## Subscription Information

ARD is published monthly; subscribers receive all supplements
ISSN 0003-4967 (print); 1468-2060 (online)

### Institutional Rates 2016

**Print**
£894; US$1744; €1207

**Online**
Site licences are priced on FTE basis and allow access by the whole institution. Details available online at http://group.bmj.com/group/subs-sales or contact the Subscription Manager in the UK (see above right)

### Personal Rates 2016

**Print** (includes online access at no additional cost)
£368; US$718; €497

**Online only**
£156; US$305; €211

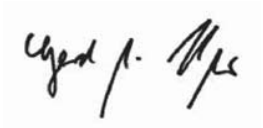
**Eular congress delegates**
Delegates to the annual Eular congress receive a free 12 month print subscription

Personal print or online only and institutional print subscriptions may be purchased online at http://group.bmj.com/group/subs-sales (payment by Visa/Mastercard only)

Residents of some EC countries must pay VAT; for details, call us or visit www.bmj.com/subscriptions/vatandpaymentinfo.dtl

# Welcome Message

Dear Colleagues,



Welcome to this EULAR Annual European Congress of Rheumatology in London!

The annual EULAR congresses which began in 2000 are today a major event in the calendar of world rheumatology. This meeting will again provide a unique occasion for the exchange of scientific and clinical information. It will facilitate interaction between patients, medical doctors, scientists, health professionals and professionals representing the pharmaceutical industry both from Europe and from around the world. You are certainly aware that participating in the congress is just one element of the annual educational package provided by EULAR. Thus in addition, the participants will have the opportunity to watch virtually all oral presentations through electronic capture and will be provided with a complimentary one-year access to the newest developments and publications in the field of RMDs.

EULAR has grown rapidly in terms of the number of participants and the quality of the submissions. Thus, more than 4'000 abstracts have been submitted to this congress in London and 199 sessions and poster tours are offered. This enormous success reflects the ever increasing interest in rheumatic and musculoskeletal diseases (RMDs) which has been seen in most societies and is now recognized also by the EU. It also reflects the availability of increased information on the size, burden and cost of these diseases for society, and a significantly improved ability to diagnose and treat them. The incorporation of health professional and patient organisations within EULAR has been a considerable stimulus for these advances.

The EULAR Congress 2016 in London will once again provide a wide range of topics including clinical innovations, clinical translational and basic science. In addition there will be significant contributions made by People with Arthritis and Rheumatism (PARE), by Health Professionals in Rheumatology (HPR) and by the health care industry. The core science and central activity of the congress will be the poster presentations and poster tours with their highly interactive exchanges between participants. The London meeting will further promote the reputation of the EULAR Congress as the most innovative and informative venue for clinical research for the practising physician. The EULAR EMEUNET organisation of young rheumatologists also hopes to attract young colleagues to the meeting and will disseminate the message that rheumatology is one of the most attractive and successful disciplines of medicine.

The city of London needs little introduction. "Tired of London, tired of life" is a quotation previously used for the 2011 EULAR congress in London, and it is even more reinforced by the recent accolade of "world city", and indicates how ideal a venue this is for an international meeting such as the EULAR Congress which has truly become a world congress. The elegance of London with its architecture, galleries, theatres and ambience should again provide an excellent background for clinical exchanges, international collaborations and renewal of friendships. It is our great pleasure and a real joy in welcoming medical doctors, patients, health professionals and representatives of the pharmaceutical industry and hope their stay in London will be delightful, informative, and educational.

GERD R. BURMESTER
*President of EULAR*

## Speakers Abstracts

### Speaker Presentations

**Wednesday, 8 June 2016**

SP0001–SP0002 WIN session 1 ..... 2
SP0003–SP0005 Catastrophizing pain in RA ..... 2
SP0006 Axial spondyloarthritis and psoriatic arthritis: emerging pathways ..... 3
SP0007 HOT session 1 ..... 3
SP0008–SP0011 Balancing benefits and risk of glucocorticoids; a challenge for implementation ..... 3
SP0012–SP0013 What CVD outcomes to use in clinical rheumatological practice? ..... 5
SP0014–SP0017 Different perspectives on pain in osteoarthritis ..... 5
SP0018–SP0020 Epigenetics solving the OA puzzle ..... 6
SP0021–SP0022 Muscle biology & inflammation ..... 7
SP0023–SP0025 Lessons from the children (monogenic causes of autoimmunity) ..... 7
SP0026–SP0027 ABC of statistics ..... 8
SP0028–SP0031 Capillaroscopy I ..... 8
SP0032–SP0033 Optimizing treatment and patient care through precision medicine: a threat or an opportunity for patients and patient organisations? ..... 9
SP0034–SP0036 EULAR projects in Musculoskeletal Imaging ..... 10
SP0037 Difficult osteoporosis ..... 10
SP0038 Clinical relevance of immunogenicity and therapeutic drug monitoring ..... 11
SP0039–SP0040 Hepatitis C and rheumatology: the impact of new therapies ..... 11
SP0041–SP0043 Outcome measures in clinical practice in gout and CPPD. The use of the new EULAR guidelines ..... 11
SP0044–SP0045 Hand osteoarthritis: state of the art and future perspectives ..... 12
SP0046–SP0047 Chronobiology of the immune reponse ..... 13
SP0048–SP0050 Nanomedicine in rheumatology ..... 13
SP0051–SP0052 HOT session 2 ..... 14
SP0053–SP0056 Beyond EMEUNET: development of a European-wide network of young clinicians from different specialties focusing on inflammatory diseases ..... 14
SP0057 Data visualisation: tables and graphs for publication and presentation I ..... 15
SP0058–SP0060 Ultrasound basic I ..... 16
SP0061 Patient organisations in action ..... 16
SP0062–SP0063 Hot topics in paediatric rheumatology ..... 16

**Thursday, 9 June 2016**

SP0064–SP0065 Plasma cells as key players and therapeutic target in rheumatic diseases ..... 17
SP0066–SP0068 Global year against joint pain ..... 17
SP0069–SP0070 HOT session 4 ..... 18
SP0071–SP0073 Designing solutions to support young people to address the challenges of living with a rheumatic or musculoskeletal disease ..... 18
SP0074 WIN session 3 ..... 19
SP0075–SP0076 Advancements in the imaging of PsA ..... 19
SP0077–SP0079 When and how to treat Raynaud's phenomenon and related complications ..... 20
SP0080–SP0081 Role of new imaging techniques as RMD outcomes ..... 20
SP0082–SP0085 "Fewer words - more action" - tailored care for men with rheumatic diseases? ..... 20
SP0086 Recent advances in our understanding of macrophage biology ..... 21

| SP0196 | Adiposity as a driver of arthritis through inflammatory mechanisms | 47 |
| SP0197–SP0200 | EULAR educational offer | 47 |
| SP0201–SP0203 | There is more than drugs | 48 |

## Scientific Abstracts

### Oral Presentations

**Wednesday, 8 June 2016**

| | | |
|---|---|---|
| OP0001–OP0002 | Axial spondyloarthritis and psoriatic arthritis: emerging pathways | 52 |
| OP0003 | Balancing benefits and risk of glucocorticoids; a challenge for implementation | 53 |
| OP0004–OP0005 | What CVD outcomes to use in clinical rheumatological practice? | 54 |
| OP0006-HPR | Different perspectives on pain in osteoarthritis | 55 |
| OP0007–OP0008 | Epigenetics solving the OA puzzle | 55 |
| OP0009–OP0010 | Muscle biology & inflammation | 56 |
| OP0011–OP0012 | Lessons from the children (monogenic causes of autoimmunity) | 56 |
| OP0013 | ABC of statistics | 57 |
| OP0014-PARE | Optimizing treatment and patient care through precision medicine: a threat or an opportunity for patients and patient organisations? | 58 |
| OP0015–OP0016 | Clinical relevance of immunogenicity and therapeutic drug monitoring | 58 |
| OP0017–OP0018 | Outcome measures in clinical practice in gout and CPPD. The use of the new EULAR guidelines | 59 |
| OP0019-HPR | Hand osteoarthritis: state of the art and future perspectives | 60 |
| OP0020–OP0021-HPR | Chronobiology of the immune reponse | 60 |
| OP0022–OP0023 | Nanomedicine in rheumatology | 61 |
| OP0024-PARE–OP0025-PARE | Patient organisations in action | 61 |

**Thursday, 9 June 2016**

| | | |
|---|---|---|
| OP0026–OP0027 | Plasma cells as key players and therapeutic target in rheumatic disaeses | 62 |
| OP0028–OP0029 | Global year against joint pain | 63 |
| OP0030–OP0038 | Diagnosis and management of SSc | 64 |
| OP0039–LB0001 | Advances in SLE therapeutics | 68 |
| OP0159–OP0166 | New pathways to treatment | 116 |
| OP0053–LB0002 | Vasculitis | 74 |
| OP0060-HPR–OP0067-HPR | Developing evidence-based non-pharmacological care | 77 |
| OP0068–OP0075 | Cartilage, bone, synovium | 80 |
| OP0076–OP0083 | SpA and PsA basic and translational research | 83 |
| OP0084–OP0091 | SpA and PsA clinical | 86 |
| OP0092–OP0099 | New horizons in osteoarthiritis | 89 |
| OP0100–OP0107 | Clinical osteoporosis: new insights | 92 |
| OP0175–OP0182 | Prognosis and outcome in RA | 122 |
| OP0116-PARE–OP0117-PARE | Designing solutions to support young people to address the challenges of living with a rheumatic or musculoskeletal disease | 99 |
| OP0118–OP0125 | New insights into imaging | 100 |
| OP0126–OP0127 | Advancements in the imaging of PsA | 103 |
| OP0128–OP0129 | When and how to treat Raynaud's phenomenon and related complications | 104 |
| OP0130–OP0131 | Role of new imaging techniques as RMD outcomes | 105 |
| OP0132-HPR | "Fewer words - more action" - tailored care for men with rheumatic diseases? | 106 |
| OP0133–OP0134 | Recent advances in our understanding of macrophage biology | 106 |
| OP0135 | Lubricants: potential as osteoarthritis treatment? | 107 |
| OP0136–OP0137 | Extraarticular complications of JIA | 107 |
| OP0138 | The elephant in the room: how to avoid biases in research? | 108 |
| OP0139-PARE–OP0140-PARE | Digital applications for the benefit of the patient | 108 |

| | | |
|---|---|---|
| OP0141–OP0142 | Optimization of MTX in RA treatment | 109 |
| OP0143–OP0144 | Joint replacement in OA: friend or foe? | 110 |
| OP0145–OP0146 | How to identify and follow patients with inflammatory back pain? | 111 |
| OP0147-HPR | Physical activity assessment - what do we know, what do we do, how does it work? | 112 |
| OP0148 | How cell death shapes immunity and tolerance | 112 |
| OP0149–OP0150 | "Smoke a joint to protect the joint". Cannabidoids & neuropeptides in pain and inflammation | 112 |
| OP0151 | Teaching clinical skills | 113 |
| OP0152-PARE–OP0153-PARE | What is done for people with rare diseases? Can we do more? | 113 |
| OP0154-HPR | The Health Professionals' approach to pain management in inflammatory arthritis and osteoarthritis | 114 |

**Friday, 10 June 2016**

| | | |
|---|---|---|
| OP0155–OP0156 | News from kinase inhibitors | 114 |
| OP0157–OP0158 | Crystal arthritis | 115 |
| OP0045–OP0052 | Scleroderma, myositis and related conditions | 71 |
| OP0167–OP0174 | Epidemiology of RMDs | 119 |
| OP0108–OP0115 | Expanding therapeutic options in spondyloarthritis | 95 |
| OP0183–OP0190 | SLE, Sjögren's and APS: clinical aspects (other than treatment) | 126 |
| OP0191-HPR–OP0198-HPR | Shared decision making | 129 |
| OP0199–OP0206 | Novel insights into B and T cell immunity in rheumatic disease | 132 |
| OP0207–OP0214 | An inflammatory update! | 135 |
| OP0215–OP0222 | Advances in paediatric rheumatology | 138 |
| OP0223–OP0230 | Developments in the treatment of RA | 141 |
| OP0231–OP0238 | Emerging concepts in genomics & genetics | 145 |
| OP0239–OP0246 | Novel clues solved in RA development | 148 |
| OP0247-PARE–OP0254-PARE | PARE abstract session | 152 |
| OP0255–OP0262 | Cormobidities | 154 |
| OP0263–OP0264 | Biomarkers: powerful or powderpuff? | 158 |
| OP0265–OP0266 | The role of nuclear medicine in rheumatology | 158 |
| OP0267-HPR–OP0268 | PROMs/PROs in rheumatological research - time for a critical appraisal? | 159 |
| OP0269-HPR | Collaboration for success. User-centred design for improvement of health services | 160 |
| OP0270–OP0271 | ER stress & rheumatic disease | 160 |
| OP0272–OP0273 | Joint EULAR - EFIS session: Do stromal cells house and cure immune cells? | 161 |
| OP0274–OP0275 | Role of imaging in childhood-onset rheumatic diseases | 162 |
| OP0276–OP0277-PARE | Physician-patient relationship in the era of interactive media | 162 |
| OP0278-PARE | It's in your hands | 163 |
| OP0279 | The EULAR School of Rheumatology - a new era of education | 163 |
| OP0280–OP0281 | Advances in large vessel vasculitis | 164 |
| OP0282–OP0283 | When and how to diagnose and treat vitamin D deficiency? | 165 |
| OP0284–OP0285 | Data harmonization across (rheumatoid arthritis) clinical cohorts and registers | 165 |
| OP0286-HPR | Telemedicine and e-health in community care | 166 |
| OP0287 | Inflammasome as therapeutic target in inflammatory diseases | 166 |
| OP0289–OP0290 | Potential targets in inflammatory fibrotic conditions in SSc | 167 |

**Saturday, 11 June 2016**

| | | |
|---|---|---|
| OP0291 | SLE: What will it be and how will it be treated 5 years from now | 168 |
| OP0292–OP0293 | Clinical outcomes for PMR/GCA | 168 |
| OP0294-HPR–OP0295-HPR | Getting active against rheumatoid arthritis fatigue | 169 |
| OP0296–OP0297 | Endothelial to mesenchymal transition and angiogenesis as driving mechanisms in systemic sclerosis. | 170 |
| OP0298–OP0299 | Cell-cell interaction in joint inflammation | 170 |
| OP0300–OP0301 | Transition of care | 171 |
| OP0302-PARE–OP0303-PARE | New approaches to understanding and managing chronic musculoskeletal pain | 172 |
| OP0304–OP0305 | Picking knowledge from other medical disciplines for SSc | 172 |
| OP0306 | Paget's and other rare bone diseases | 173 |
| OP0307 | Analytical issues of complex databases | 174 |
| OP0308-HPR | Intimate life and sexual relations in RA | 174 |

| | | |
|---|---|---|
| OP0309–OP0310 | Bone and heart: common molecular mechanisms in osteoporosis and atherosclerosis | 174 |
| OP0311–OP0312 | Adiposity as a driver of arthritis through inflammatory mechanisms | 175 |
| OP0313-PARE–OP0314-PARE | There is more than drugs | 176 |

## Late Breaking Abstracts

**Thursday, 9 June 2016**

| | | |
|---|---|---|
| LB0001 | Advances in SLE therapeutics | 70 |
| LB0002 | Vasculitis | 77 |

## Poster Presentations

**Thursday, 9 June 2016**

***Guided Poster Tours***

| | | | |
|---|---|---|---|
| T1: | THU0001–THU0010 | Immunity in rheumatic diseases | 178 |
| T2: | THU0016–THU0023 | Cartilage, bone, synovium | 183 |
| T3: | THU0029–THU0036 | Prognosis and outcome in RA | 187 |
| T4: | THU0073–THU0082 | Comorbidities update 2016, part 1 | 205 |
| T5: | THU0165–THU0173 | RA treatments - non-biological, small molecules | 243 |
| T6: | THU0213–THU0222 | Arthritis in childhood | 264 |
| T7: | THU0240–THU0251 | Walk through new parthways, biomarkers and potential treatments in SLE and Sjögren's | 275 |
| T8: | THU0363–THU0372 | SpA and PsA basic an translational research | 318 |
| T9: | THU0374–THU0383 | Axial SpA - clinical aspects | 322 |
| T10: | THU0418–THU0427 | Psoriatic arthritis | 340 |
| T11: | THU0456–THU0465 | How to treat osteoporosis in patients with elevated disease | 357 |
| T12: | THU0490–THU0499 | Crystal and metabolic bone diseases; bone diseases other than osteoporosis | 369 |
| T13: | THU0541–THU0550 | Clinical aspects of fibromyalgia | 388 |
| T14: | THU0593–THU0602 | Outcome measures of RMDs | 406 |
| T15: | PARE0001–PARE0008 | PARE Poster tour I | 1320 |

***Posters***

| | | |
|---|---|---|
| THU0001–THU0015 | Adaptive immunity (T cells and B cells) in rheumatic diseases | 178 |
| THU0016–THU0028 | Cartilage, synovium and osteoimmunology | 183 |
| THU0029–THU0072 | Rheumatoid arthritis - prognosis, predictors and outcome | 187 |
| THU0073–THU0119 | Rheumatoid arthritis - comorbidity and clinical aspects | 205 |
| THU0120–THU0164 | Rheumatoid arthritis - anti-TNF therapy | 223 |
| THU0165–THU0211 | Rheumatoid arthritis - non-biologic treatment and small molecules | 243 |

## WIN session 1

### SP0001 WHAT IS NEW IN VASCULITIS?

C.G. Kallenberg. *Dept. of Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, Netherlands*

The vasculitides comprise a heterogeneous group of disorders characterized by inflammation of blood vessels. Definitions of these conditions have been provided by the Chapel Hill Consensus Conference (updated in 2012). A large prospective study defining and validating diagnostic and classification criteria for the vasculitides (DCVAS, ClinicalTrials.gov NCT01066208) is underway.
In the ANCA-associated vasculitides morbidity and mortality is still very high, in the initial phase due to disease activity and infections, in the late phase due to cardiovascular disease and malignancies. Use of high dose corticosteroids and cyclophosphamide (CYC) plays a major role in morbidity and mortality. Recent studies have shown that CYC can be replaced by rituximab (RTX), both for induction and maintenance treatment. Phase 2 data suggests that prednisone can be replaced by an oral complement C5a-receptor inhibitor. Defining risk factors for relapse is important in order to select patients for long-term maintenance treatment. Some biomarkers for relapsing disease have been defined, such as PR3-ANCA vs. MPO-ANCA, rises in PR3-ANCA in renal disease and pulmonary hemorrhage, HLA-DPB1, and others, but prospective studies should demonstrate their clinical value with respect to level and duration of maintenance treatment.
In giant cell arteritis (GCA) aortitis has been recognized to occur in one out of three patients although being less severe in GCA than in isolated aortitis. Color duplex ultrasonography is valuable for a diagnosis of GCA, is comparable to MRI, but its use for selecting the site of biopsy did not improve the sensitivity of a temporal artery biopsy for a diagnosis of GCA. FDG-PET is useful as well for assessing active vascular inflammation in GCA and Takayasu arteritis but objective cut-off values for activity should still be defined. Levels of BAFF and Il-6 in serum are biomarkers for disease activity in GCA and PMR. In this respect, a phase 2 trial with tocilizumab in GCA has been succesful in showing that tocilizumab together with prednisone resulted in a higher rate of complete remission at a dose of 0.1 mg/kg/d at 12 weeks and a higher rate of relapse free remission at 52 weeks compared to prednisone alone. EULAR/ACR recommendations for the management of PMR have been established last year.
New developments in the other vasculitides will be discussed as well.

### SP0002 SYSTEMIC SCLEROSIS

J. Varga. *Northwestern Scleroderma Program, Feinberg School of Medicine, Evanston, United States*

Scleroderma remains a challenging disease with no effective therapy. Obstacles to development of effective therapies include the complex, multifactorial pathogenesis, lack of clear etiologic agent, uncertain role of genetic risks; patient-to-patient variability in clinical manifestations and disease outcomes; variable rates of disease progression in different organs in the same individual; lack of validated biomarkers, and lack of consensus regarding optimal clinical trial design. Each of these obstacles is being addressed by current research, and significant progress is being achieved. A large number of plausible drug targets have been identified and are being validated in preclinical models. Innovative clinical trial designs and increasingly more robust outcome measures allow more effective drug testing. Molecular omics approaches further facilitate patient stratification, and matching drugs to patients in an increasingly personalized precision approach to management.

## Catastrophizing pain in RA

### SP0003 THREE RA PATIENTS WITH PAIN CATASTROPHIZING

A. Mathiessen. *Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

Rheumatoid arthritis (RA) is a chronic inflammatory joint disease causing pain and disability. Discordance between inflammatory activity and pain in RA has earlier been reported, and one important psychosocial factor that influences the experience of pain is *catastrophizing*. Pain catastrophizing involves both cognitive and emotional components of pain perception, and leads the patient to expect the worst. Several studies have shown that pain catastrophizing is important for the pain experience in RA, with no clear correlation to objective clinical parameters.
Patients' perspective, including pain, patient global assessment and fatigue, has increasingly been recognized as an outcome measure for therapies. Catastrophizing may therefor influence disease activity scores in RA and also measurements of response to biologic disease modifying drugs (bDMARD).
Three patients with RA starting bDMARD will we presented through one-year follow-up data from the ULRABIT cohort. The patients reveal different pain catastrophizing levels during the study, and we will explore the impact of catastrophizing on subjective and composite scores, in contrast to objective inflammatory variables such as CRP, swollen joint count or ultrasound synovitis. Further, we will discuss the impact of pain catastrophizing on DAS28 remission, demonstrating the difficulties in reaching remission according to composite scores if there are increased levels of pain catastrophizing.
Patient 1: high level of pain catastrophizing both at baseline and at 12 months.
Patient 2: pain catastrophizer at baseline, but not at 12 months.
Patient 3: neither pain catastrophizer at baseline nor at 12 months.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6295

### SP0004 THE IMPACT OF CATASTROPHIZING IN OBTAINING REMISSION IN RA

H.B. Hammer. *Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

Pain catastrophizing is conceptualized as a negative cognitive–affective response to anticipated or actual pain and has been associated with a number of important pain-related outcomes. Catastrophizing is defined as a tendency to magnify or exaggerate the threat value or seriousness of pain sensations, and tendency to pain-related worry and fear, coupled with an inability to divert attention away from pain.
A Coping Strategies Questionnaire (CSQ) was developed and later a Pain Catastrophizing Scale (PCS). Factor analytic work indicated that the PCS yielded the three second-order factors helplessness, rumination and magnification. Thus pain catastrophizing evaluated by the questionnaires is characterized by the tendency to magnify the threat value of pain stimulus and to feel helpless in the context of pain, and by a relative inability to inhibit pain-related thoughts in anticipation of, during or following a painful encounter [1].
Pain catastrophizing has most typically been conceptualized and assessed as a dispositional variable. However, maladaptive thoughts are latent and in need of a cue to become manifest. Enough evidence has accumulated to suggest that high levels of catastrophizing about pain should be considered a "risk marker" for adverse immediate and long-term pain-related outcomes. Moreover, the apparent role of catastrophizing in contributing to the effectiveness of a variety of pain treatments suggests that it may become a key target of many chronic pain management programs.
Pain is the most common and disabling symptom of rheumatoid arthritis (RA). Although physicians often assume that inflammation is the stimulus for pain, many RA patients continue to have pain despite adequately suppressed inflammation. A review on pain catastrophizing [2] found that it is positively related, in both cross-sectional and prospective studies across different musculoskeletal conditions, to the reported severity of pain, affective distress, muscle and joint tenderness, pain-related disability, poor outcomes of pain treatment, and, potentially, to inflammatory disease activity. Moreover, these associations generally persist after controlling for symptoms of depression. There appear to be multiple mechanisms by which catastrophizing exerts its harmful effects, from maladaptive influences on the social environment to direct amplification of the central nervous system's processing of pain.
Several prospective studies have illustrated the longitudinal association of catastrophizing with pain in RA. In daily diary studies, patients with RA who exhibited greater catastrophizing reported more day-to-day pain and attention to pain than low catastrophizers. Findings from another prospective study suggested that baseline catastrophizing scores predicted enhanced pain and depression in patients with RA at 1-year follow-up. Catastrophizing may also influence the success of pain-related treatments in patients with musculoskeletal disease.
Our group found the level of pain catastrophizing to be highly associated to all patient's reported outcomes (joint pain VAS, patient's global VAS, MHAQ, tender joints) as well as composite scores (DAS28, SDAI, CDAI) in contrast to no associations with the more objective assessments (swollen joints, laboratory and ultrasound assessments) in established RA patients starting bDMARD [3]. This may have important consequences regarding the evaluation of disease activity of patients with established.
We also found that the level of pain catastrophizing decreased during the one-year study, indicating that pain catastrophizing may be influenced by the clinical

treatment including both psychosocial and medical factors. In addition, patients shifting from being pain catastrophizers to not being pain catastrophizers after one year, showed significantly lower levels of patient's reported outcomes than patients staying pain catastrophizers, in spite of no differences in objective measures of disease activity.
Thus, pain catastrophizing is a critically important variable in understanding the experience of pain in rheumatologic disorders as well as other chronic pain conditions. It is important to be aware of the level of pain catastrophizing in the evaluation of medical treatment of patients with different inflammatory rheumatic diseases.

### SP0005 THE PAINDETECT QUESTIONNAIRE USED AS A CLINICAL TOOL IN PATIENTS WITH ARTHRITIS

K. Amris on behalf of S. Rifbjerg-Madsen. *The Parker Institute, Copenhagen University Hospital Bispebjerg and Frederiksberg, Frederiksberg, Denmark*

Emerging evidence suggests that pain might be more effectively classified and treated according to the mechanisms underlying the onset and/or the maintenance of pain. Multiple mechanisms that can produce pain have been identified, including tissue injury and inflammation (inflammatory pain), damage to the nervous system (neuropathic pain), and abnormal responsiveness or function of the central nervous system (central sensitization, dysfunction of descending pain modulating systems). Central pain mechanisms may play an important role in rheumatic diseases, traditionally considered peripheral inflammatory entities. Inflammation sensitizes polymodal nociceptors. This peripheral sensitization induces hyperexcitability of nociceptive neurons in the central nervous system (central sensitization) and the two together generate the features of pathological pain, allodynia and hyperalgesia, confined to the inflamed tissues. Increased responsiveness of peripheral and central neurons (pain hypersensitivity) in the presence of tissue injury and inflammation is a normal response (neuroplasticity). As a rule, these sensitization phenomena extinguish themselves as the tissue heals and inflammation subsides. However, persistent pain is common in patients with inflammatory joint disorders and the key question is whether these neuroplastic changes persists in subsets of patients and leads to chronic pain states in which pain is no longer coupled to the presence of ongoing peripheral inflammation. If central pain mechanisms do play a significant role in pain processing and persistence of pain in subgroups of patients, strategies for managing pain in addition to inflammatory disease suppression may be required. Furthermore, in these patients, persistent pain hypersensitivity may lead to continuous high reports of tender joints and poor global health and pain leaving the physician with the clinical dilemma that patient reported outcomes and composite disease activity scores do not correspond to the objective level of inflammatory activity.
Simple methods assisting identification of underlying pain mechanisms in the clinical care of rheumatologic patients are therefore needed. The painDETECT Questionnaire (PDQ) is a patient administered screening questionnaire originally developed to determine the likelihood of a predominant neuropathic pain component being present. The questionnaire comprises 7 weighted somatosensory symptom and sign items and 2 items relating to the spatial (radiating) and temporal characteristics of the individual pain pattern. Although developed as a screening questionnaire for neuropathic pain, the PDQ has increasingly been used to assess neuropathic pain features as a proxy of central pain mechanisms in, for example, patients with osteoarthritis and fibromyalgia. Recently, the PDQ has also been introduced in studies assessing pain mechanisms in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA).
The clinical utility of the PDQ in patients with arthritis will be covered based on patient cases, registry data and clinical studies. The prevalence and description of PDQ-derived pain phenotypes and the prognostic value thereof will be discussed.

## Axial spondyloarthritis and psoriatic arthritis: emerging pathways

### SP0006 THE IL-17 PATHWAY IN THE PATHOGENESIS OF SPA: FOCUS ON STRUCTURAL DAMAGE

D. Baeten. *Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands*

The IL-17 pathway is now firmly established to play a central role in the pathogenesis of axial and peripheral SpA. The evidence from genetics, functional studies, experimental models, and human expression analysis has been confirmed by phase III clinical trials with anti-IL17A antibodies in ankylosing spondylitis (AS) and psoriatic arthritis (PsA) showing a profound suppression of signs and symptoms of inflammation. Interestingly, these trials also showed a suppression of articular destruction in PsA and low mSASSS progression rates in AS. A key scientific and clinical question is thus how and to what extend the IL-17 pathway contributes to structural damage in SpA.
The role of IL-17A in driving osteoclast maturation and activation is well understood. Its potential role in new bone formation, however, remains much more controversial. Recent animal experiments indicate that IL-17A may suppress osteoblast activity and new bone formation by inhibition of Wnt signaling. In contrast, however, work in the HLA-B27 tg rat model showed that IL-17A inhibition halts pathological axial and peripheral osteoproliferation. Albeit this may be an indirect effect related to suppression of inflammation, bone formation experiments with human cells indicate a direct osteoblast-promoting effect of IL-17A. This concept is further supported by recent studies in bone fracture models.
The differential effects of IL-17 family members on bone formation illustrates well that the functional outcome of cytokine signaling is highly dependent on the exact cellular and immunological context in which it is occurring, with important difference between mice and humans. Further translational studies in human patients are needed to establish whether IL-17 blockade may not only suppress inflammation but also halt both catabolic and anabolic aspects of structural damage in human SpA.

## HOT session 1

### SP0007 IMAGING IN DIAGNOSIS: HOW TO DO

M. Østergaard. *Copenhagen Center for Arthritis Research, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark*

This talk reviews the current knowledge on how to use imaging in clinical practice in the diagnostic process, when peripheral or axial inflammatory diseases, such as rheumatoid arthritis, psoriatic arthritis, axial spondyloarthritis, ankylosing spondylitis or gout, are suspected. Conventional radiography, magnetic resonance imaging (MRI), ultrasonography, computed tomography (CT), dual-energy CT and optical imaging will be addressed, as will international recommendations and criteria published by European League of Rheumatology (EULAR), American College of Rheumatology (ACR), The Assessment of SpondyloArthritis international Society (ASAS).
The main focus will be how to do in current clinical practice. However, the talk will also briefly address recent and upcoming advances, which are likely to improve our routine clinical practice with the coming few years.

## Balancing benefits and risk of glucocorticoids; a challenge for implementation

### SP0008 UNDER WHAT CONDITIONS MAY LONG-TERM GLUCOCORTICOIDS HAVE A GOOD BENEFIT-RISK RATIO?

F. Buttgereit. *Department of Rheumatology and Clinical Immunology, Charité University Medicine Berlin, Berlin, Germany*

Although there is convincing evidence for the beneficial effects of glucocorticoids at low dosages to treat rheumatoid arthritis and other rheumatic diseases, the potential harms lead patients and physicians to be grouped as glucocorticoid "supporters", "opponents" or "neutrals" (i.e. people not favouring any pro or con position, perhaps the majority). In detail, patients are usually aware of both benefits and risks of glucocorticoid therapy. There is, however, sometimes even a certain imbalance favouring the risks over the benefits. This may be reflected in serious concerns about adverse effects and sometimes even refusal to take

glucocorticoid treatment which hinders optimal treatment. Also with regard to medical doctors, nobody really questions the efficacy of these drugs, but the splitting up into the mentioned groups is primarily driven by safety concerns. And indeed, every group has their good arguments.
To approach this problem, a EULAR Task Force was convened in order to achieve consensus on specific conditions where long-term glucocorticoid therapy has an acceptably low risk of harm in the treatment of chronic inflammatory rheumatic diseases (Strehl et al., Ann Rheum Dis, 2016). After a systematic literature search, the evidence on the four most worrisome adverse effects of glucocorticoid therapy (osteoporosis, hyperglycaemia/diabetes mellitus, cardiovascular diseases, and infections) was critically reviewed. Robust evidence on the risk of harm of long-term glucocorticoid therapy was often lacking since relevant study results were often either missing, contradictory, or at a high risk of bias. The group agreed that the risk of harm is low for the majority of patients at long-term dosages of $\leq$5mg prednisone equivalent per day, whereas at dosages of $>$10mg/d the risk of harm is elevated. At dosages between $>$5 and $\leq$10mg/d, patient-specific characteristics including protective and/or risk factors need consideration when estimating the risk of harm.
In conclusion, the level of harm of glucocorticoids depends on both dose and patient-specific parameters. General, disease and glucocorticoid associated risk factors but also protective factors like a healthy lifestyle should be taken into account when evaluating the actual and future risk.

## SP0009 PATIENTS' VIEW ON THE EULAR RECOMMENDATIONS

N. Caeyers. *ReumaNet vzw, Mol, Belgium*

The use of glucocorticoids has always had a negative connotation among patients. Within the general public the beliefs still stand that the side effects cause more harm than that this medication is helping the patient. Pressure from the environment also keeps people away from the treatment with GC, as well as confrontation with visible side effects.
But not only patients, also some health professionals tend to believe GC are more harmful than good. They are especially reluctant to prescribe high doses, although for some conditions this could be lifesaving.
Patients often do a Google search on the internet when prescribed new medication. Reading these awful stories, having doubtful information and the pressure from their peers and consulting a doctor who is not convinced of the benefits of GC, might make them refuse to start treatment.
The EULAR recommendations on the use of GC can help change this perception among patients' and clinicians' communities. These recommendations are now available in a lay version which means also people with a non-medical background can read and understand the important messages. To change the view of patients, but also GP's and other health care professionals, it would be worthwhile to spread this information. Patient and scientific organisations can play an important role in the implementation.
In Flanders, we have already made the translation and put the lay version on the website, together with the original manuscript. Some quotes of people who have read the recommendations show these guidelines are also valuable for patients.
*"Finally, this is medical information that I can understand! This is useful for me"*
*"These recommendations give information in a clear and comprehensive way. They allow me to contribute in the process to get the best possible care for me. I can now make well-informed decisions and can ask more direct questions to my rheumatologist."*
*"It is nice to know patients were involved in developing these recommendations. This means also our concerns were heard."*
This lecture will feature results of a survey among Flemish and Dutch patients about their view on GC as well as their ideas to use lay versions of scientific publications.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6279

## SP0010 CAN WE CHANGE PERCEPTIONS ON THE USE OF GLUCOCORTICOIDS?

M. de Wit[1,2]. [1]*Standing Committee of People with Arthritis/Rheumatism in Europe (PARE), EULAR, Zurich, Switzerland;* [2]*Medical Humanities, VU University Medical Centre, Amsterdam, Netherlands*

Glucocorticoids have a bad reputation. not only among patients but also among health professionals and the general public. It makes that the same scientific data can be interpreted differently and leads to recommendations that are seen as arbitrary. The lack of consensus confuses patients who receive different messages when prednisolon is prescribed and it hampers an effective implementation of recommendations in clinical practice. The result is that patients are not optimally informed and educated about the real benefits and risks of the treatment. It can lead to non-adherence, under-treatment, over-treatment, the use of expensive medicines and ultimately to suboptimal disease outcomes.
With the new EULAR consensus document the first hurdle of controversial recommendations has been tackled. This document paves the way to a better education of patients, health professionals and general public. However, the key messages are difficult to understand and require an effort of all involved to develop an innovative approach to communicate the complex interplay between disease activity and the benefits and risks of glucocorticoid use to patients. The first step is to disseminate the recommendations in a tailored manner to the different audiences. Patients require other kinds of information and provided in other formats than health professionals or the general public. Examples will be presented during this session.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6372

## SP0011 LONG-TERM GLUCOCORTICOID USE AND THE SKIN

J.W. Jacobs. *University Medical Center Utrecht, Utrecht, Netherlands*

Glucocorticoids (GCs) are frequently and often chronically used for the treatment of rheumatoid arthritis (RA) and other immune diseases and vasculitis. An estimated 0.8–1.2% of the population in developed countries at any moment in time uses GCs.[1,2] EULAR guidelines state that the adverse effects (AEs) of GC therapy should be considered and discussed with the patient before treatment is initiated.[3] However, reliable quantitative data on cutaneous AEs are lacking.[4]
**Methods:** We performed a study to assess the occurrence of cutaneous AEs of GCs and its association with current and cumulative GC-doses. This cross-sectional study was performed at the outpatient departments of the Charité University Medicine Berlin and the University Medical Center Utrecht; 381 RA-patients were included. Patients were classed into 4 groups, according their mean daily dose during the past 12 months: 0 mg (n=87), $<$5mg (n=108), 5–7.5 mg (n=130), and $>$7.5 mg (n=56) of prednisolone equivalent.
Cushingoid appearance, ecchymosis, stretch marks, steroid acne, perioral dermatitis, hirsutism, and scalp hair loss were assessed by physical examination using a predefined scoring system, and by patients' self-assessments. Easy bruising, skin atrophy, and impaired wound healing were patients' self-assessed reports. Data were analyzed according GC dose categories and cumulative doses.
**Results:** Of the 381 patients, 76% was female; 67% was rheumatoid factor positive and 55% had erosive joint disease. The median (quartiles) disease duration was 9 (4–17) years. The mean number of lifetime conventional synthetic DMARDs used was 2.6 and for biological DMARDs it was 1.0. The median (quartiles) total duration of GC use was 4.0 (1.5–10) years, and the mean (sd) cumulative dose was 14 (17) g.
Cushingoid habitus, easy bruising, skin atrophy, and impaired wound healing as reported by patients occurred significantly more frequent in those using GC the past 12 months, compared to those not using GC, see figure. At physicians' assessments, only Cushingoid habitus and ecchymosis were more prevalent in GC-users, see figure. The prevalence of these AEs was statistically significantly positively associated with current and cumulative GC dose.

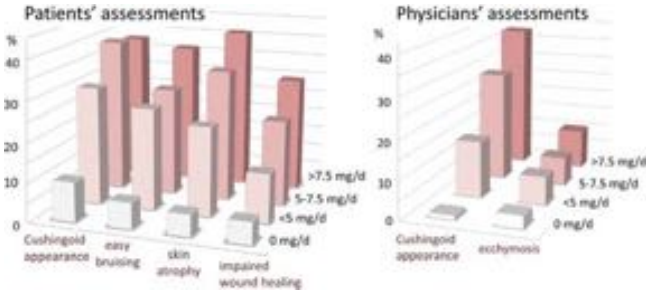

Figure 1

There was a low occurrence of abnormal stretch marks, acne, perioral dermatitis, alopecia, and hirsutism in our study, and there were no correlations between these AEs and GC therapy.
**Conclusion:** Cushingoid habitus, easy bruising, skin atrophy, impairment of wound healing, and ecchymosis are AEs of GC which can be observed relatively frequently in clinical daily practice. They are GC dose-dependent (current and cumulative dose). At the lower GC doses used in RA, abnormal stretch marks, acne, perioral dermatitis, alopecia, and hirsutism are rare AEs of GC.

## What CVD outcomes to use in clinical rheumatological practice?

### SP0012 HOW TO ASSESS THE CVD RISK IN THE INDIVIDUAL PATIENT?

N. Sattar. *BHF Centre, University of Glasgow, Glasgow, United Kingdom*

This talk will overview the methods of assessing CVD risk in patients with Rheumatoid arthritis. It will give a rationale for why CVD risk screening in RA can be done using risk scores developed for the general population and also give two examples of scores which include RA as a risk stratifier. The talk will highlight that i) CVD risk scoring is easy to do in routine clinical practice, ii) requires simple additional of non-fasting lipids and blood pressure, iii) can be intergrated to existing RA clinics and iv) can be repeated at intervals of time which is pragmatic. The talk will further emphasise that consideration of usual CVD risk factors is critically important in determing who should be recommended statins and that having RA alone does not mean individuals are necessarily at high CVD risk. A case history will be used to highlight main points discussed in the talk. Finally, the talk will also discuss the pros and cons of additional tests and discuss the recommendations from recent guidelines which will fit in with the talks conclusions.

### SP0013 IS IT ENOUGH JUST TO TREAT INFLAMMATION TO REDUCE CARDIOVASCULAR RISK?

M.T. Nurmohamed. *Amsterdam Rheumatology immunology Center (ARC) | VU University Medical Center & Reade, Center for Rheumatology and Rehabilitation, Amsterdam, Netherlands*

The risk of cardiovascular disease (CVD) is up to twofold increased in patients with inflammatory joint disorders (IJD). This increased CVD risk is due to both traditional risk CVD risk factors such as hypertension, smoking and dyslipidemia as well as the underlying chronic systemic inflammation in IJD. Traditional CV risk factors are more often present in IJD and partially a consequence of changes in physical function related to the underlying IJD. Approximately 50% of the increased CV risk is due to traditional CV risk factors and 50% due to the inflammatory process. Inflammation may have a negative impact on CV risk factors, but this effect only marginally explains the increased prevalences of CV risk factors.
CV risk management should thus not only target the inflammation but also CV risk factors. It has three main principles: non-pharmacological interventions, pharmacological management of CV risk factors, and control of disease activity.
**Non-pharmacological strategies:** Life style management should include counselling for smoking cessation (albeit that the favorable cardiovascular effects of smoking cessation might be less than in the general population) as well as increasing physical activity, and healthy (Mediterranean) diet.
**Treatment of CV-risk factors:** Thus far, adequate CV endpoint trials with statins and or antihypertensive agents have not been published. However, population and databases investigations indicate that antihypertensive agents and statins do not work less than in the general population. Indeed, statins have additional anti-inflammatory effects, that might be important from a CV point of view.
**Disease activity:** There is mounting evidence that cumulative disease activity as well as the number and duration of flares over time do contribute to the cardiovascular risk.
Hence, inflammation reduction is important for CVD risk reduction, but it appears that the type of treatment is less important. Nowadays, tapering of biologicals is becoming more and more standard of care and has several benefits, but one of the drawbacks might be the possible negative effect on thrombotic markers. As thrombotic markers normalize with biologicals therapy, this favorable effect might be reversed and thus exposing our patients to an increased CV-risk.
Furthermore, it is important to realize that it cannot be excluded some biologic agents as well as targeted synthetic DMARDs might have adverse cardiovascular effects. Finally, NSAIDs/COXIBs and steroids might have a negative impact on the cardiovascular risk profile.
**Conclusions:** The increased CV risk in IJD is widely acknowledged for about a decade. Nonetheless, CV mortality has hardly improved, despite major improvements in antirheumatic therapy. Hence, targeting disease activity only is just NOT enough to reduce the CV risk of our patients. In line of this, most (recent) studies indicate poor CV risk management in daily clinical practice and thus the CV challenge for the future is optimizing CV risk management and its implementation.

## Different perspectives on pain in osteoarthritis

### SP0014 PERIPHERAL AND CENTRAL PAIN SENSITIVITY IN OSTEOARTHRITIS

L. Arendt-Nielsen. *Center for Sensory-Motor Interaction (SMI), School of Medicine, Aalborg University, Aalborg E, Denmark*

Today's management of osteoarthritis (OA) consists mainly of symptomatic treatment of pain although traditional analgesics such as NSAIDs may offer only weak pain relief and risk serious adverse reactions. New safe and more efficient treatment regimes are needed for OA, but such a development requires a solid fundamental understanding of the peripheral and central pain mechanisms involved in OA.
OA is characterized by a progressive erosion of articular cartilage and bone remodelling which can be accompanied by pain, local inflammation, and joint degeneration. The main biological factors thought to be responsible for cartilage degradation are the matrix metalloproteinases (MMP) and aggrecanases. Biochemical markers of OA pathophysiology have received increasing attention due to their superior sensitivity in comparison with conventional structural (e.g. radiological) endpoints.
In the individual patient, little association is found between joint damage, local inflammation, and pain. Recently cytokine levels, degree of sensitization (local and spreading), descending pain control, comorbidities, and pain duration are some of the individual factors playing a role for pain severity. With the expected demographic and lifestyle changes, the incidence of joint pain will continue to increase. Better understanding of the individual fundamental pain mechanisms may improve patient profiling, help individualizing management, suggest new treatment options and thereby advance the development of new therapies.
The sources pain in OA and mechanisms responsible are not well understood. Joint nociception can lead to peripheral and central sensitization. It has consistently been shown that pain intensity, pain durations, and the number of OA locations are important drivers for sensitization in OA.
Various animal models of OA have been established to investigate the consequences of experimental OA on pain processing and various pain mechanisms, but they do not translate well into humans. As a consequence, data derived from these models for drug development programs are not always predictive of efficacy, and new strategies are needed for developing translational pain biomarkers. In clinical OA conditions, the poor relationship between joint pathology and pain is found, and better understanding and characterization of the underlying mechanisms of pain are important. Techniques for assessing pain mechanisms in OA patients provide biomarkers capable of quantifying pain mechanisms such as temporal summation, descending inhibition, spreading sensitisation, and primary and secondary hyperalgesia. Such pain biomarkers can help to phenotype OA patients based on the contribution of peripheral and central pain sensitization. Biomarkers are currently being explored as tools to facilitate better understanding of pain mechanisms and to predict pain outcomes after e.g. total knee replacement surgery. Preoperative pain intensity, acute postoperative pain, and pain sensitization have been shown to be predictors for the development of chronic postoperative pain after knee joint replacement.
Relating clinical benefit of a given therapy with quantitative assessment of the pain mechanisms involved provides new opportunities for tailored and individualized management regimes. The use of biological biomarkers in combination with techniques such as comprehensive quantitative sensory testing that explore OA pain mechanisms has increased the understanding of dynamic pathological events that lead to patients' symptoms.

### SP0015 PAIN TRAJECTORY GROUPS IN PERSONS WITH OSTEOARTHRITIS

G.M. Peat. *Arthritis Research UK Primary Care Centre, Research Institute for Primary Care & Health Sciences, Keele University, Keele, United Kingdom*

Pain in persons with osteoarthritis does not follow a simple, single, immutable 'natural history'. In recent years several prospective cohorts using repeated measures of patient-reported health states have matured and there has been a flurry of publications on the existence of discrete developmental trajectories of reported pain severity and other states. What does it all add up to? And what

does it teach us about concepts of time, heterogeneity, and prognosis in OA? This presentation will (i) briefly introduce the rationale and assumptions underlying these methods, (ii) review published findings when applied to pain and other patient-reported health states in osteoarthritis, (iii) discuss implications of these findings for research and clinical practice, (iv) contemplate productive directions for future investigation in this field.

### SP0016 EXERCISE THERAPY TO REDUCE PAIN IN KNEE OSTEOARTHRITIS: MECHANISMS AND TREATMENT OPTIMIZATION

M. Van Der Leeden. *Rehabilitation Research, Reade, Amsterdam, Netherlands*

Exercise is effective in reducing pain in knee osteoarthritis (moderate effect size)[1]. The working mechanisms of the positive effects of exercise therapy in knee OA are not fully elucidated. Improvement in physiological factors such as upper leg muscle strength, joint range of motion and proprioception have been found to be related to improvement in pain and activity limitations[2], but also psychosocial and general health related mechanism might be involved. Additionally, reduction in local as well as systemic inflammation seems to be a working mechanism of exercise therapy, although evidence is still limited.
Severe knee pain hampers the ability to participate in exercise therapy. Patients with knee OA who experience severe knee pain form a substantial group of patients with knee OA. These patients may benefit insufficiently from exercise therapy. Recently, an intervention protocol which combines standardized analgesic prescription and exercise therapy has been developed[3]. The purpose of this intervention protocol was to reduce pain by optimization of analgesics, thereby allowing the patient to participate in exercise therapy. The feasibility and outcome of this combined intervention will be presented.

### SP0017 THE EFFECT OF NON-PHARMACOLOGICAL INTERVENTIONS FOR HAND OA

J. Arokoski[1,2]. *[1]Department of Physical and Rehabilitation Medicine, Kuopio University Hospital; [2]Institute of Clinical Medicine, University of Eastern Finland, Kuopio, Finland*

The hand is a common site of peripheral osteoarthritis (OA). The most common sites for hand OA are distal and proximal interphalangeal joints and the base of the thumb. Because the natural history of hand OA is poorly understood and there is no preventive treatment or cure after the onset of development, the goal of OA treatment is the management and alleviation of pain as well as the maintenance and improvement of functional capacity. Many non-pharmacological treatments, including patient education, assistive technology, splinting, therapeutic exercises and physical therapies, has been used to treat patients with hand OA. This presentation will provide an overview the principles of these treatment methods and the scientific evidence supporting the efficacy of these treatments in relieving pain and improving function.

## Epigenetics solving the OA puzzle

### SP0018 DNA METHYLATION AND OSTEOARTHRITIS

L.N. Reynard. *Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*

One mechanism of epigenetic gene regulation is DNA methylation, which involves the addition of a methyl group to a cytosine base by DNA methyltransferase enzymes and occurs predominantly at CpG dinucleotides in mammalian cells. DNA methylation within the gene promoter regions is associated with gene repression through effects on transcription factor binding and recruitment of chromatin remodelling complexes. In contrast, gene body methylation positively correlates with gene expression and has been implicated in transcription from alternative promoters as well as alternative splicing.
DNA methylation changes occur during aging and in response to environmental factors including diet and smoking. Furthermore, aberrant DNA methylation patterns have been implicated in the aetiology of many common human disease including cancer, RA and SLE. Over the last 10 years, there has been increasing interest in the potential contribution of DNA methylation in the molecular mechanisms underlying OA pathogenesis, which will be the focus of this talk. I will begin by examining candidate gene studies that have focused on the relationship between cartilage promoter methylation, transcription factor binding and mRNA expression of genes implicated in OA, including the OA susceptibility gene *GDF5*, the chondrogenic transcription factor SOX9 and the matrix degrading enzyme MMP13. I will then review the key findings from genome-wide DNA methylation studies of osteoarthritic cartilage and bone. These DNA methylome studies have shown that hip and knee cartilage are epigenetically distinct, and have highlighted the potential importance of cartilage inflammation and TGFβ signalling in OA pathogenesis. I will finish by discussing areas for future DNA methylation studies in OA research and, given that OA is a disease of the whole joint, the potential to extend these analyses to other tissue compartments.

### SP0019 HISTONE MODIFICATION AND OSTEOARTHRITIS

S. Monteagudo. *Skeletal Biology and Engineering Research Center, KU Leuven, Leuven, Belgium*

Epigenetic mechanisms, processes that alter gene expression without changes in DNA sequence, precisely regulate gene expression by dynamic remodeling of chromatin. Eukaryotic DNA is wrapped around a histone octamer (H3/H4 heterotetramer and two H2A/H2B dimers) to form the nucleosome, the fundamental building block of chromatin. Histone proteins are subject to covalent modifications that modulate the local structure of chromatin and influence gene expression by regulating the accessibility of gene loci to transcriptional machinery. The dynamic remodeling of chromatin through histone modifications by nuclear proteins including histone acetyltransferases, deacetylases, and methyltransferases, as well as by demethylases, modulate spatiotemporal gene expression during cartilage development, homeostasis and disease.
Disruptor of telomeric silencing 1-like (DOT1L) is the main histone-modifying enzyme that catalyzes the methylation on lysine-79 of histone 3 (H3K79). The human protein DOT1L contains 1537 aminoacids, with its N-terminal part responsible for the methyltransferase activity. The remaining C-terminal part is involved in physical interactions with many transcription relevant proteins. The general function of DOT1L is to methylate H3K79 as a member of a large protein complex, which can influence the transcriptional state. DOT1L's histone methyltransferase activity has been linked to active transcription, and plays a role in many biological processes including the DNA damage response, the cell cycle, embryonic development and cell reprogramming. In cancer biology, DOT1L is involved in MLL-rearranged leukemia and in other tumors. We reported a strong genetic association between polymorphisms in the human *DOT1L* gene and hip cartilage thickness as well as osteoarthritis (OA). Variations in the *DOT1L* gene are also associated with human height. Furthermore, we earlier demonstrated that silencing of *Dot1L* inhibited chondrogenic differentiation of murine progenitor cells. Interestingly, DOT1L-associated H3K79 methylation has been linked to the Wingless-type (Wnt) cascade. Gain and loss of function studies for Wnt signaling mediator beta-catenin or Wnt antagonists such as Frizzled related protein have demonstrated that tight regulation of this pathway is key to joint health. This could specifically identify DOT1L as an attractive target for joint diseases, more particularly for OA. DOT1L is an enzyme and, thus, can be pharmacologically modulated.
We therefore hypothesized that DOT1L plays a major role in cartilage homeostasis by tightly regulating gene expression patterns of key signaling pathways, such as the Wnt cascade. New insights into the transcriptional mechanisms may contribute to the development of new epigenetics-based strategies for the treatment of joint diseases, adding a new way to modulate fundamental signaling pathways in joint disease and repair.

### SP0020 THE ROLE OF MICRORNAS IN THE PATHOGENESIS OF OSTEOARTHRITIS

I. Clark on behalf of Tracey E Swingler, Linh TT Le, Natalie Crowe, Matt J Barter, Guy Wheeler, Tamas Dalmay, David A Young. *School of Biological Sciences, University of East Anglia, Norwich, United Kingdom*

Small non-coding RNAs known as microRNAs (miRs) have recently been recognised as important regulators of gene expression in human cells. Whilst originally mooted to fine-tune gene expression, it is now clear that they can have profound effects on physiology and disease.
A role for microRNAs in chondrogenesis and osteoarthritis has become clear over the last decade. Deletion of the machinery for microRNA biogenesis specifically in the cartilage of mice has shown that, as a class, microRNAs influence the development of the skeleton and homeostasis of articular cartilage. Identifying roles for individual microRNAs has been more difficult, with the main in vivo data coming from miR-140.
This session will review the role of microRNAs in the molecular pathogenesis of osteoarthritis (OA). It will present data on the regulation of microRNAs by relevant factors and their impact on intracellular signalling. Key targets of microRNAs in OA will also be explored. It will touch upon the use of microRNAs as circulating biomarkers of disease and the potential for microRNA-based therapy.

The focus of the Clark lab has been on the role and function of microRNAs in cartilage, particularly miR-455, the miR-29 family, miR-140 and miR-3085.
MicroRNA-455 is genomically located within an intron of COL27A1. Collagen XXVII is expressed in cartilage, suggesting function of the miR in this tissue. We initially described a role for miR-455 in TGFbeta signalling, but have more recently uncovered function in Wnt signalling and in the regulation of Sirt1.
The miR-29 family have been well-researched and are known e.g. to regulate collagen gene expression, giving them a role in fibroses. We identified miR-29b as one of only two miRs which was regulated at an early time point after surgery in the murine DMM ("destabilisation of the medial meniscus") model of OA. Potential targets of miR-29 were regulated in the opposite direction to the miR, suggesting function. The miR-29 family were regulated in many models of chondrocyte differentiation and in human end-stage OA. In chondrocytes we have shown that miR-29 is negatively regulated by Sox9 and negatively regulates a number of key intracellular signalling pathways in OA. We have identified novel direct targets in the Wnt pathway and we have also shown that miR-29 directly targets a number of ADAMTS protease genes.
We used RNA-Seq to explore the full range of miRs expressed by human articular chondrocytes from OA patients. This showed that the so-called passenger strand of miR-140, miR-140-3p was more highly expressed than the guide strand, miR-140-5p in newly isolated osteoarthritic chondrocytes. We have now shown that miR-140-3p directly targets a number of enzymes in the heparan sulphate proteoglycan synthesis pathway. These studies also identified miR-3085 in human chondrocytes. This miR had only previously been annotated in rodents where it was presumed intergenic. However, in man it is located in the final intron of the CRTAC1 gene, which codes for cartilage acidic protein 1. We have shown it to directly target ITGA5, the integrin alpha5 gene, but it also strongly induces interleukin-1 signalling in chondrocytes.

## Muscle biology & inflammation

### SP0021 FREE RADICAL SIGNALING BEHIND THE MUSCLE WEAKNESS ASSOCIATED WITH RHEUMATOID ARTHRITIS

J. Lanner. *Department of Physiology & Pharmacology, Karolinska Institutet, Stockholm, Sweden*

In addition to the primary symptoms arising from inflammatory processes in the joints, muscle weakness and impaired work capacity are commonly reported by patients with rheumatoid arthritis (RA). Reduced muscle strength has always been more or less synonymous with decreased muscle mass. However, our data show that muscle weakness associated with RA is not only a result of atrophic muscles. Instead, intracellular (intrinsic) muscle dysfunction appears as important factors behind arthritis-induced muscle weakness. Our data suggests that the impaired capacity to produce force is the result of free radical (reactive oxygen/nitrogen species (ROS/RNS)) signaling altering the intracellular Ca2+ release and contractile proteins (myosin and actin) inside the skeletal muscle fibers. Here our latest data on the mechanisms behind arthritis-induced skeletal muscle weakness from animal studies and patients with RA will be presented. Altered contractile function induced by the RNS peroxynitrite (ONOO-) and the prospective of using antioxidant treatment to counteract muscle weakness in inflammatory conditions will be discussed.

### SP0022 INFLAMMATORY MEDIATORS IN INFLAMMATORY MYOPATHIES

B. De Paepe. *Neuromuscular Reference Center & Lab Neuropathology, Ghent University Hospital, Ghent, Belgium*

Idiopathic inflammatory myopathies (IM) constitute a heterogeneous group of chronic disorders which include dermatomyositis (DM), polymyositis (PM), sporadic inclusion body myositis (IBM) and necrotizing autoimmune myopathy (NAM). These diseases represent distinct pathological entities but, most often, share predominant inflammation in muscle tissue. Many of the immunopathogenic processes behind the IM remain poorly understood until today, however, the role played by various inflammatory mediators becomes more and more clear. Induction of major histocompatibility complexes on the membranes, makes that IM muscle fibers actively participate to the immune processes by becoming antigen presenters. Several myositis-specific autoantibodies have been recognized, typing different subgroups of patients with distinct clinical phenotype. Cytokines, the master regulators of leukocyte activation and migration, have especially been recognized as crucial factors. The IM are characterized by strong expression of subsets of Tumor Necrosis Factors (TNF$\alpha$, LT$\beta$, BAFF), Interferons (IFN$\alpha/\beta/\gamma$), Interleukins (IL-1/6/12/15/18/23) and Chemokines (CXCL9/10/11/13, CCL2/3/4/8/19/21) in the muscle tissue. The latter are important for attracting distinct subsets of T-cells, B-cells, macrophages and dendritic cells, and for their intra-muscular organization. The complex inflammatory network in IM pinpoints targets for neutralization through a selective therapeutic approach as a necessary alternative for patients that do not respond to conventional immune-suppressants. Results so far are promising, but have also shown the necessity for further subtyping of patients to develop future precision therapies and predict treatment outcome.

## Lessons from the children (monogenic causes of autoimmunity)

### SP0023 MONOGENIC LUPUS AND PROTEIN KINASE C DELTA DEFICIENCY

A. Belot[1,2]. *[1]Pediatric Nephrology, Rheumatology & Dermatology Department, HFME, Hospices Civils de Lyon, Bron; [2]U1111, INSERM, Lyon, France*

Next generation sequencing (NGS) represents a revolution in the field of molecular medicine, and offers a new approach to deciphering the pathogenesis of complex diseases. Paediatric-onset SLE (pSLE) is considered as a paradigm of early-onset autoimmunity and is a very rare and more severe disease than its adult-onset counterpart. These differences are possibly associated with a greater contribution of genetic aetiological factors.
Others and we have identified the deficiency of Protein Kinase C-delta (PKC-delta) as a new cause of monogenic autoimmunity. To date, six patients in four kindred have been reported. The phenotype is broad and ranges from lymphoproliferative disease to lupus-like autoimmunity.
In mouse, PKC-delta deficiency is associated to systemic autoimmunity and is B cell autonomous. We have shown that BCR- or Thapsigargin-dependent apoptosis is impaired in patient's B cells. PKC-delta is crucial in regulating B cell negative selection.
PKC-delta is widely expressed and mutations may impact on additional immune cells. One out of our three patients has developed late-onset papillomatosis suggestive for NK cell deficiency but the underlying mechanisms remain unclear. As described in other apoptosis deficiencies, PKC-delta deficiency may occur in a context of somatic mutation. As part of an exome sequencing panel project on SLE-related genes, we have recently screened 130 additional patients with early-onset SLE but we did not identified any homozygous or heterozygous variants suggesting *PRKCD* mutations remain extremely rare in juvenile SLE.

### SP0024 TYPE I INTERFERONOPATHIES

Y. Crow[1,2]. *[1]Neurogenetics, Imagine, Paris, France; [2]Genetic Medicine, University of Manchester, Manchester, United Kingdom*

Dissection of the genetic basis of Aicardi-Goutières syndrome has highlighted a fundamental link between nucleic acid metabolism and type I interferon induction, leading to the concept of the human interferonopathies, a broader set of Mendelian disorders where disease pathology relates to a primary upregulation of type I interferon activity. Here we discuss the clinical phenotypes associated with these novel inborn errors of immunity, their pathological basis, and strategies for their treatment.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6345

### SP0025 COMPLEMENT DEFICIENCIES AND RHEUMATIC DISEASES

L. Trouw. *Rheumatology, LUMC, Leiden, Netherlands*

The complement system is an integral part of both the innate and adaptive immune responses. Although a wealth of insight into the function of the different complement proteins has been obtained by biochemical studies, real insight into the overall role of complement and specific complement proteins has been obtained by studying the rare cases of complete genetic deficiency observed in the human population. The detailed analyses of the clinical manifestations of persons genetically deficient for complement proteins identified some obvious aspects, but also several rather remarkable ones. For example the genetic deficiency of circulating C3 led to increased risk for several types of bacterial infections, but deficiency in C9, an essential component of the membrane attack complex (MAC) required for lysis did only predispose to one particular type of infections; with *Neisseria*. These data indicate that complement is involved in the immune defence against infections via C3, but that lysis by the MAC is except for *Neisseria* not so relevant.
One other remarkable observations was the association between genetic deficiency for classical pathway complement proteins with autoimmunity, especially systemic lupus erythematosus (SLE). Sspecially striking is the observation that there is a hierarchy, within the pathway, with C1q being the strongest associated with SLE, followed by C4 and C2 with almost no association with C3 deficiency. How deficiency of classical pathway proteins contributes is not yet clear but

seems to be the result of an interplay between decreased clearance of dead cells and an altered adaptive immune activation threshold.
Recently we identified a new case of complete C1q deficiency and this child did not display signs of SLE (yet). We were struck by the absence of reports on follow-up data of the cases with reported C1q deficiency and conducted a questionnaire based study. From this study we could conclude that there is enormous variation in the severity of clinical symptoms between persons, with some being very affected leading to premature death and other individuals, sometimes from the same family, seemingly completely unaffected. These findings are relevant also in view of the developments of therapy as now haematopoietic stem cell transplantation (HSCT) has become a feasible option to treat such individuals. In this context we argue for a well-balanced evaluation of the pro's and con's of such treatment modalities in view of the variation in clinical symptoms and severity observed in these individuals.

## ABC of statistics

### SP0026 THE BASICS OF A REGRESSION ANALYSIS

S. Norton. *King's College London, London, United Kingdom*

The aim of this presentation is to provide a brief introduction to the basics of the regression model. This model provides the foundation of modern statistical modelling and allows us to assess whether a variable, or range of variables, is associated with an outcome variable. Extrapolating from the model we can develop predictions about the level of an outcome variable, such as disease outcome, based on the values of predictive variables. The underlying equation, meaning of key terms and basic diagnostics to determine the robustness of inference from a regression model will be explained.

### SP0027 CONFOUNDING - FRIEND OR FOE? HOW TO HANDLE?

L. Carmona. *Instituto de Salud Musculoesquelética, Madrid, Spain*

Confounding is a major issue in observational studies, and it is a bias that needs to be corrected, controlled or adjusted for whatever your research question is. In this lecture we will review the definition of confounding and ways to tackle it. We will discuss two specific biases related to confounding in drug studies: confounding by indication and channelling bias. In addition, we will explain how to handle confounding in the different phases of research: 1) design phase, with an overview, among other issues, of what causal diagrams (directed acyclic graphs, DAG) are; 2) data collection and mining; 3) and finally analysis and reporting. In this latter part, we will explain how confounding is explored in datasets and the difference between confounding and modification. We will end with an overview of propensity scores, as a ways to tackle confusion in an efficient way, and a list of recommendations.

## Capillaroscopy I

### SP0028 HOW TO DIFFERENTIATE NORMAL FROM ABNORMAL CAPILLAROSCOPIC PATTERNS: ROLE OF IN EARLY DIAGNOSIS

V. Smith on behalf of the EULAR Study Group on Microcirculation in Rheumatic Diseases. *Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium*

The difference between a normal capillaroscopy and an "abnormal" capillaroscopy is important in the differential diagnosis between a primary Raynaud's phenomenon (=not linked to any condition) from a secondary RP.
A normal capillaroscopic pattern, by qualitative assessment, is characterized by a homogeneous distribution of hairpin shaped capillaries as a "comb-like structure", with a density of between 9–14 capillaries per mm. Yet, there exists a wide intra- and inter-individual variety in a normal population (non-specific variations) which will be discussed during the workshop.
An abnormal capillaroscopic image due to systemic sclerosis (SSc) is characterized by (a combination) of specific changes (giants, capillary loss, hemorrhages and abnormal shapes (ramifications)). Depending on their relative prevalence three SSc-patterns are described by Cutolo et al. with a 200 magnification videocapillaroscope: the "early", "active" and "late" scleroderma pattern. The combination of the presence of a scleroderma pattern on capillaroscopy with the presence of an SSc-specific antibody in a patient with Raynaud's phenomenon allows the "early" diagnosis of SSc. When the patient also has "puffy" fingers he/she meets the VEDOSS criteria for very early diagnosis of SSc.
In patients with connective tissue diseases "other than" SSc and diseases of the scleroderma spectrum there are no "unique" capillary patterns. A variety of capillary abnormalities (change in morphology, dimension, presence of hemorrhages) have been observed. These abnormalities by themselves are not predictive of any defined condition and may be referred to as non-specific abnormalities.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6440

### SP0029 COUNTING AND SCORING THE CAPILLARIES: MANUAL VERSUS SEMI-AUTOMATIC SYSTEMS

A. Sulli. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

Microangiopathy is a primary clinical feature of systemic sclerosis (SSc), and nailfold videocapillaroscopy (NVC) is the standard tool to detect morphological capillary abnormalities. NVC may discover the "Early" pattern of microangiopathy, monitor its progression, inform on disease status, and also predict future organ involvement. NVC has been proposed as possible biomarker in SSc, correlating the capillary damage extent with the internal organ involvement (1–3).
SSc patients show pathognomonic capillary abnormalities, which characterize the scleroderma-pattern of microangiopathy (2,4,5). Among these, giant capillaries (dilation of both capillary branches >50 microns), microhaemorrhages, reduction of capillary number (below 9 per linear millimetre), ramified (neoangiogenic) capillaries and disorganization of the vascular array are the major capillary abnormalities. These abnormalities do not occur all together at the same time, but sequentially, and three different patterns of nailfold microvascular damage ("Early", "Active" and "Late" scleroderma-patterns) have been proposed and validated in SSc patients (4–8). As a matter of fact, in some patients the capillary pattern remain unchanged for several years, whereas other patients show a fast evolution of the microangiopathy in a few months or years, along with progressive internal organ involvement (8,9). The factors influencing the time of evolution of the microangiopathy from the "Early" to the "Late" stage have not yet been determined.
To score SSc capillary abnormalities by NVC qualitative and quantitative assessments may be adopted (9).
The qualitative assessment include the classification of the nailfold microangiopathy into one of the three patterns above reported, and to correctly identify them the following criteria may be used (7–8). "Early" NVC pattern: few (<33%) enlarged/giant capillaries, few (<33%) capillary haemorrhages, relatively well-preserved capillary distribution, absent or mild (<33%) loss of capillaries. "Active" NVC pattern: frequent (>33%) giant capillaries, frequent (>33%) capillary haemorrhages, moderate (<66%) loss of capillaries, moderate (<66%) disorganisation of the capillary architecture, absent or few (<33%) ramified capillaries. "Late" NVC pattern: irregular enlargement of the capillaries, few (<33%) or absent giant capillaries and haemorrhages, severe (>66%) loss of capillaries with avascular areas, disorganisation of the normal capillary array, ramified/bushy capillaries.
The quantitative assessment is performed by adopting a simple rating scale to score each capillary abnormalities (score 0–3) (score 0 = no changes; score 1 = less than 33% of capillary alterations/reduction; score 2 = 33–66% of capillary alterations/reduction; score 3 = more than 67% of capillary alterations/reduction, per linear millimetre. Reduction = capillary number per linear millimetre <9). The mean score value for each capillaroscopic parameter is calculated from the analysis of at least two millimetres in the centre of the nailfold, by evaluating the first row of capillaries in each finger from 2nd to 5$^{th}$ (8). Also the microangiopathy evolution score (MES) may be calculated, by summing the scores of capillary loss, capillary ramifications and capillary disorganization (score 0–9) (8).
Alternative to MES calculation, the simple capillary number per linear millimetre may be adopted to monitor SSc microangiopathy and estimate the risk of digital ulcer appearance (10).
To decrease time of assessment and intra- and inter-operator variability, and increase NVC performance and reliability, automated calculation software are under development to score nailfold capillary number (11–14). Actually, even if enough feasible in counting capillaries in healthy subjects, the performance of these software is strongly reduced when working in the capillary alteration mosaic of scleroderma microangiopathy (e.g. haemorrhages, ramifications, giant capillaries, reduced transparency of nailfold bed).

### SP0030 CAPILLAROSCOPIC VERSUS LASER DOPPLER ANALYSIS OF THE MICROCIRCULATION

A.L. Herrick. *University of Manchester, Manchester, United Kingdom*

Nailfold capillaroscopy is used primarily to study microvascular *structure,* and in patients with Raynaud's phenomenon (RP) helps to differentiate between primary (idiopathic) RP and RP secondary to an underlying systemic sclerosis-spectrum disorder. In contrast, laser Doppler techniques measure microcirculatory blood flow, and therefore assess microvascular *function.* Capillaroscopy and laser Doppler are therefore complementary. There are different laser Doppler techniques: flowmetry (using a single probe), laser Doppler imaging (LDI), and laser speckle contrast imaging (LSCI). LDI and LCSI both measure blood flow over an area rather than at a single site. Laser Doppler techniques have been applied in research studies in patients with RP and systemic sclerosis, including as outcome measures in clinical trials: protocols often involve dynamic imaging, measuring blood flow response to (for example) a standard temperature stimulus. This lecture will describe the main applications of capillaroscopy and laser Doppler techniques in clinical practice and research, relevant to the rheumatologist, and the rationale underpinning these.
Upon completion of the session, participants should be able to:
1. Discuss applications of capillaroscopy and different laser Doppler methods in patients with RP and systemic sclerosis
2. Discuss similarities and differences between the techniques.

### SP0031 HOW TO SELECT THE MOST APPROPRIATE CAPILLAROSCOPIC DEVICE: PROS AND CONS

W. Hermann. *Department of Rheumatology and Clincial Immunology, Kerckhoff-Klinik, Bad Nauheim, Germany*

One of the most important indications for performing capillaroscopy is to differentiate between primary and secondary Raynaud's syndrome. Different kinds of microscopes are at hand and generally vary in terms of picture quality or price. Before purchasing a microscope and capillaroscopy software, several considerations about the required standards of examination should be made; some of which are summarized as follows:
– The region of interest (ROI). Normal capillaries have a mean diameter of about 8 μm. For an accurate assessment a magnification of 100–200x is recommended, for an overview the magnification of 50x is sufficient.
– Measurement. Beside qualitative measures like changes in vessel architecture, there should be the possibility of quantifying the number of capillaries/mm or vessel diameters.
– Documentation. All parts of the examination have to be stored and assigned to patient and case.
– Practical aspects and handling of the device.
– Different kinds of microscopes are on the market of which three will be discussed in detail. Briefly summarized:
– Stereo microscopes.
Advantages: Very good image quality, zooming in and out without problems, relatively easy to use.
Disadvantages: device is not mobile, in patients with finger contractures examinations are difficult to perform, relatively high costs.
– Videocapillaroscopes:
Advantages: Very good image quality, easy to use, "gold standard" for capillaroscopy.
Disadvantages: No overview, zooming in and out not applicable (change of lenses required), relatively high costs.
– USB microscopes:
Advantages: low costs, zooming in and out without problems, easy to use.
Disadvantages: limited picture quality, documentation laborious.
Selecting a capillaroscopic device depends on the conditions of use ("quick look" vs. "academic evaluation and follow up"), which should be clarified before buying a device. The price range is significant and usually differs between 100€ for USB microscopes and up to 10,000€ for stereo and videocapillaroscopes.

## Optimizing treatment and patient care through precision medicine: a threat or an opportunity for patients and patient organisations?

### SP0032 COLLABORATION BETWEEN RESEARCH AND PATIENT ORGANISATIONS: IMPROVING PATIENT CARE THROUGH THE DANISH RHEUMATOLOGIC BIOBANK

B. Glintborg[1,2,3]. *[1]Department of Rheumatology, Gentofte University Hospital, Hellerup; [2]The Danish Rheumatologic Biobank; [3]The DANBIO registry, Rigshospitalet, Glostrup, Copenhagen, Denmark*

Within the field of rheumatology, the number of available medical treatments is steadily increasing. During the last decades the biological disease modifying drugs (bDMARDs) have significantly improved outcomes for patients otherwise refractory to treatment. However, adverse effects, insufficient drug response and subsequent switching from one drug to another remain a significant problem for numerous patients in daily clinical practice. Within the field of oncology, personalized treatment strategies have come a long way. But for patients with inflammatory rheumatic diseases, the ability to choose the right drug for the right patient is still limited or non-existing. International treatment guidelines all follow a "one-size-fits-all" or "trial-and-error" strategy.
The nationwide Danish Rheumatologic Biobank was established in year 2015 and is funded by the patient organization The Danish Rheumatism Association and the public hospital owners (Danish Regions). The aim of the Danish Rheumatologic Biobank is to promote the identification of new biomarkers for personalised treatment of patients with inflammatory rheumatic diseases. Biological samples (blood, synovial fluid etc.) are collected after written informed patient consent for specific research projects. Corresponding high-quality clinical data are registered prospectively in the nationwide quality and research registry, DANBIO. The treating physician registers patient demographics, previous and current treatment (DMARDs) including reasons for withdrawal, and physician-reported outcomes (clinical characteristics, treatment response, imaging) whereas the patient provides patient-reported outcomes (functional status, pain/fatigue/global scores).
Danish Rheumatologic Biobank exemplifies a unique collaboration between patients and researchers, patient organisations and hospital owners aiming to pave the road for personalized treatment of patients with inflammatory rheumatic diseases. We expect the Danish Rheumatologic Biobank to facilitate high quality research and improved patient care within the field of rheumatology.
During this lecture the rationale, infrastructure and status for DRB will be discussed.
Acknowledgements: The Danish Rheumatism Association and the Danish Regions for funding. The DANBIO registry for hosting clinical data. The Danish Departments of Rheumatology and Biochemistry for participating in DRB sample collection. Thanks to professor Merete Lund Hetland, the main initiator of DRB and the working group behind DRB: Estrid Høgdall, Tina Kringelbach and Julia Sidenius Johansen.

### SP0033 IMPROVING THE SCREENING AND MANAGEMENT OF COMORBIDITIES IN RHEUMATIC DISEASES

Y. Van Eijk-Hustings. *Patient & Care/Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands*

Research has shown that comorbidities, one or more additional disorders (or diseases) co-occurring with the primary disease, occur more frequently in patients with chronic inflammatory rheumatic diseases than in the general population, and are sub-optimally prevented, screened for and managed. In order to contribute to improvement, a EULAR task force has developed points to consider for reporting, screening and preventing selected comorbidities in daily practice. The points to consider and the results from the literature that supported their development have been presented at the EULAR conference in Rome in 2015 and have recently been accepted for publication in ARD.
In accordance with the EULAR Standardized Operating Procedures, a multidisciplinary task force from 12 different countries selected six comorbidities (ischemic cardiovascular diseases, malignancies, infections, peptic ulcer, osteoporosis, depression), based on their frequency and severity (e.g. their impact on mortality and disease outcomes) in a first meeting. Results from a systematic literature review of existing recommendations or guidelines on the reporting, screening, or prevention for each of the selected comorbidities guided the second meeting of the task force. In this consensus meeting a reporting form, an extensive list of variables to be collected in order to report history/occurrence of the comorbidity and current treatments, risk factors and screening, or prevention, was decided on. Standardization of the screening for and reporting of comorbidities will enhance implementation across Europe.
The role of patients in the management of their own disease, including the screening for comorbidities, is increasing. Facilitating patients' involvement in their own care requires various activities. Regarding comorbidities, awareness about

the points to consider by developing and disseminating a lay version is necessary but is not sufficient.
Tools such as self-administered questionnaires and supporting information can help strategic implementation of the points to consider, particularly if they are supported with further explanation to the patient whilst empowering them to become more actively engaged in comorbidity self-management. Tools however, also need to make sense to the patient, and should be easily administered and results should be easily interpreted. Also, follow-up of results should be clear.
In what way such a tool can be integrated in daily care, what educational materials for patients are necessary, and how concerns for comorbidities can be reduced needs further exploration.

## EULAR projects in Musculoskeletal Imaging

### SP0034 DEVELOPMENT OF THE EULAR RECOMMENDATIONS FOR THE USE OF IMAGING IN OSTEOARTHRITIS CLINICAL PRACTICE

A. Iagnocco on behalf of G. Sakellariou, W. Zhang, J.W.J. Bijlsma, P. Boyesen, M.A. D'Agostino, M. Doherty, D. Fodor, M. Kloppenburg, J. Maeder, F. Miese, E. Naredo, M. Porcheret, P.G. Conaghan. *Sapienza Università di Roma, Rome, Italy*

In the last few years the application of musculoskeletal imaging in rheumatology clinical practicehas become more widespread. However recommendations on its use in osteoarthritis (OA) are lacking.
**Objective:** To develop evidence-based recommendations for the use of imaging in OA clinical practice
**Methods:** After the project was approved by the EULAR Executive Committee, a task force of experts in the field of OA and imaging met in order to plan the strategy for a systematic literature review (SLR), subsequently conducted by a research fellow under the supervision of the conveners and the methodologist of the group. The task force identified areas of application of imaging in OA clinical practice and developed the research questions to drive the SLR. The imaging modalities (conventional radiography, ultrasound, magnetic resonance imaging, computed tomography, radioisotope scan) and joints (knee, hip, hand and foot) were first identified. Second, the role of imaging in the diagnosis of OA, identification of OA characteristics, detection of other diseases, managing OA, defining its prognosis, monitoring the disease progression as well asguiding treatment was addressed. A systematic search was performed separately for each question and site using PubMed and Embase.
**Results:** From an initial SLR, 6858 references were found, 1317 papers were reviewed in detail and 380 of them were included. Furthermore, to investigate evidence not addressed by the first SLR,the task force required additional SLRs to evaluate the accuracy and efficacy of imaging-guided compared to blind injections and the comparison of different radiographic projections. For the first SLR, 25 papers out of 5379 abstracts were assessed and 8 included, while for the comparison of different projections 53 papers out of 4774 abstracts were reviewed, with the inclusion of 31 papers. After analysing the results of the SLRs and giving their expert opinion, the task force developed consensus recommendations. These covered different areas such as the lack of need for diagnostic imaging in patients with typical symptoms, the role of imaging in differential diagnosis, the use of imaging in monitoring OA when no significant therapeutic modification isrelated, the first choice imaging modality, how to acquire images, the influence of different joints on selecting the type and use of imaging modalities, and the role of imaging in guiding local injections. Future research recommendations were developed based on areas where there was a paucity of literature.
**Conclusions:** EULAR recommendations for the use of imaging in osteoarthritis clinical practice have been developed thus filling a knowledge gap in the field.
**Key messages:**
– Recommendations on the use of imaging in OA clinical practice are lacking.
– Based on the results of a SLR and expert opinion, recommendations on the use of imaging in the clinical management of OA were developed.

### SP0035 DEVELOPMENT OF EULAR STANDARDISED PROCEDURES FOR RHEUMATOLOGY ULTRASOUND IMAGING (RHUS)

I. Möller. *Instituto Poal de Reumatologia, Barcelona, Spain*

The objectives of this EULAR Project are:
To update the technical requirements for performing musculoskeletal ultrasound (MSUS) of the essential lesions present in rheumatic diseases accessible by MSUS including patient position, initial probe placement, scanning method and US landmarks.
To develop procedures for additional MSUS assessment of additional musculoskeletal lesions/ abnormalities related to rheumatic diseases accessible to ultrasound evaluation.
To develop procedures for ultrasound scanning of non-musculoskeletal anatomic regions of importance in rheumatologic practice that are readily accessible to ultrasound evaluation (i.e. large vessels, salivary glands, ligaments, and peripheral nerves).
The creation of a concise illustrated manual of these procedures including internet access to video-clips accessible to all with interest in incorporating RHUS in their practice.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6324

### SP0036 THE ROLE AND TRAINING NEEDS OF NON-MEDICAL HEALTH PROFESSIONALS USING MUSCULOSKELETAL ULTRASOUND FOR THE MANAGEMENT OF PATIENTS WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES

H. Siddle on behalf of EULAR Task Force for Health Professionals undertaking Musculoskeletal Ultrasound. *Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

The role of the non-medical health professional has advanced with many health professionals undertaking training and using musculoskeletal ultrasound (MSUS) to extend their scope of practice. Guidelines to support training for rheumatologists have been identified but currently there are not any recommendations to support the education and training needs of non-medical health professionals using MSUS.
A EULAR Task Force was established to reach a consensus on the role and education and training needs of non-medical health professionals undertaking MSUS for the management of patients with rheumatic and musculoskeletal diseases (RMDs).
Based on an extensive search of the literature and expert consensus seven points to consider were formulated encompassing the role and scope of health professionals using MSUS, including the application, feasibility and added value in daily practice, and the training and competency required by health professionals. The seven points to consider are intended to support the education and training needs for health professionals using MSUS to improve the management of patients with RMDs across Europe, in conjunction with local and national regulations.

## Difficult osteoporosis

### SP0037 WHAT TO DO WHEN A FRACTURE OCCURS AFTER 3 YEARS TREATMENT WITH AN ORAL BISPHOSPHONATE?

B. Langdahl. *Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus C, Denmark*

Osteoporosis is characterised by reduced bone mass, deteriorated bone architecture and increased risk of fractures. A fracture in a patient with osteoporosis is therefore not uncommon, not even in treated patients as none of the available treatments can prevent fractures completely. Despite this knowledge a fracture is a disturbing event for the patient and should prompt the treating physician to consider the situation. First of all, compliance with the treatment including supplementation with calcium and vitamin D should be checked. Secondly, competing diseases and treatments and other risk factors may have emerged since the patient was diagnosed and started on treatment, and these conditions may attenuate the anti-fracture efficacy of the treatment (thyrotoxicosis, prednisolone, aromatase inhibitors etc). If compliance is good and no new risk factors have emerged, treatment failure should be considered.
Treatment failure can be assessed by new fractures, changes in BMD or bone turnover markers. Treatment failure is suggested if treatment has been ongoing for more than 12 months with good compliance and 2 or more new fractures occur or 1 new fracture in combination with declining BMD or non-suppressed bone turnover markers or BMD declines in combination with non-suppressed bone turnover markers.
If treatment failure is demonstrated then the treatment should be reconsidered. The absorption of oral bisphosphonates is 1–2% under optimal conditions, so the first alternative would be intravenous zoledronic acid or alternatively denosumab. Both are strong antiresorptives which have been proven to be able to increase BMD and suppress bone turnover in patients previously treated with oral bisphosphonates. If the incident fracture is a vertebral fracture, it could also be considered to change to teriparatide, a bone forming treatment with very prominent effects on spine BMD and vertebral fractures.

## Clinical relevance of immunogenicity and therapeutic drug monitoring

### SP0038 HOW CAN THE PROLIFERATION OF BIOSIMILARS IMPACT ON R&D AND QUALITY?

R. Van Vollenhoven. *Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands*

Almost twenty years ago, the advent of biological therapies changed the world of rheumatology in three ways: clinical results became dramatically better; treating patients became more complicated but also much more rewarding; and the price of antirheumatic therapy skyrocketed. The advent of biosimilars that has started recently is viewed by many as an important correction of the third aspect; it will also add a little to the complexity of treating patients; but by definition, it will not make clinical results any better at the individual patient level: "bio-*similar*".

Certainly, making antirheumatic therapy sustainable at the societal level is a laudable goal, if not for the individual physician, then at least for the health care system as a whole. But are there any downsides to the introduction in practice of biosimilars?

Part of the answer to that question can be understood if one asks another question: *why* are biosimilars less expensive than the originator products? An important part of the answer to that question is that the manufacturer of biosimilars can avoid the very large investments in research and development (R&D) that are needed for developing originator products. But this is then also the answer to the first question: the savings generated by biosimilars are to a significant extent taken from the R&D budgets in pharmaceutical industry. For those who are concerned about the long-term perspectives of health care from the societal point of view this should be a sobering thought.

A second concern is generated by the increasing number of biological products on the market, including both originator and biosimilar products. These medications are by their nature complex mixtures of proteins, the quality control of which is an extremely demanding task. The agencies charged with overseeing these processes will have to adjust to a reality where, for the treatment of RA alone, nine approved originator products will co-exist with easily as many biosimilar products, some of which are manufactured in several different places around the globe and transported across continents under varying physical conditions. To maintain the highest possible level of quality under these circumstances will be a daunting task for these agencies.

Biosimilars are now a fact of rheumatological life. Neither of the two concerns described here should be a reason not to use biosimilars when it would be medically appropriate to do so. But for those who are charged with setting health-care priorities, enthusiasm over the shorter-term financial gains with biosimilars should be balanced with prudence in view of the longer-term perspectives for future generations of patients.

## Hepatitis C and rheumatology: the impact of new therapies

### SP0039 NEW STRATEGIES FOR THE TREATMENT OF HEPATITIS C

S. Pol[1,2]. [1]*Hepatology Department, Université Paris Descartes;* [2]*INSERM U1213 and UMS-20, Institut Pasteur, Paris, France*

An average of 150 millions people are chronically infected by Hepatitis C virus (HCV) worldwide resulting in significant morbidity and mortality (1.4 millions yearly), related to hepatic and extra-hepatic manifestations. The virologic sustained virologic response (SVR) which is allowed by antiviral treatments significantly reduces both morbidity (hepatocellular carcinoma, liver transplantation) and hepatic as well as extra-hepatic mortality. The overall mortality in those patients achieving SVR was reduced by 75%, especially in cirrhotic patients but also in HIV/HCV co-infected patients and the occurrence of hepatocellular carcinoma at 5 years of follow-up dropped from 15 to 5% and need of liver transplantation from 10 to 1.2%, respectively in a recent meta-analysis of patients receiving interferon-including regimen. In a prospective study of more than 1300 HCV-infected patients with biopsy-proven cirrhosis in the Cirvir ANRS CO12 cohort, a significant decrease in the occurrence of hepatocellular carcinoma, of bacterial spontaneous peritoneal infection or other cirrhosis complications has been reported in cirrhotic patients with vs. without SVR at 3 or 5 years of follow-up but also a decrease in the occurrence of vascular disease (cardio- or cerebro-vascular disease). All these data underline the need of achieving SVR in most of HCV-infected patients which means a large screening, an improvement of access to care of infected patients.

The combination of pegylated interferon alfa and ribavirin) which led to a sustained virologic response (or SVR which corresponds to a complete recovery) in around 45% of patients with HCV genotype 1, 65% with HCV genotype 4, 70% with HCV genotype 3 and around 85% with HCV genotype 2 which was the standard of care for two decades has been replaced from 2011 to 2013 by a combination with first generation NS3/4A protease inhibitors (Telaprevir or Boceprevir) in genotype 1-infected patients, allowing around 70% of SVR with a reduction of the duration of therapy from 48 to 24 weeks in half of treated patients (23). These first-generation regimens unexpectedly disappeared in 2014 with the rapid availability of interferon-free regimens combining different direct-acting antiviral drugs (DAAs). These DAAs target the main viral proteins involved in the replication cycle of HCV and combine NS3/4A protease inhibitors (Simeprevir or Paritaprevir boosted by ritonavir), NS5B nucleos(t)idic (Sofosbuvir) and non nucleos(t)idic (Dasabuvir) polymerase inhibitors, NS5A replication complex inhibitors (Dacalatasvir, Ledipasvir, Elbasvir, Velpatasvir). This therapeutic revolution combines 2 or 3 second wave DAAs, with or without ribavirin but without interferon. The combinations are given (for 8 to 24 weeks) according to baseline factors including fibrosis stage, genotype and subtype, baseline viral load, prior therapeutic history of the patient (naïve or experienced) and pre-existing resistance-associated variants, result in a SVR rate greater than 90% with a good tolerance. The SVR rates (and the safety) are similar in the clinical trials and in the real-life, usually higher than 95% in per-protocol analysis.

Despite these great achievements, new treatments are about to be launched (Grazoprevir/elbasvir: Zepatier) and next generation are finalizing their phase III (Sofbuvir/velpatasvir in the Polaris program or the Abbvie 2nd gen with Endurance). To be competitive, these new combinations need to prove an added value regarding the pill burden (a single tablet regimen STR appears to be a pre-requisite), the reduced duration of treatment (6 or 8 weeks instead of 12 weeks) and/or a ribavirin-free regimen with drugs with a low drug-drug interaction profile and a fair safety/tolerance.

### SP0040 NEW ANTIVIRALS FOR EXTRAHEPATIC MANIFESTATIONS OF HEPATITIS C VIRUS: THE MODEL OF MIXED CRYOGLOBULINEMIA VASCULITIS

P. Cacoub. *Internal Medicine & Clinical Immunology, Hôpital Ia Pitié Salpêtrière, Paris, France*

Mixed cryoglobulinemia vasculitis (Cryovas) is a small vessel vasculitis involving mainly the skin, the joints, the peripheral nerve system and the kidneys. Hepatitis C virus (HCV) infection is the cause of Cryovas in about 80% of cases. The disease expression is variable, ranging from mild symptoms (purpura, arthralgia) to fulminant life-threatening complications (glomerulonephritis, widespread vasculitis). Most HCV-Cryovas manifestations respond to clearance of HCV during antiviral therapy. Patients who relapse for HCV infection after responding to antiviral therapy usually relapse for the Cryovas with the return of viremia.

Interferon alpha-based therapy has long been the cornerstone of HCV-Cryovas treatment. In the early 2010's, use of triple HCV therapy with pegylated-interferon/ribavirin and a direct antiviral agent (DAA, boceprevir or telaprevir) led to improved rates of sustained virological response and Cryovas remission. However, frequent side effects limited the use of such combinations. During the last two years, all oral interferon-free, DAA regimens have been used in HCV-Cryovas, associated with very high rates of sustained virological response and clinical remission of the Cryovas, and few toxicities. In daily practice, HCV-Cryovas patients with mild to moderate disease should be given an optimal all oral, interferon-free, DAA regimen. For patients with severe vasculitis control of disease with rituximab, with or without plasmapheresis, is required while starting optimal antiviral therapy. Other immunosuppressants should be given only in case of refractory forms of HCV-Cryovas.

## Outcome measures in clinical practice in gout and CPPD. The use of the new EULAR guidelines

### SP0041 GOUT-THE COMING EPIDEMIC. THE IMPACT ON THE HEALTH CARE SYSTEM AND THE SOCIETY

L.T. Jacobsson[1,2]. [1]*Department of Clinical Sciences, Malmö, Rheumatology, Lund University, Lund;* [2]*Dept of inflammation and rheumatology research, Sahlgrenska Universitetsjukhuset, Göteborg, Göteborg, Sweden*

Gout is worldwide the most common non-degenerative inflammatory joint disease, exemplified by a prevalence of 3.9% in the US and 1.7–2.5% in Europe.

The incidence increase with increasing age and BMI, is influenced by genetic, dietary factors and other life style factors as well the occurrence of comorbidity. Of the latter decreasing kidney function is by far the most important.
Several studies have pointed out that the age-adjusted incidence is rising worldwide, partly due to an increase in age and BMI, and we therefore face an upcoming epidemic.
Comorbidity outcomes: Gout identified in registers, thus reflecting the whole spectrum of the disease, has repeatedly been shown to be strongly associated with an increased morbidity in cardiovascular outcomes, deteriorating kidney function and overall mortality. To what extent this is related to hyperurecemia or systemic inflammation as reflected by clinical gout has not been completely disentangled. Very low serum-urate levels have on the other hand been suggested to increase the risk for dementia and Parkinsons disease, although this would need be confirmed.
Health related Quality of Life (HQoL): Whereas it is clinically obvious that very severe gout can have severe impact on HQoL, there is limited data to what extent early disease or more limited gout manifestations reduces HQoL
Societal costs: Once considered a disease of the wealthy, gout has recently been shown to be associated with lower income and socioeconomic class as is the case for most chronic diseases. It is difficult to disentangle the effects of joint manifestations and associated comorbidities on the incremental costs that some studies have demonstrated in groups of gout and this would need to be furthers studied.
What can we do to stop this epidemic? Apparently there are still large opportunities for improvements with regard to early detection and initiation of urate lowering therapy. In addition, improvements in life style are likely to be highly protective. Since gout is an increasing problem, there is also a high need for studies describing the effects on HQoL and costs over the whole range of the disease.

### SP0042 THE ROLE OF IMAGING IN THE MANAGEMENT OF GOUT

M. Doherty. *University of Nottingham, Nottingham, United Kingdom*

Identification of monosodium urate (MSU) crystals by microscopy remains the accepted gold standard for definitive diagnosis of gout. However, caveats include: suboptimal inter-observer agreement, lack of quantification of the extent of crystal deposition, and the impracticality of this method for diagnosis in primary care. In this presentation the pros and cons of different imaging methods for diagnosis, assessment and monitoring of gout will be discussed.
Plain radiography is readily available and can show the extent of joint damage from gout, but changes usually occur late, are largely non-specific and sensitivity of detection is low. Computed tomography (CT) and helical CT allow detection and quantification of tophi and bone erosions and dual energy CT (DECT) allows detection (with high specificity) and quantification of size and number of subclinical tophi – these techniques may also be useful in diagnosing atypical gout syndromes (e.g. radiculopathy from axial tophi). MRI can also demonstrate tophi, joint damage and associated inflammation, though specificity is low and aspirate confirmation is usually required. Ultrasound (US) can demonstrate bone erosions, tophi and the double-contour sign and although the specificity of these findings has been questioned US is a widely available imaging technique in clinical practice. DECT and US show promise in being able to monitor reduction in tophus size on urate lowering therapy in clinical trials. Raman spectroscopy is an interesting newly applied technique that currently being explored.
An important caveat to all imaging techniques is that they remain impractical in primary care where most gout patients are diagnosed and treated. Developing diagnostic methods that could be applied easily in this setting remains a priority.

