]. *[1]Kazan State Medical University; [2]Republic Clinical Hospital, Kazan, Russian Federation*

**Background:** The question of the defeat of the cardiovascular system in patients with ankylosing spondylitis (AS) is very actual
**Objectives:** To study early pre-clinical parameters of myocardial electric instability and changing the geometry of the myocardium of the left ventricle (LV) in patients with AS and their relationship to the course of the disease.
**Methods:** 30 patients (22 men and 8 women) aged 21 to 56 years (mean 40,3±10,0 years) with significant AS without clinical manifestations of cardiovascular pathology at the time of inspection, in a disease history and/or according to medical records were observed. The duration of AS symptoms at the time of examination was less than 5 years – 15 patients (50%), from 5–10 years – in 5 (16.6%), more than 10 years – in 10 (33.4%) patients. Disease activity (BASDAI) was low in 6 (20%), moderate – in 9 (30%), high – in 7 (23.3%), very high – in 8 (26.7%) patients, the mean BASDAI 5 06 ± 1,4. Echocardioscopy with determination of left ventricular hypertrophy (LVH) according to recommendations of the ASE and EAE (2005/2006) was used to estimate the heart. geometry. The direction of maximum QRS vector to the left and back, the excess of 2.0 mV on the horizontal plane, and 2.2 mV on the frontal plane were assessed by vectorcardiography
**Results:** According to echocardioscopy in 9 (30%) patients with AS revealed changes in the geometry of the heart were found: concentric remodeling – in 2 (22.2%), eccentric hypertrophy – in 4 (44.5%), concentric hypertrophy – 3 (33.3%) patients. Vectorcardiography showed changes in the QRS loop in 4 (13.3%) patients. Also, a change in direction of the maximum vector during normal QRS loop area was revealed, which is associated with an increase in the size of the left ventricular chambers. Changes of the heart geometry were different depending on the AS activity: moderate activity concentric remodeling occurred in 2 (22.2%) patients, high activity–concentric hypertrophy in 3 (33.3%) patients, very high activity–eccentric hypertrophy in 4 (44.5%) ($p \leq 0.05$). The change in QRS loop was in 1 (3.3%) patient with low activity, and in 2 (6.6%) patients with high and very high disease activity. The concentric remodeling was found in 2 (22.2%) patients, concentric hypertrophy – in 3 (33.3%) patients with disease duration from 5 to 10 years; more than 10 years – eccentric hypertrophy in 4 (44.5%) patients.
**Conclusions:** The high frequency of preclinical changes in the geometry of myocardium in AS was assessed, more frequent in patients with high activity and disease duration less than 10 years. According to echocardioscopy, electrophysiological abnormalities in the myocardium were found in patients with saved geometry

## FRI0408 A TWELVE MONTH FOLLOW-UP STUDY OF PATIENTS RECRUITED THROUGH SOCIAL MEDIA WHO FULFILLED ASAS/CALIN CRITERIA FOR INFLAMMATORY BACK PAIN

A. Moorthy[1], A.G. Wade[2], G.M. Crawford[3], A. Goyal[4]. *[1]Rheumatology, University Hospitals of Leicester NHS trust, Leicester; [2]Director; [3]Patients Direct, Glasgow; [4]Abbvie, London, United Kingdom*

**Background:** Epidemiology data on inflammatory back pain (IBP) prevalence within the UK is still lacking. Previous studies from the UK show delay in diagnosis of IBP for up to 8 years. This is partly due to lack of awareness among Public and Primary care practitioners. New criteria have been developed to identify conditions at an early stage with a view to reducing times to referral. Our previous work, using social media, helped identify patients with IBP. New IBP classification criteria were applied to the identified patients in the present analysis.
**Objectives:** To follow up IBP positive patients over a twelve month period to see how their back pain had changed, whether treatment was actively sought and what treatment(s) were provided.
**Methods:** A cross-sectional survey was carried out between December 2013 and May 2014 to identify adults (≥18 years) who had IBP. Recruitment was targeted in a novel way to enlist UK participants using social media (Facebook) and national newspaper (Daily Mail) advertisements. Online questionnaire-based surveys supplemented by telephone response were completed. Those participants who fulfilled either the ASAS or Calin criteria at the initial assessment were offered an information leaflet on IBP. The participants were also asked to complete follow-up questionnaires at 6 and 12 months.
**Results:** A total of 586 participants completed the initial survey; of these, 304 (51.87%) satisfied either the ASAS or Calin criteria for IBP. Many patients at both 6 and 12 months follow-up reported that their back pain was unchanged, with more reporting a decline (37% of responses) than an improvement (31% of responses). Evaluation of changes in quality of life using mean EQ5D scores also suggested a small deterioration.
Of the 91 patients who completed a follow-up questionnaire at 6 months 57 (63%) had seen a GP, 6 (7%) had seen a rheumatologist, 16 (18%) had physiotherapy and 8 (9%) were finally diagnosed with a spondyloarthropathy (eg. Ankylosing Spondylitis). Of the 67 patients who completed a follow-up questionnaire at 12 months 41 (61%) had seen a GP, 5 (7%) had seen a rheumatologist, 13 (19%) had physiotherapy and 9 (13%) were finally diagnosed with a spondyloarthropathy. Only 1 patient (1.5%) at 12 month follow-up (none at 6 month follow-up) had received biologic treatment with anti-TNF.
Of the 91 patients who completed the 6 month follow-up questionnaire only 28 downloaded the IBP information leaflet and no new IBP diagnoses resulted.
**Conclusions:** Patients who were IBP positive (ASAS or Calin) in an online survey, many recruited using social media, deteriorated slightly over a 12 month follow-up period. Providing these IBP positive participants with a link to an information leaflet did not result in any new IBP diagnoses. Although most patients had seen a GP, only 7% had seen a rheumatologist despite fulfilling the IBP criteria. Primary care education on IBP is key in the early diagnosis of Spondyloarthropathy.

## FRI0409 SUBCLINICAL ATHEROSCLEROSIS IN ANKYLOSING SPONDYLITIS. DOES IT REALLY EXIST AND WHICH ARE THE EFFECTS OF TREATMENTS? A SYSTEMATIC REVIEW

C. Prati[1,2], X. Guillot[2], F. Verhoeven[2], C. Demougeot[3], D. Wendling[2]. *[1]FDE EA4267, Univ. Bourgogne Franche-Comté; [2]Rheumatology, Hopital Jean Minjoz; [3]FDE EA4267, Univ. Bourgogne Franche-Comté, Besancon Cedex, France*

**Objectives:** Accelerated atherosclerosis and increased cardiovascular morbidity and mortality have been associated with ankylosing spondylitis (AS). Noninvasive angiological methods have been developped to evaluate endothelial and vascular dysfunction which is correlated with future development of atherosclerosis. The objectives were to determinate the presence or not of a subclinical vascular dysfunction in AS and if treatments could have an effect on it. A systematic review was done.
**Methods:** Studies evaluating subclinical atherosclerosis and vascular function in AS were identified using Pubmed, (Ovid, EMBASE). Search terms included

"ankylosing spondylitis" AND (endothelial OR vascular OR intima media thickness (IMT) OR Flow mediated dilatation (FMD) OR pulse wave velocity (PWV) OR atherosclerosis). This identified 353 results after limiting to French and English. The final selection identified 29 articles.

**Results:** Overall, 1529 AS patients were included representing 38 studies: 8 studies about endothelial function, 198 AS patients and 130 healthy control (HC); 20 studies about carotid IMT, 900 AS and 644 HC; 10 studies about arterial rigidity, 431 AS and 285 HC. In cross-sectional studies, 4/6 indicated endothelial dysfunction in AS versus HC, 9/18 indicated increased cIMT and 3/5 increased arterial rigidity. About ED, 3 open label studies noted positive effect of TNFα blockers and spironolactone on FMD and rosuvastatin improved FMD in a placebo controlled study after 24 weeks. TNFα blockers seems not to improve neither cIMT (2 studies) nor arterial rigidity (5 studies). Exercise alone has improved arterial rigidity in 15 patients after 12 weeks.

**Conclusions:** Whereas early and accelerated atherosclerosis is patent in AS, presence of subclinical atherosclerotic lesions is controversial in the literature especially concerning cIMT and arterial stiffness. This is reinforced by the lack of TNF blockers efficacy. Conversely it seems that endothelial dysfunction is present and reversible after treatment with TNF blockers, statin and spironolactone. These results are consistent to treat AS patients with early effective treatment to prevent the risk of CV morbidity and mortality.

## FRI0410 ULTRASONIC FOLLOW UP HALF A YEAR ETANERCEPT TREATMENT FOR EARLY SPONDYLOARTHROPATHY INDUCED PERIPHERAL ENTHESITIS

D.F. Lin[1], M.J. Zhao[1], J.Y. Cao[2], J.R. Gu[1]. *[1]Rheumatology department; [2]US department, the 3rd Affiliated Hospital of Sun Yet-sen University, Guangzhou, China*

**Background:** Mardird sonographic enthesis index (MASEI) was one of the most wide used scoring systems for peripheral enthesitis. A report ever observed the efficacy of Sulfasalazine for peripheral enthesitis in Ankylosing Spondylitis. However, no reports followed up biological agents treatment for early axial spondyloarthropathy (SpA) by MASEI method so far.

**Objectives:** Our study is to find out whether MASEI is suitable for accurately reflecting the therapy effect of biological agents like Etanercept for early axial SpA.

**Methods:** Ultrasound was performed by 2 observers blinded to the other examinations and the final diagnosis once per 3-months and it is planned to carry on for a year. All cases were diagnosed as early axial SpA fulfilling 2009 classification criteria but not 1996 New York Criteria with sacroilliac X-ray and MRI.US examination referred to MASEI related regions. The count of swollen joint, the count of tender joints, ESR, CRP, PGA, PhGA, BASDI, BASFI, BASMI, MASES, ASDAS were employed to assess disease activity.

**Results:** 1) 95 early axial SpA subjects were finally enrolled in the program. All of them finished 24-week follow up, and 33 of them finished 48-week follow up until now. Mean age was 25.0±5.9 years old, female-male ratio was 0.48:1, and disease duration was 36.3months. Only 2 were negative HLA-B27.

2) The response for Etanercept was pretty good with the evidence of all the indexes above had prominent progress both in 12 week and 24 week except the count of swollen joint between 0w and 12w (paired Wilcoxon test, sig$<$0.05)

3) The good response for Etanercept was also well reflected by the ultrasonic scores: average sum scores (0w:12w:24w = 26.51:13.57:9.57,), tendon thickness scores (0w:12w:24w = 0.88:0.50:0.58, 12w:24w sig=0.11), structure disturbance scores (0w:12w:24w = 5.94:3.13:2.04), bone erosion scores (0w:12w = 6.49: 6.52:6.42), calcification scores (0w:12w:24w = 6.45:3.09:1.98), bursitis scores (0w:12w:24w = 1.44:0.46:0.30), Power Doppler scores (0w:12w:24w = 5.32:1.87: 1.25). All the scores above were significantly decreased except tendon thickness score between 12week and 24week and bone erosion scores during half a year.

4) There are no correlations between US scores and all the disease activity indexes at baseline, 12 week or 24 week visit point in early axial SpA perhaps due to the peripheral enthesitis might not reflect the axial circumstance.

**Conclusions:** Though the trial was still carried on for the last half a year, our study proved MASEI assessment is a good tool to supervise the effect of Etanercept for peripheral enthesitis in early SpA.

**Disclosure of Interest:** None declared

## FRI0411 A CROSS SECTIONAL STUDY OF THE CLINICAL AND ULTRASOUND ENTHESEAL INVOLVEMENT IN PATIENTS WITH IBD

E. Bertolini[1], P. Macchioni[2], M. Beltrami[1], F. Bassi[1], B. Marani[1], C. Salvarani[2], M. Catanoso[2]. *[1]IBD Unit, Internal Medicine; [2]Reumatology, Internal Medicine, ASMN IRCCS Reggio Emilia, Reggio Emilia, Italy*

**Background:** Previous studies have reported the high prevalence of occult SpA in IBD patients.

**Objectives:** To investigate the presence of clinical and ultrasound peripheral entheseal abnormalities in a consecutive series of IBD patients.

**Methods:** 61 IBD consecutive patients [26 Crohn's disease (CD) and 35 ulcerative colitis (UC), M/F 32/29, mean age 35.7+12.4 years, mean disease duration 57+93 months] entered the study. Gastroenterological examination consisted of the determination of bowel involvement, extraintestinal manifestations, MAYO and CDAI score. A complete rheumatological examination which included 66 peripheral join count, MASES and Leeds entheseal evaluation, BASDAI, BASFI and evaluation of spine mobility was done at study entry. ESR and CRP were evaluated at study entry. US examination was done using an Esaote MyLabClass, 18–6MHz linear multifrequence transducer both in gary scale and with PD. The following enthesis were separately studied clinical and US by two rheumatologist unaware of the other evaluation: lateral elbow epicondyle, distal quadricipital insertion at the patella, proximal and distal patellar tendon insertions, Achilles tendon an plantar fascia insertion at the calcaneous. Knee and ankle joints were evaluated for synovial hyertrophy, PD signal and fluid. Extensor and flexor tendons of the foot and ankle were evalutaed for the presence of tendon sheat fluid, synovial hypertrophy and PD signal. Quadriceps, patellar, Achille and plantar fascia entheses were scored according to the 0–36 Glasgow Ultrasound Enthesitis Scoring System (GUESS) and power Doppler (PD). Correlations of GUESS and PD with IBD features [duration, type (CD/UC) and activity (disease activity index for CD/Truelove score for UC)] were investigated.