### SP0043 CLINICAL OUTCOMES FOR GOUT PATIENTS IN RHEUMATOLOGICAL CARE

T. Uhlig. *Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

With increased interest in gout and the advent of better management opportunities more attention has been paid to defining relevant outcomes in gout, also for use in clinical practice.
International guidelines advocate treatment to below a threshold of 360 μmol/l (6 mg/dl) and below 300 μmol/l (5 mg/dl) if a patient has tophi. While this is the target for treatment, other outcome domains have been developed as part of OMERACT work.
Identified outcomes for acute gout include mandatory core outcomes: pain, joint swelling, joint tenderness, patient global assessment of disease activity, and activity limitations. In addition there are additional domains for assessment which include: an acute phase marker of inflammation, work disability, joint impairment, joint erythema, and physician global assessment of disease activity.
Many different instruments have been used to assess the acute gout core domains. In order to reduce existing variation, standardisation of measuring the most important domains of gout is recommended.
In clinical practice flares indicate a failure of ongoing treatment of gout. On the other hand the development of a responder index is an area of investigation as is the definition of remission in gout. Ongoing research tries to define a time period in which a flare needs to be absent so the patient can be defined as in remission.

## Hand osteoarthritis: state of the art and future perspectives

### SP0044 FUNCTIONAL CONSEQUENCES OF HAND OSTEOARTHRITIS

K. Dziedzic. *Arthritis Research UK, Primary Care Sciences Research Center, Stoke-on-Trent, United Kingdom*

Hand osteoarthritis (OA) is not a single disease but a group of complex conditions ranging from a syndrome of joint pain accompanied by functional limitation to highly characterised subsets of radiographic hand OA. Whilst hand OA is one of the commonest forms of osteoarthritis there is a "knowledge-to-practice" gap in recognising and addressing functional consequences of hand OA across the clinical pathway.
This presentation will consider functional consequences of hand OA at four levels: societal (population level); health care delivery (organisational level); health care professional level; and the impact on the person living with hand OA (individual level). It will draw on findings from three large cohorts of adults 50 years and over studied in North West Midlands, UK (n=30,000) (1–3) to describe the functional consequences of hand OA at a population level. Findings from a randomised controlled trial (3), an implementation study (4) and qualitative data (5) will be used to illustrate health care (e.g. primary care; occupational therapy) for the functional consequences of hand OA. The impact on the individual will be described using qualitative data of participant experiences of living with hand OA (6).
Proposals for closing the "knowledge-to-practice" gap for the functional consequences of hand OA will be discussed.

### SP0045 ASSESSING HAND OSTEOARTHRITIS IN CLINICAL CARE AND RESEARCH

C.H.E. Van Den Ende. *Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

Assessment of hand osteoarthritis (OA) is a challenge due to the involvement of multiple joints in the disease process and the complex interplay between thumb, fingers, wrists and hands. Symptoms of hand OA, commonly addressed by non-pharmacological interventions are pain, stiffness, reduced joint mobility, instability and reduced muscle function. Treatment of hand OA focuses on the relief of symptoms, improvement of dexterity, and the improvement of hand activities. In clinical research standardization of assessment is necessary to estimate the clinical burden of the disease and to evaluate the efficacy of (novel) treatment modalities. The OMERACT (Outcome Measures in Rheumatology) identified four core domains for clinical research in OA: pain, physical function and patient global assessment for symptom modifying trials and, in addition, imaging for structure modifying trials. Recently, a working group of the OMERACT proposed a preliminary set of core (sub) domains with preliminary instruments.[1]
In clinical practice assessment of hand OA guides setting of treatment goals and the treatment plan. In addition, structured assessment of OA can be used to monitor progress and to evaluate treatment results. In general, structured assessment in clinical practice comprises a combination of self-reported, objective and performance-based measures. The choice for a specific measurement instrument should be based on the purpose of assessment (for instance to

provide information about possible targets for treatment) and on the psychometric qualities of measurement instruments. An overview of measures to assess hand OA in clinical practice and research will be presented and discussed.

## Chronobiology of the immune reponse

### SP0046 SLEEP AS A MODULATOR AND ADJUVANT IN IMMUNITY

T. Lange. *Clinic for Rheumatology, University of Luebeck, Luebeck, Germany*

Sleep and immunity are linked by bidirectional interactions. On the one hand, immune activation induces fatigue, sleepiness and non-rapid eye movement (NREM) sleep, whereas REM sleep is suppressed. On the other hand, sleep, in particular NREM sleep, regulates immune functions in an overall immunosupportive manner. Thus, NREM sleep drives the release of pro-inflammatory hormones such as growth hormone, prolactin and aldosterone at a time when anti-inflammatory hormones such as cortisol and catecholamines reach lowest levels. In healthy subjects this unique endocrine pattern during NREM sleep seems to facilitate T cell homing to lymph nodes, pro-inflammatory cytokine production by stimulated monocytes and dendritic cell precursors and vaccine-driven T and B cell responses. However, in addition to this adjuvant-like action, sleep also exerts anti-inflammatory, regulatory functions. Thus, sleep presumably counteracts sterile, low-grade systemic inflammation, shifts anti-inflammatory cytokine production of stimulated monocytes to the daytime period and supports regulatory T cell functions. In autoimmune diseases these fine-tuned interactions between sleep and immunity are distorted. Potential causes, consequences and therapeutic implications of this dysregulation will be outlined exemplarily for patients with rheumatoid arthritis, systemic lupus erythematosus and systemic sclerosis.

### SP0047 CIRCADIAN CLOCKS AND INFLAMMATION: THE CLOCK AS A PHARMACOLOGICAL TARGET FOR INFLAMMATORY DISEASE

J.E. Gibbs. *Faculty of Medical and Human Sciences, University of Manchester, Manchester, United Kingdom*

The circadian clock is a biological timing mechanism that allows organisms to align their physiology with the external daily environment. 24h rhythms are generated within every cell by a transcriptional-translational feedback loop, the cellular clock. It is now evident that the cellular clock operates within the immune system, and this explains how responses to inflammatory stimuli show circadian variation. A prime example of this is the macrophage, which is capable of generating 24h rhythms *in vivo*, but also *ex vivo* in the absence of entraining signals. Macrophage responses (pro-inflammatory cytokine release) to inflammatory stimuli are significantly greater if the provocation occurs at dusk compared to dawn. Genetic ablation of the clock, by deletion of *bmal1*, in macrophages, renders them arrhythmic, and results in loss of this time of day variation in response. The cellular clock transmits timing information through REV-ERB alpha, a nuclear hormone receptor and transcriptional repressor. From this we discovered REV-ERB alpha is a tractable pharmacological target for inflammatory disease.
Other cell types involved in the pathogenesis of inflammatory arthritis are also intrinsically rhythmic, including T cells, dendritic cells and synovial fibroblasts. Indeed, using mouse collagen-induced arthritis we have shown that levels of inflammatory markers within inflamed joints show robust 24h rhythmicity. Transcript levels of *il1b* and *il6* peak at dawn, which is remarkably consistent with clinical observations, showing a rise in circulating levels of cytokines in the early morning. Further analysis revealed that the negative arm of the molecular clock (specifically CRYPTOCHROME) suppresses arthritis during the night. Furthermore, small molecule CRYPTOCHROME activators were found to have anti-inflammatory actions in both murine and human synovial fibroblasts – re-affirming the notion that the circadian clock is a therapeutic target for inflammatory disorders.

## Nanomedicine in rheumatology

### SP0048 WHAT ARE NANOPARTICLES: PHYSICS FOR MEDICAL DOCTORS

A. Shah. *Duke University, Duham, United States*

Nanotechnology has improved the medical world broadly rheumatology specifically through a number of innovative applications used to enhance diagnostics through imaging and therapeutics through enhanced drug delivery. In order to have a better understanding of nanomedicine, however it is helpful to review the basic chemistry and quantum physics that serve as the basic fundamental science of this technology. The building blocks of the nanoworld are atoms as well as the electromagnetic forces between them are the basic forces that give nanomaterials their properties These atoms, in particular carbon, are then shaped into a variety of structures including buckyballs, carbon nanotubes and nanowires that comprise much of todays nanotechnology. In addition thermal agitation as well as cohesion between atoms and molecules serve critical roles in contributing to unique nanomaterial characteristics. Finally, light, namely viewed as a stream of particles called photons, plays a critical role in nanomedicine. Electron microscopy and scanning tunneling microscopy are only two examples of exploiting photons at the nanoscale in order to enhance the role of nanomedicine in medical imaging.

**DOI:** 10.1136/annrheumdis-2016-eular.6304

### SP0049 NANOPARTICLES AND THE IMMUNE SYSTEM

C. Strehl[1,2]. *[1]German Rheumatism Research Centre (DRFZ); [2]Department of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Berlin, Germany*

An individually tailored diagnosis and therapy (theragnostic) could be beneficial in chronic, systemic, inflammatory autoimmune diseases like rheumatoid arthritis. The destructive nature of the disease, resulting in irreversible damages of cartilage and bone, demonstrates the urgent need for a very early diagnosis. Promising candidates for such a tool are represented by nanoparticles which have been intensively investigated over the last 20 years for various *in vitro* and *in vivo* biomedical applications. For example, nanoparticles are already in use as contrast enhancer for magnetic resonance imaging due to their favorable physicochemical properties and their biocompatibility. Further developments like surface modifications are ongoing. In order to permit the medical application of nanoparticles safety aspects need consideration.
The collaborative project NanoDiaRA was funded by the European Union and focused on the “Development of novel nanotechnology based diagnostic systems for Rheumatoid Arthritis and Osteoarthritis”. Within the project, a novel generation of superparamagnetic iron oxide nanoparticles (SPION) was developed and their effect on human immune cell survival and activity was analyzed. The nanoparticles were modified stepwise until there was no negative influence of the improved type of SPION on human immune cells. Finally, the resulting generation of nanoparticles has been demonstrated to be suitable within the human system and, therefore, represent a promising tool for theragnostic in rheumatic diseases.

### SP0050 NANOMEDICINE APPROACHES IN RHEUMATOLOGY

B. Sarmento. *Institute of Biomedical Engineering, Porto, Portugal*

Rheumatoid arthritis (RA) is one of the most common and severe autoimmune diseases related to joints [1, 2]. Regrettably, RA inflammatory process remains puzzling, and finding effective therapies for the disease as well as new means for its early diagnosis have been daunting tasks. As a response to RA inflammation, the synovial tissue shows synovial lining hyperplasia as a result of Fibroblast-Like Synoviocyte (FLS) and Macrophage-Like Synoviocyte (MLS) accumulation. In fact, the synovial intimal lining in RA, instead of one or two cells deep, is frequently up to five-fold deeper. Consequently, more macrophages, lymphocytes, and fibroblasts are activated and the RA inflammatory process remains [2–4]. Thus, macrophages play a pivotal role in the features and progress of RA, and effective diagnosis and therapy may encompass the ability to target these cells.
Currently, the main target of RA therapy is to control the inherent inflammatory response and alleviate pain. Several therapeutic options have been used to manage and slow down the progression of the disease, which include the use of sulfasalazine, hydroxychloroquine or methotrexate – a first line disease modifying anti-rheumatic drug (DMARD) [5, 6]. Methotrexate (MTX), is being widely used due to its satisfactory safety profile, efficacy and low cost. It is an analogue of folic acid as it disrupts cellular folate metabolism by inhibiting its target enzyme, dihydrofolate reductase [6–8]. Still, there is a lack of specificity for MTX and/or other similar drugs.
Nanomedicine has thrived and is now providing new possibilities for the use of nanomaterials in medical applications for drug delivery and tissue regeneration [9–11]. Recent developments in the understanding of inflammation have led to an increased interest in the use of nanomedicine in the treatment of rheumatoid arthritis. Nanomedicine may also offer new opportunities to combine diagnosis and therapy in a single approach. Improved theranostics processes are being studied in order to develop new means to diagnose, fight and follow disease. The release and action of anti-rheumatic drug may be enhanced and controlled, and potentially without injuring healthy tissues and organs, while simultaneously providing a non-invasive and specific imaging tool for RA.
This presentation aims at explaining the major applications of nanomedicine in rheumatoid arthritis treatment and diagnosis. Commercial successes of RA active targeting of nanomedicine and products under development will be revised. Insights on multifunctional anti-CD64 mAb-modified nanoparticles for the combined delivery of MTX and iron oxide nanoparticles (SPIONs) proposed by

our group will be presented [12, 13]. Proposed nanoparticles have the potential to provide a new theranostic approach for RA management.

## HOT session 2

SP0051 **PAIN MANAGEMENT**

E. Choy. *Department of Rheumatology, Cardiff University School of Medicine, Cardiff, United Kingdom*

Musculoskeletal conditions are the most common causes of chronic pain leading to consultation in primary care. The most common conditions are osteoarthritis, inflammatory arthritis, chronic regional pain (e.g. back pain) and chronic widespread pain (fibromyalgia). Since musculoskeletal conditions are prevalent, it is not uncommon for a patient to suffer from more than one chronic painful musculoskeletal condition. Functional neuroimaging studies have shown that all types of pain are processed within a common human pain matrix in the brain. Inflammation causes pain in many musculoskeletal conditions. Typically, inflammation is caused by activation of the leucocytes, which release cytokines and convert arachidonic acid into prostaglandins by cyclo-oxygenase II (COX-II) enzyme. At the site of inflammation, prostaglandin E2 (PGE2) increases the responsiveness of peripheral nocioceptors and contributes to the development of peripheral sensitisation. In animal model of inflammatory arthritis, COX-2 is also upregulated in the dorsal horn of the spinal cord and contributes to the development of central sensitization. Furthermore, cytokine receptors are also expressed by sensory nocioceptive neurones, which are activated by cytokines. Therefore inflammation has direct and indirect roles in the development of chronic pain in many musculoskeletal diseases. This review will focus on treatments that could be applied to most musculoskeletal conditions rather than disease specific treatment such as disease modifying drugs for inflammatory arthritis.

The aims of treatment of chronic musculoskeletal pain are to educate patient on diagnosis, reduce severity of symptom, improve function and empower patients to self-manage. Treatment of chronic musculoskeletal pain should be tailored to the individual, addressing their particular needs and minimising the risk of side effects from treatment. The best strategy is to use a multidisciplinary holistic approach combining non-pharmacological and pharmacological interventions. National bodies such as the British Society for Rheumatology and IASP Musculoskeletal Taskforce have published management recommendations based on systematic reviews. Patient education and graded exercise are important in all patients with chronic musculoskeletal pain. Topical treatment such as ice, heat, transcutaneous nerve stimulator and manual therapies may provide symptomatic relief although the strength of evidence is weak, the risk of side effect is small. Cognitive behavioural therapy has been shown to improve pain and function. It should be considered especially in patients with difficulty in cope with pain and have significant functional impairment.

Pharmacological intervention should starts with simply analgesia such as paracetamol. Codeine phosphate or nefopam can be added if necessary. Topical and oral non-steroidal anti-inflammatory drugs (NSAIDs) or cyclo-oxygenase (COX-2) inhibitors may be added to simple analgesics for treating acute exacerbation. NSAIDs and COX2 agents should be used with caution in patients with cardiovascular diseases. Short courses of tramadol, a weak opioid analgesic with serotonergic and adrenergic activities can be used for treating moderate to severe pain. For patients with moderate to severe chronic musculoskeletal pain, satisfactory analgesia may be achieved by using a non-escalating dose of opioids with minimal risk of addiction. Depression is common in patients with chronic musculoskeletal pain. Serotonin and nor-adrenaline are important neurotransmitters involved in the pain pathway, hence many anti-depressants have pain modification property and can be used as adjunctive treatment. However, patients with severe depression should be referred for management by mental health team. All patients should be given advice for self-management and dealing with exacerbation of symptoms. For patients with persistent distress or increasing disability referral to secondary care physician, psychologist or multidisciplinary pain clinic is recommended.

SP0052 **HOW TO TREAT/MANAGE FIBROMYALGIA**

D.A. Williams. *Anesthesiology, University of Michigan, Ann Arbor, United States*

Fibromyalgia (FM) is often associated with profound suffering on the part of patients and can be quite challenging to the clinician to treat/manage. This talk will provide demographic information about FM as well as a brief summary of current research supporting putative peripheral and central nervous system mechanisms underpinning this condition. Multiple approaches have been used to diagnose FM and these methods will be reviewed and clarified for a clinical audience. Multi-modal treatment is considered optimal for the long-term management of FM and a variety of pharmacological as well as non-pharmacological options are available. This talk will review some of the evidence supporting these options and will describe how best to craft a logical treatment plan taking into account the needs of the individual patient.

## Beyond EMEUNET: development of a European-wide network of young clinicians from different specialties focusing on inflammatory diseases

SP0053 **EXPERIENCES FROM YOUNG RHEUMATOLOGISTS INTO EMEUNET**

A. Moltó on behalf of EMEUNET. *Rheumatology Department, Hopital Cochin, Paris, France*

EMEUNET, the Emerging EUlar NETwork, is a network of young clinicians and researchers in the field of rheumatology in Europe. The principal objectives of EMEUNET are:

(1) To enhance the quality of education among emerging rheumatologists and researchers by, among others:
- Dedicated content on the EMEUNET Website, facebook and Twitter and regular Newsletters
- A network of Country Liaisons responsible for communicating EMEUNET projects/activities and documents to the national societies, and particularly to young trainees and researchers in EULAR member countries
- EMEUNET initiated courses and mentoring projects
- EMEUNET Observers, recruited yearly from among EMEUNET Working Group Members on the Standing Committees of EULAR
- Participation in EULAR task forces for the development of EULAR recommendations
- Sessions proposals for "The Young Rheumatologist" track at the EULAR Annual Congress under the umbrella of the EULAR Standing Committee for Education and Training (ESCET)

(2) To promote research and create collaborations among emerging rheumatologists and researchers by, among others:
- Establishing a database of young rheumatologists involved in research and of researchers working in the field of rheumatology
- Supporting exchange of methodologies, technical data and knowledge as well as dissemination of documents between emerging researchers, through the EMEUNET Website, Facebook, and Twitter
- Organizing together with Annals of the Rheumatic Diseases the peer-review mentoring program
- Promoting networking at social events held at the EULAR and ACR Annual Congress

– Organizing mentor/mentee meetings between EMEUNET members and leaders in the field at the EULAR and ACR Annual Congress

None of these objectives could be fulfilled without the work and enthusiasm of the people involved in the 7 subgroups that form the Working Group of EMEUNET: Education, Peer Mentoring, Newsletters, Social Media, Visibility, Country Liaisons and Global Affairs.

EMEUNET subgroups are enthusiastically engaged in several activities, and the list of current and upcoming projects has quickly expanded over the past few months.

With all these initiatives and activities we hope that EMEUNET will continue to be embraced by the young rheumatology community and more and more young clinicians and researchers in rheumatology will become involved in rheumatology education, research and EULAR, making EMEUNET a successful and influential resource that fosters new and long-term collaborative endeavours and ensures that excellence in European Rheumatology and EULAR is maintained.

## SP0054 EXPERIENCES FROM YOUNG GASTROENTEROLOGISTS INTO Y-ECCO

P. Hindryckx on behalf of Young-ECCO. *Gastroenterology, University Hospital of Ghent, Ghent, Belgium*

The European Crohn's and Colitis Organisation (ECCO) is an association that aims to improve the care of patients with inflammatory bowel disease through education, research and collaboration. ECCO was founded in 2001 and has been rapidly growing over the past years. The last ECCO congress had almost 7000 attendees. The operational board of ECCO consists of the chairs of the different ECCO committees. Among these ECCO committees is Young-ECCO (Y-ECCO), which was founded in 2007 as a platform for young IBD physicians and scientists that are below 35 years of age or still in training, in order to promote friendship and collaboration between them. Y-ECCO has initiated numerous activities within ECCO (for example, a workshop on career development, literature reviews, a basic science workshop, ...) and closely collaborates with the other ECCO committees to fulfill the mission of ECCO.

## SP0055 EXPERIENCES FROM YOUNG REPRESENTATIVE OF PAEDIATRIC RHEUMATOLOGY EUROPEAN SOCIETY

E. Smith. *Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom*

The Paediatric Rheumatology European Society (PRES) is a European scientific society for healthcare professionals in the field of paediatric rheumatology. The societies missions are to promote knowledge of paediatric rheumatic diseases, stimulate research in this field, disseminate knowledge through scientific meetings and publications, provide guidelines and standards for good clinical practice. Importantly PRES provides guidelines and standards for the training of doctors and allied health professionals in the practice of paediatric rheumatology. As the young/trainee representative on the PRES council I am involved in representing the views of trainees at council meetings. PRES holds a scientific congress each year which is preceded by an annual Young Investigators Meeting (YIM), which I organize along with a local trainee(s). This is a very popular meeting which is increasing in size and currently brings together approximately 150 young investigators (clinicians and scientists) from across Europe but also America, Australia, India, Africa. It is a good opportunity for young investigators to have their first international presentation and network with senior faculty to discuss and develop research ideas. As the trainee representative I am also involved in organising and promoting PRES funded training courses and gaining opinion from trainees about the type or course they would like. PRES plans to run summer/winter schools on certain conditions in the near future. I have recently assisted the PRES Education and Training Committee in updating the European Paediatric Rheumatology syllabus which will be launched in summer 2016.

## SP0056 BEYOND EMEUNET: DEVELOPMENT OF A EUROPEAN-WIDE NETWORK OF YOUNG CLINICIANS FROM DIFFERENT SPECIALTIES FOCUSING ON INFLAMMATORY DISEASES: EXPERIENCES FROM THE YOUNG NEPHROLOGISTS' PLATFORM

A.C. Ferreira on behalf of Young Nephrologists' Platform. *Department of Nephrology, Centro Hospitalar de Lisboa Central - Hospital de Curry Cabral, Lisbon, Portugal*

The Young Nephrologists' Platform (YNP) was developed in 2012 and started its formal activity in 2013. It aims to involve all young professionals with interest in nephrology in all *European Renal Association - European Dialysis and Transplant Association* (ERA EDTA) activities. It is composed of 9 Board Members: 6 elected members from the ERA EDTA plus 3 ex-officio members, winners of the annual *Young Investigator* award.

All young (<40 years old) ERA EDTA members can apply to became Ordinary Members, and those are the ones who benefit from YNP activities.

The communication among the members is performed by electronic means, as blast emails, surveys, and using the YNP blog. In these last three years, YNP developed two programs (free membership program and the advisory program), annually prepares the annual session at the European congress and annual CME Courses, and developed a new educational tool – the hot topics.

The Free Membership Program offers 50 ERA EDTA memberships to YNP Ordinary Members, based on two types of accomplishments: the abstract-based type (30 free memberships to the 30 best abstracts submitted to annual ERA EDTA Congress) and the paper-based type (20 free memberships for manuscripts published on ERA EDTA journals by YNP members as 1st or last author).

The Advisory Program is a 9 to 12 month length unique opportunity to exchange experiences and knowledge between two participants, the advisor (an experienced nephrologist, member of ERA EDTA) and the advisee (a young professional, member of YNP).

The YNP sessions at the ERA EDTA annual congress are organized to provide an opportunity for young recognized researchers to show their experiments and results. Every year the Young Investigator Awardee is also invited to lecture during the YNP session.

The YNP CME Courses are focusing different topics each year.

The *Hot Topics* is seen as a new tool of study, and was developed to help young physicians to gather the latest information on certain topics, but also to interact with renowned experts. On each topic, YNP invites an expert to discuss a recent and relevant paper about the topic, and all YNP members can participate and communicate with the expert, via blog, adding questions or comments. Additionally, YNP members can test their knowledge with the YNP quizzes we provide on each topic.

**Disclosure of Interest:** A. C. Ferreira Grant/research support from: From the Portuguese Society of Nephrology.

# Data visualisation: tables and graphs for publication and presentation I

## SP0057 DATA VISUALISATION: TABLES AND GRAPHS FOR PUBLICATION AND PRESENTATION

M. Boers. *Epidemiology & Biostatistics; Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands*

This workshop (repeated on Friday, 15:30, Capital Suite 06) is an introduction to the principles of good graph and table design as pioneered by Cleveland[1] and Tufte[2] and updated by Few[3] so that the participant can better answer the following questions:

*Which of the messages in my research results requires a graph or table?*

Recognizing how graphs improve on simple statistics and convey much more information. Knowing when a table is better, or keeping the data in the body text.

*How can I best convey the message?*

Striving for clear vision by choice of graph, scaling, discrimination of data series, minimizing non-data ink, avoiding chart junk.Striving for clear understanding through a balance between data and explanation. Using order, subheadings, formatting and rules to guide your reader through your table data.

*Is my graph/table truthful?*

Creating a direct proportion between graph and data quantities, avoiding forms prone to misinterpretation, labels to prevent ambiguity; keeping data in context, avoiding more dimensions in the graph than in the data.

This year's course will extend introductory material available via YouTube clips on the ARD website (ard.com)! Direct link: https://www.youtube.com/playlist?list=PLXU14EQbU_V9JpmolAKsaCC0VjJzbxzAN

## Ultrasound basic I

### SP0058 SCORING OSTEOARTHRITIS (OA)

I. Möller. *Instituto Poal de Reumatologia, Barcelona, Spain*

Musculoskeletal ultrasound (US) is an imaging tool applicable in the detection and scoring of elementary lesions in patients with knee and hand OA. After defining and reaching a consensus on the US detected elementary lesions in patients with hand and knee OA, the reliability of the agreed scoring system has been tested. In both cases, using semi-quantitative and/or dichotomous scales, the results showed moderate to good reliability. The results vary depending on the elementary lesion tested. For example, there was good reliability for osteophyte scoring in hand OA but fair to moderate for cartilage with intermediate degrees of damage according to the proposed scoring systems. Other joints will be tested in the future with the purpose of assessing reliability of the scoring these elementary OA lesions.

### SP0059 SCORING LARGE VESSEL VASCULITIS

A.P. Diamantopoulos. *Rheumatology, Hospital of Southern Norway Trust, Kristiansand S, Norway*

Giant cell arteritis (GCA) and Takayasu's arteritis are the two main forms of large vessel vasculitides (LVV) predominantly affecting the large and medium vessels. GCA is the most common form of systemic vasculitis.

Studies have shown that ultrasound yields a high sensitivity and specificity in the diagnostics of GCA, and that it could also be useful as follow up tool. In coronary syndromes, the presence of increased carotid intima–media thickness (IMT) and plaques in the carotid or femoral arteries have been correlated with classic risk factors and coronary risk. Yet, in LVV, no studies exist regarding increased IMT due to vasculitis and its influence on disease activity and prognosis. Possible explanations include the lack of definitions on angiopathology, technique standardization and of a widely acknowledged scoring system. Recently, an OMERACT group on ultrasound in LVV introduced definitions on both vasculitic lesions and atherosclerosis.

This session aims to present: 1. An overview and demonstration of the ultrasonographic definitions of vasculitis, 2. Considerations around potential scoring systems.

### SP0060 IMPACT ON SCORING - MACHINE AND EXPERIENCE

G. Tamborrini. *Rheumatology, UltrasoundCenter, Basel, Switzerland*

In this practical ultrasound session we discuss exemplary studies demonstrating the feasibility and reproducibility of scoring systems for e.g. Rheumatoid Arthritis. We emphasis the importance of the quality of ultrasound machines, the correct settings and the training of sonographers for the implementation of ultrasound scoring in the routine daily care of RA patients. We promote consensus guidelines and high quality training to improve musculoskeletal ultrasound reliability.

## Patient organisations in action

### SP0061 THE ROLE OF PATIENT ORGANISATIONS IN HEALTH TECHNOLOGY ASSESSMENT

K. Facey. *Patient Involvement Methods and Impact Working Group, HTAi, Drymen, United Kingdom*

Health Technology Assessment (HTA) is defined as a multidisciplinary process that summarises information about the medical, social, economic and ethical issues related to use of a health technology (medicines, devices, vaccines, rehabilitation etc) in a systematic, transparent, unbiased, robust manner. Its aim is to inform health policy at local or national level including decisions about reimbursement and access.

Principles of good practice for HTA were published in 2008 and these included "stakeholder involvement", recognising that policy initiatives should include a democratic right for involvement. Patients and their representatives are clearly key stakeholders, but questions arise about how they should be involved in the complex processes of HTA without compromising scientific integrity.

The Health Technology Assessment International (HTAi) Interest Group for Patient/Citizen Involvement in HTA believes that patients and their representatives can provide valuable input to HTA by sharing their experiences of living with a condition, use of current health technologies and experiences and expectations of new health technologies. This unique knowledge can add value to every stage of the HTA process, but in many countries there is no involvement of patients and no transparency about how patients can be involved in HTA. So, the HTAi Interest Group works with all stakeholders to develop tools and initiatives to support HTA bodies to involve patients and patient organisations in a meaningful manner and to support patient organisations to get involved in HTA.

Any patient group's approach to HTA must be specific to their own setting, but can draw on the international recommendations made by HTAi – such as their Values and Quality Standards for Patient Involvement in HTA. Furthermore, patient groups can help support capacity building through better collaboration about their experiences in HTA and development of generic information about their condition and its unmet needs that can be shared internationally. Finally they have a crucial role in evaluating HTA processes to ensure that they are fair and transparent.

**Disclosure of Interest:** K. Facey Consultant for: A range of health technology companies, HTA bodies and patient organsiations

## Hot topics in paediatric rheumatology

### SP0062 SHARE RECOMMENDATIONS ON CONNECTIVE TISSUE DISEASES

M.W. Beresford[1,2]. [1]*Institute of Translational Medicine, University of Liverpool;* [2]*Paediatric Rheumatology, Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom*

**Introduction:** The paediatric connective tissue disorders and paediatric systemic vasculitides are rare, complex and can lead to significant associated morbidity and mortality. Evidence-based guidelines are sparse and management is mostly based on physician experience. Consequently, treatment regimens differ widely throughout Europe.

In 2013, a European initiative called SHARE (Single Hub and Access point for paediatric Rheumatology in Europe) was launched to optimize and disseminate guidelines for diagnosis and management for children and young adults with paediatric rheumatic diseases (PRD) within Europe including the connective tissue disorders and vasculitides.

**Objectives:** To provide evidence-based recommendations for diagnosis and treatment of paediatric connective tissue disorders and systemic vasculitides.

**Methods:** Evidence based recommendations were developed using the European League Against Rheumatism (EULAR) standard operating procedure. International expert committees were instituted, consisting of paediatric rheumatologists with relevant expertise along with experts from other related disciplines. A detailed systematic literature review was undertaken, articles scored for validity and level of evidence. Recommendations derived from the literature were evaluated using an online survey, reformulated and discussed at a consensus meeting using the nominal group technique. Recommendations were accepted if more than 80% agreement is reached.

**Results:** Summary results of the systematic literature reviews overview of the final consensus SHARE recommendations will be presented. These provide evidence based, internationally agreed standards of minimal care for PRDs including the paediatric connective tissue disorders, rare as well as more common vasculitides. Specific detail will focus on childhood-onset systemic lupus erythematosus and the vasculitides.

**Conclusion:** The SHARE initiative provides recommendations for diagnosis and management treatment and thereby facilitates improvement and uniformity of care for patients throughout Europe.

### SP0063 CLINICAL TRIAL DESIGN IN PEDIATRIC RHEUMATOLOGY

N. Ruperto on behalf of the Paediatric Rheumatology International Trials Organisation (PRINTO). *Pediatria II, Reumatologia, PRINTO, Istituto Giannina Gaslini, Genova, Italy*

This lecture will present a general overview, with pros and cons, of the different study design that could be employed for drug evaluation in pediatric rheumatic diseases.

Among the multitude of study designs that could be considered in pediatric rheumatology, the major trial designs are the classic parallel randomized clinical trial (RCT) with placebo or active comparator and the randomized withdrawal design. While the parallel design still remain the gold standard for establishing the efficacy and short-term safety of an experimental agent, disadvantages include ethical concerns due to the use of placebo in children with chronic condition for

which alternative treatments are available. The option of using an active control is not feasible due to the high sample size that are required by these kind of trial. The double-blind, controlled, randomized withdrawal design was proposed for the first time by Dr Lovell and Dr Giannini for use in pediatric rheumatology studies in particular for juvenile idiopathic arthritis. Eligible children are treated in an open label fashion with the experimental therapy to be tested in the trial for a few months after which responders (typically defined as those demonstrating an ACR Pediatric 30 response) are randomized in a double-blind fashion either to continue the experimental therapy or to switch to placebo. In this segment of the study, called the double-blind withdrawal phase, patients who demonstrate a pre-defined definition of disease worsening (e.g. "flare") are withdrawn from the double-blind withdrawal phase and usually re-treated with the experimental therapy in an open label fashion. The withdrawal design has proven to be very effective design and has been used in nearly all recent trials of biologic agents in children with JIA. Data gathered by use of this design led to the approval of biologic agents for children with JIA by both the FDA and EMA.

**Disclosure of Interest:** N. ## Plasma cells as key players and therapeutic target in rheumatic diseases

### SP0064 PATHOGENIC MEMORY PLASMA CELLS IN RHEUMATIC DISEASES - A CRITICAL TARGET OF THERAPY

A. Radbruch. *Cell Biology, Deutsches Rheuma-Forschungszentrum Berlin (DRFZ), Berlin, Germany*

Plasma cells can contribute to rheumatic inflammation through the secretion of pathogenic (auto)antibodies. While autoreactive plasma blasts are short-lived products of the chronic inflammation, autoreactive memory plasma cells can be generated already early on, in the preclinical phase, and continuously thereafter. They are refractory to conventional immunosuppressive therapy, such as glucocorticoids, anti-TNF or anti-CD20 antibodies, aiming at the termination of ongoing immune reactions. Memory plasma cells secreting pathogenic antibodies thus can provide the memory for chronic inflammation. In diagnostic terms, titers of (auto)antibodies maintained in spite of immunosuppressive therapy, in a given patient, indicate the presence of memory plasma cells secreting them: A therapeutic challenge. Memory plasma cells reside in special survival niches within the bone marrow, but also in the inflamed tissue itself, resting in terms of proliferation and mobility. They do not express CD20. They are not long-lived intrinsically, but kept alive by survival factors, such as VCAM1 and APRIL, provided by stroma cells and accessory cells of their survival niche. Understanding the lifestyle of memory plasma cells has provided strategic options to target them, but so far almost all therapeutic options do not discriminate between pathogenic and protective plasma cells, and thus imply loss of humoral memory and increased risk of infections. The therapeutic challenge is to ablate pathogenic plasma cells selectively and maintain protective humoral memory as much as possible, and to prevent regeneration of memory plasma cells from their precursors.

### SP0065 IMMUNOSUPPRESSIVE ACTIVITIES OF B CELLS AND PLASMA CELLS

S. Fillatreau. *Team Immunity in Health and Disease, INEM, Paris, France*

B cells can contribute to immunity through production of antibodies, presentation of antigen to T cells, and secretion of cytokines. Through these mechanisms, B cells can act both as drivers and as regulators of immunity, and these two antagonistic activities seem to be at play during the majority of immune responses. Understanding how these opposite functions are mediated shall stimulate the elaboration of novel approaches for monitoring and manipulating the immune system. Here, we will discuss specifically about how B cells negatively regulate immunity through provision of cytokines. The presentation will discuss the suppressive roles of B cells during autoimmune disorders, and infectious diseases. The signals controlling the acquisition of suppressive functions by B cells (BCR, TLR, CD40), the mediators of suppression (production of IL-10 and IL-35), and the mechanisms of suppression (effects on innate cells, effector and regulatory T cells) will be presented. Moreover, we will discuss the phenotype of the B cells providing these regulatory functions *in vivo*, emphasizing the concept that specific subsets of plasma cells/plasmablasts are the major B cell source of regulatory IL-10 and IL-35 *in vivo*.

## Global year against joint pain

### SP0066 PERIPHERAL PROCESSING AND CENTRAL MODULATION OF PAIN

S. Sikandar. *Wolfson Institute of Biomedical Research, University College London, London, United Kingdom*

The ability to perceive pain from cutaneous to deeper tissues and organs is part of the normal sensory repertoire of many animal species. Nonetheless, ongoing chronic pain substantially reduces the quality of life of suffering patients, often accompanied with co-morbidities that further add to the socioeconomic burden of chronic pain. Pain harnesses many neuronal systems from the periphery along the central neuraxis to higher centres of the brain. Following tissue or nerve injury, sustained activity in peripheral afferents can significantly increase the excitability of spinal cord neurones and higher centres in the brain, producing central sensitisation with ensuing pain and altered sensory function.

This talk will outline our current understanding of pain pathways in the peripheral and central nervous system. The significant role of supraspinal influences and changes in spinal excitability in the development and maintenance of abnormal sensitivity in chronic pain states will be discussed. Indeed, descending projections from the brain to the spinal cord can protect again persistent pain, e.g. in placebo analgesia, and central sensitization can occur in the absence of peripheral pathology, e.g. after opioid-induced hyperalgesia. This talk will cover the pro-nociceptive changes that occur in peripheral, spinal and supraspinal centres in chronic pain states and relate this to potential improvement of targeted analgesic therapies.

### SP0067 SENSITIZATION AND PAIN IN OA

T. Neogi. *Clinical Epidemiology Unit, Boston University School of Medicine, Boston, United States*

Osteoarthritis (OA) is the most common form of arthritis, with the hand, knee and hip being the most prevalent joints affected. Pain is the primary clinical symptoms of knee OA and knee OA itself is a leading cause of disability among older adults worldwide. Yet there are limited management options for the symptoms of knee OA, and no proven therapies that can alter its progression. An improved understanding of pain etiology in knee OA is critical to improving OA outcomes by identifying rational therapeutic targets.

While there are data to support the importance of structural pathology as contributing to pain in knee OA, such structural lesions do not fully account for the pain experience in OA. Whereas knee OA pain is typically activity-related earlier in the course of disease, pain can be come chronic later in the disease course, suggesting the possibility of altered neurobiological pathways playing a role in OA pain. Peripheral and central sensitization, which reflect alterations in the ascending nociceptive signals in the peripheral and central nervous systems, respectively, and inadequate descending inhibition can lead to heightened pain sensitivity.

Sensitization can be assessed in clinical studies with pressure pain threshold and temporal summation, and assessment of conditioned pain modulation provides insights into efficiency of the descending inhibitory pathways. Conditioned pain modulation has been demonstrated to be abnormal in patients awaiting joint replacement surgery, and to improve post-replacement, raising in the intriguing possibility that certain abnormalities of pain processing can be altered by removing the pathologic tissue. In terms of sensitization, pressure pain threshold is lower (i.e., more pain sensitive and/or sensitized) in subjects with knee OA than in healthy controls around the knee and other anatomic sites on both the ipsilateral and contralateral sides. Lower pressure pain threshold and temporal summation are also associated with higher likelihood of pain presence and severity both at the knee and distant to the knee, but have no clear relation to radiographic severity or duration of disease. However, synovitis and effusion, which are inflammatory lesions in knee OA, are associated with both pressure pain threshold and temporal summation. In contrast, bone marrow lesions, which are largely mechanically-driven lesions in knee OA, are not associated with these measures of sensitization. These results suggest that certain features of knee OA may result in sensitization, and offer a potential avenue for targeted therapy to reduce the occurrence of sensitization, and thereby reduce pain severity in knee OA.

### SP0068 LINKS BETWEEN ANGIOGENESIS, INFLAMMATION AND PAIN IN OA

D.A. Walsh. *Arthritis Research UK Pain Centre, Academic Rheumatology, University of Nottingham, Nottingham, United Kingdom*

Pain is the most troublesome symptom for people with arthritis, and yet the relationships between pathological change within the joint and symptoms are often weak. Key progress on understanding which specific pathological processes contribute to the generation of pain signals from the arthritic joint have pointed to new blood vessel growth (angiogenesis). Angiogenesis is a component of normal tissue growth and even pathological angiogenesis need not of itself cause pain, for example in diabetic retinopathy. However, angiogenesis is also characteristic of chronic inflammation, and the various growth factors and cytokines that stimulate blood vessel growth can also induce sensitisation of peripheral sensory nerves. Furthermore, vascular growth factors can also stimulate neuronal growth and, reciprocally, nerve growth factors might be angiogenic. This close interplay between vascular and neuronal growth is reflected in the normal sequence by which angiogenesis is followed by the extension of sensory nerve terminals, often into diseased tissues that would not normally receive innervation nor be a source of pain. Examples of tissues that might be sources of pain from arthritic, but not normal joints include the non-calcified articular cartilage and inner two thirds of knee menisci. Angiogenesis might also facilitate inflammation, permitting increased cellular recruitment, concomitant release of other neuronal sensitising factors and exacerbation of structural change. Furthermore, blood vessel growth is a prerequisite for endochondral ossification, contributing directly to structural change and altered biomechanics within the joint. Angiogenesis might be a marker for other pathological processes associated with pain. For example, vascular breaching of the osteochondral junction in OA is associated with subchondral marrow replacement by fibrovascular tissues that is characteristic of some bone marrow lesions observed by MRI scanning. Angiogenesis inhibitors have potential to prevent or relieve arthritis pain, but their application to human arthritis has been limited by potential toxicity that might result from inhibition of physiological angiogenesis (e.g. during the menstrual cycle or pregnancy) or tissue repair. Reduction of pain by angiogenesis inhibitors might result from indirect effects on inflammation that could be achieved by other strategies. However, more recent research into the plurality of effects of vascular endothelial growth factor and its isoforms suggests that inhibition of angiogenic factors might also directly influence pain transmission in the central nervous system, independent of effects on blood vessel growth. Continuing research into angiogenesis in arthritis is revealing previously unexpected insights into the relationship between joint structure and patient symptoms, particularly pain.

## HOT session 4

### SP0069 JIA AND OTHER PAEDIATRIC RHEUMATIC DISEASES

N. Ruperto on behalf of the Paediatric Rheumatology International Trials Organisation (PRINTO). *Pediatria II, Reumatologia, PRINTO, Istituto Giannina Gaslini, Genova, Italy*

Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disorder in children and is also a major cause of acquired disability and quality of life impairment in childhood. Children with oligoarticular JIA are usually treated with NSADS and intraarticular steroid injections. For children with polyarticular course JIA, methotrexate (MTX) is the drug of first choice since it provides significant clinical benefits, with an acceptable toxicity profile. For children not responding to MTX, the introduction of the biologic agents has determined a substantial advantage for the therapy of JIA since for the first time we have now drugs able to selectively block key components of the inflammation cascade.

Biologic agents can be globally divided into 2 categories: drugs able to block the tumor necrosis factor (TNF) (etanercept, infliximab, adalimumab and others) and drugs with different mechanism of action (eg abatacept, tocilizumab, anakinra, canakinumab ecc). In general biologic agents, also for their elevated cost, have to administered in children with severe arthritis non responsive to conventional therapies, primarily MTX.

The real novelty in these last years, has been the availability of biologic agents to be specifically used for the treatment of systemic JIA where, along with arthritis, children have systemic manifestations such as fever, rash, serositis, lymphadenopathy etc. These new drugs are indeed able to block selectively molecules that has been shown to be pivotal in the inflammatory process such as IL6 (tocilizumab) and IL 1 (anakinra, canakinumab and others)

Most of the biologic agents have been tested (or are currently under study) thanks to the involvement of the Pediatric Rheumatology International Trials Organisation (PRINTO at www.printo.it) and of the Paediatric Rheumatology Collaborative Study Group (PRCSG at www.prcsg.org).

This review will present a practically orientated overview of the “state of the art” for the treatment of JIA and the other major paediatric rheumatic disases including an overview on safety aspects.

### SP0070 HOW TO TREAT IGG4-RELATED DISEASE

J.H. Stone. *Rheumatology, Massachusetts General Hospital, Boston, United States*

IgG4-related disease (IgG4-RD) is an emerging condition highly relevant to rheumatologists because of its immune-mediated nature, its propensity to cause multi-organ disease, and its ability to mimic multiple classic rheumatologic conditions. IgG4-RD readily mimics Sjogren’s syndrome, lupus nephritis, granulomatosis with polyangiitis, eosinophilic granulomatosis with polyangiitis, sarcoidosis, large-vessel vasculitis (e.g., giant cell arteritis) and others. Despite its only recent recognition approximately a dozen years ago, we have learned much about the pathophysiology of this condition. Our understanding of disease mechanisms informs both current and future approaches to treatment. I will discuss the practical, hands-on management of IgG4-RD and also consider ways in which our mechanistic understanding is driving current treatment trials.

## Designing solutions to support young people to address the challenges of living with a rheumatic or musculoskeletal disease

### SP0071 THE ROLE OF YOUNG PARE IN GETTING ORGANISED: THE VIRTUAL KNOWLEDGE CENTRE

P. Balazova[1,2]. [1]*Young PARE, EULAR, Zurich, Switzerland;* [2]*Slovak League Against Rheumatism, Piestany, Slovakia*

**Background:** The EULAR Young PARE working group launched the Virtual Knowledge Centre (VKC) in March 2016. The VKC is an online toolbox exclusively for the Young PARE network of liaison persons. Liaison persons are representatives of European national organisations, with particular interests in supporting young people with rheumatic and musculoskeletal diseases (RMDs). The VKC can be found on www.youngpare.org.

**Objectives:** The objectives of the VKC were to: (1) establish a database with information about national youth organisations; (2) create the European network of RMD youth groups to exchange best practices; (3) provide support to national youth organisations; and (4) ensure that national youth organisations, via liaison persons stay in contact with each other to share knowledge and experiences.

**Methods:** The VKC interface offers the possibility to see the members of EULAR Young PARE, upload and download best practices and interact with other members via a moderated forum. The VKC is secure, and requires users to login, once approved by a moderator. When logged in members are able to send private messages to each other.

**Results:** The VKC has been designed to help patient organisations to collaborate and share knowledge about their work. It provides support to the network through interaction and gives the opportunity to communicate with each other in a secure and safe environment.

**Conclusions:** EULAR Young PARE is continuing to improve the VKC through gathering best practices and feedback from its members. EULAR Young PARE will also work on more effective management strategies of the forum, to ensure the VKC becomes a lively environment.

SP0072 **THE ROLE OF HEALTH PROFESSIONALS IN IMPROVING SHARED DECISION MAKING WITH YOUNG PEOPLE WITH RMDS**

A. Alunno. *Department of Medicine, Rheumatology Unit, University of Perugia, Perugia, Italy*

In the past, physician-patient relationship was mostly unilateral and disease-centered as the physician made all the disease-related decisions on behalf of the patients. Nowadays, based on different cultural and legal aspects, the physician-patient relationship relies on the shared decision making (SDM) process. SDM is the approach where health professionals and patients decide the best approach on disease-related decisions. In this process, patients receive from clinicians and health professionals other than medical doctors the support and all relevant information to analyze the different available options and to identify their preferences in terms of tests, treatments and daily management of the disease. In this context, SDM has a positive impact in clinical practice allowing the integration of the physician's point of view with the patients' perspective. The main target of SDM is to achieve the most effective, most satisfactory and best tolerated approach to optimize diagnostic, therapeutic and overall management strategies through: i. patients' awareness and attitude towards the disease, ii. patients' self-confidence, iii. tailored therapy, iv. therapy adherence, v. informed decision regarding disease-related daily life issues. In the field of rheumatic and musculoskeletal diseases (RMDs), the SDM process requires a multidisciplinary team involving not only rheumatologists but also other specialists and health care professionals, other than medical doctors, specialized in rheumatology. However, the multidisciplinary team pursuing this patient-centered approach, should be guided by the rheumatologist that has the widest point of view regarding all possible aspects of the disease. Such multidisciplinary approach ensures that patients are fully aware of all aspects of the disease, of how their life may be affected and, most importantly, of how to manage different situations. Patients with distinct RMDs suffer from different complaints and require different treaments according to the diagnosis. Moreover, it is well established that young people with RMDs have different priorities and needs compared to adult patients. Finally, subjects included in different age ranges within young patients are further different from each other. This requires an additional effort of the multidisciplinary team to tailor the support to specific circumstances. Self-confidence, working disability as well as social life, family life and intimacy represent some of the domains mostly affected in young patients with RMDs. Therefore, the interaction of rheumatologists, other specialists, and health professionals specialized in rheumatology is compelling to optimize the management as well as the SDM process with young patients with RMDs. In conclusion, empowering young patients with RMDs to know and manage their own condition is crucial for long-term improvement of their quality of life and should be thoroughly applied in clinical practice.

SP0073 **EMPOWERING YOUNG PEOPLE WITH RMD TO FIND THEIR VOICE AND CLAIM THEIR SPACE**

I.A. Murphy. *Galway Branch of Arthritis Ireland, Galway, Ireland*

The presentation will focus on empowering young people in relation to their condition and through participation in local, national and international structures. The importance of empowering young people to self manage their condition and navigate transitions in their lives will be explored in the context of their holistic development. The second element of the presentation will focus on participation of young people in RMD related organisations. The key model of participation will be that of Professor Laura Lundy: SPACE, VOICE, AUDIENCE and INFLUENCE and how this can be facilitated in existing organisations. Practice examples will be included. The presenter contends that the engagement of young people in RMD structures will lead to better individual outcomes and enrich existing organisations.

## Advancements in the imaging of PsA

SP0075 **LINKING HISTOLOGY AND IMAGING IN THE PATHOGENESIS OF PSA**

E. Filippucci. *Rheumatology Department, Università Politecnica delle Marche, Jesi, Italy*

Psoriatic arthritis (PsA) is a chronic inflammatory disease with a wide and heterogeneous spectrum of pathologic conditions including intra-articular and peri-tendinous synovitis, enthesitis, psoriatic plaque and onycopathy (1). Since angiogenesis plays a key role in the pathogenesis of both synovial tissue and skin involvement, the term "psoriatic disease" has been introduced to underline that the disease has the potential to affect different tissues (2). Technological advances are constantly improving the diagnostic ability of the imaging modalities, especially of ultrasound and magnetic resonance imaging, opening new sceneries in the research field (3–11). The recent availability of an ultrasound probe with a B-mode frequency reaching 22 MHz allows for a detailed morpho-structural assessment together with a highly sensitive detection of blood flow in small vessels of superficial tissues. This is of particular interest, considering that most of the PsA targets are superficial tissues. The main aims of this presentation are to discuss the most relevant investigations aiming at assessing the role of histology and imaging in PsA, and to show the diagnostic ability of the last generation imaging modalities in the evaluation of the main PsA targets (i.e. joint, tendon, enthesis, skin, and nail).

SP0076 **PROGNOSTIC VALUE OF IMAGING MARKERS IN PSORIATIC ARTHRITIS**

M. Østergaard. *Copenhagen Center for Arthritis Research, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark*

Psoriatic arthritis (PsA) is an inflammatory joint disease characterised by arthritis and often enthesitis in patients with psoriasis, but presenting a wide range of disease manifestations in various patterns. Imaging procedures used in PsA are primarily conventional radiography, ultrasonography (US) and magnetic resonance imaging (MRI), whereas other modalities such as computed tomography are not routinely used. Imaging is an integral part of management of psoriatic arthritis for multiple reasons including establishing or confirming the diagnosis, determining

extent of disease, monitoring change in disease e.g. activity and damage, assessing therapeutic efficacy, prognostication and identifying complications of disease or treatment, in the setting of clinical practise or clinical studies. These entirely different contexts may favour different imaging approaches. This talk will focus on the available data of different imaging modalities, particularly MRI and US, for predicting 1) the development of psoriatic arthritis in patients with psoriasis, 2) the response to therapy in patients with PsA and 3) the disease course in patients with PsA.

## When and how to treat Raynaud's phenomenon and related complications

### SP0077 DIFFERENTIAL DIAGNOSIS BETWEEN PRIMARY AND SECONDARY RAYNAUD'S PHENOMENON

V. Smith on behalf of the EULAR Study Group on Microcirculation in Rheumatic Diseases. *Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium*

Clinical rheumatologists frequently get patients with Raynaud's phenomenon (discoloration of extremities upon exposure to cold or stress) referred. The challenge is to distinguish patients with a primary Raynaud's phenomenon (not connected to any connective tissue disease) from patients with a secondary Raynaud's phenomenon (due to a connective tissue disease).
A large 20-year follow-up study (Koenig Arthritis Rheum 2008) of patients presenting at baseline with merely the Raynaud's phenomenon and no sign of a connective tissue disease has taught the scientific community that if a CTD is to develop in such a population then it is systemic sclerosis. Subsequently it makes sense to screen for SSc in a Raynaud's phenomenon population.
In 1992 LeRoy and Medsger proposed criteria to distinguish primary from secondary Raynaud's phenomenon. Retrospective validation of these criteria allow correct classification of a patient in one clinical consultation in 89%. Amongst other criteria, a "normal" capillaroscopy is obligatory to be able to speak of a "primary" Raynaud's phenomenon. Conversely patients with a secondary RP due to SSc have the combination of a SSc-specific antibody and a scleroderma pattern on capillaroscopy.
These criteria have prospectively been validated. The triade of RP, SSc-specific antibody and scleroderma pattern on capillaroscopy has a high positive predictive value for the development of SSc, whilst the absence of SSc-specific antibodies and a scleroderma pattern has a high negative predictive value for the non-occurrence of SSc.

### SP0078 WHEN AND HOW TO MANAGE PRIMARY RAYNAUD'S PHENOMENON

J.-L. Cracowski. *Clinical Pharmacology Department, Université Grenoble Alpes, Grenoble, France*

Primary Raynaud's phenomenon (PRP) is a common condition characterized by transient ischemia in the extremities in response to cold or emotions, which does not progress to digital ulcerations. The pathophysiology of PRP is multifactorial and complex, and while PRP is considered as a benign condition, it can be associated with significant disability during the cold season. The objective of this talk is to further clarify how a diagnosis of PRP can be performed, and to review the different pharmacological and non pharmacological treatments currently used in the management of RP, from their mechanism of action to the available evidence regarding their efficacy. We will also address the issue of drug-induced RP.
**Disclosure of Interest:** J.-L. Cracowski Grant/research support from: Pfizer; Bioprojet
**DOI:** 10.1136/annrheumdis-2016-eular.6326

### SP0079 WHEN AND HOW TO MANAGE THE SECONDARY RAYNAUD'S PHENOMENON AND RELATED CONDITIONS

A.L. Herrick. *University of Manchester, Manchester, United Kingdom*

When Raynaud's phenomenon (RP) occurs secondary to an underlying condition (most importantly to rheumatologists to connective tissue disease), it can be very severe and progress to tissue injury, for example digital ulceration.
Most work on secondary RP has been in systemic sclerosis (SSc)-related RP and this will be the focus of this lecture, in order to exemplify the key principles of management. The main aims are to reduce symptoms and to prevent progression to digital ulceration and/or critical ischaemia. The first step in management is to establish the diagnosis, and decide whether there are any aggravating or triggering factors (e.g. smoking) amenable to intervention. Non-drug therapy, drug therapy and surgical options will all be discussed, with a focus on recent advances. Although calcium channel blockers remain first-line drug therapy for RP, phosphodiesterase inhibitors are being increasingly used. In those patients who progress to digital ulceration and/or critical ischaemia, intravenous prostanoids and (for patients with recurrent digital ulcers) endothelin receptor antagonism should be considered. For those patients refractory to medical management, surgical debridement of ulcers and/or digital sympathectomy may be beneficial. Botulinum toxin (Botox) injections are given in some centres, but further research is required to establish their efficacy. Studies are ongoing investigating new approaches to therapy.
Upon completion of the session, participants should be able to:
1. Describe the general approach to management of secondary RP, including of digital ulceration and critical ischaemia.
2. Discuss the indications for "advanced therapies" (intravenous prostanoids, endothelin receptor antagonism, surgery).

## Role of new imaging techniques as RMD outcomes

### SP0080 IMAGING IN EARLY DETECTION OF RA JOINT DAMAGE. WHAT TECHNIQUE AND HOW TO USE?

S. Finzel. *Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany*

Bone erosion is a characteristic of rheumatoid arthritis. Commonly, erosion is not only used to monitor radiographic progression over time as well as therapy efficaciousness, it also helps to correctly diagnose the disease. However, there are further signs of pathological bone alterations and inflammation such as periarticular loss of bone structure, and bone marrow edema. Nowadays, treatment and diagnostic strategies do not only aim at tight disease control and treat to remission, but to diagnose rheumatoid arthritis already at a very early stage of the disease and to detect alterations in bone even before erosion have occurred.
The session will give an overview of the available modern imaging techniques, and of their strengths and weaknesses; after the session, the participant will have a clearer impression of when to use which imaging modality.

**DOI:** 10.1136/annrheumdis-2016-eular.6410

### SP0081 IMAGING IN THE MANAGEMENT OF GOUT. CLINICAL TOOL OR ENDPOINT?

N. Dalbeth. *Department of Medicine, University of Auckland, Auckland, New Zealand*

Imaging techniques can identify the core features of disease in gout: urate crystal deposition, joint inflammation and structural damage. Clinical applications include detection and measurement of urate crystal deposition using high resolution ultrasonography (US) and dual energy computed tomography (DECT), assessment of disease severity to guide treatment decisions, and detection of disease complications (eg. structural damage, tendon disease, concomitant infection). Although imaging modalities such as US and DECT are increasingly used for gout diagnosis in clinical practice, there are uncertainties about interpretation of results in asymptomatic hyperuricaemia, the sensitivity of these methods in early disease, artefact issues, and reliability. Imaging techniques also have potential to assess response to treatment, both in clinical practice and in research settings. Key questions remain about the sensitivity to change of urate crystal deposition, inflammation and joint damage using imaging techniques. Imaging techniques that allow visualisation of urate crystal deposition may play a particularly important role in patient understanding of disease and promoting engagement with long-term urate-lowering treatments.

## "Fewer words - more action" - tailored care for men with rheumatic diseases?

### SP0082 DISABILITY IN MEN AND WOMEN WITH RA. DOES IT DIFFER AND DOES IT MATTER?

M. Björk. *Department of social and welfare studies, Linköping University, Norrköping, Sweden*

With pharmacological advancements, early diagnosis and multi-professional treatment, many patients with RA today, have high expectations of being able to participate in valued life activities and to experience a high quality of life.

It is an on going discussion if and how RA affects women and men differently. For example, in the Swedish TIRA-project (Early Interventions in Rheumatoid Arthritis), women report higher pain intensity and more participation restrictions than men. This raises the question if men and women also have different needs of rehabilitation and if rehabilitation should be tailored differently for men and women.
This session will present an overview of impairments and participation restrictions of today's women and men with RA, and how men and women express their disabilities. The session will also focus on differences between women and men and discuss how this may be expressed as different rehabilitation needs.

### SP0083 BALANCING WORK AND LIFE: "WHEN IS A MAN A MAN ?"

F. Demtröder. *ÜBAG MVZ Dr. Eberhard & Partner und Klinikum Dortmund, Zentrum für Endokrinologie, Diabetologie, Rheumatologie, Dortmund, Germany*

Working is a very important part of our life.
There are lots of problems and barriers for people with chronic rheumatic diseases in starting a professional career. Furthermore it is a challenge to stay in the working process for many years.
Great and never ending efforts are needed to get over multiple obstacles. But are there special aspects for men? And (why) is working so important especially for men?
What is the meaning of working? What are the goals of working for our life and living? And what does it mean with respect to any "treat to target"?
How can we be successful and what is success? Do we have to accept limits? And what strategies are available to manage a successful working life being a man with a chronic rheumatic disease?
Even if we do not find any answers let us shed some light on these important questions from a patient's view.
**Conclusion:** To be successful for men with rheumatic diseases in balancing work and life the following strategies might be helpful:
Ability to work must be kept in mind when thinking of "treat to target" in people with chronic rheumatic diseases.
Obstacles can be overcome and problems can be solved by multiple different solutions.
Goals should be looked at from different points of view – particularly from the patient's perspective. The aims should be tailored in an individual way to achieve personally defined success and happiness.
Life is what you make it – especially in RHEUMATISM!
Right Help Empowers Us – More Action Towards Independent Self-Management.

### SP0084 BEING PHYSICAL ACTIVE IS A SALVATION? MEN'S PREFERENCES FOR PHYSICAL ACTIVITY

B.A. Esbensen[1,2]. *[1]Rigshospitalet - Glostrup, COPECARE, Centre for Rheumatology and Spine Diseases & Research Unit, Glostrup; [2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*

Physical activity (PA) has been recommended as an essential part of the non-pharmacological management of inflammatory arthritis (IA). Among others, positive health effects of PA in IA have been demonstrated as improved cardiorespiratory fitness, muscle strength, mobility, physical functioning and quality of life. Also a reduction in disease activity, pain, fatigue and stiffness has been proved. While studies reveal inconsistent results on whether persons with IA are more or less physically active than their healthy counterparts, it has repeatedly been argued that people with IA engage in less PA at the higher intensities (moderate and vigorous) compared to healthy populations.
Through previous qualitative research it has been suggested that men with IA, besides describing PA as an important strategy to manage their arthritis, also view engagement in PA an essential part of being a man. Thus, it could be argued that interventions or offers based on PA could be received as a legitimate form of health promoting activity responding to meet masculinity in needs and preferences among male patients with IA. Data from two qualitative studies focusing on men with IA will be presented as well as data from a cross-sectional study investigating physical activity behaviour, motivations, barriers and preferences for PA in men with IA.

### SP0085 DESIGN OF A SELF-MANAGEMENT INTERVENTION FOR MEN WITH RA

C.A. Flurey. *Faculty of Health & Life Sciences, University of the West of England, Bristol, United Kingdom*

Rheumatoid arthritis affects more women than men (30% male) and current research reflects this difference. Evidence from several long term conditions suggests disease impacts differently on men compared to women, leading to the proposal that men need their own health strategy (White et al 2011). However, the coping styles and support needs of men with RA has not previously been the focus of discussion within rheumatology.
If men experience and cope with RA differently to women then the support required is likely to be different. However, current self-management interventions in RA have been designed and tested mainly in women.
This talk will address the experiences and coping styles of men with RA and their preferences for the design and delivery style of a self-management intervention. This talk will discuss the potential designs for a self-management intervention and potential solutions for engaging men in taking part in such an intervention.

## Recent advances in our understanding of macrophage biology

### SP0086 TISSUE SPECIFIC DIFFERENTIATION OF INTESTINAL MACROPHAGES

A. Mowat. *University of Glasgow, Glasgow, United Kingdom*

Resident macrophages (møs) from different tissues are highly heterogeneous in terms of their functions and origins. Intestinal møs are one of the largest populations in the body and have several characteristic features, including expression of high levels of MHCII and CX3CR1, constitutive production of IL10 and TNFa and avid phagocytic activity. However they are refractory to stimuli such as TLR ligands. We have shown that adult intestinal møs are derived from circulating Ly6Chi monocytes that acquire the properties of the resident cells in the mucosa. However the mechanisms responsible for this local differentiation process are unknown. By comparing their transcriptome with monocyte- and embryonically derived møs from other tissues, here we identify a genetic signature of resident intestinal møs and validated it by Q-PCR and FACS. Soon after entry into the intestine, maturing møs become genetically distinct, even from møs in other tissues that are replenished by monocytes, such as the dermis. Many of the selectively expressed molecules are involved in tissue remodeling and in uptake of apoptotic cells, including avβ5 integrin, metalloproteases 2, 9 & 14, C1Q and CD36. Several are TGFβ inducible genes and although intestinal møs numbers are normal in CD11c-cre-TGFβR1fl/fl mice, their gene signature is altered and they show reduced expression of IL10 and CX3CR1. In parallel, chimeric mice lacking TGFβR signaling only on møs show evidence of increased inflammatory monocyte recruitment. Thus TGFβR signaling is critical for tissue specific adaptation of intestinal møs, driving the differentiation of monocytes into møs with homeostatic and anti-inflammatory functions.

## Lubricants: potential as osteoarthritis treatment?

### SP0087 NATURAL OCCURRING LUBRICANTS TO MAINTAIN JOINT HOMEOSTASIS

J. Klein. *Weizmann Institute of Science, Rehovot, Israel*

Cartilage surfaces sliding past each other in the major joints (such as hips and knees) exhibit extremely low levels of friction under physiologically-high pressures, a lubricity which is essential for their healthy perfomance. A detailed molecular-level understanding of this could benefit treatments of osteoarthritis (OA), as well as improved prosthetic joint implants. Any insight must, first and foremost, be able to account for the low friction (coefficient of friction (CoF) down to ca. 0.001) at the high pressures (which can reach 100 atm or higher) of the joints. However, the main molecular "suspects" thought to constitute the lubricating boundary layer on cartilage, namely hyaluronic acid, lubricin or phospholipids, do not, individually, provide especially good lubrication. Recently[1] we discovered that hyaluronan (HA) which is attached to a surface – to resemble its configuration at the outer cartilage surface – may complex with phosphatidylcholines (PCs), lipids that are ubiquitous in synovial joints, to form robust boundary layers. These layers act synergistically to provide the very low friction (CoF $\approx$ 0.001) characteristic of cartilage, at the highest physiological pressures, and contrast with surface-attached HA on its own, which leads to considerably higher friction. The very low friction is ultimately due to the phosphocholine groups exposed by the HA/PC surface complexes; these groups are known to be strongly and highly-hydrated, and they lubricate via the recently elucidated hydration-lubrication mechanism[2]. Our results thus point to a scenario[3] where HA, PCs and lubricin, each with a very different role, act together synergistically to reduce friction of cartilage in articulating joints. Hyaluronan, anchored at the outer surface of articular cartilage by lubricin molecules (which are known to be present in the outer superficial zone), complexes with joint phosphatidylcholines to provide

the extreme boundary lubrication of synovial joints via the hydration-lubrication mechanism.

### SP0088 HYDROGELS FOR OSTEOARTHRITIS TREATMENT

S.J. Bryant. *Chemical and Biological Engineering, University of Colorado, Boulder, United States*

Osteoarthritis is a debilitating disease that affects cartilage and bone in joints. Cartilage injuries, if left untreated, are one of the leading risk factors for developing osteoarthritis. Thus, treating cartilage injuries early may help prevent progression of osteoarthritis. There are however no clinical solutions that are capable of repairing damaged cartilage and replacing it with healthy functional articular cartilage. Thus, the focus of our research program is to develop novel hydrogels that support regeneration leading to full restoration of joint tissue and its function. Towards this goal, we focus on developing hydrogels that support differentiation and tissue growth and have begun to translate our materials *in vivo* towards the long-term goal of creating a viable clinical solution for cartilage regeneration.
Synthetically-derived hydrogels offer a highly tunable platform to create biomimetic environments that support repair of damaged or diseased cartilage. Our group has worked extensively to identify and create biomimetic, biodegradable, and photopolymerizable hydrogels. Photopolymerization offers the ability to form hydrogels directly in the defect and control gelation time (e.g., $\sim$ 10 seconds). In developing the chemistry of the biomimetic hydrogel, our research has pointed to the importance of physiochemical cues in directing stem cell differentiation for chondrogenesis and cartilage regeneration. The incorporation of cartilage specific extracellular matrix (ECM) analogs into a synthetic hydrogel combined with dynamic mechanical loading results in a synergistic response that produces a robust differentiation and improves tissue growth. These physiochemical cues appear to be more potent than either chemical or mechanical cues alone. For example, we have incorporated chondroitin sulfate, the main sulfated glycosaminoglycans found in cartilage, into a synthetic hydrogel to mimic cartilage's high fixed charge density. Upon dynamic loading, this creates an environment that induces oscillations in ion flow and leads to dynamic changes in local osmolarity and streaming potentials, both of which can regulate ion channels on the cell membrane. We have also incorporated cell adhesion peptides that enable integrins on encapsulated cells to interact with the hydrogel and which can act as mechanoreceptors. We have found that combining both ECM analogs into a cartilage biomimetic hydrogel improves ECM synthesis capabilities in chondrocytes, but only under dynamic loading. This cartilage biomimetic hydrogel enhances chondrogenesis of mesenchymal stem cells, but under dynamic loading is able to inhibit RunX2, collagen X, and MMP13 activity, which are characteristic markers of a hypertrophic phenotype in cartilage. Thus, this novel cartilage biomimetic hydrogel holds promise for maintaining a stable chondrogenic phenotype and regenerating cartilage within the joint where dynamic mechanical forces are prevalent.
In addition to identifying a local hydrogel environment that supports chondrogenesis and cartilage tissue regeneration, the success of such a therapy requires the translation *in vivo*. Towards this goal, we have created an *in vitro* model of a cartilage defect in an osteochondral plug that is subjected to physiological and dynamic compressive loading. When left untreated, the cartilage surrounding the defect undergoes rapid remodeling in four weeks, leading to loss of proteoglycans, increased collagen degradation, and a decrease in mechanical properties; signs of cartilage degeneration and a precursor to osteoarthritis. However, if the defect is filled with a mechanically supportive hydrogel that distributes the loads across the osteochondral plug degeneration could be arrested. Specifically, there was no evidence of proteoglycan loss, minimal collagen degradation, and no change in mechanical properties. Using this novel defect model, we have shown that mechanical loading can have detrimental effects on cartilage injuries if left untreated, but that a mechanically supportive hydrogel can protect the surrounding tissue from further damage.
While our research is still on going, we have identified novel cartilage biomimetic hydrogels that support differentiation and tissue growth. We are currently testing this novel biomimetic, biodegradable, and photopolymerizable hydrogel in a skeletally mature (8 month old) rabbit model with an osteochondral defect. Additionally, we are developing advanced strategies to combine our novel cartilage biomimetic hydrogel with stiff structural features to create mechanically supportive environments the enable tissue growth and protect the surrounding tissue from further degeneration. Our long-term goal is to develop clinically useful technologies that help prevent the onset of osteoarthritis by treating cartilage injuries early and restoring normal function.

## Extraarticular complications of JIA

### SP0089 OSTEOPOROSIS IN JUVENILE IDIOPATHIC ARTHRITIS

R. Cimaz. *AOU Meyer, Firenze, Italy*

In children with rheumatic disorders the physiological development of bone strength in response to mechanical loads (the mechanostat model) is frequently impaired. In this population the prolonged inflammatory process and systemic treatment with glucocorticoids (GC) represent the two main risk factors which interfere with the bone remodelling process.
Up to 6% of children with GC-treated rheumatic disorders develop a vertebral fracture in the first 12 months of therapy; children with more severe inflammation and more systemic involvement, such as those with systemic-onset JIA or connective tissue diseases, appear to be at higher risk.
Inflammation exerts a direct and detrimental effect on bone, as generalized bone loss can occur independently from GC exposure. Although cytokines are considered to be the final executors of chronic inflammation on bone, the role of immune cells (e.g. Th17) has recently been highlighted. GC therapy, often at high doses and for prolonged periods, is associated with detrimental effects on bone mass and growth by means of multiple pathogenic mechanisms. By exerting a direct effect on bone cells, GC-induced osteoporosis is characterized by a decreased bone turnover with a disproportionate reduction in bone formation over bone resorption.
The most important clinical outcome arising from lack of bone strength development in childhood rheumatic disorders is represented by fragility fractures. In order to diagnose osteoporosis in children, fracture history should be considered the base of the definition, with additional consideration for the risk factors (sun avoidance, vitamin D deficiency, reduced physical activity), and the overall BMD Z-score trajectory. Several techniques can be used to evaluated bone health in children (e.g. Dual-energy x-ray absorptiometry, peripheral quantitative computerized tomography, and quantitative ultrasound). Dual-energy x-ray absorptiometry (DXA) is the technique currently considered the most appropriate for children because of low radiation, speed, and accuracy.
In rheumatic diseases, a reduction of disease activity represent the mainstay of the treatment, and an anti-inflammatory action of medications such as methotrexate and b*iological* response *modifiers* has been associated to an improved bone health. The effect of bone-targeted therapy such as bisphosphonates on a developing skeleton has also been explored in pediatric rheumatology. In addition to correct vitamin D deficiency and encourage physical activity, oral or i.v. bisphosphonates can therefore be useful in selected patients, but caution should be used since their long-term effects on a growing skeleton are still unknown.

## The elephant in the room: how to avoid biases in research?

### SP0090 RISK OF BIAS WHEN REPORTING A TRIAL

H. Yazici. *Academic Hospital, Istanbul, Turkey*

While it is given that some or all of the biases involved in the design and the implementation of a trial are carried to the reporting, our concern in this talk is a list of biases more specific for this stage. I propose that the common denominator in this list is the "urge to prove" (1). One important outcome of this urge is the relative reluctance of the authors to acknowledge the limitations of their work. It is interesting to note that this reluctance is more pronounced in basic science (2) while it has even been said that the main purpose of the discussion sections should be authors discussing limitations of their work, naturally best known to them (3). Another manifestation of the same urge has to do with the pervasive mistaken or ill-use of the p values. As yet again brought up recently (4), the medical literature, for decades, has been replete with articles about this misconception. Physicians and investigators, with no apparent differences between the clinicians and the basic scientists, have singularly been reluctant to correctly understand and use the p value. The main elements of the said misconception seem to be a. Inadequacy in formal probabilistic thinking, the most common being that a p value represents the probability of our trial results being false positive while it actually represents the probability of obtaining the actual trial results had it been they were only due to chance; b. The power of a test is not only important in avoiding a Type II but also a Type I error; c. The information we get from any one p value much depends on the pre-test probabilities of what we try to measure in the study design in which we do this, i.e., an observational or a cross sectional study versus a placebo controlled randomized clinical trial (5). Publication bias traditionally referred to as the athors' and journal editors' propensity to publish positive or otherwise *striking* results. Recently this has been re-considered (6) and the proposal has been that a myriad of other biases, perhaps even including almost all items related to the "urge to prove" might also be included under this broader definition of a publication bias, and again perhaps now better called a

'dissemination bias'. Although much discussed this bias remains rather difficult to accurately identify and quantitate. Finally it has to be remembered, like all biases, the biases involved when reporting a trial can either be unintentional or intentional and this is equally difficult to differentiate and quantify.

## Digital applications for the benefit of the patient

### SP0091 CAN INDIVIDUAL PATIENTS BENEFIT FROM REGISTRIES?

S. Ernestam. *Rheumatology, Karolinska Institutet, Stockholm, Sweden*

SRQ, the Swedish Rheumatology Quality Care Register, has more than 60 000 registered patients with different inflammatory conditions, mainly arthritis diseases. Approximately 20 000 patients are on treatment with biologic drugs and a total of 35 000 patients have ever been treated with biological drugs. All rheumatology units in Sweden are part of the register.

The variables registered are mainly patient reported outcomes such as global health on a visual analogue scale, pain on a visual analoge scale, fatigue, HAQ and number of swollen and tender joints registered by both patient and provider. The patient may register their data before the consultation at a secure web page or at a computer in the waiting room. During the consultation the results of the patient reported outcome measurements are visualised to both the patient and provider and a shared decision of treatment are agreed on together. A treatment plan may be made on both medications and life style factors.

Patients may themselves take part of their individual results over time from home. During the session a short film about the way of working with SRQ will be shown.

### SP0092 DIGITAL INTERVENTIONS TO IMPROVE SELF-CARE FOR LONG TERM CONDITIONS

E. Murray. *Research Department of Primary Care and Population Health, University College London, London, United Kingdom*

People living with a long term condition (LTC), such as diabetes or rheumatoid arthritis have to learn to live with their health problem and to manage the consequences. Not managing is not an option – what varies is the degree to which self-management improves or harms overall health and wellbeing. Corbin and Strauss have defined three tasks for patients with an LTC: medical management; emotional management; and role management. Medical management includes adopting healthy behaviours such as healthy eating, physical activity, working with health care professionals and taking medication as prescribed. Less well recognised, but equally challenging, are managing the emotional reactions of having a long term condition, including anger, despair, shame and guilt; and the changes to one's role, or biographical narrative. For many people a diagnosis of a serious illness fundamentally alters their perceptions of their essential self, and their role in life.

Digital health interventions (DHI) have significant potential for helping people undertake these three tasks. DHI are interventions which are delivered digitally, e.g. over the web to a PC, tablet or phone, or via an app. They can combine information with interactive components such as decision support, emotional support and behaviour change support, and often deliver treatments that have previously been offered face to face, such as cognitive behavioural therapy, mindfulness training, or medication changes according to pre-defined algorithms responding to self-monitoring data entered by patients. The use of video, audio and graphics can make complex information accessible and comprehensible to people with low literacy, or poor language skills. Software programming allows information and responses to be tailored to each individual, reflecting specific needs.

In this talk I will explain how DHI can help patients with the complex tasks of self-management, providing examples of available interventions. I will also summarise the research evidence on their uptake, acceptability and effectiveness.

### SP0093 HOW INNOVATIVE TECHNOLOGIES CAN SUPPORT INDIVIDUALS TO BETTER SELF-MANAGE THEIR CONDITIONS

S.R. Stones[1,2,3]. *[1]Faculty of Life Sciences, The University of Manchester, Manchester; [2]Paediatric Rheumatology CSG, NIHR CRN:Children/Arthritis Research UK, Liverpool, United Kingdom; [3]Young PARE, EULAR, Zurich, Switzerland*

We live in a technologically-driven society; however, the acceptance of technology in the health and social care landscape has been slow and poorly acknowledged, largely due to complex health policies and frameworks in place. As highlighted in a recent industry article, technological innovations are driving forward new diagnostics, treatments, techniques, and medical monitoring [1]. Smartphones have become central to our daily lives, and are now used by 66% of adults in the United Kingdom (UK) [2]. Therefore, it appears evident to utilise the technology at the end of our fingertips to transform the way that individuals manage their health, wellbeing and relationships with healthcare professionals and peers.

The Food and Drug Administration (FDA) in the United States has now approved over 100 health apps, and in the UK, accredited apps are shown in the NHS Health Apps Library. These apps have undergone rigorous approval processes, contrary to the wealth of apps available on the internet that are widely available. In a recent international systematic review, mobile and tablet apps were considered feasible health interventions [3]; however, more studies involving larger samples, patient and professional input were deemed necessary, in order to determine the acceptability of apps, and their effectiveness in supporting disease self-management and health outcomes.

Apps and web platforms can help individuals to track their health, by recording symptoms, treatments, and other health-related aspects. However, it is equally important to connect individuals with their peers, as social interactions play an indispensable role in physical and psychological wellbeing. One of the leading platforms that has transformed the way that patients track their health is PatientsLikeMe [4]. The platform enables individuals to monitor their health, interact with other people living with similar conditions, and "donate" their data for research. In practice, patient health data is collected by medical professionals, during consultations, investigations and in-hospital admissions; however, this likely accounts for less than 10% of time. For the remaining 90% of time spent outside of the clinical setting, patients live with their conditions without effective monitoring.

Symptoms are often unpredictable for those living with rheumatic and musculoskeletal diseases (RMDs). Therefore, a clinician's understanding of how their patients are responding is based upon on memory recall, with no objective measure available to measure disease severity and quality of life in between follow-up consultations. The long-term aim of apps should therefore meet this demand, by manipulating technology that will improve communication and relationships between patients and healthcare professionals. In turn, this can empower those living with RMDs to become partners in the treatment of their disease, through better quality information and efficient shared decision making.

Aside from helping patients to track and report their symptoms, data is being generated to transform tomorrow's healthcare. The use of innovative technologies has the potential to revolutionise the way that individuals are treated and monitored in the future, as long as patients, carers, healthcare professionals and industry colleagues are involved in the development, evaluation and implementation of such technologies as equal partners.

## EULAR projects in Clinical Affairs

### SP0094 EULAR/EFORT RECOMMENDATIONS FOR PREVENTION AND MANAGEMENT OF OSTEOPOROTIC FRACTURES

W.F. Lems. *Amsterdam Rheumatology and immunology Centre, Amsterdam, Netherlands*

Fragility fractures in women and men older than 50 years are among the most frequent musculoskeletal manifestations for which patients consult healthcare workers from more than one medical specialty. Immediately following a fracture, the patient needs acute fracture care, supplied by an orthopaedic or trauma surgeon. This is followed in a later phase by subsequent fracture prevention

in patients identified at high risk for a subsequent fracture, usually under the responsibility of rheumatologists or other bone disease experts. Thus, at a local level, a close collaboration between these specialities is necessary. Both the European League Against Rheumatism (EULAR) and the European Federation of National Associations of Orthopaedics and Traumatology (EFORT) have recognised the importance of optimal fracture care and prevention of subsequent fractures in high-risk patients and have therefore collaboratively initiated this recommendation.

The recommendations will be discussed during the meeting. Some overarching principles that play a crucial role in the recommendations are:

– especially in the frail elderly with a major fracture, an orthogeriatric and multidisciplinairy approach in an in-hospital setting is warranted, to avoid complications, delirium, and prevent increased morbidity and mortality
– optimal care in the preoperative, operative and postoperative phase has an important effect on clinical outcome. As a consequence, it is very likely that limited mobility and a low quality of life in the postoperative phase may have an elevated risk of future fractures.
– for prevention of subsequent fractures, it is important that in all patients fracture risk will be investigated systematically, including DXA, imaging of the spine, fall risk evaluation and screening for secondary osteoporosis.
– for subsequent prevention of fractures in high risk patients, not only effective and safe drugs should be prescribed, but non-pharmacological treatment options and patient education are also crucial.

### SP0095 EULAR/ERA-EDTA RECOMMENDATIONS FOR THE MANAGEMENT OF ANCA-ASSOCIATED VASCULITIS

C. Mukhtyar. *Rheumatology, Norfolk and Norwich University Hospital, Norwich, United Kingdom*

We published the EULAR recommendations for the management of systemic vasculitis in 2009. We proposed and received a mandate from EULAR to revise the recommendations for the management of ANCA associated vasculitis. This project was done in partnership with the ERA-EDTA.

A team of 22 experts representing rheumatology, renal medicine, chest medicine, clinical immunology, internal medicine, ENT medicine, ophthalmology, vasculitis nursing and patient support group was formed. There was representation from 11 European countries and the USA. EULAR standardised operating procedures were followed throughout. 10 items for update and 5 new items for consideration were identified via a Delphic process. Search strings were created to identify 1347 papers. Quality scoring of manuscripts was performed using the Critical Appraisals Skills Programme. 44 papers were identified to inform the recommendations. Level of evidence was ascertained as per EULAR SOP. Statements were formed and graded for strength by the task force and by the membership of the European vasculitis society for ascertaining further validity. The level of evidence for EGPA was poor and is reflected by the low grade of recommendations.

Patients with AAV should have expert involvement in their care. A biopsy remains the gold standard for diagnosis and should be performed whenever clinically feasible. Cyclophosphamide or rituximab are the mainstay of remission induction but methotrexate and mycophenolate mofetil may be appropriate for a small number of cases. Major relapses should be treated as new – but rituximab maybe favoured over cyclophosphamide in this category. Consideration should be given to strengthening immunosuppression even for patients with minor relapses. Patients with severe renal disease or diffuse alveolar haemorrhage should be considered for plasma exchange. Remission can be maintained with either azathioprine or rituximab. In a small number of patients, methotrexate of mycophenolate mofetil may be appropriate. Remission maintenance should be continued for a minimum of 24 months after which tapering should be considered. Refractory disease should be managed at an expert centre. The role of follow-up monitoring, urological assessment, immunoglobulin monitoring, cardiovascular risk, educational needs & comorbidity assessment has also been discussed.

## Optimization of MTX in RA treatment

### SP0096 OPTIMIZATION OF MTX IN RA TREATMENT

M. Schiff. *University of Colorado, Colorado, United States*

EULAR and ACR guidelines agree that Methotrexate (MTX) should be the first part of Rheumatoid Arthritis therapy if there is no contraindication As stated in the EULAR guidelines "*MTX should be part of the first treatment strategy in patients with active RA...* and thus continues to serve as an anchor drug in RA."

After decades of successful use of MTX the ideal way to optimize MTX is still being discussed.

This presentation will address MTX as the current anchor drug in RA and how to better optimize its dosing for best patient care. Recent EULAR, ACR presentations will be highlighted.

The pharmokinetics will be illustrated from recent Annals of Rheumatic disease papers to help clinicians optimize MTX. Genetic concerns will be addressed and how they might impact the clinical utility and future dosing of MTX.

### SP0097 INTRACELLULAR MTX POLYGLUTAMATES AND CLINICAL RESPONSE

R. de Jonge. *Clinical Chemistry, VUmc, Amsterdam, Netherlands*

Low-dose methotrexate is the cornerstone disease-modifying anti-rheumatic drug in the treatment of patients with rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA). Although MTX levels can be measured easily in plasma, low-dose MTX is rapidly cleared from plasma and is therefore not routinely measured. In contrast, MTX is transported into and retained in cells long after it has been eliminated from plasma. We have developed an LC-MS/MS assay to measure MTX-polyglutamates (MTX-PG) in erythrocytes and measured drug concentrations in three prospective cohort studies in RA and JIA patients. Erythrocyte MTX-PG levels were related to clinical response in all cohorts and hence, could be used for therapeutic drug monitoring of low-dose MTX therapy. Moreover, higher baseline erythrocyte folate was associated with higher erythrocyte MTX-PG accumulation and improved clinical response. Determinants of MTX-PG concentrations were age, polymorphisms in ABC transporters, erythrocyte folate and dosing.

## Joint replacement in OA: friend or foe?

### SP0098 FOR WHOM ARE JOINT REPLACEMENTS MOST SUCCESSFUL? AN OVERVIEW OF THE CURRENT LITERATURE

L. Mandl. *Medicine, Hospital for Special Surgery, Weill Cornell Medicine, New York City, United States*

Total hip and knee replacements are are some of modern medicine's biggest success stories. They are, in general, extremely successful procedures, providing patients witih end stage arthritis significant improvements in pain, function and qualify of life. However, these procedures are not universal panaceas; in fact, it is estimated that up to 25% of total knee replacement patients may have residual chronic pain years after their original surgery. As aging babyboomers-who expect to continue an active lifestyle at higher rates than previous generations-increase the demand for joint replacements, it will become even more important to understand the risks and benefits of arthroplasty. This lecture will discuss outcomes of hip and knee replacements, with an emphasis on which patients are most likely to derive benefit.

## Physical activity assessment - what do we know, what do we do, how does it work?

### SP0099 AWARENESS AND USE OF OBJECTIVE AND SUBJECTIVE ASSESSMENTS OF PHYSICAL ACTIVITY AMONG HEALTH PROFESSIONALS AND BARRIERS FOR IMPLEMENTATION

B. Nordgren[1,2]. *[1]Department of Physiotherapy, Karolinska University Hospital, Stockholm; [2]Department of Neurobiology, Care Sciences and Society, Division of Physiotherapy, Karolinska Institutet, Huddinge, Sweden*

It is widely acknowledged that regular physical activity confers multiple health benefits in people with inflammatory rheumatic diseases. Participation in physical activity should therefore be encouraged by health professionals. Despite recognising the importance of physical activity, health professionals frequently fail to provide advice on promoting same. As advice alone is not always translated into behavior, subjective and objective measures of both physical activity and sedentary behaviour are important in order to motivate change in behaviour. Questionnaires, diaries, pedometers, accelerometers and multi-sensor devices are example of useful tools for assessing and monitoring progress of physical activity in clinic and research trials. However, health professionals awareness and use of such instruments in a clinical setting, in addition to barriers for not using same to date, has been scarcely described, and will be highlighted during this session. Data from an international cross-sectional study, describing the awareness and use of objective and subjective measures of physical activity, as well as barriers for implementation of such methods in health professionals working with patients with inflammatory arthritis in Sweden, Ireland, Denmark and Belgium, will be presented.

### SP0100 AWARENESS AND USE AMONG PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASE OF OBJECTIVE AND SUBJECTIVE ASSESSMENTS OF PHYSICAL ACTIVITY

B.A. Esbensen[1,2]. *[1]Rigshospitalet - Glostrup, COPECARE, Centre for Rheumatology and Spine Diseases & Research Unit, Glostrup; [2]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark*

People with inflammatory arthritis (IA) are more physical inactive and sedentary than the general population, which can have serious health consequences such as increased risk of cardiovascular diseases and diabetes. Increasing physical activity levels (PA) (even light intensity) and reduction of sedentary behaviour (SB) have been proved in intervention studies to be feasible for patients and also found to be associated with improvements in health outcomes, such as quality of life, fatigue, pain, physical function and self-efficacy.

Different tools can be used to measure PA. Subjective and objective measures have been used in both clinical practice and in research to assess PA and SB including questionnaires, diaries, pedometry, accelerometry, multi-sensor and observational methods. However, knowledge about patients' perspective, awareness and use of different tools to measure own level of PA and SB is still scarce. Anyhow, it is crucial for health professionals to gain insight in patients' attention to both objective and subjective assessments of PA to give advises to patients about such tools. Behavioural approaches such as making use of self-monitoring has been integrated in studies targeting both increasing PA and reduction of SB in people with IA, showing positive effects. These positive effects might be an issue for health professionals to take advantage of and e.g. teach patients about being physically active and how to make different tools be a part of own self-management.

Data from an international cross-sectional study will be presented investigating the awareness and use of objective and subjective measures of physical activity for patients with IA in Sweden, Ireland, Belgium and Denmark.

### SP0101 WHEN TO USE OBJECTIVE AND SUBJECTIVE ASSESSMENT OF PHYSICAL ACTIVITY? ISSUES OF RELIABILITY, VALIDITY AND USABILITY

T.W. Swinnen[1,2,3]. *[1]Department of Rehabilitation Sciences, Musculoskeletal Research Group; [2]Skeletal Biology and Engineering Research Center, KU Leuven; [3]Division of Rheumatology, University Hospitals Leuven, Leuven, Belgium*

Over the last decade, physical activity has become a key outcome domain in the assessment of rheumatic and musculoskeletal diseases (RMDs). Physical activity can be defined as any bodily movement produced by skeletal muscle that results in energy expenditure. Both physical and mental aspects of health in RMDs have been associated with optimal levels and patterns of physical activity. Also, intervention studies promoting physical activity in people with RMDs have largely confirmed these health benefits. Although there is consensus on its importance, the assessment of physical activity is complex and research in this area is rapidly growing. This lecture will therefore give a narrative overview of the state-of-the-art assessment of physical activity in RMDs considering the perspective of a researcher, a clinician, a patient and (to a lesser extent) the general population.

In a first part, this lecture will discuss the relationship between physical activity and energy expenditure. More specifically, we will explain how total energy expenditure can be partitioned in obligatory energy expenditure to support basal metabolism (basal/resting metabolic rate), diet-induced energy expenditure and activity-induced energy expenditure (physical activity). A quick overview of gold standard tools to assess each component will be discussed in non-technical way. We will focus on the assessment of activity-induced energy expenditure (physical activity) using patient-reported (e-)questionnaires and (e-)diaries, observer-based and technology-based outcomes in RMDs. Often used single-sensor devices e.g. pedometer but also trends in more complex-sensor devices e.g. wearables combined with apps will be discussed.

In a second part, we will shortly present the OMERACT framework to evaluate the measurement properties (i.e. how good is it?) of physical activity assessment tools. We will present the latest findings in this area for people with RMDs. Reliability and validity of commonly used outcomes e.g. steps, physical activity level or bouts of moderate to vigorous activities in RMDs and beyond will be presented.

In a last part, we will formulate guiding principles in selecting the right physical activity assessment tool for your clinical or research question taking into account cost, measurement properties and feasibility (usability) for both clinicians and patients.

**DOI:** 10.1136/annrheumdis-2016-eular.6309

### SP0102 PHYSICAL ACTIVITY ASSESSMENT – WHAT DO WE KNOW, WHAT DO WE DO, HOW DOES IT WORK? PERSPECTIVES FROM A PATIENT WITH ARTHRITIS

C. Kinneavy. *Arthritis Ireland, Newbridge, Ireland*

This speaker's experience spans thirty three years living with severe Rheumatoid Arthritis and had treatments and care to deal with a myriad of very difficult challenges involving multiple surgeries. Her medications included gold injections when she was first diagnosed to life changing biologic therapies for the past fifteen years. She will speak about her experiences and reflections of engaging with and monitoring and reviewing physical activity strategies and share her insights of new experiences using IT solutions to support this. Her exercise habits have been influenced by a fear of increased disability and serious co morbidity along with a desire for enjoyment and camraderie.

Alongside medication her favourite ally has been exercise and she self referred for physiotherapy advice and treatment, an experience which liberated her and provided new coping skills. Therapeutic exercises were prescribed and only performed intermittently for various reasons e.g. as there was not much fun involved! Through the Stanford self management programme and support from her physiotherapist she learned to experiment with gym and pool exercises, gaining confidence and enjoying the social aspect of leisure club membership. Monitoring her exercise programmes was limited initially to simple talk tests and increasing frequency, distance and duration of exercise.

The ongoing severity and nature of the disease continued to drive her and she has since become a self management educator, facilitating workshops in the community. This rewarding opportunity has helped her and many others to allay fears about exercise, monitor exercise activities, set new goals, review techniques and develop new pain management strategies. An opportunity arose to participate in a controlled gym based exercise study in 2009 which improved her fitness and increased her capacity for exercise. This motivated the speaker to organise some community based exercise groups for people with arthritis. Currently she exercises regularly by Aqua jogging in an Aqua Aerobics class, Nordic walking and gym based exercises all of which have increased her quality of life.

In 2015 she cautiously joined a modern gym with state of the art equipment to help improve cardiovascular health, maintain bone density and monitor her physical activity more closely. A longstanding trust in physiotherapy professionals has always prompted her to crosscheck her exercise regime. Perhaps there is a need for physiotherapy professionals to work more closely with community based exercise instructors so that patients with chronic disease can learn how to monitor and adjust their exercise habits for optimum effect and enjoyment?

For the past year she has been using a smartphone pedometer and it has motivated her to increase the frequency of walking. Choosing electronic monitoring devices has become very difficult as there are so many products and accuracy varies – patients with arthritis need accurate information from health professionals and exercise instructors. Monitoring exercise is not just important for individual patients. Patient organisations, family, carers, health providers, town planners, designers and community organisations can play a key role by promoting accessible facilities and exercise monitoring tools in their cultures and values. On reflection, she noted a number of concerns namely, affordability, accuracy, reliability, usability, information quality and potential inequality for patients.

During the past twenty years many advances have been made in the fields of medicine and allied care for rheumatology patients. As the field develops further, how important will exercise monitoring become? Will it change the way patients

interact with health professionals and services? Will we see monitoring devices and state of the art gym equipment in hospital settings, health centres and outdoor parks to support personalised patient exercise compliance?

## How cell death shapes immunity and tolerance

### SP0103 APOPTOTIC CELL ENGULFMENT MACHINERY AND RHEUMATOID ARTHRITIS

S. Arandjelovic. *Center for Cell Clearance, and the Department of Microbiology, Immunology and Cancer Biology, University of Virginia School of Medicine, Charlottesville, VA, United States*

Specific recognition and removal of apoptotic cells is a process that occurs throughout life in all tissues, as part of homeostasis and during pathological conditions. In active rheumatoid arthritis, apoptotic cells are seen in the synovial fluid of human patients and in mice with experimental arthritis, but their contribution to disease severity is not well understood. Recently, many components of apoptotic cell clearance machinery have been identified. Using global and conditional knockout mouse strains and primary cell cultures, we have addressed specific components of the engulfment machinery for their role in rheumatoid arthritis. We observe that molecules linked to apoptotic cell clearance can affect both the extent of inflammation and bone erosion seen during arthritis in mouse models. These data suggest that targeting the components of the engulfment machinery might be a viable therapeutic approach.