**Results:** 29/61 (47.5%) patients had at leat one entheseal alteration at clinical examination and 56 (91.8%) presented almost one US entheseal abnormality with a mean 3.05±1.7 number of abnormal enthesis /patient. The mean MASEI was 11±9 and the mean GUESS 5.8±3.9 with 56/61 patients with value $>$1. The US evidence of enthesitis was higer in CD with ileo-colon localization as compared to ileo or colon involvement (100% vs 89% and 50%, p=0.03). Patients with disease duration $>$12 months have significantly grater number of cronical (2.48±1.5vs3.7±1.7, p=0.01) and acute enthseal alteration (3.0±1.3vs1.9±1.3,p=0.01) as compared with patients with disease duration $<$12 months.

**Conclusions:** US entheseal abnormalities are present in a high percentage of IBD patients. US enthesopathy is associated with longer disease duration and topographical localization of gut disease.

## FRI0412 MANNOSE BINDING LECTIN GENE POLYMORPHISMS IN SPONDYLOARTHROPATHIES

A. Yildirim[1], O. Kudas[1], I. Turk[1], F. Yildiz[2], S. Dinkci[1], E. Erken[1]. *[1]Rheumatology-Immunology, Çukurova University Faculty of Medicine, Adana; [2]Rheumatology, Van State Hospital, Van, Turkey*

**Background:** Genetic and environmental factors are known to play a role in the pathogenesis of spondyloarthropathies (SPA). Mannose binding lectin (MBL) which is a member of collectin family proteins, is an important component of innate immunity. Low levels of MBL is associated with susceptibility to infections. Several variants of MBL gene may result in MBL deficiency. MBL gene polymorphisms and MBL deficiency are shown to be related with several autoimmune and inflammatory diseases.

**Objectives:** The relationship between the MBL levels or MBL gene polymorphisms and SPA predisposition has previously been investigated in a few small studies with conflicting results. In this particular study, we aimed to assess the relationship of the MBL genes in the develepoment of SPA in a group of Turkish patients.

**Methods:** Study included 132 patients with SPA (75 female, 57 male, mean age: 43.0±12.4) and 87 healthy subjects (58 women, 29 men, mean age: 40.3±13.4) as control group. Eighty nine of the SPA patients had ankylosing spondylitis (AS) and 43 had non-AS SPA. MBL gene single nucleotide polymorphisms (SNP) in the codons 52, 54 and 57 of exon 1 were studied by sequencing method.

**Results:** G54D G$>$A polymorphism was not different between the patient and the healthy control groups (p=0.291). The frequencies of R52C C$>$T and G57E G$>$A polymorphisms were found to be significantly higher in the SPA patients than those of the healthy controls (p=0.019 and 0.001 respectively). While the non-AS subgroup showed significancy for both R52C C$>$T and G57E G$>$A polymorphisms (p=0.004 and 0.000 respectively), the AS subgroup showed significancy only for G57E G$>$A (p=0.113 and 0.014 respectively). Clinical characteristics of either AS or non-AS SPA patients were not associated with any of the MBL polymorphisms. In a previous study, haplotypes of MBL genetic polymorphisms were found to be associated with AS in Korean patients. Our study is the first one from Turkey indicating the relationship between SPA's and MBL gene polymorphisms.

**Conclusions:** Even though we had rather small sample size, our results showed significantly higher R52C C$>$T and G57E G$>$A polymorphisms in Turkish patients with SPA. Therefore we may suggest that MBL gene polymorphisms could be related with the predisposition of the disease.

## FRI0413 CLINICAL RISK FACTORS FOR THE PRESENCE AND DEVELOPMENT OF VERTEBRAL FRACTURES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

F. Maas[1], A. Spoorenberg[1,2], B.P. van der Slik[1], E. van der Veer[3], E. Brouwer[1], H. Bootsma[1], R. Bos[2], F.R. Wink[2], S. Arends[1,2]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden; [3]Laboratory Medicine, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Vertebral fractures are the hallmark of bone fragility and are frequently present in patients with ankylosing spondylitis (AS). For treating rheumatologists, it is important to know which patients already have vertebral fractures and which patients are at risk to develop new fractures. Limited longitudinal data are available concerning the development of new vertebral fractures in AS.
**Objectives:** To investigate the prevalence and incidence of radiographic vertebral fractures and the association with patient characteristics, clinical assessments, and medication use in a large prospective cohort of patients with ankylosing spondylitis (AS) in daily clinical practice.
**Methods:** Consecutive AS patients from the Groningen Leeuwarden AS (GLAS) cohort with baseline and 2-year lateral radiographs of the thoracic and lumbar spine were included. Radiographs were scored for vertebral fractures by two readers according to the method of Genant *et al*. Vertebral fractures were defined as $\geq$20% reduction in vertebral height. Severity of fractures were divided into mild (20–25% reduction), moderate (25–40% reduction), and severe ($>$40% reduction) fractures. Differences in baseline characteristics were explored between patients with and without radiographic vertebral fractures.
**Results:** Of 292 included AS patients, 70% were male, 82% HLA-B27+, mean age was 43±13 years, median symptom duration 16 (IQR: 8–25) years, and mean BASDAI 5.3±2.2. Radiographic vertebral fractures were present in 59 (20%) patients at baseline. During 2 years of follow-up, 15 (6%) patients developed new vertebral fractures and 7 (2%) showed an increase in severity of existing fractures. Most fractures were mild and located in the mid-thoracic and thoracolumbar region of the spine.
The presence of vertebral fractures was significantly associated with older age, higher BMI, longer smoking duration, larger occiput-to-wall distance, more spinal radiographic damage, and lower hip BMD. Occiput-to-wall distance was identified as an independent risk factor for prevalent vertebral fractures; 44% of the patients with hyperkyphosis (occiput-to-wall distance $\geq$10 cm) had vertebral fractures. The development of new or progressive vertebral fractures was also associated with older age and low BMD. Patients using NSAIDs at baseline showed less prevalent (18% vs. 31%) and incident (5% vs. 17%) vertebral fractures than patients without NSAIDs.
**Conclusions:** In this large AS cohort in daily clinical practice, radiographic vertebral fractures were frequently present, especially in older patients with more advanced disease, low hip BMD, and a less healthy lifestyle. Interestingly, NSAID use was associated with a reduced vertebral fracture risk.

## FRI0414 ASSOCIATION OF ANTERIOR UVEITIS AND OTHER CLINICAL FINDINGS IN PATIENTS WITH SPONDYLOARTHRITIS

F. Aguiar, T. Martins-Rocha, R. Fonseca, A. Bernardo, I. Brito. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** Anterior uveitis (AU) is considered to be one of the most common extra-articular manifestations of spondyloarthritis (SpA), and its prevalence may vary according to the genetic background of the study population. Uveitis can appear both before and after the onset of osteoarticular symptoms. It can lead to serious complications that can compromise the visual function.
**Objectives:** The aim of this study was to compare demographic, clinical and laboratory data among SpA patients with and without AU.
**Methods:** Cross-sectional study including 190 SpA patients that fullfilled the modified New York criteria. The patients were asked to complete a questionnaire assessing their disease type, age at diagnosis, clinical presentation, disease-activity (BASDAI, ASDAS) and functional-indices (BASFI) and BASMI was calculated. The following parameters were taken out of the patients' files: the presence of HLA-B27 antigen, inflammation biological markers (ESR, CRP), and conventional radiographs of spine, hip and sacroiliac joints were evaluated. Ocular involvement passively reported by the patients and confirmed by ophthalmological exams was noted and the group with AU diagnosis (current or past) was compared to those without uveitis. The statistical analysis was performed using SPSS 21.0 software, and $p<0.05$ was taken to indicate statistical significance. To compare the differences between the groups, Mann-Whitney U, $\chi^2$ and Fisher tests were used.
**Results:** 190 patients were included, of which 56.3% were males, with median age of 46.0 (range 21–79) years. 58 (30.5%) patients had AU, which was significantly more frequent in patients with ankylosing spondylitis (84.5% of patients with AU) comparing with the other subtypes of SpA (p=0.01). There were no statistically significant differences in age at diagnosis, time to diagnosis or gender between the two groups. However, median age and disease duration were significantly greater in SpA patients with AU than those without AU (50.5 vs 44.0 years, p=0.015 and 24.0 vs 15.9 years, $p<0.001$ respectively). HLA-B27 was positive in 60,3% of patients with AU, comparing with 43.2% in those without AU ($p<0.005$). Ankylosis of bilateral sacroiliac joints was more frequent in patients with AU (46.6% vs 20.9%, $p<0.001$). The patients with AU had less frequently skin lesions and dactylitis (10.3% vs 30.3%, p=0.02 and 0% vs 7.5%, p=0.024), but there were no differences in the prevalence of peripheral arthritis or enthesitis. BASMI was significantly higher in patients with AU (median 4.9 vs 4.0, p=0.041), but there were no significant differences in disease activity, functional outcomes.
**Conclusions:** This study showed that AU could be more frequently seen in HLA-B27 positive patients with long-standing SpA, especially ankylosing spondylitis, and may be less frequent in patients with skin lesions and dactylitis.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4144

## FRI0415 SERUM AMYLOID A PROTEIN IN SPONDYLOARTHRITIS PATIENTS UNDER ANTI-TUMOUR NECROSIS FACTOR-ALPHA: AN USEFUL BIOMARKER?

F. Aguiar, T. Martins-Rocha, D. Rosa-Gonçalves, R. Fonseca, I. Brito, A. Bernardo, M. Bernardes. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

**Background:** Inflammation is known to play a major role in rheumatologic disorders. Hence quantitating the degree of inflammation has become essential to tailor the treatment strategy. Traditionally used measures to assess disease activity in spondyloarthritis (SpA) are ESR, CRP, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS). Serum amyloid A (SAA) is an acute-phase reactant predominantly synthesized in the liver by hepatocytes in response to proinflammatory cytokines. Some studies have shown that SAA correlates with disease activity in SpA and suggest it as a valuable indicator of disease activity, however it has not been extensively used in clinical practice.
**Objectives:** To investigate if SAA levels have better correlation with conventional clinical and serological assessments in SpA than CRP and ESR.
**Methods:** Cross-sectional study, including SpA patients under anti-TNF$\alpha$ treatment at a Rheumatology Department of a Portuguese Universitary Hospital. We compared the correlation between SAA, CRP and ESR levels with BASDAI, ASDAS-CRP, ASDAS-ESR, BASFI, BASMI, swollen and tender joints counts (SJC and TJC), MASES, SPARCC, and patient global assessment, physician global assessment, total back pain, nocturnal back pain rated on a visual analogue scale (VAS). The statistical analysis was performed using SPSS 21.0 software, and $p<0.05$ was taken to indicate statistical significance. Correlation was calculated using the Spearman rank correlation (r).
**Results:** 88 patients were included, 61.4% (n=54) were male. The median age was 44,0 years (range 21.0–74.6). Median disease duration was 19.0 years (2-51.6). According to ASDAS criteria, 23 patients (26.1%) had inactive disease, 21.7% moderate disease activity, 40.9% high disease activity and 11.4% very high disease activity.
SAA levels were moderately correlated with CRP levels (r=0.51, $p<0.001$) and had lower correlation with ESR (r=0.36, p=0.001). There was no statistically significant correlation between SAA levels and the following parameters: physician global assessment-VAS, total back pain-VAS, nocturnal back pain-VAS, MASES, SJC and TJC. SAA levels correlated with patient global assessment-VAS (r=0.218, p=0.04) but also did ESR (r=0.277, p=0.01). There was no significant correlation between SAA and BASDAI (r=0.161, p=0.134), however CRP levels and ESR showed little correlation (r=0.232, $p<0.03$ and r=0.366, $p<0.001$).
We found statistically significant correlation between SAA levels and ASDAS-ESR (r=0.298, p=0.005), ASDAS-CRP (r=0.330, p=0.002), SPARCC (r=0.221, p=0.034), BASFI (r=0.327, p=0.002) and BASMI (r=0.262, p=0.014). CRP and ESR also showed significant correlation with BASFI, but it was weaker than that observed with SAA (r=0.285, p=0.007 and 0.310, p=0.004, respectively). ESR and CRP did not correlate with BASMI.
**Conclusions:** This study suggests that SAA can be a valuable indicator not only of disease activity but also of damage and functional impairment, that could be introduced in clinical pratice. However more studies, with larger sample sizes, and prospective ones should be undertaken to better assess this subject.
**Disclosure of Interest:** None declared

## FRI0416 EVALUATING THE IMPACT OF A LOCAL INFLAMMATORY BACK PAIN AWARENESS CAMPAIGN IN THE UNITED KINGDOM

G. Tracey[1], J. McCaulder-Ojeda[1], R. Sengupta[1,2]. *[1]Rheumatology, R.N.H.R.D; [2]University of Bath, Bath, United Kingdom*

**Background:** The average delay to diagnosis in the UK is 8.5 years, even though

the majority of patients consult their GP within one year of symptom onset. The lack of awareness and recognition of IBP (Inflammatory Back Pain) is one of the main reasons for the unacceptable delay in diagnosis[1]. A public awareness campaign to raise awareness of IBP was held in Bath on 13th September 2014

**Objectives:** The aim of the study was to assess referral rates pre and post campaign - number of referrals for IBP, number of newly diagnosed Axial Spondyloarthritis (AxSpa)/ Ankylosing Spondylitis (AS) and mechanical back pain patients who were referred with reference to IBP and for new AxSpa/AS patients - age, length to diagnosis from symptom onset, sex, HLA B27 status and CRP were also assessed.