### SP0104 NEUTROPHILS IN THE RESOLUTION OF INFLAMMATION

M. Herrmann. *Department for Internal Medicine 3, University Hospital Erlangen, Erlangen, Germany*

Neutrophils are often considered being just cells of the first line defense against pathogens. They are endowed with an arsenal of deadly weapons like reactive oxygen species, proteases and anti-microbial peptides. In a cellular process referred to as degranulation neutrophils secrete preformed chemokines and cytokine that recruit and activate further neutrophils as well as other leukocytes. Neutrophils are phagocytes that vigorously ingest and kill bacteria. In addition, they take up several kinds of particular matter including monosodium urate crystals. After strong activation neutrophils eject their chromatin to form pro-inflammatory, chemo-attractive and bactericidal extracellular traps (NETs). These immobilize and kill pathogens and attract further leukocytes. IL8 secretion, neutrophil attraction and NETosis form a self-stimulating feed back loop that initiates and perpetuates inflammation. Important questions are (Q1) How is this potential dangerous vicious circle controlled? (Q2) Which mechanisms are responsible for the resolution of inflammation?
When the density of the neutrophils reaches a certain threshold the NETs tend to aggregate (aggNET) and form extended clumps of chromatin that are decorated with proteolytically active serine proteases. The clumps and the proteases sequester and proteolytically inactivate the neutrophil-derived cytokines and chemokines. Thus NETosis and aggNET formation play important roles for the initiation and resolution of neutrophil-driven inflammation, respectively.

## "Smoke a joint to protect the joint". Cannabidoids & neuropeptides in pain and inflammation

### SP0105 BIOCHEMISTRY AND PHARMACOLOGY OF THE ENDOCANNABINOID SYSTEM

M. Maccarrone[1,2]. [1]*Campus Bio-Medico University of Rome;* [2]*European Center for Brain Research, IRCCS Santa Lucia Foundation, Rome, Italy*

Nearly 30 years after the discovery of the psychoactive ingredient of *Cannabis sativa*, $\Delta^9$-tetrahydrocannabinol (THC) in 1964, the endogenous counterparts of THC were discovered and were collectively termed endocannabinoids (eCBs). To date, among several members of the eCB family *N*-arachidonoylethanolamine (anandamide, AEA) and 2-arachidonoylglycerol (2-AG) are widely recognized as the most bioactive substances, able to bind to and activate G protein-coupled type-1 ($CB_1$) and type-2 ($CB_2$) cannabinoid receptors, as well as other non-$CB_1$/non-$CB_2$ receptor targets. In addition, an ensemble of proteins that synthesize, transport and degrade eCBs have been identified in the last 20 years, altogether forming the so-called eCB system. eCBs control basic biological processes spanning from cell choice between survival and death, progenitor/stem cell proliferation and differentiation, and neurotransmission to reproductive events, energy balance and immune response. Unsurprisingly, in the last two decades eCBs have emerged as key regulators of human pathophysiology at multiple levels. Here, a modern view of the biochemistry and pharmacology of the eCB system will be presented, in order to put in a better perspective the impact of eCB signaling on human health and disease, both centrally and peripherally. In particular, it will be shown that eCBs regulate bone elongation and remodeling, as well as inflammation and adaptive/innate immunity. Moreover, unprecedented results on AEA and 2-AG alterations in human patients with systemic lupus erythematosus will be presented, that may help to better understand the role of lipid signaling in this disease.

### SP0106 NEUROPEPTIDES, TRPS AND INFLAMMATION: FOCUS ON THE JOINT

S. Brain. *Cardiovascular Div, King's College London, London, United Kingdom*

Arthritis is a debilitating condition characterised by chronic pain in and around the joint. Sensory nerves that contain and release neuropeptides innervate the joint and play a major role in mediating pain. We are interested in the role of the transient receptor potential (TRP) channels, that are calcium-permeable cation channels in mediating the pain and inflammation that occur in the joint during arthritis. We have used TNF and CFA murine models of joint inflammation to elucidate mechanisms. Our early work investigated the role of TRPV1, a channel that is localised to sensory nerves and best known for its activation by the chilli pepper extract capsaicin, noxious heat as well as certain lipids. Studies in TRPV1 knockout mice revealed that CFA thermal pain was alleviated, but TNF levels remained high. TRPA1 is a second TRP channel localised to TPRV1-containing sensory nerves. TRPA1 is activated, amongst other things, by noxious cold and reactive oxygen species. TRPA1 mediates pain in arthritis, as demonstrated by studies including from our laboratory, in a number of species. We have shown that TRPA1 is a vascular cold sensor, also that mice demonstrate exacerbated CFA-induced joint pain after environmental cold exposure. Finally we have now discovered evidence of a regulatory role for the TRPC5 receptor, in that TRPC5KO mice exhibit an enhanced inflammation that is mirrored in WT mice treated with a TRPC5 antagonist.
Thus there is compelling evidence that TRP receptors have potential roles in mediating pain, and in some cases the inflammation, in arthritis. They can act via pro-inflammatory and anti-inflammatory mechanisms, depending on subtype. These effects appear to depend on the TRP channels, with some evidence that the neuropeptides are also involved in pain processing.

### SP0107 CANNABINOIDS AND INFLAMMATION: FOCUS ON THE JOINT

T. Biro. *Department of Immunology, University of Debrecen, Hungary, Debrecen, Hungary*

The emerging endocannabinoid system (ECS; comprising the endogenous lipid mediators endocannabinoids [eCBs], produced in virtually all tissues; their metabotropic and ionotropic cannabinoid receptors; biosynthetic pathways and metabolizing enzymes) has been implicated in multiple regulatory functions of the human body. Namely, the ECS and its "tone", defined by the local levels of eCBs, were shown to control major functions of the central nervous system as well as of multiple peripheral organs (e.g. liver and other metabolic tissues, skin, cardiovascular and pulmonary systems, etc.). Recent studies have intriguingly suggested the existence of a functional ECS in the immune system. Indeed, most immune cells functionally express the bioactive eCBs and the ECS where their activities chiefly exert immune-suppressive and anti-inflammatory actions.
The ECS is functionally active in the joints as well. Importantly, the "eCB tone" was shown to modulate various symptoms and pathogenetic steps of rheumatoid arthritis (RA) and osteoarthritis (OA) in several models of the diseases. Indeed, activation of type-2 cannabinoid receptors (CB2) suppresses cytokine release, inhibits functions of various cells of innate and adaptive immunity, and conveys anti-inflammatory actions. Moreover, stimulation of CB1/CB2 receptors results in analgesic, anti-proliferative, and osteogenetic effects. Interestingly, with respect to fibroblast functions, CB2-coupled signaling exerts anti-fibrotic action whereas, conversely, engagement of CB1 mostly leads to augmentation of fibroblast proliferation.
This presentation reviews the current state-of-the-art of the role of the ECS in the biology of the joints. Moreover, it delineates novel, promising ECS-targeted therapeutic possibilities where synthetic, semi-synthetic or naturally occurring (e.g. from the Cannabis sativa plant) modulators of the "ECS-tone" could be successfully employed in the future clinical management of RA and OA.

## EULAR - EMA session

SP0108 **DIFFERENT APPROACHES TO DRUG APPROVAL BY EMA AND FDA – THE EXAMPLE OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS**

J. Sieper. *Charite, University Medicine Berlin, Berlin, Germany*

Recently new classification criteria have been developed for axial spondyloarthritis (SpA) covering both patients who already show radiographic evidence of structrual damage in the sacroilac joints (or spine), termed radiographic axila SpA (or using the older term: ankylosing spondylitis (AS)) and patients in the earlier phase without radiographic evidence of structural damage in the bone, termed non-radiographic (nr) axial SpA. There is general agreement that these two stages represent a continuum of the same disease and that preferentially the term axial SpA should be used. Both EMA and FDA have raised questions about the natural course of the earlier stage (nr-axSpA), the potential rate of spontaneous remission and the possibilty of overtreatment with biologcs in these patients. However, the EMA has accepted that there was an unmet need for treatment with TNF-blockers of these patients if they fail conventional therapy, which resulted in an approval for TNF-blockers for nr-axSpA - in addition to patients with AS - in the EU, if they have objective signs of inflammation such as positive CRP and/or active bone inflammation on MRI, and many other countries but not the US. The EMA has demanded post-approval studies from the TNF-blocker companies investigating what happens if the drug is stopped (or the dosage reduced) in patients who are reaching remission. These studies are ongoing and will deliver sufficient informations whether overtreatment might occur in these patients. In contrast, the FDA is asking for further phase 3 trials which include a placebo-controlled phase over 12 months. Such a study design would be very difficult to be conducted in EU countries – withholding an effective drug up to 12 months from active patients. But the different apporaches used by the two agencies also reflect that European rheumatologists have been much more familiar over the last decades with this early phase of axSpA compared to US rheumatologists. It is hoped that the results of the ongoing trials - in Europe, US and other parts oft he world – will result in a worldwide acceptance of the axial SpA concept and of the need to offer adaequate treatment to all axial SpA patients in their active phase.

## Teaching clinical skills

SP0109 **HOW TO PERFORM CLINICAL HISTORY AND PHYSICAL EXAMINATION?**

M. Doherty. *University of Nottingham, Nottingham, United Kingdom*

The GALS (gait, arms, legs, spine) screen is useful to detect musculoskeletal (MSK) abnormality as part of a general assessment (1). However, for a person with MSK complaints a more detailed assessment is required to determine the diagnosis and impact on the patient. A thorough history alone usually suggests the single most likely cause for the patient's problem(s). The examination that follows should be a targeted assessment in which the practitioner selects the required skills from a range of competencies according to specific elements in the history (i.e. not a uniform set of identical procedures in each patient). The overall assessment needs to be holistic and individualised as the enquiry proceeds, since the impact of any condition is person specific and influenced by many factors (e.g. psychosocial factors, illness perceptions, sleep, comorbidity etc.).

This presentation will cover key principles and considerations related both to the history and examination (2). Examples include:

(1) in the *history:* determination of pain localisation and features that associate with radiated pain; important pain and stiffness characteristics that differentiate mechanical usage-related pain, inflammatory pain, acute crystal synovitis pain, destructive bone pain and neurogenic pain; non-specific symptoms of inflammation

(2) in the *examination:* usual order of inspection at rest, inspection during movement, then palpation at rest and during movement; contrasting clinical findings that differentiate joint and peri-articular problems; detection of "stress pain" (pain worse in tight-pack positions but reduced/absent in loose-pack positions - the most sensitive sign of inflammation); examination for effusion, soft-tissue and firm swelling; use of resisted active movements and stress tests for peri-articular lesions.

With experience, following a thorough history and examination the combined aspects of the history and examination which differentiate between major categories of MSK conditions permit pattern recognition and a confident clinical diagnosis in the majority of cases. A simple way of assembling the clinical findings to enable them increasingly to point to a likely single diagnosis will be presented.

EULAR learning resources available at http://www.eular.org/edu_training_dvd.cfm include: (1) The "GALS" screen and (2) Principles of the musculoskeletal history and examination.

SP0110 **WHAT MAKES AN EFFECTIVE MENTOR AND AN EFFECTIVE MENTEE?**

J. Hafler. *Yale University, New Haven, United States*

Mentoring is a key teaching skill that is considered to be a core component of the duties of all medical school faculty. Effective mentoring requires understanding the needs of the mentee. How do we learn how to be an effective mentor? How we we learn how to be an effective mentee? As Daloz (1986) said "I resolved to look more closely at what good teachers and mentors actually do as they guide their charges along on their transformational journeys." In this session I will explore what good mentors and good mentees can do toward achieving successful outcomes and address specific characteristics of effective mentors. This session will be of interest to mentors and mentees in research and clinical areas.

## Local procedures including aspirations, injections and biopsies I

SP0111 **SONOGRAPHIC-GUIDED JOINT AND PERIARTICULAR ASPIRATIONS AND INJECTIONS**

N.S. Damjanov. *Institute of Rheumatology, Clinical Rheumatology Department, Institute of Rheumatology, University of Belgrade, Serbia, Belgrade, Serbia*

For more than 60 years intra-articular an peri-articular injection are part of the standard treatment of arthritis. In vast majority of interventions needles used to be guided by anatomical landmarks as orientation ("blind" join injection). However, studies of the accuracy of "blind" injections into various joints showed that about two thirds of knee and ankle injections and only half of the wrist injections were intra-articular. The accuracy of blind corticosteroid injections into the glenohumeral joint is also questionable. Tobola et al. found the accuracy of an anterior approach glenohumeral injection was 64.7%, regardless of clinician experience. Utilizing the additional measure of ultrasound or another image modality to guide injections improves accuracy. In comparison to a blind posterior injection technique, ultrasound guided injections had a greater success rate of reaching of the glenohumeral joint (72.5% vs. 92.5%. Musculoskeletal ultrasound (MSUS) allows the possibility of reliable guidance of needle during diagnostic (e.g. needle aspiration of synovial liquid for analysis) and treatment interventions (e.g., intra-articular injections of drugs). Ultrasound guidance enables the exact placement of the needle into the structure of interest and accurate injection of medication. Moreover, it helps in establishing more precise diagnosis and in confirmation of the indication for injection. Ability of ultrasound guided injections to improve clinical outcomes compared to that of palpation guided injections however remains unclear. Lee et al. compared ultrasound-guided injections of triamcinolone with blind injections. At 6 weeks, the ultrasound guided injection group did not have statistically superior improvements than blind injections in flexion, abduction, external rotation or internal rotation, although improvements from baseline were significant within both groups ($p<0.001$). The ultrasound guided injection group also did not have significantly better VAS score improvements after 3 weeks. On the contrary, one study showed that US guidance significantly improved the outcome of intra-articular steroid injections compared with anatomical palpation guidance. For successful implementation of ultrasound-guided injection technique appropriate training is required. After successful training, guidance of needle allows precise and successful diagnostic and/or treatment intervention. Moreover, ultrasound examination can visualize different tissues which could be damaged by the needle during the "blind" injection. Ultrasound visualization allows examiner to minimize possible damage of blood vessels, nerves, tendons, ligaments, cartilage and other tissues by the needle. Two main advantages of ultrasound-guided injections are increased accuracy and minimal risk of adverse events during and after the intervention.

SP0112 **MINIMALLY INVASIVE ULTRASOUND-GUIDED SYNOVIAL BIOPSY**

C.A. Scire. *Epidemiology Unit, Italian Society for Rheumatology, Milano, Italy*

Ultrasound-guided biopsy of synovial tissue is an increasingly performed procedure for diagnostic and research purposes.

In clinical practice, synovial tissue analysis may assist in the diagnostic work-up in selected (rare) joint diseases, including neoplastic or granulomatous diseases, deposition diseases including crystal-associated arthritis or infection, when synovial fluid analysis and culture are not conclusive.

As demonstrated by several studies, including the 1987 ACR classification criteria for rheumatoid arthritis (RA) study, synovial tissue analysis helps in distinguishing inflammatory from non-inflammatory arthritis and between different forms of immune-mediated inflammatory arthritis (IA). Despite morphological

and immunohistochemistry analyses are accurate in differentiating RA from spondyloarthritis, at this moment the usefulness of these tests to establish the diagnosis in clinical practice is not justified.
Further applications of synovial tissue analysis include disease activity assessment at joint and patient level, as well as prognostic stratification, but no specific prognostic biomarkers are enough specific and predictive to be included in a standard patient assessment. However, in the setting of drug development, the evaluation of biological activity of experimental drugs at the site where the disease process takes place is now a well-recognized approach, and evaluation of serial synovial biopsies assists in screening for potential efficacy of novel compounds provides insights into the mechanism of therapy.
Form a technical point of view, needle biopsy is simple, cheap and minimally invasive, while arthroscopic biopsy is regarded as the gold standard sampling method, since it provides adequate synovial tissue samples selected under direct vision from both large and small joints even from clinically uninvolved joints. The availability of more recent office-based mini-invasive ultrasound-guided techniques are increasing the diffusion of the synovial tissue analysis in inflammatory arthritis research and clinical practice.
Depending on the indication for the biopsy procedure, the tissue needs to be handled substantially differ. Under the assumption that inflammation in one inflamed joint is generally comparable to that in other inflamed joints, in order to minimize sampling error, multiple sampling (typically at least six samples from different areas throughout the joint) need to be applied. As recently demonstrated in validation studies on US-guided derived synovial samples, both at large and small joints: good quality tissue collection is feasible; quantification of digital synovial inflammation by image analysis is a valid, sensitive and time efficient; and quantitative PCR and different microarray analysis techniques can be used to analyze US synovial tissue samples for research purposes.
Future advances in the field of minimally invasive ultrasound-guided synovial biopsy will include new technical developments, identification of novel biomarkers, able to improve diagnostic/prognostic characterization of individuals at the onset of the disease, and even more importantly, to personalize treatment based on potential treatment selection biomarkers.

### SP0113 MINIMALLY INVASIVE BIOPSY OF SALIVARY GLANDS

C. Ungari, F. Filiaci, E. Riccardi, A. Agrillo. *Department of Odontostomatoly and Maxillo-Facial Surgery, Sapienza, Università di Roma, Italy, Rome, Italy*

**Background:** Salivary gland disorders include disorder of immune system, inflammatory, bacterial, viral, and neoplastic etiologies. Diagnosis is made by radiological examinations (ultrasonography, magnetic resonance imaging, computed tomography) and biopsy of salivary glands. Minimally invasive biopsy, such as Fine-needle aspiration (FNA), are commonly used in the diagnosis of salivary gland disorders. Submucosal minor salivary gland biopsy should be done if the diagnosis of Sjögren syndrome (SS) cannot be made by history and serologic testing. Fine-needle aspiration is widely applied in the preoperative diagnosis of salivary gland lesions. Distinguishing neoplastic from non-neoplastic lesions and benign from malignant tumors of the salivary glands is extremely important for medical and surgical management of salivary gland disorders.
**Aims:** The aim of this study was to provide a systematic review of the literature to analyze the role and several aspects of minimally invasive biopsy of salivary gland disorders.
**Methods:** A systematic bibliographic search of the medical literature between January 2011 and January 2016 was conducted using electronic databases of National Library of Medicine (Medline). The bibliographic search was carried out with combination of this medical subject heading terms and text words: salivary gland, biopsy, minimal invasive biopsy, histological findings and fine-needle aspiration. For the inclusion on this review, studies had to evaluate several aspect of biopsy of salivary glands. The authors to determine the eligibility on this study performed an independent review of the finding data.
**Results:** The PubMed search identified 161 items. After a first evaluation, 57 full-text articles were finally selected for further evaluation. Of these 57 articles, 38 were excluded because they did not completely meet the inclusion criteria, whereas 19 were considered eligible for this review study.
**Conclusions:** The advantages of minimally invasive biopsy of salivary glands include decreased tissue damage, no need for anesthesia, and repeated sampling when specimens are insufficient after immediate assessment at the examination site. A biopsy of salivary glands offers valuable information for planning of subsequent therapeutic management. Fine-needle aspiration is a safe diagnostic technique that has a high specificity and sensitivity for the assessment of salivary gland disorders. The sensitivity and specificity reported is high for infective, immunological and benign lesions, whereas it decreases in cases of malignant tumors for the great variety of morphological patterns found in malignant salivary gland tumors.

## MRI I

### SP0114 HOW TO DEFINE AND ASSESS INFLAMMATORY AND DESTRUCTIVE CHANGES IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS? INCLUDING QUIZ CASES

M. Østergaard. *Copenhagen Center for Arthritis Research, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark*

Compared to conventional clinical, biochemical and radiographical examinations, magnetic resonance imaging (MRI) offers improved sensitivity to early inflammatory and destructive changes in peripheral joints in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and other inflammatory joint diseases. Furthermore, MRI measures provide high sensitivity to change and prognostic value.
Accurate and reproducible assessment requires strict definitions and validated assessment methods. Such methods can be qualitative, semiquantitative or quantitative. The present talk will outline currently available definitions and assessment systems of inflammatory and destructive changes in RA and PsA. The most used methods, i.e the RAMRIS (RA MRI scoring system) and PsAMRIS (PsA MRI scoring system), both developed by the OMERACT group, will be described, as will recent alternative approaches including whole-body MRI, dynamic contrast-enhanced MRI and volume quantification.
At the end of the talk, quiz cases for audience participation will be presented.

### SP0115 MRI OF INFLAMMATORY DISEASES OF VESSELS AND MUSCLES – HOW TO APPLY, INCLUDING CASE STORIES

I. Eshed. *Diagnostic Imaging, Sheba Medical Center, Ramat Gan, Israel*

A variety of diagnostic imaging techniques have made the non-invasive evaluation of skeletal muscles and vessels in inflammatory diseases possible. The standard imaging methods for muscle evaluation are US, MRI and scintigraphy while for vessel imaging conventional angiography as well as CT angiography and PET-CT play an important role.
Magnetic resonance imaging (MRI) is especially sensitive in the diagnosis of muscle disorders and injury and has proved to be useful in determining the extent of inflammatory disease, in directing interventions, and in monitoring the response to therapies. Thus, the current imaging indications for muscles include: diagnosis, assessment of disease burden (localization) and biopsy site selection. Several experimental techniques are used nowadays for further muscle evaluation including spectroscopy (metabolic imaging), BOLD imaging (perfusion and oxygenation) and diffusion tensor imaging DTI (DTI; muscle function-structure relationship).
In vessel imaging, CT, MRI and conventional angiography help in the anatomic evaluation of disease including the evaluation of disease distribution, vessel stenosis, wall thickening (CT and MRI only) and end organ damage. MRI and FDG-PET-CT add valuable information regarding active inflammation including detection of wall edema, delayed wall enhancement and high glucose metabolic activity.
The basics of MR muscle and vessel imaging as well as the more advanced imaging techniques will be presented along with some case stories.

### SP0116 HOW TO USE MRI TO DIFFERENTIATE SPA FROM ITS DIFFERENTIAL DIAGNOSES?

T. Diekhoff on behalf of Rheuma-Imaging Working Group. *Department of Radiology, Charité Berlin, Berlin, Germany*

Magnetic resonance imaging (MRI) in axial spondyloarthritis has an increasing importance, especially in patients without or with equivocal changes in radiography. However, radiologists are often uncomfortable with imaging of rheumatic diseases and reports consequently sometimes confusing. Therefore, rheumatologists are increasingly confronted with the need to receive their own impression of radiography and MR images.
The aim of this talk is to give basic ideas on interpretation of MRI sequences with a focus on the sacroiliac joints in a case-based manner. The participants will learn to easily differentiate common MR sequences and to decide, which information can be derived of an image. They will discover to detect common differential diagnoses (such as condensing osteitis, osteoarthritis and anatomical variants) and to differentiate them from inflammatory changes. In a comparison of radiography, MRI and computed tomography they will experience the strengths and weaknesses of the different imaging methods and learn to decide, in which patients further imaging – additional to MRI – may be useful.
This talk will also provide a perspective of future innovations in MRI and what additional advantages might go along with them. In the end, the experience might encourage an intensified communication between rheumatologists and radiologists in daily practice with a better understanding of the thinking and needs within the respective medical field.

SP0117 **WHEN AND HOW TO USE MRI IN CLINICAL PRACTICE**

K.G. Hermann. *Dept. of Radiology, Charité Medical School, Berlin, Germany*

MRI is very popular among clinicians and patients are referred to a large extent to radiological facilities to help establishing diagnoses. However, despite MRI is one of the more expensive imaging tests its not automatically the one solving all clinical problems.
The lecture will highlight the value of MRI for early diagnosis of both axial and appendicular arthritides. On the other hand, certain diagnostic problems will be outlined that did benefit from additional imaging modalities or from a carefully obtained medical history.
Learning objectives:
- Learn how to use MRI for establishing a diagnosis.
- Learn how early detection differs from differentiation of arthritides.
- Identify diseases that do not benefit from MR imaging.

## The Health Professionals' approach to pain management in inflammatory arthritis and osteoarthritis

SP0118 **THE ONGOING SHIFT OF PARADIGMS WITHIN PHYSIOTHERAPY AND PAIN MANAGEMENT**

P. Åsenlöf. *Neuroscience, Physiotherapy, Uppsala University, Uppsala, Sweden*

During the past three decades the search for effective non-pharmacological pain management methods in chronic non-cancer pain conditions has been intensified. However, despite a growing body of scientific studies, there is still no cure for chronic pain, and treatments targeting pain per se do not report sufficient effects in terms or pain relief. This lecture presents some important changes in foci regarding pain management in general and physiotherapy in particular. These are: (1) *From* problem-identification *to* goal attainment, (2) *From* pain intensity *to* activity interference, (3) *From* pain relief *to* behavioural skills training. The perspectives will be described and illustrated by scientific studies underpinning this development. Implications for pain management in inflammatory diseases and physiotherapy will be discussed with the audience.

SP0119 **SYSTEMATIC REVIEWS AND META-ANALYSES FOR DUMMIES: A TUTORIAL ON HOW, WHEN, AND WHY TO GET STARTED**

R. Christensen. *Musculoskeletal Statistics Unit, The Parker Institute, Bispebjerg & Frederiksberg Hospital, Frederiksberg, Denmark*

The world today is overflowing with results from trials to the point where anyone can be overwhelmed. Being able to sort out the good systematic reviews and meta-analyses from the bad ones and then be confident in the ability to judge the quality of the evidence is critical. Systematic reviews (i.e., the process of systematically locating and synthesizing data from completed studies) and meta-analyses (i.e., the statistical component of a systematic review) are the procedures that make it possible to synthesize data from a series of studies (i.e., evidence synthesis); these are essential to summarise evidence relating to efficacy and safety of health care interventions accurately and reliably.
The process begins with a pre-specified protocol [1] asking an explicit question, in terms of the populations, alternative management strategies (an intervention, sometimes experimental and a comparator, sometimes standard care), and all patient-important outcomes [2]. After the evidence is collected, summarised, and reported [3], a good systematic review will help determine the quality of evidence based on study design, risk of bias, imprecision, inconsistency, indirectness, and magnitude of effect [4]. Quality of the evidence (QoE) reflects our confidence that the estimates of the effect are correct. High QoE: "*We are very confident that the true effect lies close to that of the estimate of the effect*" (no more research needed); Very low QoE: "*The true effect is likely to be substantially different from the estimate of effect*" [5].
Following this, guideline panels might conclude with either a strong or conditional recommendation, either for or against an intervention - indicating whether patients should receive the specific course of action {6}.

SP0120 **RECOMMENDATIONS FOR PROMPT PAIN MANAGEMENT IN INFLAMMATORY ARTHRITIS AND OSTEOARTHRITIS**

R. Geenen on behalf of EULAR HP Pain Mangement Task Force. *Psychology, Utrecht University, Utrecht, Netherlands*

Pain is a predominant symptom for people with inflammatory arthritis (IA) and osteoarthritis (OA). Health professionals should have knowledge and skills to offer the first principles of assessment and management of pain to people with IA and OA. Aim of the EULAR project was to provide "recommendations" (advice with sufficient evidence) and "points to consider" (advice that cannot be substantiated by data) that enable HPs to provide prompt and knowledgeable pain management support for people with IA or OA. A task force of health professionals, patients and rheumatologists from Europe and the United States considered recommendations and points to consider with respect to 1) background knowledge 2) assessment of the patient and the pain, and 3) management options including core prompt and general pain management that virtually any HP should be able to give and referral to specialized pain management. The detailed recommendations and points to consider will be presented and discussed.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6322

SP0121 **THE BENEFITS OF PROMPT PAIN MANAGEMENT IN INFLAMMATORY ARTHRITIS AND OSTEOARTHRITIS. A SYSTEMATIC LITERATURE REVIEW**

C.L. Overman on behalf of Task force "The Health Professionals' approach to pain management in inflammatory arthritis and osteoarthritis". *Social, Health and Organizational Psychology, Utrecht University, Utrecht, Netherlands*

**Objective:** To identify the scientific evidence associated with the benefits of the health professional's (HPs) approach to pain management for people with inflammatory arthritis (IA) and osteoarthritis (OA), serving as a basis for the the first "recommendations" and "points to consider" that enable HPs to provide prompt and knowledgeable support for pain in people with IA or OA.
**Methods:** A systematic literature search was undertaken. Cochrane, Embase, PsycINFo, PubMed, Scopus, and Web of Science were searched for records of systematic reviews, meta-analyses, (practice) guidelines and recommendation articles containing results of studies evaluating management strategies for IA and OA and their effect on pain. Quality of the body of evidence was assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.
**Results:** Of 1569 papers, 184 papers were included. Papers reviewed effects of interventions on pain for OA (141 papers), RA (42 papers), and axial spondyloarthropathies (7 papers); for psoriatic arthritis no relevant papers were found. Interventions covered by this overview of reviews were: exercise interventions (87 papers), non-exercise physiotherapy interventions such as acupuncture, transcutaneous electrical nerve stimulation, electromagnetic fields, laser, diathermy, thermotherapy, and balneotherapy (77 papers), orthotics and assistive devices (41 papers), education (21 papers), weight reduction (14 papers), and psychological interventions (10 papers).
**Conclusion:** During the conference the effects on pain and quality of the evidence will be presented per disease by type of intervention. A necessary research agenda is proposed. For IA, but also some types of OA, well-designed randomized controlled trials assessing the effect of non-pharmacological interventions on pain, are still needed. Evidence for prompt types of pain management is even more necessary.

## News from kinase inhibitors

SP0122 **KINASE INHIBITORS: CLINICAL ASPECTS**

G.S. Firestein. *USCD, San Diego, United States*

Kinases play a critical role in inflammatory disease and immune regulation. They

are critical molecules that transduce signals from the environment, including cytokines and toxic exposures. Their participation in human rheumatic disease has been confirmed through the testing and introduction of kinase inhibitors to treat various immune-mediated diseases. Janus kinase inhibitors, for example, are effective in rheumatoid arthritis, psoriasis and many others. These observations create opportunities for targeting other pathways and kinases that play a role in B cell activation and differentiation, stress responses, and cytokine signaling. Our experience with kinase inhibitors also demonstrates that the specific kinase and its inhibitor must be carefully matched to the pathogenic process. Several unsuccessful clinical development programs, such as p38 MAP kinase or Syk, show that the balance between efficacy, clinical indication, and toxicity need to be carefully considered. The future, however, is bright because there is an abundance of potential targets. Carefully designed clinical trials, use of biomarkers to stratify patients, and patience will pay off we new and creative ways to treat our patients.

## Crystal arthritis

### SP0123 GOUT: A VARIABLE INFLAMMATORY DISEASE

R. Terkeltaub Md. *San Diego VAMC Rheumatology Section Chief. Professor of Medicine, UCSD., San Diego, United States*

In patients with tissue deposits of urate crystals, acute flares of gout develop more frequently after certain dietary triggers and in early uric acid lowering therapy (ULT). However, most acute flares of gout develop and recur variably and unpredictably. New gout inflammation biomarkers, and novel, rational, lab discovery-based therapeutics targeted to them, would advance care. Elevation of serum urate, though a biomarker for long-term prognosis in gout, has no clear role in assessing the inflammatory state in gout. Moreover, the only serum biomarker of inflammation in both acute and intercritical gout appears to be elevation of IL-8. Increasing the number of options for anti-inflammatory treatment for gout also is a central unmet need. Gouty inflammation is driven by innate immune responses to urate crystals, with "first signal" priming of the NLRP3 inflammasome in macrophage lineage cells by C5a, NF-kB transcription factor activation and a variety toll-like receptor 2 and 4 (TLR2, 4) ligands, and coupled "second signals" via NLRP3 inflammasome activation driving secretion of mature IL-1beta. Sources of variability in the capacity of urate crystals to cause inflammation will be reviewed in this talk. They include not simply exogenous dietary factors, but also constitutive "master" regulation of host inflammatory responses to urate crystals. I will discuss, in depth, AMP-activated protein kinase (AMPK), a druggable master regulator of urate crystal-induced inflammation and mediator of comorbidity. AMPK is one of several biosensors of changes in nutrition and cellular energy processes (eg, glycolysis, oxidative phosphorylation) that are emerging as therapy targets for controlling adaptive and innate immune inflammatory responses, exemplified by suppression of SLE using metformin. Last, I will summarize how metabolic regulation of innate inflammation is directly relevant to gout, since both hyperuricemia and clinical expression of gouty arthritis are influenced by highly prevalent metabolic co-morbidities and dietary factors, such as the linked co-morbidities obesity, metabolic syndrome and type II diabetes, and related caloric excesses.

### SP0124 SYSTEMIC PREDISPOSITION TO CPPD AND INTERACTION WITH OSTEOARTHRITIS

A. Abhishek. *Academic Rheumatology, Nottingham University, Nottingham, United Kingdom*

Calcium pyrophosphate deposition (CPPD) is generally regarded as a local joint specific phenomenon with a few reported instances of widespread polyarticular CPPD attributed to inherited disorders, severe generalised structural arthropathy, or uncommon to rare metabolic disorders like haemochromatosis, hyperparathyroidism, hypomagnesemia and hypophosphatasia. Recent research by our group has demonstrated that chondrocalcinosis (a surrogate for CPPD) occurs due to a systemic predisposition. We have also demontrated that the association between chondrocalcinosis and osteoarthirtis is joint specific and that chondrocalcinosis at both index and distant joints modifies the radiographic phenotype of lower limb large joint osteoarthritis. For instance knee chondrocalcinosis and chondrocalcinosis at distant joints (in the absence of any knee chondrocalcinosis) associate with attrition in knees with osteoarthritis. In this lecture I will describe the pathogenesis of CPPD, review the research which demonstrates that there is a systemic predisposition to CPPD, and that its interactions with osteoarthritis are joint specific.

### SP0125 RENAL HANDLING OF URATE AND GOUT

H.-J. Anders. *Medizinische Klinik IV, LMU Munich, Muenchen, Germany*

Humans, birds, reptiles have (dinosaurs had) a tendency to develop gout because they lack sufficient uricase expression. Elimination of uric acid largely depends on excretion in the urine. A number of factors can limit this process such as genetic variants of uric acid transporters, drug-related inhibition of uric acid excretion, urine pH or loss of GFR. Visceral gout is a common phenomenon on birds, poultry, and reptiles with renal failure.
Excreting large amounts of uric acid crystals is no problem for birds and reptiles (birds droppings are white for this reason), because urine concentration takes place in the cloacae close to the external orifice. In humans urine concentration takes place in the collecting ducts, which implies that hyperuricosuria imposes a risk for urolithiasis. By contrast, uric acid retention is a common cause for hyperuricemia together with increased purine load from metabolism and diet. Conceptually, a visit is a beer garden is dangerous for two reasons, the intake of purine rich food and drinks (beer) and the intake of fructose-rich soft drinks that blocks certain urate transporters that facilitate urate excretion. A number of well-known triggers for gout relate to renal function. For example, saturnine gout, the gout of the whine-drinking romans or of noblemen of the 17$^{th}$ century related to the cups made of lead or other nephrotoxic metals used at that time that caused chronic kidney disease (CKD)-related hyperuricemia. Also the prevalence of gout and CKD increase both with age. The lecture discusses the role of hyperuricemia and gout in CKD and the role of different therapeutic options in CKD patients.

## HOT session 7

### SP0126 HOW TO TREAT/MANAGE (HOT) MYOSITIS

I.E. Lundberg[1,2]. *[1]Department of Rheumatology, University of Southern Denmark, Odense, Denmark; [2]Department of Medicine, Rheumatology Unit, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden*

The idiopathic inflammatory myopathies (IIM) or briefly myositis is a heterogenous group of disorders where muscle weakness and inflammation in skeletal muscle tissue are predominating features but other organ involvement is common, such as skin, joints, lungs, gastrointestinal tract and heart. Treatment is based on a combination of pharmacological treatment in combination with physical exercise. However, treatment effect varies and may often be disappointing with persisting muscle weakness, muscle fatigue and low health related quality of life. Thus there is a high unmet need for new therapies and for this we need a better understanding on the molecular pathogenesis and this is likely to be different in different subsets.
Based on differences in clinical and histopathological features IIM has since long been subdivided into polymyositis, dermatomyositis and inclusion body myositis. This subclassification has several limitations as treatment response and prognosis varies within these subgroups. Furthermore, the varying treatment response suggests that there may be different pathogenic mechanisms in these different subgroups. During recent years several new myositis specific autoantibodies have been identified and they are associated with distinct clinical phenotypes and thus may be associated with differences in molecular pathways. Autoantibody profile is important in the clinic to alert for organ involvement such as interstitial lung disease (ILD) and malignancy. Autoantibodies may also predict treatment response.
Pharmacological treatment is based on high doses of glucocorticoids in combination with another immunosuppressive agent to improve the immunosuppressive effect and reduce the need of glucocorticoids. Most experts recommend methotrexate or azathioprine as first line treatment together with glucocorticoids, but other agents are also used with varying effect. New biologics such as anti-TNF therapies have had limited effect and even worsened inflammation in some cases. Treatment with the B- cell blocking agent rituximab has been more successful, but still with varying results. Presence of anti-Jo-1 or anti-Mi-2 antibodies seems to predict response. Interstitial lung disease (ILD) is a major risk factor for morbidity and mortality. Careful monitoring of pulmonary function is required in these patients As first line treatment for myositis associated ILD most experts recommend high doses of glucocorticoids in combination with pulse cyclophosphamide but controlled trials are lacking. Beneficial effect of rituximab on pulmonary function has been reported in case series but needs to be evaluated under controlled conditions.
Physical exercise in combination with immunosuppressive treatment is safe and has beneficial effects on muscle performance and health related quality of life. In addition, exercise has beneficial effects on muscle metabolism and may restore a disturbed mitochondrial function and may even have anti-inflammatory effects.
To learn more about which treatment should be preferred for a specific patient we need more knowledge on predictive markers. To achieve this an international collaboration where we collect validated clinical outcome data in a standardized way on a large number of patients will be important. This will be essential to analyze treatment effects in large enough homogenous subgroups. One such initiative is the Euromyositis register, www.euromyositis.eu. In addition, we need

to perform controlled clinical trials in well-defined patient subgroups in large multi-center trials and we need to learn more about the pathogenesis of these diseases to develop new therapies.

## WIN session 6

SP0127 **YEAR IN REVIEW - OSTEOARTHRITIS**

M. Doherty. *University of Nottingham, Nottingham, United Kingdom*

This talk will highlight, and place into perspective, new research published on osteoarthritis (OA) in the past year. The focus is on studies that significantly contribute to our better understanding of OA or which may influence management of people with OA. Topics with recent key publications that will be included to date are: new genetic data on OA; correlation between symptoms and structural changes of OA; the role of inflammation in OA, including early OA; relationship between calcium crystal deposition and OA; inter-relationships between sleep, fatigue and pain in OA; the use of network meta-analysis to compare different effects sizes of available treatments; the high proportion of contextual effect of OA treatments; and ways to present results of RCTs that may reduce the efficacy paradox. Additional topics may be included depending on publications in Q2 2016.

## Difficult to treat rheumatoid arthritis

SP0128 **A CASE OF DIFFICULT TO MANAGE RHEUMATOID ARTHRITIS**

L. Schoneveld. *Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands*

Rheumatoid arthritis (RA) is a chronic inflammatory disease that requires early treatment to prevent articular damage. Treatment with first line conventional DMARDs may be accompanied by side effects. Approximately 20 percent of patients with RA fail to respond to conventional DMARDs within 5 years and require biological DMARDs. However, a significant portion of the patients on tumor necrosis factor inhibitors, lose response over time or are unable to tolerate treatment. Furthermore, treatment with biological DMARDs may result in serious infectious complications. We will discuss a case of a 76 year old man with seropositive RA whose arthritis treatment was hampered by multiple problems during the course of his disease.

## Biomarkers: powerful or powderpuff?

SP0129 **BIOMARKERS ARE CRITICAL FOR OUR FUTURE**

R. Van Vollenhoven. *Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands*

Even the best therapies do not work if given to the wrong patient. In practice we assess the activity or severity of the disease using history, physical examination and various additional tests when making a decision as to which therapy to recommend. Such tests can be called biomarkers.
For many decades, there were only a few therapeutic agents in rheumatology and the choices among them were mostly based on "hit-or-miss". As more and more effective therapies have been developed these choices are becoming more difficult and at the same time more critical, considering the impact that failure to control disease has on patient quality-of-life and long-term prognosis. But while therapy has become more sophisticated, our assessment tools have not kept pace: diagnostics rely on some biomarkers (RF, ACPA) and activity assessment on others (ESR, CRP) but clinical assessments and trial-and-error continue to play a major role.
The advent of next-generation biomarkers and biomarker panels are going to enable clinicians to become much more proactive and evidence-based in their daily practice. Data from recently published and ongoing studies show that biomarkers and biomarker panels help identify patients likely to respond to first-line or second-line therapy, patients at risk for radiographic progression, and patients more or less likely to respond to various biologics. Thus, the presence in serum of survivin, a tumor-associated cytokine found in around 1/3rd of patients with RA, was associated with poor response to MTX[1]. The multi-biomarker disease activity (MBDA) panel identified patients at risk for radiographic progression[2], and was also shown to identify which patients could benefit more from triple therapy and which ones from anti-TNF[3]. And a low interferon-α signature in RA associated with higher likelihood to respond to rituximab[4].
As rheumatology specialists, we must embrace these development in order to be able to provide our patients with the best possible treatment at cost levels that are sustainable for societies. Biomarkers are an indispensable part of our future.

## The role of nuclear medicine in rheumatology

SP0131 **FDG-PET FOR IMAGING JOINT INFLAMMATION IN CHRONIC JOINT DISEASE**

C.J. Van Der Laken. *Rheumatology, Amsterdam Rheumatology & immunology Center, location VU University Medical Center, Amsterdam, Netherlands*

As the spectrum of diagnosis of inflammatory joint diseases is shifting towards very early diagnosis and individualised treatment strategies are required to optimize treatment outcomes, there is a need for sensitive imaging techniques to detect and monitor joint inflammation. FDG-PET(-CT) allows highly sensitive imaging of (subclinical) arthritis at a molecular level. The technique provides non-invasive information of the whole body in one scan session. Both visual and quantitative analyses can be applied, the latter in particular useful for therapy monitoring. Pattern of FDG uptake in (peri-)articular tissues can aid in the diagnostic work-up of the individual patient. Most recently, hybrid PET-MRI has been introduced on the market, which enables investigation of both inflammatory and anatomical signs of arthritis, at a reduced radiation level as compared to PET-CT. The lecture will provide an overview of the current status of FDG-PET for imaging in joint inflammation in chronic joint diseases and will include comparison with other advanced imaging techniques as ultrasound and MRI.
**Disclosure of Interest:** None declared

SP0132 **60 YEARS OF RADIOSYNOVIORTHESIS - STATE OF THE ART**

W.U. Kampen. *Nuklearmedizin Spitalerhof, Hamburg, Germany*

Since its first description in 1952, radiosynoviorthesis (RSO) is performed as a local treatment of synovitis in patients with inflammatory joint disease by intraarticular injection of beta-emitting radiocolloides. The radioactive particles are phagocytized by the superficial type-A synoviocytes and the local high-energy beta radiation with a therapeutic range of only a few millimetres results in a coagulation necrosis of the superficial synovial layers. The necrotic tissue is then repelled, the respective area is demarcated by a pronounced inflammatory reaction and finally a new synovial membrane is regenerated. Clinically, a

significant reduction of both joint effusion and articular pain is noted with a consecutive improved mobility. Apart from its classical indication Rheumatoid Arthritis, RSO can be used to treat each kind of synovitis, regardless of the underlying pathology. The indication for RSO should be discussed in line with an interdisciplinary treatment regimen in cooperation between the nuclear medicine physician and a clinician experienced in rheumatology or orthopaedics, dependant on the respective patient.
Clinical results with significant pain reduction and improved joint motion are achieved in approx. 60–80% of all joints treated are published in several randomized, controlled studies on evidence level Ib in patients with rheumatoid Arthritis. The treatment is cost-effective and safe, assuming a proper patient selection and a skilful injection technique. Local complications are very rare with an overall rate of 1‰ and less.
This presentation will give an overview of the different indications for RSO, the pretherapeutic examinations and prerequisites necessary for patient selection, the procedure of the treatment itself with special aspects of radiation protection and imaging. Finally, possible side effects and complications with treatment strategies will be discussed.

## PROMs/PROs in rheumatological research - time for a critical appraisal?

### SP0133 DO WE NEED NEW PROMS OR CAN WE REUSE THEM?

S. Hewlett. *Nursing and Midwifery, University of the West of England, Bristol, Bristol, United Kingdom*

The re-use of validated PROMs from one condition into a different condition is common. However, this is often done without understanding the conceptual model of the particular health issue that the PROM attempts to capture in the first population, nor its formulation in the new target population (face and content validity). Furthermore, there is often no attempt to explore psychometric evidence for validity in the new patient population (construct, criterion, sensitivity and reliability). Second, once a PROM has been developed in the initial language, there are instances when researchers simply translate the words, without considering cultural issues in the new population. The original PROM developers may not be involved in ensuring conceptual equivalence of the health issue between the old and new populations, let alone cultural transferability. These new translations need evaluating fot only for cultural and conceptual equivalence, but also psychometric validity. Such work has implications for cost and time, but there are good examples of robust and well-thought through translation protocols by either researchers or PROM translation companies. This presentation will explore these re-use issues and provide examples of good practice (or otherwise).
**Disclosure of Interest:** S. Hewlett Grant/research support from: Unrestricted educational grant from GSK towards PhD student to develop a questionnaire, Consultant for: Institution received funding to support translation of questionnaire, from UCB and Bristol Myers Squibb

### SP0134 PATIENT'S PERCEPTIONS OF REMISSION AND THE ART OF CONCILIATION

M. de Wit[1,2]. [1]*Standing Committee of People with Arthritis/Rheumatism in Europe (PARE), EULAR, Zurich, Switzerland;* [2]*Medical Humanities, VU University Medical Centre, Amsterdam, Netherlands*

Untill recently definitions of remission have been developed on the basis of pragmatic arguments and with the purpose to create a treatment target that is achievable in a significant number of patients. Definitions were designed using statistical analysis of existing trial data sets. Patients were not involved in this exercise. Since EULAR/ACR agreed on a preliminary definition of remission in rheumatoid arthritis (RA), it was suggested to explore whether this definition, formulated in a rather artificial algorithm, also reflects the perspective of patients. Qualitative research, carried out by members of Outcome Measures in Rheumatology (OMERACT), demonstrated that patients' view on remission is quite straight forward. In RA main characteristics are the absence of any signs and symptoms of disease activity, reduction of disease impact and going back to "normality", a state similar to before diagnosis. The discordance between the patients' definition of remission derived from the ideal world and the researchers' pragmatic definition of remission as an achievable target is seen in other disease areas as well.
The widely accepted quantitative approaches to defining cutoffs for disease activity/remission are based on data that are limited to what has been collected in clinical trial datasets and hamper a serious dialogue between patients and physicians/researchers. Exclusively quantitative approaches can bring us to a set of variables that are most associated with change in disease status but cannot expand our understanding of remission. Patients' and physicians' perceptions of disease often do not align and there is great need to explicitly seek the patient perspective regarding the real life experience of remission. Even when the patients' perspective is available, efforts to reconcile physican and patient perspectives during consensus meetings may result in patients adjusting their views and agreeing on a definition of remission that is in accordance with contemporary treatment outcome expectations.
In this presentation we will present original data from an international qualitative research project in psoriatic arthritis. We will discuss the impact of disease duration on the opinions of patients and the value of the concept of Patient Acceptable State of Symptoms (PASS), and review evidence on patient definitions of remission in other rheumatic diseases.
**Results from the international qualitative project**.There were 90 participants in 16 focus groups in 6 countries. Remission was one of the themes we explored in the focus groups. There was a nuanced perception of remission of disease activity with people seeming to expect slightly different benefits from their treatment. For some remission meant the absence of symptoms, or the absence of flare, while for others remission meant complete return to normality, similar to health before diagnosis. There was even differentiation for a participant between controlled/acceptable disease status versus remission. Remission was described by patients, in its most stringent definition as complete absence of symptoms as well as any type of limitation/life impact including emotional and social life. The differences observed may be explained by personal experiences with treatment results, disease severity and access to medications.

## Collaboration for success. User-centred design for improvement of health services

### SP0135 CO-DESIGNING A MOBILE INTERNET SERVICE FOR SELF-MANAGEMENT OF PHYSICAL ACTIVITY IN RHEUMATOID ARTHRITIS

Å. Revenäs. *Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Stockholm, Sweden*

**Background:** Co-design denotes involvement of lead users, i.e. potential users of the future service, who collaborate with researchers and/or clinicians and other stakeholders in the development of health care services. This project describes the process and outcome of co-designing a mobile internet service for self-management of physical activity in rheumatoid arthritis (RA).
**Objectives:** Our aims were to describe the iterative process of deciding what features to include in a self-management service for physical activity, the challenges of co-design and the results from the evaluation of the test version of the service.
**Methods:** Principles of experience-based co-design were used to study the process and outome of the project. In the *needs inventory and idea generation phase* six focus group interviews were performed with lead users (n=26). In the *requirements specification phase* four workshops were conducted including lead users, clinical and research physiotherapists, an eHealth strategist and an officer from the Swedish Rheumatism Association (n=10). In the *system evaluation phase*, the first test version of the service was evaluated during six weeks (n=28). Qualitative methods were mainly applied except for the evaluation phase where mixed methods were used.
**Results:** Four core aspects important to consider in the development of the service were identified: features, customized options, user interface, and access and implementation (1). The core challenge of co-design was the merging of participants' different perspectives (2). The merging resulted in "tRAppen", a mHealth service for maintenance of physical activity. tRAppen included two key components: 1) "My self-regulation features" and 2) "My peer support features" (3). The evaluation demonstrated that most participants registered physical activity, sent likes and made exercise plans. tRAppen was generally rated as easy and fun

to use. The experiences of using tRAppen seemed to be influenced by physical and mental state and personal preferences.
**Conclusions:** The use of co-design in the development of the physical activity self-management service tRAppen was successful. The first test version was perceived as feasible and to have the potential to support a physically active lifestyle. Co-design in collaborative workshops involved an extensive decision-making process that put high demands on the participants' ability to find solutions, negotiate, come to agreements, and reach final decisions.

### SP0136 USER INVOLVEMENT IN THE DEVELOPMENT OF EHEALTH PRODUCTS

S. Van Der Weegen[1,2]. [1]*CAPHRI, Maastricht University, Maastricht;* [2]*Innovation & Research, Vilans, Utrecht, Netherlands*

Technology has the potential to improve quality and efficiency of healthcare. It is important to involve end users in the design process of new technologies and interventions at an early stage to enhance the fit between the user, technology, and the organization of care. It improves usability, prevents the inclusion of unnecessary features and maximizes the likelihood of a successful adoption. This presentation gives an example of user involvement during the development of an eHealth intervention to stimulate physical activity in people with type 2 diabetes or COPD and will try to inspire you to co-create with end users by providing different methods for user involvement.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6275

### SP0137 A USERS' PERSPECTIVE AND EXPERIENCE OF CO-DESIGN

K. Hakansson. *Private, Stocksund, Sweden*

**Background:** I developed RA (rheumatoid arthritis) when I was 27 years old. Soon after meeting my rheumatologist (in Stockholm), I was asked to participate in a research study. The study was to develop an internet-based programme on physical activity/exercise designed specifically to assist RA patients. The study was run by researchers at Karolinska Institutet and Uppsala University, Sweden.
I was a member of one of the six focus groups consisting of five people (all with RA).The focus groups met and discussed various ideas on important content in the future internet-based programme (1). The next step was to specify and create an application (app). To do this, one of the researchers appointed five researchers and specialists to work together with five RA patients (of which I was one) to specify the requirements of (co-design) the app. For this second phase of the study we met on 4 occasions. Each meeting was 4 to 8 hours. The objective of these meetings was for us to cooperate and decide everything about the app from the graphics and name to the content and what kind of RA-patient we wanted to reach with this app (2,3).
**Objectives:** Sharing my experience of co-designing an internet based health service.
**Methods:** Analyzing my perspective of my participation in co-design.
**Result:** In the first phase (the focus groups) I found it fun and rewarding to meet other people with RA, sharing our experiences and learning how different we are in sickness and in attitudes to physical activity. Phase 2 (the cooperative meetings) provided me with the opportunity to learn from professionals about statistics and to share our different views. As a group we were reflective and engaged. It was very enjoyable. It was extremely difficult to solve the issue/address the fact that all people with RA are different and require customized programmes for physical activity and exercise. How to resolve this and still provide an app that would be useful for as many people with RA as possible was very challenging.
**Conclusion:** Co-design is a powerful instrument to make sure patients are involved in their own healthcare. For future co-designing of applications for RA-patients I would suggest to specify the target group of RA individuals based of their physical condition and interest in physical activity to reduce all compromises and time.

## ER stress & rheumatic disease

### SP0138 THE FRUIT FLY, AS A TOOL TO STUDY ER STRESS

S. Gaumer[1,2]. [1]*Laboratoire de Génétique et Biologie Cellulaire, Université Versailles-St-Quentin-en-Yvelines;* [2]*Laboratoire Génétique Moléculaire et Physiologique, EPHE, Montigny-le-Bretonneux, France*

Endoplasmic Reticulum (ER) stress is a cellular event found misregulated in numerous diseases including osteoporosis, osteoarthritis and inflammatory pathologies. ER stress is also involved in physiological events such as fibroblast differentiation after injuries. Numerous proteins transit through the ER in which they are folded and glycosylated. This organelle is also responsible for the synthesis of lipids and calcium homeostasis. If any of these missions fails, aggregating proteins accumulate and become cytotoxic, leading to devastating pathologies. An adaptive response, known as the Unfolded Protein Response (UPR), normally prevents such accumulation by resolving the stress or ultimately eliminating the cell.

*Drosophila* is a powerful model organism to study ER stress. Indeed, the UPR is largely conserved between insects and humans. We show how *Drosophila* genetics and its numerous tools can be easily used to show that both protein aggregation and calcium dyshomeostasis activate the same PERK/ATF4 branch of the UPR to induce both caspase-dependent apoptosis and a JNK-dependent hormonal response that allows tissue homeostasis. Interestingly, this response is tissue-specific.

## Role of imaging in childhood-onset rheumatic diseases

### SP0139 THE ROLE OF ULTRASOUND IN JUVENILE IDIOPATHIC ARTHRITIS (JIA)

J. Vojinovic. *Clinical Centre, Medical Faculty, University of Nis, Nis, Serbia*

Juvenile idiopathic arthritis (JIA) is a potentially debilitating disease of early

childhood that may carry with it significant physical, psychological, and financial costs. At this time, pediatric rheumatologists rely on physical examination to diagnose JIA. There is an increased interest in the use of musculoskeletal ultrasound (MSUS) to evaluate JIA. MSUS has several advantages over other imaging techniques for use in pediatric subjects, which include non-invasiveness, rapidity of performance, ease of repeatability, high patient acceptability and lack of exposure to ionizing radiation. In addition, it does not require sedation for scanning in younger children. MSUS allow precise and thorough visualization of inflammatory and destructive joint abnormalities, including synovial hyperplasia, joint effusion, cartilage damage, bone erosion, tenosynovitis and enthesopathy. MSUS is more sensitive than physical examination and may detect early disease that is not evident on physical examination. Recent studies in children with JIA have also shown that remission defined by clinical criteria does not always equate to the complete absence of inflammation as measured by MSUS. A high prevalence of US-detected subclinical synovitis was found in joints that were recorded as normal on clinical examination. Thus early detection and treatment may prevent and/or delay adverse outcomes such as joint damage and disability in JIA.

OMERACT definitions are not applicable to pediatric patients, owing to the unique features of the growing skeleton and the changes in joint morphology during development. Thus, Pediatric Ultrasound subtask force of the OMERACT Ultrasound Group was created to develop definitions and standards for MSUS assessment in children. This group has done a great deal of effort and activity to standardize and validate the method for performing MSUS and detecting and scoring MSUS abnormalities in children through several steps: a) Development of definitions for MSUS findings in healthy children by a Delphi consensus process[1] and amendment of definitions for the MSUS features in healthy children (manuscript in preparation); b) Development of a standardized MSUS scanning method in children of different age groups and collection of images showing the physiological vascularization in several joints.[2]; c) Development of definitions for synovitis through a Delphi consensus process and validation of these definitions in a still image exercise (publication in preparation); d) Development of EULAR/PReS recommendations for usage of different imaging modalities in JIA[3]; e) Evaluation of the multiobserver and intraobserver reliability of the physiological blood vessels present in different age groups of healthy children and new scoring system to graduate maturation of ossification nuclei in healthy children (publication in preparation) and f) Development and validation of a semiqantitative scoring system for synovitis on grey-scale (GS) and Power Doppler (PD) modes. All novel knowledge is presented in details.

### SP0140 IMAGING TECHNIQUES IN PEDIATRIC CONNECTIVE TISSUE DISEASE – WHICH AND WHEN?

P. Collado. *Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain*

**Systemic lupus erythematosus:** Renal disease and haematological involvement are common in Juvenile SLE, but musculoskeletal symptoms are often present and can cause substantial morbidity. Several studies have demonstrated that ultrasonography might be convenient in visualizing the involvement of peri- and intraarticular soft tissues in JSLE as well as in adults. Osteonecrosis occurs in 10–20% of JSLE. Plain films and MRI should be considered for the diagnosis of avascular necrosis (AVN) in a JSLE patient with painful hip/limp who had been treated with steroids for long periods. Nailfold capillaroscopy (NFC) is a useful technique to differentiate primary from secondary Raynaud's phenomenon associated to several connective tissue diseases, particularly in girls with JSLE.

**Idiopathic inflammatory myopathy in childhood:** JDM is the commonest inflammatory myopathy of childhood. Diagnostic criteria continue to be based on those of Bohan and Peter, but an international survey in 2006 proposed adding items such as MRI and NFC.

Historically, MRI techniques used to evaluate muscle disorders in children have included T1-weighted images (T1WI) and water-sensitive sequences (i.e., short-tau inversion recovery (STIR) or T2-weighted images (T2WI), with or without fat suppression). These latter sequences are very sensitive to the presence of intramuscular oedema reflecting inflammation, whereas fatty infiltration and muscle atrophy can be detected on T1WI in chronically affected muscles. Whole-body MRI is useful in the assessment of disease activity in JDM as well as guiding muscle biopsy. Recent MR techniques have expanded the use of MR imaging to include quantitative analysis. Ultrasound may be a cost-effective alternative to MRI, with contrast-enhanced ultrasound (CEUS) also permitting the assessment of muscle vascularization. With ultrasound elastography, the relative tissue stiffness can be visualised. In Raynaud's phenomenon (RF), NFC can early demonstrate some typical capillary changes in patients with inflammatory myopathy that it has been called "scleroderma-like pattern".

**Sclerodermas:** Scleroderma is a rare condition in children. There are 2 main distinctive categories: juvenile systemic sclerosis (SSc) and juvenile localized scleroderma. *Localized Scleroderma* is more frequent than SSc in children but still an uncommon condition. US can demonstrate changes in dermal thickness and level of echogenicity that seems to correlate with disease activity. NFC shows typical capillary changes in RF. Unlike adults, in juvenile-onset SSc the overall capillaroscopic pattern is called "scleroderma pattern" and the classification in "early", "active" and "late" pattern has not common been applied.

During the last years, various new technologies (infrared thermography [IT], laser doppler flowmetry [LDF], high-frequency Gray Scale-ultrasound, elastography, MRI and high-resolution computed tomography thorax) have been developed for better identifying and managing of disease. Because active disease can persist for years and can involved systemic structures, recommendations for screening for cardiopulmonary involvement in JSS have recently been discussing by PRES Scleroderma Working Group.

**S. Sjögren and mixed connective tissue disease:** Primary Sjögren's syndrome (pSjS) is a systemic autoimmune disease uncommon in children. Secondary SjS has a more frequent occurrence in childhood, most commonly accompanies SLE, or less often accompanies another Connective Tissue Disease (CTD). Since salivary gland (GS) biopsy is considered as an invasive technique for children, ultrasonography could be a kind tool to provide information about parotid and major salivary glands morphology. In US assessment of SjS, parotid echogenecity is compared to thyroid echogenecity. Some studies on adult pSjS have described a typical pattern on SGUS characterised by lost of the homogeneous internal echogenicity and echotexture, with multiple oval hypoechoic areas of different size. Similar SGUS changes have been reported in juvenile pSjS.

## Physician-patient relationship in the era of interactive media

### SP0141 THE POINT OF VIEW OF PHYSICIAN. SOCIAL MEDIA: PROS AND CONS OF SHARING PATIENT AND PHYSICIAN PERSONAL EXPERIENCE

E. Nikiphorou. *Rheumatology, Whittington Hospital, London, United Kingdom*

The world of social media (SM) is rapidly evolving and we are experiencing a new era of online communication and social interaction. Aside from SM platforms being used for recreational/leisure purposes, in more recent years, they are being increasingly used for professional communication and for sharing knowledge and information. SM platforms like Twitter and Facebook are commonly used at conferences and other educational events, eliminating geographical barriers and enabling rapid dissemination of information. Educational activities on SM platforms like Twitter include journal clubs, participation in clinical/research quizzes and problem-solving. Communication between physicians and other health care professionals and patients on SM is becoming increasingly popular. SM allows for patients and physicians to connect on a different level; yet, this kind of interaction has both advantages and disadvantages. If, however, SM is used appropriately, it can be an incredibly powerful means of good communication, learning and development.

## Capillaroscopy II

### SP0142 HOW TO SELECT THE MOST APPROPRIATE CAPILLAROSCOPIC DEVICE: PROS AND CONS

F. Ingegnoli. *Dept of Clinical Sciences & Community Health, ASST G. Pini, University of Milano, Italy, Milano, Italy*

Nailfold capillaroscopy is a noninvasive technique that allows direct observation of capillaries using a magnification lens for the two-dimensional projection of the three-dimensional capillary network. After application of a drop of immersion oil, capillaries can be observed with a magnification lens because they run parallel to the epidermis at the nailfold area.
A number of different instruments are available to perform the exam. They have different characteristics in terms of their cost, quality of images, magnifications, training period, software for image analysis and storage.
Some of these instruments can be used both in clinical and research settings such as the stereomicroscope and the videocapillaroscope. The stereomicroscope allows the widefield visualization of the nailfold with low magnifications, the training is relatively short, but the examination is difficult to perform in patients with digital contractures.
There appears to be consensus regarding the use of videocapillaroscopy that allows a detailed visualisation of capillary morphology using higher magnifications (100–300x). Contact probe with polarized light microscopy permits easier observation of the skin surface, and the training period is briefer. Specific softwares are available for images analysis, storage, and complete medical reports (text + images) can be produced.
By contrast, in a clinical setting, nailfold capillaries can generally be visualised using more simple but also efficient tools such as a dermatoscope, USB microscope, ophtamloscope or smartphone device. The quality of images can be quite good, although the lower magnification means that some details are unlikely to be seen, and they often lack the possibility of image storage and measurement.

## Ultrasound advanced I

### SP0143 ULTRASOUND FOR DIAGNOSING INFLAMMATORY VERSUS MECHANICAL MIDFOOT PAIN AND RELEVANT GUIDED INTERVENTIONS WITH DEMONSTRATION

H. Siddle. *Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

The midfoot is a relatively unknown entity and difficult to examine clinically. Recent inflammatory arthritis studies have demonstrated that patients in disease remission may still have active disease in those residual joints not included in commonly used disease activity assessments.
Osteoarthritis (OA) of the midfoot has previously been reported as being relatively uncommon (prevalence of 3.8%) however recent studies have highlighted that medial midfoot OA is more prevalent than previously described. Halstead et al (2015) reported changes most frequently in the cuneiform-second metatarsal joint (73%), followed by the naviculo-medial cuneiform joint (51%), the cuneiform-first metatarsal joint (46%) and the talo-navicular joint (24%), with patients indicating pain to the dorsal midfoot area.
The midfoot is a complex structure and frequently undertreated. Differentiating between inflammatory and mechanical disease in the midfoot will enable the clinician to direct their treatment strategies more appropriately. Ultrasound imaging offers the clinician the opportunity to differentiate between joints that require treatment with mechanical interventions such as orthoses and footwear, and those that may also require local treatment of inflammatory disease which may include a guided steroid injection to improve the clinical outcome.

### SP0144 ULTRASOUND OF THE NAIL; WHY USE IT IN RHEUMATOLOGY?

I. Janta. *Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Nail psoriasis represents an important feature of psoriasis and psoriatic arthritis patients. In psoriasis patients, nail involvement represents a risk factor for psoriatic arthritis. Moreover, nail psoriasis was associated with distal interphalangeal joint arthritis. It is also one of the CASPAR classification criteria for psoriatic arthritis.
The complex anatomy of the nail, including the enthesis complex, makes the clinical assessment difficult, as well as the accurate description of the pathology for each structure.
Studies have shown a link between nail, extensor tendon enthesis and DIP joints involvement in psoriatic and psoriatic arthritis patients.
Ultrasound of the nail includes the evaluation of nail plate, nail bed, and extensor tendon enthesis.
Ultrasound of the normal nail plate shows a trilaminar structure: two hyperechoic lines, the ventral and dorsal, separated by a hypoechoic line. The nail bed appears like a hypoechoic band, between the ventral plate and the bone. Some Doppler signals may be seen in the normal nail bed.
In early nail involvement, irregularities and loss of sharpness of the dorsal plate can be seen. As the disease progresses, loss of sharpness of ventral plate and loss of trilaminar structure can be seen.
In the nail bed involvement, the distance between the ventral plate and the bone can be increased. Also, an increase of Doppler signal has been reported.
Compared to rheumatoid arthritis patients, different patterns of both nail plate and nail bed involvement have been seen in psoriatic arthritis patients.

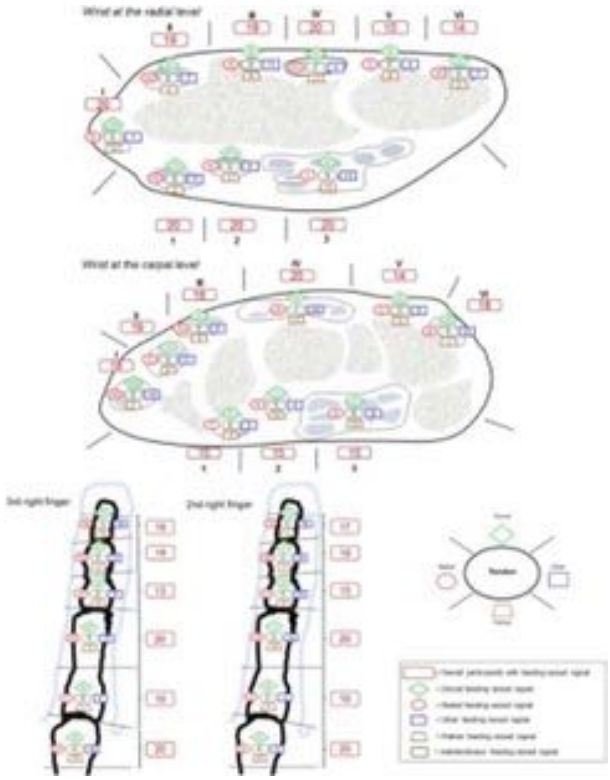
### SP0145 HOW TO DIFFERENTIATE EROSIONS AND VESSEL CHANNELS



S. Finzel. *Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany*

Cortical breaks are a common feature in periarticular bone, even in healthy individuals. The true nature of a cortical break sometimes is difficult to determine. Therefore, high-resolution imaging techniques (such as musculoskeletal ultrasound) as well as well profound knowledge of the anatomy are needed in order to not overestimate the amount of pathological cortical breaks (i.e. erosions) and correctly discern them from nutritive vascular channels.
The session focusses on pathological and physiological cortical breaks in healthy elderly individuals as well as patients with inflammatory joint diseases such as rheumatoid arthritis and psoriatic arthritis. After the lecture and demonstration the participant should be able to better understand and categorize cortical breaks.

### SP0146 3D DOPPLER ULTRASOUND FINDINGS IN HEALTHY WRIST AND FINGER TENDON SHEATHS – CAN FEEDING VESSELS LEAD TO MISINTERPRETATION IN DOPPLER-DETECTED TENOSYNOVITIS?

M. Ammitzbøll-Danielsen. *Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark*

**Introduction:** To investigate the presence of feeding vessels in or in close proximity to extensor and flexor tendon sheaths at the wrists level and in finger flexor tendon sheaths in healthy controls, using 3D ultrasound (US), which may

cause pitfalls in order to ensure correct interpretation of Doppler signals when diagnosing tenosynovitis.
**Method:** Forty healthy participants (20 women and 20 men in the age 23–67 years) without prior history of arthritis, tendon diseases or present pain in their hands were included. Twenty participants had 3D Doppler US of the 2nd and 3rd finger and twenty of the right wrist. US was carried out using a GE Logiq E9 unit with a 3D US probe. The colour Doppler settings were according to published recommendation.
**Results:** The feeding vessels in or in close proximity to the tendon sheaths were found in the flexor and extensor tendons sheaths at least once in each participant. No significant difference in feeding vessels was seen between the radial and carpal level in the wrist (p=0.06) or between the 2nd and 3rd flexor tendon sheath (p=0.84).
**Conclusion:** Doppler findings in or in close proximity to the tendon sheaths were common in wrists and fingers in healthy participants. These feeding vessels can be a source of error, not only due to their presence but also because they may be interpreted as being inside the tendon sheath due to blooming and reverberations artefacts. These vessels should be taken into consideration when diagnosing Doppler tenosynovitis.

## It's in your hands

### SP0147 A SELF-DETERMINED LIFE WITH A RHEUMATIC DISEASE? HOW CAN SOCIAL PARTICIPATION BE PRESERVED OR OBTAINED AND HOW CAN BARRIERS BE OVERCOME?

W. Mau. *Institute for Rehabilitation Medicine, Martin-Luther-University Halle-Wittenberg, Germany, Halle, Germany*

Health care professionals are increasingly aware of the multifaceted burden of rheumatic and musculoskeletal diseases (RMDs). Aside from typical symptoms such as pain and limited range of motion of the affected joints or other body parts the patients frequently suffer as much from limited social participation and even isolation. Reduced participation in the labor force associated with high indirect costs for society and potential effects of expensive medications have gained increasing attention among researchers and health care insurances.
However, other affected social roles concerning family, friends, and leisure activities have been less focused, even though they may be more prominent for individuals with RMDs than working life. The experience of limited social participation depends on medical factors such as disease severity and treatment but also on mostly neglected non-medical environmental and personal factors (i.e., social network and services, individual skills and preferences). Low communication skills may be significant barriers to social participation. In a nationwide project funded by the German League against Rheumatism (GLR) persons with RMDs reported difficulties in disease-related conversations across various situations. Significant factors of RMD-related everyday communication were identified. Based on the results, a training to enhance the communication skills of persons with RMDs in various situations significant for social participation is underway. The GLR offers various other services that facilitate social participation of individuals with RMDs. These services were evaluated by different RMD groups in order to identify the potential for further adjustment according the patients' preferences.

### SP0148 LEARNING TO CONTROL – THE POWER OVER THE DAY-TO-DAY SETBACKS IS ... OURS!

M.F. Fonseca Santos on behalf of Liga Portuguesa Contra as Doenças Reumáticas. *Patient, LPCDR, Lisboa, Portugal*

Mental training is a powerful tool to give back the control of the patient's sensations, in pain relief and in emotional influence over the setbacks of the day. Being always complementary to medical treatment, mental training gives the patient the knowledge to manipulate the perceptions of pain and frustration, anger and sadness, contributing to reduce pain and to think differently about the difficulties in each patient's life. Knowing how to deal with the day-to-day setbacks is very empowering, for the patient takes back the control of his feelings, well-being and self-awareness.
There are several techniques that can be used in pain control – distraction, moving the pain from one spot to another, increasing and decreasing its perception, putting it in another platform (for example, out of our mind). These techniques can be chosen and adapted to each patient and to each pain in particular. Every time the patient uses mental training, he will also gain in relaxation, well-being and self-confidence, so important is this constant struggle.
On the other hand, when the patient gains control of his thoughts, so many times depressive, frustrated, angry or desperate, he can then decide what to do, how to feel, how to act. The way we live and give power to suffering is a choice, not a burden. It has been already proved how our thoughts modify the body chemistry – now it's time to do it regularly and get relief more quickly.
The description of this suffering or rejection of the illness is also a good help and often shows exactly what it has been doing to the patient feelings. Writing about these sensations (of pain or frustration) and its part in day-to-day routine can show to each one how to deal with it and exactly how much damage are we prepared to let it do to our lives. Words written (where our eyes can read them, observing rather than feeling) will let our minds think about them and decide what to do next. Emotional writing, when used as a technique to relieve the patient from his suffering, is a wonderful tool. Doing this in a group session can be the beginning of a different way of feeling. Most people live alone with their suffering. Hearing what others say and write about this, and how each one copes with their illness, can make this loneliness disappear, giving space to a new way to live beyond this illness.

## The EULAR School of Rheumatology - a new era of education

### SP0149 EULAR EDUCATION: WHAT IS IN IT FOR YOU?

A. Iagnocco. *Sapienza Università di Roma, Rome, Italy*

By 2017, EULAR will be a pre-eminent provider and facilitator of high-quality education for physicians, health professionals in rheumatology, and people with rheumatic and musculoskeletal diseases. In addition to educational sessions at the annual congress and the EULAR symposia at AFLAR, PANLAR, APLAR, currently available educational offers cover different fields and are represented by online and live courses, exchange programmes, bursaries, grantsand awards, publications and other materials.
In terms of online courses, in recent years, EULAR has put substantial effort and investment into developing e-learning opportunities. All EULAR courses, as electronic ways of continuous medical education in rheumatology, are managed by a scientific course committee responsible for the structure and content of the courses and for ensuring quality control. EULAR teams of expert authors regularly review and update courses to keep up with the newest developments in the field. While the 2-year Online Course on Rheumatic Diseases offers a comprehensive introduction to and update on all aspects of rheumatology, a number of shorter online courses (i.e. US introductory, Paediatric, Health Professionals, Systemic Sclerosis) offer flexible learning for the specialist.
Live courses are currently planned and developed with the objective of making a targeted contribution to training and further education to rheumatologists and health professionals, complementing the standard range of opportunities provided by universities, hospitals and other institutions. To this end EULAR offers a number of its own branded courses and, in addition, grants "EULAR scientific endorsement" as a mark of scientific quality to selected courses and meetings run by established providers in Europe. In this context, EULAR invites other courses and scientific meetings in the field of rheumatology to apply for endorsement. EULAR views scientific endorsement as an opportunity to positively influence the quality of rheumatology training in Europe, which is in line with EULAR longer-term goals. Quality control associated with EULAR scientific endorsement focuses on the proposed content and faculty as well as on evaluation of these courses or meetings.
The purpose of the EULAR/ACR Exchange Program is to promote the international exchange of clinical and research skills, expertise and knowledge within rheumatology. The program recognizes outstanding rheumatology faculty and provides exposure to the exciting work being done by colleagues overseas. This exchange program allows participants to share knowledge and experience, and creates opportunities for collaboration.
Another EULAR objective is the use of bursaries to contribute to the personal and professional development of rheumatologists, health professionals as well as people with rheumatic diseases. To this end, EULAR facilitates attendance at the annual EULAR congress in the form of travel bursaries, also provides bursaries to attend EULAR courses in rheumatology. EULAR is committed to helping individuals develop their skills, expertise and network of contacts and therefore offers a range of educational grants tailored to the needs of researchers and clinicians, health professionals and patient organisations. Educational grants are offered at regular intervals.
In terms of publications, in addition to the two EULAR journals (ARD and RMDopen), and next to the EULAR Textbook on Rheumatic Diseases, EULAR has published the Textbook on Systemic Sclerosis, and also endorsed several books which are relevant to the EULAR live and online courses. The new EULAR Texbook on Ultrasound will be launched at the annual Congress in London, on June 2016.
Additional opportunities are represented by educational activities such as a network of imaging centres, videos which offer an insight into some EULAR courses and international events, practical DVDs with video production on undergraduate training in history and physical examination of the musculoskeletal system. New activities that will be launched in 2016 are a medical student primer, student webinars on "case of the month" and webinar monthly lecture given by experts.

**Key messages:**
– By 2017, EULAR will be a pre-eminent provider and facilitator of high-quality education for physicians, health professionals in rheumatology, and people with rheumatic and musculoskeletal diseases.
– Currently available educational offers cover different fields with online and live courses, exchange programmes, bursaries, grants and awards, publications and other materials.

## Vaccination in rheumatic patients: a two-edged sword

### SP0150 "ASIA" – AUTOIMMUNE (AUTO-INFLAMMATORY) SYNDROMES INDUCED BY ADJUVANTS

Y.J. Shoenfeld. *The Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer, Israel*

Vaccines, administered to animal and humans, are clearly one of the best achievements of modern medicine and are commonly and safely inoculated to the vast majority of subjects. However in rare occasions vaccines may induce autoimmune or auto-inflammatory conditions both in animals and in humans [1]. These conditions, either defined diseases such as Gullian Barre syndrome or enigmatic ones, have been reported following different vaccines and vaccination protocols. The susceptibility factors and the temporal association between vaccines and these rare immune mediated reactions are yet to be defined, however the similarities between vaccines and infections and the addition of an adjuvant (i.e. alum, squalene etc.) to almost every vaccine are considered major contributors to such adverse events. Perhaps the most evaluated condition is MMF, in which a cause was clearly delineated. MMF is a rare condition caused by deposition of alum, used to adjuvant different vaccines, which bring about an immune mediated muscles disease [2]. The discrepancy between the wide application of aluminum hydroxide and the rarity of MMF was resolved by the observations that alum may trigger MMF in genetically susceptible subjects carrying the HLA–DRB1*01 [3]. Thus, in only a minority of genetically prone patients alum may induce this syndrome.
A common denominator to each of these four syndromes as well as to various infectious agents is the trigger entailing adjuvant activity. Adjuvants are commonly used in medicine to augment an immune response to treatments such as the protective response induced by vaccines and were considered to be inert. Nalp3 inflammasome system. Moreover adjuvants enhance adaptive immune responses *via* inducing Th2 cell activation as well as chemokines and cytokines secretion thus helping the recruitment of B and T cells [4–6]. as well as inducing the secretion of Il-17 [7]. Alas, studies of animal models and humans demonstrated the ability of some of these adjuvants to inflict an immune mediated disease and even autoimmunity by themselves [8].
Thus, herein we will describe the syndrome entitled the "Autoimmune (Auto-inflammatory) Syndrome induced by adjuvants" (ASIA) [9]. We will also delineate who is at risk of developing autoimmune conditions upon exposure to adjuvants [10].

## Advances in large vessel vasculitis

### SP0151 CLINICAL DIAGNOSIS OF LARGE VESSEL VASCULITIS

M.A. Cimmino. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy*

Defining the clinical features of large vessel vasculitiS (LVV) is not easy because their boundaries are not completely clear, their symptoms are very often unspecific, and the correlation between clinical features and imaging, the gold standard of diagnosis, is unpredictable. LVV include giant cell arteritis (GCA), Takayasu's arteritis (TA), isolated ascending aortitis, PMR-associated LVV, retroperitoneal fibrosis, periaortitis, inflammatory abdominal aneurisms, relapsing polychondritis, and IgG4-related diseases.
The organs/tissues affected are various, as in most vasculitides, resulting in symptoms and signs localized to the joints, muscles, eye, brain, kidney, skin and lungs. An interplay between autoimmune and atherosclerosis-associated inflammation is probably at work. Systemic symptoms, including fever, weight loss, malaise, fatigue, night sweats, and depression are often present and may represent the only signs of the disease. At clinical examination, bruits may be present on auscultation. Acute phase reactants are generally unreliable especially for follow-up. Diagnosis relies on imaging, including CE-CT, CE-MRI, and PET/CT or PET/MRI. Vessel biopsy is fundamental to confirm the diagnosis although rarely performed in non-temporal arteritis LVV. Although it is commonly believed that GCA and TA cannot be distinguished by histology, adventitia is relatively spared in TA and commonly damaged in GCA. As in most other rheumatic conditions, the clinician should consider disease activity and damage, although in this case the two entities are not easy to separate. There are no outcome measures specifically developed for LVV, although disease activity has been measured by BVAS, ITAS 2010, and DEI-Tak, each showing some weakness. Damage consists mainly in stenotic or aneurismatic lesions of the vessels, which can appear also long intervals after inflammation has subsided. For this reason, follow-up of patients should continue long-term even if the disease has been apparently cured.
LVV are highly detrimental to the patients, who cannot understand the origin of their symptoms, a situation sometimes shared with the attending clinician since the diagnostic delay may be very long. In addition, long periods of asymptomatic disease, with on-going damage, are not rare. Disease-specific patients reported outcomes have not been developed in these conditions, and are a field open to research.

**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6349

### SP0152 ROLE OF IMAGING IN THE DIAGNOSIS AND TREATMENT OF LARGE VESSEL VASCULITIS

T. Bley. *Diagnostic and Interventional Radiology, Univerisity Wuerzburg, Wuerzburg, Germany*

Over the past years imaging techniques such as Color-Coded Duplex Sonongraphy (CCDS), Magnetic Resonance Imaging (MRI), Magnetic Resonance Angiography (MRA) and Positron Emission Computed Tomography (PET CT) have greatly improved their diagnostic accuracy for the diagnosis of large vessel vasculitis. This presentation summarises the specific advantages and limitations of CCDS, MRI/MRA and PET CT.
CCDS is the diagnostic procedure of first choice in the hands of an experienced observer. CCDS is readily available and may display the so called "halo-sign" of an inflamed vessel wall of the superficial temporal, axillary, carotid, vertebral and subclavian artery.
PET CT is thougt to be the most sensitive imaging modality, especially for the assessment of extracranial large artery involvement. PET CT is not as widely available, rather costly and applies radiation.
MRI and MRA are noninvasive imaging modalities that display mural inflammatory changes of intracranial, extracranial and large artery involvement. MRI and MRA do not use radiation. In relation to costs and availability MRI and MRA lie somewhere between CCDS and PET CT. Image acquisition in PET CT and MRI/MRA is standardized and largely independent of the operator.
Mural inflammatory signs depicted by CCDS, PET CT and MRI/MRA vanish over time under sufficient therapy. However, interpretation of persistant mural changes and imaging of relapsing disease is not yet fully understood.

SP0153 **EMERGING THERAPIES IN LARGE VESSEL VASCULITIS**

K. Warrington. *Mayo Clinic, Rochester, United States*

**Background:** Giant Cell Arteritis (GCA) and Takayasu arteritis (TAK) are the two main forms of large vessel vasculitis. Because of parallels in clinical, radiographic and histologic features, the therapeutic approach to GCA and TAK has generally been similar. In both conditions, glucocorticoids (GC) are effective for remission induction. However relapses frequently occur during tapering of GC, and adverse effects commonly occur. The use of conventional immunosuppressive agents has not shown consistent benefit in maintaining disease remission or reducing GC-associated adverse events.
**Emerging therapies:** Several biologic agents have been studied in observational and randomized trials for both GCA and TAK. Tumor necrosis factor-alpha inhibitors appear to be effective in the treatment of TAK based on observational study data. In clinical trials of patients with GCA, TNF inhibitors have failed to show significant therapeutic efficacy and their use is not recommended. Interleukin-6 inhibition has gained particular focus in the treatment of GCA and TAK. Observational evidence supports the use of interleukin-6 inhibitors in TAK. Several retrospective studies and a recent randomized placebo-controlled trial has demonstrated efficacy of tocilizumab in GCA. Preliminary clinical trial data also suggests that abatacept may reduce the risk of relapse in GCA. Based on a small open-label study, ustekinumab appears safe and potentially effective for refractory GCA. A possible role of B cell dysregulation may contribute to pathogenic mechanisms in large vessel vasculitis, and B cell depleting therapy may also be an emerging treatment option. Ongoing clinical trials will yield vital information on the efficacy of biologic agents for GCA and TAK within the next year.
**Summary:** Interleukin-6 inhibitors appear efficacious in the treatment of refractory cases of large vessel vasculitis. Abatacept and ustekinumab are promising targets for therapy in large vessel vasculitis but further investigation is needed before routine use is considered.

## HOT session 9

SP0154 **COMORBIDITIES OF PSORIATIC ARTHRITIS AND OTHER RHEUMATIC DISEASES**

D.D. Gladman. *Medicine/Rheumatology, University of Toronto, Toronto, Canada*

Over the past several decades it has become clear that many rheumatologic conditions are complicated by a number of comorbidities. Comorbidities are distinct from extra-articular features of a rheumatologic disorder. These are other conditions that occur in individuals with either inflammatory or non-inflammatory rheumatologic disorders, but are not directly related to the underlying condition.
Many rheumatology patients have co-existent diabetes. This is particular true among patients with psoriatic arthritis (PsA). Recent data demonstrate that diabetes occurs with higher prevalence among PsA patients, and its prevalence has increased over the past few decades. Another important comorbidity is cardiovascular disease. Cardiovascular disease occurs more commonly among patients with rheumatoid arthritis, systemic lupus erythematosus, PsA and ankylosing spondylitis, than in the general population. Moreover, cardiovascular events occur at an earlier age in patients with these inflammatory conditions. Hypertension also occurs more frequently among patients with rheumatologic conditions, partly related to the therapy provided. In each of these conditions it seems that the underlying inflammatory condition predisposes to the comorbidity, and in several studies the degree of inflammation is related to both the frequency and severity of the underlying disease. More recently it has become clear that the metabolic syndrome which incorporates obesity, diabetes, hyperlipidemia, and hypertension is increase among patients with PsA, AS and SLE, thus predisposing them to cardiovascular disease.
Another comorbidity which affects patients with rheumatologic disorders is depression. This is particularly noticeable among patients with PsA, who also suffer from psoriasis, a condition also known to be associated with depression. The depression may also be related to the inflammatory burden of both skin and joint disease.
The management of these comorbidities requires firstly screening for them. Studies have shown that we do not do a good job screening for and treating hypertension, hyperglycemia and hyperlipidemia in rheumatology patients. One issue to consider is who should be doing this, is it the rheumatologist or the family physician, and how it should be done.

## When and how to diagnose and treat vitamin D deficiency?

SP0155 **VITAMIN D AND SYSTEMIC LUPUS ERYTHEMATOSUS: WHEN AND HOW TO TREAT VITAMIN D INSUFFICIENCY/DEFICIENCY**

L. Andreoli. *Clinical and Experimental Sciences, University of Brescia, Brescia, Italy*

Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disorder with a complex pathogenesis including genetic, immunologic, hormonal and environmental factors. Among environmental modulators of SLE, vitamin D has been increasingly investigated over the years. Such interest derived from several observations: 1) SLE patients are particularly prone to vitamin D insufficiency due to the avoidance of sun exposure, but in some cases also because of the renal involvement of the disease or medications; 2) *in vitro* studies have demonstrated that vitamin D is able to modulate several different cell types (dendritic cells, T and B cells) with effects that may be beneficial in autoimmune diseases; 3) animal models of SLE have shown disease amelioration upon supplementation with vitamin D.
Recent review papers and meta-analyses confirmed that vitamin D insufficiency is widespread in SLE, affecting 38–96% of the patients. What needs to be still clarified is the relationship between low levels of vitamin D and disease activity/severity and whether vitamin D supplementation can be useful to positively influence the course of the disease. There is trend toward an inverse relationship between vitamin D insufficiency and higher disease activity, although many studies failed to describe it. In addition, vitamin D insufficiency seems to be related to cardiovascular events in SLE patients, although this association may be mediated by "traditional" cardiovascular risk factors. Interventional studies are still limited in number and did not reach definite conclusions in terms of optimal vitamin D supplementation to be applied in SLE patients.
It should be acknowledged that different results across studies may be due to methodological issues. In fact, the outcomes of a study investigating the role of vitamin D can be affected by many variables: demographic factors (age, ethnicity, body mass index, nutritional intake), sample size of the cohort and study design, compound used for supplementation (cholecalciferol vs. ergocalciferol), dosage and timing (low vs. high dose; daily/weekly/monthly schedule), outcomes of the study (variations in indices of SLE disease activity, cytokines and lymphocyte populations, inflammatory and hemostatic markers, or IFNalfa signature). By measuring 25-OH vitamin D levels, clinical studies do not get a direct picture of the actual activity of the vitamin D system. Additional relevant information may come from the evaluation of the active form 1,25-OH vitamin D and from the analysis of the polymorphisms of the vitamin D receptor.
In the clinical setting, every SLE patient should be assessed for circulating levels of 25-OH vitamin D. Supplementation should be tailored upon the individual vitamin D status and other characteristics (obesity, renal failure, etc.). Especially in those patients taking steroids and at a higher risk of osteoporosis, vitamin D levels should be kept in the range of sufficiency (above 30 ng/ml). The fascinating immunomodulatory role of vitamin D needs to be confirmed in the clinical setting in order to support a more intensive treatment with vitamin D in SLE patients. Nonetheless, it should be considered that vitamin D is a cheap intervention with an excellent safety profile, so the routine use of moderate doses of cholecalciferol (1000–2000 UI/day) in SLE patients should not raise any major concern.

## Data harmonization across (rheumatoid arthritis) clinical cohorts and registers

SP0156 **HOW TO COLLECT COMORBIDITIES**

E. Nikiphorou. *Department of Rheumatology, Whittington Hospital, London, United Kingdom*

The need to better understand and quantify the impact of comorbidity on patients and survival is well-recognised and forms an important area both for routine clinical practice and also for future research. However, there remain several challenges to overcome, a key one being the identification of optimal ways to accurately and consistently collect and measure comorbidity. To date, effective, simple and validated instruments to collect and aggregate comorbidity data are lacking. As a result, standard assessment and care for comorbidity varies considerably in rheumatology departments. Standardised ways for capturing data are therefore necessary for good quality research but more importantly for optimising patient care, quality of life, outcomes and prognosis. This talk reviews ways of collecting

comorbidities in rheumatoid arthritis based on the existing literature, discussing general and disease-specific "indices" for quantifying comorbidity burden.

## Telemedicine and e-health in community care

### SP0157 DELIVERING TECHNOLOGY ENABLED CARE SERVICES IN PRIMARY CARE

R. Chambers[1,2,3,4]. *[1]Chair, Stoke-on-Trent CCG, Stoke-on-Trent; [2]Long Term Conditions Priority Lead, WMAHSN, Birmingham; [3]Honorary Professor, Keele University, Keele; [4]Honorary professor, Staffordshire University, Stoke-on-Trent, United Kingdom*

**Background:** there are many pilots of various types of technology enabled care in general practice settings in the UK. The challenge is to integrate such technology as a natural option for delivery of care in specific pathways or for particular patient groups, across and between healthcare settings.
**Project:** Adoption of technology enabled care in Staffordshire and beyond in general practice settings, and interacting with clinicians in acute care, mental health and community settings, and pharmacies. Modes of technology included locally evolved apps, Flo telehealth, skype and videoconsultations with encrypted mode, social media (eg Facebook); foci included patients with asthma, COPD, heart failure, hypertension, AF and other conditions. The presentation will capture challenges and how these have been overcome.
**Discussion:** How do we in the NHS match patients' needs and preferences for technology enabled care? How do we prove to the commissioners of care and frontline practitioners that technology enabled care is worth doing?
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6357

### SP0158 TECHNOLOGICAL CHALLENGES IN IMPLEMENTING E-HEALTH

T. Dawson. *Rescon Technologies, Crondall, United Kingdom*

This presentation will focus on the story of a UK SME, Rescon Technologies, that started with an idea to harness history at source in 2011. This involved developing a tool to allow patients to capture their own medical history in real-time, in an accessible easy to use format. It will cover the journey from idea generation to co-development pilots through to going to market in the UK. This will include examples of how opportunities need to be embraced to allow obstacles to be overcome in getting a product to market in a fragmented health and social care ecosystem.
Specific topics that will be addressed are:

1. The issues around contemporary history taking;
2. The rise of patient reported outcome measures;
3. History as a diagnostic and prognostic tool;
4. How history relates to new outcome commissioning models;
5. Accessibility;
6. User interfaces and user experience;
7. Segmentation, quantification and digitisation;
8. Co-production;
9. System and workflow integration;
10. Competition, interoperability, and collaboration;
11. Health economics;
12. Advantages of an integrated information technology approach.

The presentation will conclude with recommended considerations before embarking on the journey of turning an idea or aspiration into a sustainable product that will improve health or social care.
**Disclosure of Interest:** T. Dawson Shareholder of: Rescon Technologies

### SP0159 ETHICAL IMPLICATIONS OF EMPLOYING E-HEALTH SOLUTIONS TO PROMOTE HEALTHY LIFESTYLES

M. Niezen. *Tilburg Institute for Law, Technology and Society, Tilburg University, Tilburg, Netherlands*

Increasingly e-health solutions and specifically eHealth applications (health apps) combine interactive persuasive technologies [1,2] with behaviour change systems [3]. Within the field of mobile health (mHealth) these technologies can be used for influencing human behaviour and empowering users to gain or maintain a healthy lifestyle. However, such health apps are relatively new emerging technologies and also come with expectations and worries with respect to their unknown and unintended effects and related ethical issues that might arise from their design or distribution. In this presentation I will discuss how health apps can raise issues on matters such as privacy, autonomy, liability and division of responsibilities among stakeholders. In addition, I will discuss potential ways of developing e-Health applications in a more responsible manner, taking into account ethical, legal and social preconditions for e-Health's acceptance.

## Inflammasome as therapeutic target in inflammatory diseases

### SP0160 PROTECTIVE AND DETRIMENTAL ROLES OF INFLAMMASOMES

M. Lamkanfi[1,2]. *[1]VIB; [2]Ghent University, Zwijnaarde, Belgium*

Inflammasomes are multi-protein platforms that assemble in the cytosol of immune cells to cope with pathogens and cellular stress. The pattern-recognition receptors NLRP1, NLRP3, NLRC4, AIM2 and Pyrin all assemble canonical platforms for caspase-1 activation, and the related inflammatory caspases 4, 5 and 11 respond to cytosolic detection of the Gram-negative lipopolysaccharides. Inflammasomes contributes importantly to controlling pathogen replication through their roles in maturation and secretion of the inflammatory cytokines interleukin-(IL)1β and IL18, and they also induce pyroptosis. Contrasting to their beneficial roles in these host defense responses, deregulated inflammasome activation is thought to be detrimental in the context of chronic inflammatory arthritis and autoinflammatory diseases such as cryopyrin-associated periodic fever syndromes (CAPS) and Familial Mediterranean Fever (FMF).

## What's new: latest advances in treatment and management of systemic sclerosis and fibromyalgia

### SP0161 LATEST ADVANCES IN THE TREATMENT AND MANAGEMENT OF SYSTEMIC SCLEROSIS

U. Müller-Ladner on behalf of Otylia Kowal-Bielecka, for the EUSTAR/EULAR Recommendation Group. *Rheumatology and Clinical Immunology, Justus-Liebig University Giessen, Kerckhoff Klinik Bad Nauheim, Bad Nauheim, Germany*

Based on the 2009 EULAR recommendations for the treatment of systemic sclerosis (SSc), a complete set with attention to new therapeutic approaches was analysed and verified for clinical use. This update of the previous treatment recommendations was performed according to EULAR standard operating procedures. The task force consisted of 32 SSc clinical experts from Europe and USA, two patients nominated by the pan-European patient association for SSc (FESCA), a clinical epidemiologist and 2 research fellows. All centers from the EULAR Scleroderma Trials and Research (EUSTAR) group were invited to submit and select clinical questions concerning SSc treatment using a Delphi approach. Accordingly, 46 clinical questions addressing 26 different interventions were selected for systematic literature review. The new recommendations were based on the available evidence and developed in a consensus meeting with clinical experts and patients. The procedure resulted in sixteen recommendations being developed (instead of 14 in 2009) that address treatment of several SSc-related organ complications: Raynaud's phenomenon (RP), digital ulcers (DUs), pulmonary arterial hypertension (PAH), skin and lung disease, scleroderma renal crisis, and gastrointestinal involvement. Compared with the 2009 recommendations, the 2015 recommendations include phosphodiesterase type 5 (PDE-5) inhibitors for the treatment of SSc-related RP and DUs, riociguat, new aspects for endothelin receptor antagonists, prostacyclin analogues, and PDE-5 inhibitors for SSc-related PAH. New recommendations regarding the use of fluoxetine for SSc-related RP and haematopoietic stem cell transplantation for selected patients with rapidly progressing SSc were also added. In addition, several comments regarding other treatments addressed in clinical questions and suggestions for the SSc research agenda were formulated. Taken together, these updated data- and consensus-derived recommendations will help rheumatologists to manage patients with SSc in an evidence-based way. These recommendations also give directions for future clinical research in SSc and add to the emerging novel therapies for the different aspects of SSc.

## EULAR projects in Investigative Rheumatology

### SP0162 BECOMING A BOOKMAKER: THE ODDS OF RHEUMATOID ARTHRITIS

D. Van Der Woude. *Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

"Doctor, what exactly is my risk of getting rheumatoid arthritis?"
Despite all our knowledge about rheumatoid arthritis (RA), this question is often difficult to answer.
This presentation will review familial risk in RA and the underlying genetic risk factors, as well as environmental risk factors for disease. Autoantibodies are a potent prognostic marker when it comes to the risk of developing RA, and play a key role in current pathophysiological hypotheses. The latest concepts of how the various risk factors contribute to disease onset will be discussed, along with strategies to easily communicate the concept and extent of RA-risk to our patients.

## WIN session 8

### SP0163 WHAT IS NEW: IDIOPATHIC INFLAMMATORY MYOPATHIES

J. Vencovsky. *Institute of Rheumatology, Praha, Czech Republic*

Myositis or Idiopathic inflammatory myopathies (IIMs) are acquired, heterogeneous autoimmune disorders characterized by immune-mediated skeletal muscle inflammation leading to muscle weakness and to damage to muscle tissue. Traditionally IIMs include dermatomyositis, polymyositis, cancer associated dermatomyositis, juvenile dermatomyositis and myositis as part of the overlap syndromes. Immune mediated necrotizing myopathy (IMNM) is newly recognized myositis subgroup with a majority of patients having anti-SRP or anti-HMGCR antibody in their serum. The data shows that anti-HMGCR+ IMNM is associated with previous use of statins that presumably induce autoimmune reaction towards the 3-hydroxy-3-methyl glutaryl-coenzyme A reductase (HMGCR). The incidence of this form of IMNM is increasing, probably due to the growing use of statins in the population. Patients with anti-HMGCR+ IMNM tend to respond to immunosuppressive treatments and if resistant to this, then usually favourably react to intravenous immunoglobulins, even without concomitant glucocorticoids. Anti-SRP+ patients, on the other hand, are notoriously difficult to treat. Recent studies showed that some of these patients may respond to rituximab.
Inclusion body myositis (IBM) is a late onset myositis leading to progressive muscle wasting. It is still debated whether IBM is a primary autoimmune disease or a degenerative myopathy. Recent discovery of antibodies to cytosolic 5'-nucleotidase 1A (anti-cN1A) that are present in a certain proportion of IBM patients points to immune pathogenesis. This is supported by the fact that anti-cN1A may be seen also in some other autoimmune diseases. IBM is usually resistant to immunosuppressive treatment. Several new directions in the treatment are being explored in the early phases of clinical trials, e.g. with ariclomol (increases expression of cytoprotective heat shock proteins in muscle), bimagrumab (monoclonal antibody that blocks the activin IIA and IIB receptors that bind myostatin) or follistatin (gene therapy inhibiting myostatin expression).
Patients with IIMs may have several myositis specific autoantibodies (MSA) which are associated with particular clinical manifestations. The most recent addition to this rule is the antibody to muscle-specific protein FHL1. Presence of anti-FHL1 is predictive for muscle atrophy, dysphagia, pronounced muscle fibre damage, and vasculitis. Interestingly, mutations of the gene encoding four-and-a-half LIM domain 1 (FHL1) are the causative factor of several X-linked hereditary myopathies, suggesting that antibodies to this protein may have pathogenic properties.
Most of the recent treatment studies performed in patients with IIMs did not meet primary endpoints, with the exception of the trial in juvenile DM, in which combination of prednisone with either cyclosporine or methotrexate was more effective than prednisone alone. The safety profile and steroid-sparing effect favoured the combination of prednisone plus methotrexate.
Newly developed criteria for clinical response quantitatively assess the improvement on the 0–100 scale and use thresholds for minimal, moderate, and major improvement. They provide a sensitive and specific tool for longitudinal patient follow-up and hopefully will perform better in proving efficacy of new treatments in the future.

## The elderly patient with osteoarthritis

### SP0164 PROBLEMS IN CONVENTIONAL THERAPY IN OSTEOARTHRITIS: A CASE PRESENTATION

W.-Y. Kwok. *Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

In this case presentation a 57-year old male patient is illustrated, who suffers from non-inflammatory arthralgia due to osteoarthritis. He visits the outpatient clinic with the specific question for advice with respect to pain management, especially for his hand pain since he is a technician in a dental laboratory. However, non-steroidal anti-inflammatory drugs (NSAIDS) are contra-indicated by his ischemic cardiomyopathy, cerebral vascular accident, hypertension and ulcus duodeni in the past.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6274

### SP0165 BALNEOTHERAPY:EFFICACY AND SAFETY IN OSTEOARTHRITIS

T. Bender. *Physical Therapy, Hospitaller Brother of St. John of God, Budapest, Hungary*

**Background:** The scientific field dealing with balneotherapy is called balneology.Balneotherapy means the use of natural mineral waters, natural peloids and muds, natural sources of different gases for medical purposes.
**Objectives:** A growing number of evidence is available about the beneficial effect of balneotherapy for patients suffering from Osteoarthritis. The lecture would like to give a survey about the efficacy and safety of balneotherapy in Osteoarthritis
**Methods:** We searched in the medical database (Pubmed, Scopus, Pedro, Web of Sciences, Sciences Direct) and took into consideration articles only published in the English language. We focused on the clinical studies, but we paid attention on the possible side effects,risks and harmful effects of balneotherapy. We overviewed not only the RTC studies, but also the reviews,meteaanalysis and guidelines.
**Results:** Untill now more than 50 RTC single or double blind studies had been published on the effect of balneotherapy in OA(this number continually increased).The majorities of the studies dealing with the role of the balneotherapy on the knee arthrosis, but there are studies involved with the shoulder,neck,hand,hip and lumbar regions too. On the basis of the available evidence, balneotherapy has a beneficial effect on pain and quality of life for OA patients. As for as the safety of balneotherapy,the side effects during the treatment are negligible. On account of the latest OARSI guideline, balneotherapy is an appropriate treatment in case of multi- joint type OA with comorbidities.
**Conclusion:** On the basis of the available evidence balneotherapy is effective and safe, non-pharmacological therapy in the treatment of OA, but further multicentric studies are necesseray to prove its efficacy.

## SLE: what will it be and how will it be treated 5 years from now

### SP0166 THE INTERFERON PATHWAY IN SLE: FROM IMMUNOLOGY TO NEW INSIGHTS AND NEW TREATMENT

L. Rönnblom. *Department of Medical Sciences, Uppsala University, Uppsala, Sweden*

The interferons (IFNs) consist of a large family of proteins classified as type I-III IFNs and originally defined by their capacity to interfere with viral replication. Subsequent studies revealed that IFNs also have many immunomodulatory effects and can act as immune adjuvant. Among the immunostimulatory effects by type

I IFN are maturation and differentiation of dendritic cells, activation of T cells and enhanced antibody production by B cells. There are several observations suggesting an important role for the type I IFN system in the etiopathogenesis of SLE. Among these are the reported development of autoimmune diseases, including SLE, during treatment with IFN and a prominent increase in the expression of type I IFN regulated genes (an IFN signature) in cells from SLE patients. Recent data also show that the regulation of the type I IFN system is abnormal in SLE, which all together suggests that inhibition of the type I IFN system could be beneficial in SLE. Many different therapeutic targets exists and several studies are in progress aiming to block, or down-regulate, the activated type I IFN system in SLE. A number of studies with monoclonal anti-IFN-alpha antibodies have been reported, and a small study investigating vaccination with an interferon-alpha-kinoid against IFN-alpha has been published. Trials targeting the type I IFN receptor are also under way, and preliminary data was recently reported. Other possibilities include elimination of endogenous IFN inducers and inhibition of key molecules in the type I IFN signaling pathway. The results so far show that it's possible to partially suppress the IFN signature, improve several biomarkers and reduce disease activity in a subset of SLE patients. No major safety problems have been observed so far, but complete inhibition of the type I IFN system will automatically increase the risk for severe infections.
**Disclosure of Interest:** L. Rönnblom Grant/research support from: Astra/Zeneca
**DOI:** 10.1136/annrheumdis-2016-eular.6232

### SP0167 OUTCOME ASSESSMENT IN SLE

R. Fischer-Betz. *Rheumatology, Heinrich-Heine-University, Duesseldorf, Germany*

Outcome is defined as "something that follows as a result or consequence of an activity or process". Although the outcome of patients with SLE has improved within the last decades (e.g. considering mortality rates), the disease is a condition still associated with considerable burden and increased morbidity. In routine care the assessment of SLE patients is biased by the experience of the treating physician which leads to significant variability. This may impact quality of care offered to patients and ultimately influence outcomes. Almost five years ago, a 'core set' of minimal variables for the assessment and monitoring of patients with SLE in clinical practice was developed which includes e.g. disease activity, damage and co-morbidities. More recently, targets have been defined in order to improve the long-term outcome. In this context, consensus definitions of "low disease activity state" (LLDAS) and of "remission" in SLE were generated. First retrospective studies showed that e.g. achievement of LLDAS was associated with significantly reduced organ damage accrual. Therefore in 5 years from now, outcome assessment will hopefully change from a "passive approach" to an active process leading to targeted treatment decisions.
**Disclosure of Interest:** None declared

### SP0168 HOW NEW TREATMENTS IN LUPUS ARE CHANGING THE LANDSCAPE

A. Voskuyl. *rheumatology, VU University Medical Center, Amsterdam, Netherlands*

For decades patients with systemic lupus erythematosus have been been treated with classical immunosuppressive drugs, either as single use or in combination, with or without low-medium- high dose corticosteroids. The ultimate goal of treatment is cure, although low disease activity and preferably remission are the primary goals of treatment, yet. Prevention of lupus flares and reduction of corticosteroids dose are in line with these goals. An overview will be given on the current use (indication, efficacy, side effects) of biologicals (i.e. rituximab, belimumab) in lupus, in particular in daily clinical practice. Also, the following questions will be discussed: Do the use of biologicals add to the former mentioned goals of treatment? What can be expected from the use of biologicals in lupus in the future? Which new treatments, including biologicals, are currently being investigated in clinical trials?
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6301

**SATURDAY, 11 JUNE 2016**

## HOT session 10

### SP0169 PHARMACOLOGICAL MANAGEMENT OF OSTEOPOROSIS

S. Papapoulos. *Center for Bone Quality, Leiden University Medical Center, Leiden, Netherlands*

The aim of any intervention for osteoporosis is the prevention of fractures at all skeletal sites in patients who have not yet fractured or of the progression of the disease in patients who have already sustained a fragility fracture. Correction of deficiencies/insufficiencies in vitamin D (and calcium) should be the first step in management. The effects of pharmacological interventions are above those obtained with calcium and vitamin D, as in clinical trials these are usually given to placebo-treated patients. The evidence of the antifracture efficacy of pharmacological interventions varies among approved agents and for treatment decisions the highest level of available evidence should be selected. Consistent with the pathophysiology of osteoporosis, pharmacological interventions are distinguished into inhibitors of bone resorption, stimulators of bone formation and compounds whose action on bone remodeling has not yet been fully elucidated, such as strontium ralenate. Of those, only the bisphosphonates alendronate, risedronate and zoledronate and the RANKL-inhibitor denosumab have been shown to reduce the risk of all osteoporotic fractures with variable efficacy up to 5 years of treatment. Despite the fact that the primary action of all four agents is the reduction of bone resorption and turnover, there are also considerable differences between bisphosphonates and denosumab that can be considered in clinical practice. In the absence of head-to-head studies with fracture endpoints these data together with the safety profile should be considered in therapeutic choices for individuals at risk. Cathepsin K inhibitors that decrease bone resorption while maintaining bone formation are not yet available for clinical use. Reduction of bone resorption, though essential for the maintenance or improvement of bone strength, cannot replace already lost bone. For this, specific stimulation of bone formation is required. The teriparatide paradigm illustrated the possibility of stimulating bone formation in osteoporotic patients and opened the way for the development of novel forms of PTH or PTHrP are at different stages of clinical development but a synthetic analog of PTHrP (abaloparatide) given for 18 months was recently shown to decrease the incidence of vertebral and nonvertebral fractures in women with osteoporosis. However, optimal pharmacological management of osteoporosis should aim at concurrently decreasing bone resorption and stimulating bone formation at all skeletal envelopes. Such approach will not only prevent the structural decay of bone tissue but will also substantially increase bone mass leading to enhanced reduction of the risk of fractures particularly at sites with predominantly cortical bone. The combination of teriparatide with denosumab that allows continuous stimulation of bone formation by teriparatide by blocking its concurrent stimulating effect on bone resorption by denosumab may be an interesting option in severely affected patients. The recognition of the central role of the Wnt signaling pathway in bone formation provided attractive targets, such as sclerostin, for the development of bone building pharmaceuticals that reduce also bone resorption. Neutrlizing antibodies to sclerostin (romosozumab, blosozumab) represents a very promising novel anabolic therapy for patients with osteoporosis, in whom 2-year data of phase II studies are available. These new developments may allow tailoring pharmacotherapy to the specific needs and pathophysiological profile of the individual patient. Because osteoporosis is a chronic disease, knowledge of the long-term efficacy and risk profile of every individual agent prescribed is essential for proper patient care.

## "Time is joint": early recognition and treatment of arthritis

### SP0170 TIME TO JOINT: EARLY RECOGNITION AND TREATMENT OF ARTHRITIS – THE HEALTH PROFESSIONALS PERSPECTIVE

P.D. Kirwan[1,2]. [1]*School of Physiotherapy, Royal College of Surgeons in Ireland;* [2]*Physiotherapy Dept, Connolly Hospital, Dublin, Ireland*

Early recognition of inflammatory arthritis is of utmost importance, as failure to do so can delay appropriate treatment and result in permanent joint damage and disability. This presentation will set out to explore the role a Physiotherapist/Healthcare Professional can play in recognition of inflammatory joint disease. Healthcare Professionals/Physiotherapists are often the first point of contact for patients suffering from joint/musculoskeletal pain. They are therefore very well positioned to be the first to identify possible inflammatory sources of pain versus non-inflammatory sources. The question as to whether a physiotherapist can recognise inflammatory joint disease versus non-inflammatory joint conditions will be explored with the aim being to highlight the important role a physiotherapist can play in this important diagnostic challenge. With reference to ongoing clinical and research work in this field, this presentation will set out to ask whether or not a Healthcare Professional/Physiotherapist can acurately recognise/diagnose inflammatory arthritis and whether they miss inflammatory arthritis.

## Clinical outcomes for PMR/GCA

### SP0171 EULAR/ACR GUIDELINES FOR PMR – THE UPDATED EVIDENCE

C. Dejaco. *Rheumatology, Medical University Graz, Graz, Austria*

Polymyalgia rheumatica (PMR) is the second most common inflammatory

rheumatic disease in older people after rheumatoid arthritis. According to the 2015 EULAR-ACR recommendations for the management of PMR, oral glucocorticoids (GC) are the first choice treatment for this condition. It is recommended to choose the minimum effective GC dose within a range of 12.5–25mg prednisone equivalent daily as the initial therapy and to gradually taper the dose, based on regular monitoring of patient disease activity, laboratory markers and adverse events. An early introduction of methotrexate (MTX) in addition to GCs may be considered, particularly in patients at high risk for relapse and/or prolonged therapy as well as in cases with risk factors, co-morbidities, and/or concomitant medications where GC related adverse events are more likely to occur. For other conventional disease modifying anti-rheumatic drugs (DMARDs), a specific recommendation was not possible due to the absence of good evidence. Among biological agents, infliximab and etanercept failed its primary endpoint in randomized controlled trials, and consequently, a strong recommendation against the use of TNF-a blocking agents was made.
Since the publication of 2015 EULAR-ACR recommendations, observational studies and small, randomized trials reported promising results about the effective use of interleukin (IL)-6 blocking agents in PMR. If these preliminary data are confirmed by larger randomized controlled trials, IL-6 blockade might become an important therapeutic option for PMR patients in future.
In this session, we will discuss current evidence on the role of steroid sparing agents in the treatment of PMR including the promising new results from studies on IL-6 blockade.

### SP0172 GLUCOCORTICOID-INDUCED COMPLICATIONS IN PATIENTS WITH POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS

F. Buttgereit. *Department of Rheumatology and Clinical Immunology, Charité University Medicine Berlin, Berlin, Germany*

With over 60 years of experience with glucocorticoids (GC), the number of patients treated and the range of clinical applications is more extensive than with other treatments. GC are still widely used in clinical medicine today, and they form a mainstay of therapy for polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) since they are cost-effective drugs which exert strong anti-inflammatory and immunosuppressive.
However, there is increasing awareness of the potential for these drugs to produce adverse effects. Especially if higher dosages have to be given over longer periods of time, cardiovascular, gastrointestinal, dermatological, ophthalmological, and metabolic adverse effects, an increased risk of infection, the incidence of a Cushingoid phenotype, and in particular GC-induced osteoporosis (GIOP) are to be mentioned. The available data describing frequency and severity of these adverse effects are fragmentary. For example, it is difficult to distinguish specific adverse effects of a GC therapy from other causations (e. g., the treated disease itself, other concomitant diseases or concomitant therapies).
Therefore, as a general rule, also in PMR and GCA as much GC as necessary, but as little as possible should be administered. Recommendations and guidelines have been developed describing in detail suggested approaches for using GC in induction therapy, during initial and further tapering until discontinuation, and flare management. It should be noted however, that these algorithms base upon expert opinion and assessment of the literature, but they have not been formally tested in randomized controlled trials.
Treatment of PMR and GCA is usually required for 1–3 years, but frequently also longer and often with daily GC doses around 5 mg prednisone equivalent. Therefore, a recent publication of a EULAR Task Force is important since it reports the risk of harm to be low for the majority of patients at long-term dosages of $\leq$5mg prednisone equivalent per day, whereas at dosages of $>$10mg/d the risk of harm is elevated. At dosages between $>$5 and $\leq$10mg/d, patient-specific characteristics including protective and/or risk factors need consideration when estimating the risk of harm.

### SP0173 POLYMYALGIA RHEUMATICA: IMPROVING OUTCOMES FOR PATIENTS IN PRIMARY CARE

T. Helliwell. *Primary care sciences, Keele University, Institute of Primary Care and Health Sciences, Keele, United Kingdom*

Polymyalgia rheumatic (PMR) is the most common inflammatory arthritis managed in primary care settings. The majority of clinical care is typically provided by General Practitioners (GPs) with evidence suggesting that current management is suboptimal. This talk will highlight some of the key challenges faced by GPs highlighting areas where the diagnosis, monitoring and long term care can be improved.

## Getting active against rheumatoid arthritis fatigue

### SP0174 HEALTH BEHAVIOUR CHANGE TECHNIQUES TO EFFECTIVELY PROMOTE PHYSICAL ACTIVITY IN PEOPLE WITH RHEUMATOID ARTHRITIS

K. Knittle. *Department of Social Research, University of Helsinki, Helsinki, Finland*

Engaging in sufficient levels of physical activity (PA) is of particular importance for patients with rheumatoid arthritis (RA), as it can help to maintain functional ability and reduce the risk of cardiovascular disease. While many healthcare professionals have the ability to effectively promote PA among patients with RA, some techniques common in clinical practice can actually be counterproductive. As consultations are becoming increasingly shorter, having a clear understanding of the evidence on how to best promote PA in practice can help healthcare providers' to improve the efficiency and effectiveness of their PA promotion efforts. This session will provide an overview of prominent behavioural determinants and theories, and outline how behaviour change typically unfolds among patients with rheumatoid arthritis. It will then present research which has identified behaviour change techniques associated with increased motivation and intention for PA and changes in PA behaviour itself. Finally, it will provide practical, evidence-based tips that can be implemented to help guide behaviour and lifestyle change efforts in clinical settings, even when time is short.

### SP0175 ACTIVITY MONITORING TO SUPPORT PATIENT GOALS AND ASSESS PROGRESS

N.N. Kennedy. *Clinical Therapies, University of Limerick, Limerick, Ireland*

Increasing participation in PA is important for everyone, including people with RA (1,2). The reported benefits of PA for the RA population include improved aerobic fitness and muscle strength, resulting in enhanced ability in activities of daily living and health-related quality of life and an improvement in disease related characteristics, such as pain and stiffness (2). However, studies have shown that physical activity is reduced in people with arthritis (1). Enhancing physical activity and reducing sedentary time are thus important goals for people with arthritis, however achieving long-term behaviour change relating to physical activity can be challenging. Monitoring of physical activity for patients with chronic disease can be valuable in supporting patients achieve their goals and to help with assessing progress. There are a number of considerations when using physical activity monitoring in this way including practical aspects of monitoring over long periods, patient preferences, type of monitors available and suitability of the device to match patient goals (3, 4). This presentation will consider these issues and will provide a context for the use of activity monitors and subjective monitoring to support goal setting and monitor progress in achieving activity goals. Numerous devices and subjective measures have been used, with some validated, to measure activity in people with arthritis (5, 6) - a review of these will be presented with consideration of how they can be used to monitor varying aspects of activity and physical fitness. The perspective of the person with arthritis will also be presented to allow consideration of how well activity monitoring matches patients' goals for activity. A key message from the talk will be the importance of matching the patient goals with the activity monitor. The importance of understanding what aspects of physical activity and/or sedantariness are to be measured will be emphasised to ensure that progress can be appropriately recorded.

## Endothelial to mesenchymal transition and angiogenesis as driving mechanisms in systemic sclerosis

### SP0176 ROLE OF ENDOTHELIAL TO MESENCHYMAL TRANSITION IN THE PATHOGENESIS OF THE VASCULAR ALTERATIONS IN SYSTEMIC SCLEROSIS

S.A. Jimenez. *Jefferson Institute of Molecular Medicine and Scleroderma Center, Thomas Jefferson University, Philadelphia, United States*

Systemic Sclerosis (SSc) is a systemic autoimmune disease characterized by progressive fibrosis of skin and multiple internal organs and severe fibroproliferative microvascular alterations. Despite currently available therapeutic approaches SSc has a high mortality rate. The high mortality of SSc is largely caused by severe, progressive and generalized vascular involvement resulting in the development of multiple organ alterations including SSc-associated interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH). These two complications have emerged as the most frequent causes of disability and mortality in SSc.
The pathogenesis of the fibrotic process and the progressive fibroproliferative vasculopathy in SSc is complex and despite extensive investigation the exact mechanisms have remained elusive. Myofibroblasts are the cells ultimately responsible for tissue fibrosis and fibroproliferative vasculopathy in SSc. Tissue myofibroblasts originate from several sources including expansion of quiescent tissue fibroblasts and transmigration and tissue accumulation of circulating CD34+ bone-marrow-derived fibrocytes. Besides these sources, myofibroblasts may result from the phenotypic conversion of epithelial cells, adipocytes or endothelial cells into activated myofibroblasts. The transdifferentiation of endothelial cells into myofibroblasts involves numerous and complex biochemical, molecular, and gene expression events collectively known as endothelial to mesenchymal transition or EndoMT.
Recently, it has been postulated that EndoMT may play a role in the development of tissue fibrosis and SSc-associated ILD and PAH. However, despite the demonstration of the occurrence of EndoMT in experimentally induced cardiac, renal, and pulmonary fibrosis and in several human disorders, the contribution of EndoMT to the pathogenesis of tissue fibrosis and fibroproliferative vasculopathy in SSc has not been generally accepted. Here, the experimental evidence supporting the concept that EndoMT plays a role in the pathogenesis of the vascular alterations in SSc and, more specifically, in the development of SSc-associated ILD and PAH will be critically reviewed.

## Cell-cell interaction in joint inflammation

### SP0177 INHIBITORY PATHWAYS OF SYNOVIAL ANGIOGENESIS

E. Brahn on behalf of Cell-Cell Interaction in Joint Inflammation. *Division of Rheumatology, UCLA School of Medicine, Los Angeles, United States*

**Introduction:** Angiogenesis occurs in a variety of normal processes, such as wound healing, organ development and the menstrual cycle. However, angiogenesis is also associated with numerous disease processes, including tumor growth, proliferative retinopathy, atherosclerosis and proliferative synovitis. Consequently, these pathologic processes are attractive therapeutic targets. Healthy joint vasculature is maintained by an appropriate balance between proangiogenic and antiangiogenic molecules. However, in rheumatoid arthritis (RA), this balance is disrupted; the levels of VEGF, hypoxia-inducible factor (HIF) and basic FGF (b-FGF), all of which are proangiogenic, are elevated in the joints of both patients with RA and in adjuvant-induced arthritis. The elevation of these proangiogenic factors occurs in the absence of adequate counterbalancing antiangiogenic factors. The new vasculature permits synovial hyperplasia which ultimately contributes to joint inflammation and structural damage.
**Results:** In the United States, there are already at least 13 FDA approved anti-cancer therapies with recognized antiangiogenic properties in oncology that target the endothelial cell, pericyte, or tumor cell. These agents, which interrupt critical cell signaling pathways involved in tumor angiogenesis and growth, comprise three primary categories: 1) Monoclonal antibodies directed against specific proangiogenic growth factors and/or their receptors; 2) Small molecule tyrosine kinase inhibitors (TKIs) of multiple proangiogenic growth factor receptors; and 3) Inhibitors of mTOR (mammalian target of rapamycin). In addition there are other angiogenic agents whose mechanisms are not completely understood. A variety of angiogenesis inhibitors are being examined for their potential in treating RA, and although none of these compounds have advanced beyond phase II clinical trials, several angiogenesis inhibitors have demonstrated efficacy in preclinical RA models.
**Conclusions:** Angiogenesis is an attractive therapeutic target although blood vessel growth is complex with multiple mechanisms. Different diseases may utilize different dominant pathways but surrogate markers such as bFGF, VEGF, and vessel density, may be helpful as predictors of likely candidates for therapeutic intervention. Angiogenesis inhibitors warrant further studies in rheumatic diseases. They lend themselves to combination therapies 1) that target multiple vessel proangiogenic pathways or 2) that could be used with biologic response modifiers.

## Transition of care

### SP0178 TRANSITION CARE PROGRAMMES: A EUROPEAN PERSPECTIVE

K. Minden[1,2]. *[1]Epidemiology unit, German Rheumatism Research Centre; [2]Department of Medicine/Rheumatology and Clinical Immunology, University medicine Charité, Berlin, Germany*

The special health care needs of adolescents and young adults with chronic diseases and the inadequate state of services for them have been on the agenda for almost 30 years. But still too many young people, including those with inflmmatory rheumatic diseases, do not receive the care they expect and need. In fact, approximately half of young people are not satisfied with the experienced mode of transition. One in two wishes a better preparation for adult health care. For one third the transfer to adult care comes too early, unplanned or abruptly. Up to half of young people with rheumatic diseases do not make a successful transfer to adult rheumatology and are therefore at particular risk of unfavorable outcome. In response to this, there have been a number of guidelines and activities across Europe seeking to reduce the risks associated with moving to adult services and to implement developmentally focused adolescent care as normal part of a health-care plan.
This lecture will describe European initiatives, which aim at improving health care transition services, such as specific and generic transition care programmes or checklists, education programmes, recommended frameworks and pathways to implement and assess transition programmes.
**Disclosure of Interest:** K. Minden Grant/research support from: Pfizer, Abbvie
**DOI:** 10.1136/annrheumdis-2016-eular.6419

### SP0179 TRANSITION CARE PROGRAMMES: A NORTH AMERICAN PERSPECTIVE

L. Tucker. *Pediatrics, BC Childrens Hospital, Vancouver, Canada*

Adolescents with rheumatic diseases frequently continue to require rheumatologic care into adulthood, either due to continued active disease and requirement for treatment, or management of sequelae of disease. In addition, these vulnerable adolescents need to manage transition in schooling, work, living situation, health insurance coverage, and peer relationships. In the recent years, there has been increased focus on improving transition support to adolescents with chronic diseases, resulting in a variety of specialized programs and resources. Objectives for this talk are:

a) To describe North American transition guidelines and models for youth with rheumatic diseases, and how these are applied across different centres and regions.
b) To compare transition practices in pediatric rheumatic programs in North America.
c) To review new transition planning resources for use in the pediatric rheumatology setting.

## New approaches to understanding and managing chronic musculoskeletal pain

### SP0180 ADVANCES IN THE GENETICS OF CHRONIC PAIN SYNDROMES: HOW TWIN STUDIES HELP

F.M. Williams. *Twin Research and Genetic Epidemiology, King's College London, London, United Kingdom*

Chronic widespread musculoskeletal pain and fibromyalgia are increasingly viewed as spectrum disorders, and they co-exist with many other pain syndromes within individuals and their families. Large scale epidemiological studies are superior to clinical collections for providing evidence of overlap in the chronic pain syndromes and allowing the genetic and environmental risk factors to be

determined. Twin registers are a special case of this and allow many different types of study, which provide answers to important questions in chronic pain.
In this talk I will introduce the following concepts:-
1. The chronic pain syndromes
2. The concept of heritability
3. TwinsUK – an NIHR BioResource at KCL
4. Twin study designs which help shed light on chronic pain mechanisms
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6415

### SP0181 CHRONIC PAIN CONTROL - EXPERIENCE OF A PORTUGUESE PATIENT GROUP INITIATIVE

C.S. Marques. *Patient Group of Chronic Pain, LPCDR – Portuguese League Against Rheumatic Diseases, Lisbon, Portugal*

The Patient Group of Chronic Pain (Núcleo da Dor) of the LPCDR - Portuguese League Against Rheumatic Diseases (which also has Osteoarthritis, Sjögren Syndrome and Scleroderma patients' groups), was born in 2014 and is centred in the chronic pain associated to rheumatic diseases. Its primary mission is to make this health condition VISIBLE to other people and to support the improvement of quality of life of all patients suffering from this pathology (about 30% of Portuguese people).
The Patient Group of Chronic Pain (ND) is a participatory group that wants to share experiences, learn and implement coping strategies, with a positive, global, ecological and effective attitude.
Besides the central role of the rheumatologist (an ally in pain reduction, disease control and treatment compliance), the support of all health professionals, family and friends, we know that the main role belongs to the patient as an expert of his body, and he's also the first to be involved in adapting daily life to new needs, difficulties and constraints. Each day with chronic pain is an emotional, functional and behavioural challenge that requires enhanced skills. Therefore, we believe that we do not choose to be sick, but we can choose to live better - with well-being and dignity - and that is in our hands to act and control the impact of pain on daily life. That's why ND is committed to:
Sharing experiences and self-effective strategies; Learning to live with pain; Reducing disturbances associated to pain experience; Informing, raising public awareness and call to action; Being committed to an effective treatment, therapeutic and additional activities; Capitalizing positive synergies; Identifying scientific, therapeutic, recreational, behavioural approaches; Preserving the dignity and the patient's well-being; Taking responsibility in pain's self-control; Defining priorities and reset beliefs, values, attitudes, behavior and skills (coping) ... and believing in the social responsibility of patients for a sustainable health.
How? Among other activities and events already developed, we launched a National Photography Contest "Chronicles of Paint" which was one of our starting points. It was an opportunity to raise awareness on the invisibility of pain while generating artistic products with powerful visual messages. As a result, the selected photographs provided us material for exhibitions, enabling us to reach out to different audiences. The "Chronicles of Pain" were exhibited at FNAC Alfragide Shopping Centre, at the National Association of Pharmacies and at the Rectory of the New University of Lisbon. We have also presented a poster about this initiative at the Annual Conference of PARE in Zagreb (2014). In 2015, the selected photos were published in the book commemorating the 33rd anniversary of LPCDR, "Turn the Page", along with 33 texts received for Edgar Stene Prize (2005–2014).
We have analysed the submitted photographs and the underlying perceptions of pain and suffering traduced in the visual snapshot, since the goal of the contest was to associate an image to pain. We have also analysed the preferences of a specific public, more closely related with rheumatic and musculoskeletal diseases. The results provided us some guidance towards a communication strategy.
Our Thematic Sessions also provided us some unmet needs that we are addressing, by developing larger projects (like POSSO - Oriented Program for Overcoming RMDs and Optimize Health) for a better management of pain and chronic conditions.
We must do something to draw the attention, talk about it, and call to action to reduce this PAIN scourge. There is no time to loose ... don't you agree?

## Seronegative inflammatory arthritis: diagnostic and management challenges

### SP0182 IS THIS REALLY RHEUMATOID ARTHRITIS?

M. Gaudé on behalf of Xavier Puéchal, MD, PhD, National Referral Center for Rare Systemic Autoimmune Diseases, Hôpital Cochin, Université Paris-Descartes, Paris, France. *Hôpital Edouard Herriot, Lyon, France*

**Background:** Whipple's disease is a chronic, systemic, curable bacterial infection, caused by *Tropheryma whipplei* and often mistaken for rheumatoid arthritis. Indeed, the classical form usually begins with intermittent joint involvement several years before the development of weight loss and diarrhea, associated with other diverse clinical manifestations.
**Objectives:**
- To know the main clinical presentations of Whipple's disease and *Tropheryma whipplei* localized infections.
- To consider a diagnosis of Whipple's disease in a middle-aged man presenting with isolated intermittent arthritis before the development of chronic persistent polyarthritis and of digestive signs and symptoms.
- To be able to diagnose Whipple's disease by performing *Tropheryma whipplei* polymerase chain reaction from stools, saliva and synovial fluid.
- To know how to interpret polymerase chain reaction tests and pathological examination results.
- To know the therapeutic options in Whipple's disease according to central nervous system involvement.

**Methods:** This presentation describes a patient with a 28-year history of isolated chronic severe bilateral destructive polyarthritis. Blood tests showed elevated acute phase reactants, persistent leukocytosis, but rheumatoid factor and antinuclear antibody tests were negative. He was treated for a presumed seronegative rheumatoid arthritis. He then presented with fever, weight loss, diarrhea and adenopathy.
**Results:** *Tropheryma whipplei* polymerase chain reaction was positive from synovial fluid, synovial tissue, and lymph node specimens. Duodenal biopsy confirmed periodic acid-Schiff-positive macrophages. Whipple's disease was diagnosed. *Tropheryma whipplei* was successfully cultivated from the synovial fluid. Antibiotic treatment was instituted in the patient, after which his symptoms remitted.
**Conclusions:** Particular attention to a diagnosis of *Tropheryma whipplei* infection is warranted in a middle-aged man presenting with unexplained isolated intermittent arthritis. *Tropheryma whipplei* polymerase chain reaction from stools and saliva should be performed. Antibiotic therapy usually ensures the full resolution of all manifestations, which can otherwise be fatal, in case of late diagnosis of extended systemic forms.

## HOT session 11

### SP0183 2016 UPDATE OF THE EULAR RECOMMENDATIONS FOR THE MANAGEMENT OF EARLY ARTHRITIS

B. Combe on behalf of the EULAR Task Force on Early Arthritis Management. *Département de Rhumatologie, Hopital Lapeyronie, Université de Montpellier, Montpellier, France*

**Objectives:** In 2007 the EULAR recommendations for the management of early arthritis have been published. In 2010 EULAR also published recommendations for the management of rheumatoid arthritis (RA) with synthetic and biological DMARDs, which were updated in 2013. These later recommendations focussed on the generic pharmacological treatment of RA including Early RA, whereas the 2007 recommendations on early arthritis covered the entire spectrum of the management of early arthritis including also recognition of arthritis, referral, diagnosis, prognosis, classification, information, education, non-pharmacological interventions, and monitoring of the disease process. Between January 2005, when the systematic literature research (SLR) was performed to develop the 2007 recommendations, and 2015 an abundant and rich literature has been published in the field of early arthritis. Taken these points together, it seems important to currently update the EULAR recommendations on early arthritis management.
**Methods:** In accordance with 2014 EULAR Standardised Operating Procedures, the task force pursued an evidence-based approach and an approach based on expert opinion. The task force involved 20 rheumatologists, two patients and one health professional representing 12 European countries. One of them (RL) served as an epidemiologist in order to control the scientific content of the process. The group defined the focus of the task force, the target population, formulated an operational definition of "management" and selected the research questions. A SLR was performed by two fellows (CD, CH) with the help of skilled librarian. A set of draft recommendations was proposed on the basis of the research questions and the results of the literature search. For each recommendation the categories of evidence were clearly identified then the strength of the recommendation was derived and level of agreement was determined after voting process.
**Results:** Fifteen research questions, covering the entire spectrum of "management of early arthritis" were formulated. The updated recommendations comprise 3 overarching principles and 12 recommendations for the management of early arthritis. The selected statements included recognition of arthritis, referral, diagnosis, prognostication, imaging, classification, treatment of early arthritis (information, education, non pharmacological interventions, pharmacological treatments, and monitoring of the disease process) as well as strategy. The

strength of each recommendation was provided. On the basis of expert opinion, 10 items were identified as being important for future research.
**Conclusion:** These recommendations provide Rheumatologists, General Practitioners, Health professionals, Patients, and other stakeholders with an updated EULAR consensus on the management of patients with early arthritis
**Disclosure of Interest:** None declared

## Paget's and other rare bone diseases

### SP0184 PAGET'S DISEASE: NEW DEVELOPMENTS

S.H. Ralston. *Rheumatic Diseases Unit, University of Edinburgh, Edinburgh, United Kingdom*

Paget's disease of bone (PDB) is a common skeletal disorder characterised by increased and disorganised bone remodelling affecting one or bone skeletal sites. Although about 20% of patients that come to clinical attention are asymptomatic others develop complications including bone pain, deformity, nerve compression syndromes and fragility fractures. Genetic factors play an important role in the pathogenesis of PDB and there is strong evidence that susceptibility is determined by variants within or close to genes that regulate osteoclast function. At the present time eight predisposing genes and loci have been discovered. Environmental factors also play a key role but little is known about the nature of these triggers. Bisphosphonates are a highly effective treatment for the elevations in bone turnover that are characteristic of PDB and are effective in the treatment of bone pain associated with Paget's disease but current evidence sugegsts that they do not prevent complications at least when administered to patients with established disease. Studies are currently in progress to determine if prophylactic treatment of patients with early asymptomatic disease might yield benefits in preventing the development of new lesions and perventing long term complications.

### SP0185 REFLEX DYSTROPHY: DIAGNOSIS AND TREATMENT

A. Giusti. *Bone Clinic, Department of Ortho-Geriatrics, Rehabilitation and Stabilization, Galliera Hospital, Genoa, Italy*

Complex Regional Pain Syndrome type I (CRPS-I), in the past called reflex dystrophy, is a disabling disorder affecting a peripheral limb, usually developing after a trauma to an extremity. Several different diagnostic criteria have been proposed, and recently updated "Budapest Criteria" have been widely accepted, to diagnose CRPS-I. The diagnosis is made using clinical criteria and is based on the sole clinical history and examination. CRPS-I is characterized by the presence of spontaneous or stimulus-induced pain, disproportionate to the inciting event, allodynia and hyperalgesia. These symptoms are associated to a wide variety of autonomic and motor disturbances, or trophic abnormalities. There are no specific laboratory or radiological diagnostic procedures for CRPS-I, but a variety of tests may be useful to exclude other clinical conditions. These include x-rays, three-phase bone scintigraphy and MRI.
At present, several pharmacological treatments (e.g., analgesics, anesthetics, anticonvulsants, antidepressants, oral muscle relaxants, corticosteroids, calcitonin, bisphosphonates, and calcium channel blockers) have been proposed to reduce pain and pain sensitization, and to improve functional status in patients presenting with CRPS-I. While most of these medications demonstrated poor or partial efficacy on the short-term, bisphosphonates (BPs) showed better long-term beneficial effects on pain reduction and functional recovery.
BPs are potent inhibitors of osteoclastic activity widely used for the management of osteoporosis and other metabolic bone diseases. Their primary pharmacological action is the reduction of bone turnover. An enhanced osteoclastic activity has never been clearly demonstrated in CRPS-I. Therefore, it is likely that the positive effects of BPs in this condition are not related to their anti-resorptive properties, but to a more complex interaction between these pharmacological agents and the pathophysiological mechanisms underlying CRPS-I.
Results of several clinical trials have suggested the potential beneficial effects of BPs in CRPS-I. In five randomized-controlled trials, oral and intravenous alendronate, and intravenous clodronate, pamidronate and neridronate demonstrated to be effective in reducing pain and improving physical function in patients presenting with CRPS-I, with a good profile of safety and tolerability. Although these trials have a number of limitations, including the small samples enrolled, there is sufficient evidence to support the use of BPs as agents of choice in the management of CRPS-I.

### SP0186 GLUCOCORTICOID-INDUCED OSTEOPOROSIS

F. Buttgereit. *Department of Rheumatology and Clinical Immunology, Charité University Medicine Berlin, Berlin, Germany*

Glucocorticoids remain to be among the most important and most frequently used anti-inflammatory and immunosuppressive or immune-modulatory acting drugs to treat rheumatic (and other) diseases. Unfortunately, glucocorticoids also exert undesired effects, especially if higher dosages have to be given over longer periods of time. In this regard, cardiovascular, gastro-intestinal, dermatological, ophthalmological, and metabolic adverse effects, the increased risk of infection, the incidence of a Cushingoid phenotype, and in particular glucocorticoid-induced osteoporosis (GIOP) are to be mentioned.
However, the available data describing frequency and severity of these adverse effects are fragmentary. For example, it is difficult to distinguish specific adverse effects of a glucocorticoid therapy from other causations (e. g., the treated disease itself, other concomitant diseases or concomitant therapies). This statement is especially true for GIOP in the context of chronic inflammatory rheumatic diseases, since GIOP is counted among the two most important adverse effects of glucocorticoid therapy, by both rheumatologists and patients. This top (negative) ranking of GIOP stands in sharp contrast to the state of knowledge and scientific data, being sparse, partly conflicting and often derived from over-aged projects or studies.
With regard to the pathophysiology of GIOP it seems clear, however, that glucocorticoids contribute to early and rapid bone loss and increased fracture risk which is mediated by direct effects on osteoblasts (decreased bone formation), osteoclasts (increased bone resorption) and osteocytes (increased apoptosis and sclerostin levels), and indirect effects through alterations in gonadal hormones and the neuromuscular system (Rizzoli & Biver, Nat Rev Rheum, 2015).
With regard to the management of GIOP, general preventive measures comprise using the lowest possible GC dose, good nutrition with sufficient intake of calcium, vitamin D, regular weight-bearing exercise, the avoidance of tobacco use and alcohol abuse and other recommendations.
The treatment of GIOP consists of an early introduction of anti-osteoporotic therapy for patients receiving glucocorticoid therapy who are at increased risk of fracture. This treatment should be continued as long as the glucocorticoid dose is above intervention thresholds or fracture risk is increased. (Rizzoli & Biver, Nat Rev Rheum, 2015).

## Analytical issues of complex databases

### SP0187 WHY MISSING DATA IS A PROBLEM, AND WHAT YOU SHOULDN'T DO TO SOLVE IT

T. Frisell. *Karolinska Institutet, Stockholm, Sweden*

Missing data, where either entire observations or individual variable values are for some reason not available for analysis, is a common challenge to research using complex data bases. Although missing data clearly lead to a loss of information and hence reduced statistical power, a more insidious consequence is that this lack of data may introduce selection bias, which could potentially invalidate the entire study. Fortunately, many solutions to this problem has been put forth, based on different ways of filling out (imputing) values where there are none. Unfortunately, several of these solutions are inherently flawed and may introduce more bias then they remove.
This brief presentation will introduce central concepts in the literature on missing data, go through the circumstances when missing data may introduce selection bias, and show some flaws in several methods sometimes used to impute data.

### SP0188 MULTIPLE IMPUTATION: A POSSIBLE SOLUTION TO THE PROBLEM OF MISSING DATA

J.C. Sergeant[1,2]. *[1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust; [2]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom*

Multiple imputation (MI) is a statistical technique that can be used to handle the problem of missing data. MI enables the use of all the available data without throwing any away and can avoid the bias and unrealistic estimates of uncertainty associated with other methods for handling missing data. In MI, the missing values in the data are filled in or "imputed" by sampling from distributions observed in the available data. This sampling is done multiple times, resulting in multiple datasets. Each of the multiple datasets is analysed and the results are combined to give overall results which reflect the uncertainty about the values of the missing data.

This talk will explore what MI is, when it can be used and how to use it. The content will be accessible to a wide audience and illustrated with clear examples.

### SP0189 WHY CHOOSE RANDOM EFFECTS MODELS FOR LONGITUDINAL DATASETS?

S. Norton. *King's College London, London, United Kingdom*

Longitudinal data, where there are multiple repeated observations of an outcome variable for each individual, requires appropriate analysis to account for the non-independence of observations within individuals. A variety of methods are available, including random-effects (aka multi-level or mixed) models and marginal (GEE) models. Random-effects models, the focus of this presentation, extend the standard regression model to allow for subject-specific estimates of the baseline level of the outcome variable (random intercepts) and its rate of change over time (random slopes). Under certain circumstances both random-effects and marginal model approaches give equivalent estimates. However, in many situations they will not and it can be difficult to decide whether one approach should be favoured over the other.
This presentation will provide an introduction to the random-effects model for longitudinal data using data from the Early Rheumatoid Arthritis Study. Particular strengths of random-effects models such as how missing data on outcome variables at some assessments are handled and the clustering of individuals within hospitals will be considered. Furthermore, differences in the interpretation of coefficients between random-effects and marginal models where the outcome variable is dichotomous will be discussed, with guidance on situations where each approach is more useful.

## Intimate life and sexual relations in RA

### SP0190 LIVED EXPERIENCES OF INTIMATE LIFE IN MEN AND WOMEN WITH EARLY RA

A. Sverker[1,2]. *[1]Departement of Rehabilitation Medicine and Departement of Medical and Health Sciences, Linköping University; [2]Department of Activity and Health, and Department of Medical and Health Sciences, Linköping University, Linköping, Sweden*

**Background:** Women and men with rheumatoid arthritis (RA) experience restrictions in everyday life in spite of the development of new medications. Recent research has described in detail how participation limitations are experienced in everyday life from a patient perspective. However, knowledge of how sex and intimate relationships are affected is still scarce.
**Objectives:** The aim of this study was to explore sex life experiences in relation to sexual function and sexual relationships in women and men with early RA.
**Methods:** This study is part of the Swedish TIRA-project (the Swedish acronym for the prospective multi centre early arthritis project). The data collection includes 45 interviews with 24 women and 21 men, aged 20–63, which were recorded and transcribed verbatim. Critical Incident Technique was used to collect data, and content analysis to categorize the results.
**Results:** Half the participants stated that RA affected their sex life. The general descriptions formed five categories: sex life and tiredness, sex life and aging, emotional consequences of impaired sexual function, facilitators of sexual function and sexual relationships, and strain on the sexual relationship.
**Conclusions:** Sex life is still affected in early RA despite new effective treatment strategies. New strategies of communication, assessment and self-managing interventions concerning the sex life of patients with RA need to be implemented multi-professionally in health car
**Disclosure of Interest:** None declared

### SP0191 SEXUAL HEALTH IN RHEUMATOID ARTHRITIS - THE ROLE OF THE PHYSIOTHERAPIST TO ENHANCE SEXUAL HEALTH

K. Areskoug Josefsson. *Jönköping University, Jönköping Academy for Health and Welfare, Jönköping, Sweden*

Sexual health is often negatively affected by rheumatoid arthritis (RA), but rarely discussed between patients and health care professionals. Experienced reasons for decreased sexual health vary among patients, but pain, stiffness, reduced mobility, fatigue and negative feelings towards one's own body are common factors. In addition to negative effects experienced to be due to RA, there are also negative influences on sexual health by other factors, such as insufficient physical activity, low self-esteem, depression and stressful influences in life.
Physiotherapy is a common intervention for patients with RA and patients have reported improved sexual health due to physiotherapy. Regular physiotherapy interventions for patients with RA often include coaching towards increasing physical activity levels, hydrotherapy, pain reductive treatment and mobility exercises, both individually and in groups. The physiotherapy interventions leading to improved sexual health (according to patients with RA) has been regular interventions for patients with RA and not specifically aimed at enhancing sexual health. The patients do seldom describe that the physiotherapist has informed them of how physiotherapy might enhance sexual health, but they have themselves experienced how physiotherapy has improved their sexual life.
Patients describe that they experience joy, increased self-esteem and a more positive approach to their body, when participating in physiotherapy and that this positive feeling is affecting their life, including their sexual life. They also describe how increased physical capacity reduces fatigue and increases their capacity to engage in valued life activities, including sexual activities.
The way that the physiotherapist can further enhance sexual health, is by informing the patient of how sexual health is linked to experienced symptoms of RA and how physiotherapy interventions, for example increasing physical activity, can enhance also sexual health.

### SP0192 DISEASE IMPACT ON SEXUALITY AND ITS MANAGEMENT IN RHEUMATOLOGY CARE

S.J. Ryan. *Rheumatology, Haywood Hospital, Stoke on Trent, United Kingdom*

This presentation will identify how the symptoms of Inflammatory Arthritis, including joint pain, joint stiffness and fatigue, have the potential to impact on sexuality. Although the issue of sexuality is often neglected in rheumatology care, health professionals can offer advice and support to reduce the effect of the condition on sexuality. Guidance that can be provided within a clinical setting will be discussed.

### SP0193 NINE YEARS OF MARRIAGE AND THREE IN BED - MYSELF, MY HUSBAND AND MY RA

C. Zabalan. *Romanian League Against Rheumatism, Bucharest, Romania*

The most difficult adjustment within a life-threatening chronic illnesses and disabilities involves sexual activities.
Communicating openly and directly with partners, doctors and other health care professionals is not always easy in this field. People often have trouble discussing sexual issues or simply feel lucky to manage on their own in the daily program, therefore, as if they don't have the right to "complain" about changes in sexual functioning.
Problems that we ran into everyday, problems like joint movement limitations, chronic pain, chronic fatigue, weakness, stiffness, decreased mobility, decreased libido, altered genital sensation, vaginal dryness, side effects from medications (for example, risk for infections, weight gain or bloating) they affect all aspects of our lives (personal, family, professional and social) - they all can affect our self-esteem, self-image and, of course, our sexuality. We have negative moods, we have feelings like resentment, anger, guilt, grief, blame, depression, fears of isolation and of being rejected sexually, worries about sexually satisfying one's partner...
Solutions like acceptance, 100% communication, an individualized physical activity, planning the intercourse, devoting plenty of time to foreplay, devising a communication code for pain and pleasure, comfortable and safe positions, alternate ways to enjoy sex, learning some of the 64 Kama Sutra techniques and mastering some of the ancient arts a courtesan used to know, using sex toys and sex toy adjustments ... are all here, presented in my personal view.

**Conclusion:** Arthritis can lead to various sexual problems that require constant adjustment on the part of the individual with arthritis and the couple. But keeping in mind that "*our most powerful sex organs, as they always say, are our minds" will make us feel self-worth and will reassure ourselves that we are deserving a strong, loving, committed emotional and physical relationship.*

## Bone and heart: common molecular mechanisms in osteoporosis and atherosclerosis

### SP0194 DO BONE EROSIONS RESULT FROM LOCAL SYNOVITIS OR BONE MARROW EDEMA?

P. Geusens. *Rheumatology, MUMC&UHasselt, Maastricht & Hasselt, Belgium*

Bone erosions are one of the hallmarks in the diagnosis, prediction and follow-up in RA and other inflammatory rheumatic diseases, such as SpA, erosive hand OA and gout.
Osteoclast activation is the final pathway leading to bone destruction. Why bone erosions in RA occur by preference at the peri-articular regions of finger joints is unclear. The cortex at the finger joints is extremely thin and is, in the bare area, not covered by cartilage or periost, and is therefore easily susceptible for developing erosions. The classical outside-in hypothesis considers synovitis as the primary trigger, which attracts osteoclasts from the circulation, resulting in bone erosions at the bare area and beneath articular cartilage and secondary bone marrow edema (BME). In contrast, the inside-out hypothesis considers bone marrow involvement as the primary trigger. A first argument is the role of ACPA antibodies produced by B-cells: they are able to directly stimulate osteoclasts, are present more than 10 years before clinical RA, and, in subjects with ACPA, bone erosions occur before the clinical onset of arthritis. Second, peri-articular bone loss precedes the occurrence of erosions. Third, BME precedes clinical RA, predicts future erosions and consists of lymphocytic inflammatory infiltrates. Other hypotheses include the role of mechanical stress, as erosions are mostly found at the radial and ulnar site of MCP's, the main location of peri-articular entheses.
However, bone erosions are also frequently found in healthy controls (HC), using conventional radiography (CR), MRI, ultrasound (US) and high-resolution peripheral quantitative computer tomography (HRpQCT). In normal conditions, the only well documented peri-articular cortical breaks are blood vessels that perforate bone from the periost toward the bone marrow at the epiphyses, proximal and distal to the growth plate. These vascular connections enable a direct local communication between bone marrow and synovium. In the context of the above hypotheses, pre-existing vascular connections and angiogenesis stimulated by inflammation could predestine the occurrence of erosions at these pre-existing vascular channels.
In SpA, bone erosions are preceded by BME in the SI joints and at the entheses of the vertebrae and peripheral joints. Here the hypothesis is that mechanical stress at the entheses is a predilection site for inflammation and bone destruction. Again, the predictive value of the presence of BME for developing erosions suggests that inflammation in the bone marrow could precede the occurrence of erosions.
Currently, CR of the hands and feet are the gold standard for imaging bone erosions in RA in research and clinical practice settings. However, CR is less sensitive in detecting bone erosions than MRI, US and HRpQCT. In order to better understand the occurrence of bone erosions, the availability of high-resolution 3D imaging, such as HRpQCT, and other techniques, such as PET-scan using specific inflammation markers, will allow more insights in the above hypotheses and should be studied in prospective studies in RA and in other rheumatic diseases with risk of bone destruction.

### SP0195 OSTEOPOROSIS AND CARDIOVASCULAR DISEASE

W.F. Lems. *Amsterdam Rheumatology and immunology Centre, Amsterdam, Netherlands*

Both osteoporotic fractures and cardiovascular events can be devastating events, which are more commonly in the elderly. This could be related to some risk factors that play a role in the pathogenesis of both events: postmenopausal estrogen deficiency, smoking, immobility and low-grade inflammation. A systematic review on the association of cardiovascular diseases and osteoporosis in the general population will be mentioned. The relationship between osteoporotic fractures and cardiovascular events could be even stronger in patients with systemic inflammatory diseases such as RA or AS. Finally, it will be discussed whether in patients with a recent cardiovascular event, it is useful to screen for underlying osteoporosis, and whether in patients with a recent fracture, cardiovascular risk factors should be determined.

## Adiposity as a driver of arthritis through inflammatory mechanisms

### SP0196 OBESITY AND DIET IN EXPERIMENTAL MODELS OF OA

T. Griffin. *Aging and Metabolism, Oklahoma Medical Research Foundation, Oklahoma City, United States*

Obesity is a significant modifiable risk factor for osteoarthritis in both weight bearing and non-weight bearing joints. Pre-clinical animal models of diet-induced obesity and genetic models of obesity provide new insight into the pathogenesis of obesity-induced osteoarthritis and the underlying cellular and molecular mechanisms involved in this process. Multiple mechanisms appear to be responsible for this increased risk, including biomechanical, inflammatory, post-traumatic, genetic, and metabolic factors. A central finding of many of these studies is that increased dietary lipids and adiposity promote osteoarthritis pathology, even independent of weight gain. Adipose tissue inflammation is considered a central mechanism by which obesity increases osteoarthritis risk, and I will present evidence from the literature and our recent findings that explore this link in obese animal models, focusing on systemic versus local sources (e.g., abdominal versus infra-patellar fat pad). These findings indicate that the infra-patellar fat pad is a source of inflammatory mediators but does not recapitulate the pathogenesis of inflammation that occurs with abdominal adiposity. Additional evidence suggests that obesity alters pathways regulating chondrocyte metabolism. I will discuss these findings and present a working model for how obesity-associated increases in chondrocyte lipid metabolism may impair the homeostatic response of chondrocytes to biomechanical and inflammatory stresses.

## EULAR educational offer

### SP0197 EULAR EDUCATIONAL OFFER: WHERE ARE WE NOW?

E. Hachulla. *National Reference Centre for Rare Autoimmune and Systemic Diseases, University of Lille, Claude Huriez Hospital, Lille, France*

Education is one of the major commitments of EULAR. Over time EULAR has developed a broad educational program which today includes courses, both physical and online, rheumatology textbooks, DVDs demonstrating diagnostic and treatment practices, as well as workshops and young rheumatologist sessions scheduled at the annual EULAR congress. In addition, EULAR provides various forms of education and training grants to individuals.
Listed below is an overview of the current offers:
**EULAR Live Courses**
EULAR ultrasound course
EULAR ultrasound trainer course
EULAR epidemiology course
EULAR postgraduate course
EULAR capillaroscopy course
**EULAR Scientific Endorsement**
Course on systemic lupus erythematosus
European workshop for rheumatology research (ewrr)
**EULAR On-Line Courses**
EULAR on-line course on rheumatic diseases
EULAR on-line course on connective tissue diseases
EULAR on-line course on systemic sclerosis
EULAR on-line introductory ultrasound course
EULAR on-line course in paediatric rheumatology
EULAR on-line course for health professionals
Except for the rheumatic diseases on-line course, which lasted 2 years (with 42 Modules), all other courses correspond to a one-year training course (with 7 to 10 Modules each).
Each module consists of:
– a main review text including learning objectives, pictures, summary points and key references
– at least two in-depth discussions expanding on clinical problems
– two interactive clinical cases with questions and answers
– assessment questions at the end of each module
**The EULAR Bookshelf**
EULAR textbook on rheumatic diseases
EULAR textbook on systemic sclerosis
Coming soon: EULAR textbook on paediatric rheumatology
Musculoskeletal ultrasound in rheumatology
Atlas of capillaroscopy in rheumatic diseases
EULAR training DVDS: Principles of the musculoskeletal history and examination and a second one dedicated to the GALS examination (G = gait, A = arms, L = legs, S = spine)

**EULAR Educational Grants**
Training bursaries for young rheumatologists
Educational visits for health professionals in rheumatology
**EULAR Fellow Sessions During the Annual Congress**
**EULAR Awards presented at the Annual Congress**
**EMEUNET:** the Emerging EUlar NETwork, is a EULAR working group of young clinicians and researchers in rheumatology promoting education and research
Further information: http://www.eular.org/edu_publications.cfm
**Disclosure of Interest:** None declared

## SP0198 A MASTERCLASS ON ASSESSMENT QUESTIONS IN ONLINE COURSES

C. Haines. *The Medical School, The university of Nottingham, -Nottingham, United Kingdom*

The Educationalist for EULAR, Catherine Haines, will give a brief summary of the crucial importance of assessment in ensuring effective practice for newer entrants to the specialism. The session is suitable for all who are involved in the educational processes in EULAR, including trainees and will focus on:
- why skilled assessment is important
- golden rules for skilled assessment
- quick ways to generate skilled assessment questions

**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6401

## SP0199 DEVELOPMENTS IN EULAR EDUCATIONAL PROJECTS IN ULTRASOUND

E. Naredo. *Rheumatology, Hospital GU Gregorio Marañón, Madrid, Spain*

Over the last two decades, an increasing number of rheumatologists have progressively incorporated musculoskeletal ultrasound (MSUS) as a valuable diagnostic and monitoring tool in their clinical practice and research. US is also expanding its applications to new anatomic regions of importance in rheumatologic practice such as large vessels, salivary glands, ligaments, and peripheral nerves. In the first decade of the 21st century, the increasing utility of MSUS in rheumatology has led to a great demand for appropriate education in this imaging modality among rheumatologists worldwide. The European League Against Rheumatism (EULAR) has promoted for many years education in MSUS among rheumatologists in Europe and other continents. The EULAR has supported many educational projects in MSUS such as the development of the content and conduct of a high-quality multi-level MSUS training programme that culminates with a competency assessment systems for rheumatologic MSUS. In addition, EULAR qualifies European centres to become part of a network of Imaging training centres which includes MSUS. Currently EULAR is developing an Imaging Library that will offer images from the wide spectrum of imaging modalities used in rheumatology for the purpose of learning or teaching.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.6207

## SP0200 COMPETENCY ASSESSMENT IN US: AN EXAMPLE OF QUALIFICATION OFFERED BY EULAR

A. Iagnocco. *Sapienza Università di Roma, Rome, Italy*

The use of musculoskeletal ultrasound in rheumatology clinical practice has become widespread with increasing demand from rheumatologists attending EULAR Sonography Courses and participating in educational activities in the field. However, musculoskeletal ultrasound is widely considered an operator dependent imaging technique for which high level training and appropriate competency assessment are crucial in order to ensure the quality of ultrasound examinations. EULAR offers a huge educational programme in musculoskeletal ultrasound, with a number of own branded multi-level live sonography courses and an online introductory course on ultrasound, of which high quality structure and content is ensured. In addition, EULAR grants “scientific endorsement” as a mark of scientific quality to selected courses organised by established experts. Moreover, EULAR guidelines and recommendations on how to perform musculoskeletal ultrasound in rheumatology, and for the content and conduct of ultrasound, including teach-the-teachers, courses have recently been published, thus filling a knowledge gap in the field.
There was however, still the need for assessing the level of competency of delegates attending these educational courses in order to improve and regulate the skills of rheumatologists performing ultrasound. As a result, the EULAR competency assessment in musculoskeletal ultrasound in rheumatology was launched in 2015 with this objective. This new system represents an example of certification offered by EULAR and is based on 2 levels of competency: 1) Level 1 (i.e. the minimum level required to independently perform full rheumatologic musculoskeletal ultrasound, the contents of which are included in the EULAR online, basic, intermediate and advanced courses). 2) Level 2 (i.e. the minimum level required to teach musculoskeletal ultrasound). The EULAR faculty, a group of highly qualified and experienced experts in the field, assess the attendees of the annual EULAR sonography and teach-the teachers courses in order to provide EULAR certification approving their level of competency. All these procedures are regulated by rules available on the EULAR web site (www.eular.org).
The competency assessment requirements are reported below:
**Level 1**
- To complete the EULAR online MSUS course successfully.
- To attend the Basic and Intermediate EULAR MSUS course, or equivalent EULAR scientifically endorsed MSUS course and the Advanced EULAR MSUS course with a maximum of 2 years in between each course.
- To perform and document a minimum of 10 standardized complete MSUS examinations of each joint region (i.e. shoulder, elbow, wrist&hand, hip, knee, ankle&foot) of different normal subjects, after having attended the Basic MSUS course (EULAR or EULAR endorsed).
- To perform a minimum of 200 documented MSUS examinations of different anatomic areas(i.e. shoulder, elbow, wrist&hand, hip, knee, ankle&foot) of different patients with rheumatologic diseases that covers the full range of conditions included in the basic and intermediate level, after having attended the Intermediate MSUS course.
- The latter requirement of performing normal and pathological ultrasound images can be replaced with the achievement of level 1,2 or 3 of MSUS competency in rheumatology as stated by EFSUMB (European Federation of Societies for Ultrasound in Medicine and Biology). (Ref. Terslev L, et al. Ultraschall in Med; published online May 21, 2013;www.efsumb.org/guidelines)
- To successfully pass a practical exam that takes place during the Advanced EULAR MSUS course.

**Level 2**
- To have achieved level 1 competency.
- To attend the annual EULAR MSUS Teach the Teacher course and successfully pass the theoretical and practical examination on MSUS teaching capability that takes place during said course.
- The level 2 competency certification can be delivered under particular circumstances (and after having verified the particular requirements, by the EULAR Faculty members) to MSUS experts who have been a teacher in a EULAR MSUS Teach the Teacher course within the previous 3 years or have been a teacher in three Intermediate/Advanced EULAR MSUS courses within the previous 5 years.

Key messages:
- Appropriate training and competency assessment are highly important to ensure an appropriate and skilled use of musculoskeletal ultrasound by rheumatologists
- The EULAR competency assessment in musculoskeletal ultrasound represents a unique opportunity to guarantee a high level of competency of rheumatologist ultrasonographers

# There is more than drugs

## SP0201 SPORT AND EXERCISE FOR ARTHRITIS PATIENTS

K. Pfeifer. *Institute of Sport Science and Sport, Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany*

The positive health enhancing effects of exercise, physical activity (PA), and sport for the general population as well as for persons with musculoskeletal diseases like osteoarthritis or rheumatoid arthritis are indisputable. High potential lies in activating biopsychosocial exercise interventions that target long-term changes of physical activity behavior, and thus think beyond short intervention periods with mostly short-term effects on physical functions. Those behavioral interventions are related to the framework of the International Classification of Functioning, Disability and Health (ICF) of the World Health Organization (WHO) and consider – in addition to the classical target area of restoration of body functions and structures – relevant activities and aspects of participation as well as personal context factors. Based upon recent psychological health behavior change (HBC) theories and using the principles of intervention mapping we identified 28 exercise-related techniques that impact relevant modifiable personal factors of PA. Together with classical exercise components these techniques were integrated into an ICF-based concept of a “Behavioral Exercise Therapy” (BET). This concept serves as a theory-driven “tool box” for designing complex BET programs to promote PA and to build and strengthen individual movement-related health competence. In BET relevant contents and methods are didactically arranged on three intervention levels to enable the development of movement-related health competence: 1) physical exercise and training, 2) learning/education, and 3) experience. Movement-related health competence is composed of the three components movement competence, control competence and self-regulation competence. It is regarded as a personal resource for the movement and mobility demands in daily life, for autonomous health enhancing physical activity and sport, and for coping with or adjustment to health disorders and diseases.

## SP0202 PSYCHONEUROIMMUNOLOGY: FROM PSYCHE TO IMMUNE ACTIVITY AND BACK

C. Schubert. *Clinic for Medical Psychology, Medical University Innsbruck, Innsbruck, Austria*

Current biomedical thinking is characterized by mind-body dualism and reductionism. Psychoneuroimmunology (PNI) is a modern research area of psychosomatic medicine which tries to overcome such paradigmatic engravings. PNI investigates the interrelationship between psychological factors and stress system activities. In normal individuals, chronic psychosocial stress is associated with increased releases in cortisol (hypercortisolism), lower levels in T helper type 1 (TH1) and higher levels in T helper type 2 (TH2) immune activity. Such stress-induced TH1/TH2 shift promotes diseases in which TH1 is protective (e.g. virus infection) and TH2 is damaging (e.g. allergy). In traumatized patients, stress system functioning is disturbed which is associated with blunted cortisol decreases (hypocortisolism) and inflammation increases under stressful conditions. Inflammation increases, on the other hand, trigger behavioral symptoms related to atypical depression (e.g. fatigue). Investigating bidirectional PNI effects (from psyche to immune, from immune to psyche) is not possible by applying biomedical research approaches (e.g. pre-post design). PNI findings from integrative single-case studies on lupus patients will be presented.

## SP0203 HOW THE DANISH RHEUMATISM ASSOCIATION WORKS WITH COMPLEMENTARY AND ALTERNATIVE TREATMENT

D.J. Pedersen on behalf of Henriette Thorseng. *The Danish Rheumatism Association, Gentofte, Denmark*

In The Danish Rheumatism Association, complementary and alternative treatment, is a subject of great interest and demand among people affected by rheumatic and musculoskeletal diseases (RMDs).

We offer free information about complementary and alternative treatment on our website, and free counselling from our mailbox and hotline advice service. Our overall approach is open-minded; we neither recommend nor advice against the use of such treatments, as documentation often is insufficient.

In our conducted surveys, we have investigated the relationship between people with RMDs and complementary and alternative treatment, to learn more about the use and experience. From these surveys we know, that people with RMDs use such treatments more often than the general population.

## Axial spondyloarthritis and psoriatic arthritis: emerging pathways

### OP0001 EFFECT OF SECUKINUMAB, AN INTERLEUKIN-17A INHIBITOR, ON SPINAL RADIOGRAPHIC CHANGES THROUGH 2 YEARS IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: RESULTS OF THE PHASE 3 STUDY, MEASURE 1

J. Braun[1], X. Baraliakos[1], A. Deodhar[2], D. Baeten[3], J. Sieper[4], P. Emery[5], Z. Talloczy[6], R. Martin[6], H.B. Richards[7]. *[1]Rheumazentrum Ruhrgebiet, Herne, Germany; [2]Oregon Health & Science University, Portland, United States; [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [4]Charité University Medicine Berlin, Berlin, Germany; [5]Leeds Musculoskeletal Biomedical Research Unit/Institute Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [6]Novartis Pharmaceuticals Corporation, East Hanover, United States; [7]Novartis Pharma AG, Basel, Switzerland*

**Background:** Inhibition of radiographic spinal changes, which are primarily osteoproliferative in nature in active ankylosing spondylitis (AS), represents a main goal of therapy.
**Objectives:** To assess the effects of secukinumab on radiographic progression up to 104 weeks (wks) in the MEASURE 1 trial (NCT01358175).
**Methods:** In MEASURE 1, 371 patients (pts) with active AS were randomized to secukinumab or placebo (pbo). Pts on secukinumab received a 10 mg/kg intravenous (i.v.) loading dose at baseline (BL), Wks 2 and 4, and then 150 or 75 mg subcutaneously (s.c.) every 4 wks (q4w) from Wk 8. Pbo was given on the same schedule. Pbo pts were re-randomized to secukinumab 150 or 75 mg s.c. q4w based on ASAS20 response at Wk 16 (non-responders switched at Wk 16; responders at Wk 24). Lateral radiographs of the cervical and lumbar spine performed at BL and Wk 104 were read centrally applying the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Two independent readers, blinded to treatment arm and radiograph sequence, scored the images. Pts initially randomized to secukinumab, who had x-rays available at BL and Wk 104 (n=168), were included in this analysis. Observed data are shown.
**Results:** Secukinumab data were pooled for both the 150 mg and 75 mg doses as there were no major differences in radiographic results between the two doses. At BL, 104/168 (62%) pts had syndesmophytes, 105/168 (63%) had elevated (>5 mg/L) CRP levels, 42/168 (25%) were smokers, and 123/168 (73%) were male. The mean (±SD) mSASSS at BL was 10.22±16.62; mean change from BL at Wk 104 was 0.30±2.53. Approximately 80% of pts showed no radiographic progression (mSASSS change ≤0) from BL to Wk 104 (Figure). At Wk 104, new syndesmophytes were found in 3/64 (5%) pts who were without syndesmophytes at BL. Approximately 70% of pts with syndesmophytes at BL developed no additional syndesmophytes through Wk 104. Overall, BL mSASSS and mean mSASSS change at Wk 104 were higher in males (mean change 0.38±2.79 vs 0.08±1.58 in females), those with BL syndesmophytes (0.47±3.20 vs 0.02±0.26 in pts with no BL syndesmophytes), or elevated CRP levels at BL (0.47±2.66 vs 0.02±2.27 in pts with normal CRP levels). There were no major differences between the secukinumab only and pbo→secukinumab groups in terms of mSASSS change through Wk 104. Inter- and intra-reader agreement on mSASSS scores was 85% (Kappa 0.70) for both.

**Conclusions:** In secukinumab-treated pts, the mean change in mSASSS was low, with no major difference between doses. Changes were higher in pts who were male, had BL syndesmophytes, or elevated BL CRP. No radiographic progression was observed in ~80% of the pts receiving secukinumab over 104 wks. This is the first report of interleukin-17A inhibition on structural changes in patients with AS.

### OP0002 TOFACITINIB IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A PHASE 2, 16-WEEK, RANDOMISED, PLACEBO-CONTROLLED, DOSE-RANGING STUDY

D. van der Heijde[1], A. Deodhar[2], J.C. Wei[3], E. Drescher[4], D. Fleishaker[5], T. Hendrikx[6], D. Li[6], S. Menon[5], K. Kanik[5]. *[1]Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; [2]Division of Arthritis & Rheumatic Diseases, Oregon Health & Science University, Portland, United States; [3]Division of Allergy, Immunology and Rheumatology, Chung Shan Medical University Hospital, Taichung, Taiwan, Province of China; [4]Csolnoky Ferenc Hospital, Veszprém, Hungary; [5]Pfizer Inc, Groton; [6]Pfizer Inc, Collegeville, United States*

**Background:** Tofacitinib is an oral JAK inhibitor that has been investigated for the treatment of ankylosing spondylitis (AS).
**Objectives:** To investigate for the first time the effects of tofacitinib in adult patients (pts) with active AS.
**Methods:** This was a 16-week (wk), Phase 2, multicentre, randomised, double-blind, placebo (PBO)-controlled, dose-ranging study (NCT01786668) to investigate efficacy, safety and dose-response of tofacitinib in pts with AS. Pts fulfilling the modified New York criteria (central read) were randomised 1:1:1:1 to PBO or tofacitinib 2, 5 or 10 mg BID for 12 wks plus 4 wks follow-up. Primary efficacy endpoint was ASAS20 response rate at Wk 12 using a 3-parameter Bayesian $E^{max}$ model by assuming a monotonic response. Secondary endpoints included ASAS40 response rate, AS disease activity score using C-reactive protein (ASDAS), Bath AS disease activity index 50% (BASDAI50) response rate, Bath AS functional index, Bath AS metrology index (linear method), Spondyloarthritis Research Consortium of Canada (SPARCC) score of sacroiliac (SI) joints and spine. Safety endpoints included adverse events (AEs) and laboratory outcomes.
**Results:** 208 pts were randomised and 207 treated; 196 pts completed the study. 51 pts (PBO group) and 52 (each tofacitinib group) were included in analyses. Baseline demographics and disease characteristics were balanced between groups and typical of AS populations (87.4% HLA-B27 positive; 81.2% white; 69.1% male; mean age 42 years; mean disease duration 6.3 years; mean BASDAI 6.7).
The table summarises safety and efficacy results. The ASAS20 $E^{max}$ model showed tofacitinib 10 mg BID had a high response rate and its confidence bounds met a pre-specified efficacy decision rule. ASAS20 response rates by NRI were significantly greater with tofacitinib 5 mg BID vs PBO, compared with 2 or 10 mg BID. All tofacitinib groups had ASAS40, ASDAS and BASDAI50 improvements of similar magnitude vs PBO. Tofacitinib 2 mg BID did not differ vs PBO in remaining clinical efficacy measures or SPARCC scores. Tofacitinib 5 and 10 mg BID had greater clinical efficacy vs PBO, with minimal differences between doses, and significantly improved SPARCC SI joint and spine scores vs PBO.
No tofacitinib-related safety issues unique to the AS population or new safety concerns were identified. Two treatment-related herpes zoster cases were reported (1 each with tofacitinib 2 and 10 mg BID). No cases of tuberculosis,

malignancy, gastrointestinal perforation or death were reported. Dose-dependent changes in laboratory outcomes commonly reported in other tofacitinib studies were observed and returned to approximately baseline values by Wk 16.

**Table. Summary of efficacy and safety endpoints**

| | Placebo (n=51) | Tofacitinib 2 mg BID (n=52) | Tofacitinib 5 mg BID (n=52) | Tofacitinib 10 mg BID (n=52) |

*p<0.05, **p<0.01, ***p<0.001

[a]NRI/LOCF [b]vertigo [c]spinal pain (placebo), hypertransaminasemia (placebo), peripheral swelling (tofacitinib 5 mg BID), herpes zoster (tofacitinib 10 mg BID) [d]50, 51, 52 and 50 patients receiving PBO, and tofacitinib 2, 5 and 10 mg BID, respectively were included in this analysis.

AE, adverse event; ALC, absolute lymphocyte count; ALT, alanine aminotransferase; ANC, absolute neutrophil count; ASAS, assessments in ankylosing spondylitis improvement; ASDAS, ankylosing spondylitis disease activity score using C-reactive protein; AST, aspartate aminotransferase; BASDAI, Bath ankylosing spondylitis disease activity index; BASFI, Bath ankylosing spondylitis functional index; BASMI, Bath ankylosing spondylitis metrology index (linear method); BID, twice daily; CfB, change from baseline; Hb, haemoglobin; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; LOCF, last observation carried forward; LS, least squares; N/A, not applicable; NRI, non-responder imputation; SD, standard deviation; SE, standard error; SPARCC, Spondyloarthritis Research Consortium of Canada; TEAE, treatment-emergent AE; ULN, upper limit of normal.

**Conclusions:** Tofacitinib 5 and 10 mg BID demonstrated greater clinical and imaging efficacy vs PBO in reducing the signs and symptoms of AS in adults with active AS. Safety was similar to that reported for tofacitinib studies in other indications.

## Balancing benefits and risk of glucocorticoids; a challenge for implementation

### OP0003 DEVELOPMENT OF A GLUCOCORTICOID TOXICITY INDEX USING MULTI-CRITERIA DECISION ANALYSIS

E.M. Miloslavsky[1], R.L. Naden[2], J.H. Stone[1] on behalf of Glucocorticoid Toxicity Index Development Group. *[1]Massachusetts General Hospital, Boston, United States; [2]McMaster University, Hamilton, Canada*

**Background:** Glucocorticoids (GC) are associated with substantial treatment morbidity. New immunomodulatory agents offer the possibility of limiting GC exposure. To assess the comparative benefits of such agents, investigators must accurately measure their ability to prevent or reverse GC-related toxicity. No comprehensive instrument for measuring GC toxicity has previously been developed.

**Objectives:** We aimed to develop a GC Toxicity Index (GTI) to assess GC-related morbidity and GC-sparing ability of new agents. Intermediate aims were to 1) define toxicity items for inclusion in the GTI 2) assign relative weights to items and 3) begin the validation process.

**Methods:** 22 physician experts from 11 subspecialties with extensive experience in the clinical use, pharmacology, and toxicity of GCs were invited, and 19 participated. Ten investigators were from the United States and 9 were from Canada, Europe, or Australia. Group consensus methods and multi-criteria decision analysis using forced-choice technique (1000Minds platform) were utilized. The development process included ten 1-hour conference calls and a 12-hour face-to-face meeting.

*GTI components:* The GTI is composed of the Composite GTI (CGTI) and the Specific List. The CGTI reflects GC toxicity that is likely to change over the course of a trial and is designed to distinguish between low and high GC users. The toxicities included in the CGTI vary with GC exposure and are expected to occur in >5% of patients over the course of a clinical trial lasting 6 months to 3 years. The items in the CGTI are weighted and scored. The Specific List is designed to capture GC toxicity not included in the CGTI. Toxicities in the Specific List are comparatively less common and – although impactful for patients – are less likely to contribute to delineating between high and low dose GC regimens. Items of the Specific List are therefore tabulated but not weighted.

**Results:** *Item inclusion and definitions:* Thirty-one toxicity items derived from the literature and reviewed by the investigators were included in the CGTI, and 23 were included in the Specific List (Figure). The CGTI items reflect both improvement and worsening of GC toxicity and account for medication effects (e.g., anti-hypertensives) in scoring. The 31 mutually-exclusive CGTI items are organized in order of severity within nine domains. Only one item in each domain can be scored.

**Figure – Glucocorticoid Toxicity Index (GTI) composed of weighted CGTI and Specific List***

| Composite GTI | Item Weight | Specific List |
|---|---|---|
| **Body mass index** | | |
| Improvement in BMI | -8 | Major increase in BMI |
| No change in BMI | 0 | |
| Moderate increase in BMI | 21 | |
| Major increase in BMI | 36 | |
| **Glucose tolerance** | | |
| Improvement in glucose tolerance | -8 | Diabetic retinopathy |
| No change in glucose tolerance | 0 | Diabetic nephropathy |
| Worsening of glucose tolerance | 32 | Diabetic neuropathy |
| Worsening of glucose tolerance despite treatment | 44 | |
| **Blood pressure** | | |
| Improvement in blood pressure | -10 | Hypertensive emergency |
| No change in blood pressure | 0 | Posterior reversible encephalopathy syndrome |
| Worsening hypertension | 19 | |
| Worsening hypertension despite treatment | 44 | |
| **Lipids** | | |
| Improvement in lipids | -9 | |
| No change in lipids | 0 | |
| Worsening hyperlipidemia | 10 | |
| Worsening hyperlipidemia despite treatment | 30 | |
| **Bone density** | | |
| Improvement in bone density | -1 | Insufficiency fracture |
| No change in bone density | 0 | Major decrease in bone density |
| Decrease in bone density | 29 | |
| **Steroid myopathy** | | |
| No steroid myopathy | 0 | Severe steroid myopathy |
| Mild steroid myopathy | 9 | |
| Moderate steroid myopathy or greater | 63 | |
| **Skin toxicity** | | |
| No skin toxicity | 0 | Severe skin toxicity |
| Mild skin toxicity | 8 | |
| Moderate skin toxicity or greater | 26 | |
| **Neuropsychiatric toxicity** | | |
| No neuropsychiatric symptoms | 0 | Psychosis |
| Mild neuropsychiatric symptoms | 11 | GC-induced violence |
| Moderate neuropsychiatric symptoms or greater | 74 | Other severe neuropsychiatric symptoms |
| **Infection** | | |
| No significant infection | 0 | Grade 4 infection |
| Oral/vaginal candidiasis or uncomplicated zoster | 19 | Grade 5 infection |
| Grade 2 infection or greater | 93 | |
| **Endocrine** | | Adrenal insufficiency |
| **Gastrointestinal** | | Perforation |
| | | Peptic ulcer disease |
| **Musculoskeletal** | | Avascular necrosis |
| | | Tendon rupture |
| **Ocular** | | Central serous retinopathy |
| | | Intraocular pressure elevation |
| | | Posterior subcapsular cataract |
| **Total** | 36 to 439 | |

* Definitions for each item have been developed but are not shown.

*Weighting and evaluation of the CGTI:* Relative weights for each item in the CGTI were derived at a face-to-face meeting utilizing multi-criteria decision analysis (Figure). In order to assess reliability, all participants assigned toxicity items on the CGTI to 15 paper cases. Inter-rater agreement was high (kappa 0.89). To assess the degree to which the CGTI corresponds to expert clinical judgement, participants ranked 15 cases by clinical judgement in order of highest to lowest GC toxicity. Expert rankings were then compared to case ranking by the CGTI, yielding excellent agreement (weighted kappa 0.87).

**Conclusions:** We describe the development and initial evaluation of the GTI - a comprehensive instrument intended primarily for use in prospective, randomized clinical trials for the assessment of GC toxicity. The GTI can be used across clinical disciplines in trials that employ GCs to assess the comparative value of GC-sparing therapies, and to measure the impact of GC toxicity.

## What CVD outcomes to use in clinical rheumatological practice?

### OP0004 COLLECTION AND MANAGEMENT OF SELECTED COMORBIDITIES AND THEIR RISK FACTORS IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES IN DAILY PRACTICE IN FRANCE

L. Gossec, A. Baillet, S. Dadoun, C. Daïen, F. Berenbaum, E. Dernis, F. Fayet, C. Hudry, M. Mézières, S. Pouplin, C. Richez, A. Saraux, C. Savel, E. Senbel, M. Soubrier, L. Sparsa, D. Wendling, M. Dougados. *Rencontres d'Experts en Rhumatologie 2015 working group, Paris, France*

**Background:** In chronic inflammatory rheumatic diseases including rheumatoid arthritis, spondyloarthritis and connective tissue diseases, comorbidities such as cardiovascular diseases and infections are sub-optimally prevented, screened and managed. EULAR recently developed points to consider to collect and report comorbidities but did not include the management phase. (ref)

**Objectives:** To develop a pragmatic form to collect, report and give management recommendations for selected comorbidities and risk factors, from a rheumatologist perspective.

**Methods:** Comorbidities were selected by an expert group of 18 persons, using the previous experience of the recent EULAR points to consider for comorbidities. (ref) The collection and reporting of these comorbidities and risk factors were adapted from the EULAR recommendations. (ref) To develop management recommendations, the process comprised (1) systematic literature reviews by 3 fellows and (2) a 2-day consensus process involving 110 experts (rheumatologists and health professionals). Votes of agreement (Likert 1–5 where 5 indicates full agreement) were obtained from the group.

**Results:** The six selected comorbidities were ischemic cardiovascular diseases, malignancies, infections, gastrointestinal diseases, osteoporosis and depression. The literature review retrieved 158 articles, mostly developed for the general population. The consensus process led to a pragmatic reporting form to collect the existence of a comorbidity (eg heart failure yes/no), current treatment (e.g. stent yes/no), risk factors (e.g. hypertension), screening (e.g. mammography) and prevention (e.g. vaccination). Furthermore, existing management recommendations were adapted to rheumatologists (or developed when unavailable) leading to 28 practical forms. These include physical examination elements such as blood pressure or lymph node examination, prescribing screening procedures, and interpreting results to refer in a timely manner to appropriate other health professionals. Agreement was high (mean, 4.37 ± 0.33 on a 1–5 scale).

**Conclusions:** Using an evidence-based approach followed by expert consensus, this initiative furthers the dissemination and the adaptation to a national context of the EULAR comorbidities initiative, and clearly defines what part of the management of comorbidities is potentially within the remit of rheumatologists. The pragmatic developed document should facilitate the periodical systematic review of patients suffering from chronic inflammatory rheumatic diseases. Next steps include dissemination and implementation of this document.

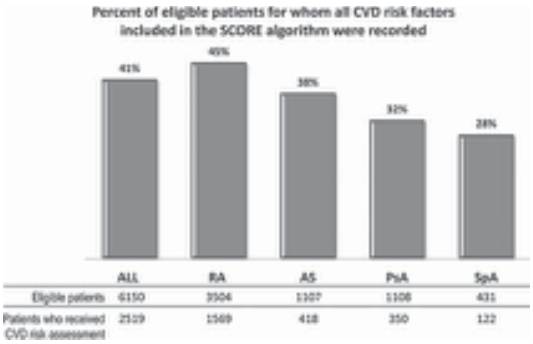
### OP0005 HOW TO IMPLEMENT CARDIOVASCULAR DISEASE RISK ASSESSMENT FOR PATIENTS WITH INFLAMMATORY JOINT DISEASES IN DAILY RHEUMATOLOGY PRACTICE: AN OVERWIEW OF THE NATIONWIDE NOCAR PROJECT



E. Ikdahl[1], S. Rollefstad[1], G. Wibetoe[1], F. Krøll[2], D.M. Soldal[3], I.C. Olsen[4], T.K. Kvien[4], G. Haugeberg[5], A.G. Semb[1]. *[1]Preventive Cardio-Rheuma Clinic, Dept. Rheumatology, Diakonhjemmet Hospital, Oslo; [2]Dept. Rheumatology, Lillehammer Hospital for Rheumatic Diseases, Lillehammer; [3]Dept. Rheumatology, Hospital of Southern Norway, Kristiansand; [4]Dept. Rheumatology, Diakonhjemmet Hospital, Oslo; [5]Dept. Rheumatology, Martina Hansens Hospital, Bærum, Norway*

**Background:** Patients with inflammatory joint diseases (IJD) have a high risk of cardiovascular disease (CVD). The EULAR recommendations for CVD risk management in patients with IJD states that CVD risk assessment should be considered annually in this patient population, and emphasizes that such assessment easily can be incorporated into a routine rheumatology visit. While other patient groups with high CVD risk often have structured programs to ensure adequate CVD prevention, these measures are rarely implemented for IJD patients.

**Objectives:** The aim of the NOrwegian Collaboration on Atherosclerosis in patients with Rheumatic joint diseases (NOCAR) was to design a program of annual CVD risk assessment for IJD patients that could be implemented into routine visits in rheumatology outpatient clinics.

**Methods:** NOCAR was started in April 2014 for quality assurance purposes, and comprises 11 rheumatology centres across Norway. All IJD patients >30 years registered in the electronic patient journal program GoTreatIt® Rheuma (GTI) are eligible. The CVD risk factors recorded in NOCAR are imputed directly into the GTI journal and are collected in a multidisciplinary manner: 1) Patients self-report CVD risk factors, 2) non-fasting lipids are ordered by health secretaries in addition to routine laboratory tests and 3) rheumatology nurses perform blood pressure measurement. Based on the Systematic COronary Risk Evaluation (SCORE) algorithm, GTI automatically calculates the patient's 10-year risk of a fatal CVD event. If the SCORE estimate is ≥5%, the rheumatologist forwards a note to the patient's primary physician to inform that there is indication for initiation of CVD-preventive measures (e.g. medication and lifestyle changes). Additionally, the rheumatologists and rheumatology nurses are instructed in how to deliver brief advice regarding smoking cessation and healthy diet. We report the initial capture rate in 3 NOCAR centres from which visit data was extracted in October 2015. We evaluated how many of the eligible patients who had received a CVD risk evaluation during these first 1.5 years of the NOCAR project. A CVD risk assessment was defined as having recoded all of the CVD risk factors included in the SCORE algorithm (total cholesterol, systolic blood pressure, smoking status, age and sex).

**Results:** Of the 6150 IJD patients (Rheumatoid arthritis [RA]: 3504, ankylosing spondylitis [AS]: 1107, psoriatic arthritis [PsA]: 1108, and other spondyloarthritides [SpA]: 431) who were eligible for the NOCAR project, 2519 (41%) patients received a CVD risk assessment during this 1.5 year interval (RA: 1569 [45%]), AS: 418 [38%], PsA: 350 [32%], SpA: 122 [28%]). The major obstacles to successful implementation encountered in NOCAR were time scarcity; defining a date for annual CVD risk assessment and making sure that lipids were measured before seeing the rheumatologist.

**Conclusions:** To our knowledge, this is the first multi-centre clinical project to show that incorporation of CVD risk assessment into routine rheumatology visits is feasible. Future studies are warranted to elucidate success criteria for optimal implementation of CVD preventive strategies in rheumatology.

## Different perspectives on pain in osteoarthritis

OP0006-HPR **EVEN IN THE LONG RUN NORDIC WALKING IS SUPERIOR TO STRENGTH TRAINING AND HOME BASED EXERCISE FOR IMPROVING PHYSICAL FUNCTION IN OLDER PEOPLE WITH HIP OSTEOARTHRITIS - AN RCT**

T. Bieler[1], V. Siersma[2], S.P. Magnusson[1], M. Kjaer[3], N. Beyer[4]. *[1]Institute of Sports Medicine – Copenhagen and Musculoskeletal Rehabilitation Research Unit, Department of Physical & Occupational Therapy, Bispebjerg and Frederiksberg Hospitals, University of Copenhagen; [2]The Research Unit for General Practice and Section of General Practice, Dept. Public Health, University of Copenhagen; [3]Institute of Sports Medicine – Copenhagen; [4]Musculoskeletal Rehabilitation Research Unit, Dept. Physical & Occupational Therapy, Bispebjerg and Frederiksberg Hospitals, University of Copenhagen., Copenhagen, Denmark*

**Background:** Lack of regular physical activity is a risk factor for functional decline. In hip osteoarthritis, exercise therapy aims to improve patients' overall function. Systematic reviews have shown beneficial effects on pain and physical function from exercise therapy (1) but also that these positive effects are not sustained in the long term (2). The patients' self-efficacy and additional booster sessions offered after the treatment period are factors shown to positively influence physical activity maintenance (3) and beneficial posttreatment effects (2).
**Objectives:** In an observer-blinded, randomized trial to compare the long term effects of 4 months of supervised strength training (ST), supervised Nordic Walking (NW), and unsupervised home based exercise (HBE, control group) on functional performance.
**Methods:** 60+ years old people (n=152; 49 men, 103 women, age 70±6 years) with clinical hip osteoarthritis not on a waiting list for surgery were randomized to ST in a local fitness center (n=50), NW in a local park (n=50) or HBE (n=52). The ST- and NW-groups were offered individual counseling interviews, patient education and telephone-assisted counselling in order to improve adherence and maintenance of exercise/physical activity. Functional performance, i.e. 30s chair stand test (primary outcome), timed stair climbing and 6-minute walk test; and secondary self-reported outcomes, i.e. physical function, pain, physical activity level, self-efficacy and health related quality of life, were measured at baseline, 4- and 12 months.
**Results:** Intention-to-treat-analyses showed equal improvements (mean (95%CI)) after intervention in number of chair stands in all three groups at 4-months (ST: 0.9 (0.2–1.6), NW: 1.9 (0.8–3.0), HBE: 1.1 (0.1–2.0)), while a between-group difference in favor for the NW-group (1.4 (0.0–2.8)) compared to ST-group were present at 12 months. Significant between-group differences ($p<0.001$- $p<0.05$) in favor of NW compared to ST and HBE were found for functional performance at all follow-up time-points. Furthermore, NW was superior ($p<0.01$) to HBE for improving vigorous physical activity and to both ST and HBE for improving ($p<0.01$) mental health at all follow-up time-points, and ($p<0.05$) self-efficacy at 12 months.
**Conclusions:** Based on these results NW can be recommended compared with ST and HBE for older adults with hip osteoarthritis.

## Epigenetics solving the OA puzzle

OP0007 **DEEP RNA SEQUENCING REVEALS ARTHRITIS-SPECIFIC LNCRNA TRANSCRIPTOMES OF SYNOVIAL FIBROBLASTS AT DIFFERENT ANATOMIC LOCATIONS**

M. Frank-Bertoncelj[1], G. Russo[2], A. Bratus[2], C. Kolling[3], A. Filer[4], B.A. Michel[1], R.E. Gay[1], C.D. Buckley[4], S. Gay[1], C. Ospelt[1]. *[1]Center of Experimental Rheumatology, University of Zurich and University Hospital Zurich, Schlieren; [2]Functional Genomics Center Zurich, ETH Zurich and University of Zurich; [3]Schulthess Clinic, Zurich, Switzerland; [4]Center for Translational Inflammation Research, University of Birmingham, Birmingham, United Kingdom*

**Background:** A number of susceptibility loci for rheumatoid arthritis (RA) map to noncoding genomic regions. Long noncoding RNA (lncRNA) represent the largest part of noncoding transcriptome and are key regulators of gene expression. We have recently shown that the expression pattern of noncoding RNA in synovial fibroblasts (SF) - one of the key local effector cells in arthritis – is largely determined by anatomic joint location.
**Objectives:** The aim of the present study was to identify arthritis-specific lncRNA transcriptomes of SF at different anatomic locations, focusing on RA and osteoarthritis (OA).
**Methods:** RNA was isolated from cultured SF, passages 5–8, obtained from hands, shoulders and knees of RA and OA patients and knees of non-arthritic patients experiencing joint pain (normal) (n=3 per each group). RNA sequencing (Illumina HiSeq2000) of SF was followed by read alignment to the reference genome and transcriptome (the Ensembl GRCh37, STAR version 2.3.0e_r291), identification of differentially expressed (DE) genes between diagnoses and locations (DESeq2, Bioconductor Version 3.0, log(foldchange) $>|0.5|$, $p<0.01$,) and pathway analysis (Metacore, Thomson Reuters) of DE protein-coding genes.
**Results:** RNA sequencing revealed that ~15.000 protein-coding RNA and 4000 lncRNA are expressed in SF at each joint location. Comparing different joints, 101, 182 and 155 of expressed lncRNA were DE between knee-hand, knee-shoulder and hand–shoulder SF, representing 2.4%, 4.1% and 3.5% of expressed lncRNA, respectively. Furthermore, comparing different diagnoses at each joint location 101 (2.4%) lncRNA were identified as DE between OA-RA hands (e.g. MALAT1, HOXA11-AS), 36 (0.8%) between OA-RA shoulders (e.g. DNAJC3-AS1, MIR29B1), 19 (0.5%) between OA-RA knees (e.g. TBX5-AS1, ITGB2-AS1), 136 (3.5%) between OA-normal knees (e.g. CTC-529P8.1) and 108 (2.6%) between RA-normal knees (e.g. IL21-AS1), respectively, with 51 lncRNA altered in OA and RA vs. normal knee SF. This showed that lncRNA transcriptional programmes of SF in particular differ between OA and RA hands with a difference comparable to that seen between healthy vs. arthritic knees and between anatomic locations. Only a minor number of joint-specific lncRNA were altered by arthritis. Pathway analysis revealed the enrichment of platelet-endothelial-leucocyte adhesion and ECM remodelling networks between RA and OA hands, inflammation – MIF signalling and cytoskeleton-intermediate filaments networks between OA and RA shoulders and chemotaxis and cadherin and integrin adhesion networks between OA and RA knees.
**Conclusions:** Our study identifies joint-specific alterations in stromal synovial lncRNA profiles in RA and OA and shows that in the same type of arthritis different disease pathways are activated at different joint locations. In particular in hands, stromal noncoding transcriptional programmes significantly differ between different types of arthritidis, emphasizing the central role of anatomic location when studying arthritis pathogenesis.