**Methods:** Referrals to the Royal National Hospital for Rheumatic Diseases (RNHRD), Bath Pre Campaign from January-March 2014 and Post Campaign in Months October-December 2014 were evaluated.

Referral letters were reviewed and categorised as either likely inflammatory referrals or likely non-inflammatory referrals. A referral was considered as inflammatory if it contained key words such as Sacroiliitis, HLA B27 status, mention of Family history of Ankylosing spondylitis/Axial spondyloarthritis, spondyloarthropathy or inflammatory back pain/arthropathy

Based on history and investigations, patients were classified using the ASAS Axial SpA classification criteria as either nr-AxSpa orAS, or if they didn't meet the criteria "Mechanical Back pain". It was assessed whether this was a new or an old diagnosis.

**Results:** There were 91 back pain referrals pre campaign and 96 post campaign. Pre campaign, 40 patients with AxSpa were referred. 8/40 were diagnosed as new AS (20%) and 16 had known AS. 10/40 (25%) were diagnosed as new nrAxSpa. 6 had known nrAxSpA. Of the 18 new AxSpa cohort 14 had "inflammatory" referrals from the referrer. ie. 77% accurate referrals.51 cases of mechanical back pain were diagnosed; 19 of the referrals contained "inflammatory" key words

Post campaign,38 patients with AxSpA were referred. 3/38 were diagnosed with new AS. 11/38 were diagnosed with new nrAxSpa. 12/14 of new AxSpa patients had "inflammatory" referrals.ie 85% accuracy.

58 cases of mechanical back pain were diagnosed; 21 of the referrals had "inflammatory" key words.

| AxSpA patients | Pre campaign | Post campaign |
|---|---|---|
| Males | 9/18 (50%) | 10/14 (71%) |
| Mean age (years) | 40.6 | 41.1 |
| HLAB27 +ve | 6/16 (38%) | 10/12 (83%) |
| Raised CRP | 5/16 (31%) | 4/14 (29%) |
| Mean symptom duration | 8 years | 12.1 years |

**Conclusions:** In a local setting, the campaign did not significantly increase the number of new back pain referrals to rheumatology. Reassuringly, we found that the index of suspicion from referrers for AxSpA to be high in both cohorts.

## FRI0417 PREVALENCE OF OSTEOPOROSIS IN AN ANKYLOSING SPONDYLITIS COHORT

G. Fitzgerald[1], D.J. Lundon[2], P. Gallagher[3], K. O'Rourke[4], C. Sheehy[5], C. Sullivan[6], C. Silke[7], F. Stafford[8], M. Haroon[9], R. Mullan[10], O. FitzGerald[3], F. O'Shea[11]. *[1]Department of Rheumatology, St James's Hospital, Dublin 8; [2]School of Medicine and Medical Sciences, University College Dublin; [3]Department of Rheumatology, St Vincent's Hospital, Dublin; [4]Department of Rheumatology, Midlands Regional Hospital, Tullamore; [5]Department of Rheumatology, University Hospital Waterford, Waterford; [6]Department of Rheumatology, Galway University Hospital, Galway; [7]Department of Rheumatology, Sligo General Hospital, Sligo; [8]Department of Rheumatology, Blackrock Clinic, Dublin; [9]Department of Rheumatology, Kerry General Hospital, Kerry; [10]Department of Rheumatology, Tallaght Hospital; [11]Department of Rheumatology, St James's Hospital, Dublin, Ireland*

**Background:** The Ankylosing Spondylitis Registry of Ireland (ASRI) is a web-based database established in 2013, the objectives of which are to provide descriptive epidemiological data on the ankylosing spondylitis (AS) population in Ireland and to establish a registry for potential future studies of genetics, aetiology and therapeutics. The prevalence of osteoporosis is higher in AS patients than age- and sex-matched controls, with potential for vertebral fractures increased. However, the true prevalence is unknown. There is no data on the prevalence of osteoporosis in an Irish cohort.

**Objectives:** To determine the prevalence of low bone mineral density (BMD) in an Irish AS cohort.

**Methods:** A standardised detailed clinical assessment was performed on each patient. Disease activity was assessed by Bath AS Disease Activity Index (BASDAI), function by the Bath AS Functional Index (BASFI) and Health Assessment Questionnaire (HAQ) and quality of life by AS Quality of Life (ASQoL). Structured interviews provided patient-reported data. Presence or absence of dual-energy x-ray absorptiometry (DXA) testing and result was recorded. Bone mineral density (BMD) was categorised according to the World Health Organisation criteria into normal BMD, osteopenia or osteoporosis. Statistical analysis was performed using SPSS.

**Results:** As of October 2015, 416 patients are enrolled in ASRI: 78.1% males, mean age 47.95 (SD 12.4), mean disease duration 20.9 years (SD 12.2), average delay to diagnosis of 8.8 years (SD 8.3). Mean BASDAI is 3.8 (SD 2.5), BASFI 3.7 (SD 2.7), HAQ 0.53 (SD 0.51) and ASQoL 6.15 (SD 5.5). DXAs have been performed in 24.75% (n=103) of the cohort, of which 39.8% (n=41) have osteopenia and 10.7% (n=11) have osteoporosis. Low BMD is significantly correlated with men and advancing age. There is no association with disease activity or duration. Low BMD is more prevalent in patients treated with one or more biologics compared to those never treated. The self-reported prevalence of osteoporosis is 6.4% (n=27; 19 males).

**Conclusions:** There is an elevated prevalence of low BMD in this cohort, with no association with disease severity. The majority of affected patients were unaware, as demonstrated by the low self-reported prevalence. More research and education is needed.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.6012

## FRI0418 MALE GENDER BUT NOT HLA-B27 POSITIVITY OR OCCURRENCE OF UVEITIS AS SEVERITY PROGNOSTIC FACTOR IN SARDINIAN ANKYLOSING SPONDYLITIS PATIENTS

G. Porru[1], M. Marras[2], M. Piga[1], A. Floris[1], V. Ibba[1], S. Marcia[3], A. Mathieu[1], A. Cauli[1]. *[1]Rheumatology, University of Cagliari; [2]Radiology unit, AO Brotzu; [3]Interventional radiology unit, ASL8, Cagliari, Italy*

**Background:** Susceptibility to develop Ankylosing Spondylitis (AS) is strongly influenced by the presence of the HLA-B27 gene, but much less defined are prognostic factors which may predict erosions and new bone formation lesions leading to organic damage and spinal ankylosis. Given the differences in the genetic background among populations, it is conceivable that prognostic factors may also mirror this genetic variability.

**Objectives:** The main aim was to study, in a cohort from the genetic isolate of Sardinia, possible clinical prognostic factors which may predict a more severe spinal damage as assessed by a validated radiological score.

**Methods:** Medical history, clinical and radiological data from 100 consecutive patients with AS were collected in a tertiary referral rheumatology clinic; 73 were male (mean age 44.9±10.5; disease duration 18.3±10.6 years) and 27 females (mean age 44.5±13.0; disease duration 14.9±8.9 years). Radiological cervical and lumbar spinal assessment was performed by means of the mSASSS index, sacro-iliac joints were evaluated according to New York criteria. Rx films were blindly assessed by an expert rheumatologist (GP) and by a radiologist (MM). Results were expressed as mean or median, according to numerical distribution. Statistical analysis was performed by means of GraphPad Prism software according to Mann-Whitney and Spearman's tests.

**Results:** Analysis of data revealed a good inter-observer and intra-observer agreement 0.94 (0.91–0.97) and 0,95 (0,88–0,96), respectively. Radiological spinal and sacroiliac joint severity indexes were positively correlated with patient's age and disease duration ($p<0.0001$). mSASSS was shown to correlate with BASDAI, BASFI and BASMI ($p=0.002$, $p<0.0001$ and $p<0.0001$, respectively) while New York sacroiliac score was found to correlate with BASMI only ($p<0.0001$). Radiological spinal involvement resulted more severe in male vs female patients (mSASSS 8; 3.5–33 vs 4; 1–10, p=0,008), mainly due to a greater involvement of the lumbar tract with similar cervical severity. These objective data are in contrast to clinical metrology and patient reported outcomes which showed similar BASMI and BASFI scores and lower BASDAI (2.5±2.1 vs 3.9±2.3, p=0.02) in male versus female. Interestingly, the occurrence of an extra-articular feature such as acute anterior uveitis (AAU) did not result to be a severity prognostic factor (p=ns). Furthermore, it is noteworthy that no statistical differences were noted comparing HLA-B27 positive patients for radiological severity (mSASS 6.5; 2–19) vs HLA-B27 negative (mSASS 8.5; 2–45 p=ns), as well as for disease activity, functional and metrology indexes (BASDAI 2.8±2.3 vs 3.9±2.3; BASFI 2.7±2.6 vs 3.4±2.9; BASMI 2.3±2.4 vs 3.8±3.1; p=ns). Finally, mSASSS or sacroileiitis indexes were not correlated with anti-TNF treatment.

**Conclusions:** In AS patients from the genetic isolate of Sardinia, male gender but not HLA-B27 positivity or occurrence of AAU is associated with a more severe radiological outcome.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.5924

## FRI0419 ASSOCIATION BETWEEN OBJECTIVELY ASSESSED PHYSICAL ACTIVITY AND DISEASE PROGRESSION IN A POPULATION BASED SAMPLE OF ANKYLOSING SPONDYLITIS PATIENTS

H.I. Khan, D. Aitken, P. Lewis, J. Zochling. *Musculoskeletal Unit, Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia*

**Background:** Ankylosing spondylitis (AS) is a chronic, systemic disease that is characterized by inflammation, especially at the spinal column. Chronic inflammation of the spinal and extraspinal joints and enthesis frequently lead to

limitation of spinal and joint mobility. Although AS results in decreased physical and functional capacity, recent studies have suggested that physical activity (PA)/exercise is as crucial as drug treatment in the management of AS [1,2]. However the relationship between PA and AS disease activity remain s uncertain as the studies conducted thus far have used non-objective measures to assess PA.
**Objectives:** The aim of this study was to examine the association between PA at baseline and AS disease progression over 2 years especially in male participants.
**Methods:** 113 participants, initially recruited if they had inflammatory back pain or extra-articular features of AS for 10 years or less, were studied at baseline and 2 years. PA was assessed at the baseline visit only using a pedometer (steps/day) over 10 days. MRI scans of the spine were performed to assess inflammation at baseline and 2 years. Images were scored, using the Spondyloarthritis Research Consortium of Canada method. Disease activity, functional limitations and mobility were assessed at both time points using the Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI) and Bath AS Metrology Index (BASMI) respectively.
**Results:** 113 participants [mean-age (years) 41 (range 17–72); 64% male, BMI 27 (18–54)] were studied at baseline and two years. 62% of the participants had radiographic evidence of AS according to the modified New York criteria. 100 participants showed some evidence of spinal inflammation (mean 9.86 (0–60)). Mean steps/day were 4665 (1666–9711).
Higher number of steps/day at the baseline visit showed an independent negative association with change in spinal MRI inflammation (β (per 1000 steps) = -0.49 (-0.91, -0.07) over 2 years. Further analysis (figure-1) showed a dose response relation between PA and change in spinal inflammation. Participants who had an increase in severity of inflammation had on average least number of steps/day, whereas participants who had a decrease in severity of inflammation had the highest number of steps/day at the baseline visit.
Higher number of steps/day at the baseline visit were negatively associated with change in BASDAI (β (per 1000 steps) = -0.33 (-0.66, -0.04) score over 2 years. However we did not see any significant associations between PA and changes in BASFI and BASMI scores.
We further explored sex interactions for the associations between PA and changes in spinal inflammation and BASDAI scores, and found that higher number of steps/day resulted in a significantly higher decrease in the severity of MRI inflammation and BASDAI scores ($p<0.05$) in the male participants.