OP0008 **SYNOVIAL FIBROBLAST PROLIFERATION IS ENHANCED BY MICRORNA-223 DELIVERY THROUGH MONOCYTE-DERIVED MICROPARTICLES**

F.M. Meier[1], D.S. Gilchrist[1], D.W. McCarey[1], D. McIntyre[1], E.G. Melchor[1], B.E. Morton[1], U. Müller-Ladner[2], I.B. McInnes[1], M. Kurowska-Stolarska[1]. *[1]Institute of Infection, Immunity and Inflammation, College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom; [2]Dpt of Internal Medicine and Rheumatology, Kerckhoff Clinic, JLU Giessen, Bad Nauheim, Germany*

**Background:** Microparticles (MPs) have been described to function as extracellular vehicles that shuttle microRNAs (miR) from platelets to endothelial cells[1] and regulate recipient cell gene expression. Crosstalk of synovial monocytes (MC) with synovial fibroblasts (SF) is a key step to the inflammatory process in rheumatoid arthritis (RA).
**Objectives:** Herein, we investigated whether delivery of specific miRs by MC-derived MPs affects RASF behaviour.
**Methods:** Blood samples of healthy volunteers and RA patients were collected. MPs were obtained by differential centrifugation. $CD14^+$ cells were isolated from PBMCs by using positive selection and the cells were stimulated with 50 ng/ml recombinant human M-CSF for 6 days. Scanning electron microscopy, nanosight trafficking analysis and flow cytometry (FACS) have been applied to characterize MPs from human $CD14^+$MCs and THP-1 cells. Total and smallRNA sequencing were performed on macrophages (n=4) and RASFs (n=4) as well as on macrophage-derived MPs (n=4). (Pre-)miR-223 expression and copy number was quantified in cells or tissues via TLDA, qPCR & in situ hybridisation with specific primers and probes. Targeted pathways were identified using prediction algorithms (TargetScanHuman6.2). Transfer of miR-223 from MCs to SFs was determined by fluorescence microscopy, direct cell co-culture and FACS, as well as transwell co-culture. RASF proliferation assays with FGF-2 as positive control, as well as THP-1 derived MPs, miR-223 mimic, miR-223 inhibitor, control mimic and inhibitor were carried out.
**Results:** MPs from MCs & THP-1 cells are about 250nm in size (range 50–800nm). SmallRNA sequencing revealed high levels of miR-223 in macrophages as opposed to a lack of its expression in RASF. If co-cultured with MCs for 3d, RASF acquire miR-223 expression, but not pre-miR-223 to a significant extent (n=6, $C_t$ values $<30$) confirming transfer of mature miR-223 between cells. Prediction algorithms identified FBXW7 as a candidate target for miR-223

in RASF. FBXW7 acts as an ubiquitin ligase targeting cyclin E. Co-culture of RASF with THP-1 derived MPs increased RASF proliferation to a similar extent as FGF-2 (n=8, $p<0.01$). Transfection of RASF with miR-223 inhibitor prior to stimulation with THP-1 MPs abrogates their proliferative effect (n=5, $p<0.05$). miR-223 transfection (25nM & 50nM) itself led to an increase of RASF proliferation after 72 and 96h (n=6–8, $p<0.01$ for all).

**Conclusions:** miR-223 transport from MCs to SFs by MPs represents a novel intercellular mechanism that could stimulate SF proliferation during initiation or chronicity of synovial inflammation in RA.

## Muscle biology & inflammation

### OP0009 DISTINCTIVE IMMUNOFLUORESCENCE PATTERN IN STATIN-ASSOCIATED AUTOIMMUNE MYOPATHY WITH ANTI-HMGCR AUTOANTIBODIES

M. Alvarado-Cardenas[1], A. Marin[2], M.A. Martinez[3], I. Pinal-Fernandez[4], M. Labrador-Horrillo[4], P.J. Moreno[5], J.C. Millisenda[5], J.M. Grau[5], R. Pujol[2], C. Juárez[3], A. Selva-O'Callaghan[4]. *[1]Internal Medicine, Vall d'Hebron General Hospital; [2]Immunology, Vall d'Hebron General Hospital. Universitat Autonoma de Barcelona; [3]Immunology, Sant Pau Hospital. Universitat Autonoma de Barcelona; [4]Internal Medicine, Vall d'Hebron General Hospital. Universitat Autonoma de Barcelona; [5]Muscle Research Group. Internal Medicine, Hospital Clinic. Universitat de Barcelona, Barcelona, Spain*

**Background:** A statin-associated autoimmune myopathy with anti-HMGCR antibodies has recently been described. Identification of these patients is of paramount importance because immunosuppressive therapy is usually needed for clinical improvement. Herein we report a new pattern of immunofluorescence (IIF) that could alert of the presence of this antibody in routine autoantibody screening on kidney, liver, stomach sections.

**Objectives:** Our objective was to study the concordance of this IIF pattern with anti-HMGCR in a series of patients with immune-mediated necrotizing myopathy (IMNM).

**Methods:** Seventeen patients diagnosed with IMNM positive for anti-HMGCR antibodies were tested for the presence of IIF pattern. As a control group, 90 patients diagnosed with systemic autoimmune diseases (SLE, autoimmune hepatitis, systemic sclerosis, rheumatoid arthritis, Sjögren syndrome, and dermatomyositis – 15 from each group), and 45 patients treated with statins (15 with familial severe dyslipidemia, 15 with a recent cerebrovascular event – treated high dose of atorvastatin, and 15 from the community) were also studied. Anti-HMGCR antibodies were measured by means of two ELISA assays: a in-house confirmed by blot using hidroxi-methil-glutharil-CoA (Sigma H7039) as antigen and commercial QUANTA Lite HMGCR ELISA Innova (San Diego). Indirect immunofluorescence studies on triple tissue (rat liver, kidney and stomach) was performed using Nova Lite assay (Innova Diagnostic, San Diego, USA). We used different commercial substrates (Innova, Euroimmune, ByoSistems, and Aeskulides) in order to confirm that the reactivity of the pattern do not depend on the commercial source. Indirect immunofluorescence on HEp-2 Slides (INOVA Diagnostics, Inc., San Diego Hep-2 ANA slides) was also performed. Immunoabsorption studies were performed using HMGCR human antigen (Sigma, St Louis, MO,USA) at different dilutions (PBS 10%) in those patients with a positive IIF pattern

**Results:** A cytoplasmatic pattern in scattered hepatocytes with perivascular distribution was observed in 15 out of 17 (88%) IMNM positive for anti-HMGCR antibodies. No patients from the autoimmune systemic disease group or those treated with statins disclosed this characteristic pattern. Consequently, the overall agreement between rat triple tissue IIF and ELISA confirmed by blot was 98.7% (kappa 0.93). Dispersed hepatocyte cytoplasmatic pattern (DHCP) was specifically absorbed by incubation with human purified antigen. A granular cytoplasmatic fluorescence pattern was observed in 6 out of 17 (35%) patients with human Hep cells.

**Conclusions:** A new distinctive IIF pattern on routine rat triple tissue is described in patients diagnosed with IMNM whit anti-HMGCR antibodies. It could be useful to alert of the presence of anti-HMGCR antibodies when performing a routine unexpensive autoantibody profile.

**Disclosure of Interest:** None declared

### OP0010 THIGH MAGNETIC RESONANCE IMAGING REVEALS INCREASED ACTIVE AND CHRONIC MUSCLE DAMAGE IN NECROTIZING MYOSITIS COMPARED TO POLYMYOSITIS AND DERMATOMYOSITIS

I. Pinal-Fernandez[1], M. Casal-Dominguez[2], A. Lahouti[2], P. Basharat[3], M. Albayda[2], J. Paik[2], S. Ahlawat[4], S. Danoff[5], T.E. Lloyd[6], A.L. Mammen[1], J. Carrino[7], L. Christopher-Stine[2]. *[1]Muscle Disease Unit, NIAMS/NIH, Bethesda; [2]Rheumatology, Johns Hopkins Hospital, Baltimore, United States; [3]Rheumatology, University of Western Ontario, London, Canada; [4]Radiology; [5]Pulmonology; [6]Neurology, Johns Hopkins Hospital, Baltimore; [7]Radiology, Hospital for Special Surgery, New York, United States*

**Background:** The autoimmune myopathies include polymyositis (PM), dermatomyositis (DM), and necrotizing myositis (NM). Patients with clinically amyopathic dermatomyositis (CADM) have the cutaneous features of DM but with minimal or no muscle involvement. Muscle abnormalities can be assessed with magnetic resonance imaging (MRI), which detects edema (a feature of active muscle disease) and fatty replacement (a feature of chronic damage).

**Objectives:** To compare the prevalence of active and chronic muscle damage in patients with DM, PM, NM, CADM, and IBM using thigh MRI (tMRI).

**Methods:** All the patients of the Johns Hopkins Myositis Cohort with an available tMRI that fulfilled criteria for DM, PM, IBM, NM or CADM were included in the study. Fifteen muscles of the gluteal, lateral rotator, anterior, medial and posterior thigh compartments were studied bilaterally. In each muscle, the presence of edema, fatty replacement, and fascial thickening was recorded. We compared the tMRI features of clinical subsets using univariate and multivariate regression analysis. We also studied the effect on the tMRI, independently of the clinical subset, age at onset, sex, race and time from the onset to the tMRI.

**Results:** Six hundred and sixty-seven patients were included in the study (153 IBM, 101 NM, 176 PM, 220 DM and 17 CADM). The prevalence of edema, atrophy, and fatty replacement showed a gradient among different clinical subsets (IBM>NM>PM>DM>CADM). Similar to patients with IBM, tMRI of NM patients revealed more frequent edema (difference >22%), atrophy (difference >27%), and fatty replacement (difference >14%) than in PM or DM. Analysis of the different muscle compartments confirmed that, as previously described, IBM is characterized by fatty replacement and atrophy in the anterior compartment; in contrast, NM was associated with atrophy and fatty replacement in the lateral rotator compartment. Fascial thickening was the hallmark of DM (found in 51%; $p<0.001$) while PM was not associated with any specific pattern. Independent of the clinical subset, increased age at onset was associated with more muscle atrophy ($OR_{10\ years}$=1.2, 95%CI 1.01–1.3), fatty replacement ($OR_{10\ years}$=1.4, 95%CI 1.2–1.6), and muscle edema ($OR_{10\ years}$=1.3, 95%CI 1.2–1.5); the time from the onset of the disease to the tMRI was only associated with fatty replacement ($OR_{10\ years}$=1.7, 95%CI 1.2–2.5).

**Conclusions:** Patients with NM had more frequent edema, fatty replacement, and atrophy on tMRI compared to those with either DM or PM, suggesting that NM is often a more severe, and perhaps undertreated, form of myositis. In NM, fatty replacement occurred most frequently in the lateral rotators, whereas in IBM chronic damage was more frequent in the anterior compartment. As reported in other studies, increased fascial thickening was a hallmark feature of DM. In contrast, the lack of a consistent pattern of muscle involvement suggests that PM is a heterogeneous entity.

## Lessons from the children (monogenic causes of autoimmunity)

### OP0011 INDUCED PLURIPOTENT STEM CELL-DERIVED MONOCYTIC CELL LINES FROM CONGENITAL IMMUNOLOGICAL DISORDERS SERVE A VERSATILE PLATFORM FOR PHENOTYPE-BASED COMPOUND SCREENING

M. Saito, T. Nakahata. *Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan*

**Background:** One of the main players of immune system and immunological disorders is white blood cells, such as lymphocytes, monocytes, and neutrophils. Although the elucidation of their cellular pathophysiology has been largely based on *in vitro* studies using patient-derived primary hematopoietic cells, this approach has potential limitations. Patient-derived cells cannot be obtained in unlimited quantities, and their *in vitro* functions can be affected by *in vivo* conditions, such as the cytokine milieu or presence of therapeutic agents.

Due to their pluripotency and capacity for self-renewal, human induced pluripotent stem cells (iPSCs) are potential sources of cells for use in drug screening, toxicology testing and the investigation of disease mechanisms [1,2]. However, the phenotypic variance often hampers quantitative functional evaluation of iPS-derived progenies. Moreover, directed differentiation into immune cells financially prohibitive and labor-intensive. One of the solution of these issues is to immortalize iPSC-derived progenitor cells and use these cells as a source of

functional analysis. Here we took advantage of immortalization of iPSC-derived myeloid progenitors (iPS-MLs) that can differentiate into functional macrophages and dendritic cells.
**Objectives:** To overcome the limitations of iPSC-based study for immunological disorders, we are aiming at establishing a versatile and robust platform for disease modeling and high-throughput compound screening system by establishing iPS-MLs.
**Methods:** Generation of iPS cells from congenital immunological disorder patients was performed as described previously [1]. Hematopoietic cell differentiation was performed according to previously described protocols with some modifications [3,4]. For establishment of iPS-MLs, lentiviral constructs encoding *BMI1*, *cMYC* and *MDM2* floating hematopoietic cells differentiated into the monocytic lineage from iPSCs were collected on days 14 or 21. The cells were transfected with the lentiviral vectors encoding *BMI1*, *cMYC* and *MDM2* and subsequently cultured in the presence of M-CSF and. We differentiated the iPS-MLs into macrophages and used for subsequent analysis.
**Results:** We established iPSCs from patients with congenital immunological dysorders such as autoinflammatory syndrome and immunodeficiency. iPSCs were then immortalized immature monocytic progenitors by introducing three transgenes [5]. iPS-MLs expand rapidly and be able to differentiate both macrophages and dendritic cells. By taking advantage of iPS-ML, we constructed phenotypic screening system by evaluating cytokine production or morphological changes in intracellular granules.
**Conclusions:** Our system provides a large number of functional monocytic lineage cells and versatile platform for compound screening for modifying diseases-associated phenotypes. Therefore, it is useful for screening candidate compounds for treatment of congenital immunological disorders associated with monocytic lineage cells.

## OP0012 MICRORNA ASSOCIATED WITH ACTIVE SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS REGULATE CD163 EXPRESSION IN POLARIZED MACROPHAGES THROUGH TWO DISTINCT MECHANISMS

S. Thornton[1], T.D. Do[1], R. Tan[1], A. Sproles[2], M. Bennett[3], M. Medvedovic[3], M. DeLay[2], N. Shen[4], A. Grom[1], G. Schulert[1]. *[1]Pediatric Rheumatology; [2]Flow Cytometry Core, Cincinnati Children's Hospital Medical Center; [3]Environmental Health, University of Cincinnati; [4]Center for Autoimmune Genomics and Etiology, Cincinnati Children's Hospital Medical Center, Cincinnati, United States*

**Background:** CD163 is a hemoglobin scavenger receptor and serves as a marker of activated monocytes and macrophages. It is also expressed on monocytes from children with active systemic juvenile idiopathic arthritis, and highly enriched on hemophagocytic macrophages that characterize the emergence of macrophage activation syndrome. However, the regulation of CD163 expression during monocyte and macrophage polarization is poorly understood. MicroRNA are small non-coding RNA that post-transcriptionally regulate gene expression, often serving as feedback loops to "fine tune" gene expression programs.
**Objectives:** Determine microRNA regulation of CD163 at the protein and mRNA levels using novel flow cytometry techniques.
**Methods:** Human THP-1 monocytic cells and primary monocytes and monocyte-derived macrophages (MDMs) from healthy donors were polarized with activating conditions including M1 (LPS and IFNg), M2a (IL-4), M2b (LPS and immune complexes) and M2c (TGFb or IL-10). CD163 expression was determined by quantitative RT-PCR or on a single-cell level using RNA flow cytometry. Transcripts were detected using the PrimeFlow kit, with probes specific for CD163 mRNA and other cell surface markers. Cells were also transfected with specific microRNA mimics.
**Results:** Significantly increased CD163 mRNA levels were detected only in monocytes and macrophages polarized towards M2c by IL-10 treatment. Similarly, single-cell RNA analysis showed markedly increased CD163 mRNA upon IL-10 treatment, with more modest increases in protein expression. Several candidate microRNA may regulate CD163. As such, our studies indicate that overexpression of miR-125a and miR-181c significantly reduced CD163 mRNA expression in IL-10 polarized macrophages. Notably, both of these microRNAs were significantly increased in monocytes from children with active systemic JIA. *In vitro*, miR-125a and miR-181c were both elevated in polarizing conditions that restrict CD163 expression. Interestingly, these microRNAs regulated CD163 expression through distinct mechanisms. Computationally, miR-181 is predicted to bind directly to CD163 mRNA. Indeed, using RNA immunoprecipitation (RIP) we found that overexpression of miR-181c significantly increased delivery of CD163 mRNA to the RNA-induced silencing complex. In contrast, CD163 does not have a predicted miR-125a binding site. Using whole transcriptome analysis of macrophages overexpressing miR-125a-5p, significantly reduced levels of mRNA encoding several macrophage receptors, including IL10RA and TGFbR2, was observed. This suggests that miR-125a-5p exerts more global effects to restrict M2c polarization.
**Conclusions:** These data show that microRNAs regulate the IL-10-induced expression of CD163 in human macrophages through distinct mechanisms, directly targeting of CD163 mRNA and indirectly inhibiting cytokine receptor expression. These findings illustrate how microRNA "fine-tune" innate immune activation during inflammatory responses, and expand the understanding of the phenotype of activated monocytes and macrophages in systemic JIA.

## OP0013 PREDICTION OF NON-RESPONSE TO METHOTREXATE THERAPY IN THE RHEUMATOID ARTHRITIS MEDICATION STUDY (RAMS)

J.C. Sergeant[1,2], K.L. Hyrich[1,2], J. Anderson[1,2], K. Kopec-Harding[1], H.F. Hope[1,2], A. Barton[2,3], S.M.M. Verstappen[1] on behalf of RAMS Co-Investigators. *[1]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre, University of Manchester; [2]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust; [3]Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom*

**Background:** Methotrexate (MTX) is the disease modifying drug of first choice in the treatment of rheumatoid arthritis (RA). However, response to MTX varies and the ability to predict likely non-response could enable earlier access to alternative drugs and the avoidance of disease progression for some patients.
**Objectives:** To predict non-response to MTX in the Rheumatoid Arthritis Medication Study (RAMS), a cohort of RA patients commencing MTX therapy for the first time.
**Methods:** RAMS is a national multi-centre observational study recruiting RA patients in the UK who are $\geq$18 years old and starting MTX for the first time. Data on potential predictors of response to MTX was acquired at baseline via questionnaires, case notes and blood samples and used to predict non-response to MTX at six months after commencement. Non-response to treatment was defined as failing to fulfil the EULAR criteria for good response: disease activity score-28 (DAS28) at six months $\leq$3.2 and reduction in DAS28 from baseline to six months $>$1.2. Potential predictors were chosen as candidate variables in a multivariable logistic regression model for non-response based on previous univariable analysis. The baseline measures included were body mass index (BMI), current smoking (yes/no), drinking of alcohol (yes/no), symptom duration, DAS28, functional disability (Health Assessment Questionnaire, HAQ), C-reactive protein (CRP), creatinine, anxiety and depression scores (Hospital Anxiety and Depression Scale, HADS) and beliefs about medicines necessity and concerns scores (Beliefs about Medicines Questionnaire, BMQ). All candidate predictors were initially included in a full model before backwards selection was used to remove non-significant terms ($p>0.05$) and produce a parsimonious final model. The ability of the models to discriminate between responders and non-responders was assessed using the area under the receiver operating characteristic curve (AUC).
**Results:** Data on baseline predictor values and response at six months was available on 781 participants: 546 (70%) female, median age 59 (IQR 48–68) years, median symptom duration 9 (IQR 4–28) months. 549 participants (70%) were non-responders. Multivariable age- and sex-adjusted odds ratios for the predictors in the full and final models are shown in Table 1. The full model had

Table 1. Multivariable age- and sex-adjusted logistic regression models for non-response to MTX at six months

| Predictor | Full model | | Final model | |
|---|---|---|---|---|
| | OR (95% CI) | p | OR (95% CI) | p |
| BMI (kg/m$^2$) | 1.05 (1.02, 1.09) | <0.01 | 1.06 (1.03, 1.09) | <0.01 |
| Current smoking (yes/no) | 1.57 (1.00, 2.47) | 0.05 | 1.59 (1.02, 2.48) | 0.04 |
| Drinking of alcohol (yes/no) | 0.72 (0.50, 1.04) | 0.08 | | |
| Symptom duration (months) | 1.00 (1.00, 1.00) | 0.27 | | |
| DAS28 | 0.65 (0.56, 0.76) | <0.01 | 0.68 (0.60, 0.78) | <0.01 |
| HAQ score | 1.27 (0.92, 1.75) | 0.15 | | |
| CRP (mg/l) | 1.00 (0.99, 1.00) | 0.24 | | |
| Creatinine (mg/dL) | 1.00 (0.99, 1.01) | 0.56 | | |
| HADS anxiety score | 1.09 (1.03, 1.15) | <0.01 | 1.11 (1.06, 1.15) | <0.01 |
| HADS depression score | 1.00 (0.94, 1.07) | 0.9 | | |
| BMQ necessity score | 1.01 (0.97, 1.06) | 0.67 | | |
| BMQ concerns score | 0.99 (0.94, 1.03) | 0.53 | | |

an AUC of 0.70. The final model, containing BMI, current smoking, DAS28 and HADS anxiety score, had an AUC of 0.69.
**Conclusions:** Baseline values of lifestyle, clinical and psychosocial predictors were used to predict non-response to MTX at six months. A model with a parsimonious set of core variables had similar discriminatory performance to a model with a full set of predictors. Of note is the role of participant anxiety on commencing treatment with MTX in predicting response, which may be related to subsequent adherence.

## Optimizing treatment and patient care through precision medicine: a threat or an opportunity for patients and patient organisations?

### OP0014-PARE UPDATING THE PATIENT PARTNER EDUCATIONAL PROGRAM FOR RHEUMATOID ARTHRITIS IN BELGIUM: A SYSTEMATIC, SCIENTIFIC-BASED APPROACH LED BY PATIENT EXPERTS

J. Van Rompay[1], A. Hoet[1], C. Geysen[1], E. Binnard[1], G. Patteet[1], L. Ovaere[1], W. Wilmots[1], K. Van der Elst[2], R. Westhovens[2]. *[1]Patient Partners® Program Belgium, Vosselaar; [2]Rheumatology, University Hospitals Leuven, Leuven, Belgium*

**Background:** Patient Partners (PP) are expert patients who train medical students, general practitioners and other healthcare providers about the clinical presentation of rheumatoid arthritis (RA). A direct objective is to improve musculoskeletal examination skills, facilitating appropriate referrals, fast diagnosis and early treatment initiation.
**Objectives:** We sought to critically review and update the PP Program for RA in Flanders because of changing needs based on new data about early intensive treatment strategies, patient beliefs and preferences in early RA, as well as about the hurdles to implement optimal care strategies.
**Methods:** We followed a structured plan of action, in which we aimed to make the course content more applicable to the new needs, and this for patients who are also more likely to present themselves without joint deformities, continuing their normal life as much as possible. Four content modules were developed by seven patient partners with RA who took the lead in this project. The other members of the project team were one rheumatologist, one nurse specialist and two doctoral researchers active in the field of early RA.
**Results:** After a brainstorm session by PP, a first team meeting was held to review their ideas and to add scientific input. They particularly indicated that the patient perspective (e.g., perceptions, impact of disease, general health advice) could be improved in the course content. Subsequently, the current content was reviewed and part of it was removed (focus on classical joint deformities), part of it was differently clustered. During this first debriefing, four content modules were proposed: aspects of treatment delay, treatment strategies and perceptions about medication (from a patient and healthcare provider perspective), the patient and his/her environment, and active participation. Next, the PP formed subgroups and worked out the modules. In a second debriefing, the modules were further refined and the new course structure was discussed including necessary adaptations to course material. We agreed on the implementation strategy. Thereafter, the updated program was presented to the entire group of PP during their annual meeting, and a credibility check was performed with a general practitioner and a medical student. Final changes were integrated based on their feedback. Lastly, during a two-day meeting, all PP were trained by the project team to implement the new content and structure in their lessons.
**Conclusions:** The update of the Belgian PP program for RA is an example of how expert patients can substantially be involved in updating educational programs. We strived to include new insights about RA and the patient perspective to a higher extent in the course content. Four content modules were implemented: aspects of treatment delay, perceptions about medication, the patient and his/her environment, and active participation. Making medical students and healthcare providers aware of the patient perspective is an important step towards optimal care in RA.

## Clinical relevance of immunogenicity and therapeutic drug monitoring

### OP0015 ANTIBODIES TO INFLIXIMAB IN REMICADE-TREATED RHEUMATIC PATIENTS SHOW IDENTICAL REACTIVITY TOWARDS BIOSIMILAR CT-P13

B. Ruiz-Argüello[1], A. Maguregui[1], A. Ruiz del Agua[1], D. Pascual-Salcedo[2], A. Martínez[2], T. Jurado[3], C. Plasencia[3], A. Balsa[3], J. Rosas[4], F. Llinares-Tello[5], N. Torres[1], A. Martínez[1], D. Nagore[1]. *[1]R&D, Progenika-Grifols, Derio; [2]Immunology; [3]Rheumatology, Hospital La Paz, Madrid; [4]Rheumatology; [5]Clinical Analysis, Hospital Marina Baixa, Villajoyosa, Spain*

**Background:** The first infliximab (IFX) biosimilar (CT-P13) in Europe is marketed as two brand names, Inflectra (IFT) and Remsima (RMS), that contain the same IFX molecule produced with the same manufacturing process. One of the main questions is whether patients treated with Remicade (RMC) can be effectively and safely switched to CT-P13.
**Objectives:** To determine if antibodies to infliximab (ATI) in RMC-treated patients cross-react with CT-P13.
**Methods:** Consecutive patients (250) with active rheumatoid arthritis (RA) and spondyloarthritis (SpA) under RMC treatment and never exposed to CT-P13, were retrospectively selected according to clinical information and anti-drug antibody (ADA) status. 37 IFX-naïve rheumatic patients, 19 IFX-naïve rheumatic patients with anti-adalimumab antibodies (AAA), and 21 healthy individuals were assayed as controls. ATI trough levels were measured in parallel with three different ELISA assays: #1 Promonitor-ANTI-IFX (Progenika, Spain) which uses RMC to crosslink patient ADA; #2 the same assay but using RMS, and #3 the same assay but using IFT.
**Results:** In total, 126 samples out of 250 Remicade-treated patient samples were tested positive with Promonitor-ANTI-IFX (50.4%, 131 patients). All were ATI-positive when either IFT or RMC bridging assays were used (Fig1). Positive and Negative Percent Agreements were 100%/100% for any comparison: RMC vs. IFT or RMC vs. RMS or IFT vs. RMS, respectively. Spearman's coefficients were determined to be 0.995, 0.996 and 0.998, for RMC vs. IFT, RMC vs. RMS, and IFT vs. RMS, respectively ($p<0.001$). No differences between RA and SpA, or between concomitant immunosuppressives, were observed. This is the first study that demonstrates cross-immunogenicity between RMC and a biosimilar molecule in patients with rheumatic diseases. Results are in agreement with previous data in patients with inflammatory bowel diseases[1].

**Conclusions:** ATI of RMC-treated patients cross-react with either IFT or RMS. Results suggest that the epitopes raising the immune response to the innovator drug are responsible for the same degree of reactivity when sera are confronted to the biosimilar molecule, although it must be noted that the biosimilar might present new epitopes due to different glycosylation pattern or impurities, and even conformational epitopes due to potential aggregations. ATI-positive patients treated with RMC should not be switched to a biosimilar treatment, since preexisting ATI will interact with the new drug, enhance clearance and potentially lead to loss of response and infusion-related reactions. Further studies with biosimilar-treated patients are warranted to increase our knowledge about potentially different immunogenic responses. Results also demonstrate that Promonitor-ANTI-IFX test can be used to monitor antibodies to CT-P13 in biosimilar-treated patients. This finding supports the utility for therapeutic drug monitoring before a switching strategy is considered.

### OP0016 INCREASED FREQUENCY OF ANTI-DRUG ANTIBODIES IN PATIENTS CARRYING COMPATIBLE IGG1 ALLOTYPES AND TREATED WITH ANTI-TNF ANTIBODIES

R. López-Rodríguez[1], A. Martínez[2], C. Plasencia[2], A. Jochems[2], D. Pascual-Salcedo[2], A. Balsa[2], A. Gonzalez[1]. [1]*Instituto de Investigación Sanitaria- Hospital Clínico Universitario de Santiago, Santiago de Compostela;* [2]*Instituto de Investigación Hospital Universitario La Paz (IDIPAZ), Madrid, Spain*

**Background:** One of the causes of insufficient response to biological drugs is the production of anti-drug antibodies (ADA) (1). These antibodies can decrease the effectiveness of treatment by altering bioavailability or by neutralizing the drug. In addition, they may contribute to hypersensitivity reactions. Some ADA are directed against IgG allotypes, which are protein polymorphisms able to induce an immune response in incompatible subjects. Infliximab (INX) and adalimumab (ADM) have the G1m17,1 allotypes, while about 50% of the Europeans are homozygous for the incompatible G1m3,n allotypes. Therefore, the allotypes could contribute to ADA and, in this way, explain the recently described loss of efficiency of INX in allotype-incompatible RA patients (2).
**Objectives:** We aimed to analyze the usefulness of IgG1 allotypes as biomarker of the development of ADA against INX and ADM.
**Methods:** The presence of ADA was determined in 252 consecutive patients with inflammatory arthritis in the Hospital La Paz (116 with rheumatoid arthritis (RA), 74 with ankylosing spondylitis (AS), 26 with psoriatic arthritis, 17 with non-radiographic spondylitis, 11 with spondylitis and inflammatory bowel disease, 3 with uveitis and 5 with other arthropathies). Patients were assessed during INX treatment (151), or with ADM (82), or sequentially during treatment with INX and ADM (19). ADA were determined by two-site bridging ELISA as described (1). Allotypes of IgG1 were determined by genotyping 2 SNPs, rs1071803 (for allotype G1m17/G1m3) and rs11621259 (for allotype G1m1/null) with the SNaPshot Multiplex kit (Applied Biosystems) as reported (2).
**Results:** Patients with compatible allotypes (carriers of G1m17,1) showed a larger frequency of ADA (33% *vs.* 20%, p=0.02) and a trend toward higher titers of these antibodies ($18.0x10^3$ *vs.* $8.3x10^3$ AU, ns) than patients with incompatible allotypes (homozygous for G1m3,n). This association was clearer in patients treated with INX (41% *vs.* 25%, p=0.03) than in those treated with ADM (18% *vs.* 12%, ns). ADA were more frequent in patients treated with INX than in those treated with ADM, as already known. Multivariate analysis showed that the frequency of ADA was increased in patients with RA compared to other diseases (OR =7.6, $p<0.0001$), and decreased in older patients (OR =0.65 per 10 years, $p<0.001$). Other factors, such as sex, having AS against other diseases, and treatment with methotrexate or corticosteroids, were not associated with ADA.
**Conclusions:** Patients with compatible allotypes showed more frequently ADA than patients with incompatible allotypes, showing for the first time this association in patients treated with INX and reinforcing the previously reported association for ADM (3). These results suggest a genetic factor in linkage with the allotype, but different from it, that will predispose to ADA.

## Outcome measures in clinical practice in gout and CPPD. The use of the new EULAR guidelines

### OP0017 MEDICATION TAKING BEHAVIOUR OF ALLOPURINOL TREATMENT AMONG PATIENTS WITH GOUT: A RETROSPECTIVE COHORT STUDY IN THE CLINICAL PRACTICE RESEARCH DATALINK (CPRD)

L.E. Scheepers[1], A.M. Burden[2], B. Spaetgens[1,2], I.C. Arts[3], F. de Vries[2], A. Boonen[1]. [1]*Rheumatology, CAPHRI, Maastricht University, Maastricht;* [2]*Pharmacoepidemiology and Clinical Pharmacology, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht;* [3]*Epidemiology, CARIM, CAPHRI, and MaCSBio, Maastricht University, Maastricht, Netherlands*

**Background:** Lowering serum uric acid concentrations is effective to control gout attack and prevent formation of tophi. Persistence with and adherence to uric acid lowering therapy are important to achieve benefit from medication. Therefore, insights into medication taking behaviour and factors influencing it, are extremely important.
**Objectives:** To describe patterns of persistence with and adherence to allopurinol treatment among gout patients in the UK, and explore determinants of non-persistence and non-adherence.
**Methods:** A retrospective cohort study using the UK Clinical Practice Research Datalink (CPRD) was conducted. Patients with a first ever diagnosing coding for gout between 1st January 1987 and 30th June 2014 were included. Start of follow-up was defined as the first prescription of allopurinol after the start of valid data collection. Patients were excluded if they were younger than 40 years, were (ever) users of febuxostat and probenecid, or had a follow-up of less than 90 days after completion of the first prescription. Determinants included patient characteristics (at baseline), medication use (6 months prior to index-date) and other comorbidities (ever before index-date). Medication taking behaviour was described by non-persistence (occurrence of a first gap of 30 or 90 days) and non-adherence (proportion of days covered [PDC] over observation period) to allopurinol treatment. Kaplan Meier survival and multivariable Cox- and logistic regression were used to estimate the median time until discontinuation, and the strength of the association between determinants with non-persistence (90-day gap) and non-adherence, respectively.
**Results:** A total of 47.744 gout patients (75.6% men; mean age 63.9 years) received allopurinol exclusively. After 5.3 years (SD 4.6) of follow-up 77% had a gap of 30-days and 54% had a gap of 90-days, and were non-persistence. Median survival time until discontinuation was 229 days (95% confidence interval [CI] 224 – 235) for a 30-day and 1059 days (CI 1012 – 1107) for a 90-day gap. The median PDC was 0.67 (IQR: 0.64). Over half of the patients (61%) were non-adherent ($PDC<0.80$) over the study period.
Females (HR 1.10; 95% CI 1.06–1.13; OR 1.21; CI 1.15–1.28) and current smokers (HR 1.15; CI 1.11–1.20; OR 1.17; CI 1.10–1.25) have an increased risk on non-persistence and non-adherence, while older age (ref: <50 years) (HR 0.77: CI, 0.74–0.80; OR 0.61; CI 0.58–0.65), overweight (HR 0.89; CI 0.86–0.92; OR 0.86; CI 0.82–0.91), receiving anti-hypertensive (HR 0.92; CI 0.89–0.96; OR: 0.64; CI 0.60–0.67), colchicine (OR 0.94; CI 0.89–0.98) and suffering from dementia (HR 0.58; CI 0.45–0.73; OR 0.59; CI 0.46–0.77), depression (HR 0.94; CI 0.89–0.99), diabetes (HR 0.86; CI 0.83–0.89; OR 0.90; CI 0.84–0.96) and dyslipidaemia (OR 0.81; CI 0.77–0.85) appear to decrease the risk of non-persistence and/or non-adherence.
**Conclusions:** This is the first large population based study in Europe which showed poor medication taking behaviour among gout patients initiating allopurinol. Females and current smokers have an increased risk, while an older age, overweight, receiving anti-hypertensives and suffering from certain comorbidities appear to decrease the risk of non-persistence and non-adherence.

**DOI:** 10.1136/annrheumdis-2016-eular.3107

### OP0018 HYPERURICEMIA INCREASES MORTALITY ONLY IN PATIENTS WITH GOUT AND EXISTING CARDIOVASCULAR DISEASE. A PROSPECTIVE ANALYSIS FROM THE BUSSELTON HEALTH STUDY

J. Nossent[1,2], W. Raymond[2], M. Divitini[3], L. Host[1], M. Knuiman[3]. [1]*Department of Rheumatology, Sir Charles Gairdner Hospital;* [2]*School of Medicine & Pharmacology;* [3]*School of Population Health, University of Western Australia, Perth, Australia*

**Background:** Hyperuricemia is increasingly prevalent and associated with cardiovascular disease [1]. While hyperuricemia can induce endothelial dysfunction, oxidative stress and inflammation uncertainty remains regarding the association between hyperuricemia and vascular events [2,3].
**Objectives:** Investigate whether baseline and/or time averaged UA levels were associated with cardiovascular events and mortality in the Busselton Health Study (BHS) cohort.
**Methods:** Prospective study of the BHS cohort (n=4,171), using baseline serum UA measures and 15 year follow-up [4]. Outcomes included were cardiovascular events (CVE) and mortality, derived from State-wide registries. Hazard ratios (HR) for UA level as continuous and categorical (low, medium, high) predictor of outcomes, stratified for baseline cardiovascular disease and a history of gout were analysed by multivariate Cox regression.
**Results:** Hyperuricemia was present in 9.4% in participants free of CVE and 16.5% in those with CVE at baseline. In those free of CVE (n=3,475), a 0.1mmol/L rise in UA level was associated with increased mortality (HR 1.19, CI 1.04–1.36), cardiovascular mortality (HR 1.27, CI 1.03–1.57) and first CVE (HR 1.28, CI 1.13–1.44) after age & sex adjustment. Hyperuricemia significantly increased the risk of a first CVE (HR 1.52, CI 1.13–2.04). However, adjustment for a range of traditional cardiovascular risk factors attenuated these associations. Results were similar for the subset of 2,139 participants using multiple UA measures over time. In the fully adjusted model, gout was a significant independent predictor of mortality only in participants with a history of CVE at baseline (HR 1.75; CI 1.04–2.95).
**Conclusions:** Hyperuricemia is highly prevalent in the Busselton region of Western Australia and independently increased the risk CVE or mortality events in those with existing CVE and gout. UA lowering therapy for CVE prevention is advisable for patients with a history of gout and CVE, but clearly not warranted in those with asymptomatic hyperuricemia.

## Hand osteoarthritis: state of the art and future perspectives

### OP0019-HPR EFFECTIVENESS OF A PROGRESSIVE RESISTANCE STRENGTH PROGRAM ON HAND OSTEOARTHRITIS: A RANDOMISED CONTROLLED TRIAL

M.V. Nery, A. Jones, F. Jennings, M.C. Souza, J. Natour. *Rheumatology, Universidade Federal de São Paulo, São Paulo, Brazil*

**Background:** Hand osteoarthritis is highly prevalent, affecting 55–70% of the population over 55 years with an age-related progressive increase. The OA of interphalangeal and carpometacarpal joints may have varying degrees of deformity associated with pain, decreased of grip and pinch strength, decreased range of motion and functional impairment. Effects of exercise in HOA in pain, function and strength is stiill unclear and based on experts opinions.
**Objectives:** To assess the effectiveness of progressive resistance strength training program on pain, function and strength in hand OA patients.
**Methods:** Diagnostic of hand OA according to ACR of at least 1year,over 50 years, both genders, pain in IF joints between 3–8 cm on NPS. Sixty patients who met the eligibility criteria were randomised into exercise group (EG) and control group (CG). Both groups performed a session regarding joint protection and energy conservation before randomisation. The EG performed a progressive resistance strength training program for intrinsic muscles of the hand for 12 weeks. The outcome measures were NPS, AUSCAN and COCHIN for hand function; grip and pinch strength using hydraulic hand dynamometers and patient satisfaction using a Likert scale. A blinded evaluator performed the evaluations at baseline, 6 and 12 weeks after treatment baseline.
**Results:** The groups were homogeneous at baseline except for the key pinch strength for nondominant hand and palmar pinch strength for both hands. The comparison between groups using repeated measures ANOVA shows an statistically difference between groups in AUSCAN (total score, p=0.005; pain, p=0.006 and function, p=0.047), COCHIN (p=0.042) and Likert scale (p=0.001) with better results for the EG. Results were presented in table 1.

## Chronobiology of the immune reponse

### OP0020 THE ASSOCIATION OF GONADOTROPIN-RELEASING HORMONE AND CYTOKINES IN RHEUMATOID ARTHRITIS

A. Kåss[1], I. Hollan[2], H.C. Gulseth[1], Ø. Førre[3]. *[1]Department of Rheumatology, Betanien Hospital, Skien, Norway; [2]Division of Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, United States; [3]Department of Rheumatology, Oslo University Hospital, Oslo, Norway*

**Background:** Improvement of rheumatoid arthritis (RA) in pregnancy, and worsening postpartum is well known. This led to the finding that cortisone had anti-inflammatory effects. The hypothalamic proinflammatory hormone, gonadotropin-releasing hormone (GnRH), is the master regulator of the reproductive system, and also has a circadian rhythm. GnRH activity diminishes in pregnancy and increases postpartum. Prior to our AGRA (Antagonist to Gonadotropin Releasing Hormone in RA) trial, no research in RA had been performed on this principal hormone. GnRH can act like a cytokine in the periphery, being secreted by T cells (1). In the AGRA trial, GnRH antagonism showed anti-inflammatory effects including a significant reduction in TNF in RA patients. GnRH antagonists decrease inflammatory cytokine mRNA, and downregulate the NF-κB pathway. Conversely, GnRH agonists are associated with the onset and flares of autoimmune diseases.
**Objectives:** The purpose of this study was to investigate for the first time whether GnRH exists in the periphery in patients with an autoimmune disease. If GnRH exists in the periphery in patients with RA, is GnRH associated with cytokines?
**Methods:** Predefined endpoints from our proof-of-concept randomized, double-blind, Norwegian AGRA study (N=99, ITT population) with active RA have been reported earlier (ClinicalTrials.gov NCT00667758). Patients were randomized using computer-generated allocation (1:1) in dynamic blocks stratified for sex. Patients were assigned to cetrorelix, a GnRH antagonist (5mg days 1–2, 3mg days 3–5) or corresponding volumes of placebo. Blood sampling was at the same time of day and frozen to -80. We investigated serum GnRH baseline pretreatment levels using newly available ELISA assays according to the manufacturer's instructions, in duplicates, inter-assay CV<10% (USCN Life Science Inc.). Four serum cytokines were measured with multiplex technology (Luminex Inc.).
**Results:** Mean peripheral GnRH level at baseline was 241 pg/mL (s.d. ±83 pg/mL).

Table 1. Correlations of absolute levels of baseline cytokines, GnRH and confounding hormones in RA patients

| Variable | TNF | IL1 | IL10 | IL2 |
|---|---|---|---|---|
| GnRH (n=96) | 0.220 * | 0.396** | 0.239* | NS |
| Luteinizing Hormone (n=99) | NS | NS | NS | NS |
| Follicle-Stimulating Hormone (n=98) | NS | NS | NS | NS |
| Cortisol (n=99) | NS | NS | NS | NS |
| TNF (n=98) | – | 0.761** | 0.873** | 0.912** |
| IL1 (n=98) | 0.838** | – | 0.958** | 0.974** |
| IL10 (n=99) | 0.752** | 0.958** | – | 0.991** |
| IL2 (n=99) | 0.856** | 0.974** | 0.991** | – |

*p<0.05; **p≤0.001; NS, non-significant.

By day 5, TNF levels were significantly reduced by the GnRH antagonist vs. placebo (p=0.023). GnRH levels were not significantly changed by day 5.
**Conclusions:** Peripheral GnRH is presented for the first time in autoimmunity. Due to GnRH's potential association with cytokines, the existence of peripheral GnRH may be due to GnRH production by T cells (1). These results could support preexisiting literature on GnRH and the immune system, that GnRH stimulates the secretion of cytokines peripherally, and help to explain clinical observations. These results warrant confirmation.

### OP0021-HPR SLEEP DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND RELATIONSHIP WITH DISEASE ACTIVITY

L. Villarreal[1], J. Bello[2], P. Santos-Moreno[2], N. Palacio[3], C. Castro[4], D. Buitrago-Garcia[4]. *[1]Psychology; [2]Rheumatology; [3]Nursing; [4]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** The rheumatoid arthritis (RA), as known, causes inability in various performance areas mostly in the musculoskeletal. Reduced physical activity, substantial disability and also sleep disorders have previously been described in people with RA.
**Objectives:** The aim of this study was to describe the socio-demographic profile and sleep disorders in RA patients from a specialized RA clinic in Colombia.
**Methods:** A descriptive cross-sectional study was performed in a specialized clinic dedicated to care patients with rheumatoid arthritis (RA). 1298 patients were included in the study, which were seen by the area of psychology, which information was collected through semi-structured interviews and non-probability sampling. Descriptive epidemiology was applied for continuous variables, using measures of central tendency and dispersion for categorical and qualitative variables by averages and percentages. We used chi2 test to study a possible relationship between the severity of disease activity and the sleep disorders.
**Results:** Total sample of patients was 1298, 1048 (80%) were women and 250 (19%) were men. Patients had a DAS28 2.6 in average ± 1.1; mean age was 55.1 ± 8.8 years; 846 (65%) were in remission, 205 (16%) were in low disease activity, 208 (16%) in moderate disease activity and 42 in severe disease activity (3%). Regarding education, 6% were illiterate, 44% had elementary school, 33% high school, 8% had a technical degree and only 7% had college level. 373 (28%) patients showed any sleep disorder, among type of sleep disorders were seen: primary insomnia 299 patients (80% of women and 20% of men), related sleep

disorder breathing (OSAS) 33 Patients (70% of women and 30% of men) and 20 patients with circadian rhythm disorder (74% of women and 26% of men), and hypersomnia 13 patients (92% of women and 8% men). It was established a relationship between having a sleep disorder and severity of disease activity statistically significant ($p<0.00$).
**Conclusions:** According to these findings sleep disorders are likely present in a great proportion patients with RA and in many cases linked with disease activity. Primary insomnia is the most prevalent.
**Disclosure of Interest:** None declared

## Nanomedicine in rheumatology

### OP0022 TARGETING FIBROBLASTOID-LIKE CELLS BY DRUG LOADED ENGINEERED GOLD NANOPARTICLES AS A NOVEL APPROACH FOR ILD-SSC TREATMENT

E. Cova[1], V. Codullo[2], S. Inghilleri[3], M. Colombo[4], D. Prosperi[5], F. Meloni[3], C. Montecucco[2]. *[1]Pneumology Unit; [2]Rheumatology Unit; [3]IRCCS policlinico San Matteo Foundation, Pavia; [4]Biotechnologies and Biosciences Dept; [5]University of Milan, Milan, Italy*

**Background:** Systemic Sclerosis (SSc) is an autoimmune fibrotic disorder characterised by collagen and extracellular matrix deposition in the skin and internal organs, such as the lung. Interstitial lung involvement (ILD) is frequent in SSc but effective therapies are lacking and ILD represents one of the most frequent causes of death. Gold nanoparticles (GNPs) have a great potential in biomedical applications among which drug-delivery. Previously, we proved that GNPs containing everolimus and functionalized with anti-CD44 antibody targeted to mesenchymal cells from patients with chronic lung allograft rejection (CLAD) specifically inhibited these cells. We proved that also fibroblastoid-like cells (FLCs) isolated from bronchoalveolar lavage (BAL) of ILD-SSc patients express CD44.
**Objectives:** we loaded GNPs with the drug imatinib (GNP-HCim) with the aim to specifically inhibit FLCs from ILD-SSc patients.
**Methods:** GNPs with imatinib and exposing an anti-CD44 antibody were engineered, as previously described (1).
GNP-HCim were incubated 2h with FLCs from three patients with ILD-SSc. Cell apoptosis (Annexin V) and proliferation (CFSE) were evaluated at different times by flow cytometry. Cell viability was assessed by MTT test. As control, functionalized GNPs without imatinib (GNP-HC) or imatinib alone (IM) were used. Fluorescent GNP-HC were generated to assess cell uptake by confocal microscopy and flow cytometry.
Statistical differences were evaluated using ANOVA by Graph Prism 5.0 program.
**Results:** Fluoresce experiments showed that only HC-functionalized nanoparticles entered FLCs within 1 h. The results showed that GNP-HCim inhibited cell proliferation without significant differences between the three cell lines. In particular, the effect of GNP-HCim was significant at 48 ($p<0.001$) and 72h ($p<0.01$). A significant inhibition was also observed in presence of GNP-HC both after 48 ($p<0.01$) and 72h ($p<0.05$). No changes were produced by IM alone (fig. 1). MTT assay confirmed the results obtained by CFSE since a significant reduction ($p<0.001$) of cell viability was observed with GNP-HCim and GNP-HC starting from 48 h. IM treatment affected the FLCs viability ($p<0.05$ at 48h; $p<0.001$ at 72h). Functionalized nanoparticles were able to significantly increase apoptosis after 8 ($p=0.0051$) and 24 h ($p<0.001$) compared to uFLCs. However, only drug-loaded nanoparticles still significantly increased apoptotic rate after 48 h ($p=0.004$).
**Conclusions:** We proved that specifically engineered GNPs significantly inhibit proliferation and induce apoptosis of FLCs from ILD-SSc patients, as already described for CLAD patients. FLCs treatment with imatinib alone was not effective as GNP-HCim demonstrating the superiority of the nanoparticles. Our results also suggest an unspecific effect of nanoparticles themselves which has to be further clarified before the possibility to use engineered nanoparticles to develop new pharmacological treatment for patients with pulmonary fibroproliferative disorders.

### OP0023 TARGETED POLYMERIC NANOPARTICLES AS DIAGNOSTIC AND THERAPEUTIC TOOL FOR RHEUMATOID ARTHRITIS

F. Colombo[1], L. Nunez[2], P. Durigutto[1], S. Biffi[3], E. Rampazzo[4], B. Belmonte[5], D. Sblattero[1], A. Gulino[6], P.L. Meroni[7], F. Tedesco[7], P. Macor[1]. *[1]Department of Life Sciences, University of Trieste, Trieste, Italy; [2]BioTarget Chicago, Illinois, United States; [3]Institute for Maternal and Child Health, IRCCS "Burlo Garofolo", Trieste; [4]Department of Chemistry "G. Ciamician", University of Bologna, Bologna; [5]Department of Human Pathology; [6]Tumor Immunology Unit, Department of Health Sciences, University of Palermo, Palermo; [7]Division of Rheumatology, Department of Clinical Sciences and Community Health, University of Milan Istituto Auxologico Italiano, Milan, Italy*

**Background:** Rheumatoid arthritis (RA) is a chronic, systemic autoimmune disease affecting joints due to the persistent synovial tissue inflammation. RA treatment has dramatically evolved in the last 20 years due to the production of biological Disease Modifying Antirheumatic Drugs (bDMARDs). However, side effects and the high costs of biological drugs are holding back their widespread usage. Moreover, some patients fail to respond to bDMARDs, for all of these reasons, DMARDs remains the main desired strategy for the treatment of RA, and Methotrexate (MTX) is still the "anchor" drug to treat RA. A successful treatment depends also on the early diagnosis, treating patients as soon as possible to prevent the late stages of the pathology.
**Objectives:** The aim of this work is to develop targeted biodegradable nanoparticles (tBNPs) that could be used as a platform suitable to delivery drugs or diagnostic tracers specifically into the inflamed synovial tissue. This approach usually allows to enhance the efficacy and to reduce the side effects.
**Methods:** We used polymeric biodegradable nanoparticles, made of polylactic acid, polycaprolactone and polyethylene glycol and coated with a peptide characterized for its ability to target only inflamed synovial tissue. The tBNPs diameter was 170 nm with a low negative charge. Toxicity was studied in-vitro assay and in-vivo. Immunofluorescence technique was used to initially assess the ability of fluorescent-tBNPs to preferentially target inflamed synovial tissue. The biodistribution of the nanoparticles and the efficacy of the treatment with tBNPs loaded with MTX were studied in a rat model of antigen-induced arthritis (AIA). Finally, tBNPs efficacy was also studied in a mouse model of collagen-induced arthritis (CIA).
**Results:** Targeted BNPs evidenced the ability to specifically bind inflamed synovial tissue both in vitro and in vivo. The targeting is dependent on the inflammation degree and this highlights the potentiality of the tBNPs as an early diagnostics tools. A single injection of targeted BNPs loaded with MTX completely abrogated the inflammatory process in acute AIA rat model while the same dose of free-MTX was ineffective. Equivalent therapeutic effects were obtained comparing MTX-loaded tBNPs and the same dose of free-MTX in the mouse model of chronic CIA and no toxic effect was documented when MTX was loaded in nanoparticles in these animals.
**Conclusions:** Our results demonstrated that tBNPs can efficiently and selectively delivery drugs and diagnostic probes to inflamed synovial tissue, providing a new platform for an early detection and efficient chronic treatment of inflammatory arthritis, with minimal side effects.

## Patient organisations in action

### OP0024-PARE DEVELOPMENT AND USE OF A CANADIAN ARTHRITIS PATIENT CHARTER

D.P. Richards, L. Wilhelm, L. Proulx, N. Robertson. *Canadian Arthritis Patient Alliance, Toronto, Canada*

**Background:** In 2001, the Arthritis Society in Canada created a Canadian Arthritis Patient Bill of Rights with multiple stakeholders[1]. In the subsequent 15 years, the landscape of arthritis and its care has changed dramatically. A patient-led and driven not for profit organization, the Canadian Arthritis Patient Alliance (CAPA), wished to provide patients and healthcare providers a new tool that reflected this evolution – a Canadian Arthritis Patient Charter (Charter)[2]. The Charter was created to enable conversation, better partnership, and improved patient outcomes. CAPA believes patients have both rights and responsibilities in the care and management of their disease, and as such, the Charter includes both.
**Objectives:** In 2014, CAPA led the creation of the Charter - a modernization of the Canadian Arthritis Patient Bill of Rights. We present the Charter's development and launch, its publicity, uses and perceived effect on patient care.
**Methods:** CAPA has driven this project with support from multiple arthritis stakeholders within Canada (including the Ontario Rheumatology Association, the Arthritis Society, the Arthritis Alliance of Canada, the Canadian Rheumatology Association, Arthritis Consumer Experts, Patient Partners, the Canadian Spondylitis Association, and individual patients). One Board member acted as

project manager and sought input from members of the arthritis community. Methods to achieve this included phone calls, in person meetings, emails, and online surveys.
**Results:** A Charter was created with input from all arthritis stakeholders, including patients, family and friends, health care professionals, not for profit, and industry. Through meetings over a year, the stakeholders outlined a draft Charter. Public feedback solicited through an online survey publicized by stakeholders through their own networks (including newsletters, social media, websites) led to over 730 survey responses. The Charter (postcard and poster versions in Canada's two official languages) permanently resides on CAPA's website and was mailed to all Canadian Rheumatology Association members. CAPA and its partners disseminated news about the Charter for September's Arthritis Month (newsletters, social media, articles online); these efforts continue. The Charter has been shared in blogs[3,4] and journals[5,6] and on Facebook and social media, and we will present the number of downloads and hits the CAPA website has had. Its limited use in rheumatology offices will be discussed and patients' perceptions on how it has impacted their care will be presented.
**Conclusions:** The Canadian Arthritis Patient Charter was created to support increased patient engagement in their rheumatology care. It was intended to help increase patients dialogue with their healthcare providers, help them understand rights and responsibilities associated with their care, and improve outcomes.

### OP0025-PARE INFORMATIVE AND PREVENTIVE CAMPAIGNS AT THE CITY COUNCILS IN THE GALICIAN REGION

A.I. Vázquez Lojo[1], V. Romero Pazos[2], C. Van Riel[3], F.J. Carreira Roca[4] on behalf of Liga Reumatolóxica Galega. *[1]Board of Directors; [2]Project Manager; [3]Educational Dept; [4]Accesibility Dept., Liga Reumatolóxica Galega, A Coruña, Spain*

**Background:** There are more than 250 types of rheumatic diseases (RDs), in Galicia there are 1.065.841 persons affected (40% of the population), these cause 50% of the incapacities and 20% of the medical leaves. These diseases affect children and young adults and they become chronic in most of the cases.
**Objectives:** To prevent affected population without a diagnosis.
40% of the population is affected by RDs, many of these pathologies present themselves very quietly. There are many myths around RD patients like it only affects old people or that it does not have cure, because of this many of them do not go to the doctor or they wait too long to go. It is also very common to recognize indications of denial or selfdeception. The presence of these diseases increase exponentially with the increase of the population and the actual pace of life. In Galicia this fact is aggravated because of the aging of the population and it is heading to the early appereance in people in their 40s.
**Methods:** Our team is formed by:
1 psychologist who detects pychological indications, point out the denial signs and the conflict with the illness.
1 rheumatologist who informs about the nature of the RDs.
2 occupational therapists who inform about alert signals and preventive measures of the articular damage.
1 expert patient who transmit his experience on how it feels to be affected by a RD.
1 coordinator in charge of stablising the link between the city council and our organization through scedules and coordination of the activities.
We visit diferent city councils, setting up previously the dates for the general and specific informative sessions. During those sessions we detect possible profiles of denial, doubt, etc. And afterwards we do the data processing.
**Results:** Out of 100 persons that go to these informative campaigns 3 of them go to the Rheumatology Department in their Health Center and end up with a positive diagnosis. This does not mean that these are the only ones but at least we increase the consultations.
We have developed a standarized quiz for the doctors to questions their patients about how they got to decide about consulting a rheumatologist.
**Conclusions:** The Galician population presents an alarming lack of awarness on how to identify RDs and it is ignoranto to its consequences.
In many cases, the affected person does not go to the general practitioner and because of this he is not derivated to the rheumatologist, missing the key phase, meaning=Early diagnosis.
RDs are very serious pathologies that if not treated for a long time can derivate in incapacities, joint affections and irreversible vital organs malfunction.

## Plasma cells as key players and therapeutic target in rheumatic disaeses

### OP0026 SYNOVIAL FLUID MONONUCLEAR CELLS PROVIDE AN ENVIRONMENT FOR LONG-TERM SURVIVAL OF ANTIBODY SECRETING CELLS AND PROMOTE THE SPONTANEOUS PRODUCTION OF ANTI-CITRULLINATED PROTEIN ANTIBODIES

P.F. Kerkman[1], A.C. Kempers[1], E.I. van der Voort[1], M. van Oosterhout[2], T.W. Huizinga[1], R.E. Toes[1], H.U. Scherer[1]. *[1]Department of Rheumatology, Leiden University Medical Center, Leiden; [2]Department of Rheumatology, Groene Hart Ziekenhuis, Gouda, Netherlands*

**Background:** Rheumatoid arthritis (RA) is characterized by the presence of antibodies against citrullinated protein antigens (ACPA). The striking efficacy of B cell-depleting interventions and an increasing number of experimental observations suggest that ACPA and/or ACPA-expressing B cells could be actively involved in initiating, aggravating and/or perpetuating the disease process. We recently demonstrated that ACPA-expressing B cells circulate in the peripheral blood of patients with ACPA-positive RA[1,2]. Next to ACPA-expressing memory B cells, we could identify a population of plasmablasts/-cells (PB/PC) that actively secrete ACPA in this compartment. To date, however, it is unknown whether these circulating PB/PC home to secondary lymphoid organs to compete for survival niches, or whether the synovial compartment of inflamed joints could be one of the tissues attracting these cells. As PC can produce excessive amounts of antibodies and survive in respective niches for years, they could be involved in driving and maintaining disease-specific pathogenic processes.
**Objectives:** To study whether cells from the synovial environment impact on the longevity of auto-reactive B cell responses against citrullinated antigens.
**Methods:** Synovial fluid and peripheral blood mononuclear cells (SFMC/PBMC) were obtained from patients with established RA and assessed for the presence of B cell subpopulations. Cells spontaneously secreting ACPA-IgG directly ex vivo were detected and enumerated by antigen-specific ELISpot. In addition, SFMC and PBMC were cultured without additional stimuli to assess the degree of spontaneous ACPA-IgG secretion. Cells surviving for several weeks in culture were characterized by CFSE-labelling and Ki-67 staining.
**Results:** Cells spontaneously secreting ACPA-IgG were readily detectable in peripheral blood and synovial fluid (SF) of ACPA-positive RA patients. SFMC showed an up to 200-fold increase in ex vivo ACPA-IgG secretion compared to PBMC despite lower numbers of B cells in SFMC. ELISpot confirmed the presence of spontaneously ACPA-IgG secreting cells, accounting for up to 50% (median 12%) of all IgG-secreting cells in SF. Spontaneous ACPA-IgG secretion was remarkably stable in SFMC cultures, maintained upon depletion of the $CD20^+$ B cell compartment prior to culture, and detectable for several months. CFSE labelling and Ki-67 staining confirmed the long-term survival of non-dividing plasma cells.
**Conclusions:** This study demonstrates a high frequency of differentiated, spontaneously ACPA-IgG secreting cells in SF. These cells are supported by SFMC for prolonged survival and autoantibody secretion, demonstrating that the synovial compartment is equipped to function as inflammatory niche for plasma cell survival.

OP0027 **ABNORMAL B CELL ACTIVATION THROUGH CELLULAR METABOLIC REPROGRAMMING AND ITS RELEVANCE TO THE PATHOGENESIS OF SLE**

M. Torigoe[1,2], S. Iwata[1], K. Sakata[1,3], S. Nakayamada[1], Y. Tanaka[1]. *[1]First Department of Internal Medicine, University of Occupational & Environmental Health, Japan, Kitakyushu; [2]Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Oita University, Oita; [3]Mitsubishi Tanabe Pharma, Yokohama, Japan*

**Background:** B cells play a pivotal role in autoimmune diseases. In SLE, IFN signature is displayed and aberrant function of Toll-like receptors (TLR) for recognizing nucleic acids contributes to its pathology. Peripheral plasmablasts increase in active SLE, but the relevance of cellular metabolisms to B cell differentiation to plasmablasts remains unclear.
**Objectives:** To examine the mechanism by which cellular metabolic reprogramming regulates human B cell differentiation in vitro, and its involvement in pathological processes of SLE.
**Methods:** Human B cells were obtained from peripheral blood of healthy donors (HDs), and separated into 3 subsets; naïve ($IgD^+CD27^-$), IgM memory ($IgD^+CD27^+$) and class-switched (CS) memory B cells ($IgD^-CD27^+$). Each subset was cultured with CpG DNA (ligand of TLR9) and/or IFN-α. Plasmablast ($CD27^{hi}$) differentiation, immunoglobulin (IgM, IgG), and cytokine production (IL-6, IL-10), and cellular metabolism (mTORC1, AMPK, glycolysis) were assessed.
**Results:** When IgM memory B cells and CS memory B cells were stimulated with CpG, robust production of IL-6 and IL-10 as well as differentiation to plasmablasts were induced. The gene expression of IRF4, XBP1 and PRDM1 was increased by CpG, whereas that of BACH2 and BCL6 was decreased. These responses were amplified by IFN-α, which was abrogated by anti-IFNAR2 Abs. A JAK inhibitor tofacitinib did not attenuate CpG-induced B cell differentiation to plasmablasts, indicating that JAK-mediated signaling by autocrine IL-6 and IL-10 was not relevant to the differentiation. Next, we analyzed cellular metabolic reprogramming during B cell differentiation, which was recently highlighted for its involvement in T cell differentiation. CpG stimulation strongly induced p-mTORC1 and lactic acid production, indicating that there is a metabolic shift to glycolysis in B cells. IFN-α further augmented this pathway. However, a glycolysis inhibitor, 2-deoxy-D-glucose and an mTORC1 inhibitor, rapamycin significantly abrogated lactic acid production, cytokine production and plasmablast differentiation of B cells in a dose-dependent manner. AMPK activators, metformin and AICAR, which are known to indirectly inhibit mTORC1, not only suppressed plasmablast differentiation but also induced $IgD^-CD27^-$ memory B cells. These results indicate that CpG and IFN-α shifted mTORC1/AMPK balance toward mTORC1 activation and glycolysis, leading to plasmablast differentiation. Interestingly, p-mTORC1 was significantly enhanced in B cells of SLE patients, compared to HDs ($p<0.05$), and it positively correlated with percentage of peripheral plasmablasts ($r=0.709$, $p<0.01$) and SLEDAI score ($r=0.453$, $p<0.05$), and negatively correlated with CH50 ($r=-0.452$, $p<0.05$).
**Conclusions:** CpG and IFN-α shifted mTORC1/AMPK balance toward mTORC1 activation and glycolysis, resulting in plasmablast differentiation, especially in memory B cells. The metabolic shift to anabolism supplied sufficient proteins and nucleic acids for rapid cell proliferation, permitting efficient differentiation to plasmablasts. Abnormal B cell activation through cellular metabolic reprogramming could contribute to SLE pathology. Thus, we first propose the disturbance of "immunometabolism" in B cells, and the regulation of B cell metabolism can provide a new therapeutic strategy against SLE.

## Global year against joint pain

OP0028 **ASSOCIATION OF DIFFERENTIAL SYNOVIAL EXPRESSION PATTERNS IN EARLY OSTEOARTHRITIS WITH PAIN AND PROGRESSION OF JOINT DAMAGE**

A. Blom[1], M. van den Bosch[1], H. Cats[2], F. van den Hoogen[2,3], F. Lafeber[4], W. van den Berg[1], P. van Lent[1], P. van der Kraan[1]. *[1]Experimental Rheumatology, Radboud University Medical Center; [2]Rheumatology, Sint Maartensclinic; [3]Rheumatology, Radboud University Medical Center, Nijmegen; [4]Univ. Med. Center, Utrecht, Netherlands*

**Background:** The cause for chronic pain in OA is largely unknown. Over 50% of osteoarthritis (OA) patients show synovial inflammation, even at early stages of the disease. However, if and how this synovial activation contributes to joint pathology and pain, is not known.
**Objectives:** To identify pathways that predict progression of cartilage damage and osteophyte (OP) formation in OA. In addition, we identified association between gene expression and pain in a cross-sectional approach.
**Methods:** From 25 patients with knee OA that entered the CHECK Cohort study (Cohort Hip and Cohort Knee) synovial biopsies were collected at baseline. CHECK is a prospective 10-year follow-up study on patients with early osteoarthritis-related complaints initiated by the Dutch Arthritis Foundation. Progression over 5 years was determined radiographically based on change of joint space width (JSW) and OP size in these radiographs. Pain was assessed at baseline by the WOMAC pain questionnaire. Synovial samples from baseline were studied using histology and microarray (affymetrix U133-plus-2.0), and Functional Annotation Clustering (FAC).
**Results:** We identified patients that were marked progressors or non-progressors, either based on JSW (respectively n=13 vs n=8) or OP size (respectively n=10 vs n=11) at these time points. Among the genes that were differentially expressed by OP progressors were MMP1, 2, 3, 9 and -14, whereas in JSW-progressors only MMP1 was differentially expressed. In the group of JSW-progressors, macrophage markers like CD14, S100A8, S100A9, MHC class II genes, and CXCR2 were positively associated with progression. This indicates that expression of these factors predict progression of cartilage damage in OA patients. The OP-progressors showed an increase of most of these markers, but to a far lesser extent. Using FAC we identified inflammatory response, macrophage differentiation, blood vessel formation, ossification and cell migration to be enriched in JSW-progressors. Blood vessel formation, wound healing, ossification and cell proliferation were enriched in OP-progressors. Histologically, in the JSW-progressors the lining layer was thicker and the cellularity was higher in the sublining compared to non-progressors, and compared to OP progressors. Both JSW-progressors and osteophyte-progressors showed increased vascularisation compared to non-progressors.
At baseline, FAC analysis pointed out that dendrite formation (p=0.036) response to heatshock/stress (p=0.015) and voltage gated ion transport (p=0.013) were annotation clusters that were related to pain. Surprisingly, no positive relation was found between inflammatory mediators and pain. In line with this, no relation between histological inflammation or lining thickness and pain was found.
**Conclusions:** We found evidence for a difference in underlying processes in the synovium regarding progression of cartilage damage and progression of osteophyte formation. The presence of macrophages, especially in the lining layer, is associated with progression of cartilage damage, whereas synovial expression of MMPs correlated to progression of osteophyte formation. Pain was associated with several nerve fiber related processes.
**Disclosure of Interest:** None declared

OP0029 **PAIN SENSITIZATION AND RESPONSE TO PHYSIOTHERAPY TREATMENT IN PEOPLE WITH MODERATE TO SEVERE OSTEOARTHRITIS OF THE KNEE**

H. O'Leary[1], C. Doody[1], K. Smart[2], N. Maloney[3]. *[1]School of Physiotherapy and Performance Science, University College Dublin; [2]Physiotherapy Department, St. Vincent's University Hospital, Dublin, Ireland; [3]Department of Health Sciences, Macquarie University, New South Wales, Australia*

**Background:** The clinical relevance of pain sensitization in knee osteoarthritis (OA) has been highlighted, whereby individuals with more severe knee pain demonstrate widespread hyperalgesia and increased temporal summation report. Physiotherapy is a frequently recommended conservative intervention for knee OA, however not all patients achieve clinically meaningful improvements in pain and function. To date the relationship between QST parameters and subsequent response to physiotherapy has not been prospectively investigated.
**Objectives:** The purpose of this prospective cohort study was to compare the somatosensory characteristics of people with knee OA who responded to physiotherapy with those who did not show a clinically meaningful response. We hypothesized that the non-responders to physiotherapy would demonstrate more evidence of pain sensitization at baseline.
**Methods:** A comprehensive battery of Quantitative Sensory Testing (QST) was conducted in 122 participants with knee OA referred for physiotherapy. QST measures included pressure pain thresholds (PPTs) measured at local, distal and remote sites, temporal summation (TS) at local and remore sites and conditioned pain modulation (CPM), in addition to measuring vibration threshold and mechanical detection thresholds.
Following physiotherapy participants were classified into responder and non-responder groups based on their change in WOMAC pain and function scores, and participants' global rating of change using the Outcome Measures in Rheumatology- Osteoarthritis Research Soceity International (OMERACT-OARSI) criteria.
A one-way between-groups multivariate analysis of variance (MANOVA) was performed to investigates effects of group (responder/non-responder) differences on QST parameters using a Bonferroni adjusted alpha level (p=.0083).
**Results:** 43 participants (35%) were responders to physiotherapy and 79 participants (65%) were non-responders. There were no significant differences in gender and age between the two groups. Likewise there were no significant differences between the groups with respect to sensory hypoesthesia (vibration and light touch).

The responder group demonstrated significantly higher PPTs at the arm (M =375kPa, SD =93.5) and tibia (M =378 kPa, SD =116) compared to the non-responder group (arm PPT, M =330 kPa, SD =85.2; tibia PPT, M =318.5, SD =96). Significantly lower temporal summation was also demonstrated in the responder group at the arm (M=1.1, SD=1.2) and at the knee (M =1.9, SD =1.6) compared to the non-responder group (TS arm M =1.9; SD =1.3; TS knee M =2.8, SD =1.46). The responder group also showed a more efficient CPM response (103% CPM change) compared to the non-responder group (99% CPM change), however these differences were not statistically significant (p=.056).

**Conclusions:** In knee OA non-responders to physiotherapy have a different somatosensory profile, showing increased hyperalgesia and enhanced temporal summation. While the results do not address predictors of treatment response, participants with greater indications of pain sensitization were more likely to be "non-responders" to physiotherapy. Patients identified at baseline as less likely to benefit from physiotherapy may warrant an alternate treatment approach.

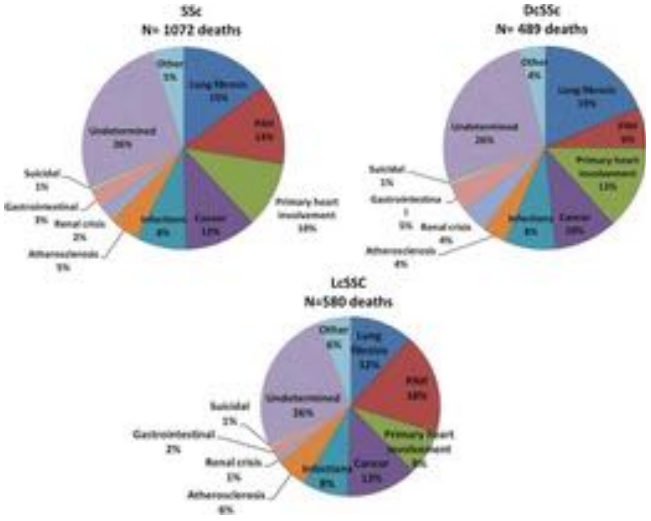
## Diagnosis and management of SSc

### OP0030 ASSOCIATED FACTORS WITH MORTALITY AND DERIVATION OF A SIMPLE 5-FACTORS TO PREDICT MORTALITY IN SSC-PATIENTS IN THE EUSTAR COHORT

M. Elhai[1], C. Meune[2], E. Hachulla[3], A. Balbir-Gurman[4], G. Riemekasten[5], P. Airò[6], P. Carreira[7], Y. Allanore[8] on behalf of EUSTAR. *[1]Rheumatology A, Cochin Hospital, Paris; [2]Université Paris XIII, Bobigny, Bobigny; [3]CHU Lille, Lille, France; [4]Technion–Institute of Technology, Haifa, Israel; [5]University of Lübeck, Lübeck, Germany; [6]Clinica Spedali Civili Brescia, Brescia, Italy; [7]Hospital Universitario 12 de Octubre, Madrid, Spain; [8]Cochin Hospital, Paris, France*



**Background:** Systemic sclerosis (SSc) remains a devastating condition associated with a high risk of mortality. However, the main causes of death and risk factors for mortality are only partially known.

**Objectives:** To investigate causes and independent predictors of death in a large European population of SSc-patients.

**Methods:** We performed a longitudinal observational study using the latest 2014 data extract from the EUSTAR cohort. We looked at (i) deaths and causes of death (SSc, non-SSc) and (ii) effect of demographics, disease characteristics and comorbidities on mortality. Investigators from each center were asked to indicate the single primary cause of death according to standardized definitions. Associated factors with mortality were analyzed first in univariate analysis using t-test, chi2 or fisher exact test as necessary, followed by multivariable Cox modeling. Based on cox multivariate analysis, a simple score was generated (SScore) by adding the integer of each hazard ratio of variables independently associated with mortality. The ability of the SScore was compared to the previous modified 5-factor score to predict overall and 5-years mortality, and SSc-related mortality during follow-up using C-statistics.

**Results:** A total of 11,194 SSc-patients were included: 86% of women, 31% of diffuse cutaneous forms, and mean disease duration: 5.9 [2.4–11.8] years. During mean follow-up of 27±33 months, 1072 (9.6%) patients died. Of these, 617 patients (58%) died from SSc-related cause, 270 from non-SSc cause (25%), whereas the cause of death remains unknown in 185 (17%). Main causes of death were lung fibrosis (14.7%) followed by PAH (12.9%), primary heart involvement (10.5%), cancer (11.5%), infections (8%) and atherosclerosis (4.8%).

The SScore comprised the following predictors: male gender (2 points), upper gastrointestinal involvement (2), proteinuria (5), LVEF<50% (3), DLCO<60% of predicted (2). Each increase of 1 point of the SScore was associated with a 35.9% [31.7–40.3] increase in mortality at 5 years. Areas under the ROC of the SScore to predict total mortality and SSc-related mortality were 0.70 (0.68–0.82) and 0.74 (0.72–0.76).

The accuracy of the previous 5-factor score was lower than the SScore to predict total mortality (p=0.005) and 5 years-mortality (p=0.003).

Further analyses looked at various subsets of SSc: by example, DcSSc patients had reduced survival as compared to LcSSc and causes of death were different: in DcSSc, the main causes of death were pulmonary fibrosis (18.6%), primary heart involvement (13.3%) and cancer (10.0%), whereas PAH (18.1%), cancer (12.8%) and pulmonary fibrosis (11.6%) were the leading causes in LcSSc (Figure).

**Conclusions:** Using the largest worldwide available cohort of SSc patients in which 1072 deaths have been recorded and characterized, we provide insight into the causes of deaths and emphasis on the contribution of the cardiopulmonary system.

In addition, we have established a new score to estimate the 5-year survival of SSc patients.

### OP0031 RISK FACTORS FOR MALIGNANCIES SYNCHRONOUS TO THE ONSET OF SYSTEMIC SCLEROSIS IN PATIENTS POSITIVE FOR ANTI- RNA POLYMERASE III ANTIBODIES: A EUSTAR MULTICENTRE STUDY

M.G. Lazzaroni[1], I. Cavazzana[2], E. Colombo[3], O. Distler[4], R. Dobrota[4], J. Hernandez[4], R. Hesselstrand[5], L. Czirjak[6], C. Varju[6], G. Nagy[6], V. Smith[7], P. Caramaschi[8], V. Riccieri[9], E. Hachulla[10], K. Romanowska-Prochnicka[11], A. Balbir-Gurman[12], E. Chatelus[13], A.C. Araùjo[14], Y. Allanore[15], P. Airò[2]. *[1]Spedali Civili and University of Brescia; [2]Spedali Civili of Brescia, Brescia; [3]University of Sassari, Sassari, Italy; [4]University Hospital Zurich, Zurich, Switzerland; [5]Lund University, Lund, Sweden; [6]University of Pécs Medical Center, Pécs, Hungary; [7]Ghent University Hospital, Ghent, Belgium; [8]Azienda Ospedaliera Universitaria Integrata, Verona; [9]University Sapienza of Rome, Rome, Italy; [10]University Lille Nord-de-France, Lille, France; [11]Medical University of Warsaw and Department of Connective Tissue Diseases, Institute of Rheumatology, Warsaw, Poland; [12]Rambam Health Care Campus, Rapport Faculty of Medicine, Haifa, Israel; [13]Strasbourg University Hospital, Strasbourg, France; [14]Hospital de Curry Cabral, Centro Hospitalar Lisboa Central, Lisbon, Portugal; [15]University Paris Descartes and Cochin Hospital, Paris, France*

**Background:** Patients with anti-RNA polymerase III antibodies (anti-RNAP) have an increased risk of malignancies synchronous to the onset of Systemic Sclerosis (SSc). In a multicentre EUSTAR case-control study, however, only moderate odd ratio was observed (OR 3.85, 95%CI 1.3–10.9), except than for breast cancer (OR 20.2, 95%CI 1.4–355) (1). Defining clinical and demographic features characteristic of anti-RNAP+ SSc patients who suffer from simultaneous malignancy would be useful to individuate risk factors who can guide the clinicians in every-day practice to screen anti-RNAP+ SSc patients for cancer.

**Objectives:** To individuate risk factors for malignancies synchronous to the onset of SSc in anti-RNAP+ patients.

**Methods:** EUSTAR centers were asked to participate to this study, providing data on malignancy history of their anti-RNAP+ patients in a dedicated form.

**Results:** Among 158 anti-RNAP+ SSc patients collected from 13 EUSTAR centers, 14 cases of malignancies synchronous to the onset of SSc were identified. When compared with the other 144 anti-RNAP+ patients, patients with synchronous malignancies had an older mean age at SSc onset (65.3 yrs (SD 10.0) vs 49.3 (SD13.3); p<0.001) and an increased proportion of diffuse cutaneous subset (96% vs 56%; p:0.008; OR: 10.5 95%CI 1.33–82.6). A trend for increased proportion of males was also observed (43% vs 21%; p:0.06). In particular, the risk of non-breast cancer synchronous with SSc was greatly higher in male than in female patients (43% vs. 0.8%; p<0.001; OR 95.2 95%CI 10.2–890).

**Conclusions:** Anti-RNAP+ SSc patients of older age, and with diffuse cutaneous subset, are particularly at risk for malignancies synchronous to the onset of SSc. The risk of malignancies other than breast cancers is greatly increased in male patients. These risk factors may help in the screening for cancer in these patients.

## OP0032 GASTROINTESTINAL DISEASE AND MICROBIAL TRANSLOCATION IN PATIENTS WITH SYSTEMIC SCLEROSIS: AN OBSERVATIONAL STUDY ON THE EFFECT OF NUTRITIONAL INTERVENTION AND IMPLICATIONS FOR THE ROLE OF THE MICROBIOMA IN THE PATHOGENESIS OF THE DISEASE

M.M. Luchetti[1], A. Festa[1], T. Schnitzler[1], D. Benfaremo[1], R. Bagnati[1], M. Rossini[1], L. Albani[1], M. Cardinali[1], C. Fischetti[1], P. Bonazzi[2], E. Berardi[3], A. Gabrielli[1]. *[1]Scienze Cliniche e Molecolari, Università Poiltecnica delle Marche; [2§]Dipartimento Gastroenterologico e dei Trapianti, Polo Didattico Ospedaliero "Umberto I-G.M. Lancisi-G.Salesi"; [3]Laboratorio di Genetica Microbica, Università Poiltecnica delle Marche, Ancona, Italy*

**Background:** Systemic Sclerosis (SSc) is an autoimmune disease characterized by progressive deposition of extracellular matrix components in the skin and visceral organs (1). Recently, it has been shown that microbial translocation plays an important role in immune system activation (2), and that dietary changes may affect gut microbiota, altering immune system activation and conditioning the development of several autoimmune diseases (3).
**Objectives:** The aims of the study were to investigate: a) which serum biomarkers could be used to evaluate and monitor GI disease in SSc patients and b) if nutritional intervention may reduce GI involvement, immune system activation and, finally, improve clinical symptoms and quality of life of SSc patients.
**Methods:** Thirty-eight SSc patients affected by GI involvement were enrolled in the study. At baseline. the following serum biomarkers were evaluated: intestinal-type fatty acid-binding protein (I-FABP), lipopolysaccharide (LPS), and soluble CD14 (sCD14) serum levels, markers of enterocyte damage, microbial translocation and immune system activation, respectively. Moreover, in each examination clinical symptoms and patient's reported outcomes (SF-36) were collected.
After six months from the assumption of a mediterranean diet with low introduction of meat and diary products (4), clinical symptoms and SF-36 were evaluated in all patients and sCD14, LPS and I-FABP in 14 SSc patients. Twenty-five normal subjects constituted the control group.
**Results:** At baseline, sCD14, LPS, and I-FABP resulted significantly higher in sera of SSc patients than healthy controls (Fig. 1A), and there was a strong correlation between sCD14/ I-FABP and LPS/I-FABP serum levels (Fig. 1B).

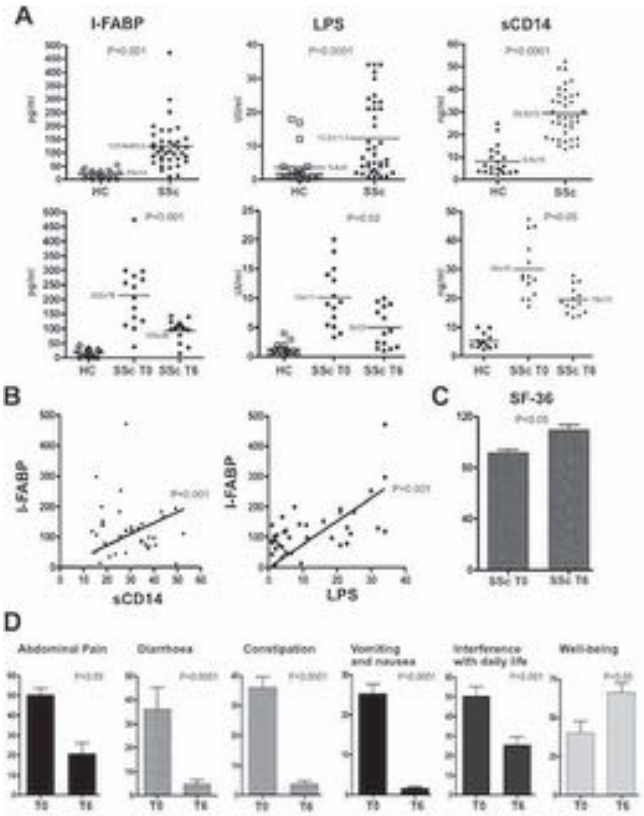

**Figure 1. Evaluation of gastrointestinal (GI) damage, microbial translocation, immune system activation and clinical symptoms before and after nutritional intervention in patients affected by Systemic Sclerosis (SSc). A.** Upper panel: Intestinal-type fatty acid-binding protein (I-FABP), lipopolysaccharide (LPS), and soluble CD14 (sCD14) serum levels, measured by ELISA, in SSc patients (SSc pts) and healthy controls (HC) at basal and, lower panel, after 6 months (T6) of mediterranean diet with low introduction of meat and diary products. **B.** Correlation between serum levels of I-FABP with sCD14 (left) and LPS (right) in sera of SSc patients. **C.** Evaluation of the quality of life in SSc pts before (T0) and after 6 months of semi-vegetarian and low-gluten nutritional intervention (T6). SF-36: Short Form (36) Health Survey questionnaire. **D.** Evaluation of GI symptoms and quality of life in SSc pts before (T0) and after 6 months of semi-vegetarian and low-gluten nutritional intervention (T6), carried out with the Visual Analogue Scale for Irritable Bowel Syndrome (VAS-IBS) questionnaire (Dengiavi M et al. BMC Gastroenterology 2007, 7:16). Horizontal bars: mean values ± SD. Statistical analysis has been carried out by the GraphPad Instat software. All the p-values have been calculated by Mann-Whitney unpaired test.

Higher LPS plasma levels (β=10.2, 95% CI (2.6, 17.9), p=0.01, $R^2$ =0.17), but not sCD14 and I-FABP, were associated with the presence of Small Intestine Bacterial Overgrowth (SIBO). There were no statistical differences between patients with and/or without elevated bowel transit time, as assessed by lactulose breath test.
After 6 months of diet, a significant decrease of sCD14, LPS and I-FABP was observed and patients reported a consistent improvement of GI symptoms as well as of the quality of life (Fig. 1A-D).
**Conclusions:** This work suggests that GI damage, and the consequent microbial translocation, triggers immune system activation and sustain clinical symptoms in SSc patients. Moreover, specific nutritional intervention significantly improves the clinical symptoms and the GI damage (I-FABP), thus reducing microbial translocation (LPS) and immune system activation (sCD14).
Gut microbioma and microbial translocation may play an important role in the activation of the immune system and, thus, in the pathogenesis of SSc disease.

## OP0033 EUROPEAN SCLERODERMA STUDY GROUP ACTIVITY INDEX CAPTURES VARIATIONS IN DISEASE ACTIVITY OVER TIME AND PREDICTS ORGAN DAMAGE IN EARLY SYSTEMIC SCLEROSIS: DATA FROM THE CANADIAN SCLERODERMA RESEARCH GROUP

T. Nevskaya[1], M. Baron[2], J.E. Pope[1] on behalf of Canadian Scleroderma Research Group. *[1]Department of Medicine, Division of Rheumatology, University of Western Ontario, Schulich School of Medicine and Dentistry, London; [2]Division of Rheumatology, Jewish General Hospital, McGill University, Montreal, Canada*

**Background:** Endpoints in systemic sclerosis (SSc), such as modified Rodnan skin score (mRSS) and pulmonary function tests represent only parts of a multisystem disease. The European Scleroderma Study Group (EScSG) developed an SSc activity index, which captures involvement of multiple organs. The predictive validity of the SSc activity index is unclear.
**Objectives:** To estimate the effect of disease activity as measured by EScSG activity index, on the risk of subsequent organ damage in the Canadian Scleroderma Research Group (CSRG) cohort.
**Methods:** Of 421 SSc patients from the CSRG database with disease duration of ≤3 years, 197 who had no evidence of endstage organ damage initially and 3-year follow-up were included. Disease activity was assessed by EScSG activity index with two variability measures: 1. adjusted mean (am) EScSG activity score (the area under the curve of EScSG activity index over observation period), and 2. persistently active disease (PAD)/flare (EScSG score of ≥3 at follow-up visit). Internal organ involvement assessed over follow-up was based on Medsger severity scale and included accrual of a new severity score overall and by specific organ systems. Adjusted odds ratios (OR) for association between disease activity, severity and progression were calculated using regression analysis.
**Results:** After adjustment for covariates, amEScSG activity score was the most consistent predictor of risk at 3 year follow-up: disease progression as accrual of a new severity grade (Δ≥1) in any of the major internal organs (OR 1.42, 95%CI 1.14–2.25, p=0.007), lung disease (OR 1.86, 95%CI 1.31–2.64, p<0.0001), decline in FVC (OR 3.05, 95%CI 1.47–6.31, p=0.003) and DLCO (OR 1.61, 95%CI 1.06–2.46, p=0.026), ΔHAQ (OR 1.729, 95%CI 1.250–2.391, p<0.001), severity of visceral disease (Table). amEScSG predicted accrual of organ damage only in diffuse cutaneous SSc (dcSSc). In the multivariable analysis, progression of lung disease in dcSSc was predicted by amEScSG activity score (p=0.006), and severity of lung disease by amEScSG (p<0.0001), older age (p=0.023), mRSS (p<0.001) and initial severity of lung disease (p<0.0001). The best predictor of renal disease severity at 3-year was initial severity of kidney involvement (p<0.0001).

Table 1. Predictive value of EScSG activity index for a total severity score in cardiac, pulmonary and renal systems on Medsger's severity scale, at 1 and 3-year observation in regression analysis

## OP0034 THE SEROTONIN RECEPTOR 2 INHIBITOR TERGURIDE HAS BENEFICIAL EFFECTS ON SKIN FIBROSIS: RESULTS FROM A PHASE 2 PROOF OF CONCEPT STUDY

O. Distler[1], B. Maurer[1], S. Vettori[2], S. Blumhardt[1], D. Frey[1], A. Distler[3], C. Beyer[3], J.H. Distler[3]. *[1]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Rheumatology Unit, Second University of Naples, Naples, Italy; [3]Department of Internal Medicine 3, University of Erlangen, Erlangen, Germany*

**Background:** Circumstantial evidence from preclinical studies indicates a key role of serotonin (5-HT) signaling via the 5-HT-2B receptor in the development of fibrosis. Terguride is an orally available 5-HT-2 receptor inhibitor that has shown beneficial effects in different animal models of systemic sclerosis (SSc).
**Objectives:** To evaluate the efficacy of Terguride for the treatment of fibrosis in patients with SSc in an investigator initiated phase 2 proof of concept study.
**Methods:** Main inclusion criteria were fulfillment of ACR classification criteria and diffuse cutaneous SSc (dcSSc). Patients with end-stage organ involvement and treatment with potentially disease modifying agents including immunosuppressives were excluded. Patients were treated with Terguride at up to 3 mg/d p.o. or standard of care (post hoc control) for three months. Primary efficacy endpoints were changes of pre-defined skin biopsy biomarkers over the three months treatment period. Secondary efficacy endpoints included change of mRSS and lung function parameters. Serious adverse events (SAEs) and AEs were coded using MedDRA. The study was externally monitored.
**Results:** Twelve patients were recruited into the Terguride group and 6 patients into the control group. The primary endpoints, skin biopsy biomarkers, showed a consistent and statistically significant down-regulation compared to the control group (Figure) for dermal thickness, myofibroblast counts and mRNA levels of col1a1, col1a2 as well as for the Lafyatis 4-gene biomarker set (COMP, THSP-1, SIGLEC-1, IFI-44). This was accompanied by a reduction in mRSS of - 32.3% versus baseline in the Terguride group versus stable values in the control group ($p<0.05$). Lung function parameters did not change significantly. Overall, 33 AEs (n=27 mild and n=6 moderate) and one SAE (pyelonephritis, not related) occurred in the Terguride group, most often consisting of nausea and vomiting (9% and 13% of patients respectively).Twelve patients were recruited into the Terguride group and 6 patients into the control group. The primary endpoints, skin biopsy biomarkers, showed a consistent and statistically significant down-regulation compared to the control group (Figure) for dermal thickness, myofibroblast counts and mRNA levels of col1a1, col1a2 as well as for the Lafyatis 4-gene biomarker set (COMP, THSP-1, SIGLEC-1, IFI-44). This was accompanied by a reduction in mRSS of - 32.3% versus baseline in the Terguride group versus stable values in the control group ($p<0.05$). Lung function parameters did not change significantly. Overall, 33 AEs (n=27 mild and n=6 moderate) and one SAE (pyelonephritis, not related) occurred in the Terguride group, most often consisting of nausea and vomiting (9% and 13% of patients respectively).

**Conclusions:** Terguride was well tolerated in patients with dcSSc. Strong and consistent effects on fibrosis related skin biopsy biomarkers could be observed in this open-label controlled phase 2 proof of concept study, which was further supported by a significant improvement of the mRSS over the control group. These data justify further investigation in an upcoming randomized placebo controlled phase 3 study.

## OP0035 CIRCULATING PLASMABLASTS LEVELS REFLECT INFLAMMATORY ACTIVITY IN IGG4-RELATED DISEASE LESIONS AS ASSESSED BY QUANTITATIVE POSITRON EMISSION TOMOGRAPHY

A. Berti[1], C. Canevari[2], F. Gallivanone[3], M. Lanzillotta[1], E. Bozzalla Cassione[1], C. Campochiaro[1], G.A. Ramirez[1], M.G. Sabbadini[1], E. Della Torre[1]. *[1]Internal Medicine and Clinical Immunology; [2]Nuclear Medicine, San Raffaele Scientific Institute, Milan; [3]IBFM, CNR, Segrate, Milan, Italy*

**Background:** IgG4-Related Disease (IgG4-RD) is a systemic inflammatory condition characterized by fibrous swelling of affected organs, serum IgG4 elevation, and IgG4+ plasmacells tissue infiltration. 18-Fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) scan is emerging as a promising imaging technique to detect organs involved by IgG4-RD and to assess disease response to treatment. The relationship between FGD-PET findings and immunological perturbations occurring in IgG4-RD has never been evaluated.
**Objectives:** To correlate the intensity and distribution of FDG-PET uptake with clinical and immunological parameters in patients with active untreated IgG4-RD.
**Methods:** Patients with active, untreated, biopsy proven IgG4-RD were included in the study. Disease activity was assessed through clinical (IgG4-RD Responder Index (RI)) and immunological (erythrocyte sedimentation rate (ESR), C reactive protein (CRP), serum IgG4, and circulating plasmablasts) parameters. Plasmablasts, a recently characterized disease biomarker, were identified as CD19+CD20-CD27+CD38bright cells on flow cytometry. FDG-PET/CT was performed in all patients at diagnosis. Quantitative assessment of FDG uptake was measured using the mean Standardized Uptake Value corrected for the Partial Volume Effect (PVC-SUV). Lymph nodes <1 cm of diameter were excluded from the analysis because of the risk of PVC-SUV over/under-estimation. In patients with multiorgan involvement, the IgG4-RD lesion with the highest PVC-SUV was selected to correlate FGD uptake with clinical and serological parameters.
**Results:** We studied 15 patients (7 males, 8 females) with a mean age of 63 years (range, 30–77 years). Twelve (80%) patients had multiorgan IgG4-RD involving lymphnodes (7 patients); aorta (5 patients); parotids glands and pancreas (3 cases each); bones, skin, thyroid, lung, submandibular and lachrymal glands (2 cases each); meninges, nasal cavity, oropharynx, palate, liver, CNS, and retrorbital space (one case each). The median IgG4-RD RI was 9 (range 6–16; normal =0). The median levels of ESR, CRP, serum IgG4 and plasmablasts at baseline were 30 mm/h (range 6–121 mm/h, normal <20 mm/h), 11.0 mg/L (range 0.0–48.0 mg/L; normal <6mg/L), 284.0 mg/dL (range 45–2100 mg/dL, normal <121 mg/dL), and 3870 cells/mL (range 1000–10000 cells/mL, normal <690 cells/mL), respectively. The median PCV-SUV was 6.24 (range 2.48–16.39). Significant positive correlation was found between PVC-SUV and serum plasmablasts levels (r=.84, p=.004). No correlation was found between PVC-SUV and either CRP, ESR, serum IgG4 levels, number of organs involved, and IgG4-RD RI at baseline ($p>.05$).
**Conclusions:** Our study demonstrates for the first time a positive correlation between circulating plasmablasts and inflammatory activity in IgG4-RD lesions as assessed by PVC-SUV on FDG-PET. Our results further strengthen the utility of circulating plasmablasts as a biomarker of disease activity. Conventional inflammatory markers, serum IgG4 levels, and IgG4-RD RI do not appear to correlate with metabolic activity in IgG4-RD lesions.

## OP0036 SCREENING FOR PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: COMPARISON OF THE PREDICTIVE ACCURACY OF VARIOUS ALGORITHMS

A. Young[1], V. Nagaraja[2], S. Visovatti[1], V. McLaughlin[1], D. Khanna[1]. *[1]University of Michigan, Ann Arbor; [2]University of Toledo, Toledo, United States*

**Background:** Pulmonary arterial hypertension (PAH) is one of the leading causes of mortality in systemic sclerosis (SSc) and has a 3 year survival rate of approximately 50%. Early screening for PAH in SSc may improve survival.
**Objectives:** To compare the predictive accuracy of two SSc-PAH screening algorithms, DETECT and Australian Scleroderma Interest Group (ASIG), to the

2009 European Society of Cardiology/European Respiratory Society (ESC/ERS) screening recommendations in a well-defined North American cohort.
**Methods:** Consecutive SSc patients with suspected PAH according to the 2013 recommendations for screening PAH (1) undergoing right heart catheterization (RHC) were evaluated. Those patients with no pulmonary hypertension or PAH on RHC who also had clinical variables available for applying the various screening algorithms had DETECT (2), ASIG (3) and 2009 ESC/ERS (4) screening algorithms applied. For each model, contingency table analysis was used to determine sensitivity, specificity, and positive and negative predictive values (PPV and NPV, respectively) for PAH [defined as mean pulmonary artery pressure (mPAP) > or =25, pulmonary capillary wedge pressure (PCWP) < or =15, and no/mild interstitial lung disease (ILD) on high-resolution CT scan of chest (HRCT), or FVC > or =70%].
**Results:** A total of 108 patients were screened for PAH, 77 of those patients met the recommendations for RHC, and 65 of those patients underwent RHC. The prevalence of PAH was 17%. Those patients with RHC values indicating no PH (N=35) or PAH (N=11) who also had biochemical markers available for review were identified and DETECT, ASIG, and ESC/ERS algorithms were applied to all of those patients. Those patients who met inclusion/exclusion criteria for DETECT and ASIG were also separately evaluated. DETECT and ASIG both had similar performances with sensitivity of 100% for those who met the respective inclusion/exclusion criteria. ESC/ERS had a sensitivity of 80% (Table 1).

Table 1. Summary of the predictive accuracies of screening algorithms for PAH in SSc

| | DETECT | | ASIG | | 2009 ESC/ERS |
|---|---|---|---|---|---|
| | All patients | Patients who met inclusion/ exclusion criteria* | All patients | Patients who met inclusion/ exclusion criteria** | All patients |
| Number of patients | 46 | 6 | 44 | 20 | 44 |
| Sensitivity | 1.00 | 1.00 | 0.90 | 1.00 | 0.80 |
| Specificity | 0.40 | 0.25 | 0.56 | 0.55 | 0.67 |
| Positive predictive value | 0.34 | 0.40 | 0.38 | 0.62 | 0.42 |
| Negative predictive value | 1.00 | 1.00 | 0.95 | 1.00 | 0.92 |

*Coghlan J et al. Ann Rheum Dis 2014; **Thakkar V et al. Arthritis Res Ther 2012.

**Conclusions:** In a well-defined North American cohort, DETECT and ASIG performed similarly and were superior to 2009 ESC/ERS screening recommendations in the detection of PAH in SSc patients. Many patients who are at-risk for PAH did not meet the inclusion/exclusion criteria for DETECT and ASIG in our cohort.

## OP0037 FIRST PILOT STUDY OF AN IMPLANTABLE LOOP RECORDER (ILR) IN SYSTEMIC SCLEROSIS DETECTS SIGNIFICANT CARDIAC ARRHYTHMIAS WITH CMR ABNORMALITIES

L.-A. Bissell[1,2], R. Dumitru[1,2], B. Erhayiem[3], G. Fent[3], J.P. Greenwood[3], S. Plein[3], J. Andrews[1,2], L. Graham[3], M.H. Buch[1,2]. *[1]NIHR LMBRU; [2]LIRMM; [3]LIGHT, University of Leeds, Leeds, United Kingdom*

**Background:** SSc-cardiomyopathy associated conduction abnormalities carry a poor prognosis, but their pathogenesis is unclear. Early detection to prevent complications is essential. ILRs are well-established in cardiology practice.
**Objectives:** To determine the spectrum of cardiac conduction abnormalities (CCA) using the REVEAL® ILR & their association with CMR in patients (pts) with SSc with no known cardiac disease.
**Methods:** 20 pts with (ACR/EULAR criteria) SSc, with no diabetes &/or more than 1 cardiovascular (CV) risk factor, were assessed for SSc/CV profile & comprehensive CV assessment performed, inc. 3T delayed enhancement-CMR (reported by CMR-cardiologists) & ILR insertion. ILR data was downloaded 3 monthly +/– at pt request if indicated. One yr data is reported. CMR compared to 30 healthy controls.
**Results:** ILR data was available for 19 pts; 63% female, 84% Caucasian; mean (SD) age 53 (12)yrs, time from 1st non-RP symptom 9 (8)yrs; 32% dcSSc, 32% ACA+ve, 21% Scl70+ve, 54% palpitations hx, 42% known ILD, 11% DU hx, 0% pulmonary hypertension. Ten (52%) pts had ILR abnormalities; 4 with dcSSc, 3 ACA+ve, 3 Scl70+ve, 6 with palpitations hx, 4 known ILD, 3 DU hx. Subanalysis; 8 (42%) pts had supraventricular ectopics (SVE), 2 (11%) with ventricular ectopics (VE), 4 (21%) with arrhythmias of which 1 atrial flutter, 1 SVT, 1 VT & 1 complete heart block (CHB). Of the 4 pts with arrhythmias; 2 had dcSSc, 1 ACA+ve, 1 Scl70, 3 palpitations hx, 2 known ILD, 2 DU hx. Pt with CHB (dcSSc) had few SVE/VEs & 3 couplets on 24hr ECG 6 weeks previous. CMR data was available for 15 SSc pts (DE in 14; 1 pt claustrophobic, no IV access in 2, 1 CMR abandoned due to pacemaker insertion for CHB). Trend towards lower LVmass & distensibility (ie greater arterial stiffness) & higher extracellular volume (ECV, fibrosis marker) seen in pts with ILR abnormalities (p>0.05). Trend for higher ECV in those with SVE [unadj. mean difference (diff.) (95%CI) 1.1 (-2.5, 4.7)% p0.513], VE [0.7 (-4.9, 6.3)% p0.789] & arrhythmias [1.8 (-3.7, 7.3)% p0.486]. ECV was higher in SSc vs. controls; mean diff. 4.9 (3.2, 6.6)% p<0.001 $R^2$ 0.568, adj. for age/sex; with trend for lower LV mass & distensibility.

Table 1. CMR measures in SSc pts with/without ILR abnormalities

| CMR variable | ILR normal n (%) = 7 (47) | ILR abnormal n (%) = 8 (53) | Mean diff. [95% CI] p | Mean diff. [95% CI] p adj. age/sex |
|---|---|---|---|---|
| LVEF, % | 58.7 (3.5) | 61.3 (5.1) | 2.6 [–2.4, 7.5] 0.286 | 0.3 [–5.2, 5.8] 0.908 |
| LVmass/BSA, g/m$^2$ | 47.1 (13.7) | 42.9 (7.0) | –4.2 [–17.2, 8.9] 0.488 | –6.1 [–18.0, 5.7] 0.280 |
| LV mass/EDV, g/ml | 0.54 (0.07) | 0.54 (0.08) | –0.01 [–0.09, 0.08] 0.895 | 0.02 [–0.11, 0.11] 0.974 |
| Torsion, ° | 12.4 (4.1) n=6 | 13.5 (6.1) n=7 | 1.1 [–5.4, 7.6] 0.714 | –0.7 [–8.9, 7.5] 0.849 |
| Distensibility, $10^{-3}$mmHg$^{-1}$ | 4.6 (3.0) | 3.6 (2.6) n=7 | –1.0 [–4.3, 2.3] 0.510 | 0.3 [–3.5, 4.1] 0.863 |
| ECV, % | 29.1 (4.2) | 31.1 (1.7) n=7 | 2.0 [–2.0, 5.9] 0.278 | 1.7 [–3.1, 6.5] 0.444 |
| Late gad enhancement presence | 3 (42.9)* | 2 (28.6) n=7* | p=1.00 | p=0.784 |

Values = mean (SD) *n (%).

**Conclusions:** This first ILR in SSc study demonstrates its utility in the incidental detection of CCA, including serious cardiac arrhythmias & suggests associated CMR abnormalities. These data support the need for identification of pts at risk that would benefit from ILR & provide insights into the pathogenesis of SSc-cardiomyopathy

## OP0038 IMPROVED SURVIVAL IN DERMATOMYOSITIS AND POLYMYOSITIS: A GENERAL POPULATION-BASE STUDY

L. Li[1], L.M. Belvedere[2], E.C. Sayre[2], J.A. Avina-Zubieta[1,2,3]. *[1]Experimental Medicine Program, University of British Columbia, Vancouver; [2]Arthritis Research Canada, Richmond; [3]Division of Rheumatology, University of British Columbia, Vancouver, Canada*

**Background:** Dermatomyositis (DM) and polymyositis (PM) are associated with significant mortality and morbidity. However, mortality trends for these two diseases are unknown, especially in the general population context.
**Objectives:** To address this knowledge gap, we assess mortality trends for individuals with PM and DM between January 1, 1997 and December 31, 2012 in the general population.
**Methods:** Using an administrative health database from province of British Columbia, Canada, we identified all incident cases of both PM and DM and up to 10 non-disease controls matched on sex-, age- and entry-time for each. Study cohorts for both PM and DM were divided into two subgroups based on the year of diagnosis (ie., 1997–2004 and 2005–2012).Mortality rates were calculated, as well as hazard ratios (HR) using a Cox proportional hazard model. HRs were adjusted for potential confounders (e.g., number of hospitalization and outpatient visits, Charlson's comorbidity index, glucocorticoid use, cardiovascular drugs, cox-2 inhibitors).
**Results:** Mortality rates (cases per 1000 person-years) in the early cohorts (ie.,1997–2004) for PM and DM patients were considerably higher than those in the later cohorts (ie., 2005–2012) (for PM: 226.1 vs 73.3; for DM: 287.0 vs 56.9). In contrast, smaller improvements were observed in the comparison groups (for PM: 28.9 vs 16.2; for DM: 31.0 vs 13.5). Corresponding to these two time periods, HRs for mortality for PM were 5.6 (95% CI, 3.2–9.9) and 3.1 (95%CI, 1.8–5.3), respectively, and 8.0 (95% CI, 4.0–16.0) and 2.9 (95%CI, 1.7–5.2) for DM, respectively. Testing for difference between incident cohorts via an interaction term were all significant (see table, p. 68).
**Conclusions:** This population-based study shows that the survival of PM and DM patients has improved in recent years, suggesting that new treatment strategies and improved management of PM and DM and its associated complications have led to significant improvements in PM- and DM-associated mortality.
**Disclosure of Interest:** None declared

**THURSDAY, 9 JUNE 2016**

## Advances in SLE therapeutics

### OP0039 IMPACT OF BELIMUMAB USE ON FLARES AMONG PATIENTS DIAGNOSED WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN A US COMMERCIALLY INSURED DATABASE: 2010-2014

M. Stott-Miller[1], P. Egger[1], A. Eudy[2,3], J. Maskell[1], Q. Fu[2], H. Kan[4], R. Alfonso-Cristancho[2,5], K. Costenbader[6]. *[1]GlaxoSmithKline, Stockley Park, Middlesex, United Kingdom; [2]GlaxoSmithKline, Collegeville, PA; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [5]University of Washington, Seattle, WA; [6]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States*

**Background:** Belimumab, a B-lymphocyte stimulator, was FDA-approved March 2011 for the treatment of adult patients with active, autoantibody-positive SLE receiving standard of care medications. There is a need to evaluate belimumab's effectiveness in real-world practice settings.
**Objectives:** To describe the effectiveness of initiating belimumab treatment on flare episodes.
**Methods:** Patients aged 18–64 years at first belimumab infusion (index date) between 01 Jan 2010 – 31 Dec 2014 were selected from the US Truven Health MarketScan® Commercial Database (study ID 204999). SLE diagnosis (ICD-9 code 710.0) was documented prior to/on index date. We included patients with complete medical and pharmacy benefits ≥6 months prior to index (baseline period). Moderate and severe SLE flare episodes were defined using previously published algorithms developed for claims data (Garris C, 2013). Incidence rates (IRs) and 95% CIs were calculated per subject for 3-month intervals, with two intervals in the baseline period and a variable number of intervals in the follow-up period. In primary "as treated" analyses, person-time spanned the duration of belimumab exposure including one month after last infusion. Sensitivity analyses were performed using "intention to treat" (ITT) analysis including all follow-up during each interval for person-time. To statistically compare the period before and after belimumab initiation, IRs were calculated in the total baseline and follow-up period per patient in both as-treated and ITT analyses, and compared using the Wilcoxon signed-rank test.

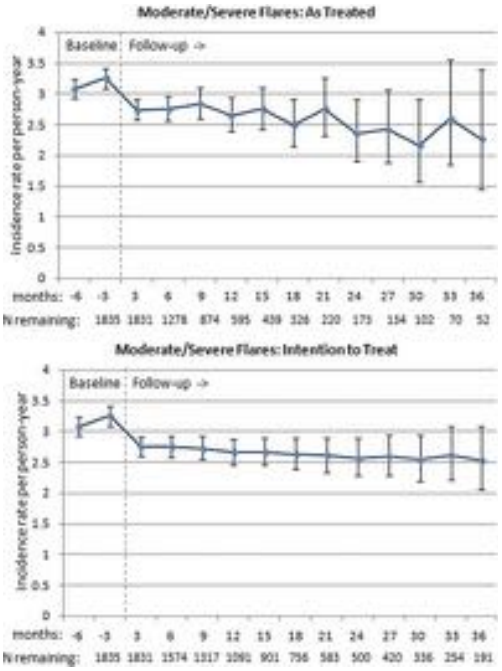

Figure 1. Incidence rates and 95% CIs for moderate and severe SLE flares among 1835 patients initiating belimumab: six month baseline period and follow-up.

**Results:** We identified 1835 belimumab initiators (mean age 43 years, SD 11; 94% female). SLE comorbidities in the baseline period included arthritis (46%), lupus nephritis (7%), anemia (20%), rash (27%), arthralgia (43%), and mood disorders (34%). Similarly, 15% were hospitalized and 27% had ER visits. Baseline medications included antimalarials (68%), oral corticosteroids (71%), immunosuppressants (59%), and NSAIDs (32%). Belimumab continuation rates were 81% at 6 months, 55% at year 1, 35% at year 2 and 27% at year 3 post index. There was a marked and sustained decrease in moderate/severe flare incidence following belimumab initiation (Figure 1). This pattern was similar in the ITT sensitivity analysis. The Wilcoxon signed-rank test yielded highly statistically significant results for both the primary as treated analysis and the ITT analysis ($p<0.001$).
**Conclusions:** In this large sample of SLE patients initiating belimumab, the rates of moderate/severe SLE flares during belimumab treatment were significantly lower compared with those in the pre-belimumab period. The comparative effectiveness of belimumab vs. standard of care immunosuppressants, as well as causes and effects of belimumab discontinuation should be further explored.

### OP0040 PERIPHERAL BLOOD TRANSCRIPTIONAL CHANGES ELICITED BY TREATMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS WITH DAPIROLIZUMAB PEGOL (A PEGYLATED ANTI-CD40L FAB')

A. Ranger[1], N. Allaire[1], P. Colman[2], C. Wager[1], H. Li[1], A. Thai[1], P. Cullen[1], C. Otoul[3], J. Czerkowicz[1], C. Roberts[1], C. Chamberlain[2], L. Burkly[1], G. Johnston[2]. *[1]Biogen, Cambridge, United States; [2]UCB Pharma, Slough, United Kingdom; [3]UCB Pharma, Braine L'Alleud, Belgium*

**Background:** CD40-CD40L is a critical costimulatory pathway necessary for normal immune function (including B cell differentiation, germinal center formation and antibody isotype switching) and strongly implicated in the pathogenesis of autoimmune disorders such as SLE. In a randomised, placebo-controlled, parallel group Phase 1 study, dapirolizumab pegol (DZP), a pegylated anti-CD40L Fab', was administered to patients with active SLE on stable background therapy (NCT01764594).
**Objectives:** To examine the effect of DZP on peripheral blood RNA transcripts associated with immune cell subsets and SLE disease activity as biomarkers for proof of biological activity.
**Methods:** Twenty-four subjects were randomised (2:1) to receive DZP or placebo and 22 subjects completed the study. Subjects randomised to DZP received a loading dose of 30 mg/kg followed by 15 mg/kg every 2 weeks for a total of 6 doses and were subsequently followed for 18 weeks. For transcriptional analyses, blood was collected in PAXgene tubes at Weeks 0, 2, 4, 8, 12, 20 and 28. A panel of 96 genes was selected for analysis by qPCR including genes expressed in plasma cells, B cells and other immune cells. Also included were transcripts associated with SLE disease activity, such as the Type I Interferon (IFN) signature. For the analysis, genes were grouped into functional domains (such as B cells, T

cells, IFN) and decision criteria were designed to identify consistent expression changes within a domain. At a gene level, a positive signal required a >2 fold up- or down-regulated change from baseline, and occurring on at least 2 successive visits. Differences in changes from baseline between DZP and placebo groups were considered significant at <0.0894 (to achieve a 5% false positive rate at a functional domain level).
**Results:** Changes in genes within the plasma cell and B cell domains had the greatest degree of statistical significance. Among the plasma cell genes, the DZP group exhibited rapid decreases in the expression of several immunoglobulin-associated genes (secretory IgA, IgG, Igk, Igl, J chain) starting at Week 2 and maintained over the treatment period. Among the B cell genes, the DZP group showed a transient increase in CD19 and CD20 RNA transcripts at Week 2 that was mirrored by flow cytometry data. Additionally, there were transient increases in membrane IgD, membrane IgM and TCL1A genes which are associated with naïve B cells. Several of the patients in the DZP group also exhibited a ≥2 fold reduction in the expression of IFN-responsive genes (MX1, OAS1, IFITM3, G1P2) for at least 2 time points. No other consistent changes in other functional group expression patterns were observed.
**Conclusions:** In summary, DZP treatment resulted in changes in peripheral blood RNA transcripts found in plasma cells and B cells consistent with the inhibition of CD40L:CD40 signaling. A trend in the reduction of the IFN signature was also observed with DZP. The utility of this approach to monitor biological activity, early clinical response and patient stratification will be further explored.

## OP0041 JNJ-473 POTENTLY AND SPECIFICALLY DEPLETES PDCS IN SLE PATIENT BLOOD IN VITRO AND ABLATES TLR9-INDUCED INTERFERON ALPHA RESPONSES

K.A. Monaghan[1], T.Y. Tai[1], J. Benson[2], B. Linggi[3], S. Oon[4,5], M. Ng[1], A. Hoi[6], E. Morand[6], N.J. Wilson[1]. *[1]CSL limited, Melbourne, Australia; [2]Janssen Research and Development LLC, Spring House; [3]Janssen Research and Development LLC, La Jolla, United States; [4]The Walter and Eliza Hall Institute; [5]The Royal Melbourne Hospital; [6]Monash University, Melbourne, Australia*

**Background:** Plasmacytoid dendritic cells (pDCs) are potent producers of IFNα and are thought to have a pathogenic role in Systemic Lupus Erythematosus (SLE). JNJ-473, previously known as CSL362, is an Fc engineered, neutralising anti-IL-3Rα (CD123) monoclonal antibody that depletes CD123 expressing cells, such as pDCs. CSL362 has recently completed a phase I clinical trial in acute myeloid leukemia.
**Objectives:** To investigate the *in vitro* depletion of pDCs with JNJ-473 in SLE patient blood and evaluate novel biomarkers of JNJ-473 efficacy.
**Methods:** Blood samples from 34 SLE patients (31 female and 3 male; mean age = 44.5; mean SLEDAI = 4, range 0–21) and 34 healthy controls (HC), matched for age and gender, were obtained. Whole blood (WB) was analysed by flow cytometry (FACS) for absolute cell counts of various cell subsets (pDC, myeloid DC, basophils, monocytes, T-cell subsets, B-cell subsets, neutrophils, eosinophils and natural killer (NK) cells) and for CD123 expression. Peripheral blood mononuclear cells (PBMC) from SLE patients and HC were cultured with JNJ-473 (0, 0.0041, 0.0123 or 1 μg/ml) for 20 h and depletion of cell subsets analysed by FACS. Serum was assayed for 117 analytes by Luminex and RNA was extracted for RNAseq. PBMC from 9 SLE patients and 9 HC were cultured with 1 μg/ml JNJ-473 or isotype control for 20 h before stimulation with 0.5 μM CpG for 24 h and culture supernatant analysed by Luminex for 87 analytes.
**Results:** pDCs expressed the highest level of CD123 and SLE patients had significantly higher CD123 expression than HC (49325 vs 44152 receptors per cell). JNJ-473 induced potent and specific *in vitro* depletion of pDCs via NK cell mediated ADCC in PBMC from SLE patients (mean 85.80% depleted) and HC (mean 93.79% depleted). Basophils, which also express high levels of CD123, were partially depleted in SLE (mean 33.07% depleted) and HC (mean 66.64% depleted). NK cells were functional as demonstrated by up-regulation of the degranulation marker CD107a, and down-regulation of CD16 after JNJ-473 treatment and by effective depletion of pDCs. In SLE sera, 27 analytes were significantly increased compared to HC, including IFN inducible proteins IP-10 and ITAC. RNAseq analysis showed that SLE patient samples had 605 up-regulated and 498 down-regulated transcripts when compared to HC. These included many secreted proteins, some of which (IP-10, ITAC, IGFBP2, MCP-2 and BAFF) were upregulated at both the RNA and protein level in SLE. Depletion of pDCs with JNJ-473 prevented TLR9 agonist (CpG)-induced production of IFNα and other proteins including IP-10, ITAC and MCP-2.
**Conclusions:** JNJ-473 potently and specifically depletes SLE patient peripheral blood pDCs *in vitro*. JNJ-473–mediated depletion of pDCs resulted in reduced TLR9-induced IFNα and IFN-regulated protein production. These JNJ-473 modulated proteins were significantly elevated at both the protein and RNA level in our SLE patient cohort. These findings suggest JNJ-473 could effectively deplete pDCs and inhibit TLR9-induced proteins in SLE.

## OP0042 HUMANISED ANTI-CD20 ANTIBODIES IMPROVE DEPLETION AND RESPONSE IN SLE PATIENTS WITH RESISTANCE TO RITUXIMAB: RESULTS FROM THE FIRST 100 PATIENTS AT A SINGLE CENTRE

M.Y. Md Yusof[1,2], H. Cassamoali[1], T. Hawkins[1], A. Rawstron[3], E. Dunn[4], P. Emery[1,2], E.M. Vital[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit; [3]Haematological Malignancy Diagnostic Service; [4]Renal Medicine, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

**Background:** Rituximab (RTX) is effective for refractory SLE based on strong evidence for efficacy from open label evidence. We have observed cases of SLE patients who previously responded well to RTX developing anti-rituximab antibodies (HACA). We have therefore treated these patients with alternative, humanised anti-CD20 antibodies.
**Objectives:** To evaluate the incidence of secondary non-response to RTX and efficacy of switching to humanised anti-CD20 antibodies in SLE.
**Methods:** We conducted a retrospective observational study of the first 100 consecutive SLE patients treated with RTX at a single centre (total follow-up: 445 patient-years). Each cycle of RTX consisted of 2x1000mg infusions repeated on clinical relapse. Patients who demonstrated features of HACA, ie: infusion reaction >24 hours after the second infusion with <50% B cell depletion as analysed using HSFC were treated either with 2x1000mg ocrelizumab (OCR) or 2x700mg ofatumumab (OFT). Response was defined as improvement to ≤1 persistent BILAG B and no A/B flare.
**Results:** 94 patients with complete response data at 6 months were studied. In Cycle 1 (C1), 81/94 (86%) achieved a BILAG response. 1 patient with severe SLE whom B cell had not depleted and C1 non-responder was retreated with RTX but subsequently developed HACA. She was treated with OCR resulted in depletion and biological response ie: normalisation of anti-dsDNA but died 6 months later with multi-organ failure. Of the C1 responders, 63 patients received RTX on clinical relapse. Of this, 54/63 (86%) responded and 8/9 (13%) were non-responders due to HACA. Of the C2 non-responders, 3/9 patients were treated with OCR resulted in depletion in 2/3 and all responded. 1/9 was treated with OFT achieved depletion for the first time as well as stabilisation of renal function. In C3, 1 had HACA and was treated with OFT, resulted in depletion and response.

| Characteristic | Previous rituximab cycle | | Rituximab cycle with secondary non-response (n=5) | | 1st Alternative anti-CD20 antibody cycle | |

| Memory B cells | 0.0068 | 0 | 0.0210 | 0.0054 | 0.0116 | 0 |
| Plasmablasts | 0.0203 | 0.0032 | 0.0103 | 0.0073 | 0.0029 | 0.0005 |
| Total B cells | 0.0722 | 0.0032 | 0.0946 | 0.0210 | 0.0383 | 0.0009 |

**Conclusions:** Following initial response to RTX, the incidence of secondary non-response was 15%, mostly due to HACA. Switching to alternative humanised anti-CD20 antibodies improves depletion and clinical response in rituximab-resistant patients in this largest case series to date. Humanised anti-CD20 may be more appropriate than RTX in SLE.

## OP0043 CORTICOSTEROID USE OVER TIME IN THE SYSTEMIC LUPUS INTERNATIONAL COLLABORATING CLINICS (SLICC) INCEPTION COHORT - A DESCRIPTIVE ANALYSIS

J. Little, M. Lunt, B. Parker, I.N. Bruce on behalf of The Systemic Lupus International Collaborating Clinics Group. *Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Institute of Inflammation and Repair, University of Manchester, Manchester, United Kingdom*

**Background:** Corticosteroid (CS) use has been identified as a key factor associated with damage in SLE but detailed analyses of patterns of use in large international cohorts have not previously been reported.
**Objectives:** To describe oral (PO) and parenteral CS use in a large international SLE cohort.
**Methods:** The SLICC Inception Cohort recruited patients within 15 months of developing ≥4 1997 American College of Rheumatology (ACR) criteria for SLE, between 2000 and 2011. Details of PO and parenteral steroid use were captured at enrolment and each annual assessment, including type, dose and course dates. All CS data was converted to prednisolone equivalents and analysed using Stata 13.
**Results:** 1848 patients have been recruited to the Cohort. Those with follow up data (1686) are included in this analysis, providing data on 10,572 annual follow-up (FU) intervals. The mean (SD) total FU is 6.72 (3.60) years; 1072 (63.5%) patients contributed ≥5 years FU; 343 (20.3%) contributed ≥10 years FU.
The proportion of time spent on PO CS can be calculated for 10,098 (95.5%) FU intervals. For the majority of FU intervals (n=9103 (90.1%)), NONE (4494 (44.5%)) or ALL (4609 (45.6%)) of the time was spent on PO CS. In 995 (9.9%) FU intervals, only a proportion of the time was spent on PO CS. In those FU intervals where PO CS have been received (n=5604) the median (IQR) "average daily PO dose" was 6.5 (4.75–10) mg. The average daily CS dose decreased in later FU intervals: median (IQR) at FU 1=10 (5–15) mg and at FU 5=5.5 (4.8–10.0) mg. 558 (34.7%) patients have been on PO CS for ALL of their time in the study, 720 (44.8%) for some of it and 330 (20.5%) have never been on PO CS. 228 patients (13.5%) received parenteral CS prior to and/or at enrolment at a median (IQR) total dose of 1.5 (0.5–3.0) g. CS pulses were given during 429 (4.37%) FU intervals at a median (IQR) total dose of 679.5 (120–2500) mg. This compares to a median (IQR) cumulative total PO dose between FUs of 2565 (1575–4462) mg. PO CS use between FUs (using various definitions - see table 1) was higher in those FU intervals in which pulsed CS have also been given.

Table 1. Point estimates (medians) of various CS exposures, grouped according to the total dose of pulsed CS received between visits

| Total dose of of pulsed CS between visits* | Total cumulative PO CS dose in FU interval (mg) | Average daily PO CS dose in FU interval (mg) | Maximum daily PO CS dose in FU interval (mg) | Total time on PO CS (days) | Proportion of time between visits on PO CS |
|---|---|---|---|---|---|
| >1000mg (n=175) | 5184 | 14.0 | 30 | 364 | 1 |
| 250–1000mg (n=59) | 3960 | 10.0 | 20 | 352 | 1 |
| <250mg (n=143) | 1430 | 4.6 | 10 | 256 | 0.81 |
| 0mg (n=9841) | 600 | 1.5 | 10 | 163 | 0.39 |

*Total dose available for 377/429 intervals.

**Conclusions:** CS are widely prescribed in this international SLE cohort. 79.5% have been on CS at some point and 1 in 3 patients have taken CS throughout their entire disease duration. PO CS tend to be given at low daily doses for long periods of time but with a higher average daily dose earlier in the disease. Parenteral steroid use is associated with higher overall PO CS use, however PO CS contribute most to the total cumulative dose that patients receive. Current management of SLE still relies on CS use as a mainstay of therapy in a high proportion of patients.
**Acknowledgement:** The Systemic Lupus International Collaborating Clinics (SLICC) acknowledge funding support of UCB Pharma for this study.

## OP0044 SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) RESPONDER INDEX [SRI(4)] RESPONSE IS ASSOCIATED WITH GLOBAL BENEFIT IN PATIENTS WITH MODERATE TO SEVERE SLE

R. Furie[1], L. Wang[2], J. Drappa[2], G. Illei[2]. *[1]Northwell Health, Great Neck; [2]MedImmune, Gaithersburg, United States*

**Background:** The SRI(4) is a composite endpoint used in SLE clinical trials. A *post-hoc* analysis of two Phase III studies of belimumab[1] showed that the achievement of an SRI(4) response at 52 weeks is associated with clinically meaningful benefits, irrespective of the treatment assignments. Confirmation of these findings in independent cohorts will enhance the wider acceptance of SRI(4) as a measure of clinically meaningful improvement.
**Objectives:** We assessed the global clinical benefit represented by the achievement of an SRI(4) response in patients with moderate to severe SLE.
**Methods:** Changes from baseline in clinical, laboratory, and patient reported outcome measures at Day 365 were compared between SRI(4) responders (n=396) and non-responders (n=340) in the combined dataset of two Phase II studies that evaluated sifalimumab and anifrolumab in moderate to severe SLE.
**Results** (detailed in Table): Baseline demographics were similar between the two studies. At Day 365, a greater percentage of responders than non-responders had a ≥7-point reduction in SLE Disease Activity Index 2000 (SLEDAI-2K) and achieved a reduction of oral corticosteroid dose to ≤7.5 mg/day. Responders also had a greater percentage change from baseline in clinical SLEDAI scores, greater improvements in the Physician's Global Assessment (PGA) score and the number of organ domains with improvement on SLEDAI-2K. The rates of British Isles Lupus Assessment Group (BILAG) "A" or "2B" flares were lower in SRI(4) responders compared with non-responders. Among patients with ≥8 swollen and ≥8 tender joints at baseline, a larger percentage of responders had a ≥50% improvement in swollen and tender joint counts. In patients with moderate to severe skin disease at baseline, defined as a Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) activity score ≥10, a greater percentage of responders had ≥50% improvement in CLASI. In patients with abnormal baseline serological parameters, responders had greater improvements in anti-double stranded DNA concentrations; however, the differences in complement C3 and C4 concentrations were not significant. Responders also had greater improvements in patient-reported outcomes: percentage change from baseline in Patient Global Assessment, and absolute change in Short Form 36 Health Survey (SF-36) [Physical Component Summary (PCS) score; Mental Component Summary (MCS) score; Vitality domain], and Functional Assessment of Chronic Illness Therapy (FACIT)–Fatigue scores.

## LB0001 EFFICACY AND SAFETY OF SUBCUTANEOUS BELIMUMAB PLUS STANDARD CARE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) WITH LOW COMPLEMENT AND POSITIVE ANTI-DSDNA

A. Doria[1], W. Stohl[2], A. Schwarting[3], M. Okada[4], M. Scheinberg[5], R. van Vollenhoven[6], A.E. Hammer[7], J. Groark[8], D. Bass[8], N.L. Fox[9], D. Roth[8], D. Gordon[8]. *[1]University of Padua, Padua, Italy; [2]University of Southern California, Los Angeles, United States; [3]ACURA Kliniken, Bad Kreuznach, Germany; [4]St Luke's International University, Tokyo, Japan; [5]Rheumatology Hospital Abreu Sodre, San Paulo, Brazil; [6]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [7]GSK, RTP; [8]GSK, Philadelphia; [9]GSK, Rockville, United States*

**Background:** In post hoc analyses of the BLISS trials, patients with SLE with positive anti-dsDNA and low complement (C3/C4) had a greater response to intravenous belimumab (BEL) compared with patients without these characteristics.[1]
**Objectives:** To assess the efficacy and safety of subcutaneous (SC) BEL plus

standard SLE care (SoC) in patients with SLE with low C3/C4 and positive anti-dsDNA.
**Methods:** BLISS-SC (BEL112341; NCT01484496) was a randomised, double-blind, multicentre, placebo-controlled trial. Patients with SELENA-SLEDAI (SS) ≥8 were randomised (2:1) to weekly BEL 200 mg SC or placebo (PBO), plus SoC. The primary endpoint was the SLE Responder Index 4 (SRI4; ≥4-point decrease in SS, <0.3 increase in Physician's Global Assessment, and no new BILAG A or ≤1 BILAG B organ domain scores, from baseline) at Week 52. Secondary endpoints included time to severe flare and reduction in steroid dose. Adverse events (AEs) were used to assess safety. Efficacy and safety data have been presented[2]; here, data are reported for a subset of patients who were anti-dsDNA positive and hypocomplementemic at baseline.
**Results:** Of 839 patients randomised, 356 had low C3/C4 and positive anti-dsDNA; baseline characteristics were similar between groups.

Baseline characteristics

| | PBO (n=108) | BEL 200 mg SC (n=248) |
|---|---|---|
| Mean (SD) age, years | 34.6 (10.38) | 34.6 (10.96) |
| Median (range) disease duration, years | 4.0 (0, 32) | 5.1 (0, 35) |
| Mean (SD) SS | 11.7 (3.14) | 11.5 (3.31) |
| Mean (SD) steroid dose (prednisone equivalent), mg/day | 11.4 (7.39) | 12.2 (8.34) |
| Antimalarials, % | 63.0 | 71.4 |
| Immunosuppressants, % | 54.6 | 47.2 |

At Week 52, SRI4 response was PBO 47.2% vs BEL 64.6% (odds ratio: 2.23 [95% CI 1.36, 3.64]; p=0.0014); SRI components were statistically significant. The BEL group was 62% less likely to experience a severe flare vs PBO (hazard ratio: 0.38 [95% CI 0.24, 0.61]; p<0.0001); median time to first severe flare among those having a severe flare was PBO 126.5 vs BEL 90.0 days. Numerically but not statistically (p=0.0844) more patients reduced steroid dose by ≥25% to ≤7.5 mg/day during Weeks 40–52 in the BEL group (20.7%) vs PBO (11.4%).
AE incidence was PBO 81.5%, BEL 78.2%; the most common (≥10% in either group) were headache (PBO 9.3%, BEL 10.5%) and nasopharyngitis (PBO 4.6%, BEL 10.1%).
Serious AE incidence was PBO 23.1%, BEL 13.3%; none occurred in ≥2.0% of patients. There were 5 deaths (PBO 1.9%, BEL 1.2%). The incidence of depression was PBO 2.8%, BEL 4.4%, with 1 case of suicide ideation (BEL 0.4%).
**Conclusions:** Patients with SLE with low C3/C4 and positive anti-dsDNA had significantly greater SRI4 responses and fewer severe flares with BEL 200 mg SC vs PBO (plus SoC). The treatment effect for SRI4 response was numerically larger compared with the overall population.[2] Safety in both groups was similar.

## Scleroderma, myositis and related conditions

### OP0045 EARLY DETECTION OF LUNG INVOLVEMENT IN SYSTEMIC SCLEROSIS USING MOLECULAR TARGETED IMAGING

J. Schniering[1], S. Haller[2], Z. Guo[1], C. Feghali-Bostwick[3], R. Schibli[2], O. Distler[1], C. Müller[2], B. Maurer[1]. [1]*Division of Rheumatology, University Hospital Zurich, Zurich;* [2]*Center for Radiopharmaceutical Sciences ETH-PSI-USZ, PSI-Villigen, Switzerland;* [3]*Division of Rheumatology & Immunology, Medical University of South Carolina, Charleston, United States*

**Background:** Interstitial lung disease (ILD) is one of the leading causes of death in systemic sclerosis (SSc). Since routine diagnostics such as CT and pulmonary function tests only detect impaired organ function and/or damage, there is an unmet need for the non-invasive diagnosis of ILD at earliest, possibly still reversible disease stages.
**Objectives:** To assess nuclear imaging for the detection of SSc-ILD by using radiotracers specifically targeting integrin $\alpha_v\beta_3$ as a pathophysiologic key molecule of early inflammation-dependent fibrosis in the murine model of bleomycin-induced pulmonary fibrosis and in the multisystemic Fra-2 transgenic (tg) mouse model of SSc.
**Methods:** Expression of integrin $\alpha_v\beta_3$ was analysed in lung sections from patients with SSc-ILD, idiopathic pulmonary fibrosis (IPF), healthy controls (n=5) as well as from bleomycin-treated mice, Fra-2 tg mice and respective controls (n=4) using immunohistochemistry. *In vivo* imaging was performed using $^{111}$In-DOTA-RGD radioconjugates specifically targeting integrin $\alpha_v\beta_3$. SPECT (single photon emission computed tomography) was performed using a small-animal SPECT/CT scanner (NanoSPECT/CT, Mediso). Animals were scanned at early disease time points to visualise inflammation-dependent pulmonary fibrosis. The pulmonary accumulation of the radiotracer was confirmed by *ex vivo* SPECT/CT, biodistribution, and autoradiography studies. Nonparametric non-related data were expressed as median$_{(Q1,Q3)}$. For statistical analysis, the Mann-Whitney U test was applied. P-values <0.05 were considered statistically significant.
**Results:** In lung sections of patients with SSc-ILD and IPF, the expression of integrin $\alpha_v\beta_3$ was increased by 3.7-fold and 2.9-fold, respectively as compared to healthy controls (p<0.009, p<0.02). Lungs of bleomycin-treated and Fra-2 tg mice, but not of controls showed a significant increase in integrin $\alpha_v\beta_3$ expression (upregulation by 5.7-fold and 4.8-fold, respectively) as we have similarly observed in SSc-ILD and IPF patients (p<0.03 each, Fig. C). Integrin $\alpha_v\beta_3$ was primarily expressed on endothelial cells, inflammatory cells and myofibroblasts as indicated by sequential stainings with cell type-specific markers. Notably, at day 7 after intratracheal bleomycin installation, the peak of pulmonary inflammation, nuclear SPECT/CT with $^{111}$In-DOTA-RGD targeting integrin $\alpha_v\beta_3$, successfully visualised pulmonary inflammation and incipient fibrosis in the model of bleomycin-induced pulmonary fibrosis. Similarly, imaging of integrin $\alpha_v\beta_3$ in Fra-2 tg mice at 13 weeks of age, the starting point of pulmonary fibrosis, showed a higher pulmonary uptake of the radiotracer in Fra-2 tg mice than in controls (Fig. A). *Ex vivo* SPECT/CT of isolated lungs, biodistribution and autoradiography studies confirmed the *in vivo* results and validated the specific radiotracer uptake in lungs from bleomycin-challenged mice and Fra-2 tg mice as compared to controls (Fig. B).

**Conclusions:** Our data provide the first evidence that targeting pathophysiologic key molecules using nuclear imaging methods for the visualization of inflammation-dependent fibrosis is a promising non-invasive approach for the early detection of lung involvement in SSc.

## OP0046 DECREASED CIRCULATING ILC2 LEVELS CORRELATE WITH SKIN FIBROSIS IN HUMAN SYSTEMIC SCLEROSIS AND ARE ASSOCIATED WITH A SKEWING OF THE ILC1/ILC2 BALANCE IN THE SKIN

P. Laurent[1], P. Manicki[1], I. Douchet[1], E. Lazaro[2], P. Duffau[1,3], C. Richez[1,4], J. Sénéschal[5], J. Constans[6], T. Pradeu[1], P. Blanco[1,7], C. Contin-Bordes[1,7], M.-E. Truchetet[1,4]. *[1]Laboratoire d'immunologie, Université de Bordeaux, Bordeaux; [2]Service de Médecine Interne, CHU Haut-Lévèque, Pessac; [3]Service de Médecine Interne, CHU Saint-André; [4]Service de Rhumatologie, CHU Pellegrin; [5]Service de Dermatologie; [6]Service de Médecine Vasculaire, CHU Saint-André; [7]Laboratoire d'Immunologie, CHU Pellegrin, Bordeaux, France*

**Background:** Interleukin (IL)13 is considered as a key downstream mediator in the development of Systemic sclerosis (SSc) fibrosis[1]. The recently described type 2 innate lymphoid cells (ILC) produce higher amounts of IL13 than Th2 cells under certain stimulatory conditions[2]. Our recent work show that endothelial cells are an important source of thymic stromal lymphopoietin (TSLP) in SSc[3], which is an inducer of IL13 production by ILC2. Altogether, we assume that ILC2 could have a role in the promotion of SSc fibrosis.
**Objectives:** To analyse ILC populations in whole blood and skin of SSc patients and heatlhy donors (HD) and to correlate to clinical parameters.
**Methods:** 25 SSc and 15 HD were prospectively enrolled between September 2015 and January 2016 in the University Hospital of Bordeaux. Skin biopsies were performed in fibrotic skin for 2 SSc patients and in pieces of brachioplasty for HD. All patients signed informed consent. Analysis were done on fresh blood after Red Blood lysis and on cells from skin biopsies digested with liberase and DNase. ILC were measured by flow cytometry using Beckman Coulter and Miltenyi Biotech kits respectively. For peripheral blood and skin, results are expressed as median and means respectively. Mann-Whitney test is used for comparisons.
**Results:** In SSc patients, circulating ILC were significantly decreased both in frequency (0.0094% of total cells [0.0005–0.052] in HD vs. 0.0024% [0.0002–0.029] in SSc, p=0.006) and in absolute counts (0.146 [0.0089–1.641] in HD vs. 0.032 [0.0049–0.427] in SSc, p=0.0005). This global decrease was mainly due to the decrease of the ILC2 frequency (0.0077% of total cells [0.0009–0.031] in HD vs. 0.0024% [0.00–0.01] in SSc, p=0.0009) and absolute counts (0.123 [0.0153–0.574] in HD vs. 0.033% [0.00–0.167] in SSc, p<0.0001).
The number of ILC2 in peripheral blood was inversely correlated to skin fibrosis as assessed by the modified Rodnan skin score (r=-0.6, p=0.0041, using a Pearson test).
Analysis of ILC content in total cells showed that ILC2 are present in both normal and SSc skin. However, we showed a skewing towards ILC2 (83.6% of total ILC in SSc vs. 66.4% in HD) at the expense of ILC1 (7.5% in SSc vs. 18.85% in HD) in SSc skin, while ILC3 were not affected.
**Conclusions:** SSc patients are characterized by a decrease of the ILC2 subpopulation in peripheral blood inversely correlated to skin fibrosis and a skewing of the type 1/type 2 ILC balance in the skin towards ILC2. Altogether these results show for the first time flow cytometry analysis of ILC content in whole blood and skin of SSc patients, which pave the road for further extensive phenotypic analysis.

## OP0047 EXPRESSION OF HEAT SHOCK PROTEIN 90 IN MUSCLE TISSUE AND PLASMA IS INCREASED IN IDIOPATHIC INFLAMMATORY MYOPATHIES AND CORRELATES WITH DISEASE ACTIVITY, SKELETAL MUSCLE, HEART AND LUNG INVOLVEMENT

H. Storkanova[1], O. Krystufkova[1], M. Klein[1], H. Mann[1], L. Vernerova[1], M. Spiritovic[1,2], J. Zamecnik[3], K. Pavelka[1], L. Senolt[1], J. Vencovsky[1], M. Tomcik[1]. *[1]Dept. of Rheumatology, 1st Faculty of Medicine, Institute of Rheumatology; [2]Faculty of Physical Education and Sport; [3]Dept. of Pathology and Molecular Medicine, 2nd Medical School and University Hospital Motol, Charles University, Prague, Czech Republic*

**Background:** Heat shock proteins (Hsps) are chaperones playing important roles in skeletal muscle physiology, adaptation to exercise/stress, and activation of inflammatory cells.
**Objectives:** To assess Hsp90 expression in muscle biopsies and plasma of patients with idiopathic inflammatory myopathies (IIM) and to characterize its association with IIM-related features.
**Methods:** Total of 277 patients with IIM (198 females, 79 males; mean age 54.8; disease duration 4.1 years; dermatomyositis (DM, 104)/polymyositis (PM, 104)/cancer associated myositis (CAM, 42)/ necrotizing myopathy (IMNM, 27)) and 100 age-/sex-matched healthy individuals were included in plasma analysis and 50 muscle biopsy samples were stained for Hsp90 (PM-10, DM-10, IMNM-10, myodystrophy-10, myasthenia gravis-10). Patients with PM/DM fulfilled Bohan and Peter criteria and CAM was defined as cancer within 3 years of IIM diagnosis. Plasma Hsp90 was measured by ELISA (eBioscience, Vienna, Austria). Clinical disease circumstances were evaluated by Myositis Disease Activity Assessment (MYOACT), Myositis Intention to Treat Index (MITAX), Myositis Damage Index (MDI), physician and patient global activity using VAS and manual muscle testing (MMT8). CK, LD, ALT, *AST* and CRP were analyzed by routine techniques and IIM-specific autoantibodies by in-line blot and immunoprecipitation. Data are presented as median.
**Results:** In muscle biopsies Hsp90 expression was higher in IIM than in myodystrophy (myasthenia gravis used as another control was negative). Increased Hsp90 was detected in perifascicular degenerating and regenerating fibers, inflammatory cells (DM, PM), and necrotic and regenerating fibers (IMNM). Plasma Hsp90 levels were increased in IIM patients compared to healthy controls (20.2 vs. 9.2 ng/ml, p<0.0001), and in individual subgroups of IIM vs. healthy controls (PM: 19.4, DM: 22.4, CAM: 19.1, IMNM: 19.6 ng/ml, p<0.0001 for all). Hsp90 levels in all patients positively correlated with LD and AST (r=0.551, p<0.0001; r=0.372, p<0.0001, respectively), and there was a trend towards correlation with CK (r=0.111, p=0.068). Increased Hsp90 was associated with decreased MMT8 values (r=-0.136, p=0.029), in particular in proximal muscles. Hsp90 positively correlated with patient and doctor disease activity (r=0.222, p=0.0004; r=0.217, p=0.0005, respectively), pulmonary and muscle disease activity (r=0.201, p=0.001; r=0.146, p=0.018, respectively), MITAX and MYOACT (r=0.175, p=0.005; r=0.159, p=0.012, respectively), and with MDI extent/severity (r=0.215, p=0.003; r=0.120, p=0.041, respectively). Higher Hsp90 was found in patients with interstitial lung disease, cardiac involvement and dysphagia (25.4 vs. 18.9, p=0.004; 27.5 vs. 19.3, p=0.004; 25.0 vs. 18.2, p=0.018, respectively).
**Conclusions:** We demonstrate increased Hsp90 expression in IIM muscle biopsy samples, specifically in inflammatory cells, degenerating, regenerating and/or necrotic fibers. Increased Hsp90 plasma levels in IIM patients are associated with disease activity and damage, and with the involvement of proximal skeletal muscles, heart and lungs.

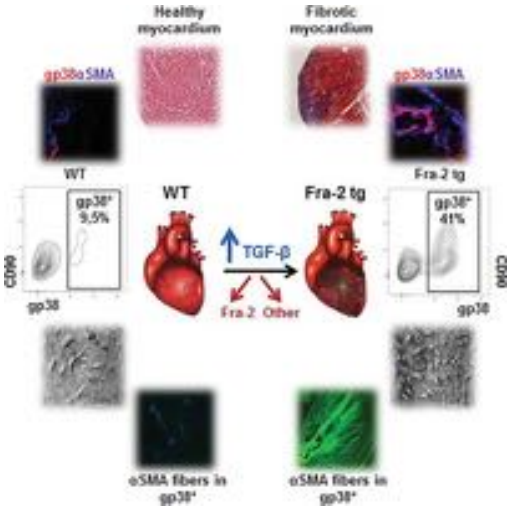
## OP0048 IL-31 IS AN INFLAMMATORY PRO-FIBROTIC FACTOR ELEVATED IN A SUBSET OF SCLERODERMA PATIENTS WITH SEVERE PRURITUS



N. Arumalla[1], S. Zafar[1], H. Rosario[1], B. Ahmed Abdi[2], Z. Taki[2], C. Denton[1], D. Abraham[2], R. Stratton[1], N. Mazumder[1], O. Etomi[1], A. Mohamed[1], F. Xing[2]. *[1]Rheumatology, Royal Free Hospital; [2]University College London, London, United Kingdom*

**Background:** Systemic sclerosis (SSc) is an autoimmune rheumatic disease associated with fibroblast activation in the skin and visceral organs. In SSc, refractory pruritus is a common symptom in a subgroup of patients. IL-31 is a Th2 cell derived cytokine implicated in severe itch in other conditions including atopic dermatitis and T cell lymphoma. T-lymphocyte-derived factors provide a possible link between autoimmune inflammation and fibrosis reported in SSc. In this study we measured IL-31 levels in SSc tissue fluid and plasma, and sought correlation with itch severity and clinical parameters. Recombinant IL-31 was found to influence fibroblast and fibroblast precursor activity.
**Methods:** IL-31 was measured by ELISA of dermal tissue fluid samples obtained by a suction blister analysis method from the involved skin of SSc patients or matched site of healthy controls (SSc n=28, controls n=15), and matched plasma samples. IL-31 receptor mRNA expression was assayed by qPCR of SSc and control fibroblast lysates, as well as epithelial tissue biopsy samples. Normal skin fibroblasts as well as fat derived mesenchymal stem cells (MSCs) were treated with IL-31 (50 ng/ml) and migratory and fibrotic responses were assayed.
**Results:** IL-31 levels were increased in dermal interstitial fluid in SSc patients compared to controls (mean of 99.4 pg/ml vs 2.3 pg/ml in controls, P<0.0003) and in plasma samples (mean plasma IL-31 1370 vs 196 pg/ml, P<0.01). Dermal fluid IL-31 levels correlated strongly with itch severity in these patients R=0.72, P<0.0038). Raised blister fluid IL-31 was characteristic of a subgroup of SSc patients with severe pruritus, which included individuals from both limited and diffuse SSc clinical subsets. Both normal and disease fibroblast extracts contained IL-31 receptor mRNA (qPCR relative copy number 6.4 SSc vs 1.4 controls, p<0.01) which was also seen in epidermal tissue extracts (qPCR 18.4 SSc vs 8.2 in control, p NS). Treatment of normal dermal fibroblasts with IL-31 led to induction of type I collagen but not CTGF, and promoted fibroblast and MSC migration dependent on ERK and PI3kinase pathways.
**Conclusions:** This is the first analysis of IL-31 in systemic sclerosis and we have shown increased expression in the skin and plasma of a subgroup of SSc patients, correlating with severe itch. IL-31 protein induced fibroblasts and MSCs and may link T-cell autoimmune responses to fibroblast and precursor cell activation in SSc. Blocking IL-31 therapeutically may provide effective treatment in a subgroup of SSc patients identified clinically by severe pruritus.

## OP0049 MYOCARDIAL FIBROGENESIS IN SYSTEMIC SCLEROSIS: INVOLVEMENT OF A NOVEL STROMAL SUB-POPULATION

M. Stellato[1], M. Rudnik[1], F. Renoux[1], E. Pachera[1], K. Sotlar[2], K. Klingel[3], J. Henes[4], P. Blyszczuk[5], O. Distler[1], G. Kania[1]. *[1]Division of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Institute of Pathology, Munich; [3]Institute of Molecular Pathology, University Clinic Tubingen; [4]Division of Rheumatology, University Hospital Tubingen, Tubingen, Germany; [5]Center of Molecular Cardiology, University of Zurich, Zurich, Switzerland*

**Background:** Cardiac dysfunction is a significant cause of the high mortality in systemic sclerosis (SSc). Heart involvement in SSc patients resembles inflammatory dilated cardiomyopathy (iDCM) with inflammation and fibrosis. Myofibroblasts are the main players in cardiac fibrogenesis, but their origin remains unknown.
**Objectives:** Here, we aim to determine the role of specific myocardial stromal cell populations in myocardial remodeling in SSc.
**Methods:** The Fos-related antigen 2 (Fra2) tg mouse model of SSc/iDCM was studied. Immunohistochemistry (IHC) and immunofluorescence (IF) were performed on endomyocardial biopsies (EMBs) from SSc/iDCM patients (n=10) and on hearts from Fra2 tg mice (n=5). Flow cytometry analysis was used to identify subsets of myocardial stromal cells ($Ter119^-CD45^-CD31^-Sca1^+CD29^+$). Different stromal cell subsets were sorted, cultured and stimulated with TGFβ1. The differentiation potential was assessed by qPCR, IF, stress fiber staining, SIRCOL and contraction assay on sorted cells. The antisense oligonucleotide GapmeR was used to downregulate Fra2.
**Results:** Fra2 tg mice showed increased $CD45^+$ leukocyte infiltrates and massive collagen deposition in the heart tissue similarly to the myocardium of SSc/iDCM patients. Moreover, the myocardium of Fra2 tg mice revealed increased expression of pro-fibrotic markers such as αSMA, vimentin, collagen I and fibronectin compared to wild type mice.
Four myocardial stromal cell populations were identified: $gp38^+CD90.2^-$, $gp38^+CD90.2^+$, $gp38^-CD90.2^+$ and $gp38^-CD90.2^-$. The frequency of $gp38^+CD90.2^-$ (single positive) cells and $gp38^+CD90.2^+$ (double positive) cells was significantly higher in Fra2 myocardium compared to control mice (p=0.009; n=11).
Importantly, in the myocardium of Fra2 tg mice, the majority of $gp38^+$ cells co-expressed αSMA, vimentin, collagen and fibronectin indicating that myocardial $gp38^+$ stromal cells might proliferate and/or differentiate towards the myofibroblast phenotype.
Myocardial single and double positive stromal cells were cultured *in vitro*. After TGFβ1 stimulation, both cell populations up-regulated αSMA mRNA levels. Importantly, stromal cells from Fra2 tg mice showed the presence of αSMA fibers and stress fibers even without TGFβ1 stimulation as well as an increased contraction capability compared to control cells. These findings indicate that Fra2 overexpression might trigger the differentiation of these cells.
Consequently, Fra2 silencing resulted in a decreased differentiation capability of $gp38^+$ stromal cells: mRNA levels of the pro-fibrotic genes αSMA and collagen I were significantly downregulated (p=0.0075 and p=0.0073; n=5). Moreover, Fra2 downregulation impaired the secretion of collagens and the formation of αSMA fibers.

**Conclusions:** We suggest that cardiac $gp38^+$ stromal cell populations might serve as a cellular source of pathological myofibroblasts playing a pivotal role in TGFβ/Fra2-driven myocardial remodeling in SSc.
A better understanding of the mechanisms triggering myocardial dysfunction in SSc might be helpful in developing novel and effective therapies.

## OP0050 SERUM LEVELS OF ADIPOKINES IN THE CATEGORIES OF BODY MASS INDEX (BMI) IN PATIENTS WITH SYSTEMIC SCLEROSIS

E. Praino[1], C. Rotondo[1], C. Scioscia[1], M.G. Anelli[1], A. Chialà[1], L. Coladonato[1], S. Perniola[1], D. Natuzzi[1], C. Bruni[2], S. Guiducci[2], M. Matucci-Cerinic[2], G. Lapadula[1], F. Iannone[1]. *[1]DIM Rheumatology Unit, University of Bari, Bari; [2]Dept Experimental and Clinical Medicine - Section of Rheumatology, University of Florence, Florence, Italy*

**Background:** Adipose tissue is a source of factors stimulating the pro-oxidative-antioxidant system, such as adipokines, whose functions are closely associated with metabolic abnormalities and damage by oxidative stress. There are only few reports in literature about the correlation between body mass index (BMI), serum levels of adipokines and clinical manifestations of SSc.
**Objectives:** We evaluated serum levels of adipokines (leptin, resistin, visfatin, adiponectin) and cytokines (TNFα, IFNγ, IL-2, IL-10, IL-17) in SSc and controls (HD) and their pattern according the clinical and laboratory SSc features.
**Methods:** 89 SSc pts satisfying ACR EULAR criteria (age 52 ± 14.4 years and disease duration of 8.14 ± 6.6) and 26 HD were enrolled. Serum levels of Adiponectin, Leptin, Resistin, Visfatin, TNFα, IFNγ, IL-2, IL-10, IL-17A were measured using Bio-Rad kits and Multiplex Immunoassay tool. In all participants we collected clinical and laboratory features, such as visceral involvement, BMI, WHR (Waist to Hip Ratio), index of cardiovascular risk, acute phase reactants, cholesterol, triglycerides, smoking status, comorbidity and therapy. Data were analysed using IBM-SPSS Statistics 20 software. Mann-Whitney U-test or t-Student for unpaired data or Kruskal-Wallis test or ANOVA were used for comparison between groups. Spearman's or Pearson's test were used for correlations. A p-value $\leq$0.05 was considered statistically significant.
**Results:** The weight of SSc and HD differed ($p<0,05$) which was higher in HD. Serum levels of Leptin, Resistin, Visfatin and IL-10, IL-17 were increased in SSc compared to HD ($p<0.05$). In SSc, TNFα serum levels were not different from HD. Leptin levels positively correlated with body weight and BMI that in turn correlated with the values of ESR, CRP, WHR, triglycerides and cholesterol serum levels. Increased levels of IL-2, IL-10, IL-17, IFNγ, Leptin and Visfatin were found in overweight/obese SSc pateints ($p<0.05$) in respect to HD. TNFα was significantly increased in underweight patients (p=0.03) and there was a significant difference compared with normal weight (p=0.018). TNFα levels correlated with IL-2, IL-10, IL-17 and IFNγ levels and with esophageal involvement. There were no differences in cytokine levels between groups when correlated to skin subset, disease duration (Early/Late) and different class of cardiovascular risk. In HD, no statistically significant correlation between weight, TNFα and Leptin levels was detected.
**Conclusions:** Adipokines may play a role in inflammatory and immune pathways in SSc pathogenesis. The present data suggest a role for Leptin and TNFα as new potential SSc related circulating biomarker. Categories of modified BMI (underweight and obesity) seem to be associated to a different and a significant organ involvement in SSc. In underweight subjects, the increase of TNFα may be involved in the cachectic status, thus the role of TNFα needs be confirmed in further prospective longitudinal studies investigating also its correlation with disease severity and activity.

## OP0051 DIPEPTIDYL-PEPTIDASE-4 (DPP4) CHARACTERIZES A SUBPOPULATION OF FIBROSIS-PROMOTING FIBROBLASTS AND IS A MOLECULAR TARGET FOR THE TREATMENT OF FIBROSIS

A.M. Soare[1], C. Dees[1], Y. Zhang[1], R. Liang[1], T. Wohlfahrt[1], S. Rauber[1], N. Lin[1], C.-W. Chen[1], A. Ramming[1], O. Distler[2], C. Mihai[3], G. Schett[1], J. Distler[1]. *[1]Department of Internal Medicine 3 and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Center of Experimental Rheumatology and Zurich Center of Integrative Human Physiology, University Hospital Zürich, Zürich, Switzerland; [3]Department of Internal Medicine and Rheumatology, "Dr. I. Cantacuzino" Clinical Hospital, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania*

**Background:** Dipeptidyl-peptidase-4 (DPP4/CD26) has been recently identified as a marker for a special fibroblast lineage responsible for the tissue remodeling during physiological wound healing. Fibrotic disease may be considered as a consequence of persistent, exaggerated and uncontrolled tissue repair processes. Systemic sclerosis (SSc) is associated with the highest mortality among the

connective tissue disorders and effective antifibrotic therapies are still lacking. DPP4 inhibitors are already used in treatment of diabetes.
**Objectives:** The aim of the study was to characterize the DPP4 positive cells, investigate the expression of DPP4 in SSc skin and to evaluate the antifibrotic effect of DPP4 inhibitors in preclinical models of systemic sclerosis.
**Methods:** Mouse fibroblasts were isolated and DPP4 positive cells characterized by fluorescence activating cell sorting. Expression of DPP4/CD26 in human and murine skin was analyzed by immunofluorescence. DPP4 inhibitors were tested in two different concentrations administered orally (Sitagliptin 3mg/kg/d and 10mg/kg/d, Vildagliptin 1,5mg/kg/d and 15mg/kg/d) in bleomycin induced skin fibrosis and in sclerodermatous chronic graft-versus-host disease mouse model (cGvHD). The antifibrotic effect on skin was assessed by hydroxyproline assay, alpha smooth muscle cells quantification and measuring the dermal thickness. Inflammatory infiltrate was assessed by CD45 immunofluorescence staining.
**Results:** We have demonstrated that DPP4/CD26 positive cells are a unique population of cells implicated in fibrosis. DPP4/CD26 positive cells were increased not only in experimental fibrosis, but also in skin biopsies from SSc patients as compared to healthy volunteers. Treatment with DPP4 inhibitor reduced dermal thickness in both mouse models ($p<0.05$). The differentiation of resting fibroblasts into myofibroblasts was also significantly decreased ($p<0.05$) in all treatment groups. Hydroxyproline content of the skin diminished by 40% in comparison with NaCl injected mice or syngeneic transplanted mice. Moreover, DDP4 inhibitors reduced the inflammatory infiltrate in a dose dependent manner in the bleomycin injected skin.
**Conclusions:** DPP4/CD26 identifies a subpopulation of fibrosis-promoting fibroblasts that plays a key role in the pathogenesis of fibrosis in SSc. Moreover, inhibitors of DPP4 show a significant antifibrotic effect in several mouse models of SSc in well tolerated doses. These results may have direct clinical implications as DPP4 inhibitors are already in clinical use for diabetes.

## OP0052 AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IMPROVES FUNCTIONAL EVALUATION OF SYSTEMIC SCLEROSIS PATIENTS

K.R. Costa Pereira[1], J. Elias[1], D. Moraes[1], A.L. Guimarães[1], J. Garcia[1], E. Cardoso[2], V. Leopoldo[3], A. Zombrilli[3], E. Gonçalves[3], T. Costa[1], A.B. Stracieri[1], B. Simões[1], M.C. Oliveira[1]. *[1]Ribeirao Preto Medical School; [2]Ribeirao Preto School of Philosophy, Sciences and Literature; [3]Ribeirao Preto School of Nursing, Ribeirao Preto, Brazil*

**Background:** Systemic sclerosis (SSc) is associated with impairment of physical function, daily life activities and quality of life. Autologous hematopoietic stem cell transplantation (AHSCT) has been investigated as treatment for patients with severe SSc, promoting reduction of skin thickening and at least stabilization of pulmonary involvement.
**Objectives:** To evaluate the impact of AHSCT on skin involvement, functional capacity and quality of life (QoL) of SSc patients, and to compare these results with those from SSc patients under conventional immunosuppressive treatment.
**Methods:** This is a prospective longitudinal study of a cohort of SSc patients treated at a University Hospital in Brazil. Patients treated with AHSCT (transplant group) and patients under conventional immunosuppressive treatment (control group) were evaluated before, 6 and 12 months after treatment. The evaluations included respiratory muscle strength test (maximal inspiratory pressure – MIP and maximal expiratory pressure - MEP), hand function assessments (hand-grip strength, finger-to-palm distance - FTP, COCHIN questionnaire), six-minute walk test (6MWT), modified Rodnan's skin score (mRSS) and quality of life questionnaire (SF-36). Statistical significance was established at $p<0.05$.
**Results:** Nine SSc patients were included in the transplant group and 8 in the control group. When compared before, 6 and 12 months after AHSCT, patients presented improvement of MIP (p=0.0019), 6MWT distance (p=0.0459), right hand FTP (p=0.0086), right (p=0.0001) and left (p=0.0001) hand-grip strength, COCHIN (p=0.0005), mRSS (p=0.0007), and of the physical components score of SF-36 (p=0.0236). No significant differences were detected in the remaining evaluations. In the control group, no significant changes were observed 6 and 12 months after treatment at any of the evaluations. Patients from the transplant group presented better scores than those from the control group at the 6 months time point regarding MIP (p=0.0050), 6MWT distance (p=0.0418), right (p=0.0024) and left (p=0.0047) hand-grip strength, COCHIN (p=0.0088), mRSS (p=0.0272), and physical components score of SF-36 (p=0.0342). At the 12 months time point, transplanted patients presented better scores than controls concerning MIP (p=0.0242), right (p=0.0131) and left (p=0.0005) hand-grip strength, and physical components score of SF-36 (p=0.0350).
**Conclusions:** AHSCT promotes improvement of functional capacity, skin involvement and of physical components of quality of life in SSc patients. Scores are also significantly better than those from patients treated with conventional immunosuppressive treatment. These results can be interpreted as positive outcomes of AHSCT for SSc.

Mills[14], J. Mooney[15], M. Segelmark[16], V. Tesar[17], K. Westman[18], A. Vaglio[19], N. Yalçındağ[20], D. Jayne[21], C. Mukhtyar[2]. *[1]Norwich Medical School, University of East Anglia; [2]Rheumatology, Norfolk and Norwich University Hospital, Norwich, United Kingdom; [3]Pathology, Leiden University Medical Center, Leiden, Netherlands; [4]Department of Autoimmune Diseases, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [5]Department of Pulmonology, Bichat-Claude Bernard University Hospital, Paris, France; [6]Immunologie-Zentrum Zürich, Zürich, Switzerland; [7]Klinik für Innere Medizin, Kirchheim-Teck; [8]Rheumazentrum Schleswig-Holstein Mitte, Neumünster; [9]Department of Otorhinolaryngology, University of Kiel, Kiel, Germany; [10]Trinity Health Kidney Centre, Dublin, Ireland; [11]Nuffield Department of Orthopaedics Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; [12]Hôpital Saint-Louis, Paris, France; [13]University of Pennsylvania, Philadelphia, United States; [14]Vasculitis UK, Matlock; [15]University of East Anglia, Norwich, United Kingdom; [16]Linköping University, Linköping, Sweden; [17]Charles University, Prague, Czech Republic; [18]Skåne University Hospital, Lund and Malmö, Sweden; [19]University Hospital of Parma, Parma, Italy; [20]Ankara University, Ankara, Turkey; [21]Addenbrooke's Hospital, Cambridge, United Kingdom*

**Background:** The European League Against Rheumatism (EULAR) Recommendation for primary and small vessel vasculitis were published in 2009.
**Objectives:** To update the 2009 recommendations with the focus being ANCA-Associated Vasculitis (AAV) using systematic literature review, as well as expert opinion where appropriate.
**Methods:** A combined taskforce from European League Against Rheumatism (EULAR), the European Renal Association (ERA-EDTA) and European Vasculitis Society (EUVAS) conducted a modified Delphi exercise to identify key areas of guideline for update. The identified themes were then used to generate keywords for literature searches. For the purpose of update a date period of 1st January 2007 to 1st February 2015 was chosen, to interrogate the main medical literature databases (MEDLINE, EMBASE, CENTRAL). From an initial 1,347 hits, 82 clinically relevant studies were identified. The evidence presented was discussed and summarized by the experts in the course of a consensus finding and voting process. Levels of evidence and grades of recommendations were derived and levels of agreement (strengths of recommendations) were determined.
**Results:** The 15 recommendations cover general aspects, such as attainment of remission and the need for shared decision-making between rheumatologists and patients. The more specific items relate to starting immunosuppressive therapy using a strategy in combination with glucocorticoids to induce remission, followed by a period of remission maintenance. For remission induction of life or organ-threatening AAV, cyclophosphamide and rituximab are considered to have similar efficacy. Azathioprine, rituximab and methotrexate are the preferred choices for remission maintenance. The recommendations address plasma exchange which is recommended, in the setting of rapidly progressive renal failure or severe diffuse pulmonary haemorrhage. To enable the recommendations to have maximum validity the voting process was also repeated amongst the members of EUVAS.
**Conclusions:** The recommendations have been updated and changes include; choice of drug therapy (both for induction, relapse and remission maintenance), monitoring for complications, the usefulness of repeated biopsy in those thought to having relapsing disease, monitoring for hypoimmunoglobulinaemia and recommendations on patient education. These recommendations are intended for use by healthcare professionals, doctors in specialist training, medical students, pharmaceutical industries and drug regulatory organisations.

## OP0054 NEUROIMMUNOMODULATION OF NEUTROPHILS AS A NOVEL MECHANISM OF LEVAMISOLE-INDUCED VASCULITIS

P.C. Grayson[1], C. Carmona-Rivera[1], J. Graf[2], J. Irizarry-Caro[1], K. Phillips[3], K. Preston[3], M. Purmalek[1], V. Subramaniam[4], P. Thompson[4], M. Waldman[5], M.J. Kaplan[1]. *[1]NIAMS, National Institutes of Health, Bethesda; [2]Rheumatology, UCSF, San Francisco; [3]NIDA, National Institutes of Health, Baltimore; [4]Biochemistry and Molecular Pharmacy, University of Massachusetts, Worcester; [5]NIDDK, National Institutes of Health, Bethesda, United States*

**Background:** Levamisole, an anti-helminth drug and known cholinergic agonist, has been implicated in cases of drug-induced autoimmunity in humans exposed to cocaine adulterated with levamisole for profit. Clinical manifestations of levamisole-

induced autoimmunity include cutaneous vasculitis and specific autoantibodies (e.g. anti neutrophil cytoplasmic antibodies, ANCA; antinuclear antibodies, ANA). Neutrophil extracellular trap (NET) formation is a novel cell death mechanism implicated in certain idiopathic autoimmune diseases that share features with levamisole-induced autoimmunity.
**Objectives:** The objective of this study was to determine the role of NET formation in the pathogenesis of levamisole-induced autoimmunity.
**Methods:** Human and mouse neutrophils were exposed to graded concentrations of levamisole. NET formation was visualized and quantified by fluorescence microscopy. To assess the pathways involved in levamisole-induced NETosis, the following inhibitors were tested: diphenylene iodonium (DPI), an inhibitor of reactive oxygen species, and Cl-amidine, an inhibitor of peptidylarginine deiminase (PAD) enzymes. Involvement of Akt and Raf-MEK-ERK kinase pathways was assessed by Western blot. The role of Toll-like receptors (TLRs) and muscarinic receptors (MR) in levamisole-induced NETosis was investigated. Pharmacologic inhibitors and MR knockout mice were used to study specific MR subtypes implicated in NETosis. MR subtype receptors on neutrophils from disease comparators and healthy controls were assessed by flow cytometry. Autoantibodies against specific NET-components were examined in cocaine users exposed to levamisole.
**Results:** Levamisole induced prominent NETs in human and murine neutrophils that contained the antigenic targets of ANCA. NETs were seen in vasculitic lesions from cocaine/levamisole users. NET formation induced by levamisole was dependent on phosphorylation of Akt and Raf-MEK-ERK kinase pathways. DPI and Cl-amidine significantly abrogated levamisole-induced NETosis, highlighting that levamisole stimulates NETs via generation of reactive oxygen species and activation of PAD enzymes. Both levamisole and acetylcholine induced NETs through MR engagement on the surface of neutrophils and not through stimulation of TLRs. Atropine, a non-selective MR antagonist, blocked levamisole mediated NETosis. Screening experiments with pharmacologic inhibitors and neutrophils from MR knockout mice demonstrated that levamisole-induced NETosis was mediated through engagement of the M3 muscarinic receptor. Increased M3 receptors were seen on neutrophils from patients with systemic lupus erythematosus compared to controls. In a cohort of 21 cocaine users, 100% had quantifiable levamisole in urine, and novel autoantibodies against NET components were detectable in sera. In longitudinal observations, ex-vivo spontaneous NET formation correlated with periods of active cocaine use.
**Conclusions:** Levamisole induces NETosis through engagement of M3 muscarinic receptors on the surface of neutrophils. These findings implicate a novel interaction between the cholinergic nervous system and innate immunity in the pathogenesis of levamisole-induced autoimmunity.

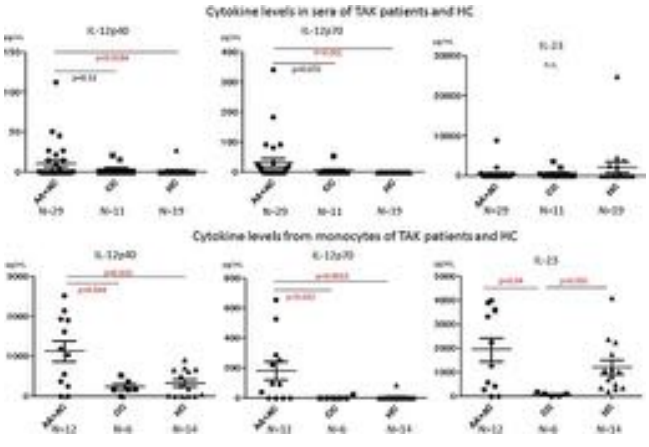
## OP0055 USING THE BIRMINGHAM VASCULITIS ACTIVITY SCORE AS A SCREENING TOOL IN PATIENTS WITH SUSPECTED VASCULITIS

A. Floris[1,2], N. Goodfellow[1], J. Sznajd[1], K. Wawrzycka-Adamczyk[1,3], H. Querin[1,4], A. Craven[1], J. Rosa[1], P.A. Merkel[5], R.A. Watts[6], R.A. Luqmani[1] on behalf of DCVAS investigators. *[1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; [2]Rheumatology Unit, University Clinic, Cagliari, Italy; [3]Dept. of Internal Medicine, Jagiellonian University, Krakow, Poland; [4]School of Medicine and Dentistry, James Cook University, Cairns, Australia; [5]Div. of Rheumatology, University of Pennsylvania, Philadelphia, United States; [6]Rheumatology Department, University of East Anglia, Ipswich, United Kingdom*

**Background:** The Birmingham Vasculitis Activity Score (BVAS) is validated to assess disease activity in systemic vasculitis, but has not been widely tested in conditions mimicking vasculitis.
**Objectives:** To explore the utility of BVAS in screening patients with suspected vasculitis.
**Methods:** We analysed data from the ACR/EULAR Diagnostic and Classification Criteria in Vasculitis Study (DCVAS), using the submitting physician's diagnosis (certainty >75%) as the gold-standard, with predetermined criteria to identify appropriate comparators for each vasculitis. BVAS score and frequency of individual items were evaluated in: giant cell arteritis (GCA); Takayasu arteritis (TAK); polyarteritis nodosa (PAN); and the anti-neutrophil cytoplasm antibody (ANCA) associated vasculitides (AAV) comprising granulomatosis with polyangiitis (GPA), eosinophilic GPA (EGPA) and microscopic polyangiitis (MPA); and their comparator conditions.
**Results:** 1122 patients with vasculitis and 487 comparators were analysed. The BVAS score (median (IQR)) was significantly higher ($p<0.0001$) in patients with each type of AAV vs comparators: GPA 19 (12–25) vs 11 (6–17); EGPA 18 (12–26) vs 11 (6–17); MPA 19 (14–24) vs 11 (5–17). Between 5–12 individual BVAS items were found significantly more frequently in each of these vasculitides than their comparators: bloody nasal discharge/nasal crusts, sinus involvement, pulmonary infiltrate, nodules/cavities in lung, proteinuria, haematuria for GPA; pulmonary infiltrate, wheeze, sensory peripheral neuropathy, mononeuritis multiplex, heart involvement (pericarditis, ischaemic pain, cardiomyopathy or congestive failure) for EGPA; fever, bloody nasal discharge/nasal crusts, pulmonary infiltrate, proteinuria, haematuria and any renal function abnormalities for MPA. These items were used to develop classification trees whose performance is shown in the table. We analysed whether including an ANCA result in the trees altered their performance (table). This led to an increase in sensitivity for MPA (from 71% to 98%), whereas only slight changes were recorded for GPA and MPA. For PAN, GCA and TAK there was no significant difference in BVAS score compared to comparators, and few or no BVAS items were discriminative.

Table 1. Classification tree performance

| | Sensitivity | | Specificity | |
|---|---|---|---|---|
| | Not including ANCA result | Including ANCA result* | Not including ANCA result | Including ANCA result |
| GPA | 82% | 88% | 81% | 81% |
| EGPA | 82% | 89% | 94% | 92% |
| MPA | 71% | 98% | 83% | 80% |



*For GPA: c-ANCA and/or PR3-ANCA were included; for EGPA and MPA: p-ANCA and/or MPO-ANCA.

**Conclusions:** BVAS consists of several items highly specific for GPA, EGPA and MPA, from which we have developed classification trees which can facilitate accurate and systematic screening of patients with suspected AAV based on clinical parameters alone. Whilst the ANCA result contributed to the classification of MPA, it had little additional value in distinguishing GPA or EGPA from their comparator conditions, limiting the value of ANCA testing for the purpose of screening for AAV. By contrast, BVAS is not effective in distinguishing PAN, GCA or TAK from comparator conditions.

## OP0056 ASSOCIATION OF IL-12P40 AND IL-12P70 WITH PATHOPHYSIOLOGY OF TAKAYASU ARTERITIS

T. Nakajima[1], H. Yoshifuji[1], C. Terao[2], K. Kitagori[1], K. Murakami[1], R. Nakashima[1], Y. Imura[1], M. Tanaka[1], K. Ohmura[1], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology Graduate School of Medicine, Kyoto University; [2]Center for Genomic Medicine. Kyoto-University, Kyoto, Japan*

**Background:** We preliminarily found a SNP (rs6871626, A vs. C) in *IL-12B* region as a susceptibility gene to Takayasu arteritis (TAK) by genome-wide association study. *IL-12B* encodes IL-12p40 that is a component of both IL-12p70 and IL-23. The significance of IL-12p40 in pathophysiology of TAK has not been fully investigated yet. Moreover, there has been no consistent evidence about whether IL-12p70 or IL-23 is important in TAK.
**Objectives:** 1) To investigate the expression of IL-12p40 in patients with TAK, 2) reveal which is more important to pathophysiology of TAK, IL-12p70 or IL-23, and 3) examine the influence of SNP to the cytokine production.
**Methods:** We collected sera from 43 TAK patients and 19 healthy controls (HCs), and measured IL-12p40, IL-12p70 and IL-23 with ELISA. Next, we collected whole blood from 18 TAK patients and 12 HCs, and isolated monocytes with RosetteSep™. The monocytes were incubated with IL-6, IL-10 and GM-CSF, and then stimulated with INF-$\gamma$ and LPS. Then we measured the cytokines in culture supernatant with ELISA.
**Results:** IL-12p40 and IL-12p70 in sera of TAK patients were significantly higher than those of HCs ($p=0.031$ and $p<0.001$, respectively), whereas there were no differences in serum of IL-23 levels between TAK patients and HCs. IL-12p40 and IL-12p70 in sera of TAK patients whose allele at rs6871626 is AA or AC (defined as risk patients) were significantly higher than those of HCs ($p=0.018$

and p<0.001, respectively), whereas there were no differences in serum IL-23 levels among risk patients, TAK patients with CC allele (defined as non-risk patients) and HCs. Supernatant IL-12p40 and IL-12p70 levels from monocytes of risk patients were significantly higher than those of non-risk patients (p=0.044 and p=0.032, respectively) or those of HCs (p=0.032 and p=0.0015, respectively). Supernatant IL-23 from monocytes of risk patients were significantly higher than those of non-risk patients (p=0.04).
**Conclusions:** IL-12p40 and IL-12p70 but not IL-23 may play an important role in pathophysiology of TAK, and the risk allele of rs6871626 could contribute to production of these cytokines.
**Disclosure of Interest:** None declared

## OP0057 URINARY AND SERUM KIM-1, MCP-1 AND TYPE IV COLLAGEN LEVELS IN THE ASSESSMENT OF ANCA-ASSOCIATED NEPHRITIS ACTIVITY

N. Bulanov, A. Serova, E. Kuznetsova, P. Novikov, S. Moiseev. *Sechenov First Moscow State Medical University, Moscow, Russian Federation*

**Background:** Kidney involvement is common in ANCA-associated vasculitis (AAV), but early detection of glomerulonephritis often presents a challenge.
**Objectives:** We evaluated diagnostic significance of urinary levels of kidney injury molecule-1 (uKIM-1), monocyte chemoattractant protein-1 (uMCP-1) and type IV collagen (uCollagenIV) and serum levels of MCP-1 (sMCP-1) and CollagenIV (sCollagenIV) and their relationship with nephritis activity and prognosis in AAV.
**Methods:** We enrolled 78 patients with AAV, diagnosed according to CHCC2012 definition (GPA=48, MPA=19, EGPA=11), 32 male, 46 female, aged 55 (45;61). To assess disease activity and kidney involvement we measured proteinuria, hematuria, serum creatinine (SCr), eGFR (CKD-EPI), BVAS and VDI. Urinary and serum concentrations of biomarkers were measured by ELISA.
**Results:** 28 patients had active renal AAV (35.9%, group 1), 26 had active nonrenal AAV (33.3%, group 2) and 24 were in long-term remission (30.8%, group 3). Median urinary levels of all biomarkers in active renal AAV were significantly higher than in groups 2 and 3 (Table), and did not depend on age and nosological form of AAV. Urinary excretion of all molecules was comparable in groups 2 and 3. There was a significant difference in sMCP-1 levels only between groups 1 and 3. sCollagenIV levels were similar in all groups.

| | Group 1, n=28 | Group 2, n=26 | Group 3, n=24 | |
|---|---|---|---|---|
| uKIM-1, pg/mL | 3724.4 (3023.6; 5428.7) | 1478.7 (1150.0; 2525.7) | 1890.0 (1218.1; 3280.3) | $p_{1-2}$=0.00001; $p_{1-3}$=0.0009; $p_{2-3}$=0.23 |
| uMCP-1, pg/mL | 407.4 (205.5; 795.2) | 120.9 (49.9; 197.2) | 124.3 (79.7; 335.3) | $p_{1-2}$=0.00002; $p_{1-3}$=0.002; $p_{2-3}$=0.49 |
| uCollagenIV, mcg/L | 3.88 (2.03; 7.06) | 1.6 (1.23; 2.67) | 1.68 (1.0; 2.59) | $p_{1-2}$=0.002; $p_{1-3}$=0.0006; $p_{2-3}$=0.76 |
| sMCP-1, pg/mL | 873,4 (609,7; 1095,8) | 708,6 (573,7; 836,85) | 589,9 (478,7; 750,8) | $p_{1-2}$=0.18; $p_{1-3}$=0.02; $p_{2-3}$=0.06 |
| sCollagenIV, mcg/L | 133,8 (107,64; 189,2) | 113,5 (93,3; 158,4) | 115,2 (97,0; 134,0) | $p_{1-2}$=0.22; $p_{1-3}$=0.10; $p_{2-3}$=0.87 |

Significant positive correlations were found between urinary excretion of all biomarkers and features of nephritis activity: hematuria, proteinuria, renal component of BVAS (all p<0.05). uCollagenIV level also had a significant positive correlation with SCr and a negative correlation with eGFR (all p<0.05).
sMCP-1 level showed no association with signs of nephritis activity, but had a positive correlation with CRP and total BVAS (p<0.05). sCollagenIV level had no association with disease activity but had a correlation with SCr and eGFR (all p<0.0001).
ROC-analysis showed that uMCP-1≥159 pg/mL identified renal involvement with sensitivity 89%, specificity 67% (AUC 0.80). uKIM-1≥2283.3 pg/mL had similar sensitivity (92%) and lower specificity (58%), AUC 0.76. uCollagenIV≥3.09 mcg/L showed the worst sensitivity (57%), but the highest specificity (86%), AUC 0.76.
**Conclusions:** Urinary excretion of all biomarkers was significantly increased in active renal vasculitis. We suggest that uKIM-1 and uMCP-1 levels reflect local renal inflammation, while elevated uCollagenIV is likely to represent both glomerular basement membrane damage and activation of renal fibrogenesis. Limited specificity or sensitivity of individual urinary biomarkes may justify their combined use to identify active renal AAV. In contrast serum MCP-1 and CollagenIV only show a weak correlation with overall inflammatory activity and kidney dysfunction respectively, but have no association with nephritis activity.

## OP0058 USING MASS SPECTROMETRY TO QUANTIFY RITUXIMAB AND PERFORM INDIVIDUALIZED IMMUNOGLOBULIN PHENOTYPING IN ANCA-ASSOCIATED VASCULITIS

D. Cornec[1,2], J.R. Mills[2], S. Dasari[2], P.M. Ladwig[2], A.M. Hummel[2], M. Cheu[3], D.L. Murray[2], M.A. Willrich[2], M.R. Snyder[2], G.S. Hoffman[4], C.G. Kallenberg[5], C.A. Langford[4], P.A. Merkel[6], P.A. Monach[7], P. Seo[8], R.F. Spiera[9], E.W. St. Clair[10], J.H. Stone[11], U. Specks[2], D.R. Barnidge[2]. *[1]CHU Brest, Brest, France; [2]Mayo Clinic, Rochester; [3]Genentech Inc., South San Francisco, CA; [4]Cleveland Clinic Foundation, Cleveland, OH, United States; [5]University of Groningen, Groningen, Netherlands; [6]University of Pennsylvania, Philadelphia, PA; [7]Boston University Medical Center, Boston, MA; [8]Johns Hopkins University, Baltimore, MD; [9]Hospital for Special Surgery, New York, NY; [10]Duke University, Durham, NC; [11]Massachusetts General Hospital, Boston, MA, United States*

**Background:** Therapeutic monoclonal antibodies (mAbs) are used to treat patients with a wide range of disorders including autoimmune diseases. To perform pharmacokinetics analyses, they are commonly quantified using immunoassays (such as ELISAs) based on the specific affinity of the mAb to its target antigen. However the development of these tests is long and fastidious. A new method which could quantify any mAb without relying on their antigen specificity would be useful. Heavy and light chains from each therapeutic mAb have a specific molecular weight based on their unique amino acid sequence. New generation mass spectrometers have the mass accuracy and resolution to identify distinct mAbs using mass measurements and can quantify large peptides such as light chains in the serum of patients with high precision.
**Objectives:** To develop a new method based on mass spectrometry (MS) to quantify rituximab in the serum of patients treated for an autoimmune disease, and to compare its performance to a traditional ELISA test.
**Methods:** We analyzed 775 serum samples from the 99 patients included in the Rituximab for ANCA-associated vasculitis (RAVE) trial who received rituximab. Serum was first enriched for IgG then reduced to dissociate heavy and light chains. The molecular weight of each serum light chain was analyzed by microflow-liquid chromatography (LC) followed by ESI-Q-TOF MS. Rituximab was quantified using a unique software package developed by our group. Rituximab quantification by ELISA was performed as previously described.
**Results:** The peak corresponding to rituximab light chain molecular mass was easily recognized and quantified using our method (figure). The performance parameters of our assay were within acceptable limits (coefficients of variation: intra-day 5.0%, inter-day 14.1% at 50 μg/mL and 14.8% at 200 μg/mL; acceptable linearity from 0 to 250 μg/mL of rituximab; and lower limit of quantification of 14.3 μg/mL). The rituximab concentrations determined by MS were in good agreement with those found by ELISA ($R^2$=0.853/m=0.70). In addition, endogenous monoclonal and oligoclonal light chain immunoglobulins secreted into circulation during the course of treatment were documented using the LC-MS assay.

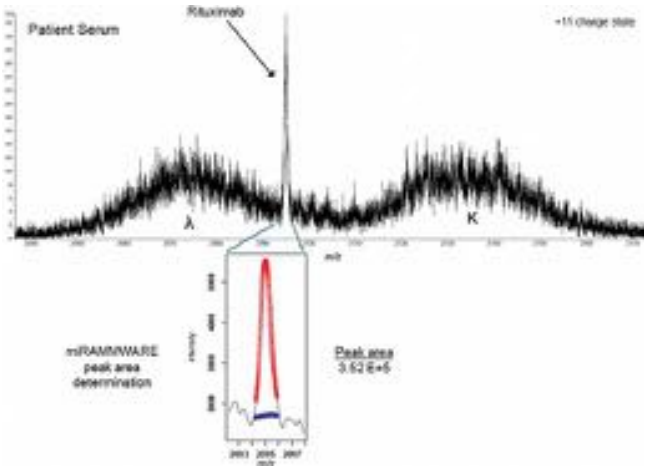

Figure 1

**Conclusions:** Our LC-MS assay was able to quantify a therapeutic mAb in a large cohort of patients in a clinical trial without the need for specific reagents. Our method could be applied to the quantification of any therapeutic mAb. This fact, coupled with the ability to phenotype a patient's polyclonal repertoire in the same analysis further shows the potential of this innovative approach to mAb analysis.

**Background:** Chemokines are multifunctional mediators that control leukocyte recruitment into the inflammatory sites and enhance immune responses. It remains to be investigated which chemokines are important in Behcet's disease (BD).
**Objectives:** The objective of this study was to investigate serum levels of (C-X-C motif) CXC chemokines in BD patients and its association with clinical manifestations and disease activity.
**Methods:** Blood samples were collected from 109 BD patients and 34 age-, sex matched healthy controls (HCs). Twenty two follow-up samples were collected in BD patients. Serum CXC chemokines were assayed for the neutrophil chemoattractants (CXCL1 and CXCL8) and lymphocyte chemoattractants (CXCL9, CXCL10, CXCL12, CXCL13 and CXCL16) by using a multiplex assay. Cell surface makers such as CD3, CD4 and CXCR3 in peripheral blood mononuclear cells were investigated by flow cytometry. The clinical features including disease activity, laboratory tests and current medication were evaluated at the time of blood collection. C-X-C chemokine receptor 3 (CXCR3) expression in skin and intestinal lesions from BD patients were assessed via immunohistochemistry.
**Results:** Serum levels of CXCL8, CXCL10 and CXCL12 were significantly higher in the BD patients than in HC (p=0.001, p=0.007 and p=0.003, respectively). Serum CXCL10 levels were significantly correlated with disease activity in both Behcet's Disease Current Activity Form (BDCAF) and Behcet's Syndrome Activity Score (BSAS) (rho =0.336, p<0.001 and rho =0.253, p=0.009, respectively) as well as with number of genital ulcer and erythema nodosum (EN) (rho =0.222, p=0.020 and rho =0.329, p<0.001, respectively). In follow-up BD patients, changes of serum CXCL10 levels were correlated with those of BDCAF (rho =0.425, p=0.048).
CXCR3 receptor expression was significantly increased on CD3 positive T cells versus CD3 negative cells in peripheral blood mononuclear cells of both BD patients and HCs (p=0.009 and p=0.031, respectively). Levels of serum CXCL10 were inversely correlated with percentage of CXCR3 expression on CD3 positive T cells in BD patients (rho = -0.523, p=0.022). In immunohistochemistry, the CXCR3 positive inflammatory cells were increased in skin lesions of BD patients than in those of HCs.
**Conclusions:** These results suggest that CXCL10/CXCR3 axis contribute to pathogenesis of BD particularly mucocutaneous lesions. Measurement of serum CXCL10 may help to assess disease activity in BD patients.

Ruppert[13], A. Bourgarit-Durand[14], B. Bienvenu[15], L. Geffray[16], B. Terrier[17], M. Groh[17], C. Le Jeunne[17], L. Mouthon[17], P. Ravaud[3], L. Guillevin for the French Vasculitis Study Group[17]. *[1]Hôpital Cochin, National Referral Center for Rare Systemic Autoimmune Diseases, Paris, Francse; [2]Mount Sinai Hospital, Toronto, Canada; [3]CHU Hôtel Dieu, Paris; [4]CH, Valenciennes; [5]CHU Hôtel Dieu, Nantes; [6]CH, Dax; [7]CHU, Limoges; [8]CHU, Clermont-Ferrand; [9]CH, Vannes; [10]Hôpital Henri Mondor, Créteil; [11]Hôpital Saint-Antoine; [12]Hôpital Bichat, Paris; [13]Hôpital Tenon, Paris; [14]CHU, Bondy; [15]CHU, Caen; [16]CH, Lisieux; [17]Hôpital Cochin, National Referral Center for Rare Systemic Autoimmune Diseases, Paris, France*

**Background:** Glucocorticoids (GC) achieve remission in most patients with systemic necrotizing vasculitides (SNVs) without poor-prognosis factors based on the 1996 Five-Factor Score. However, more than a third of them relapse, mainly during the first 2 years after treatment onset.
**Objectives:** This study aimed to determine whether combined GC and azathioprine (AZA) could achieve higher remission and lower relapse rates than GC alone in patients with newly diagnosed eosinophilic granulomatosis with polyangiitis (EGPA), microscopic polyangiitis (MPA) or polyarteritis nodosa (PAN), without increasing adverse events.
**Methods:** All patients included in this multicenter, randomized, double-blind trial received GC, initially 1 mg/kg/day, then gradually tapered over 12 months (asthmatic patients' doses were lowered as much as possible while controlling asthma symptoms) and were randomly assigned to receive concomitant 12 months of oral AZA (2 mg/kg/day) or placebo. Patients were followed for another 12 months, for 24 months of follow-up. The primary endpoint was rate of remission without subsequent relapses at month (M) 24. Analyses used a modified intent-to-treat strategy and were adjusted according to the vasculitis.
**Results:** 95 patients (51 EGPA, 25 MPA, 19 PAN) met the inclusion criteria and received at least 1 dose of AZA (n=46) or placebo (n=49). At endpoint, 52.2% AZA-arm patients achieved remission without subsequent relapse versus 51.0% placebo recipients (odds ratio [OR], 0.93; [95% CI, 0.40–2.17]). Secondary endpoints were also comparable between arms: remission rate (95.7% vs. 87.8%), number of patients with minor (30.2% vs. 28.5%) or major relapses (11.6% vs. 11.9%). Two (4.1%) AZA-arm patients died both at M11 (1 sudden death while in complete remission, 1 86-year-old died of congestive heart failure). Mean GC doses and area under the curve for GC use were also comparable between arms. At least 1 severe treatment-related adverse event occurred in 8 (17.4%) AZA-arm and 3 (6.1%) placebo-arm patients (OR, 3.23 [0.76–13.70]). For EGPA patients, neither the primary endpoint nor the numbers with exacerbated asthma/rhinosinusal disease differed between arms.
**Conclusions:** At study M24, AZA adjunction to GC induction compared to GC alone in non-severe SNVs did not improve remission rate or lower the risk of relapse, had no steroid-sparing effect, or did not reduce EGPA patients' rate of asthma/rhinosinusal disease exacerbations.