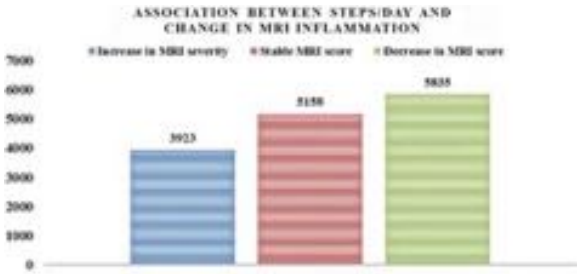

Figure-1 Association between steps/day and change in MRI inflammation

**Conclusions:** Higher PA was associated with a decrease in disease activity both clinically and on imaging.

## FRI0420 PLASMA CALPROTECTIN IN SPA-PATIENTS, A BIOMARKER FOR PERIPHERAL ARTHRITIS

I.M. Hansen[1], G. Bakland[2], Ø. Førre[3]. *[1]Medical departement, Helgelandssykehuset, Mo i Rana; [2]Rheumatology, University Hospital of Northern Norway, Tromsø; [3]Rheumatology, University of Oslo, Oslo, Norway*

**Background:** Spondyloarthritis (Spa) is a rheumatic disease with axial and peripheral inflammatory arthritis. The disease is associated with psoriasis, inflammatory bowel disease and uveitis. Inflammatory biomarkers as Sedimentation rate (SR) and CRP ar not as well correlated with disease activity in Spa as it is in Rheumatoid arthritis. Calprotectin, mainly secreted by neutrophilic granulocytes is elevated in sites of active inflammation Serum or plasma Calprotectin is elevated in rheumatoid arthritis, SLE and in IBD
**Objectives:** To investigate Plasma Calprotectin in Spa patients from Rana, Norway. Is Calprotectin elevated in Spa compared to healthy relatives, and relatives with symptoms of Spa? Is Calprotectin associated to age and gender? Is Calprotectin correlated to body mass index, other markers of inflammation, disease manifestations?
**Methods:** Patients with spondyloarthritis, were recruited from hospital registers, family doctors and by advertisement in local newspaper. Clinical data, Crp and HLAB27 were collected, x-ray and mri of SI-joint was performed if the patient had inflammatory backpain. If they fulfilled the ESSG-critera for Spondylarthritis they were included. The first degree relatives of the included patients were contacted and asked for symptoms of synovitis or inflammatory backpain by questionnaire. Symptomatic relatives were investigated, and included if they fulfilled the ESSG-critera. 387 spondylarthrits patients were included. 273 patients had mri of SI-joints235 patients, 51 symptomatic relatives and 74 healthy relatives were tested for Plasma Calprotectin, by Statistic testing with SPSS Chi square test or Students T-test
**Results:** Calprotectin levels are not significantly different in men and women, in Spa-patients, relatives with symptoms and healthy relatives of Spa patients. In Spa-patients there is no difference in Calprotectin-levels in inflammatory back-pain, radiological sacroiliitis, sacroiliitis on mri, psoriasis, inflammatory bowel disease, acute uveitis, reactive arthritis and HLA B27 positivity. Calprotectin levels are correlated to other inflammatory markers: SR, Crp, Hb and Trc, The best correlation is with Crp. Calprotectin is correlated to swollen joint count but not to BASDAI, BASFI or MHAQ

| Calprotectin | N | Calprotectin (nG/mL), mean | T-test |
|---|---|---|---|
| Healthy relatives/Spa-patients | 74/235 | 460/719 | 0.308 |
| Symptomatic relatives/ Spa-patients | 61/235 | 520/719 | 0.515 |
| Male | 158 | 812 | 0.097 |
| Female | 202 | 501 | |
| Correlations with Calprotectin in spa-patients | 235 | Spearmans rho | Chi-square test |
| Body mass index | | 0.164 | 0.013 |
| Age | | –0.105 | 0.111 |
| Disease duration | | 0.050 | 0.480 |
| SR | | 0.421 | 0.000 |
| Crp | | 0.725 | 0.000 |
| Hb | | –0.249 | 0.000 |
| Trc | | 0.545 | 0.000 |
| Lkc | | 0.050 | 0.457 |
| Tender joint count | | 0.057 | 0.437 |
| Swollen joint count | | 0.250 | 0.002 |
| Basdai | | –0.044 | 0.504 |
| Basfi | | 0.003 | 0.962 |
| MHAQ | | 0.024 | 0.745 |

**Conclusions:** Se-Calprotectin could be a valuable biomarker I Spa, especially in peripheral Spa with polyarthritis

## FRI0421 WHAT IS THE LOCATION OF ENTHESITIS IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS PATIENTS AND HOW DO THEY RESPOND TO ANTI-TNF TREATMENT?

J. Kelsall[1], D. Choquette[2], P. Rahman[3], R. Arendse[4], M. Teo[5], I. Fortin[6], J.A. Avina-Zubieta[7], E. Rampakakis[8], E. Psaradellis[8], K. Maslova[9], B. Osborne[9], C. Tkaczyk[9], F. Nantel[9], A.J. Lehman[9]. *[1]Saint Paul's Hospital, Vancouver; [2]Institut de Rhumatologie de Montréal and University of Montreal, Montreal; [3]Memorial University, St. John's; [4]University of Saskatchewan, Saskatoon; [5]Penticton Regional Hospital, Penticton; [6]Centre de Rhumatologie de l'Est du Québec, Rimouski; [7]Arthritis Research Canada, Richmond; [8]JSS Medical Research, Montreal; [9]Janssen Inc., Toronto, Canada*

**Background:** Enthesitis is characterized by inflammation at the insertion of ligaments, tendons, joint capsule, or fascia to bone, and represents a well-known characteristic feature of ankylosing spondylitis (AS) and related spondyloarthropathies.
**Objectives:** To identify the location of enthesitis in ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients and to determine their response to anti-TNF treatment.
**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis, AS, or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included AS and PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 who had available information on enthesitis. The paired sampled t-test was used to compare the enthesitis count at baseline and 12 months.
**Results:** A total of 260 AS patients and 261 PsA patients were enrolled with a mean (SD) age at baseline of 46.1 (13.0) vs. 50.0 (12.0) years, respectively, and disease duration of 6.4 (9.8) vs. 5.2 (6.8) years. Among patients with AS, 28.1%, 21.7%, 22.4% had enthesitis at baseline, 6 months and 12 months, respectively. For PsA these numbers were 32.2%, 19.7%, and 22.6%, respectively. The presence of enthesitis by anatomical site and visit are described in Table 1 with

higher proportions observed for the greater trochanter (GT) in AS patients and the lateral epicondyle humerus (LEH) in PsA patients.

Table 1: Presence of enthesitis by anatomical site

| | AS | | | PsA | | |
|---|---|---|---|---|---|---|
| | Baseline (N=260) | 6 Months (N=203) | 12 Months (N=134) | Baseline (N=261) | 6 Months (N=189) | 12 Months (N=133) |
| LEH, % | 10.8 | 6.9 | 7.5 | 16.1 | 8.5 | 6.8 |
| MEH, % | 8.1 | 5.9 | 4.5 | 12.6 | 7.4 | 6.8 |
| PA, % | 10.8 | 5.4 | 3.0 | 13.0 | 6.4 | 6.8 |
| GT, % | 14.2 | 8.4 | 10.4 | 10.7 | 9.0 | 6.0 |
| IPF, % | 7.7 | 3.4 | 4.5 | 11.9 | 5.3 | 3.8 |
| SI, % | 11.5 | 8.9 | 7.5 | 10.7 | 8.0 | 8.3 |
| QIP, % | 6.9 | 3.9 | 1.5 | 9.6 | 5.9 | 6.0 |
| PATT, % | 6.9 | 4.4 | 1.5 | 13.8 | 5.9 | 8.3 |

LEH: Lateral epicondyle humerus; MEH: Medial epicondyle humerus; PA: Proximal achilles; GT: Greater trochanter; IPF: Insertion plantar fascia; SI: Suprapsinatus insertion; QIP: Quadriceps insertion patella; PATT: Inferior pole patella or tibial tubercle.

Presence of enthesitis in all anatomical sites was significantly associated with higher HAQ among AS and PsA patients. The mean (SD) enthesitis count at baseline and 12 months was 4.4 (3.4) vs. 2.6 (2.3) (P=0.061) among AS patients and 5.0 (3.8) vs. 3.8 (3.0) (P=0.006) in PsA patients, respectively.

**Conclusions:** A considerable proportion of PsA and AS patients had enthesitis at anti-TNF initiation in this Canadian real-world cohort. Overall, presence of enthesitis was associated with significantly higher functional disability. Treatment with IFX or GLM for 12 months was associated with significant reduction in the mean enthesitis count.

## FRI0422 PERIODONTAL DISEASE IN SPONDYLOARTHRITIS SUBTYPES. IS THERE A DIFFERENCE?

J.C. Rueda[1], W. Bautista-Molano[2], J. De Ávila[3], J.M. Bello-Gualtero[4], D.M. Castillo[5], G.I. Lafaurie[5], J. Londoño[6], R. Valle-Oñate[7], C. Romero-Sánchez[3]. *[1]Faculty of Medicine, Universidad de la Sabana, Chia; [2]Universidad Militar Nueva Granada; [3]UIBO Institute (Oral Basic Research Unit) School of Dentistry, Universidad El Bosque; [4]Faculty of Medicine, Universidad Militar Nueva Granada; [5]Universidad El Bosque; [6]Spondyloarthropathy Group, Rheumatology Department; [7]Hospital Militar/Universidad de la Sabana, Bogotá, Colombia*

**Background:** Spondyloarthritis (SpA) are a group of interconnected inflammatory arthritides that include ankylosing spondylitis (AS), reactive arthritis (ReA), and undifferentiated SpA (uSpA). Periodontal disease (PD) is a chronic inflammatory disease that may increase the risk for immune diseases like rheumatoid arthritis and AS.

**Objectives:** To evaluate the periodontal condition and presence of *Porphyromona gingivalis* (*P. gingivalis*) and *P. gingivalis* IgG1 and IgG2 antibodies within three subgroups of SpA (AS, uSpA and ReA) and establish possible associations with disease activity measures.

**Methods:** A cross-section observational study was designed. Seventy-nine subjects were included (AS: 19, ReA: 14 and uSpA: 46). Clinical evaluation of rheumatologic and periodontal condition was performed. *P. gingivalis* presence by polymerase chain reaction (PCR) and *P. gingivalis* IgG1 and IgG2 antibodies as well as erythrocyte sedimentation rate (ESR), high sensitive C reactive protein (hsCRP), rheumatoid factor, cyclic citrullinated peptide antibody (ACPAs), HLA-B27 and disease activity measures were assessed. A descriptive analysis of frequency distributions for clinical, laboratory and demographic data was made. Associations between clinical and microbiological markers of *P. gingivalis* infection, including IgG1 and IgG2 antibodies, and SpA disease activity measures were evaluated. Chi-squared test was performed to determine associations. Comparisons between groups were made with Kruskal Wallis, Mann-Whitney U and Wilcoxon test. The study was approved by local ethics committee.

**Results:** Forty-four (55.7%) patients with SpA presented PD, of which uSpA had a higher frequency (65.2%). Most patients had moderate PD (AS: 26.3%, uSpA: 50.0%, ReA: 21.4%). A high frequency of retired uSpA patients (87.5%) had moderate PD (p=0.044). The clinical attachment level (CAL) ≥4mm (8.1 ± 10.5) and % of CAL ≥4mm (5.7 ±7.7) was more frequent in uSpA patients (p=0.033 and p=0.034 respectively). *P. gingivalis* presence in uSpA patients was associated with the use of sulfasalazine (p=0.017), and in retired patients (p=0.028). In AS patients, positive IgG1 to *P gingivalis* was associated with % periodontal pocket depth ≥4mm (p=0.04) and % sites with sample pocket depth (SPD) ≥4mm (p=0.02). Also in this subtype, positive IgG2 was associated with bacterial plaque index (p=0.03). Positive levels of IgG2 in uSpA were associated with bleeding of probing (BOP) (p=0.03) and the number of compromised periodontal interproximal sites (p=0.05). See Table 1.

**Conclusions:** We found a high frequency of PD in patients with SpA without significant statistical differences between each subtype. The differences in clinical periodontal variables in SpA subtypes probably suggest a better oral hygiene in these patients. *P. gingivalis* IgG antibodies may be a useful tool for the physician to assess periodontal condition in these patients.

Table 1. Spondyloarthritis subtypes and periodontal disease

| | SpA (n = 79) | AS (n = 19) | uSpA (n = 46) | ReA (n = 14) |

## FRI0423 FREQUENCY OF DACTYLITIS AND ENTHESITIS IN SPONDYLOARTHRITIS ASSOCIATED WITH INFLAMMATORY BOWEL DISEASES:A CASE-CONTROL STUDY

C. Nannini[1], L. Niccoli[1], E. Cassarà[1], O. Kaloudi[1], P. Gionchetti[2], F. Cantini[1]. *[1]Rheumatology, Hospital of Prato, Italy, Prato; [2]IBD Unit, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy*

**Background:** Dactylitis, is observed in approximate 30% of patients spodnyloarthritis (SpA),with the highest frequency in psoriatic arthritis (PsA).SpA features complicate inflammatory bowel diseases (IBD) in at least one third of the cases.The frequency of dactylitis in IBD-SpA has been assessed in a few open studies with conflicting results[1,2].

**Objectives:** *Primary end point:* To compare the frequency of dactylitis in a clinical series of patients with IBD-associated SpA (IBD-SpA) compared with other types of SpA. Secondary end point: to evaluate the frequency of articular and extra-articular manifestations of IBD-associated SpA compared to controls.

**Methods:** 24-month case-control study. *Case patients:* all consecutive patients meeting the ASAS criteria for both axial and peripheral SpA,and with a diagnosis of Crohn's disease (CD) or ulcerative colitis (UC) certified by the gastroenterologist. *Controls:* the 2 consecutive patients with other SpA (ASAS criteria) observed after the case patient during the same time interval. Dactylitis diagnosis was accepted if observed at visit or if certified in the past by a rheumatologist working in our center.Patients were followed by the same rheumatologist,and follow-up visits were scheduled at baseline and every 4 months.All clinical and laboratory data were recorded in a computed patients'chart. The date of the last visit constituted the end of the follow-up.