## Developing evidence-based non-pharmacological care

OP0060-HPR **CROSS-CULTURAL VALIDATION OF THE SYSTEMIC SCLEROSIS QUALITY OF LIFE QUESTIONNAIRE IN SIX EUROPEAN COUNTRIES: A TOOL VALIDATION STUDY**

M. Ndosi[1], B. Alcacer-Pitarch[1], Y. Allanore[2], F. Del Galdo[1], M. Frerix[3], S. García Díaz[4], F. Guidi[5], R. Hesselstrand[6], C. Kendall[3], M. Matucci-Cerinic[5], U. Müller-Ladner[3], G. Sandqvist[6], V. Torrente-Segarra[4], A. Redmond[1]. *[1]University of Leeds, Leeds, United Kingdom; [2]Hôpital Cochin, Paris, France; [3]Justus-Liebig-University Gießen, Bad Nauheim, Germany; [4]Hospital Sant Joan Despi, Barcelona, Spain; [5]University of Florence, Florence, Italy; [6]Lund University Hospital, Lund, Sweden*

**Background:** The Systemic Sclerosis Quality of Life (SScQoL) questionnaire is a 29-item tool developed in UK to measure needs-based patient-reported quality of life in people with systemic sclerosis (SSc).
**Objectives:** To undertake a cross-cultural adaptation and validation of the SScQoL in six European countries.
**Methods:** This was a cross-sectional study involving six European countries: Germany, France, Italy, Spain, Sweden and UK. Adult patients with a definite diagnosis of SSc, who were willing and able to complete the SScQoL were eligible. The English SScQoL was adapted into the five European languages using a forward-backward translation process.[1] The translated SScQoL was completed by patients and the data was analysed using Rasch models. Where local response dependency was evident, items were grouped into subscales (function, emotion, sleep, social and pain) and re-analysed to test the scaling

SD, Standard deviation; DF, Degrees of freedom; PSI, Person separation index reliability; Pooled* excludes Germany dataset; Pooled-Adj** adjusted to account for Italy differential response in the social subscale.

properties and cross-cultural equivalence, thus allowing calibration of the SScQoL into an interval scale.
**Results:** The adaptation of the SScQoL into European languages was seamless except in Germany, where patients reported problems in deciding yes/no responses for some items. Cross-cultural validation included 849 patients (mean age =57.9 years, SD =13.9), 87% of whom were women. All country-specific data except Germany had good fit to the Rasch model after correcting for local dependency. See table 1. After excluding Germany from the analysis, the scale was validated and calibrated with cross-cultural adjustment for Italy in the social subscale.
**Conclusions:** The SScQoL translated versions can be used as a valid common measure in France, Spain, Sweden, UK and Italy; the latter with adjustments in the social subscale. The German version requires further work.

## OP0061-HPR THE EFFECT OF A CONTEXTUALLY RELEVANT NON-PHARMACOLOGICAL INTERVENTION ON THE FUNCTIONING OF SOUTH AFRICAN WOMEN WITH OSTEOARTHRITIS: A RANDOMIZED CONTROLLED TRIAL

C. Hendricks, R. Parker, J. Jelsma. *Health and Rehabilitation Sciences, University of Cape Town, Cape Town, South Africa*

**Background:** Osteoarthritis (OA) is more commonly found in women. Joint pain, stiffness, decreased levels of physical activity, obesity and chronic diseases are common problems experienced[1]. A non-pharmacological patient-centered management approach using exercise, education and self-management strategies, may help to ameliorate the impact of joint pain and chronic diseases of life style (CDL) on function, pain and health-related quality of life [2].
**Objectives:** To establish if an intervention programme incorporating physical activity and health education and using self-management principles would result in improved physical functioning, a decrease in pain and improved health related quality of life (HRQoL) in women.
**Methods:** Women with osteoarthritis and hypertension were randomized in two groups (experimental group and control group that received standard care in a form of a support group). The primary outcome was improved physical function using World Disability Schedule (WHODAS) and the Aggregated Locomotor Functioning Score (ALF). Secondary outcomes were decreased joint pain (BPI), improved HRQoL using EQ-5D, decreased Body Mass Index (BMI), decreased blood glucose levels and blood pressure. Measures were taken by a blinded observer at baseline, at six and twelve weeks. The intervention was offered on a weekly basis for six weeks and was led by a physiotherapist.
**Results:** Thirty-five participants were allocated to the experimental and 38 to the control group. There was no difference between the baseline outcome measurements, apart from blood glucose which was ranked higher in the control group (p=0.037). Post-intervention, the WHODAS score was significantly lower (better) (p=.032), the ALF was significantly lower (better, p=.013), joint pain was significantly less ($p<.001$); and the HRQoL significantly higher (Visual Analogue Scale p=.002) in the experimental group. Blood glucose remained lower in the experimental group (p=0.034) and within-group analysis indicated that whereas the control group had not lowered their glucose (p=.656), the experimental group had (p=.002). However, there was no difference in BMI (p=.340) or blood pressure category (p=.558).
**Conclusions:** The six week intervention significantly improved physical functioning, pain, HRQoL and blood glucose levels. However, it did not lower Blood pressure or BMI. It is recommended that this intervention be rolled out in primary health care clinics as it is relatively low cost and requires minimal exercise equipment. The results of this study support the inclusion of physiotherapists as members of the primary health care team in the management of osteoarthritis and chronic diseases of lifestyle.

## OP0062-HPR EFFICACY OF TAILORED EXERCISE THERAPY IN PATIENTS WITH KNEE OSTEOARTHRITIS AND COMORBIDITY: A RANDOMIZED CONTROLLED TRIAL

M. De Rooij[1], M. van der Leeden[1,2], J. Cheung[3], M. van der Esch[1], A. Arja Häkkinen[4], D. Haverkamp[3], L.D. Roorda[1], J. Twisk[5], J. Vollebregt[1], W.F. Lems[6], J. Dekker[2]. *[1]Amsterdam Rehabilitation Research Center | Reade; [2]Department of Rehabilitation Medicine, VU University Medical Centre, EMGO Institute for Health and Care Research; [3]Department of Orthopedics, Slotervaart Hospital, Amsterdam, Netherlands; [4]Department of Health Sciences, University of Jyväskylä and Jyväskylä Central Hospital, Jyväskylä, Finland; [5]Department of Epidemiology and Biostatistics, VU University Medical Centre, EMGO Institute for Health and Care Research; [6]Department of Rheumatology, VU University Medical Centre, Amsterdam, Netherlands*

**Background:** Exercise therapy is a key intervention in the management of knee osteoarthritis (OA). It is an effective intervention to improve physical functioning and reduce joint pain in patients with knee OA. Comorbidity, which is highly prevalent in OA, interferes with the application of exercise therapy and contributes to non-adherence to exercise therapy.
**Objectives:** To evaluate the efficacy and safety of tailored exercise therapy on physical functioning in patients with knee osteoarthritis (OA) and comorbidity
**Methods:** A randomized clinical controlled trial was performed, comparing comorbidity-adapted exercise therapy with a control intervention. The study was conducted in an outpatient rehabilitation center. Patients with a clinical diagnosis of knee OA and at least one of the target comorbidities, i.e., coronary disease, heart failure, type 2 diabetes, COPD or obesity (body mass index$\geq$30kg/m) with severity scores $\geq$2 on the Cumulative Illness Rating Scale were included. The intervention group received a 20 weeks individualized, comorbidity-adapted exercise program, with 2 sessions of 30 -60 minutes a week. Participants in the control group received their current medical care for knee OA and were placed on a waiting-list for exercise therapy. Measurements were performed at baseline, at 10-weeks, 20-weeks (post-treatment) and 32 weeks (3-months post-treatment). Primary outcome measures: physical functioning (WOMAC subscale physical functioning and six minute walking test). Generalized Estimating Equation analysis was used to estimate group differences over time, adjusting for baseline value of outcome measure.
**Results:** In total, 126 participants were randomised, of which 63 participants in the experimental group and 63 in the control group. Statistically significant differences were found over time between the intervention and control group with respect to physical functioning WOMAC-pf and the six minute walk test in favour of the intervention group. The improvements in the experimental group were clinically relevant. The mean improvements in the intervention group on physical functioning were 33% on the WOMAC-pf scale and 15% on the six-MWT at 3 months follow up. No serious adverse events occurred during the intervention.
**Conclusions:** This is the first study showing that tailored exercise therapy is safe and effective in improving physical functioning, in patients with knee OA and comorbidities. These results should encourage clinicians to consider exercise therapy as a treatment option for patients with knee OA, even in the presence of comorbidity.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3855

## OP0063-HPR HIGH PROPORTION OF NON-CONTRACTILE TISSUE IN THE VASTUS MEDIALIS MUSCLE IS ASSOCIATED WITH MUSCLE WEAKNESS IN PATIENTS WITH KNEE OSTEOARTHRITIS; RESULTS FROM THE AMS-OA COHORT

M. Van Der Esch[1], P. Juch[2], M. van der Leeden[1], M. Jansen[3], W. Wirth[4], L. Roorda[1], W.F. Lems[5], J. Dekker[6]. *[1]Rehabilitation; [2]Rheumatology; [3]Radiology, Reade, centre for rehabilitation and rheumatology, Amsterdam, Netherlands; [4]Radiology, Institute of Anatomy, PMU, Salzburg, Austria; [5]Rheumatology, Amsterdam Rheumatology and immunology Centre, location VUmc; [6]Department of Rehabilitation Medicine, VU University Medical Center, Amsterdam, Netherlands*

**Background:** Muscle weakness is of clinical interest in knee osteoarthritis (OA). High proportion of non-contractile tissue including fatty tissue and connective tissue could contribute to muscle weakness in patients with knee OA.
**Objectives:** The study aims were to establish the association of non-contractile tissue in the vastus medialis muscle, assessed by magnetic resonance imaging, to muscle strength in patients with established knee OA.
**Methods:** A sample of 94 patients were included. Sagittal T1 weighted MRI, conducted at 3 Tesla, were performed using a phased array knee coil. Within a standardized region of interest located at the distal end of the vastus medialis, non-contractile tissue was distinguished from contractile tissue based on pixel grayscale values. The amount of non-contractile tissue was expressed as the percentage of non-contractile tissue pixels in proportion to the total amount of pixels. Muscle strength was assessed isokinetically (Nm). The GUG test was used as a measurement of physical function. Percentage of non-contractile tissue was dichotomized into low and high percentage non-contractile tissue groups. With Student's *t*-test, differences in demographics and clinical characteristics between the group of low percentage of non-contractile tissue versus a high percentage of

non-contractile tissue were calculated. In regression analysis the associations of the percentage of non-contractile tissue with muscle strength and GUG test were determined, controlled for BMI, gender, age and radiographic severity.
**Results:** Mean ± SD age and BMI were 61.68 ± 7.09 years and 29.13 ± 4.72kg/m$^2$, respectively. A K&L grade of 2 or higher was found in 68% of the participants. The mean ± SD of the percentage of non-contractile tissue was 16.03 ±15.31 with a median of 11%. The participants with a high percentage of non-contractile tissue (>11%) had on average less muscle strength, a longer GUG time and a higher BMI than participants with a low percentage of non-contractile tissue (≤11%) (*P*=0.031, *P*=0.021, *P*=0.026, respectively). In univariable regression analysis, associations of the percentage of non-contractile tissue to muscle strength and the GUG test were found (B= -19.04, 95% CI = -36.34 to -1.73, *P*=0.031; B=1.09, 95% CI = 0.17 to 2.01, *P*=0.021, respectively). Multivariate regression analysis, adjusting for BMI, gender, age and radiographic severity, showed that the percentage of non-contractile tissue was negatively associated with muscle strength (B= -13.94, 95% CI = -27.56 to -0.33, *P*=0.045), but no association was found with the GUG (B=0.674, 95% CI = -0.20 to 1.55, *P*=0.130).
**Conclusions:** In patients with established knee OA, non-contractile tissue in the vastus medialis muscle measured by clinical MRI is associated with muscle strength, but not with physical performance (GUG test) after adjustment for BMI, gender, age and radiographic severity.
**Disclosure of Interest:** None declared

## OP0064-HPR A MODEL INCLUDING FOOT-RELATED FACTORS IMPACTING ON QUALITY OF LIFE (QOL) IN SYSTEMIC SCLEROSIS

B.A.-P. Alcacer-Pitarch[1], A. Redmond[1,2], F. Del Galdo[1,2], M. Buch[1,2], A.-M. Keenan[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine and Leeds NIHR Biomedical Research Unit, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals Trust, Leeds, United Kingdom*

**Background:** While foot problems in patients with systemic sclerosis (SSc) have been described previously and the association with disability noted, the impact of such problems on the quality of life (QoL) in people living with SSc has yet to be quantified.
**Objectives:** To identify the factors, including those arising from foot pathology, that impact on QoL in SSc.
**Methods:** Structural equation modelling (SEM) was used to explore the multi-factorial pathways impacting on QoL in a cross section cohort of people with SSc. Potential candidate factors were identified through: i) a literature review with expert consultation; and ii) a cross-sectional study capturing clinical features. QoL was measured using the disease-specific SScQoL questionnaire.
**Results:** One hundred and twenty one patients with SSc were recruited (106 female; median age 59, ranges 25 to 86 years) with a median disease duration of nine years (IQR:4,13) and a median modified Rodnan Skin Score of 2 (IQR:0, 5). The model that best explained the factors contributing to the SSc impact on QoL showed complex inter-relationships between 11 factors (Figure1) (c2=37.022, df=37, p=0.468, RMSEA=0.002, GFI=0.951, CFI=1.000). Combined, these factors explained 84% of the impact on QoL ($R^2$ =0.84) in patients with SSc. General disease factors, including physical function (standardised total effect 0.64), breathing problems (standardised total effect 0.493), and depression (standardised total effect 0.428) had the greatest impact. Foot problems had a substantial but indirect effect on quality of life (foot function and foot pain standardised total effect 0.343 and 0.327). A summary of the effects of the factors included in the model is provided in the Table 1.
**Conclusions:** The impact of SSc on QoL is substantial and complex. While loss of physical function is the most influential factor on QoL, followed by breathing difficulty and depression, foot problems significantly contribute to this impact.

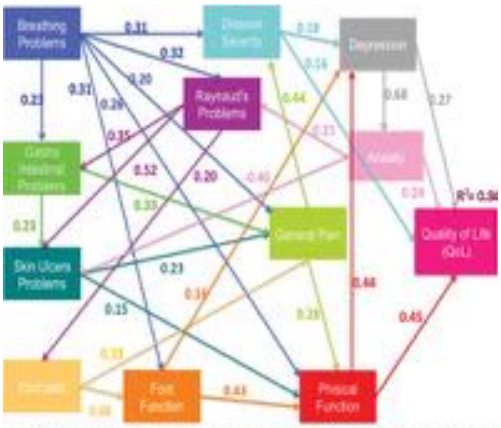

Figure 1: SEM for the factors contributing to QoL in Systemic Sclerosis (SSc) The arrows represent the direction in which the relationship is and the values on top of each line are the regression weights. The larger the regression weights the better predictor the variable is of the variable that the arrow is feeding into.

Table 1. Standardised direct, indirect and total effect of the variables as they relate to QoL, including foot problems

| Variable | Direct effect | Indirect effect | Total effect |
|---|---|---|---|
| Physical function | 0.454 | 0.186 | 0.640 |
| Breathing problems interference | 0.000 | 0.493 | 0.493 |
| Depression | 0.270 | 0.158 | 0.428 |

## OP0065-HPR

WITHDRAWN

OP0066-HPR **PERFORMANCE-BASED MEMORY IS NOT IMPAIRED IN FIBROMYALGIA. A STUDY IN A LARGE SAMPLE ALSO TESTING GENDER DIFFERENCES. THE AL-ÁNDALUS PROJECT**

F. Estévez-López[1,2], I.C. Álvarez-Gallardo[2], A. Soriano-Maldonado[2], M. Borges-Cosic[2], D. Camiletti-Moirón[3], M. Herrador-Colmenero[2], M. Pulido-Martos[4], D. Munguía-Izquierdo[5], R. Geenen[1], M. Delgado-Fernández[2], V. Segura-Jiménez[2,3]. *[1]Department of Psychology, Faculty of Social and Behavioural Sciences, Utrecht University, Utrecht, Netherlands; [2]Department of Physical Education and Sport, Faculty of Sport Sciences, University of Granada, Granada; [3]Department of Physical Education, Faculty of Education Sciences, University of Cádiz, Cádiz; [4]Department of Psychology, School of Humanities and Sciences of Education, University of Jaén, Jaén; [5]Department of Sports and Computer Science, Section of Physical Education and Sports, Universidad Pablo de Olavide, Seville, Spain*

**Background:** Many fibromyalgia (FM) patients experience a deteriorated cognitive function. This is one of the reasons why FM diagnosis has been moved from a pain-focused classification to a more encompassing diagnosis including cognitive difficulties. It is noteworthy that self-reported cognitive difficulties by FM patients are commonly inaccurate (1). Additionally, when cognitive function is measured by performance-based tests in FM patients, with some studies claiming the existence of cognitive deficits and other studies concluding a lack of such impairments. Finally, most of previous studies measuring performance-based memory was conducted in relatively small samples and did not examine gender differences.
**Objectives:** The aim of the present study was to compare performance-based memory of FM patients and non-FM controls and to assess potential gender differences.
**Methods:** A total of 507 FM patients (21 men) and 308 non-FM controls (57 men) participated in the present cross-sectional study. Four composite scores were obtained by means of the Rey Auditory Verbal Learning Test (RAVLT): learning rate, proactive and retroactive interference, and retention. Mixed-design analyses of covariance (ANCOVA) were performed on each of the RAVLT composite scores (within-subjects factor) with sample group (FM vs. non-FM controls) and gender as between-subjects factors, and education level as covariate.
**Results:** Performance-based memory observed in FM and non-FM participants was similar in every single composite score of the RAVLT (all $P>0.05$). There were not gender differences in proactive interference, retroactive interference and retention (all $P>0.05$), although women had a higher learning rate (i.e. greater number of words recalled) than men ($P<0.01$).
**Conclusions:** Our results do not support performance-based memory impairments in FM. Overall, gender differences were not observed in performance-based memory; except for learning rate, where women outperformed men regardless of sample group (i.e., FM or non-FM). Therefore, the gender differences observed seem to be an extension of the picture observed in general population rather than a disease-specific feature. Future research focusing on factors that are associated with the perception of memory deficits and the discrepancy between objective and subjective measures of memory performance is warranted.

OP0067-HPR **EXCERSISE AS MEDICINE? DESCRIPTION OF OA TREATMENT IN DISCHARGE REPORTS**

G. Grønhaug. *ISM, Norwegian University of Science and Technology, ISM, Trondheim, Norway*

**Background:** The use of discharge reports (DR) as communication are mandatory in health care in most countries. Interprofesional collaboration is based on shared information and the DR is a minimum base for information sharing in most health care systems. To ensure treatment quality and patient safety, the information shared in DR must be precise and all terms used must be well understood by all professions in need of information regarding treatment modalities and treatment outcome.
Several studies have revealed that OA treatment is not in line with evidence based guidelines (1,2,3). This study assesses how physiotherapists are communicating their treatment of OA patients in the outpatient clinics to referring physician.
**Objectives:** To assesses how physiotherapists are communicating their treatment of OA patients in the outpatient clinics to referring physician.
**Methods:** Patient records in the hospital region of middle Norway were searched to identify patients with knee OA. A letter was sent to the identified patients (N=83) asking for information about which physiotherapist they had seen for treatment. A letter was then sent to the physiotherapists asking for the discharge report, which they are obliged to send to the referring physician. A survey of the content in the discharge reports was conducted by three independent well qualified health professionals.
**Results:** Response rate from patients was 93 percent (N=81). Of the 81, 13 (15 percent) had not been referred to physiotherapy treatment. Response rate from physiotherapists (N=68) was 39 (56 percent).
The information given in the DR's was incomplete and the language was imprecise regarding OA treatment. None of the DR met the criteria for what is supposed to be in a DR. In 11% of the DR's it was not possible to rule out what kind of treatment was provided to the patient. Descriptions used was "easy strength training", "hip and knee group", and "deep massage, hip and lumbal training"; these are all examples of complete information on knee OA treatment extracted from the DR's.
**Conclusions:** This study indicates that the physiotherapists do not list the information needed by other health care professions regarding OA treatment. There seem to be a need to stress the importance of describing exercise as if it was medication, in terms of what kind of medication (type of exercise), the dose (how intense), ratio (how often). If a patient is to be followed up of another health care provider (MD, PH or other) imprecise description,- or lack of description of treatment provided may be harmful for the patient. It may also make it difficult to compare different treatment regimes if the information in the DR's are incomplete or missing

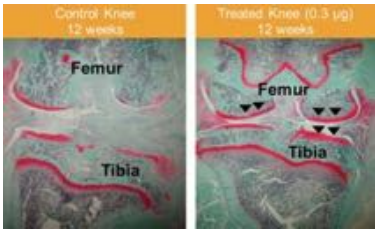
## Cartilage, bone, synovium

OP0068 **WISP1 INDUCES PATHOLOGY IN EXPERIMENTAL OSTEOARTHRITIS AND PREDICTS DISEASE PROGRESSION IN EARLY OSTEOARTHRITIS PATIENTS**

M. van den Bosch[1], A. Blom[1], A. Maeda[2], T. Kilts[2], W. van den Berg[1], P. van Lent[1], M. Young[2], P. van der Kraan[1]. *[1]Radboud university medical center, Nijmegen, Netherlands; [2]NIDCR/NIH, Bethesda, United States*



**Background:** Many osteoarthritis (OA) patients show synovial activation, which is suggested to be involved in joint destruction. Previously, we found strong upregulation of *Wnt2b* and *Wnt16* in the synovium of two experimental OA models. In addition, we found strongly increased *Wisp1* expression, a protein induced by canonical Wnt signaling.
**Objectives:** To determine whether there is a relation between *WISP1* expression and progression of OA in a cohort study of patients with early symptomatic OA. Furthermore, we will elucidate whether WISP1 plays a role during experimental OA by inducing OA models in wild type (WT) and *Wisp1*$^{-/-}$ mice.
**Methods:** Microarray analysis was performed on synovium from patients enrolled in the CHECK study, initiated to follow the progression of early symptomatic OA patients. Expression data were correlated with progression of OA (defined as a decrease in joint space width of $\geq$1mm and progression of osteophyte formation of $\geq$4x in size) between baseline and the five-year follow-up measurement. Human end-stage OA synovium was stimulated with WISP1. Joint pathology in WT or *Wisp1*$^{-/-}$ mice was assessed by histology after induction of collagenase-induced OA (CIOA), destabilization of the medial meniscus (DMM) and anterior cruciate ligament transection (ACLT) experimental models of OA. The aggrecan neoepitope NITEGE was visualized using immunohistochemistry. Gene expression in the synovial tissue was evaluated using qRT-PCR.
**Results:** Microarray analysis of synovial tissue from patients in the CHECK cohort showed significantly increased WISP1 expression at baseline in OA progressors versus non-progressors. To determine the mechanism of how WISP1 might be involved in OA pathology, we stimulated human OA synovium with WISP1. This increased the expression of *MMP2/3/9/13* and *ADAMTS4/5*. Next, we determined the *in vivo* role of WISP1. First, we found that spontaneous cartilage damage was not different between WT and *Wisp1*$^{-/-}$ mice at 3, 6 and 12 months of age. Next, we assessed joint pathology 42 days after induction of CIOA in WT and *Wisp1*$^{-/-}$ mice. Cartilage damage was significantly decreased in the tibio-femoral joints of the *Wisp1*$^{-/-}$ mice as compared with the WT controls. In line with the CIOA, we found significantly decreased cartilage degeneration in the *Wisp1*$^{-/-}$ mice in the DMM and ACLT at day 56 after induction. In addition we found decreased expression of *Mmp3*/*9* and the aggrecanases *Adamts4*/*5* in the synovium, 7 days after induction of CIOA in *Wisp1*$^{-/-}$ mice, in line with the increased expression of

these factors after stimulation of human OA synovium with WISP1. Furthermore, the expression of the protease inhibitor *Timp1* was decreased in the *Wisp1*$^{-/-}$ mice, whereas the expression of *Timp3*, an important inhibitor of ADAMTS-4/5, was unaffected. Finally, the protease activity in the cartilage, as assessed by the staining of the neoepitope NITEGE, was decreased in the *Wisp1*$^{-/-}$ mice.
**Conclusions:** Increased WISP1 expression may play an important role in OA pathology via increased synovial MMP/ADAMTS expression. Furthermore, because of the tight regulation and complexity of Wnt signaling and its role in many physiological processes, targeting WISP1 may more specifically target the OA-related pathological events, while minimizing interference with physiological processes.

## OP0069 DISCOVERY OF A SMALL MOLECULE INHIBITOR OF THE WNT PATHWAY (SM04690) AS A POTENTIAL DISEASE MODIFYING TREATMENT FOR KNEE OSTEOARTHRITIS

J. Hood, C. Barroga, Y. Hu, V. Deshmukh. *Samumed, San Diego, United States*

**Background:** Osteoarthritis (OA) is characterized by increased subchondral bone and thinning cartilage. The Wnt signaling pathway has the capacity to regulate both of these processes. Increased Wnt signaling induces stem cells in the joint to become osteoblasts while decreased Wnt signaling induces chondrogenesis[1]. Wnt signaling is increased in the joints of OA patients and polymorphisms in genes involved in Wnt signaling are associated with an increased susceptibility to development of OA[2].
**Objectives:** SM04690, a novel, small molecule inhibitor of the Wnt pathway, was evaluated in a series of preclinical studies to determine its capacity to induce chondrogenesis and improve joint health.
**Methods:** Inhibition of the Wnt pathway was determined with a cellular screen utilizing a luciferase reporter controlled by a Wnt-responsive promoter. Chondrogenesis was evaluated by histology using differentiation of mesenchymal stem cells (MSCs) to chondrocytes. Protease release from human chondrocytes was measured by ELISA. Pharmacokinetics of SM04690 were evaluated by intra-articular (IA) injection in rats and dogs followed by analysis of compound concentration in the joints and plasma. Safety of SM04690 was assessed by IA injection in rats and dogs followed by evaluation of clinical signs and histology. *In vivo* activity of SM04690 was evaluated in the rat instability model combining anterior cruciate ligament transection with medial meniscal tear. SM04690 was injected into the IA space of the damaged knee, followed by histological evaluation using OARSI scoring and measurement of biomarkers.
**Results:** *In vitro*, SM04690 reduced TCF7 expression leading to selective inhibition of Wnt pathway activation with an $EC_{50}$=3 nM. Consistent with Wnt's role in chondrogenesis, SM04690 induced MSCs to express chondrogenic genes and differentiate into chondrocytes. SM04690 inhibited production of proteases from human chondrocytes, while increasing expression of GAG suggesting it has the capacity to block cartilage degradation and stimulate matrix generation. *In vivo*, a single IA injection of SM04690 resulted in a joint concentration above the target $EC_{50}$ with no detectable systemic exposure. No systemic toxicity was observed after single or 9 monthly IA injections of doses >1400× the therapeutic dose in rats and dogs. In the rat instability model, a single IA injection of SM04690 2 weeks post-injury improved cartilage health in a dose-dependent manner relative to vehicle control. Representative histology showed increased cartilage thickness in SM04690-treated animals relative to vehicle control (Figure 1). At the optimal IA dose in rats (0.3 mg/knee) OARSI scores decreased significantly, p=0.006.

**Conclusions:** SM04690 has been shown in these experiments to inhibit the Wnt pathway, induce chondrogenesis, inhibit protease production and improve cartilage health in rodent models of OA after a single IA injection. SM04690 was maintained in the joint space with no detectable exposure in the plasma, indicative of a low potential for systemic toxicity. These data suggest that locally injected SM04690 has potential as a disease modifying therapy for OA.

## OP0070 PD-L2 – A NEW LINK BETWEEN INFLAMMATION AND BONE MODULATION IN RHEUMATOID ARTHRITIS

S.R. Greisen[1,2], A.H. Sharpe[3,4], T.W. Kragstrup[1,2], E.-M. Hauge[2,5], W. Qiu[6], M. Hvid[1,5], B. Deleuran[1,2]. *[1]Dept. of Biomedicine, Aarhus University; [2]Dept. of Rheumatology, Aarhus University Hospital, Aarhus, Denmark; [3]Dept. of Pathology, Brigham and Women's Hospital; [4]Dept. of Microbiology and Immunobiology, Harvard Medical School, Boston, United States; [5]Dept. of Clinical Medicine, Aarhus University, Aarhus; [6]Molecular Endocrinology Laboratory (KMEB), Odense University Hospital, University of South Denmark, Odense, Denmark*

**Background:** Inflammatory conditions affect bone turnover, as is seen in rheumatoid arthritis (RA). Inflammatory cytokines in RA stimulate osteoclasts and shift the balance between bone formation and resorption. Programmed death-1 (PD-1) and its ligands PD-L1 and PD-L2, are important for maintaining self-tolerance, and this pathway plays a prominent role in RA. Recently, repulsive guidance molecule b (RGMb) and bone morphogenetic protein (BMP) was identified as a novel receptor complex for PD-L2 (1). We previously showed the PD-1 pathway to be associated with radiographic progression in RA (2). The interaction of PD-L2 with the RGMb/BMP receptor complex could potentially provide a link between bone homeostasis and the PD-1 pathway.
**Objectives:** To investigate the possible association between bone homeostasis and the PD-1 pathway in RA.
**Methods:** We generated osteoclasts from RA synovial fluid mononuclear cells (SFMCs) (3), stimulated them with recombinant (rec) PD-1 and PD-L2, and subsequently evaluated these osteoclasts for TRAP activity, and expression of PD-1, PD-L2 and RGMb. We induced RA-like disease in PD-1-and PD-L2-KO mice by immunization with Freund's adjuvant and chick collagen, and evaluated clinical arthritis. After sacrifice, paws were paraffin embedded and stained for TRAP and osteocalcin. The femur was subjected to ex vivo DXA scanning. In addition, we stimulated normal mouse calvarial cells with the recombinant proteins in a BMP reporter assay to evaluate the potential of PD-1 and PD-L2 to affect BMP signaling.
**Results:** Recombinant PD-1 and PD-L2 increased TRAP activity in osteoclasts generated from RA SFMCs, at day 21 (p=0.046). Pre-osteoclasts in the culture expressed both PD-L2 and RGMb. The KO mice did not develop clinical signs of arthritis, ensuring intact mobility and constant bone load. DXA scan revealed that immunized PD-L2 KO mice had a higher bone mass density than other KO mice, WT and non-immunized PD-L2 KO (p=0.03). These mice did not differ histologically in TRAP and osteocalcin expression. Rec PD-L2 significantly decreased BMP signaling in the BMP reporter assay.
**Conclusions:** The clinical association between the PD-1 pathway and radiographic progression in early RA points to its importance in RA bone homeostasis. The increase in TRAP activity after incubation with recombinant PD-L2 supports this association. The increased bone mass density observed in immunized PD-L2 KO mice further supports a potential role for PD-L2 in bone homeostasis. The expression of PD-L2 in pre-osteoclasts also suggests a role for PD-L2 in bone homeostasis. These data provide a new insight into the close relation between the immune system and bone, as well as suggest a potential therapeutic target in diseases involving inflammatory bone changes.

## OP0071 ADIPOKINE EFFECTS ON DIFFERENTIATION OF OSTEOPOROSIS AND OSTEOARTHRITIS SPONGIOSA-DERIVED MESENCHYMAL STROMAL CELLS

L. Tsiklauri[1], J. Werner[2], K. Frommer[1], U. Mueller-Ladner[1], S. Rehart[3], S. Wenisch[2], E. Neumann[1]. *[1]Justus-Liebig-University Giessen, Department of Internal Medicine and Rheumatology, Kerckhoff-Klinik, Bad Nauheim; [2]Justus-Liebig-University Giessen, Institute of Veterinary-Anatomy, -Histology and –Embryology, Clinic of Small Animals, Giessen; [3]Orthopedics & Trauma Surgery, Markus-Hospital, Frankfurt, Germany*

**Background:** Osteoporosis predominantly affects elderly people and is characterized by bone loss, increased fracture risk and reduced regeneration ability. Age-related bone loss and articular cartilage damage correlate with increased bone marrow fat infiltration. With respect to age and age-related osteoporosis, there is an inverse relationship between bone mass and bone marrow adiposity. Bone marrow adipose tissue is metabolically active: It releases proinflammatory (e.g. adipokines) and matrix-degrading proteins (e.g. matrix metalloproteinases, MMPs), which promote progressive bone loss observed in osteoporosis and osteoarthritis. Moreover, bone marrow adipocytes share the same precursor with osteoblasts, the mesenchymal stem cell (MSC). Adipocyte-derived factors might influence differentiation of bone marrow-derived MSCs into osteoblasts and adipocytes. However, information on interactions between adipose tissue-derived factors and MSC differentiation is limited.
**Objectives:** To analyze the presence of adipokines (visfatin, resistin and leptin) in the bone marrow cavity and their effects on differentiation of MSCs.

**Methods:** Spongiosa containing bone marrow from femoral heads of patients undergoing hip replacement after osteoporotic femoral neck fracture or osteoarthritis were collected. Primary spongiosa-derived mesenchymal stromal cells (hMSCs) as well as commercially obtained MSCs were cultured in adipogenic and osteogenic media 3 weeks with/without adipokines. mRNA expression of adipokines, bone marker genes, TIMPs and MMPs of stimulated hMSCs/MSCs and as well as of bone samples were evaluated by real time PCR.
**Results:** Expression of visfatin was significantly increased in osteoporotic bone (n=14) compared to non-osteoporotic bone. Higher expression of leptin was also detectable in osteoporotic bone (n=13). The stimulation with visfatin of hMSC during adipogenic differentiation significantly increased MMP13-expression (e.g. d21: 72-fold) but not leptin and resistin. In osteogenic differentiated cells, a reduction of MMP2 by stimulation of all adipokines could be observed (n=3). In contrast to adipogenic differentiation of hMSC, visfatin led to reduced expression of MMP13 during osteogenic differentiation (e.g. d21: 55-fold). In addition,visfatin decreased TIMP1 (e.g. d21: 2.86-fold), TIMP2 (e.g. d21: 3.17-fold), and RunX2 (e.g. d21: 5.85-fold) production, whereas leptin and resistin showed no effect on these molecules.
**Conclusions:** Visfatin and leptin levels were found to be increased in osteoporotic bone tissue. The altered MMP and TIMP production, mediated especially by visfatin, might therefore influence bone remodeling at the adipose tissue/bone interface. Moreover, high levels of leptin in the osteoporotic bone might enhance bone degradation. Although leptin had no local effect on MSCs differentiation *in vitro*, it may also modulate bone degradation by affecting other cell types such as inflammatory cells.
**Disclosure of Interest:** None declared

## OP0072 INHIBITION OF NOTCH1 PROMOTES HEDGEHOG SIGNALING IN A HES1-DEPENDENT MANNER AND EXACERBATES EXPERIMENTAL OSTEOARTHRITIS

N.Y. Lin[1], A. Distler[1], C. Beyer[1], A. Philipi-Schöbinger[1], M. Stock[1], A. Niemeier[2], F. Dell'Accio[3], G. Schett[1], J.H. Distler[1]. *[1]Department of Internal Medicine III and Institute for Clinical Immunology, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen; [2]Department of Orthopedics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]School of Medicine and Dentistry, Queen Mary, University of London, J Vane Centre, Charterhouse Square, William Harvey Research Institute, Barts and The London, London, United Kingdom*

**Background:** The Notch pathway is one of the so-called morphogen pathways, which are evolutionary conserved key-regulators of embryonic development. Notch signaling has recently been implicated in the pathogenesis of osteoarthritis (OA). However, cell-type and context dependent differences in outcome have been reported and the underlying molecular mechanisms are incompletely understood.
**Objectives:** OA is characterized by degeneration of articular cartilage, limited intraarticular inflammation with synovitis, changes in periarticular and subchondral bone and osteophyte formation by endochondral ossification. Several studies have identified Notch- and Hedgehog-signaling as essential pathways involved in cartilage development and bone remodeling.
**Methods:** Notch and hedgehog signaling were analyzed by real-time PCR and immunohistochemistry. Mice overexpressing a Notch-1 antisense construct (Notch-1 AS) were employed as a model of impaired Notch signaling. Experimental OA was induced by destabilization of the medial meniscus (DMM). The extent of cartilage destruction and osteophyte formation was analyzed by safranin-O staining with subsequent assessment of the OARSI and Mankin scores and $\mu$CT scanning. Collagen X staining was used as a marker of chondrocyte hypertrophy. The role of Hes-1 was investigated with knockdown and overexpression experiments.
**Results:** Notch signaling was activated in human and murine OA with increased expression of Jagged1, Notch-1, accumulation of the Notch intracellular domain (NICD1) and increased transcription of Hes-1. Notch1 AS mice showed exacerbated osteoarthritis with increases in OARSI scores, osteophyte formation, increased subchondral bone plate density, collagen X and osteocalcin expression and elevated levels of Epas1 and ADAM-TS5 mRNA. Inhibition of the Notch pathway induced activation of hedgehog signaling with induction of Gli-1 and Gli-2 and increased transcription of hedgehog target genes. The regulatory effects of Notch signaling on Gli-expression were mimicked by Hes-1.
**Conclusions:** Inhibition of Notch signaling activates hedgehog signaling, enhances chondrocyte hypertrophy and exacerbates experimental osteoarthritis including osteophyte formation. These data suggest that the activation of the Notch pathway may serve to limit aberrant hedgehog signaling in OA.
**Disclosure of Interest:** None declared

## OP0073 RNA-SEQ BASED IDENTIFICATION OF FACTORS INVOLVED IN KNEE JOINT REGENERATION AFTER INDUCED OSTEOARTHRITIS IN NOTOPHTHALMUS VIRIDESCENS

C. Schoenfeld[1], M. Geyer[1], C. Schreiyaeck[1], S. Junker[1], U. Lange[1], M. Looso[2], T. Braun[2], E. Neumann[1], U. Mueller-Ladner[1]. *[1]Rheumatology and Clinical Immunology, University of Giessen, Kerckhoff-Clinic; [2]Max-Planck-Institute for Heart and Lung Research, Bad Nauheim, Germany*

**Background:** While tissue damage in mammals is mostly accompanied by fibrotic scar formation, many urodele amphibians including the red-spotted newt *Notophthalmus viridescens* are able to restore damaged organs or even lost appendages. To study endogenous knee joint regeneration in adult vertebrates, the newt has been established as a model organism in our working group. Like in murine models, osteoarthritis (OA) like symptoms can either be induced by surgical damage to articular cartilage or by intra-articular injection of enzymes, e.g. collagenase. In contrast to murine OA models, newts display symptoms including joint instability and luxation, but joint function is restored in these animals within 3 months.
**Objectives:** To evaluate the molecular pathways involved in knee joint regeneration.
**Methods:** To induce OA, animals were either treated by intra-articular injection of collagenase, mono-iodoacetate or by surgical manipulation of articular cartilage. To study gene expression changes on the transcriptional level during regeneration in the newt, RNA from knee joints was isolated and pooled. Subsequently, a quantitative transcriptome analysis using Illumina® next-generation sequencing (NGS) was performed. Relevant molecular pathways guiding regeneration were analyzed in all OA models tested. Candidate genes using public available databases have been selected, and pathway analyses of the gained data have been performed. Verification of selected candidate genes on the mRNA level has been done by Real Time PCR analyses. Adhesion of newt-derived cell lines and primary newt cells to Tenascin-C (TN-C) was analyzed *in vitro*. To compare molecular pathways guiding wound healing in amphibians and mice, the expression pattern of selected candidate genes (TN-C and cysteine-rich protein 61 (Cyr61/CCN1)) was also analyzed in murine OA models on the mRNA (Real Time PCR) and protein level (immunohistochemistry).
**Results:** During regeneration, several matricellular proteins including TN-C, CCN family members and their related pathways were found to be differentially regulated. In contrast to the murine OA models, Cyr61/CCN1 mRNA expression levels peaked at day 5 (5.9±0.72 in the collagenase model) and ceased afterwards, while mRNA expression levels in collagenase (day 10 0.6±0.07 to 2.5±0.61 at day 60) and surgically treated newts (day 10 3.39±0.64 to 1.6±0.2 at day 60) showed higher expression levels during later time points. On the protein level, CCN1 expression was detectable in chondrocytes and osteophytes in the collagenase induced murine OA model. In adhesion experiments using the newt-derived cell line B1H1 TN-C coating had anti-adhesive properties (TN-C vs. Control 42% reduction).
**Conclusions:** Extracellular matrix proteins are important during regenerative and repair processes, since they may alter cellular adhesion and guide migration. Identification of novel proteins and evaluation of their impact on cellular behaviour can help to understand the pathways involved. Future experiments on cells from OA patients might help in the development of new treatment options for human OA.

## OP0074 EBSELEN IS A POTENTIAL ANTI-OSTEOPOROSIS AGENT BY SUPPRESSING RECEPTOR ACTIVATOR OF NUCLEAR FACTOR KAPPA-B LIGAND-INDUCED OSTEOCLAST DIFFERENTIATION IN VITRO AND LIPOPOLYSACCHARIDE-INDUCED INFLAMMATORY BONE DESTRUCTION IN VIVO

J.M. Baek[1], J.-Y. Kim[1], K.-H. Yoon[2], J. Oh[1], C.-H. Lee[3], M.S. Lee[3]. *[1]Anatomy, School of Medicine, Wonkwang University; [2]Imaging Science-based Lung and Bone Diseases Research Center; [3]Internal Medicine, Wonkwang University Hospital, Iksan, Korea, Republic Of*

**Background:** Ebselen is a non-toxic seleno-organic drug with anti-inflammatory and antioxidant properties that is currently being examined in clinical trials to prevent and treat various diseases, including atherosclerosis, stroke, and cancer.
**Objectives:** We investigated the effects of ebselen on RANKL-induced differentiation of osteoclasts and their functions and the underlying molecular mechanisms. Furthermore, we determined the effects of ebselen on LPS-induced bone erosion *in vivo*.
**Methods:** To generate osteoclasts from BMMs, we cultured BMMs for 4 days in the condition of M-CSF and RANKL pretreated with ebselen. The cells were then stained with TRAP solution, rhodamine-conjugated phalloidin for F-actin ring labeling and DAPI solution to detect apoptotic body formation. The change of F-actin ring on mature osteoclasts induced by ebselen was quantified by calculating the ratio of actin ring positive (AR+) osteoclasts versus actin ring negative (AR-) osteoclasts. to detect the formation of apoptotic osteoclasts, we performed TUNEL (TdT-mediated dUTP-biotin nick end-labeling) assay. Primary calvaria osteoblasts and BMCs were co-cultured and were re-seeded in hydroxyapatite-coated plates or dentin slices with or without ebselen. ICR mice were divided into

4 experimental groups comprising 5 mice each: phosphate-buffered saline-treated (control) group, ebselen only-treated group, LPS only-treated group, and LPS- and ebselen-treated group. Ebselen (10 mg/kg) or PBS was administered orally every 8 days, and LPS was injected intraperitoneally on days 1 and 4. Micro-computed tomography (μ-CT) data containing 3D images and bone parameters and histological data were acquired

**Results:** Ebselen suppressed the formation of TRAP-positive multinucleated cells in an osteoblast/osteoclast co-culture by regulating the ratio of RANKL/osteoprotegerin secreted by osteoblasts. In addition, ebselen treatment in the early stage of osteoclast differentiation inhibited RANKL-dependent osteoclastogenesis by decreasing the phosphorylation of IκB, PI3K, and Akt in early signaling pathways and by subsequently inducing c-Fos and nuclear factor of activated T-cells c1. Further, ebselen induced apoptosis of osteoclasts in the late stage of osteoclast differentiation. In addition, ebselen treatment suppressed filamentous actin ring formation and bone resorption activity of mature osteoclasts. Reflecting these *in vitro* effects, administration of ebselen recovered bone loss and its μ-CT parameters in lipopolysaccharide-mediated mouse model. Histological analysis confirmed that ebselen prevented trabecular bone matrix degradation and osteoclast formation in the bone tissues. Finally, it was proved that the anti-osteoclastogenic action of ebselen is achieved through targeting N-methyl-D-aspartate receptor.

**Conclusions:** Finally, it was proved that the anti-osteoclastogenic action of ebselen is achieved through targeting N-methyl-D-aspartate (NMDA) receptor.

**Disclosure of Interest:** None declared

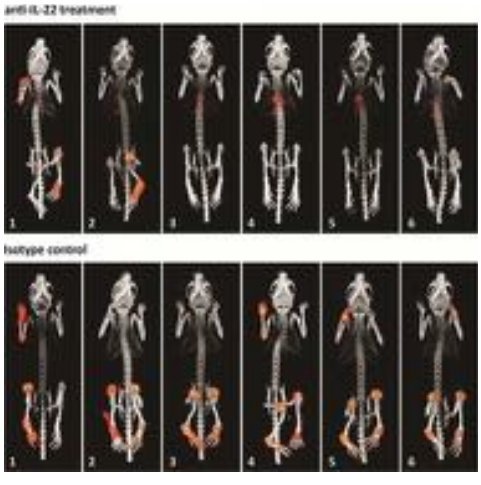
### OP0075 SENSITIVE SPECT/CT IMAGING OF SYNOVIAL FAP EXPRESSION AFTER ANTI-IL-22 TREATMENT IN EXPERIMENTAL ARTHRITIS



D.M. Roeleveld[1], T. van der Geest[2], T.K. Nayak[3], C. Klein[4], B. Walgreen[1], M.M. Helsen[1], M. Hegen[5], P. Laverman[2], O.C. Boerman[2], M.I. Koenders[1]. *[1]Experimental Rheumatology; [2]Radiology & Nuclear Medicine, Radboud umc, Nijmegen, Netherlands; [3]Pharmaceutical Research & Early development, Roche, Basel; [4]Pharmaceutical Research & Early development, Roche, Zurich, Switzerland; [5]Immunoscience Research Unit, Pfizer Worldwide Research and Development, Cambridge, United States*

**Background:** Rheumatoid arthritis (RA) synovial tissue has been demonstrated to express high levels of fibroblast activation protein (FAP) using anti-FAP-antibody 28H1. In addition, RA patients show elevated levels of IL-22 and IL-22-producing T helper cells that correlate to erosive disease, suggesting a role for this cytokine in the pathogenesis of RA.

**Objectives:** The purpose of this study was to determine the feasibility of $^{111}$In-28H1 SPECT/CT imaging of FAP-expressing synovium to monitor the therapeutic potential of neutralizing IL-22 during experimental arthritis.

**Methods:** Collagen-induced arthritis (CIA) was induced in male DBA/1J mice. Mice were treated 3 times per week with anti-IL-22 antibodies (8 mg/kg), while the control group received rat IgG1 isotype control antibodies. To monitor the therapeutic effect after 2 weeks of treatment, SPECT/CT images were acquired 24 h after injection of $^{111}$In-labeled DTPA-conjugated anti-FAP antibody, 28H1. After image acquisition, mice were euthanized and dissected. Imaging results were compared with the macroscopic arthritis scores and radiographic bone damage scores acquired by X-ray.

**Results:** Blocking IL-22 during CIA was a potent approach to prevent arthritis development, reaching a disease incidence of only 50%, versus 100% in the control group. SPECT/CT imaging using indium-labeled anti-FAP antibodies showed that joint uptake of the tracer was reduced highly significant (p=0.002) in anti-IL-22-treated mice (4.3 ± 3.4%ID/g) compared to the isotype control group (12.7 ± 3.7%ID/g) (See figure). This was confirmed by the corresponding macroscopic arthritis scores and radiographic bone damage scores that were significantly (p=0.047 and p=0.017 respectively) lower in the anti-IL-22-treated group. Besides its sensitivity, the in vivo FAP-based SPECT/CT had the great advantage to visualize sites of inflammation that were overlooked during clinical scoring, like in knee, hip, elbow and shoulder (See figure).

**Conclusions:** These findings demonstrate that IL-22 plays an important role in the development of experimental arthritis, and targeting this cytokine seems an attractive new strategy in RA treatment. Most importantly, SPECT/CT imaging of the inflamed synovium using the labeled anti-FAP antibody $^{111}$In-DTPA-28H1 can be used to specifically monitor response to therapy in an objective and quantitative way, and is potentially more sensitive in disease monitoring compared to the standard method of clinical arthritis scoring by macroscopic inspection.

### OP0076 AUTOANTIBODIES AGAINST CD74 – A NEW DIAGNOSTIC MARKER FOR SPONDYLOARTHRITIS (SPA)

E. Schweikhard[1], T. Matthias[2], S. Reuter[1], J. Georgi[3], N. Baerlecken[4], T. Witte[4], M. Köhler[3]. *[1]R&D; [2]CEO, AESKU. Diagnostics GmbH&Co KG, Wendelsheim; [3]Internal Medicine and Rheumatology, Helios Ostseeklinik Damp, Damp; [4]Immunology and Rheumatology, Medical University Hannover, Hannover, Germany*

**Background:** Spondyloarthritis (SpA) is a common debilitating inflammatory disorder. Pathogenesis of axial SpA (axSpA) including ankylosing spondylitis (AS) is still largely unclear.

**Objectives:** Diagnosis is difficult, since abnormalities in conventional X-rays develop with a latency of several years and only HLA-B27 is used as laboratory marker. The presence of radiographic sacroiliitis is essential for SpA diagnosis. To prevent destructive effects early diagnosis and intervention in SpA patients may be important. To evaluate antibodies to the human leukocyte antigen class II-associated invariant chain peptide (anti-CD74) as a diagnostic marker of SpA.

**Methods:** Sera of 117 patients with axial SpA and 38 non-SpA patients were analyzed for IgA and IgG antibodies against CD74 by ELISA. HLA-B27 status was available in 112 patients. All donors provided informed consent for the study approved by the local ethics committee (project number 4928).

**Results:** Anti-CD74 antibodies were detected in 85.1% of SpA patients but only in 5% of non-SpA patients ($p \leq 0.0001$). Detection of both IgG and IgA anti-CD74 antibodies for diagnosing SpA revealed a sensitivity of 77% and a specificity of 90%. Remarkably, IgA autoantibodies against CD74 alone had a sensitivity of 67% and a specificity of 95%. IgA anti-CD74 antibodies were even more frequent in SpA patients with short disease duration and significantly correlate with more advanced radiological sacroiliitis and reduced spinal mobility.

**Conclusions:** Anti-CD74 IgA antibodies were strongly associated with SpA. Antibodies against CD74 could provide an important additional tool for diagnosis of SpA.

**Disclosure of Interest:** None declared

### OP0077 IL-20 AND IL-24 LINK INNATE IMMUNE ACTIVATION AND NEW BONE FORMATION IN SPONDYLOARTHRITIS

T.W. Kragstrup[1,2], M.N. Andersen[1], B. Schiøttz-Christensen[3], A.G. Jurik[4], M. Hvid[1], B. Deleuran[1,2]. *[1]Department of Biomedicine, Aarhus University; [2]Department of Rheumatology, Aarhus University Hospital, Aarhus C; [3]Department of Rheumatology, Hospital Lillebaelt, Middelfart; [4]Department of Radiology, Aarhus University Hospital, Aarhus C, Denmark*

**Background:** The pathogenesis of spondyloarthritis (SpA) involves activation of the innate immune system, inflammation and new bone formation. The innate immune system is activated through pattern recognition receptors including Toll like receptor 4 (TLR4). Inflammation is a result of increased production of pro-inflammatory cytokines and chemokines including tumor necrosis factor alpha (TNFα) and monocyte chemoattractant protein 1 (MCP-1). New bone formation by osteoblasts is determined by a balance between the inhibitory effect of Dickkopf-1 (DKK1) and the stimulatory effect of bone morphogenetic proteins (BMPs) including BMP2. The two cytokines IL-20 and IL-24 have been shown to link innate immune activation and tissue homeostasis.(1) Previously, we have found increased plasma levels of IL-20 and IL-24 in SpA patients.

**Objectives:** We hypothesized that IL-20 and IL-24 are secreted as part of activation of the innate immune system and affect bone homeostasis. The aim was to describe associations of IL-20 and IL-24 and disease activity and magnetic resonance imaging (MRI) scores and to identify the sources and targets of the two cytokines in SpA.

**Methods:** Patients with axial SpA (n=83) were included in the study of associations between cytokine levels and disease activity and MRI scores. Patients with peripheral SpA (n=16) were included for studying sources and targets of IL-20 and IL-24 among synovial fluid mononuclear cells (SFMCs), peripheral blood mononuclear cells (PBMCs), and fibroblast-like synoviocytes (FLSs) using lipopolysaccharide (LPS) and TNFα as positive controls. Healthy human osteoblasts were used for studying the effect of the two cytokines on mineralization using BMP2 as a positive control. The secretion of IL-20, IL-24, MCP-1 and DKK1 were measured by enzyme linked immunosorbant assays and flow cytometry, and mineralization was measured by hydroxyapatite deposition. Plasma IL-20 and IL-24 levels were analyzed with the Mann-Whitney U test and the Spearman correlation. Supernatant cytokine concentration and flow cytometry median fluorescence intensity data were calculated as ratios, log-transformed and compared with the paired or unpaired t-test.
**Results:** The plasma IL-20 and IL-24 levels were increased in SpA patients compared with healthy controls (HCs) by 57% and 83%, respectively (both $p<0.0001$) and there was a trend towards associations with both future switch to biologic therapy (p=0.031 and p=0.11, respectively), and spine MRI chronicity score (p=0.10 and p=0.15, respectively). The production of IL-20 and IL-24 was increased by LPS, and this TLR4 induced secretion was greater in SpA PBMCs compared with HC PBMCs. IL-20 and IL-24 increased the production of MCP-1 by SpA SFMCs (but not by SpA FLSs), decreased the production of DKK1 by SpA FLSs (but not by SpA SFMCs) and increased mineralization by human osteoblasts. The IL-20 and IL-24 induced production of MCP-1 among the SFMCs was found in activated synovial monocytes only.
**Conclusions:** Taken together, our findings indicate that IL-20 and IL-24 are novel links between activation of the innate immune system and new bone formation.

## OP0078 SYNOVIAL MYOFIBROBLASTS FROM SPONDYLOARTHRITIS PATIENTS PRODUCE IL-26 SPONTANEOUSLY AND THE PRODUCTION IS ENHANCED UPON IL-1, TNF-α AND LPS STIMULATION

L.D. Heftdal[1], M. Hvid[1,2], B. Deleuran[1,3], T.W. Kragstrup[1,3]. *[1]Department of Biomedicine; [2]Department of Clinical Medicine, Aarhus University; [3]Department of Rheumatology, Aarhus University Hospital, Aarhus C, Denmark*

**Background:** New bone formation in spondyloarthritis involves myofibroblasts [1]. IL-26 is part of the IL-10 cytokine family and was recently reported to increase Th17 differentiation [2]. It was first discovered in herpesvirus saimiri–transformed T cells and thus suspected to be a T-cell cytokine [3]. However, more recent studies of RA patients show IL-26 expression in synoviolin-postive cells harvested from the synovia [2]. The knowledge about IL-26 is compromised by lack of IL-26 in mice and no studies of IL-26 in spondyloarthritis (SpA) and its regulation have been conducted.
**Objectives:** In the present study we aim to characterize IL-26 producing cells in spondyloarthritis (SpA).
**Methods:** IL-26 was measured by ELISA in plasma and synovial fluid (SF) of 14 SpA patients attending the clinic with a swollen joint and in plasma samples from 7 age and gender matched healthy controls. Synovial-fluid-mononuclear-cells (SFMC) and fibroblast-like-synoviocytes (FLS) were cultured and stimulated for 48 hours with IL-1β, TNFα, TGF-β, IL-17A and LPS. The supernatants were harvested and analyzed for IL-26 by ELISA. Tissue samples of inflamed synovial membrane were stained with a fluorochrome conjugated rabbit IL-26 antibody for immunofluorescence. Imaging of the sections was performed by confocal microscopy. For flow cytometry analysis, FLS were surface stained for CD90 and a live-dead marker, and subsequently permeabilized and stained intracellularly for α-Smooth-Muscle-Actin (αSMA) and IL-26. Samples were run on the flow cytometer within 24 hours of staining. Data are expressed as mean ± SD.
**Results:** IL-26 levels were significantly higher in synovial fluid compared with plasma; this applied to plasma from the healthy controls (HC) as well as SpA patients. (HC plasma: 5.8 ± 3.3 pg/ml, SpA plasma: 6.6 ± 1.8 pg/ml, SpA SF: 41.6 ± 6.8 pg/ml - P-values HC vs. SF: 0.0020, P-value SP vs. SF: <0.0001.) Staining of synovial membrane revealed IL-26 presence in synovial cells with fibroblast-like morphology. ELISA analysis of the supernatants from culturing and stimulation of FLS and SFMC showed a high level of IL-26 in both cell populations as well as drastic increase in IL-26 production after stimulation with IL-1, TNF-α and LPS. The vast majority of the IL-26 producing FLS were $\alpha SMA^+$ and $CD90^+$ myofibroblasts by flow cytometry.
**Conclusions:** IL-26 levels in synovial fluid are significantly higher than in plasma, suggesting a local production of IL-26 in the inflamed joint. We found IL-26 positive cells in the synovial membrane with fibroblast morphology and FLS from the inflamed joints of SpA patients produce high amounts of IL-26. By flow cytometry we established that these IL-26 producing fibroblasts seem to be myofibroblasts primarily.

## OP0079 INCREASED FREQUENCIES OF IL-23R POSITIVE T CELLS AND IL-22 AND IL-17 PRODUCING MAIT CELLS IN THE PERIPHERAL BLOOD OF PATIENTS WITH ANKYLOSING SPONDYLITIS: PRELIMINARY RESULTS

E. Toussirot[1], C. Laheurte[2], B. Gaugler[3], P. Saas[3]. *[1]Clinical Investigation Center Biotherapy, University Hospital; [2]Clinical Investigation Center Biotherapy, EFS B/FC, Plateforme de BioMonitoring; [3]INSERM UMR1098, EFS BFC, Besançon, France*

**Background:** Ankylosing spondylitis (AS) is the prototypic and most common form of spondyloarthritis (SpA). It was recently suggested that IL-23 could play a pivotal role in the pathophysiology of SpA. Indeed, there is a strong genetic association of SpA with polymorphisms of the *IL-23* receptor (IL-23R) gene. In experimental models, IL-23 is produced during the misfolding phenomenon of HLA-B27 heavy chain in the endoplasmic reticulum. Furthermore, in animal models, IL-23 overexpression induced a SpA-like disease via IL-23+ resident T cells infiltrating entheseal structures and producing IL-17 and IL-22. In addition, there is an increased number of circulating cells producing IL-17 in patients with AS. Recent data also suggested that IL-17A is a potential target in the treatment of patients with AS.
**Objectives:** Cells that expressed IL-23R as well as those producing IL-17 and/or IL-22 have been poorly characterized in AS and/or SpA. Thus, we aimed to better delineate the peripheral blood T cells that expressed IL-23R and the IL-17 and IL-22 producing cell subsets, notably conventional T cells as well as mucosal associated invariant T cells (MAIT) in patients with AS.
**Methods:** 36 patients with AS (modified NY criteria; 27 M; age: 44.7 ± 2.6, disease duration: 12.7 ± 1.6; all under NSAIDs or traditional DMARDs) and 31 healthy controls (HC) (8 M; age: 46 ± 2.3) were evaluated. For each subject, peripheral blood T cell subsets were assessed using multi-color flow cytometry. Intracellular cytokine IL-17A, IL-22 and IFN-γ were evaluated after phorbol myristate acetate and ionomycine activation and permeabilization and analysed by flow cytometry. MAIT cells were identified by using TCRVα7.2 specific monoclonal antibodies. IL-22 serum levels were determined by ELISA using commercially available kit.
**Results:** the number and percentage of CD3+ T cells, CD3+CD4+ and CD3+CD8+ T cells were comparable between patients and HC. Circulating IL-22 levels did not differ between patients and HC (22.6 ± 8.4 vs 15.1 ± 4.4 pg/ml, p=0.7). IFN-γ producing $CD4^+$ and $CD8^+$ T cells were decreased in AS compared to HC (4.6 ± 1.7 vs 11.4 ± 2.5% and 23.3 ± 1.9 vs 34.3 ± 2.3%, respectively, p=0.005 and p=0.002). $CD8^+$ T cells expressing IL-23R were significantly increased in AS: 72.8 ± 1.5 vs 65.2 ± 2% (p=0.009). The percentage of MAIT T cells did not differ between patients and HC but we found an increased percentage of MAIT cells that produced IL-17 and IL-22: MAIT IFN-$\gamma^-$ IL-$17^+$: 0.43 ± 0.1 vs 0.12 ± 0.008%, p=0.006; MAIT IFN-$\gamma^-$ IL-$22^+$: 0.83 ± 0.1 vs 0.3 ± 0.1%, p=0.004. No correlation was found between the percentage of $CD8^+$ IL-$23R^+$ T cells and measurements of disease activity as well as between IL-$17^+$ or IL-$22^+$ MAIT cells and disease activity.
**Conclusions:** These preliminary results suggest that the peripheral blood of patients with AS is enriched in $CD8^+$ IL-$23R^+$ T cells as well as IL-17 and IL-22 producing MAIT cells. Since MAIT cells are involved in antibacterial immunity and bacterial agents are potentially involved in SpA, our preliminary data suggest that this T cell subset could potentially play a role in AS via IL-17 and IL22 production. This remains to be clarified by future and complementary studies.

## OP0080 HIGHER SERUM LEVEL OF LEPTIN MIGHT BE RESPONSIBLE FOR LESS STRUCTURAL DAMAGE IN THE SPINE IN FEMALE PATIENTS WITH ANKYLOSING SPONDYLITIS

D. Poddubnyy[1], A. Hartl[1], K.-G. Hermann[1], M. Rudwaleit[2], J. Sieper[1]. *[1]Charité Universitätsmedizin Berlin, Berlin; [2]Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany*

**Background:** Fat tissue synthesizes and releases a series of biologically active substances (adipokines), which are involved in bone metabolism through effects on bone formation and resorption. There are gender-specific differences in the expression of adipokines and there are also gender specific-differences in the development of structural damage in the spine in patients with ankylosing spondylitis - AS. The reason for less structural damage in the spine in female AS patients is not well understood until now.
**Objectives:** The aim of this study was to investigate the gender-specific role of adipokines as predictors of radiographic spinal progression in patients with AS.
**Methods:** Altogether 120 patients (82 men and 38 women) from the ENRADAS

trial who completed the study per protocol were included into the analysis. Spinal radiographs (lumbar and cervical spine, lateral views) were scored independently by two trained readers according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) scoring system. Radiographic spinal progression was defined as 1) mSASSS worsening by ≥2 units after 2 years, and 2) development of at least one new syndesmophyte or progression of existing syndesmophytes (i.e., formation of a bridging syndesmophyte) after 2 years. Serum levels of adipokines (leptin, adiponectin, lipocalin-2, omentin, visfatin, resistin, and chemerin) were measured at baseline.

**Results:** A significant association with radiographic spinal progression was found for leptin only. Mean baseline leptin levels were significantly lower in patients with mSASSS worsening by ≥2 units after 2 years (n=29) as compared to those without progression (n=91): 10.3±8.8 vs. 15.9±13.7 ng/ml, respectively, p=0.002, and in patients with syndesmophyte formation (n=25) as compared to those without syndesmophyte formation (n=95): 10.1±9.6 vs. 15.7±13.4 ng/ml, respectively, p=0.002. This difference was especially evident in males, but not in females. However, in females the serum level of leptin at baseline was in general significantly higher than in males: 24.0±17.4 vs. 10.2±6.8 ng/ml, p<0.001 that was independent of body mass index.

In the ROC analysis leptin had an area under the curve (AUC) of 0.69 (95% CI 0.57–0.81) for no mSASSS worsening by ≥2 units and 0.70 (95% CI 0.57–0.82) for no syndesmophyte formation. Leptin level of 7.5 ng/ml was identified in the ROC analysis as an optimal threshold for the prediction of protection from radiographic spinal progression after two years – table.

In the logistic regression analysis, a protective value of higher leptin serum level regarding radiographic spinal progression could be confirmed: odds ratio (OR) =1.15 (95% CI 1.02–1.3) for no mSASSS worsening by ≥2 units, and OR =1.28 (95% CI 1.1–1.5) for no syndesmophyte formation (meaning a 15%/28% increase of the odds for no radiographic spinal progression after 2 years with each baseline leptin serum level increase by 1 ng/ml), both adjusted for baseline syndemophytes, elevated C-reactive protein (CRP), smoking, body mass index, sex, and NSAIDS intake score.

**Table.** Baseline serum leptin level >7.5 ng/ml (an optimal cut-off in the ROC analysis) as a predictor of protection from radiographic spinal progression after two years in patients with ankylosing spondylitis (n = 120).

| Outcome | Sensitivity, % | Specificity, % | OR, unadjusted | OR, adjusted* |
|---|---|---|---|---|
| No mSASSS worsening by ≥2 points | 78 | 55 | 4.4 (95% CI 1.8-10.6) | 9.2* (95% CI 2.5-34.0) |
| No syndesmophyte formation / progression | 77 | 56 | 4.2 (95% CI 1.7-10.6) | 11.7* (95% CI 2.8-47.8) |

*Adjusted for baseline syndemophytes, elevated CRP, smoking, body mass index, sex, and NSAIDs intake score

**Conclusions:** Higher serum levels of leptin seem to protect patients with AS from radiographic spinal progression. Female patients with AS have significantly higher leptin levels that might explain lesser extent of structural damage in the spine in female AS patients in general.

**Disclosure of Interest:** None declared

## OP0081 TISSUE DEFICIENCY OF THE ATYPICAL CHEMOKINE RECEPTOR D6 IS ASSOCIATED WITH THE SELECTIVE INCREASE OF GUT-DERIVED PRO-INFLAMMATORY CXCR1HIGHLY6HIGHTL1A+IL-23+CCR7+ CELLS IN THE PERIPHERAL BLOOD, SYNOVIAL FLUIDS AND BONE MARROW OF AS PATIENTS

F. Ciccia[1], G. Guggino[1], H. Nigil[2], V. Ranganathan[2], A. Rizzo[3], R. Alessandro[1], G. Triolo[1]. *[1]University of Palermo, Palermo, Italy; [2]University of Toronto, Toronto, Canada; [3]Azienda Ospedaliera Villa Sofia Cervello, Palermo, Italy*

**Background:** Gut derived innate lymphoid cells of type 3 (ILC)3 are increased in number in the circulation and inflamed tissues of AS patients. Factors influencing the maintainace of ILC3 in an activated status are not clear. The atypical chemokine receptor D6 is a decoy and scavenger receptor for most inflammatory CC chemokines and acts preventing exacerbated inflammatory reactions. Mice lacking D6 expression in the non-hematopoietic compartment display a significant increase of pro-inflammatory monocytes in the peripheral blood and in secondary lymphoid tissues. The role of D6 in human inflammatory disorders has not been inverstigated.

**Objectives:** To evaluate whether modulation of D6 expression occurs in the gut and in BM of AS patients and accompanied with a selective increase of pro-inflammatory CXCR1$^{high}$Ly6$^{high}$TL1A$^{+}$CCR7$^{+}$ cells in the circulation and inflamed tissues of AS and to study the effect of these cells in modulating ILC3 differentiation.

**Methods:** RT-PCR and immunohistochemistry were used to evaluate the expression of D6 in the gut and bone marrow of AS patients and controls. Different monocyte substes were analyzed by flow cytometry in the peripheral blood, gut, synovial fluids and bone marrow of AS patients and controls. Isolated peripheral CXCR1$^{high}$Ly6$^{high}$TL1A$^{+}$CCR7$^{+}$ cells were co-coltured with isolated peripheral ILC3 and changes in ILC3 frequency were evaluated by flow cytometry.

**Results:** D6 was significantly down-regulated in the ileum and in the bone marrow of AS patients compared to controls. D6 deficiency was accompanied by a complex monocyte/macrophage signature. Tissue resident CXCR1$^{high}$Ly6$^{low}$ macrophages were expanded in the ileum of AS patients compared to controls. A significant increase in the frequency of pro-inflammatory CXCR1$^{high}$Ly6$^{high}$ monocytes producing high levels of TL1A and IL-23 was observed in the ileum of AS patients. In the peripheral blood a statistically significant increase in the frequencies of both bone marrow derived CXCR1$^{low}$Ly6$^{High}$ and intestinal derived CXCR1$^{high}$Ly6$^{high}$CCR7$^{+}$TL1A$^{+}$IL-23$^{+}$ monocytes, the latest being also expanded in AS synovial fluids and bone marrow. Isolated pro-inflammatory CXCR1$^{high}$Ly6$^{high}$TL1A$^{+}$IL-23$^{+}$CCR7$^{+}$ monocytes from peripheral blood of AS induced the expansion and activation, evaluated through the production of IL-22 and IL-17, of ILC3.

**Conclusions:** In this study we provide the first demonstration that absence of D6 expression in the gut and in the inflamed tissues of AS patients selectively induced the intestinal accumulation and re-circulation of pro-inflammatory CXCR1$^{high}$Ly6$^{high}$TL1A$^{+}$IL-23$^{+}$CCR7$^{+}$ monocytes. Since the ability of these cells in promoting ILC3 expansion and activation, these cells may promote a sustained pro-inflammatory status in AS.

**Disclosure of Interest:** None declared

## OP0082 INFECTIONS OF THE GUT, UROGENITAL AND RESPIRATORY TRACT AND APPENDICITIS DURING CHILDHOOD, AND THE RISK OF DEVELOPING ANKYLOSING SPONDYLITIS

U. Lindström[1], S. Exarchou[2], E. Lie[3], M. Dehlin[1], H. Forsblad-d'Elia[4], J. Askling[5], L.T.H. Jacobsson[1]. *[1]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Rheumatology and Inflammation Research, Gothenburg; [2]Department of Clinical Sciences, Lund University, Section of Rheumatology, Lund, Sweden; [3]Diakonhjemmet Hospital, Rheumatology Unit, Oslo, Norway; [4]Umeå University, Institution of Public Health and Clinical Medicine/Rheumatology, Umeå; [5]Department of Medicine, Karolinska Institutet, Rheumatology Unit & Clinical Epidemiology Unit, Stockholm, Sweden*

**Background:** Data supporting the role of specific environmental exposures in the development of AS are scarse. Microbial exposure, both in the form of infections and gut flora, has been implicated in the pathogenesis of several spondyloarthritis related conditions, such as reactive arthritis and inflammatory bowel disease (IBD). Gut dysbiosis has also been recognized in ankylosing spondylitis, but it is not known if this is a result of the disease or occurs before disease onset.

**Objectives:** To determine if infections during childhood, primarily gut, urogenital and respiratory tract infections (RTI) as well as appendicitis, predict a diagnosis of AS.

**Methods:** This is a register based study using several national registers. All individuals having ≥1 visit to specialized health care with an associated ICD-code for AS were identified in the national health care register, 1964–2009. For each index case 5 matched controls (sex, age, county) were retrieved from the population register. Cases and controls were linked to the National Patient Register (NPR) to identify hospitalization with an ICD-code indicating an infection (gastrointestinal, urogenital, respiratory tract or appendicitis) at an age of 0–16 years.

In order to ensure complete exposure information only cases and controls living in Sweden up until their 17th birthday were included. In order to increase the likelihood of a temporal relationship all cases and controls with any diagnosis of a rheumatic disease, psoriasis, IBD or iridocyclitis before the age of 17 and juvenile idiopathic arthritis ever were excluded.

Univariate conditional logistic regression analyses were used to determine odds ratios (OR) with confidence intervals (CI) for development of AS, with regard to the infectious exposures.

**Results:** Based on 2643 cases with AS and 11064 matched controls, childhood appendicitis reduced the odds for a later diagnosis of AS by 40% and hospitalization with a RTI increased the odds by 20%. Hospitalization for urogenital or gastrointestinal tract infections did not predict an AS diagnosis (Table 1). Similar (and statistically significant) results were obtained when excluding all cases/controls with a diagnosis of IBD up until 2 years after the first AS-diagnosis of the index case. The trend was stronger for men than women (data not shown).

| Table 1. Exposure | AS cases (N=2643) exposed | Controls (N=11064) exposed | OR | 95% CI |
|---|---|---|---|---|
| Appendicitis | 40 (1.5%) | 280 (2.5%) | 0.59 | 0.42 – 0.82 |
| Gastrointestinal tract infections | 84 (3.2%) | 336 (3.0%) | 1.03 | 0.80 – 1.32 |
| Respiratory tract infections | 225 (8.5%) | 808 (7.3%) | 1.18 | 1.01 – 1.39 |
| Urogenital tract infections | 11 (0.4%) | 47 (0.4%) | 0.96 | 0.49 – 1.85 |

**Conclusions:** Appendicitis during childhood decreased and RTI increased the risk of developing AS in this case-control study. Appendicitis/appendectomy has previously, repeatedly, been described to decrease the risk for ulcerative colitis, but has not been investigated for AS. Our findings suggest that early immune

phenotype, either affecting the risk for severe childhood infections, or being modulated by such infections, may represent an early pathophysiological phase of AS.

## OP0083 MIR-125A DECREASED IN PSA SYNOVIUM AND PERIPHERAL BLOOD CD14+ MONOCYTES AND CORRELATES TO JOINT ANGIOGENESIS

S. Wade[1], M. Connelly[1], S. Cregan[1], C. Orr[1], D. Veale[1], U. Fearon[2]. *[1]Centre of Rheumatic Disease, St Vincents University Hospital, UCD; [2]School of Medicine, Trinity College Dublin, TCD, Dublin, Ireland*

**Background:** Psoriatic Arthritis (PsA) is a chronic immune-mediated inflammatory disease, characterised by proliferation of synovial tissue and destruction of articular cartilage/bone with associated psoriasis. Dysregulated angiogenesis is one of the key early pathogenic processes in PsA. Monocyte subpopulations are increasingly recognized contributors to angiogenesis. Circulating monocytes can differentiate into tissue resident macrophages, monocyte derived dendritic cells and osteoclasts, which orchestrate both pro-inflammatory and pro-angiogenic signalling. These processes may be governed by microRNA (miRNA), a class of evolutionary conserved short non-coding RNAs which function as post-transcriptional repressors of gene expression. On such miRNA is miR-125a-5p, which in cancer, has been previously associated with altered angiogenesis, invasion and migration.
**Objectives:** To examine the expression and angiogenic associations of miR-125a-5p in PsA.
**Methods:** Synovial tissue biopsies were obtained from patients with PsA and osteoarthritis (OA). In parallel, CD14+ monocytes and CD3+ T cells were isolated from peripheral blood mononuclear cells. MiR-125a-5p levels were analysed by real-time PCR. To examine possible factors involved in regulating miR-125a-5p expression in endothelial cells,microvascular endothelial cells (HMVEC) were cultured with candidate pro-inflammatory stimuli including; TLR ligands (PAM, PolyIC, LPS), pro-inflammatory cytokines (TNFa, IL-1b, IL-17) and growth factors (VEGF, Ang2). Matrigel tube formation assays were performed with pre- and anti- 125a treated HMVEC to elucidate angiogenic function. Immunoistochemical analysis of synovial vasculature was performed using factor VIII (DAKO).Cliical markers assertained at the time of arthroscopy, includding synovitis and vascularity were correlated with synovial miRNA expression.
**Results:** Expression of miR-125a-5p was significantly decreased in PsA synovial biopsies (n=8) compared to OA (n=4) ($p<0.05$). CD14+ peripheral blood monocytes showed a significant decrease in miR-125a-5p compared to whole PBMC ($p<0.05$). No difference was observed for CD3+ T cells. Anti-125a-5p treated HMVEC displayed increased tube formations. Angiogenic growth factor, Ang2, induced miR-125a-5p in HMVEC ($p<0.05$). Lower synovial expression of miR-125a-5p displayed a higher degree of factor VIII staining compared to patients with higher miR-125a-5p expression. This was further demonstrated in representative arthroscopic images.
**Conclusions:** Our data demonstrates decreased expression of miR-125a in the joint and peripheral CD14+ monocytes in PsA patients. MiR-125a expression was associated with joint vascularity, a hallmark of PsA, suggesting its important role in mediating key pro-angiogenic and thereby pro-inflammatory mechanisms in the synovium. Correcting these microRNA deficiencies, either by conventional pharmacological agents or as novel targets, may provide a therapeutic benefit, especially in early disease stages.

# SpA and PsA clinical

## OP0084 VALIDATION OF THE ASAS HEALTH INDEX: RESULTS OF A MULTICENTER INTERNATIONAL STUDY IN 23 COUNTRIES

U. Kiltz[1], D. van der Heijde[2], A. Boonen[3], J. Braun[1] on behalf of ASAS HI International Validation Study. *[1]Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany; [2]Department of Rheumatology, Leiden University Medical Center, Leiden; [3]Division of Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands*

**Background:** The ASAS Health Index (ASAS HI) was developed to measure functioning and health in patients with spondyloarthritis (SpA) aiming to better define the impact of disease in these patients. The 17 questions of the questionnaire (range 0–17, with a lower score indicating a better health status) have now been translated into 18 languages worldwide. Face validity and feasibility (time of completion) have already been assessed in a field test.[1]
**Objectives:** To test construct validity, discrimination across relevant health states, reliability and responsiveness of the original English version and the 16 translations of the ASAS HI in 23 countries
**Methods:** A convenient sample of SpA patients fullfilling the ASAS classification criteria for either axial (axSpA) or peripheral SpA (pSpA) were included into the study from 33 centers of 23 countries worldwide. Data were collected by the local rheumatologist. Construct validity against other health outcomes was evaluated by Spearman correlation. Discrimination across patient reported health states was decribed. Test-retest reliability was assessed by intraclass correlation coefficient (ICC) in patients without treatment changes (stable disease state, interval 4–7 days). In those patients who required a therapeutic change because of high disease activity, responsiveness was tested (standardized response mean (SRM)) after 2–24 weeks depending on the type of medication.
**Results:** 1548 patients were included: 64.9% male, mean (SD) age 42.0 (13.4) years, mean (SD) BASDAI 4.1 (2.5)). There were 1299 patients with axSpA (375 nr-axSpA and 924 AS patients) and 256 patients with pSpA. The total score of the ASAS HI was 6.7 ± 4.3 (mean ± SD). Floor or ceiling effects were limited (0.8 and 6.9%, respectively). Convergent validity ranged as hypthesized with Spearman correlations from low (age: 0.10) to good (BASDAI: 0.70). ASAS HI scores showed a high internal consistency with a Cronbachs-$\alpha$ of 0.93. The ASAS HI discriminated well between patients with different stages of disease activity and function irrespective of the tool applied (ASDAS, BASDAI and BASFI) (table). The groups with greater disease activity and more impaired functioning had higher mean ASAS HI scores (indicating impaired functioning) than those with lower disease activity. Reliability (tested in 578 patients) was good (ICC: 0.87 (95%CI 0.84 to 0.89), $p<0.01$) and comparable across all disease subtypes. Sensitivity to change (tested in 246 patients) showed a moderate SRM of -0.44 for NSAIDs (n=75 patients), 0.69 for DMARDs (n=41) and -0.85 for TNFi (n=127). The smallest detectable change in this cohort was 3.0.

Table 1. Discriminative ability of the ASAS HI stratified by disease activity

| | ASDAS status groups | | | |
|---|---|---|---|---|
| | Inactive (n=245) | Moderate (n=283) | High (n=500) | Very high (n=289) |
| ASAS HI | 2.9±3.1 | 5.1±3.5 | 7.3±3.6 | 10.4±3.5 |
| BASFI | 0.9±1.4 | 2.1±1.9 | 3.7±2.5 | 5.9±2.5 |
| BASDAI | 1.2±0.9 | 2.7±1.3 | 4.7±1.7 | 7.0±1.6 |

All values given as mean ± SD.

**Conclusions:** The ASAS HI is a valid, reliable and responsive measure of disease severity in people affetcte by SpA. It should be used in clinical trials to evaluate the impact of SpA and its treatment on overall functioning and health.

## OP0085 DOES THE PRESENCE OF MULTIPLE SPA-FEATURES IN PATIENTS WITH CHRONIC BACK PAIN ALWAYS LEAD TO DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS?

Z. Ez-Zaitouni[1], P. Bakker[1], M. van Lunteren[1], M. Reijnierse[2], I.J. Berg[3], R. Landewé[4], M. van Oosterhout[5], M. Lorenzin[6], D. van der Heijde[1], F. van Gaalen[1]. *[1]Rheumatology; [2]Radiology, LUMC, Leiden, Netherlands; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Rheumatology, AMC, Amsterdam; [5]Rheumatology, GHZ, Gouda, Netherlands; [6]Rheumatology, University of Padova, Padova, Italy*

**Background:** The number of clinical SpA-features plays an important role in the Assessment of SpondyloArthritis international Society (ASAS) modified Berlin algorithm for the diagnostic work-up of patients (pts) with a suspicion of axial SpA (axSpA).
**Objectives:** To investigate whether all pts with short duration chronic back pain (CBP) and multiple SpA-features are always diagnosed as axSpA by the rheumatologist and to describe the features of these patients.
**Methods:** The SPondyloArthritis Caught Early (SPACE)-cohort includes CBP pts ($\geq$3 months, $\leq$2 years, onset $<$45 years) from various European rheumatology centres. Baseline data were used for the analyses. Following a fixed protocol all pts underwent a full diagnostic work-up consisting of performance of MRI and radiographs of sacroiliac joints (MRI-SI and X-SI), acute phase reactants, HLA-B27 testing, and assessment of other SpA-features (inflammatory back pain (IBP), good response to NSAIDs, family history for SpA, peripheral arthritis, dactylitis, enthesitis, uveitis, inflammatory bowel disease (IBD), and psoriasis). Local radiologists or rheumatologists from the different centres interpreted MRI-SI and X-SI on presence of sacroiliitis (yes/no) using global assessment as part of routine clinical practice. Total number of SpA-features was calculated excluding sacroiliac imaging and HLA-B27 status. The treating rheumatologist provided clinical diagnosis of pts and the ASAS-criteria for axSpA were used for classification.
**Results:** A total of 522 pts were analysed in this study: before sacroiliac imaging and HLA-B27 testing 164/522 (31.4%) pts had no or 1 SpA-feature, 148/522 (28.4%) pts had 2 SpA-features, 85/522 (16.3%) pts had 3 SpA-features, and 125/522 (23.9%) pts had $\geq$4 SpA-features respectively. IBP, good response to NSAIDs, and positive family history for SpA were most common in all subgroups

(0 or 1 feature: 26.8%, 8.5%, and 16.5% of pts; 2 features: 72.3%, 34.5%, 39.9%; 3 features: 87.1%, 60.0%, 54.1%; ≥4 features: 94.4%, 83.2%, 68.0% respectively). Of the pts with 2 and 3 SpA-features with negative X-SI 20/132 (15.2%) and 9/78 (11.5%) did not have axSpA diagnosis despite being HLA-B27+ (Figure 1). All pts with ≥4 SpA-features and X-SI+ (n=28) were diagnosed with axSpA. In contrast to what would be expected by following the modified Berlin algorithm for pts with ≥4 SpA-features, 18/94 pts (19.1%) with negative imaging (of which 4 HLA-B27+), were not diagnosed with axSpA by their rheumatologist. Multivariate regression analysis of presence of SpA-features identified MRI-SI+ (OR 41.7;95%CI 17.3.1–100.5), X-SI+ (OR 31.5;95%CI 3.1–321.0), HLA-B27+ (OR 4.7;95%CI 2.5–8.6), uveitis (OR 4.3;95%CI 1.5–12.7), IBP (OR 2.5;95%CI 1.4–4.7), heel enthesitis (OR 5.5;95%CI 2.7–11.4), IBD (OR 3.2;95%CI 1.2–8.8), elevated CRP/ESR (OR 2.7;95%CI 1.4–5.3), and psoriasis (OR 2.5;95%CI 1.0–6.0) as significant independent predictors of axSpA diagnosis.

**Figure 1.** Diagnosis and classification of patients with 2, 3 and 4 or more SpA-features (after medical history taking, physical examination and measurement of acute phase reactants), followed by sacroiliac imaging and HLA-B27 testing.

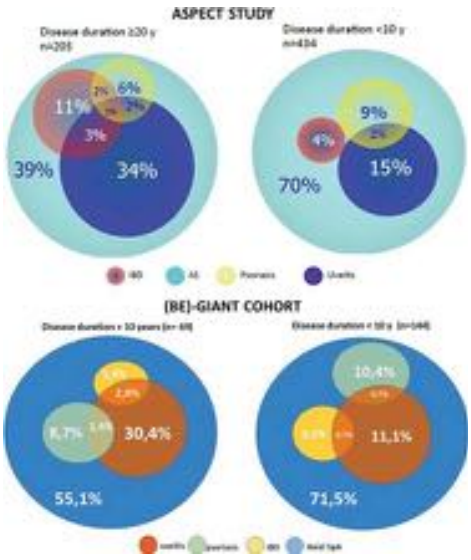
## OP0086 WHICH CELLS CORRESPOND TO THE TYPICAL SIGNALS FOR FATTY AND INFLAMMATORY LESIONS SEEN IN MAGNETIC RESONANCE IMAGING IN ANKYLOSING SPONDYLITIS? A PROSPECTIVE STUDY USING BIOPSY MATERIAL OBTAINED DURING SPINAL SURGERY -



X. Baraliakos[1], H. Boehm[2], A. Samir[2], G. Schett[3], J. Braun[1]. [1]*Rheumazentrum Ruhrgebiet, Herne;* [2]*Clinic for spinal surgery, Bad Berka;* [3]*Medizinische Klinik 3, Universitätsklinikum Erlangen, Erlangen, Germany*

**Background:** The occurrence of bone marrow edema (BME) and fat metaplasia detected by magnetic resonance imaging (MRI) were shown to be significantly associated with syndesmophyte formation in patients with ankylosing spondylitis (AS). The cell type responsible for the fat signal seen in MRI has not been defined to date.
**Objectives:** To histologically analyze the cells seen in fatty lesions (FL) as detected by MRI in spinal biopsies of AS patients and compare them with controls.
**Methods:** Spinal biopsies from vertebral edges of patients with AS and controls who underwent surgery for spinal deformity or spinal stenosis were prospectively collected. All patients had spinal STIR- and T1-weighted MRIs available exactly from the area of biopsy, and all biopsies were taken from areas that had a fat signal on MRI. The biopsies were analysed blinded to patients' diagnosis. Histomorphological analyses were performed to detect normal bone marrow, fat cells, inflammatory cells and fibroblasts. Histologic results were compared with MRI findings.
**Results:** Biopsies mostly obtained from the lower thoracic and the lumbar spine of 13 AS patients (mean age 56.3 years, mean disease duration 26 years) and 6 controls (mean age 53.4 years) were available. Similar proportions of AS patients, (12/16, 75%) and non-AS patients (4/6, 67%) had vital bone marrow. Fat cells were found in all 13 biopsies obtained from AS patients from the area of the fat signal vs. only 2 non-AS patients (33%), while inflammatory cells were found in 9 AS patients (56.3%), all of which also had BME on MRI, vs. 3 non-AS patients (50%). Fibroblasts were seen in 3 AS (18.9%) and 2 non-AS patients (33%).
**Conclusions:** The underlying cell types of FL and BME as detected by MRI in these long standing AS patients were fatty and inflammatory cells. The main difference between AS and non-AS patients was the proportion of biopsies containing fat cells. This suggests that fat cells are responsible for the MRI signal, at least in patients with longstanding ankylosing spondylitis.

## OP0087 THE ASSOCIATION OF EXTRA-ARTICULAR MANIFESTATIONS WITH DISEASE DURATION IN AXIAL SPA: RESULTS FROM THE (BE-) GIANT COHORT AND THE ASPECT STUDY

G. Varkas[1,2], H. Cypers[1,2], N. Vastesaeger[3], L. Van Praet[2], P. Carron[2], F. Van den Bosch[2], D. Elewaut[1,2] on behalf of Be-Giant Consortium. [1]*VIB Inflammation Research Centre;* [2]*Department of Rheumatology, Ghent University Hospital, Ghent;* [3]*MSD, Brussels, Belgium*

**Background:** The prevalence of extra-articular manifestations (EAMs) in ankylosing spondylitis (AS) is well-known. However, as the diagnosis of axial spondyloarthritis (AxSpA) is now made much earlier in the disease the prevalence of the EAMs may be different. Moreover, the introduction of anti-TNF therapy may have altered the incidence of EAMs.
**Objectives:** to assess the association of EAMs with disease duration in AxSpA patients (n=215) in the post-anti-TNF era compared to a historic cohort of Belgian AS patients (n=847) from the pre-anti-TNF era.
**Methods:** The BelGian Inflammatory Arthritis and spoNdylitis cohorT (Be-Giant) and The Ghent Inflammatory Arthritis and spoNdylitis cohorT (GIANT) are post-anti-TNF observational cohorts that include consecutive patients since 2010, diagnosed with AxSpA by their treating rheumatologist. Patients who fulfill the ASAS classification criteria, are prospectively followed every 6 months. Follow-up consisted of patient-reported outcomes, a standardized clinical examination (peripheral joints, entheses, axial metrology), standard laboratory analysis and imaging. The ASPECT cohort is a Belgian pre-anti-TNF cross-sectional AS database containing information on 847 patients who fulfilled the New York modified criteria for AS between February 2004 and February 2005.
**Results:** In the (Be-)Giant cohort and ASPECT cohort respectively 47% and 67.9% of patients were male. Mean age was 34.5 (SD 9.6) in the (Be-)Giant cohort and 44.6 (SD 12.1) in the ASPECT cohort. Mean symptom duration was respectively 7.9 and 18.5 years. HLA-B27 was positive in respectively 76.5% and 83% of patients with HLAB27 determination. In a cross-sectional analysis of the baseline data of 215 AxSpA patients from the (Be-) GIANT cohorts, about 66.5% (143/215) of patients had not experienced any EAMs compared to only 58% (491/847) of AS patients in the ASPECT cohort. Additionally, 71.5% (112/144) of patients with a symptom duration of less than 10 years had not experienced any EAMs at baseline in the (Be-)GIANT cohort. However, in patients with more than 10 years of symptom duration, only about half of patients remained EAM- free (P=0.021). Similarly, in patients from the ASPECT cohort with a disease duration of less than 10 years, 70% of patients (304/434) had not experienced any EAM at baseline, whereas only 39% (79/203) of patients remained EAM- free after 20 years of disease. A subanalysis of 118 newly diagnosed non-radiographic AxSpA (nr -AxSpA) patients demonstrated a prevalence of 70.3% (83/118) of EAM-free patients at diagnosis.

**Conclusions:** The prevalence of extra-articular manifestations seems to increase with disease duration both in the pre-anti-TNF and the post-anti-TNF era, and may be linked to longer cumulative exposure to inflammation.

## OP0088 INFLAMMATION ON MRI OF THE SPINE IS LONGITUDINALLY RELATED TO DISEASE ACTIVITY IN SMOKERS BUT NOT IN NON-SMOKERS IN AXIAL SPONDYLOARTHRITIS: 2-YEAR DATA FROM THE DESIR COHORT

V. Navarro-Compán[1,2], S. Ramiro[1], R. Landewé[3,4], M. Dougados[5], C. Miceli-Richard[5], P. Richette[6], D. van der Heijde[1]. *[1]LUMC, Leiden, Netherlands; [2]U.H. La Paz, Madrid, Spain; [3]ARC, Amsterdam; [4]AMC, Heerlen, Netherlands; [5]Cochin Hospital; [6]Hôpital Lariboisière, Paris, France*

**Background:** In axSpA, the effect of disease activity on radiographic progression over time is more pronounced in males and smokers, but the reason for this is unclear. Recently, we have demonstrated a longitudinal relationship between MRI-inflammatory lesions and clinical disease activity measures (DA) in males, but not in females. However, whether or not there is also a disparity in this relationship based on the smoking status is unknown.
**Objectives:** To investigate the role of smoking status in the longitudinal relationship between inflammatory lesions on MRI of the spine and DA in patients with axSpA.
**Methods:** Two-year follow-up data from 164 patients fulfilling ASAS axSpA criteria in the DESIR cohort with ≥2 MRIs of the spine available during this period were analysed. Interactions were tested between smoking status and DA (ASDAS, BASDAI, patient's global disease activity, night pain, CRP and ESR) on the longitudinal relationship with MRI of the spine (Berlin score), analysed with a GEE model of i) absolute and ii) change scores. All models were adjusted for age, symptom duration and HLA-B27. Since there was a significant interaction with gender in previous analyses, analyses were repeated in males and females separately.
**Results:** Baseline characteristics of patients included were: 50% males, mean (SD) age: 33 (9) years, 39% smokers, 82% HLA-27+ and symptom duration: 18 (11) months. A significant interaction with smoking status was found for most of the DA, indicating that the relationship between MRI-inflammatory lesions and DA was different in smokers than in non-smokers. In the model of absolute scores (i), MRI-scores were statistically significantly related to most of the DA in smokers, while only CRP was significantly and weakly related in non-smokers (Table 1A). In the model of changes (ii), ASDAS and pain at night remained significantly related to MRI-inflammatory lesions, but no statistically significant relationship between MRI and DA was found in non-smokers (Table 1B). When stratifying for gender, the subgroups were small and the relationships were no longer statistically significant.

| | Smokers | | Non-smokers | |

| **Table 1B** | | | | |
| ASDAS | **0.733** | **0.137 to 1.137** | 0.103 | –0.109 to 0.315 |
| BASDAI (0–10) | 0.214 | –0.047 to 0.529 | 0.018 | –0.058 to 0.094 |
| Night pain (0–10) | **0.298** | **0.101 to 0.495** | 0.042 | –0.005 to 0.089 |
| Pt's gb disease (0–10) | 0.187 | –0.030 to 0.403 | 0.055 | –0.002 to 0.111 |
| CRP (mg/L) | 0.020 | –0.001 to 0.041 | –0.003 | –0.032 to 0.025 |

**Conclusions:** In patients with axSpA, there is a longitudinal relationship between MRI inflammatory lesions of the spine and DA in smokers, but not in non-smokers. This disparity may explain the stronger effect of disease activity on radiographic progression observed in smokers.
Whether both gender and smoking have an effect on this relationship between MRI and DA remains to be elucidated.