**Results:** *Case patients:*88 IBD-SpA patients, 29 UC and 59 CD, 42 F/46M, mean age 47.66±15.09 ys, 10 (11.3%) B27+.Mean IBD duration was 60.05±54.66 months. *Controls:* 176 SpA patients, 98 PsA, 46 AS, and 32 non-radiographic axial SpA (nrx-AxSpA); 89F/87M, mean age 46.35±24.88 ys. 70 (40.7%) B27+, mean disease duration of 43.21±28.34 months. In IBD-SpA axial involvement was observed in 46 (52%) patients, peripheral in 29 (33%) and mixed in 13 (15%). Peripheral SpA was oligoarticular (≤4 joints involvement) in 26/29 (90%) patients and polyarticular in 3 (10%). Psoriasis (Pso) was associated in 14/88 (16%) of the cases. Dactylitis was recorded in 4 (4.5%) of IBD-SpA patients and in 30 (17.4%) of controls with a significant statistical difference (p=0.018). Dactylitis was recorded in only 2/74 (2.7%) IBD-SpA patients without Pso (p vs controls=0.010).Also enthesitis prevalence was significantly lower in IBD-SpA occurring in 16/88 (18.1%) patients and in 78/176 (44.3%) controls (p=0.004). Enthesitis frequency

was significantly higher in 14 IBD-SpA patients associating Pso (28.5%) compared with the remaining 74 cases (16.2%) (p=0.012). Dactylitis occurred in 2/29 (6.9%) and in 2/59 (3.38%) patients with UC and CD, respectively. Anterior uveitis was recorded in 3 (3.4%) IBD-SpA patients and in 26 (14.7%) controls (p=0.02).

**Conclusions:** Dactylitis and enthesitis were significantly lower in IBD-SpA patients compared to other SpA. As reported[3], Pso was frequent in our cohort of IBD-SpA,and its coexistency significantly increased the frequency of enthesitis and to a lesser extent of dactylitis.Anterior uveitis was significantly less frequent in IBD-SpA compared to controls.

## FRI0424 ACCESSIBILITY TO BIOLOGICAL THERAPY FOR PATIENTS WITH ANKYLOSING SPONDYLITIS IN ROMANIA IS INFLUENCED BY AREA OF RESIDENCE, SOCIO- ECONOMIC AND DEMOGRAPHIC FACTORS

L. Enache[1], C. Codreanu[1], C. Mogosan[1], G. Gutoiu[1], C. Popescu[1], M. Parvu[2], S. Rednic[3], R. Ionescu[4]. *[1]Rheumatology, Clinical Center for Rheumatic Diseases; [2]Rheumatology, Colentina Hospital, Bucharest; [3]Rheumatology, 3County Hospital, Cluj Napoca, Cluj Napoca; [4]Rheumatology, Sfanta Maria Hospital, Bucharest, Romania*

**Background:** The efficacy of anti TNFblockers in active ankylosing spondylitis (AS) is widely accepted. In Europe, high costs related to biological treatment lead to significant differences regarding the patient's accessibility to treatment depending on the level of economic development of different countries. In Romania, according to the national reimbursement protocol, a patient is eligible for treatment with TNF blockers if the disease is active despite using at least two non-steroidal anti-inflammatory drugs and sulfasalazine (for peripheral arthritis).

**Objectives:** The aim of the study is to assess the accessibility of patients with AS to biological therapy in Romania, depending on their area of residence and socio- economical indicators for each region.

**Methods:** A cross-sectional study was performed in 41 counties and Bucharest. Data were collected from the Romanian Registry of Rheumatic Diseases and the socio- economic indicators from the yearbook of the National Institute for Statistics.

**Results:** Data were gathered for 2013 AS patients treated with biologics. The mean age was 45.46 yrs (±12.07), 78% were male, 71% live in urban residences and the mean disease duration was 11.53 yrs. 74% (n=1498) of patients had access to biologics in their county of residence, while 26% (n=524) of patients had to travel for treatment to another county. Compared to the group treated inside their county of residence, those treated outside, originated from areas with a lower gross domestic product per capita (5701.77 € compared to 8722.44 €; $p<0.001$; t test) and with high deficit of physicians (1.28 physicians/ 1000 inhabitants, compared to 2.63 physicians/ 1000 inhabitants; $p<0.001$; t test). The urban habitat was associated with a higher accessibility to biologics (75.9%) inside their county of residence compared to patients living in rural areas (69.2%) (p=0.002, $\chi^2$ test); so the latter have to travel in order to being cared by a rheumatologist. The patients' age had a great influence on the accessibility to biologics: the patients treated outside of their county of residence were younger than those treated inside (44.1 yrs compared to 45.9 yrs; p=0.003, t test). On a national scale, the majority of AS patients treated outside their county of residence (86%; 449); were treated in Bucharest (the capital city); so the majority of patients treated with biologics in Bucharest are originating from other counties (60%; n=449/751).

**Conclusions:** In Romania, although there is a national protocol for biological therapy in AS, applied in the same way in every region of the country, the accessibility to biologic therapy varies a lot, mostly due to differences in the socio-economic status of each area of residence.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.5955

## FRI0425 SEROLOGICAL MARKERS AND THEIR CORRELATION WITH DISEASE ACTIVITY INDEXES AND IMAGING IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS (ITALIAN CENTER OF SPACE STUDY)

M. Lorenzin[1], A. Ortolan[1], P. Frallonardo[1], S. Vio[2], F. Oliviero[1], M. Zaninotto[3], C. Cosma[3], C. Lacognata[2], L. Punzi[1], R. Ramonda[1]. *[1]Department of Medicine–DIMED, Rheumatology Unit-University of Padova; [2]Radiology Unit; [3]Department of Laboratory Medicine, University of Padova, Padova, Italy*

**Background:** Recently studies have focused on the role of new markers to diagnose early axial spondyloarthritis (axSpA), to evaluate disease activity (DA) and to predict patients (pts) at higher risk for a worse outcome. Common biomarkers, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) are often ineffective in assessing DA.

**Objectives:** To evaluate some biomarkers and their correlation with clinical parameters, DA indexes and imaging in pts with early axSpA.

**Methods:** Sixty pts with low back pain (≥3 months, ≤2 years, onset ≤45 years) attending the SpA-UOC Rheumatology of Padua (SpondyloArthritis-Caught-Early SPACE study), were studied following a protocol including physical examination, questionnaires', lab tests, X-rays and MRI of spine and sacroiliac joints (SIJ)at baseline.An experienced rheumatologist made axSpA diagnosis according to ASAS criteria. The DA and physical functioning were assessed using: Bath Ankylosing Spondylitis Metrology Index (BASMI); Maastricht Ankylosing enthesitis Spondilities Score (MASES); Bath Ankylosing Spondylitis Disease Activity Index (BASDAI); Bath Ankylosing Spondylitis Functional Index (BASFI); Ankylosing Spondylitis disease activity score (ASDAS); Visual Analogue Scale (VAS pain); VAS night pain; VAS disease activity;Bath Ankylosing Spondylitis Patient Global Score (BASG1); BASG2; Health Assessment Questionnaire (HAQ); ESR; serum ultrasensitive CRP (hs-CRP); matrix metalloproteinase (MMP3); interleukin (IL) IL-22, IL-17, IL-23.Positive spine and SIJ MRI images were scored independently by 2 readers using the Spondyloarthritis Research Consortium of Canada (SPARCC) method; the spine and SIJ X-rays images were scored using mSASSS and NY-criteria. After the X-rays and MRI images of all pts were read, they were classified into the following cohorts: pts with signs of radiographic sacroiliitis (r-axSpA), pts without signs of radiographic sacroiliitis but with signs of sacroiliitis on SIJ-MRI (nr-axSpA MRI SIJ+), pts without signs of sacroiliitis on MRI and X-rays (nr-axSpA MRI SIJ-).The Spearman test and Kruskal Wallis test were used to compare all indexes in these cohorts.

**Results:** There was a significant difference between the three cohorts with regard to the prevalence of radiographic sacroiliitis, active sacroiliitis on MRI and the SPARCC SIJ score (Table 1). There were no differences in these groups in IL-17, IL-22, IL-23, MMP-3 and hsCRP. ILs remained below detection value in all cohorts. The correlation of IL-17 and IL-23 with other indexes was not significant. There was instead a correlation between IL-22 and some clinical indexes (BASFI, BASG1, HAQ, VAS pain). The correlation between mSASSS and MMP3 and hsCRP was an interesting finding.

Table 1. Serological and DA indexes and imaging score at baseline in all patients (n=60) and in the following three cohorts (r-axSpA, nr-axSpA MRI SIJ+, nr-axSpA MRI SIJ -)

| Serological and DA indexes and imaging | Cohort 1 r-axSpA, n=20 | Cohort 2 nr-axSpA MRI SIJ+, n=17 | Cohort 3 nr-axSpAMRI SIJ-, n=20 | p § | totale=60 pts |
|---|---|---|---|---|---|
| ESR (mm/h), mean (SD) | 17.57 (14.48) | 18.41 (12.73) | 18.00 (21.83) | ns | 18.27 (18.61) |

ESR, erythrocyte sedimentation rate; hsCRP, high sensitive C-reactive protein; MMP-3 matrix-metallo-proteinase 3; IL, interleukin; mLA-B27, mu man Leukocyte Antigen; BASMI, Bath Ankylosing Score Metrology Index; MASES, Maastricht Ankylosing Spondilitis Enthesitis Score; BASFI: Bath Ankylosing Spondylitis Functional Index; HAQ: Health Assessment Questionnaire; BASG1,Bath Ankylosing Spondylitis Patient Global Score 1; BASG2, Bath Ankylosing Spondylitis Patient Global Score 2,BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; VAS, Visual Analogue Scale; ASDAS, Ankylosing Spondylitis Disease Activity Score; SPARCC, Spondyloarthritis Research Consortium of Canada; mSASSS, modifiedStokeAnkylosingSpondylitis Spine Score, SIJ, sacroiliac joints. * Sacroiliitis MRI according ASAS/EULAR
** Sacroiliitis x-ray according New York criteria §§ Anova (Kruskal Wallis) at baseline: p<0.05

**Conclusions:** ILs, MMP-3 and hsCRP values were not significantly increased in any of the study groups and were not related to radiographic SIJ involvement or to clinical and DA indexes. This finding can probably be explained by the fact that pts had early stage axSpA and by the small sample size. Further studies are needed to analyze the validity and reproducibility of these biomarkers in early axSpA.

**Disclosure of Interest:** None declared

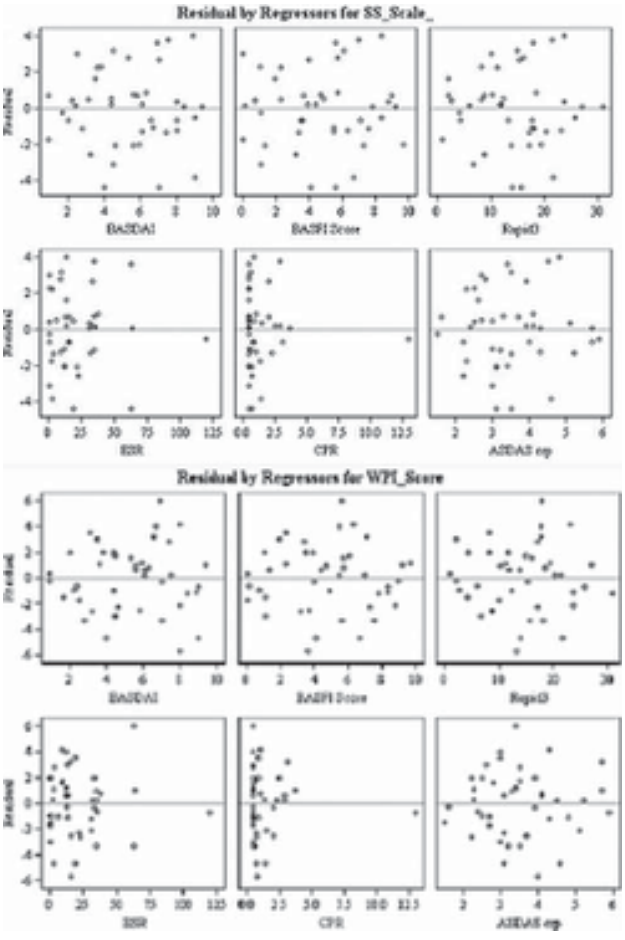
## FRI0426 DO THE VALIDATED TOOLS OF DISEASE AND FUNCTIONAL ACTIVITY IN ANKYLOSING SPONDYLITIS MEASURE FIBROMYALGIA SYMPTOMS?

M.N. Magrey, M.A. Khan. *Rheumatology, Case Western Reserve University Medical School at Metrohealth Medical Center, cleveland, United States*



**Background:** Concomitant fibromyalgia syndrome is a common problem in ankylosing spondylitis (AS) and its recognition is important for optimal management of

AS. There is a concern that validated tools of disease activity, function and patient reported outcomes in AS may be measuring fibromyalgia pain and symptoms in patients with concomitant AS and fibromyalgia.

**Objectives:** We studied the relationship between the validated AS measures of disease activity, functional index, and markers of inflammation and ACR fibromyalgia diagnostic criteria.

**Methods:** Study was approved by our IRB. We prospectively recruited 51 subjects ≥18 years of age with AS (meeting modified New York criteria with grade 3 or 4 sacroiliitis and high disease activity (BASDAI ≥3). Demographic and clinical data were collected and stored in Redcap data base. Various validated Questionnaires to assess disease, functional activity and patient reported outcomes in AS were administered to the patients. The frequency of FMS was determined using validated 2010 ACR diagnostic criteria for fibromyalgia [1]. The patient met the fibromyalgia criteria if (i) widespread pain index (WPI) of ≥7 & symptom severity score (SS) ≥5 or WPI 3–6 & SS score ≥9,(ii) symptoms were present at a similar level for at least 3 months and (iii) the pain was not attributed to AS by the clinician. ESR and CRP was measured using routine laboratory methods. Descriptive analysis included continuous variables (the mean ± SD) and the categorical variables percentage. Linear regression analysis was performed to assess the association between BASDAI, BASMI, ASDAS, Rapid 3 and fibromyalgia status

**Results:** There 34 males and 17 females with mean age of 49.8 ± 12.2; 30.6% African-Americans, 63.2% whites and 4.0% Asians, with 47.0% HLA-B27 positive, 29.4% negative and 23% unknown.18/47 (38.3%) have had acute anterior uveitis. 45% of the patients had been on TNF-α inhibitors. Mean BASDAI was 5.23 (±2.5); BASFI 4.7 (± 2.8); PGA 5.1 (±2.4); ASDAS-CRP 3.4 (±1.13); and RAPID 3 score 13.76 (± 7.21), ESR 22.4 mm/hr (±22.0) and CRP 1.3 mg/dl (±1.9).21 AS patients (41.2%) satisfied the diagnostic criteria of fibromyalgia. No statistically significant relationship was found between WPI score (Figure 1) with BASDAI (p=0.56), ASDAS (p=0.19), BASFI (0.50), RAPID 3 (p=0.70), CRP (p=0.25), and ESR (p=0.30). Also, no statistically significant relationship was found between SS score (Figure 1) with BASDAI (p=0.12), ASDAS (p=0.87), BASFI (0.73), RAPID 3 (p=0.75), CRP (p=0.79), and ESR (p=0.90).

**Conclusions:** Despite high frequency of fibromyalgia prevalence in our patients with AS and active disease, the validated tools of disease and functional activity in AS did not measure fibromyalgia pain and symptoms.

**Disclosure of Interest:** None declared

## FRI0427 THE PREVALENCE OF AXIAL SPONDYLOARTHRITIS IN PATIENTS PRESENTING WITH ACUTE ANTERIOR UVEITIS

M. Sykes[1], L. Hamilton[1], C. Jones[2], K. Gaffney[1]. [1]*Rheumatology;* [2]*Ophthalmology, Norfolk & Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom*

**Background:** Estimates for the prevalence of axial spondyloarthritis (axSpA) in patients presenting with acute anterior uveitis (AAU) range from 11–28%. However, to date no studies have classified patients according to the MRI-based Assessment of Spondyloarthritis International Society (ASAS) criteria.

**Objectives:** To determine the prevalence of axSpA in patients presenting with AAU and identify new "undiagnosed" cases using contemporary MRI-based classification criteria.

**Methods:** Consecutive adult patients presenting to a university teaching hospital between February 2014 and March 2015 with a diagnosis of non-traumatic, non-infective AAU were invited to participate. Patients with a pre-existing diagnosis of axial SpA or another underlying cause of AAU (e.g. sarcoidosis) were not evaluated further. Patients who reported chronic back pain commencing before age 45 were evaluated clinically by an experienced rheumatologist and investigated with laboratory tests and magnetic resonance imaging (MRI). Those patients newly diagnosed with axSpA were classified according to ASAS criteria and the burden of disease recorded.

**Results:** Two hundred and forty-one of 366 patients responded; 57 had a pre-existing diagnosis of axSpA, 77 others fulfilled the study eligibility criteria and 73 (95%) completed the study. Sixteen patients (22%) were diagnosed with axSpA according to the ASAS definition of a positive MRI (12 sacroiliac, 4 spinal). Including those with a previous diagnosis, the minimum prevalence of axSpA in patients presenting with AAU was 19.9%; of these 22% were previously undiagnosed.

The median age of "new" axSpA patients was 54 (IQR 41.5 – 58) and 8 (50%) were female. Nine patients (56%) were HLA-B27 positive; 31.3% had a raised CRP. The median duration of back pain was 20.5 years (IQR 17–30.25), and median number of episodes of AAU prior to the diagnosis of axSpA was 3 (IQR 1–7). The median duration of back pain at the time of first episode of uveitis was 15.5 years (IQR 8.5–20.5).

Amongst the undiagnosed cases, 6.3% of patients had a pre-existing diagnosis of psoriasis, 18.8% inflammatory bowel disease, 12.5% peripheral inflammatory arthritis and 6.3% a family history of axSpA. The mean BASDAI was 3.17 (SD 1.50), spinal pain visual analogue scale 4.31 (SD 2.02), BASMI 1.63 (SD 1.36), BASFI 2.74 (SD 2.20) and BAS-G 4.70 (SD 1.45).

**Conclusions:** This is the first study to use MRI in order to classify patients with AAU and chronic back pain. At least one fifth of patients presenting to secondary care with AAU have an underlying diagnosis of axSpA. There was a significant hidden burden of disease in that 22% of axSpA patients were previously undiagnosed despite having a long duration of symptoms. Patients presenting with AAU should be screened for chronic back pain and referred to a rheumatologist; this represents an opportunity to shorten the diagnostic delay.

## FRI0428 EPIDEMIOLOGY OF ANKYLOSING SPONDYLITIS IN TAIWAN: A NATIONWIDE POPULATION STUDY

M.-Y. Hsieh, C.-F. Kuo. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease and there are few nationwide estimates for prevalence and incidence in Taiwan.

**Objectives:** The aim of this study was to determine trends in the incidence and prevalence of AS between 2005 and 2010 among general population of Taiwan.

**Methods:** The National Health Insurance Research Database was used to identify gout patients and to estimate the prevalence and incidence of AS for each year from 2005 to 2010. To determine the trends in prevalence, incidence and management of AS, we calculated age- and sex-standardised prevalence and incidence of gout in each calendar year from 2005 to 2010 with the population structure in year 2010 as the reference.

**Results:** A total of 54,857 cases with an AS diagnosis alive in December 2010 was identified. Men had a higher prevalence (0.28% versus 0.19%) and incidence (0.51 versus 0.33 per 1,000 person-year) of AS than women. The standardised prevalence of AS had decreased from 0.30% in 2005 to 0.24% in 2010. The incidence of AS is between 0.42 and 0.50 per 1,000 person-years during 2005 and 2010. The incidence of AS in men was low in individuals younger than 19 years of age, peaked rapidly in the ages 20 to 24 years and decreased gradually. The incidence and prevalence of regions in 2010 highest in the town of Tainan (0.6% and 1.79 per 1,000 person-years) and Ilan (1.17% and 1.52 per 1,000 person-years) than other regions.

**Conclusions:** AS is a common rheumatic disease in Taiwan with a similar prevalence to rheumatoid arthritis.

**Disclosure of Interest:** None declared

## FRI0429 WHAT IS THE LOCATION OF DACTYLITIS IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS PATIENTS AND HOW DO THEY RESPOND TO ANTI-TNF TREATMENT?

R. Arendse[1], P. Rahman[2], J.A. Avina-Zubieta[3], D. Choquette[4], M. Zummer[5], M. Baker[6], J. Stewart[7], I. Fortin[8], M. Teo[7], E. Rampakakis[9], E. Psaradellis[9], B. Osborne[10], C. Tkaczyk[10], K. Maslova[10], F. Nantel[10], A.J. Lehman[10].
*[1]University of Saskatchewan, Saskatoon; [2]Memorial University, St. John's; [3]Arthritis Research Canada, Richmond; [4]Institut de rhumatologie de montréal; [5]Université de Montréal, Montreal; [6]University of Victoria, Victoria; [7]Penticton Regional Hospital, Penticton; [8]Centre de Rhumatologie de l'Est du Québec, Rimouski; [9]JSS Medical Research, Montreal; [10]Janssen Inc., Toronto, Canada*

**Background:** Dactylitis is one of the most commonly reported features in spondyloarthritis. It has been hypothesized that dactylitis is a functional enthesitis at the proximal interphalangeal joints, resulting in synovitis, tenosynovitis, bone and soft tissue oedema to the digit, and may simultaneously involve more than one digit.
**Objectives:** Our objective was to identify the location of dactylitis in ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients and to determine their response to anti-TNF treatment.
**Methods:** BioTRAC is an ongoing, prospective registry of patients initiating treatment for rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA) with infliximab (IFX) or golimumab (GLM). Eligible people for this analysis included AS and PsA patients treated with IFX who were enrolled since 2005 or with GLM enrolled since 2010 who had available information on dactylitis. The McNemar (paired Chi-square) test was used to compare the presence of dactylitis over time.
**Results:** A total of 260 AS patients and 261 PsA patients were enrolled with a mean (SD) age at baseline of 46.1 (13.0) vs. 50.0 (12.0) years, disease duration of 6.4 (9.8) vs. 5.2 (6.8) years, and proportion of females 40.6% vs. 48.5%, respectively. Among patients with AS, dactylitis was reported in 6.2% and 2.2% of patients at baseline and 6 months, respectively; at 6 months of treatment 73.3% of AS patients with dactylitis at baseline had no dactylitis and 1.6% developed dactylitis (P=0.057). For PsA higher proportions of dactylitis were observed with 30.7%, and 12.7%, respectively; at 6 months of treatment 69.0% of PsA patients with dactylitis at baseline had no dactylitis and 4.6% developed dactylitis (P<0.001). The distribution of dactylitis amongst digits is described in Table 1 with the highest prevalence observed for feet in AS and PsA patients.

Table 1. Distribution of dactylitis amongst digits in AS and PsA

| | AS | | PsA | |
|---|---|---|---|---|
| | Baseline (N=260) | 6 Months (N=207) | Baseline (N=261) | 6 Months (N=189) |
| HD1, % | 1.9 | 0.5 | 4.2 | 2.6 |
| HD2, % | 3.1 | 1.0 | 9.2 | 5.3 |
| HD3, % | 3.1 | 2.4 | 8.0 | 5.3 |
| HD4, % | 1.5 | 1.0 | 8.0 | 2.6 |
| HD5, % | 1.5 | 1.4 | 5.4 | 3.2 |
| FD1, % | 2.7 | 0.5 | 8.0 | 1.1 |
| FD2, % | 3.8 | 0.5 | 12.6 | 3.7 |
| FD3, % | 2.3 | 0.5 | 11.1 | 3.2 |
| FD4, % | 2.3 | 1.0 | 14.9 | 5.3 |
| FD5, % | 1.5 | 0.0 | 10.0 | 1.6 |

HD=hand digit; FD=foot digit.

Presence of dactylitis in hands or feet (any digit) was associated with significantly higher HAQ in AS and PsA (AS: ΔHAQ=1.36 (P≤0.001); PsA: ΔHAQ=0.64 (P≤0.001)).
**Conclusions:** A considerable proportion of PsA patients had dactylitis at anti-TNF initiation in this Canadian real-world cohort. Although a lower proportion of patients had dactylitis among AS patients, the presence of dactylitis was associated with higher functional disability in both AS and PsA patients. Treatment with IFX or GLM for 6 months was associated with significant reduction in the prevalence of dactylitis.

## FRI0430 GOLIMUMAB IN REFRACTORY UVEITIS RELATED TO SPONDYLOARTHRITIS. MULTICENTER STUDY OF 15 PATIENTS

N. Palmou-Fontana[1], V. Calvo-Río[1], R. Blanco[1], M. Santos-Gomez[1], E. Rubio-Romero[1], M. Cordero-Coma[2], A. Gallego-Flores[3], R. Veróz[3], I. Torre[4], F.F. Hernández[5], A. Atanes[6], J. Loricera[1], M. Gonzalez-Vela[1], J.L. Hernandez[7], M.A. González-Gay[1]. *[1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander; [2]Ofthalmology, Hospital de León, León; [3]Rheumatology, Hospital de Mérida, Badajoz; [4]Rheumatology, Hospital de Basurto, Bilbao; [5]Rheumatology, Hospital Dr. Negrín, Canarias; [6]Rheumatology, Hospital Universitario Complejo a Coruña, A Coruña; [7]Internal Medicine, Hospital Universitario Marques de Valdecilla, Santander, Spain*

**Objectives:** To assess the efficacy of golimumab (GLM) in refractory uveitis associated to spondyloarthritis (SpA).
**Methods:** Multicenter study of SpA-related uveitis refractory to at least one immunosuppressive drug. The main outcome variables were degree of anterior and posterior chamber inflammation, visual acuity, and macular thickness.
**Results:** Fifteen patients (13 men/2 women; 18 affected eyes; mean age 39±6 years) were evaluated. The underlying SpA subtypes were ankylosing spondylitis (n=8), psoriatic arthritis (n=6) and non-radiographic axial SpA (n=1). The ocular involvement patterns were recurrent anterior uveitis in 8 patients and chronic anterior uveitis in 7. Before GLM they have received methotrexate (n=13), sulfasalazine (n=6), pulses of methylprednisolone (n=4), azathioprine (n=3), leflunomide (n=2) and cyclosporine (n=1). Ten of them had also been treated with TNF-α blockers; etanercept (n=7), adalimumab (n=7), infliximab (n=6), and certolizumab (n=1). GLM was given at the standard dose (50 mg/sc/monthly) as monotherapy (n=7) or in combination with conventional immunosuppressive drugs (n=8), mainly methotrexate. Most patients had rapid and progressive improvement of intraocular inflammation parameters. The median number of cells in the anterior chamber at 2 years (0 [0–0]) was significantly reduced compared to baseline findings (1 [0–3]); p=0.04). The mean best corrected visual acuity value also improved (0.84±0.3 at 2 years versus 0.62±0.3 at baseline; p=0.03). Only minor side effects were observed after a mean follow-up of 23±7 months.
**Conclusions:** Our results indicate that GLM may be a useful therapeutic option in refractory SpA-related uveitis.
**Disclosure of Interest:** None declared

## FRI0431 FATIGUE IS A DETERMINANT OF REDUCED WORK PRODUCTIVITY IN ANKYLOSING SPONDYLITIS: RESULTS FROM A PROSPECTIVE COHORT STUDY

N. Basu[1,2], K. Druce[3], L. Aikman[4], M. Dilleen[5], T. Barata[6], A. Burden[6], P. Szczypa[4]. *[1]ARUK-MRC Centre for Musculoskeletal Health and Work; [2]Epidemiology, University of Aberdeen, Aberdeen; [3]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester; [4]Medical Affairs; [5]Statistics Group, Pfizer Ltd, Sandwich; [6]Quanticate, Hitchin, United Kingdom*

**Background:** Work disability is a critical issue for patients with ankylosing spondylitis (AS). In the general population, fatigue is a principal determinant of reduced work productivity. This potentially modifiable risk factor has yet to be investigated in AS.
**Objectives:** To investigate the relationship between fatigue and work productivity among AS patients.
**Methods:** Data were obtained from an observational study which followed a large German cohort of AS patients treated with etanercept as part of routine clinical practice between October 2007 and May 2014.
The exposure of interest, fatigue (Bath Ankylosing Spondylitis Disease Activity Index subscale, BASDAI), was collected at baseline (at etanercept commencement) and 6 months. Putative confounders were also evaluated at these time-points: age, gender, pain (visual analogue scale, VAS), depression (EQ5D item), physician's disease activity assessment (VAS) and C-reactive protein (CRP).
The primary outcome, work productivity loss, was measured using subscale 3 of the Work Productivity and Activity Index: Specific Health Problem (WPAI: SHP).
Two stepwise ANCOVA models (adjusted for confounders and baseline work productivity loss) were developed to examine: 1) the association between baseline fatigue and 6 month work productivity loss; 2) the association be-

Table 1. Multivariate analyses examining relationship between fatigue and work productivity loss

| Predictor | p-value | Coefficient Estimate | Standard Error |
|---|---|---|---|
| Model 1: Work Productivity Loss at 6 months | | | |
| BASDAI (fatigue) score at Baseline | 0.0346 | 1.116 | 0.527 |
| Work productivity loss at Baseline | <0.0001 | 0.218 | 0.042 |
| Age (years) at Baseline | <0.0001 | 0.576 | 0.095 |
| Gender (male relative to female) | 0.0208 | –5.021 | 2.165 |
| Pain Score at Baseline | 0.0330 | 1.242 | 0.580 |
| Model 2: Change in Work Productivity Loss from Baseline to 6 months | | | |
| Change in BASDAI (fatigue) score from Baseline | 0.0444 | 0.869 | 0.431 |
| Work productivity loss at Baseline | <0.0001 | –0.601 | 0.032 |
| Age (years) at Baseline | <0.0001 | 0.381 | 0.089 |
| Change in Pain Score from Baseline | <0.0001 | 2.629 | 0.456 |
| Change in Physician's Disease Activity Assessment from Baseline | 0.0006 | 1.696 | 0.494 |

tween change in fatigue and change in work productivity loss (baseline to 6 months).
**Results:** Of the n=1663 study participants included in the analysis population, n=1003 (60%) were in employment at baseline: mean (SD) age 40.7 (10.6) years, 63.3% male, mean (SD) disease duration 7.3 (7.8) years at baseline. At 6 months, 837 contributed to the analyses of which 93% remained on etanercept therapy. Following adjustment of putative confounders, baseline fatigue was significantly associated with work productivity loss at 6 months (p=0.035, see table). Similarly, the change in fatigue levels between baseline and 6 months was independently associated with a change in work productivity loss (p=0.044, see table).
**Conclusions:** In AS patients receiving etanercept therapy, high levels of fatigue are predictive of future work productivity loss. Furthermore, reductions in fatigue are significantly associated with improvements in work productivity. Together, these data support a potential causal role for fatigue in AS related work disability.

## FRI0432 INCREASE IN IL-31 SERUM LEVEL IN RECENT SPONDYLOARTHRITIS: DATA FROM THE DESIR COHORT

N. Rosine[1], A. Etcheto[2], A. Molto[2], Y. Taoufik[3], H. Chavez[3], C. Roux[2], K. Briot[2], M. Dougados[2], C. Miceli-Richard[1]. *[1]Université Paris Descartes, Service de Rhumatologie B, Hôpital Cochin - Assistance Publique- Hôpitaux de Paris, Unité Mixte Pasteur/APHP – Département d'Immunologie – Institut Pasteur - Paris; [2]Université Paris Descartes, Service de Rhumatologie B, Hôpital Cochin - Assistance Publique- Hôpitaux de Paris, INSERM (U1153): Clinical epidemiology and biostatistics, PRES Sorbonne Paris-Cité; [3]Laboratoire d'Immunologie, Hôpital le Kremlin Bicêtre, APHP, Paris, France*

**Background:** IL-31 is a newly-described cytokine mainly produced by activated Th2 cells. IL-31 acts through IL31-RA and oncostatin heterodimeric receptors that activate STAT3 and STAT5. So far, IL31 has been mainly involved in airway hypersensitivity and atopic dermatitis. More recent data suggest its involvement in psoriasis, inflammatory bowel disease and osteoporosis.
**Objectives:** We aimed to assess IL-31 serum levels in patients with recent onset axial spondyloarthritis (SpA) from DESIR cohort.
**Methods:** The DESIR cohort is a prospective, multicenter French cohort of 708 patients with early inflammatory back pain (IBP) (duration >3 months and <3 years) suggestive of AxSpA (mean age 33.8 years; 53.8% women, 57% fulfilled the ASAS criteria). IL-31 and sCD40L were assessed using the multiplex and high sensitive 17-Plex ELISA (Bio-Plex Pro Human Cytokine 17-Plex Immunoassay, BioRad). Serum levels were assessed at baseline in 3 subgroups of patients: i. patients from the DESIR cohort fulfilling the ASAS criteria (ASAS+ group, n=443); ii. IBP patients from the DESIR cohort not fulfilling the ASAS criteria (ASAS– group, n=265); iii. Healthy controls age and sex-matched to a random sample of the DESIR cohort patients (control group, n=79).
**Results:** IL31 was significantly increased (p<0,001) in the ASAS+ group (median=7.7 pg/ml ± 15.4, mean 12.6 pg/ml) and ASAS– group (6.3 pg/ml ± 16, mean=11.3 pg/ml) compared to the control group (median=0.0±3.1, mean=1.1 pg/ml). IL31 was correlated with sCD40L (r=0.62; p<0.0001), and with DKK-1 (r=0.27; p<0,001). Patients exhibiting a high level of IL31 had a mSASSS score <1 (Yes 7.7 ± 10.7 versus No 13.02 ± 15.07; p=0.005). The multivariate analysis in ASAS+ group showed an association between IL-31 and sCD40L (p<0.0001), mSASSS≥1 (p=0.007), DKK-1 (p=0.002) and low bone density defined by Z-score < -2 (p=0.04). In the multivariate logistic analysis, IL-31 was independently associated with low bone density (p=0.02) in a model also including age (ns), gender (p=0.0008), and CRP (P=0.0003).When assessing patients with osteoporosis (T score <2.5), IL-31 was still independently associated (p=0.025) as well as gender (p=0.005). IL-31 was also independently associated with protection from axial structural damages (OR 0.07 [0.96–0.99];p=0.005) as well as other parameters included in the model: age (p<0.0001), and smoking (p=0.04). The same significant association between IL-31 and protection from structural damage when focussing on ASAS+ patients (p=0.007) or on patients fullfilling the Amor criteria (p=0.009). Only a trend was observed for patients fullfilling the ESSG criteria (p=0.07).

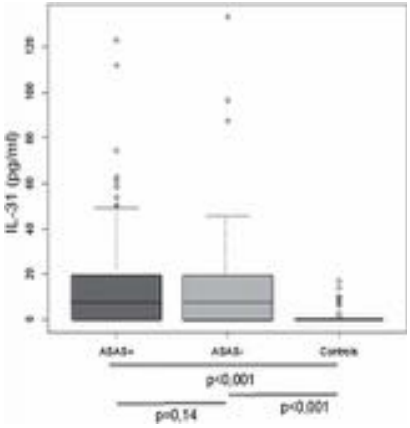

Figure 1. levels of IL31 in ASAS+ group, ASAS– group, Controls groups

**Conclusions:** IL31 serum levels are correlated with sC40L suggesting the role of activated T-cells in IL-31 expression. IL31 is also significantly correlated with the Wnt signaling inhibitory protein DKK-1. Increased levels of IL-31 might protect patients from structural damages but are also associated with low bone density. These preliminary results regarding IL-31 mediated bone effects in DESIR cohort need to be confirmed in more severe forms of the disease.
**Disclosure of Interest:** None declared

## FRI0433 FACTORS ASSOCIATED WITH ELEVATED ACUTE PHASE REACTANTS IN PATIENTS WITH RECENT INFLAMMATORY BACK PAIN: IMPACT OF C REACTIVE PROTEIN ON THE PHENOTYPE OF PATIENTS. DATA FROM THE PROSPECTIVE MULTICENTER FRENCH COHORT DESIR

P. Manicki[1], J. Morel[1], B. Combe[1], D. Van der Heijde[2], C. Lukas[1]. *[1]Rheumatology, CHU Lapeyronie, Montpellier, France; [2]Leiden University Medical Centre, Leiden, Netherlands*

**Objectives:** To determine the prevalence of increased C reactive protein (CRP) in patients with recent inflammatory back pain (IBP) suggestive of spondylarthritis (SpA) and to describe the overall features of these patients.
**Methods:** The DESIR cohort is a prospective multicenter French cohort of 708 patients with early IBP suggestive of SpA. An abnormal acute phase reactants level was determined based on normal upper range of values determined by centralized assessment of CRP. Data on the baseline demographic characteristics, functional status and quality of life, imaging features and HLA B27 status were compared in patients with and without increased CRP. We studied the total population of 708 patients and the subgroup of patients fulfilling ASAS criteria at the inclusion. Significant parameters in univariate analysis were tested in multivariate models.
**Results:** The prevalence of increased CRP (>5mg/L) at inclusion in the DESIR cohort was 233/684 (34.1%). The presence of increased CRP was significantly associated (univariate) with a younger age, previous history of arthritis, a history of dactylitis, clinical synovitis, BMD, radiographic sacroiliitis, a higher baseline modified Score of Ankylosing Spondylitis Spinal Score (mSASSS), MRI inflammatory lesions of spine and sacroiliac joints, scores of disease activity including Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity (ASDAS-CRP), physical function assessed by Bath Ankylosing Spondylitis Functional Index (BASFI), and health status indicators (Ankylosing Spondylitis Quality of Life, Health Assessment questionnaire for Ankylosing Spondylitis and the Physical Component Score from Short Form 36) in both populations. Increased CRP was associated with the absence of HLA-B27 only in the subgroup of patients fulfilling ASAS criteria.
Stepwise multivariate analysis found an association between increased CRP and male gender, younger age, history of arthritis, BMD >25kg.m$^2$, radiographic sacroiliitis, mSASSS, MRI inflammation on sacroiliac joints and ASDAS-CRP (p<0,05).
**Conclusions:** In recent IBP suggestive of SpA, increased CRP is associated with younger age, presence of peripheral articular manifestations, radiologic abnormalities, and both with higher activity and functional disability. Patients with elevated acute phase reactants seem to have a more severe form of the disease.
**Disclosure of Interest:** None declared

## FRI0434 PREVALENCE OF STRUCTURAL CARDIAC DISEASE AND DIASTOLIC DYSFUNCTION IN AXIAL SPONDYLOARTHRITIS: A PROSPECTIVE CASE-CONTROL STUDY

R. Reejhsinghani[1], K.M. Brown[2], N.B. Schiller[1], G. Yoon[3], E. Foster[1], L.S. Gensler[3]. *[1]Cardiology, University of California, San Francisco, United States; [2]Cardiology, Kelowna General Hospital, Kelowna, Canada; [3]Rheumatology, University of California, San Francisco, United States*

**Background:** Aortic dilation, aortic insufficiency (AI) and diastolic dysfunction (DD) have been described as complications of Ankylosing Spondylitis (AS), although their prevalence remains uncertain. Newer therapies for Axial Spondyloarthritis (AxSpA) may have further influenced the prevalence of cardiac disease. Prior studies were small and uncontrolled, resulting in controversial recommendations for routine echocardiographic screening of AxSpA patients.
**Objectives:** The objective of our study was to describe the prevalence of structural heart disease (SHD) and DD among a cohort of AxSpA patients matched with a healthy control population.

**Methods:** Prospective transthoracic echocardiograms were performed on 125 AxSpA patients and 56 age-matched controls. Leading edge aortic root (AoR) measurements were made and normalized for body size. Measurements were also taken at the aortic annulus, sino-tubular junction and ascending aorta. DD was graded according to the American Society of Echocardiography guidelines. Chi square tests and Wilcoxan rank sum analyses were used in the univariate analysis. A subgroup analysis was performed in a matched group of 90 AS patients meeting the modified New York criteria and 45 healthy controls.
**Results:** Participants were 68% male with a mean age of 43 ± 12 years. Mean AxSpA disease duration was 18 ± 12 years. mSASSS for the overall AxSpA population was 7.1 ± 14.5 units and was 9.9 ± 16.5 units for the AS population. Mean AoR diameter was 3.29 ± 0.36 cm for cases and 3.24 ± 0.32 cm for controls. There were no differences in linear aortic measurements, AI or DD between groups. The subgroup analysis of AS patients alone did not show differences in any of these outcomes when compared to controls.

Table 1

| Characteristics | AxSpA cases (n=125) | AS cases (n=90) |
|---|---|---|
| Baseline CRP (mg/L), Reference range <6.3 mg/L | 16.2±22.7 | 13.6±14.8 |
| CRP at time of echo (mg/L), Reference range <6.3 mg/L | 5.5±6.5 | 6.12±6.8 |
| Baseline disease activity (ASDAS – CRP) | 2.97±1.3 | 3.09±1.4 |
| Disease activity at time of echo (ASDAS – CRP) | 2.0±0.9 | 1.99±0.9 |
| NSAID therapy | 57% | 46% |
| TNFi therapy | 52% | 56% |

**Conclusions:** AxSpA patients showed no differences in AoR size or AI when compared with healthy controls. While there were differences among individual measurements used to assess diastology, there is no clinically relevant difference in DD between groups. These findings are the first evidence-base to support the recommendations against routine echocardiographic screening in asymptomatic AxSpA patients.

## FRI0435 ABOUT HALF OF THE PATIENTS WITH ANKYLOSING SPONDYLITIS ALREADY HAVE RADIOGRAPHIC CHANGES IN T SPINE AT THE POINT OF DIAGNOSIS; CROSS SECTIONAL STUDY, BY WHOLE SPINE CT

S.-H. Lee[1], J.-Y. Choi[2], R. Song[3], Y.-A. Lee[2], S.-J. Hong[2], H.-I. Yang[3].
*[1]Rheumatology, Hospital at Gandong, Kyung Hee University; [2]Kyung Hee university Hospital; [3]Hospital at Gandong, Kyung Hee University, Seoul, Korea, Republic Of*

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory disease, which destructs spine. After ivnolvement of sacroiliac joint, inflammation usually spreads from lower L spine to C spine. But it is hard to evaluate radiographic changes in T spine due to air in lung by X-ray.
**Objectives:** We performed this study to find out how many patients have radiographic changes in T spine at first visit and if bone spurs of vertebral bodies are associated with radiographic changes in facet joints in spine.
**Methods:** We enrolled the patients who were diagnosed as AS by modified NY criteria in Kyung Hee university hospital at Gangdong in Seoul, South Korea from Mar 2008 to Dec 2015. After diagnosis, we performed a whole spine CT in each patient according to the routine protocol of our clinic to evaluate the radiographic involvement of spine. Total 1,170 patients were enrolled and analyzed. We examined the presence of bone spurs in vertebral bodies (VB) and radiographic changes of facet joints in L and T spine and costovertebral joints (CVJ).
**Results:** Of the 1,170 enrolled patients. 920 were men (79%) and 85% were HLA B27 positive. Incidences of past history of peripheral arthritis and uveitis were 29.0% and 30.6%, respectively. Mean age was 33.0 ± 10.0 years and mean disease duration was 10.5 ± 9.5 years. 34.1% of patients had at least one bone spur and 26.3% had at least one lesion in facet joints in L spine. In T spine, 47. 2% of patients had already at least one bone spur, 28.2% had at least one lesion in facet joints. 32.8% had already at least one lesion in CVJs. Each radiographic change is associated with one another (p=0.00). These all radiographic changes were significantly more frequently observed in the patients with old age and long disease duration at the point of diagnosis (p=0.00). The lesion of CVJs and facet joints in T spine were observed more frequently in male than female significantly (respectively p=0.02, 0.00). 19.2% of the patients had radiographic changes in T spine without in L spine.
**Conclusions:** At the point of diagnosis, many patients already had radiographic changes in T spine. We suggest if radiographic change of T spine is included in radiographic progression score system such as mSASSS, we can more sensitively detect radiographic progression even in a short interval.

## FRI0436 FATIGUE IS ASSOCIATED WITH WORK PRODUCTIVITY IMPAIRMENT IN UK PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSPA): A CROSS-SECTIONAL OBSERVATIONAL STUDY

S. Espahbodi[1], P. Bassett[2], W. Tillett[3], C. Cavill[1], J. Hole[1], M. Freeth[1], A. Thomas[1], R. Sengupta[3,4]. *[1]Research, Royal National Hospital for Rheumatic Diseases, Bath; [2]Statsconsultancy Ltd., 40 Longwood Lane, Amersham, Bucks; [3]Rheumatology, Royal National Hospital for Rheumatic Diseases; [4]University of Bath, Bath, United Kingdom*

**Background:** Many patients with axSpA experience work disability (WD: not working due to axSpA) which is preceded by impairment whilst working (presenteeism), absenteeism, and overall work productivity loss (WPL). Studies addressing these and health-related factors are few, with only one done in a UK sample.
**Objectives:** To determine key factors associated with absenteeism, presenteeism, WPL, and daily activity impairment (other than employed work) in UK patients with axSpA using standardized measures.
**Methods:** In a cross-sectional, observational study, during visits to the Royal National Hospital for Rheumatic Diseases axSpA clinic, 490 patients completed validated questionnaires for: (1) Work productivity using the Work Productivity and Impairment questionnaire (WPAI) which produces 4 measures: absenteeism, presenteeism, WPL and activity impairment; (2) Health-related disease factors using: BASDAI, BASFI, BASMI, Jenkins Sleep scale, Patient Global Assessment (PGA) for disease activity, back pain at night, back pain at any time, EQ-5D for mobility, self-care ability, usual daily activities, pain/discomfort, anxiety/depression, EQ-VAS for Health State Today, FACIT for fatigue in the last week scale, and the Margolis Pain Diagram. Statistics package STATA V. 13.1 was used for analyses. Univariate and multivariate linear and logistic regression were applied to determine associations between WPAI measures and health-related factors.
**Results:** Of 490 patients, 301 (61%) provided WPAI measurements, 261 (53%) were in employment, 76% were male, 87% HLA-B27+, mean (±SD) years (i) age of first symptoms 21.5 (8.8), (ii) age at diagnosis 30.8 (11.7), (iii)disease duration 21.7 (13.0), and 29% were receiving biologics. Mean scores: BASDAI 3.8 (2.2), BASFI 4.0 (2.7), BASMI 3.8 (2.1), Jenkins 13.0 (2.7), PGA 3.9 (2.6), PGA night pain 3.3 (2.6), PGA pain anytime 3.6 (2.6), FACIT 34 (12), EQ-VAS 63 (22), Margolis pain 8.7 (6.9). Mean WPAI scores for absenteeism were=5.1% (19.2), presenteeism=22% (24.3), WPL=23.2% (25.7), activity impairment=34.8% (27.3).

### FRI0437 WHAT PREDICTS ABSENCE OF SPINAL DAMAGE IN PATIENTS WITH SPONDYLOARTHRITIS AFTER PROLONGED FOLLOW UP?

W.P. Maksymowych[1], S. Wichuk[1], P. Chiowchanwisawakit[2], R.G. Lambert[3], S.J. Pedersen[4]. *[1]Medicine, University of Alberta, Edmonton, Canada; [2]Medicine, Mahidol University, Bangkok, Thailand; [3]Radiology, University of Alberta, Edmonton, Canada; [4]Rheumatology, University of Copenhagen, Copenhagen, Denmark*

**Background:** After 20 years of follow up the majority of patients with axial SpA have developed new bone in the spine although disease may remain isolated in the sacroiliac joints (SIJ) without any new bone in the spine. Assessment of these patients may provide new insights into the factors that influence disease progression. A new hypothesis has proposed that MRI can identify a "progressive phenotype" in early SpA characterized by the appearance of fat metaplasia in the SIJ. Fat metaplasia can occur both in subchondral bone and at the site of erosion after resolution of inflammation, this being termed backfill.
**Objectives:** To determine which clinical and MRI lesions in the SIJ are associated with absence of spinal damage after extensive follow up of patients with AS.
**Methods:** In the FORCAST prospective cohort, AS patients (n=431) attending community and academic practices were assessed for clinical and laboratory outcomes every 6 months, radiography every 2 years, and MRI annually. MR scans of the SIJ were assessed by SPARCC SIJ and SSS methods for inflammation and structural features, respectively, by 2 readers and an adjudicator. Absence of spinal damage was pre-specified as no syndesmophytes or ankylosis on cervical and lumbar spine radiographs after ≥10 years from onset of symptoms and for the entire duration of prospective follow up. Patients with and without spinal damage were matched for age and symptom duration and compared by t-test, Mann-Whitney, and Fisher's exact tests. We used univariate and multivariate conditional logistic regression to determine which demographic, clinical, and imaging variables were associated with absence of spinal damage.
**Results:** Mean (SD) duration of symptoms and prospective follow up was 18.0 (7.0) and 2.3 (0.49) years in cases with no damage (n=42) and 17.5 (8.2) and 2.6 (1.4) years in those with damage (n=81). The group with no damage had fewer males (p=0.004), lower CRP (p=0.02), and lower MRI SIJ scores for fat (p=0.03) and ankylosis (p=0.003) while score for SIJ erosion was significantly higher (p=0.02). Definite SIJ ankylosis (SSS score ≥2 by both readers) was evident in 20.7% of cases in the no damage group versus 53.3% of those with damage (p=0.007). Univariate regression indicated that no damage was associated with female sex (p=0.002), lower ASDAS (p=0.048), and lower SSS values for fat (p=0.032), backfill (p=0.014), and ankylosis (p=0.001). Smoking and B27 were not significant. A multivariate logistic regression model that included gender, ASDAS, and MRI SIJ features indicated that lower values for SSS backfill and ankylosis were independently associated with no damage (OR [95%CI]=0.83 [0.69–0.99] and 0.89 [0.82–0.96], respectively). When all definite MRI features (SSS score ≥2 by both readers) were included in the model, definite SIJ ankylosis was significantly less likely in those who did not develop spinal damage (OR [95%CI]=0.24 [0.08–0.70].
**Conclusions:** The absence of radiographic damage in the spine after prolonged duration of symptoms is associated with the lack of fat metaplasia and ankylosis in the SIJ on MRI. This supports the hypothesis that fat metaplasia identifies a progressive phenotype and that its appearance in the SIJ, together with SIJ ankylosis, may predispose to spinal progression.

### FRI0438 DESCRIPTION AND PREVALENCE OF SPONDYLOARTHRITIS IN A LARGE COHORT OF PATIENTS WITH ANTERIOR UVEITIS: THE SENTINEL INTERDISCIPLINARY COLLABORATIVE PROJECT

X. Juanola[1], E. Loza[2], M. Cordero-Coma[3] on behalf of the SENTINEL Study Group: María Aparicio Espinar, Juan Jose Aznar Sanchez, Clemencia Torrón Fernandez, Oscar Ruiz Moreno, Jesus Leciñena Bueno, Fernando Jiménez Zorzo, Carmen Sánchez-Garrido Jiménez, Marcelino Revenga Martínez, Mª Yolanda Cordero Pérez. *[1]Rheumatology Unit, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona; [2]INMUSC, Madrid; [3]Uveitis Unit, University Hospital of León, León, Spain*

**Background:** While the diagnosis of many SpA is usually made in rheumatology units based on other clinical findings as the inflammatory low back pain or arthritis (1,2), it has been described that there could be patients with AU with an undiagnosed SpA (3). Therefore, an early recognition of a possible SpA in patients attending the ophthalmology units with uveitis is vital in order to improve these patient's management
**Objectives:** To describe and analyse the prevalence of spondyloarthritis (SpA) in patients with anterior uveitis (AU).
**Methods:** In a multicentric prospective study, consecutive patients with AU HLA-B27 positive or HLA-B27 negative with more than one episode of AU separated by at least 3 months were selected and evaluated by an ophthalmologist and a rheumatologist following a pre-defined visits schedule. Patients with previous diagnosis of SpA were excluded. Sociodemographic and clinical variables including the diagnosis of SpA according to ASAS criteria and an exhaustive ophtalmological examination were collected. Baseline descriptive, bivariate and concordance analyses were performed.