## OP0089 ARE INDIVIDUAL OR COUNTRY LEVEL SOCIO-ECONOMIC DETERMINANTS RELATED TO DISEASE ACTIVITY AND SELF-REPORTED PHYSICAL FUNCTION IN PATIENTS WITH SPONDYLOARTHRITIS? RESULTS FROM MULTI-NATIONAL CROSS-SECTIONAL STUDY ASAS-COMOSPA

P. Putrik[1], S. Ramiro[2], A. Moltó[3], A. Keszei[4], M. Dougados[3], D. van der Heijde[2], R. Landewé[5], A. Boonen[1]. *[1]MUMC, Maastricht; [2]LUMC, Leiden, Netherlands; [3]Paris Descartes University, Paris, France; [4]Medical Informatics, Uniklinik RWTH Aachen University, Aachen, Germany; [5]ARC, Amsterdam, Netherlands*

**Background:** In RA, previous studies observed inequalities in health across countries as well as across individual level socio-economic factors, and unequal uptake of biologic DMARDs (bDMARDs) played an important role in these inequalities. It is not known whether the same pattern is present for patients with spondyloarthritis (SpA).
**Objectives:** To assess: (1) independent associations of individual and country level socio-economic determinants with health outcomes in patients with SpA and (2) if confirmed, whether this relation is mediated by uptake of bDMARDs.
**Methods:** Data from the cross-sectional multinational COMOrbidities study in SpA (COMOSPA) were used. Contribution of individual socioeconomic factors (age, gender, education) and country of residence to ASDAS and BASFI was explored in regression models, adjusting for clinical confounders. Next, country of residence was replaced by gross domestic product adjusted for purchasing power parity (GDP PPP) (low, medium, and high, based on tertile distribution). Finally, the role of bDMARDs uptake in the relationship between education or GDP and ASDAS was explored by testing indirect effects.
**Results:** In total 3,984 patients with SpA from 22 countries were included: 65% males, mean age 44 (SD14), ASDAS 2.0 (±1.1) and BASFI 3.0 (±2.7). Five to 68% of patients were currently treated with bDMARDs. Females (vs. males) had higher ASDAS (β=0.21 [95%CI 0.13;0.28]) and BASFI (β=0.45 [95%CI 0.31;0.59]). The effect of age was negligible for both outcomes. Low vs high educated individuals had higher ASDAS and BASFI (β=0.29 [0.21;0.36] and β=0.46 [0.24;0.69], respectively) (Table). Independent of the individual confounders, large country differences were observed. Low GDP (vs. high GDP) was associated with higher ASDAS (β=0.27 [0.17;0.36]) and higher BASFI (β=0.20 [0.03;0.38] (Table). Current uptake of bDMARDs did not mediate relationship between education or GDP with ASDAS.

Table 1. Association between individual and country level (GDP) factors with ASDAS and BASFI

## OP0090 MRI LESIONS ORIGINATING FROM EITHER AXSPA OR DEGENERATION ARE RELATED TO SITE OF PAIN IN PATIENTS WITH CHRONIC BACK PAIN INCLUDED IN THE SPACE-COHORT

M. de Hooge[1], F. de Bruin[2], L. de Beer[2], P. Bakker[1], R. van den Berg[1], S. Ramiro[1], F. van Gaalen[1], K. Fagerli[3], R. Landewé[4], M. van Oosterhout[5], R. Ramonda[6], T. Huizinga[1], J.L. Bloem[2], M. Reijnierse[2], D. van der Heijde[1]. *[1]Rheumatology; [2]Radiology, LUMC, Leiden, Netherlands; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Clinical Immunology and Rheumatology, AMC, Amsterdam; [5]Rheumatology, GHZ, Gouda, Netherlands; [6]Rheumatology, University of Padova, Padova, Italy*

**Background:** MRI-lesions in the spine (and SI-joints) are frequent in patients (pts) with axial spondyloarthritis (axSpA) and other pathologies like degenerative disease. It is relevant to know whether MRI-lesions (either axSpA or degenerative changes) are related with the site of back pain.
**Objectives:** To determine associations between MRI-lesions originating from either axSpA or degeneration and site of pain in pts with chronic back pain (CBP) of ≤2 years.
**Methods:** Pts with CBP (≥3 months, ≤2 years, onset <45 years) included in the SPACE cohort indicated site(s) of pain (thoracic, lumbar, buttock). Average MRI-scores from two readers for axSpA lesions and from two other readers for degenerative lesions were used. Readers were blinded for clinical data and scores of the other readers. AxSpA lesions considered inflammatory and fatty lesions, erosions and syndesmophytes/ankylosis on MRI-SI and MRI-spine. In addition, sclerosis was scored on MRI-SI. Each vertebral unit was scored for disc degeneration (Pfirrmann class >2), high intensity zone (HIZ), herniation, Schmorls' nodes and Modic changes (type I and type II). In addition, degenerative disc disease (DDD) was defined as degenerative complex with disc degeneration, an HIZ and herniation in an intervertebral disc.
Associations between MRI-SI lesions and buttock pain were investigated by logistic regression. Associations between axSpA or degenerative lesions and pain in the spine (thoracic and lumbar) were investigated by multilevel analysis with generalized estimating equations, taking the level of the spine into account. Interactions with gender, age, HLA-B27 and fulfilment of ASAS axSpA criteria were tested.

**Results:** In 348 pts (126 males, 127 fulfilling ASAS axSpA criteria, mean age 29.4 years) MRI-spine was available (in 342 pts also MRI-SI). Pain was present in thoracic (35.9%), lumbar (82.5%) spine and/or buttock (57.8%). The figure shows the significant associations between MRI-SI axSpA lesions and pain and between degenerative MRI-spine lesions and pain. AxSpA lesions on MRI-spine were not associated with pain at the same site (data not shown).

| AxSpA MRI-SI lesions (Logistic regression) | n | Stratification groups‡ | OR | 95% CI | P-value |
|---|---|---|---|---|---|
| Inflammatory lesions | 342 | No | 1.06 | 1.00 – 1.13 | 0.04* |

| | 216 | HLA-B27- | 3.14 | 1.91 – 5.17 | 0.000* |
| | 127 | ASAS+ | 2.07 | 1.03 – 4.15 | 0.041* |
| | 221 | ASAS- | 4.66 | 2.24 – 8.97 | 0.000* |

‡Where a statistically and clinically relevant interaction was found, results are shown stratified for variable(s) indicated in this column. No stratification means no relevant interaction with age, sex, HLA-B27 status or fulfilment of ASAS axSpA criteria. *P-value <0.05. §Analyses were stratified according to age

**Conclusions:** Inflammatory axSpA lesions in the SI-joints were associated with buttock pain. Specific degenerative lesions -but not typical axSpA lesions- in the spine were associated with pain at the same location, especially in HLA-B27 negative pts without axSpA and pts ≥35 years.
**Disclosure of Interest:** None declared

## OP0091 PSORIATIC ARTHRITIS COMORBIDITY INDEX: DEVELOPMENT AND VALIDATION OF A NEW SPECIFIC TOOL FOR CLASSIFYING PROGNOSTIC COMORBIDITY IN PSORIATIC ARTHRITIS PATIENTS

Y. El Miedany[1], M. El Gaafary[2], S. Youssef[3], S. Bahlas[4], I. Ahmed[5], M. Hegazi[6]. *[1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; [2]Community and Public health; [3]Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt; [4]Rheumatology, King Abdel Aziz University, Jeddah, Saudi Arabia; [5]Medicine, Cairo University, Cairo, Egypt; [6]Medicine, Adan Hospital, Kuwait, Kuwait*

**Background:** Specific comorbidity index can guide the management of psoriatic arthritis (PsA) patients and optimize their outcomes. So far, no disease-specific models are currently available for this purpose.
**Objectives:** 1. identify comorbidities with greatest impact on PsA patients' health status. 2. develop and validate a prospectively applicable comorbidity index for classifying PsA patients according to their comorbid conditions which might alter their risk of hospitalization and mortality.
**Methods:** This was a retrospective multicenter cohort analysis of PsA patients in a rheumatology clinical registry, assessing the effect of different comorbidities measured at patients' visits over 10-years period, on predicting future death and hospitalization. A weighted index that takes into account the number and seriousness of comorbid disease was developed in a cohort of 1707 PsA patients monitored over 10-years. Logistic and Cox Regression analyses were implemented to estimate the risk of mortality. Regression coefficients were used to develop the morbidity index score. ROC curve for the invented index was used to evaluate the discriminating ability of the index and identify different cutoff values that can delineate patients at different stages for risk of death. Disease activity parameters were considered.
**Results:** PsA patients who had higher incidence of comorbid condition and were at high risk of hospitalization were men, with older age at disease onset, high BMI at baseline ($p<0.05$). The most prevalent comorbidities strongly associated with the 10-year death risk or hospitalization in PsA patients were: Cardiovascular (7 comorbidities), osteoporosis, falls, depression/ anxiety, diabetes mellitus, renal and liver diseases, lung and GIT affection, as well as infection ($p<0.001$). Multivariate regression analysis identified Multidimensional Disease Relapse score (including 5 parameters: DAPSA, PASI, Functional disability score, ESR and CRP) as independent predictor for disease status associated with the 10-year death risk or hospitalization (Wald $\chi^2=9.2$, $p=0.002$, OR=24.6). Binary regression analysis revealed that: male gender, cardiovascular diseases, evident fall risk, diabetes, infection, anxiety, and the multidimensional relapse score were significant independent factors affecting the 10-years outcome of the disease. A comorbidity index weighted according to the regression coefficient of the variables extracted through the logistic regression analysis was developed. The score ranges from 0 to 38. A cut off point of 14.5 was associated with a sensitivity of 97.5% and a specificity of 87%. Validation using ROC curve revealed AUC of 98.5%.
**Conclusions:** The PsA-comorbidity index is a valid method for estimating risk of death in PsA patients. It enables the clinicians to include comorbidities assessment and management in their standard practice. It can be used to predict resource utilization, identify targets for reducing high costs, by prospectively identifying PsA patients at high risk. Rigorous application of systematic evaluation of comorbidities may permit earlier detection, which may ultimately result in an improved outcome of patients with PsA.

# New horizons in osteoarthiritis

## OP0092 IDENTIFICATION OF PAIN SUBTYPES ASSOCIATED WITH PLACEBO-RESPONSE: DATA FROM TWO PHASE 3 RANDOMIZED CLINICAL TRIALS IN SYMPTOMATIC KNEE OSTEOARTHRITIS

A.R. Bihlet[1], M. Karsdal[2], I. Byrjalsen[1], A.-C. Bay-Jensen[2], C. Christiansen[2], J.R. Andersen[1], H. Gühring[3], C. Ladel[3], M. Michaelis[3], B. Riis[1], I. Valter[4]. *[1]Clinical Development; [2]Nordic Bioscience, Herlev, Denmark; [3]Merck, Darmstadt, Germany; [4]CCBR, Talinn, Estonia*

**Background:** Pain is the principal clinical symptom of osteoarthritis (OA), and development of safe and effective analgesics for OA pain is needed. Trials of new analgesics for OA pain is impaired by substantial placebo-response (PR), and data describing characteristics and pain sub-types particularly associated with placebo-response is needed.
**Objectives:** The purpose of this post-hoc analysis was to investigate clinical characteristics and pain subtypes associated with PR as measured by the five pain questions of the Western Ontario and McMasters Arthritis (WOMAC) Index of the target (T)- and the non-target (NT) knees in the pooled data of two phase III randomized clinical trials of an oral treatment in OA.
**Methods:** Pooled data from the placebo-groups of two phase III randomized clinical trials (NCT00486434 and NCT00704847) in patients with knee OA followed for two years were analyzed. Main inclusion criteria for T knees were a Kellgren-Lawrence grade of 2 or 3, Joint-Space Width (JSW) of minimum of 2.0 mm at the medial tibio-femoral joint, and WOMAC pain ≥150 out of 500 mm. All analyses were performed on data from the T knees (N=771) and a sub-group of NT knees matching the pain inclusion criteria of the T knees (N=256). All subjects in the analysis belonged to the Per-Protocol population.
Pain of the T and NT knees was measured using the WOMAC pain sub-index, five questions: Q1; during walking on a flat surface, Q2; using stairs, Q3 at night while in bed, Q4; sitting or lying and Q5; while standing. Changes in percent from baseline pain were calculated at months 1, 6, 12 and 24, and differences between individual questions were assessed using a repeated measures ANOVA. Pain by category ("under load"; WOMAC questions 1, 2 and 5 and "idle"; WOMAC questions 3 and 4) were similarly analyzed for change over time, and compared in a repeated measures ANOVA. Selected patient baseline characteristics; pain by WOMAC question, Joint-space width (JSW), age, and BMI were assessed for association with PR defined as change in percent from baseline to year two using Spearman's correlation.
**Results:** Baseline pain was significantly higher in WOMAC Q2, compared to other pain questions ($p<0.001$). This was observed for both T- and NT knees. WOMAC Q2 was furthermore associated with the highest PR for both T, and NT knees (36.8% ±52.4 (SD) and 28.0% ±44.4, respectively) at year two. The observed PR was higher in the T knee, compared to the NT knee at all corresponding time-points.
The level of PR was significantly higher in questions related to pain while under load (Q1, Q2, Q5) compared to pain while idle (Q3, Q4), and this was statistically significant in the T knee ($p<0.005$) at month 1 and onwards (Fig. 1), but did not reach statistical significance for the NT knee.
Baseline BMI, age and JSW was not associated with PR. This indicates while no common clinical characteristics were associated with PR, other, perhaps psychological, factors may affect the susceptibility to PR.

**Fig 1: Placebo-effect by pain category - Target knee**

**Conclusions:** These results indicate that the level of PR is significantly different between pain subtypes, as pain under load is significantly more susceptible to lead to PR than pain while idle.

## OP0093 DOES "PAIN ELSEWHERE" INFLUENCE THE ASSOCIATION BETWEEN KNEE STRUCTURAL PATHOLOGY AND KNEE PAIN?

F. Pan[1], D. Aitken[1], J. Tian[2], F. Cicuttini[3], T. Winzenberg[1], C. Ding[1], G. Jones[1]. *[1]Musculoskeletal Unit; [2]Public Health, Menzies Institute for Medical Research, University of Tasmania, Hobart; [3]Department of Epidemiology and Preventive Medicine, Monash University Medical School, Melbourne, Australia*

**Background:** The association between structural abnormalities and knee pain remains controversial. It may be that the association is weaker in those with generalized pain compared to localized pain.
**Objectives:** To determine the effect of pain at other sites on the association between knee structural pathology and knee pain in knee osteoarthritis (OA).
**Methods:** 1099 participants (average age 63 years; range 51 to 81 years) from the population-based Tasmanian Older Adult Cohort study were studied. Presence of pain (yes/no) at the neck, back, hands, shoulders, hips, knees and feet was assessed by questionnaire. T1-weighted or T2-weighted fat saturated MRI of the right knee was performed to measure cartilage defects, bone marrow lesions (BMLs) and effusion. Osteophytes and joint space narrowing (JSN) were assessed by X-ray. Data were analyzed using multi-nominal logistic regression with adjustment for potential confounders including age, sex, body mass index, physical activity, smoking history and pain medication.
**Results:** Knee pain only, knee plus any other site pain, and any other site pain were present in 3%, 44% and 41% of participants respectively. In multivariable analyses, knee pain only was strongly associated with the presence of cartilage defects (OR 16.96, 95% CI 4.03 to 71.32), BMLs (OR 3.27, 95% CI 1.01 to 10.53), effusion (OR 3.52, 95% CI 1.06 to 11.68) and osteophytes (OR 8.22, 95% CI 2.10 to 32.27). There were significant but weaker associations with knee pain plus any other site pain (OR=3.03 to 3.38, all $P<0.05$). Any other site pain was not found to be associated with any knee structural abnormalities. There was a dose-response relationship between number of knee structural abnormalities, and knee pain only and knee plus any other site pain (both P for trend$\leq$0.002).
**Conclusions:** Knee structural abnormalities are more strongly associated with localized knee pain than generalized pain, suggesting that pain elsewhere may influence the association of knee structural pathology and knee pain. The underlying mechanism may be due to central sensitization implicated in generalized pain which is no longer coupled to peripheral stimuli. Implication of this finding for clinicians and researchers is that pain at other sites needs to be considered while developing an approach to slow OA progression and alleviate symptom by targeting structural abnormalities.
**Disclosure of Interest:** None declared

## OP0094 PHYSICIAN AND PATIENT ESTIMATES OF GLOBAL STATUS ARE MORE LIKELY TO BE DISCORDANT IN OSTEOARTHRITIS THAN IN RHEUMATOID ARTHRITIS

I. Castrejon, J. Chua, J.A. Block, T. Pincus. *Rheumatology, Rush University Medical Center, Chicago, United States*

**Background:** Concordance between global estimates of clinical status by physicians and patients may influence shared decisions concerning therapy toward better compliance and outcomes. However, discordance has been described in most rheumatology settings in which it has been studied carefully[1,2]. While osteoarthritis (OA) generally is regarded as a less severe medical problem than rheumatoid arthritis (RA), recent evidence suggests similar disease burdens in both OA and RA.
**Objectives:** To analyze discordance between physician global estimates (DOCGL) and patient global estimates (PATGL) in OA vs RA patients seen in a routine rheumatology academic setting.
**Methods:** In this setting, all patients complete a multidimensional health assessment questionnaire/routine assessment of patient index data (MDHAQ/RAPID3), which includes 0–10 scores for physical function, pain, and PATGL compiled into a 0–30 RAPID3, as well as fatigue VAS, a symptom checklist, and a RADAI self-report joint count, and demographic data. Patients with primary diagnoses of OA or RA were classified into 3 categories: PATGL$\geq$DOCGL by 2/10 units, PATGL=DOCGL, and DOCGL$\geq$PATGL by 2 units. The percentage of patients in each group was compared between RA and OA using chi-square. Variables were compared using ANOVA.
**Results:** The study included 216 patients with RA, 39 (18%) were discordant with PATGL>DOCGL and 243 patients with OA, 82 (34%) were similarly discordant. Concordance with PATGL=DOCGL was seen in 144 patients (67%) with RA and 136 patients (56%) with OA, while discordance with DOCGL>PATGL was seen in 33 patients (15%) of patients with RA and 25 (10%) with OA ($p<0.001$). Age did not differ in the groups, other than older patients with OA (72.6 yrs) curiously were among the fewer OA patients who were more likely to show DOCGL>PATGL than younger patients with OA (64.6–64.8 yrs). Patients with PATGL>DOCGL had lower formal education levels ($p<0.05$ in RA but not OA). Other MDHAQ measures were higher in OA patients than in RA patients with (Table). Highest MDHAQ scores were seen in patients with PATGL>DOCGL than in PATGL=DOCGL than in DOCGL>PATGL ($p<0.001$ other than symptoms and RADAI).

Table 1. Comparison of 3 groups of patients with RA and OA according to PATGL and DOCGL

| | PATGL>DOCGL | PATGL=DOCGL | DOCGL>PATGL | P values |
|---|---|---|---|---|
| Rheumatoid arthritis | 39 (18%) | 144 (67%) | 33 (15.1%) | |
| Age | 57.6 | 56.4 | 55 | 0.79 |
| Education | 12.7 | 14.3 | 15.3 | 0.03 |
| RAPID2 (0–20) | 10.8 | 6.8 | 3.8 | <0.001 |
| Pain (0–10) | 7.3 | 4.3 | 2.7 | <0.001 |
| Function (0–10) | 3.6 | 2.5 | 1.3 | <0.001 |
| Fatigue (0–10) | 5.8 | 3.8 | 1.9 | <0.001 |
| Symptom checklist (0–60) | 9.6 | 7.4 | 6.0 | 0.08 |
| Self-report RADAI joint count (48) | 18.3 | 9.4 | 4.5 | <0.001 |
| Osteoarthritis | 82 (34%) | 136 (56%) | 25 (10%) | |
| Age | 64.6 | 64.8 | 72.6 | 0.02 |
| Education | 13.0 | 14.3 | 13.6 | 0.06 |
| RAPID2 (0–20) | 11.2 | 8.3 | 7.0 | <0.001 |
| Pain | 7.8 | 5.7 | 4.9 | <0.001 |
| Function | 3.4 | 2.6 | 2.0 | <0.001 |
| Fatigue | 6.3 | 4.4 | 3.0 | <0.001 |
| Symptom checklist (0–60) | 12.3 | 9.7 | 6.9 | 0.005 |
| Self-report RADAI joint count (48) | 16.5 | 11.1 | 7.8 | 0.008 |

**Conclusions:** Patients with OA are more likely to have their clinical status underestimated by rheumatologists than patients with RA, although the burden of disease in OA in these patients was greater than in RA. These data suggest a need to revise generally held views that OA is less severe than RA.

## OP0095 RANDOMIZED, PLACEBO-CONTROLLED TRIAL TO EVALUATE CLINICAL EFFICACY AND STRUCTURE MODIFYING PROPERTIES OF SUBCUTANEOUS ETANERCEPT (ETN) IN PATIENTS WITH EROSIVE INFLAMMATORY HAND OSTEOARTHRITIS (OA)

M. Kloppenburg[1], R. Ramonda[2], W.-Y. Kwok[3], K. Bobacz[4], D. Elewaut[5], P. Frallonardo[2], T.W. Huizinga[3], F. Kroon[3], J. Smolen[4], B. Vander Cruyssen[5], R. Wolterbeek[6], L. Punzi[2], G. Verbruggen[5], R. Wittoek[5]. *[1]Rheumatology, Clinical Epidemiology, Leiden University Medical Centre, Leiden, Netherlands; [2]Medicine DIMED, Rheumatology Unit, University of Padua, Padua, Italy; [3]Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; [4]Internal Medicine III, Div. of Rheumatology, Medical University of Vienna, Vienna, Austria; [5]Rheumatology, Ghent University Hospital, Ghent, Belgium; [6]Biostatistics, Leiden University Medical Centre, Leiden, Netherlands*

**Background:** Erosive OA involves interphalangeal joints (IPJs), resulting in a high disease burden, for which treatment options are limited. Although it is characterized by joint inflammation, earlier treatment with TNF blockers was equivocal.
**Objectives:** To investigate the 1-year efficacy of ETN in erosive OA.
**Methods:** In a European multicentre study (NTR 1192) patients were equally randomized to subcutaneous ETN (24 weeks 50 mg weekly, thereafter 25 mg weekly) or placebo. Patients with erosive ($\geq$1 IPJ with radiographic pre(erosive) anatomical phase ("J"/"E") according to Verbruggen-Veys system) inflammatory ($\geq$1 IPJ with soft swelling/erythema and with positive power Doppler at US) symptomatic (VAS pain >30/100 on NSAID use, flare after NSAID washout) OA were included. VAS pain, hand function (FIHOA), quality of life (SF-36), no. of tender joints and grip strength were assessed after 4, 8, 12, 24, 36 weeks and 1 year. Radiographic progression of IPJs was scored blindly in paired order (baseline, 24 weeks and 1 year) following the quantitative Ghent University Scoring System (GUSS, 0–300 per IPJ).
With linear mixed models VAS pain was compared between treatment groups at 24 weeks (primary outcome), and 1 year in intention-to-treat (ITT) analyses. With general estimated equations secondary outcomes were analysed. Adjustments were made for centre, baseline values and patient effects were appropriate. Completers fulfilling the extensive inclusion criteria were included in per-protocol (PP) analyses.
**Results:** Of 284 screened patients, 90 (mean age 60 years, 81% women, 96% fulfilled ACR hand OA criteria) were randomized; 22 discontinued the study prematurely. At baseline patient characteristics did not differ between the groups. VAS pain in all patients decreased -24.8 mm (95%CI -29.2;-20.5 ($P<0.001$)) at 24 weeks. In ITT differences in pain between the groups were in favour of ETN, but did not reach statistical significance. However, in PP the difference reached statistical significance (table). No differences were seen on secondary clinical outcomes. The PP analysis of GUSS showed a mean difference in favour of

ETN (table), indicating more remodelling in the ETN group. Additional analyses showed an interaction between soft swelling/erythema and ETN treatment on GUSS, resulting in a statistical significant ($P<0.05$) mean difference between ETN and placebo groups. More patients dropped out on placebo than on ETN (6 vs. 3) due to inefficacy, whereas more on ETN than on placebo (6 vs. 1) due to adverse effects.

Table. Joint pain and GUSS score at baseline by study drug, and mean differences between study groups for both intention-to-treat (ITT) and per-protocol (PP) analyses.

| | ETN | Placebo | Mean difference ETN-Placebo (95%CI) | | | |
|---|---|---|---|---|---|---|
| | Baseline | Baseline | 24 weeks | P | 1 year | P |
| ITT | N=45 | N=45 | N=90 | | N=90 | |
| Pain (mm) | 71.1 (15.7) | 68.4 (12.8) | -5.7 (-15.9; 4.5) | 0.27 | -8.5 (-18.6; 1.6) | 0.10 |
| PP | N=28 | N=33 | - | | N=61 | |
| Pain (mm) | 68.9 (13.3) | 65.9 (12.3) | - | | -11.8 (-23.0; -0.5) | 0.04 |
| PP | N=23 | N=31 | - | | N=54 | |
| GUSS score/ joint | 286 (37) | 288 (34) | - | | 3.1 (0.8; 5.4) | <0.05 |

Data represent mean (standard deviation) ; CI= confidence interval

**Conclusions:** In erosive OA ETN was not superior over placebo on VAS pain at 24 weeks. However in the symptomatic and inflammatory patients completing the study ETN was superior over placebo both on pain and structural damage assessed by GUSS; ETN was especially effective in joints with signs of inflammation.

**Acknowledgement:** Pfizer for supply of study medication and research grant.

## OP0096 MENISCAL EXTRUSION AND BONE MARROW LESIONS ARE INDEPENDENTLY ASSOCIATED WITH INCIDENT AND PROGRESSIVE KNEE OSTEOARTHRITIS

J. Martel-Pelletier[1], A.J. Teichtahl[2], F.M. Cicuttini[3], F. Abram[4], Y. Wang[5], J.-P. Pelletier[1]. *[1]Osteoarthritis Research Unit, University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada; [2]Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Monash University, Alfred Hospital; Baker IDI Heart and Diabetes Institute; [3]Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Monash University, Alfred Hospital, Melbourne, Australia; [4]Medical Imaging Research & Development, ArthroLab Inc., Montreal, Canada; [5]Department of Epidemiology and Preventive Medicine, School of Public Health and Preventive Medicine, Monash University, Alfred Hospital, Melbourne, Australia*

**Background:** Whether meniscal extrusion and bone marrow lesions (BMLs) independently predict the risk of knee osteoarthritis (OA) remains to be clarified. Yet, while prospective cohort studies have shown that both meniscal extrusion and BMLs increase the risk of progressive knee OA, these studies have focused on the medial rather than the lateral knee joint, and examined people with established knee OA. It remains unclear whether these structural abnormalities predate incident knee OA, or whether meniscal extrusion or BMLs independently predict progressive disease.

**Objectives:** The aim of this 72 month longitudinal study was to examine whether compartmental baseline meniscal extrusion and BMLs were independently associated with incident and progressive knee OA, as measured by i) cartilage volume loss, ii) incident or progressive radiographic OA (ROA), and iii) total knee replacement (TKR).

**Methods:** Data was extracted from the Osteoarthritis Initiative (OAI) cohort. Participants were grouped according to the absence (Kellgren-Lawrence (KL) grade $\leq$1, n=2120) or presence (KL $\geq$2, n=2249) of ROA. Baseline meniscal extrusion, BMLs and cartilage volume were assessed on magnetic resonance imaging (MRI). Cartilage volume of the tibial plateau was assessed at baseline and 72 months, while ROA was assessed at baseline and 48 months. TKR was assessed at 72 months.

**Results:** In those with ROA, the presence of a baseline meniscal extrusion (independent of BMLs) was associated with accelerated cartilage loss (medial tibia: -2.1%/annum vs. -1.5%; lateral tibia: -2.6%/annum vs. -1.6%; both $p<0.001$), progressive ROA and TKR (OR range 1.4 to 1.8; 95% CI range 1.1 to 2.9, $p\leq0.04$). The presence of a baseline BML (independent of meniscal extrusion) was associated with accelerated cartilage loss (medial tibia: -2.1%/annum vs -1.6%; lateral tibia: -1.9%/annum vs -1.6%; $p\leq0.02$), progressive ROA and TKR (OR range 1.5 to 2.4; 95% CI range 1.1 to 3.4, $p\leq0.02$). In those with no ROA, a baseline medial meniscal extrusion was associated with accelerated cartilage loss (medial tibia: -2.1%/annum vs. -1.2%, $p<0.001$) and a baseline medial BML with incident ROA (OR 1.7, 95% CI 1.1 to 2.9, p=0.03).

**Conclusions:** Baseline meniscal extrusion and BMLs predict incident and progressive knee OA and represent important and independent structural targets for patient selection in disease-modifying OA drug (DMOAD) trials.

## OP0097 IMMUNOSCINTIGRAPHIC DETECTION OF TNF BY RADIOLABELED CERTOLIZUMAB PEGOL IN PATIENTS WITH EROSIVE HAND OSTEOARTHRITIS IN RELATION TO DISEASE ACTIVITY AND STRUCTURAL PROGRESSION: A PROOF OF CONCEPT STUDY

R. Wittoek[1], P. Carron[1], B. Lambert[2], P. Meersseman[1], A. Verbruggen[1], F. Van den Bosch[1], D. Elewaut[1]. *[1]Department of Rheumatology, Ghent University Hospital; [2]Department of Radiology and Nuclear Medicine, Ghent University, Ghent, Belgium*

**Background:** A recent randomized clinical trial in erosive osteoarthritis (EOA) of finger joints with a TNF blocking agent, adalimumab, showed inhibition of radiographic progression in joints showing inflammatory signs (palpable swelling) at baseline (1). We anticipate the use of radio-labelled antibodies can help in identifying their *in vivo* abundance in joints (2) and might help to identify joints at particular risk for progression amenable for target therapies.

**Objectives:** To investigate the uptake of radiolabeled $^{99m}$Tc-certolizumab pegol in patients with EOA and study associations with other markers of active disease, including radiography, clinical examination and ultrasound (US).

**Methods:** Certolizumab Pegol was conjugated with S-HYNIC and radiolabeled with Tc99m. At baseline, static images of both hands of 5 patients with EOA (F/M: 4/1; median disease duration 8.4 years; median age 55.6 years) were acquired at 2 time points (immediately following administration (early phase) and after 4–6 hours post injection (late phase)). All 18 IP finger joints were scored according to the anatomical phase scoring system (3) on Xrays. All patients underwent clinical examination (presence of tenderness and palpable swelling of the joints) and Gray-scale and Power Doppler (PD) US one day prior to scintigraphy. Immunoscintigraphic findings were independently scored in a semi-quantitative way (uptake: 0 = absent, 1 = weak; 2 = strong). Descriptive statistics on joint level were calculated. Likelihood ratio (LR) for uptake in late phase was calculated in respect to tenderness, swelling, US and radiographic features (resp. with no tenderness, no swelling, no inflammatory US sign and normal phase as reference).

**Results:** In total, 90 IP joints were studied. Active tracer uptake was seen in 7 joints in early phase (7.8%) (all weak) and in at least 24 joints in late phase (26.7%) (19 weak, 5 strong). No uptake was seen in MCP joints.

Early and late uptake were present in 5 (15.2%) and 12 (36.4%) of 33 tender joints and in resp. 2 (3.5%) and 12 (21.1%) of 57 non-tender joints (LR =2.2, p = NS).

Interestingly, this relation was most pronounced with palpable joint swelling: early and late uptake were present in 5 (21.7%) and 14 (61.0%) of 23 swollen joints and in resp. 2 (3.0%) and 10 (14.9%) of 67 non-swollen joints (LR =8.9, $p<0.001$). Early and late uptake were present in resp. 6 (9.7%) and 18 (29.1%) of 62 sonographic active joints (= any presence of effusion or PD signal or synovial proliferation) and in resp. 1 (3.6%) and 6 (21.4%) non-inflammatory joints (LR =1.5, p = NS).

Immunoscintigraphic uptake was observed in all anatomical phases (i.e. N, S, J, E or R) but the strongest association was found with R phase (LR =1.86 with "N" as reference).

**Conclusions:** This is the first *in vivo* demonstration of TNF abundance in EOA. We found strong associations of certolizumab uptake with presence of swelling of the affected joints. The strongest association with TNF was found in the remodeling phases of the disease. These data further solidify the rationale for cytokine directed therapies in EOA.

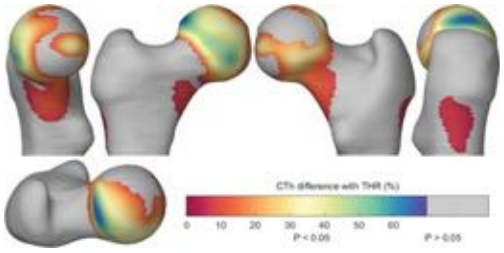
## OP0098 EFFECT OF ETANERCEPT ON SYNOVITIS AND BONE MARROW LESIONS IN EROSIVE HAND OSTEOARTHRITIS

F.P. Kroon[1], R. Wittoek[2], G. Verbruggen[2], I.K. Haugen[3], T.W. Huizinga[1], M. Kloppenburg[1,4]. *[1]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [2]Rheumatology, Ghent University Hospital, Ghent, Belgium; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Erosive osteoarthritis (OA), a subset of hand OA with high disease burden, is hypothesized to develop in distinct anatomical phases. These can radiographically be identified as loss of joint space (pre-erosive phase), followed by erosions and remodelling (E- and R-phase, according to the Verbruggen-Veys (VV) system). It is unknown which disease processes play a role in this development, although synovitis and bone marrow lesions (BMLs) on MRI

have shown to be associated with radiographic progression in OA finger joints. Therefore synovitis and BMLs could be a target for therapy.
**Objectives:** To investigate the presence of synovitis and BMLs in erosive compared to non-erosive joints, and to study the effect of TNF inhibition on these MRI abnormalities.
**Methods:** Analyses were performed in a subset of patients participating in a double-blind trial (NTR 1192), comparing etanercept (ETN, 25–50mg/week) to placebo. Patients with symptomatic erosive OA with clinical and ultrasonographic signs of inflammation in ≥1 interphalangeal joint (IPJ) were included. This analysis concerned 20 patients who underwent contrast-enhanced MRI of the 8 distal and proximal IPJs of one hand at baseline and 1 year. Images were scored for synovitis and BMLs (0–3 per joint, total score 0–24), blinded for patient characteristics, according to the OMERACT hand OA MRI score (HOAMRIS). Radiographs of the same hand were scored according to the VV system. Logistic regression with generalised estimating equations (GEE) were used to associate the presence of an MRI feature in a joint with being in an erosive (E/R) versus non-erosive anatomical phase (N=normal/S=stationary) (adjusted for age and sex, excluding IPJs from the ETN group at 1 year). A treatment effect of ETN on the change in MRI features over 1 year on joint level was also estimated with GEE.
**Results:** The total synovitis score was similar at baseline and 1 year in both the placebo (median (range): 10.5 (7–16) and 10.3 (6–14) respectively) and ETN group (7.0 (3–17) and 6.9 (3–14)). For BMLs, the total score was 5.4 (2–9) and 7.0 (0–9) in the placebo, versus 4.5 (3–9) and 3.7 (0–8) in the ETN group. The presence of BMLs was associated with being in E-phase (OR 12.5, 95% CI 2.1–74.7) and R-phase (OR 3.9, 1.2–12.0). Synovitis was not associated with these anatomical phases. Synovitis did not change in either group, whereas BMLs decreased more in the ETN compared to the placebo group (table). The same effect was observed in analyses on patient level (total score and number of IPJs with a feature, data not shown). Besides, an interaction was observed between ETN treatment and the presence of grade 2/3 synovitis at baseline in that IPJ (table).

| | Association with change in BML (beta (95% CI))† | p-value |
|---|---|---|
| Baseline synovitis grade 2/3 present | 0.01 (-0.23 to 0.25) | 0.95 |
| Treatment with etanercept | -0.22 (-0.35 to -0.09) | 0.001 |
| Baseline synovitis grade 2/3*treatment | -0.59 (-0.97 to -0.20) | 0.003 |



†Change between baseline and 1 year, negative score indicates a decrease over time (improvement), range 0-3. BML, bone marrow lesion; CI, confidence interval.

**Conclusions:** The presence of BMLs, but not synovitis, was associated with the presence of an erosive anatomical phase in a joint. Treatment with ETN appeared effective in inhibiting these lesions, suggesting a role for TNF in the pathophysiology of erosive OA, possibly through an effect on subchondral bone. The inhibitory effect of ETN on BMLs was more pronounced in IPJs with severe synovitis at baseline, suggesting that inflamed synovial tissue could be a source of TNF production in erosive OA.

## OP0099 3D CORTICAL BONE MAPPING OF THE PROXIMAL FEMUR IN A LARGE PROSPECTIVE POPULATION-BASED STUDY SUPPORTS THE GANZ HYPOTHESIS OF HIP OSTEOARTHRITIS CAUSATION: THE AGES-REYKJAVIK STUDY

I.S. Burkov[1], G. Treece[2], A. Gee[2], T. Turmezei[2], F. Johannesdottir[1], S. Sigurdsson[3], T. Aspelund[3], H. Jónsson[4], V. Gudnason[3], K. Poole[1].
*[1]Medicine; [2]Engineering, Cambridge University, Cambridge, United Kingdom; [3]The Icelandic Heart Association, Kopavogur; [4]Medicine, University of Iceland, Reykjavik, Iceland*

**Background:** The mechanical aetiology hypothesis of hip osteoarthritis (OA) implicates focal mechanical wear of the joint surface from increased contact pressures, often associated with subtle abnormalities in 3D structure, such as those identified in femoro-acetabular impingement. Related to this, thickening of subchondral bone is emerging as an important disease feature in OA and may also be implicated in pathogenesis. Cortical bone mapping (CBM) is a proven technique that has been used to accurately measure structural properties of bone [1].
**Objectives:** CBM technique was applied to hip clinical computed tomography (CT) scans in a large prospective study of healthy older individuals to identify locations where cortical and subchondral bone in people who were destined for eventual total hip replacement (THR) to treat OA differed, on average, from healthy controls. We hypothesise that areas of thickening will coincide with lifelong habitual contact pressures, such as during walking.
**Methods:** We undertook a prospective nested case-control study within a cohort of 3133 subjects with an average 5-year follow-up from the Age, Gene/Environment Susceptibility-Reykjavik Study (AGES-REYKJAVIK). Using a previously published method [1], CBM was applied to clinical CT scans (slice thickness 1mm) to identify the regions where cortical thickness (CTh) in the proximal femur was significantly associated to eventual THR. After quality control 25 of the samples were rejected leaving 90 THR that were performed on 75 participants (49 female, 26 male, mean±sd age 74±4.7 yrs) at a mean±sd of 35.6±24.6 months after baseline CT scan, matched to 185 controls (117 female, 68 male, mean±sd age of 74±4.7 matched for calendar year of recruitment, sex and age). CTh measurements were spatially aligned onto an average femur surface and statistical parametric mapping used to analyse the results presented as percentage difference between cases and controls. The model allowed for size, the first five non-rigid shape modes, group (case*control), age, sex, weight and height.
**Results:** We found highly focal regions of up to 70% greater CTh in the proximal femur, especially at the femoral head, among men and women who had a subsequent THR when compared to controls. Cortical and subchondral bone plate thickening in OA coincides with simulated peak contact pressure areas of the human hip [2], but is absent in less loaded regions of the hip.

**Conclusions:** CBM and SPM show a pattern of femoral cortical bone and subchondral bone plate thickening in a large population destined for THR compared with controls in a novel 3D analysis that does not rely on subjective assessment of CT images. Such thickening patterns support the mechanical aetiology (Ganz) hypothesis of hip OA causation.

Grauer[3]. *[1]Aarhus University Hospital, Aarhus, Denmark; [2]UCB Pharma, Brussels, Belgium; [3]Amgen Inc., Thousand Oaks; [4]Bethesda Health Research Center, Bethesda, United States; [5]Laval University and CHU de Québec (CHUL) Research Centre, Quebec City, Canada; [6]Medical Plus, Uherske Hradiste, Czech Republic; [7]BioClinica Inc., Hamburg, Germany; [8]Department of Medicine, Massachusetts General Hospital, Boston; [9]Department of Radiology, University of California San Francisco, San Francisco, United States; [10]Ghent University Hospital, Gent, Belgium; [11]Hvidovre University Hospital, Hvidovre, Denmark; [12]Servicio de Endocrinología, Hospital Universitario Quirón, Madrid, Spain; [13]University of California Berkeley, Berkeley, United States; [14]University of British Columbia, Vancouver, Canada; [15]Department of Medicine, Semmelweis University, Budapest, Hungary; [16]Universitat Autònoma de Barcelona, Barcelona, Spain; [17]Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina; [18]Reumalab Centro Integral de Reumatologia, Medellin, Colombia; [19]Instituto Latinoamericano de Investigaciones Médicas, Córdoba, Argentina*

**Background:** In a phase 2 study, treatment with romosozumab significantly increased bone mass in women with low bone mineral density (BMD).
**Objectives:** To report the results of STRUCTURE, a phase 3 study evaluating the effect of romosozumab or teriparatide (TPTD) in women with postmenopausal osteoporosis (PMO) transitioning from bisphosphonate (BP) therapy (NCT01796301).
**Methods:** This open-label study enrolled women with PMO who had taken an oral BP for ≥3 years prior to screening and alendronate (70 mg QW or equivalent) in the year prior to screening; had a BMD T-score ≤–2.5 at the total hip (TH), lumbar spine (LS), or femoral neck (FN); and had a history of nonvertebral fracture after age 50 or vertebral fracture. Women were randomized to receive SC romosozumab 210 mg QM or TPTD 20 μg QD for 12 months. The primary endpoint was percent change from baseline in BMD by DXA at the TH through month 12. Secondary endpoints included percent change from baseline at months

6 and 12 in BMD by DXA at the TH, LS, and FN; hip integral and cortical BMD by quantitative computed tomography (QCT); and estimated hip strength by finite element analysis.
**Results:** The 436 women enrolled in the study had a mean age of 72 years and mean TH, LS, and FN T-scores of –2.2, –2.9, and –2.5, respectively. Through 12 months, the mean (95% CI) percent change from baseline in TH BMD by DXA was 2.6% (2.2, 3.0) with romosozumab and –0.6% (–1.0, –0.2) with TPTD ($p<0.0001$ between groups). TH BMD changes at months 6 and 12 were significantly larger with romosozumab than with TPTD ($p<0.0001$): month 6, 2.3% (1.9, 2.7) vs –0.8% (–1.2, –0.4); month 12, 2.9% (2.5, 3.4) vs –0.5% (–0.9, 0), respectively. Romosozumab also resulted in significantly larger BMD gains at the LS at months 6 and 12 vs TPTD ($p<0.0001$): month 6, 7.2% (6.6, 7.8) vs 3.5% (2.9, 4.0); month 12, 9.8% (9.0, 10.5) vs 5.4% (4.7, 6.1), respectively. QCT assessments of the hip demonstrated significantly greater gains in integral and cortical BMD with romosozumab vs TPTD at months 6 and 12 ($p<0.0001$). Estimated hip strength gains were also significantly larger with romosozumab at both time points ($p<0.0001$) and declined from baseline in TPTD-treated subjects at month 6. The subject incidences of adverse events were generally balanced between treatment groups.
**Conclusions:** In subjects transitioning from BP therapy, romosozumab was well-tolerated and associated with greater BMD gains and improved estimated hip strength compared with TPTD.

## OP0101 BISPHOSPHONATES DURING PREGNANCY: A PROSPECTIVE STUDY

A. Sokal[1], E. Elefant-Amoura[2], T. Leturcq[1], D. Beghin[2], X. Mariette[1], R. Seror[1].
*[1]Rheumatology Paris Sud University, le Kremlin Bicetre; [2]Centre de réference des agents tératogènes, Paris, France*

**Background:** Bisphosphonates (BPs) are sometimes prescribed to young women in childbearing age for bone disorders or corticosteroid induced osteoporosis. However their effects on pregnancy outcome have been poorly studied.
**Objectives:** The aim of our study was to determine pregnancy and newborn outcomes in women exposed to BPs during pregnancy.
**Methods:** Cases and controls were collected from the CRAT database (French Reference Centre of Teratogenic Agents),an ongoing prospective follow-up of drug-exposed pregnant women. Cases were all patients that received BPs within the 6 weeks before or during pregnancy between 1987 and 2014. Since pregnancy outcomes may be affected by the underlying maternal disease two sub-groups were defined: pregnant women with inflammatory diseases treated mainly for steroids-induced osteoporosis and pregnant women with bone diseases. Likewise, two control groups were selected from the CRAT database: pregnant women with inflammatory diseases and not exposed to BPs and healthy pregnant women non-exposed to teratogenic drugs. For each case, 4 controls were assigned. Pregnancy outcomes were compared between inflammatory cases and controls, and between bone disease cases and healthy controls.
**Results:** 39 women were identified as having be exposed to BPs during pregnancy. Median age was 33 [27;36] years and 20% of patients were primiparous. Among them, 23 had inflammatory diseases including systemic lupus erythematosus (n=5), rheumatoid arthritis (n=5), anti-phospholipid syndrome (n=1), vasculitis (n=6) or other connective/auto-immune disease (n=6) and 16 had bone diseases including osteoporosis (n=9), malignancy (n=3) and other bone disease (n=4). Characteristics are reported in table 1. Compared to their 92 matched controls, women with inflammatory diseases exposed to BPs were more likely to receive steroids (78% vs 47%, p=0.009), methotrexate (26% vs 5% p=0.008), and colchicine (17% vs 2%, p=0.014) but less likely to receive anti-malarial drugs (p=0.019). 26% of cases vs 13% of the controls had voluntary or therapeutic pregnancy termination (p=0.195, OR=2.33, IC95 [0.63; 7.94]). Among the remaining patients, the rate of live births did not differ (94% vs 80%, p=0.29, OR=3.96, IC95 [0.53; 177.94]). No difference was found on birth weightssizes or congenital malformations (9% vs 4%, p=0.345, OR 2.08 IC95 [0.18;15.7]).

**Table 1: Main characteristics of the patients and maternofetal outcomes**

| | Inflammatory cases | Inflammatory controls | | Bone cases | Healthy controls |
|---|---|---|---|---|---|
| | N= 23 | N=92 | | N= 16 | N=64 |
| Maternal characteristics | | | | | |
| Age (y) | 27 [25.5;34] | 30 [27;33] | | 34 [33;39] | 32 [29;35] |
| Previous pregnancy | 0 [0;1.5] | 1 [0;2] | | 1.5 [1;3] | |
| Previous delivery | 0.5 [0;1.25] | 1 [0;2] | | 1.5 [0;2] | |
| Disease | | | Disease | | |
| - Systemic lupus erythematosus (%) | 5 (22) | 40 (43) | - Osteoporosis | 9 (56) | 0 |
| - Rheumatoid arthritis (%) | 5 (22) | 24 (26) | - Malignance (%) | 3 (19) | 0 |
| - Anti-phospholipid syndrome (%) | 1 (4) | 12 (13) | - Other (%) | 4 (25) | 0 |
| - Systemic vasculitis (%) | 6 (26) | 3 (3) | | | |
| - Other inflammatory disease (%) | 6 (26) | 13 (14) | | | |
| Drug | | | Drug | | |
| - Risedronate (%) | 15 (65) | 0 | - Risedronate (%) | 1 (6) | 0 |
| - Alendronate (%) | 6 (26) | 0 | - Alendronate (%) | 9 (56) | 0 |
| - Etidronate (%) | 1 (4) | 0 | - Etidronate (%) | 2 (13) | 0 |
| - Ostevine (%) | 1 (4) | 0 | - Clodronate (%) | 1 (6) | 0 |
| | | | - Ibandronate (%) | 1 (6) | 0 |
| | | | - Pamidronate (%) | 3 (19) | 0 |
| Exposition | | | | | |
| - Within 6 weeks before pregnancy (%) | 1 (4) | 0 | | 4 (25) | 0 |
| - 1-3 month of pregnancy (%) | 21 (91) | 0 | | 9 (56) | 0 |
| - 3-4 month of pregnancy (%) | 4 (17) | 0 | | 3 (19) | 0 |
| - 4-9 month of pregnancy (%) | 4 (17) | 0 | | 0 | 0 |
| - All trimester (%) | 1 (4) | 0 | | 0 | 0 |
| Therapeutic or voluntary Abortion | 6 (26) | 12 (13) | | 3 (19) | 2 (3) |
| Live birth among the remaining patients (%) | 16/17 (94) | 64/80 (80) | | 9/13 (69) | 62/62 (100) |
| Congenital malformations | 1 (9) | 4 (6) | | 0 (0) | 1 (2) |

In women with a bone disease the rate of therapeutic or voluntary abortions tended to be higher than in controls (19% vs 3%, p=0.054). However, among the remaining women, those treated with BPs had a lower live birth rate than healthy controls (69% vs 100%, p=0.0005), partly due to 3 spontaneous abortions in the BPs group. No difference on birth weights, sizes, or congenital malformations (p=1.00) was observed. In both groups, no neonatal hypocalcemia occurred.
**Conclusions:** Despite its limited sample size, this study is to our knowledge the largest one on pregnancy outcomes among women exposed to bisphosphonates during pregnancy, especially during the first trimester. Results are reassuring and did not show any major teratogenic effect of BPs. However, we observed a higher rate of spontaneous abortions in patients with bone disease treated with BPs, potentially related to an underlying malignancy. Collecting characteristics of child's follow-up is ongoing and will provide additional data, particularly on post-natal growth.

## OP0102 GENETIC EFFECTS ON TRABECULAR AND CORTICAL VOLUMETRIC BONE MINERAL DENSITIES AND BONE MICROSTRUCTURE MEASURED BY HRPQCT

F. Pan[1], K. Squibb[1], R. Thomson[2], T. Winzenberg[1], R. Zebaze[3], G. Jones[1].
*[1]Musculoskeletal Unit; [2]Statistics Unit, Menzies Institute for Medical Research, University of Tasmania, Hobart; [3]Austin and Repatriation Medical Centre, University of Melbourne, Melbourne, Australia*

**Background:** While both genetic and environmental factors affect areal BMD (aBMD), as much as 80% of variation in BMD is attributable to genetic factors [1]. aBMD measured by dual x-ray absorptiometry (DXA) is used as a surrogate measure for bone strength and is the gold standard for diagnosis of osteoporosis. However, structural abnormalities independent of aBMD may contribute to bone fragility. Bone structural parameters quantified using high-resolution pQCT (HRpQCT) may help more accurately identify individuals at risk for fracture than aBMD alone [2]. The heritability of cortical and/or trabecular bone microstructure determined by HRpQCT are unknown.
**Objectives:** To estimate heritability of trabecular density (TD), cortical density (CD), trabecular thickness (TT) and cortical thickness (CT) at tibia and radius measured by HRpQCT and investigate the genetic correlations of these between the tibia and radius.
**Methods:** Participants were 174 mother-child pairs from 161 families (161 mothers, mean age 52 years; 174 children, mean age 26 years). Cortical and trabecular bone microstructure at tibia and radius were measured by HRpQCT. SOLAR software was used to conduct quantitative genetic analyses with adjustment for covariates.
**Results:** In multivariable analysis, maternal tibial TD, CD, TT and CT were independently associated with all corresponding bone microstructures in the children ($\beta$=0.14 to 0.37, all $P<0.05$) after adjustment for age, sex, weight, height, smoking history and physical activity. Additive genetic factors explained 67%, 36%, 33% and 46% of the variation in TD, CD, TT and CT, respectively (adjusted $P<0.05$). Similar results were observed at the radius, but the heritability estimates were lower than that at tibia (range, 12%>57%). Genetic correlations for TD and TT between tibia and radius ($r_g$=0.80 for TD; 0.86 for TT) were greater than that of CD and CT ($r_g$=0.47 for CD; 0.50 for CT).
**Conclusions:** Genetic factors appear to have an important role in the development of peak bone microarchitecture and are partly shared for the tibia and radius. The heritability estimates of radius were lower than that of tibia, suggesting tibia is affected by environmental factors to a greater extent than radius, possibly due to more loading at tibia.

## OP0103 FRACTURE LIAISON SERVICE IMPLEMENTED IN A METROPOLITAN TERTIARY CENTRE IN WESTERN AUSTRALIA IMPROVED TREATMENT AND RECURRENT FRACTURE RATES BY 12 MONTHS

C.A. Inderjeeth[1], W. Raymond[1], E. Geelhoed[2], A. Briggs[3], K. Briffa[3], D. Oldham[4], J. McQuade[5], D. Mountain[6]. [1]*Rehabilitation & Aged Care, Sir Charles Gairdner Hospital;* [2]*School of Population, The University of Western Australia;* [3]*Physiotherapy & Exercise Science, Curtin University of Technology;* [4]*North Metropolitan Health Service, WA Health;* [5]*Arthritis & Osteoporosis Foundation of WA;* [6]*Accident & Emergency, Sir Charles Gairdner Hospital, Perth, Australia*

**Background:** Osteoporotic fractures impose a significant morbidity, mortality and economic burden (1). Research within our hospital confirmed low rates of identification and secondary prevention for patients discharged from Emergency Department (ED) with a fracture (2). The Fracture Liaison Service (FLS) aimed to identify, review and then manage these patients following their discharge from the ED.
**Objectives:** To evaluate the performance of a FLS in a Western Australian hospital.
**Methods:** Patients aged >50 yrs who presented to the Emergency Department after a fracture at Sir Charles Gairdner Hospital (SCGH) were invited to the FLS. A retrospective control group from SCGH determined the historical fracture risk without an active FLS intervention. Fremantle Hospital was used as a prospective control cohort.
Demographic data was collected at baseline then patients were followed up at 3 & 12 months. The follow-up survey collected information on: awareness of osteoporosis, investigations undertaken (e.g. BMD testing), had a diagnosis been made, medication usage, health care utilisation, falls & fracture information and quality of life (EQ-5D).
**Results:** The FLS reduced the recurrence of minimal trauma fractures over 12 months by between 9.2 to 10.2% compared to a retrospective cohort & a prospective control cohort. 167 or 69.3% of eligible patients agreed to attend the Fragile Bone Clinic. As the program becomes more main-stream the utilisation of the service is expected to increase.
The FLS demonstrated a 17.1% increase in patient *awareness of osteoporosis* compared to other sites and by 35.6% compared to the SCGH retrospective group over 12 months ($p<0.001$). The FLS had better prescription rates of calcium (57.4% vs 28.8%), vitamin D (59.8% vs 33.0%), optimised calcium & vitamin D (48.4% vs 19.8%) and anti-resorptive therapy (29.9% vs 16.2%) compared to the retrospective cohort at SCGH. At 12 months the FLS had the highest number (n=82) and rate (46.9%) of patients initiated on pharmacological treatment compared to other sites 17 (41.5%) and SCGH Retrospective 12 (16.0%). The FLS incrementally improved the prescription, adherence and compliance with of osteoporosis treatment.
**Conclusions:** By 12 months the Fracture Liaison Service demonstrated that it reduced the recurrent fracture rate and significantly improved rates of pharmacological treatment initiation & patient awareness of osteoporosis.

## OP0104 BONE QUALITY, AS MEASURED BY TRABECULAR BONE SCORE, IN FEMALE POSTMENOPAUSAL PATIENTS WITH SYSTEMIC SCLEROSIS AND RHEUMATOID ARTHRITIS

A. Casabella[1], C. Seriolo[1], G. Botticella[1], L. Molfetta[2]. [1]*Osteoporosis, Bone and Joint Disease Research Center, CROPO, Research Laboratory and Academic Unit of Rheumatology, University of Genoa;* [2]*Osteoporosis, Bone and Joint Disease Research Center, CROPO, Osteoporosis, Bone and Joint Research Center, CROPO, Genoa, Italy*

**Background:** Patients affected by Systemic Sclerosis (SSc) and Rheumatoid Arthritis (RA) might present an increased risk of low bone mass as a result of multisystemic disorder including treatment, low vitamin D levels and physical inactivity[1]. Trabecular Bone Score (TBS) is an index extracted from the dual-energy X-ray absorptiometry (DXA) that provides an indirect measurement of bone axial microarchitecture and allows to get informations about bone quality[2].
**Objectives:** The aim of this study was to assess bone quality in SSc patients using TBS in comparison with a "high-risk" population with RA.
**Methods:** 74 patients (mean age 65±9 years) affected by SSc, 98 RA patients (mean age 61±8 years) and 60 age-matched healthy controls (mean age 64±11 years) were studied. Bone Mineral Density (BMD, g/cm$^2$) of the lumbar spine (L1-L4) was analyzed using DXA scan (Lunar Prodigy). Lumbar spine TBS was derived for each spine DXA examination blinded to clinical parameters and outcomes using TBS iNsight Medimaps (Lunar Prodigy). TBS value >1.350 is considered normal whereas TBS value <1.200 indicates a degraded bone microarchitecture.
**Results:** Out of 74 enrolled patients with SSc, 56 (76%) presented bone loss; in particular 32 (43%) showed osteoporosis and 24 (32%) osteopenia. In RA patients bone loss was observed in 78 patients (80%); in particular 52 osteoporosis (53%) and 41 (42%) osteopenia. BMD was found significantly lower in SSc and RA patients compared with matched control group (respectively, Lumbar spine: 0.998±0.161 g/cm$^2$ and 0.862±0.194 g/cm$^2$ vs 1.240±0.932 g/cm$^2$; Femoral neck: 0.784±0.212 g/cm$^2$ and 0.668±0.141 g/cm$^2$ vs 0.845±0.164 g/cm$^2$; Ward 0.563±0.173 g/cm$^2$ and 0.486±0.221 g/cm$^2$ vs 0.657±0.106 g/cm$^2$; Trochanter: 0.666 ±0.104 g/cm$^2$ and 0.598±0.231 g/cm$^2$ vs 0.725±0.143 g/cm$^2$; Total hip: 0.827±0.182 g/cm$^2$ and 0.764±0.244 g/cm$^2$ vs 1.033±0.161 g/cm$^2$, all $p<0.001$). Lumbar spine TBS was found significantly lower in SSc and RA patients compared with matched control group (respectively, 1.032±0.163 and 0.904±0.148 vs 1.361±0.126, both $p<0.001$). There was no significant difference in mean lumbar spine TBS between patients with SSc and RA ($p=0.238$).
**Conclusions:** This detailed study shows a decreased BMD and TBS values in SSc and RA patients when compared to healthy controls. In addition TBS, evaluated at the lumbar spine, with lumbar and femoral BMD, could discriminate patients with alterated bone microstructure and could become a new clinical tool in the general diagnosis of osteoporosis in inflammatory rheumatic diseases, such as SSc and RA.

## OP0105 THE PREDICTORS FOR 12 MONTHS EFFICACY OF DENOSUMAB, AN ANTI-RANKL ANTIBODY, ON OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM MULTICENTER STUDY (TBCR-BONE)

Y. Hirano[1], Y. Kanayama[2], M. Isono[1], N. Ishiguro[3], T. Kojima[3] on behalf of TBCR-BONE. [1]*Rheumatology, Toyohashi Municipal Hospital, Toyohashi;* [2]*Orthopaedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota;* [3]*Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

**Background:** Although medication of rheumatoid arthritis (RA) has been improved by early intensive treatment using MTX and biological agents (BIO) for decades, treatment of concomitant disease in RA patients, such as osteoporosis (OP), will be more important to improve activity of daily living of RA patients. Although denosumab (DMB), an anti-RANKL antibody, was approved for treatment of OP in Japan in 2013, clinical data in real world is lacking in patients with RA.
**Objectives:** To investigate the 12 months efficacy of DMB on OP in patients with RA (RA-OP) and predictors of efficacy from multicenter registry study in Japan (TBCR-BONE).
**Methods:** 64 female cases with RA-OP were included in this study. Bone mineral density (BMD) of lumbar spine (LS-BMD) and total hip (TH-BMD) and bone turnover markers (P1NP and TRACP-5b) were measured at baseline and every 6 months to 12 months.
**Results:** Mean age was 69 years old. Mean RA duration was 16 years. Mean DAS28-CRP was 2.7. 44% of cases had the past history of fracture. Mean FRAX was 26%. Daily teriparatide was used in 12 cases before DMB treatment. LS-BMD at 6m and 12m was significantly increased compared with baseline (4.3% and 5.9%) (Fig1). TH-BMD at 6m and 12m was significantly increased compared with

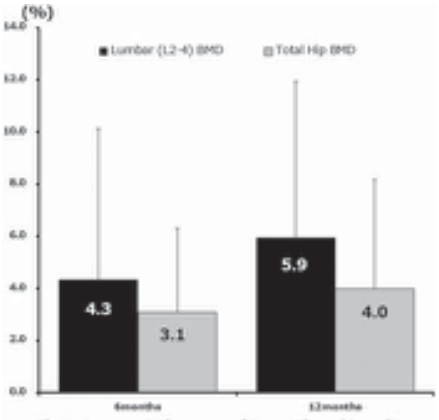

Fig 1. Average % increase of Bone Mineral Density

baseline (3.1% and 4.0%) (Fig1). Mean decrease in P1NP were 39.9% at 6m and 34.3% at 12m. Mean decrease in TRACP-5b were 31.5% at 6m and 27.2% at 12m. Next, all cases were divided into two group, good outcome group (GO group) and non-good outcome group (non-GO group), by mean %increase of LS-BMD and PF-BMD at 12 months. %increase of LS-BMD at 6m in LS-GO group (n=31) was significantly larger than that in LS-non-GO group (n=30) (7.6% vs. 0.9%). Baseline P1NP in LS-GO group was also larger than that in LS-non-GO group (62.5μg/l vs. 45.4μg/l). There were no significant differences in changes of BTMs between two groups. %increase of TH-BMD at 6m in TH-GO group (n=30) was significantly larger than that in TH-non-GO group (n=31) (5.0% vs. 1.2%). There were no significant differences in changes of BTMs between two groups.
**Conclusions:** DMB was effective in RA-OP. Early response of BMD and baseline P1NP level were suggested to be the predictors of the efficacy of DMB in RA-OP. Higher baseline P1NP and higher LS-BMD increase at 6m were the predictors of better LS-BMD increase at 12m. Higher TH-BMD increase at 6m was the predictors of better LS-BMD increase at 12m.

## OP0106 CHANGE IN BONE MINERAL DENSITY WITH HIGH-DOSE PREDNISONE IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Rasch[1], L. van Tuyl[1], M. Kremer[1], I. Bultink[1], M. Boers[2,3], W. Lems[1,3].
*[1]Amsterdam Rheumatology and immunology Center, location VU University Medical Center; [2]Epidemiology and Biostatistics, VU University Medical Center; [3]Amsterdam Rheumatology and immunology Center, location Reade, Amsterdam, Netherlands*

**Background:** Recently, we showed that treatment with COBRA-light therapy including prednisone with initially 30 mg/day, was as effective as the original COBRA scheme, with initially 60 mg/day [1,2], in the treatment of rheumatoid arthritis (RA). Since high-dose glucocorticoids are associated with bone loss and vertebral and nonvertebral fractures, we investigated the differences in bone mineral density (BMD) after one year of treatment in both arms.
**Objectives:** To compare 1-year changes in BMD (lumbar spine [L1-L4], total hip, and femoral neck) between the treatment groups.
**Methods:** An open-label, randomised controlled, non-inferiority trial of patients with active, newly diagnosed RA following a treat-to-target protocol.
**Results:** BMD data were determined in 144 out of 164 included RA patients, all randomized to either COBRA (n=71) or COBRA-light (n=73) therapy. Overall bone loss was very limited, and no significant difference in change in BMD between COBRA and COBRA-light was found at any site (*Table 1*). However, in secondary analyses, COBRA-light showed a significant decrease in BMD in the lumbar spine and total hip after 52 weeks, whereas the femoral neck and the COBRA group did not.

Table 1. Changes in bone mineral density between baseline and week 52 during COBRA and COBRA-light therapy

| | COBRA (n=71) | | | COBRA-light (n=73) | | |
|---|---|---|---|---|---|---|
| | baseline | week 52 | change | baseline | week 52 | change |
| Lumbar spine | 1.12 (0.17) | 1.12 (0.17) | 0.01% | 1.10 (0.15) | 1.09 (0.15) | −1.02%* |
| Total hip | 0.95 (0.14) | 0.95 (0.14) | 0.05% | 0.95 (0.12) | 0.94 (0.13) | −1.16%* |
| Femoral neck | 0.90 (0.16) | 0.89 (0.17) | −0.59% | 0.88 (0.12) | 0.87 (0.11) | −0.98%* |

*Significant change between baseline and week 52 ($p<0.05$). Values are reported as mean (SD), unless otherwise specified.

**Conclusions:** During the trial, overall bone loss was very limited and not significantly different between the treatments. These findings strengthen the hypothesis that positive effects associated with the large reduction in disease activity as a result of combination therapy and tight control treatment counteract the negative effects of (high-dose) prednisone on bone.

## OP0107 TERIPARATIDE AND DENOSUMAB COMBINATION THERAPY AND SKELETAL METABOLISM

A. Fassio, D. Gatti, O. Viapiana, V. Braga, L. Idolazzi, G. Adami, M. Rossini.
*Rheumatology Section, Department Medicine, University of Verona, Verona, Italy*

**Background:** Despite therapeutic options for osteoporosis have greatly expanded over the past few decades, the treatment of patients with established severe osteoporosis still remains challenging. Recently the combined teriparatide (TPD) and denosumab therapy was shown to increase bone mineral density (BMD) more than either agent alone.
**Objectives:** The aim of this study was to compare the changes in bone turnover markers and in inhibitors of the Wnt canonical pathway in patients treated with either denosumab alone or TPD alone or when TPD was added to patients previously treated with denosumab.
**Methods:** Open label prospective randomized study, involving 59 women over 65 years old affected by severe postmenopausal osteoporosis (with the evidence of at least two moderate-severe vertebral fractures), Bone turnover markers C-terminal telopeptide of type I collagen (CTX) and intact N-propeptide of type I collagen ad (P1NP) and inhibitors of the Wnt canonical pathway sclerostin (SOST) and Dickkopf-related protein 1 (DKK1) were evaluated.
**Results:** In the groups treated with TPD or with denosumab alone bone turnover markers rose and decreased, respectively. In TPD group a later significant increase in DKK1 was observed, while in denosumab group a progressive increase in SOST was associated with a progressive significant decrease in DKK1. In the group treated first with denosumab and in which TPD was added 3 months later, the rounded values of both CTX and P1NP increased 3 months after the beginning of TPD by approximately the same absolute and percentage value of the group of patients treated with TPD alone, showing that the strong effect of denosumab on bone turnover is easily reversed by TPD treatment. In this group, SOST increased as in the denosumab alone group, while DKK1 progressively increased as in the TPD alone group.
**Conclusions:** In conclusion, in this study we showed that TPD is able to express its biological activity even when bone turnover is fully suppressed by denosumab treatment. The combination therapy is associated with significant increases in both DKK1 and SOST, suggesting that the Wnt signalling pathway is not involved in the positive bone balance seen in the combination TPD-denosumab group.

# Expanding therapeutic options in spondyloarthritis -

## OP0108 BIMEKIZUMAB, A MONOCLONAL ANTIBODY THAT INHIBITS BOTH IL-17A AND IL-17F, PRODUCES A PROFOUND RESPONSE IN BOTH SKIN AND JOINTS: RESULTS OF AN EARLY-PHASE, PROOF-OF-CONCEPT STUDY IN PSORIATIC ARTHRITIS

S. Glatt[1], F. Strimenopoulou[1], P. Vajjah[1], S. Shaw[1], L. Ionescu[2], S. Popa[3], D. Baeten[4]. *[1]UCB Celltech, Slough, United Kingdom; [2]UCB BioPharma SPRL, Anderlecht, Belgium; [3]Arensia Exploratory Medicine, Republican Clinical Hospital, Chisinau, Moldova, Republic of; [4]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

**Background:** Bimekizumab (UCB4940) is a potent and selective monoclonal antibody inhibiting the activity of both IL-17A and IL-17F, which are key pro-inflammatory cytokines overexpressed in skin lesions of patients with psoriasis.[1] Blocking both IL-17A and IL-17F may provide a therapeutic advantage.
**Objectives:** To study the safety/tolerability and efficacy of multiple-dose bimekizumab in patients with PsA with inadequate responses to at least 1 DMARD and/or 1 biologic DMARD (NCT02141763).
**Methods:** 52 patients were randomized to receive either bimekizumab (N=38) or PBO (N=14). Four active dose-level groups were studied using a single loading dose (80–560 mg bimekizumab) administered at wk 0; further doses (40–320 mg bimekizumab) were administered at wks 3 and 6. ACR and PASI scores were examined; safety and PK variables were also investigated.
**Results:** At baseline, patients had a mean SJC (66) of 12.6 and TJC (68) of 29.6, and mean baseline CRP of 12.5 mg/mL. For patients with skin involvement of >3% (N=23) a mean baseline PASI of 15.9 (SD=14.6) was observed. Onset of response was rapid for both skin and joints: by wk 8, an ACR20 RR of 80% was observed for the top 3 doses (N=32) compared with 17% in the PBO group (N=12). Clinically relevant responses in disease activity measures were observed to wk 20. A summary of results in skin and joints is presented in the table.

| | Baseline | | Week 8 | |
|---|---|---|---|---|
| | PBO | Bimekizumab top 3 doses | PBO | Bimekizumab top 3 doses |
| Joints: | | | | |
| ACR20 RR [95% CI] | N/A | N/A | 17% [5%, 45%], N=12 | 80% [63%, 91%], N=30 |
| ACR50 RR [95% CI] | N/A | N/A | 8% [2%, 35%], N=12 | 40% [25%, 58%], N=30 |
| Mean DAS(CRP) [95% CI] | 5.1 [4.6, 5.6], N=11 | 5.0 [4.6, 5.4], N=30 | 3.9 [3.2, 4.6], N=11 | 3.1 [2.7, 3.6], N=29 |
| Skin: | | | | |
| PASI 90 RR [95% CI] | N/A | N/A | 0% [0%, 43%], N=5 | 87% [62%, 96%], N=15 |
| Mean PASI [SD] | 17.6 [18.0], N=5 | 11.1 [9.2], N=15 | 14.1 [17.9], N=5 | 0.2 [0.6], N=15 |

Bayesian analysis on wk 8 data indicated a >99% probability that ACR score improvement, and ACR20 RR, were greater than PBO and exceed the pre-defined clinically relevant threshold ($ACRn_{tr}$: 0.31 and ACR20: 25%). Additionally, there was a high posterior probability of >99% that the bimekizumab ACR20 RR

was greater than that reported for the current SOC biologic treatment, including anti-IL-17 therapies (59.7%) at wk 8.[2,3]
All doses of bimekizumab were well tolerated, with no unexpected safety findings. No patient discontinued due to treatment-emergent AEs. No treatment-related serious AEs were reported. Bimekizumab had a linear PK, with an expected half-life of ~24 days.
**Conclusions:** In patients with PsA, bimekizumab demonstrated rapid onset, sustained and deep efficacy on disease activity in skin and joints, and within this limited patient and exposure set, was safe and well tolerated. Bayesian analysis indicated that bimekizumab ACR20 RR is greater than that reported for current therapies including anti-IL-17A. Results support that inhibition of both IL-17A and IL-17F could provide additional clinical benefit in IL-17-mediated diseases.

## OP0109 EFFICACY AND SAFETY OF IXEKIZUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: 52 WEEK RESULTS FROM A PHASE 3 STUDY (SPIRIT-P1)

P.J. Mease[1], M. Okada[2], M. Kishimoto[2], C.L. Shuler[3], H. Carlier[3], C.-Y. Lin[3], J. Mou[3], S.R. Moriarty[3], C.H. Lee[3], D.D. Gladman[4]. *[1]Swedish Medical Center and University of Washington, Seattle, United States; [2]St Luke's International Hospital, Tokyo, Japan; [3]Eli Lilly and Company, Indianapolis, United States; [4]University of Toronto, Toronto, Canada*

**Background:** Ixekizumab (IXE) is an IgG4 monoclonal antibody that binds with high affinity and specificity to the proinflammatory cytokine IL-17A. In this phase 3 study (SPIRIT-P1), IXE was superior to placebo (PBO) in achieving American College of Rheumatology 20 (ACR20) response at Week 24 in biologic disease-modifying antirheumatic drug-naive (bDMARD-naive) patients with active psoriatic arthritis (PsA)[1].
**Objectives:** To evaluate efficacy and safety of IXE over 52 weeks in patients with active PsA.
**Methods:** A total of 417 bDMARD-naive patients with active PsA were randomized 1:1:1:1 to IXE 80 mg once every 4 weeks (Q4W) or once every 2 weeks (Q2W) including a 160 mg starting dose, to 40 mg adalimumab (ADA), or to PBO (all subcutaneous dosing) during the Double-Blind Treatment Period (DBTP: Weeks 0 to 24). Of these, 381 patients completed the DBTP and entered the Extension Period (EP: Weeks 24 to 52) where they were assigned to 80 mg IXE Q4W or Q2W. Patients randomized to IXE at Week 0 continued the same dose regimen in the EP. Patients randomized to PBO or ADA at Week 0 were re-randomized (1:1) to 80 mg IXE Q4W or Q2W at Week 16 (inadequate responders) or 24. Those patients who initially received PBO started IXE at Week 16 or 24; patients who initially received ADA started IXE at Week 24 or 32 after an 8 week wash out period. Efficacy measures included ACR20/50/70 response, Health Assessment Questionnaire-Disability Index (HAQ-DI) Score, Disease Activity Score 28 diarthrodial joint count based on C-reactive protein (DAS 28-CRP), Psoriasis Area and Severity Index 75, 90, 100 (PASI 75/90/100), Leeds Enthesitis Index (LEI), and Leeds Dactylitis Index-Basic (LDI-B). Efficacy and safety were analyzed using the EP population defined as all patients who received at least 1 dose of study drug in the EP. Missing values were imputed by nonresponder imputation for categorical data and modified baseline observation carried forward for continuous data.

Table 1. Efficacy and Safety Outcome Measures at Week 52+ (Extension Period Population)

| | IXE Q4W (N=560) | IXE Q2W (N=560) | ADA (N=446) | ADA (N=446) | PBO (N=470) | PBO (N=470) | Total (N=1031) | Total (N=1030) |

Abbreviations: ACR20/50/70=American College of Rheumatology 20/50/70 index; ADA=adalimumab 40 mg; AE=adverse event; CFB=change from baseline; DAS 28-CRP=Disease Activity Score 28 diarthrodial joint count based on C-reactive protein; HAQ-DI=Health Assessment Questionnaire-Disability Index; IXE=ixekizumab; IXE Q2W=ixekizumab 80 mg once every 2 weeks; IXE Q4W=ixekizumab 80 mg once every 4 weeks; LDI-B=Leeds Dactylitis Index-Basic; LEI=Leeds Enthesitis Index; n=number of patients in the analysis population; n=number of responders; PASI 75/90/100=Psoriasis Area and Severity Index 75/90/100; PBO=placebo; SAE=serious adverse event; SD=standard deviation; TEAE=treatment-emergent adverse event;
+ For efficacy analyses, baseline was defined as the last non-missing assessment recorded on or prior to the date of first injection of study treatment at Week 0. For analyses of TEAEs, baseline was defined as AEs which started prior to the study drug injection at Week 24 with an exception of patients who were randomized to ADA during the entire Double-Blind Treatment Period and started IXE at Week 32 where baseline was defined as AEs which started prior to the study drug injection at Week 32.
‡ Only patients with psoriatic lesions ≥3% of BSA at baseline were included in the analysis.
¢ Only patients with enthesitis at baseline were included in the analysis.
Φ Only patients with enthesitis and LEI >0 at baseline were included in the analysis.
Ψ Only patients with dactylitis at baseline were included in the analysis.
ξ Only patients with dactylitis and LDI-B >0 at baseline were included in the analysis.

**Results:** A total of 304 patients completed the EP. Efficacy and safety results in the EP population are summarized in Table 1. Improvements from baseline in ACR20/50/70, HAQ-DI, DAS 28-CRP, PASI 75/90/100, LEI and LDI-B were observed at Week 52. The frequency of treatment-emergent adverse events (AEs) in the EP was similar to that observed in the DBTP; the majority were mild or moderate in severity. Serious AEs occurred in 12 patients and no deaths occurred in the EP population.
**Conclusions:** IXE demonstrated clinically significant improvement in signs and symptoms of PsA including arthritis, dactylitis and enthesitis as well as skin manifestations across treatment groups in the EP. The safety profile of IXE observed in the EP was similar to that observed in the DBTP and other phase 3 studies of IXE in patients with plaque psoriasis (UNCOVER studies).

## OP0111 ANTI-TNF THERAPY IN AXIAL SPONDYLOARTHRITIS: PREDICTION OF THERAPEUTIC RESPONSES USING IMMUNOLOGICAL SIGNATURES

L. Rogge[1], S. Menegatti[1], E. Latis[1], H. Yahia[1], C. Leloup[1], N. Ménagé[2], A. Moltó[2], C. Miceli-Richard[2], M. Dougados[2], E. Bianchi[1]. *[1]Immunology, Institut Pasteur; [2]Rheumatology B, AP-HP Cochin Hospital, Paris, France*

**Background:** The introduction of anti-TNF therapy has proven effective to reduce inflammation and clinical symptoms in several chronic inflammatory diseases. However, TNF-blockers are effective only in a subpopulation of patients and can be associated with serious side effects. Despite intense efforts, it is currently not possible to predict responsiveness of patients to anti-TNF treatment. To address this issue, we have asked whether the analysis of the immune functions of patients will allow us to define biomarkers that can predict therapeutic responses to TNF blockers.
**Objectives:** The goals of this project were to define (i) the impact of anti-TNF therapy on immune responses to microbial challenges and stimuli targeting specific immune pathways in axial spondyloarthritis (axSpA) patients and (ii) to identify immunological correlates associated with therapeutic responses to TNF blockers before the initiation of therapy.
**Methods:** We have recently developed a set of whole-blood, syringe-based assays to assess innate or adaptive immune responses to stimuli targeting different signaling pathways (e.g. cytokines and TLR/NLR agonists), or mimicking infections in patients (1). This "TruCulture" system is designed to capture immune cell activity in response to specific stimuli without introducing sample collection and manipulation variables. Using this assay system, we have investigated immune responses to 20 different stimuli in a pilot study involving 12 axSpA patients before and 3 months after initiation of anti-TNF therapy. We are currently validating our findings in a replication cohort.
**Results:** We noted a highly significant reduction of the secretion of IL-1ra, IL-1β, and MIP-1β in response to selected stimuli after treatment with TNF-blockers. In contrast, TNF blockers had only minor effects on cytokine/chemokine production in unstimulated cultures, indicating that the effects of anti-TNF therapy can be measured when immune cells are challenged, but not at steady state. We also tested whether there is a correlation between the responses of immune cells to specific stimuli and the clinical response to TNF-blockers. For this, we calculated the "Ankylosing Spondylitis Disease Activity Score" (ASDAS) before treatment and 3 months after initiation of anti-TNF therapy and determined the "Improvement Score" ($ASDAS_{before\ treatment} - ASDAS_{after\ treatment}$). We found that axSpA patients who secreted the highest levels of inflammatory cytokines and chemokines in response to specific immune stimuli before initiation of anti-TNF therapy had the best therapeutic responses (highest improvement score).
**Conclusions:** Our results show that TruCulture assays are an efficient and robust

tool to monitor immune functions in patients and that anti-TNF therapy induces specific changes in immune responses to selected stimuli. Our data also indicate that analyzing immune responses in patients before therapy is a promising strategy to develop biomarkers predicting therapeutic efficacy of TNF-blockers.

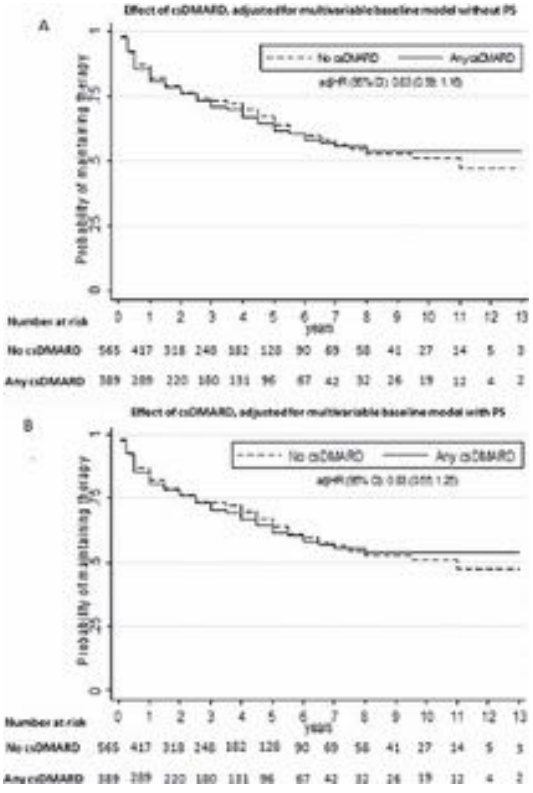
## OP0112 EFFECT OF COMEDICATION WITH CONVENTIONAL SYNTHETIC DMARDS ON TNF INHIBITORS-RETENTION IN PATIENTS WITH SPONDYLOARTHRITIS: A PROSPECTIVE COHORT



A. Sepriano[1,2], S. Ramiro[1,2], D. van der Heijde[2], P. Ávila-Ribeiro[3], R. Fonseca[4], J. Borges[5], L. Teixeira[6], P. Carvalho[7], M. Cerqueira[8], J. Neves[8], T. Meirinhos[9], A. Barcelos[9], G. Sequeira[10], M.J. Salvador[7], J.A. Canas da Silva[6], H. Santos[5], M. Bernardes[4], E. Vieira-Sousa[3,11], H. Canhão[3,11], J. Branco[1,12], F. Pimentel-Santos[1,12], R. Landewé[13]. *[1]CEDOC, NMS, Lisbon, Portugal; [2]LUMC, Leiden, Netherlands; [3]Lisbon Academic Medical Center, Lisbon; [4]Centro Hospitalar São João, Porto; [5]Instituto Português de Reumatologia, Lisbon; [6]Hospital Garcia de Orta, Almada; [7]Centro Hospitalar e Universitário de Coimbra, Coimbra; [8]ULSAM, Ponte de Lima; [9]Centro Hospitalar do Baixo Vouga, Aveiro; [10]Hospital de Faro, Faro; [11]Instituto de Medicina Molecular; [12]Hospital de Egas Moniz-CHLO, Lisbon, Portugal; [13]ARC, Amsterdam, Netherlands*

**Background:** The effects of comedication with conventional synthetic disease modifying antirheumatic drugs (csDMARDs) on TNF inhibitors (TNFi)-retention in spondyloarthritis (SpA), are inconclusive. Results from previous observational studies may have easily led to spurious conclusions, since confounding, especially "confounding by indication", was not fully addressed.

**Objectives:** To evaluate if comedication with csDMARD influences TNFi-retention in patients with SpA, while performing a comprehensive set of adjustments to best handle confounding.

**Methods:** Patients with SpA (according to their treating rheumatologists) from the Rheumatic Diseases Portuguese Register (Reuma.pt), with first TNFi started between 2001 and 2014 were included in this prospective, multicenter, cohort study. Our main outcome was time to first TNFi discontinuation. Cox-regression was used to estimate the effect of csDMARD comedication on TNFi-retention in two types of models, one including baseline (time-fixed) variables and the other with time-varying variables, including socio-demographic features, measures of disease activity, physical function and co-treatment with other drugs (NSAIDs and oral steroids). To control for possible "confounding by indication", the effect of csDMARD comedication on TNFi-retention was also tested after propensity score (PS)-adjustment.

**Results:** In total, 954 patients (mean (SD) age 41.5 (12.0) years; 59.6% males; 13.7 (10.4) years of disease duration) were included and 289 (30.3%) discontinued their first TNFi after a median follow-up time of 2.5 years (range: 0.08–13 years). A large proportion of patients were treated with csDMARDs at baseline (389; 41%). Inefficacy was the most common reason for TNFi discontinuation (55.7%), followed by adverse events (31.1%). In the multivariable analysis comedication with csDMARDs had no effect on TNFi-retention, neither in the baseline model (HR: 0.83; 95% CI: 0.59; 1.16) (figure A) nor during follow-up adjusting for time-varying covariates (HR: 1.13; 95% CI: 0.71; 1.80). The effect of csDMARDs remained not statistically significant after PS-adjustment (figure B).

**Conclusions:** Comedication with csDMARDs does not prolong TNFi-retention in SpA patients in clinical practice suggesting no benefit in the concomitant use of these drugs.

**Disclosure of Interest:** None declared

## OP0113 NO INCREASED INCIDENCE OF INFLAMMATORY BOWEL DISEASE AMONG SECUKINUMAB-TREATED PATIENTS WITH MODERATE TO SEVERE PSORIASIS, PSORIATIC ARTHRITIS, OR ANKYLOSING SPONDYLITIS: DATA FROM 14 PHASE 2 AND PHASE 3 CLINICAL STUDIES

S. Schreiber[1], B.E. Sands[2], A. Deodhar[3], D. Baeten[4], J. Huang[5], K. Gandhi[5], C. Karyekar[5], T. Fox[6], C. Gaillez[6]. *[1]Christian-Albrechts-Universität, Kiel, Germany; [2]Mount Sinai Hospital, New York; [3]Oregon Health & Science University, Portland, United States; [4]Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands; [5]Novartis Pharmaceuticals Corporation, East Hanover, United States; [6]Novartis Pharma AG, Basel, Switzerland*

**Background:** Secukinumab (SEC), a fully human anti–interleukin-17A monoclonal antibody, has been evaluated and approved for the treatment of moderate to severe psoriasis (PsO), active psoriatic arthritis (PsA) and active ankylosing spondylitis (AS). Inflammatory bowel disease (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), is commonly associated with PsO, PsA and AS.[1,2] The risk of CD in PsO pts is ~4-fold higher than that in the general population; this risk is even higher among PsO pts with PsA, reported at a rate of 0.05 cases per 100 pt-years.[1] The rate of CD among placebo (Pbo) treated pts in AS trials has been reported as 0.7 cases per 100 pt-years.[3] Endoscopic subclinical inflammation occurs in up to 50% of AS patients.[2]

**Objectives:** To assess the incidence of CD and ulcerative colitis (UC) among SEC-treated pts in the PsO, PsA, and AS clinical trial programs.

**Methods:** This analysis included data from 10 Phase 2 and Phase 3 studies in moderate to severe PsO, 2 Phase 3 studies in active PsA, and 2 Phase 3 studies in active AS, pooled per indication. Most studies included short-term, Pbo treatment arms; 1 PsO study included an etanercept (ETN) active comparator arm. Pts with prior history of, but not active, IBD could be enrolled. Study durations varied; data from all pts receiving ≥1 SEC dose up to Week (Wk) 52 (PsO studies) or Wk 112 visit were included. Data are reported as crude frequency rates (%) in the short-term (Wk 12 in PsO studies and Wk 16 in the PsA/AS studies) and exposure adjusted incidence rates (EAIR; per 100 pt-years) over the entire treatment period.

**Results:** Overall, 3430, 974, and 571 pts received ≥1 SEC dose in the PsO, PsA, and AS studies, respectively. AEs of CD or UC were reported infrequently amongst SEC-treated pts in both the short- and long-term treatment periods (Table). Rates of CD and UC were similar across the PsO and PsA cohort, and rates with SEC were similar to those seen with ETN in PsO pts. Across all

Table: Incidence of CD and UC Across the PsO, PsA and AS Secukinumab Clinical Trial Programs

## OP0114 SECUKINUMAB FOR THE TREATMENT OF ANKYLOSING SPONDYLITIS: COMPARATIVE EFFECTIVENESS RESULTS VERSUS ADALIMUMAB USING A MATCHING-ADJUSTED INDIRECT COMPARISON

W. Maksymowych[1], V. Strand[2], D. Baeten[3], P. Nash[4], H. Thom[5], S. Cure[6], E. Palaka[7], K. Gandhi[8], H. Richards[9], S. Jugl[9]. *[1]University of Alberta, Edmonton, AB, Canada; [2]Stanford University, Palo Alto, CA, United States; [3]Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [4]University of Queensland, Brisbane, Australia; [5]University of Bristol, Bristol; [6]MAPI group, Uxbridge, United Kingdom; [7]Novartis Ireland Ltd, Dublin, Ireland; [8]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [9]Novartis Pharma AG, Basel, Switzerland*

**Background:** Secukinumab 150 mg (SEC) is approved for the treatment of active AS in adults with inadequate response to conventional therapy. The MEASURE 2 (M2) trial showed superiority for SEC over placebo for the primary outcome measure, ASAS20 response, at week 16 and for multiple secondary outcomes. Efficacy was sustained up to 2 years. The ATLAS trial compared adalimumab 40 mg (ADA) with placebo, but there is no head-to-head trial of SEC vs. ADA. Placebo patients could switch to active treatment as early as week 12 in ATLAS and at week 16 in M2. Matching-adjusted indirect comparison (MAIC) can assess comparative effectiveness by re-weighting patient level data (PLD) resulting in a reduced effective sample size (ESS), to match the baseline patient characteristics of another trial. Thus, MAIC is able to simulate head-to-head comparisons.
**Objectives:** To assess the relative efficacy of SEC vs. ADA using adjusted PLD from M2 and published ATLAS data.
**Methods:** PLD from the SEC arm in M2 (n=72) was re-weighted to match baseline characteristics of the ADA arm in ATLAS (n=208). Logistic regression was used to determine weights for age, sex, mean BASFI score, mean CRP level, and prior biologic use. Sensitivity analyses including adjustment for BASDAI score were performed. Correlation analyses of baseline characteristics with ASAS20/40 responses were not available before the regression analyses. Both trials reported non-responder imputation (NRI) results until week 24; beyond which ATLAS used LOCF with n=311, including placebo switchers. Weighted outcomes from M2 (ESS n=34) were compared with outcomes from ATLAS. Pairwise comparisons using relative risks (RR) were performed. Results are presented as probability of response (95% CI) and RR (95% CI).
**Results:** SEC treatment led to statistical significantly higher ASAS responses at week 24 vs. ADA for ASAS20 (72.3% [62–83]; RR 1.43 [1.12–1.84] $p$=0.004) and ASAS40 (61.4% [50–73]; RR 1.56 [1.14–2.14] $p$=0.006). The ASAS20 and 40 response rates for ADA were 50.5% (44–57) and 39.4% (33–46) respectively. At week 52, SEC led to higher ASAS responses vs. ADA. The ASAS20 and 40 response rates for SEC were 78.9% (69–89) and 57.6% (46–69) respectively, and for ADA were 65.4% (60–71) and 47.1% (42–53). The SEC vs. ADA comparison at ASAS20 approached significance (RR 1.21 [0.996–1.461] $p$=0.055). No significant differences were observed at week 12 and 16. Sensitivity analyses support these findings.
**Conclusions:** SEC demonstrated statistically significant higher symptomatic improvement in terms of ASAS20 and 40 responses vs. ADA at week 24 in this first MAIC in AS. A similar trend was noted up to week 52, even though SEC NRI data was compared with ADA LOCF data at week 52. Differences in study designs, such as the early-escape criteria and disease duration together with the small ESS (n=34) for SEC may result in potential limitations, warranting further MAIC analyses in AS.

## OP0115 RELATIVE EFFICACY OF ADALIMUMAB VERSUS SECUKINUMAB IN ACTIVE ANKYLOSING SPONDYLITIS: A MATCHING-ADJUSTED INDIRECT COMPARISON

K.A. Betts[1], M. Mittal[2], J. Song[1], M. Skup[2], A. Joshi[2]. *[1]Analysis Group, Inc., Boston, MA; [2]AbbVie Inc., North Chicago, IL, United States*

**Background:** Two phase 3 clinical trials, MEASURE 1 and 2, demonstrated the efficacy of secukinumab for active ankylosing spondylitis (AS). However, there is limited data comparing the efficacy of secukinumab with established AS treatments.
**Objectives:** The objective of this study was to compare relative efficacy between adalimumab and secukinumab, estimate the number needed to treat (NNT), and evaluate the incremental cost per responder (CPR) for the treatment of active AS.
**Methods:** An indirect comparison was conducted using individual patient data from the adalimumab clinical trial (ATLAS)[1] and published data from the secukinumab trials (MEASURE 1 and 2).[2] Only dosages approved by the European Medicines Agency (adalimumab 40mg and secukinumab 150mg) were included in the analysis. To adjust for the cross-trial differences, individual patients in ATLAS were re-weighted to match the mean baseline characteristics in the MEASURE trials.[3,4] Specifically, age, weight, gender, duration of AS, baseline methotrexate use, baseline sulfasalazine use, presence of positive HLA-B27, BASDAI score and total back pain score were included in the baseline matching. The ASAS20, ASAS40 and ASAS 5/6 response rates relative to placebo at the end of the trial period (adalimumab: 12 weeks, secukinumab: 16 weeks) were compared. NNTs to achieve one additional ASAS20, ASAS40 and ASAS 5/6 responder and the corresponding incremental CPRs were also calculated. Drug costs in terms of 2015 Euros were obtained from the Lauer Taxe.[5]
**Results:** After matching, mean baseline characteristics were balanced across the ATLAS and MEASURE 1 and 2 populations. Compared to secukinumab (n=197), adalimumab (n=204) demonstrated similar efficacy in ASAS20/40 and ASAS 5/6. The mean differences (95% confidence interval) between adalimumab and secukinumab in relative ASAS20, ASAS40 and ASAS 5/6 response rates were 2.3% (-12.8%, 17.5%), -0.4% (-14.1%, 13.4%), and -3.1% (-17.3%, 11.2%),

respectively. The NNTs to achieve one additional responder were also comparable between adalimumab and secukinumab: 2.9 vs 3.1 in ASAS20, 3.7 vs 3.7 in ASAS40, and 3.1 vs 2.8 in ASAS 5/6. Incremental CPRs relative to placebo were lower for adalimumab compared to secukinumab across all efficacy measures (Figure 1).

**Figure 1.** Incremental CPR of ASAS 20, ASAS 40 and ASAS 5/6 relative to placebo of adalimumab (12 weeks) vs. secukinumab (16 weeks)

**Conclusions:** In the absence of head to head trials comparing adalimumab and secukinumab, the current indirect comparison reduced cross-trial differences and provides timely and reliable evidence for physicians and payers. After adjusting for cross-trial differences in baseline characteristics, adalimumab demonstrated similar efficacy as secukinumab in terms of ASAS20, ASAS40 and ASAS 5/6 responses and was associated with lower incremental CPR compared with secukinumab over the trial period among patients with active AS.

## Designing solutions to support young people to address the challenges of living with a rheumatic or musculoskeletal disease

### OP0116-PARE DEVELOPMENT OF THE GUIDE FOR NATIONAL ONLINE YOUTH PLATFORMS INCLUDING IMPLEMENTATION IN THREE COUNTRIES

W. Olsder, L. Van Nieuwkoop, R. Van Boerdonk, N. Des Bouvrie.
*Youth-R-Well.com, Schiedam, Netherlands*

**Background:** Several countries have interest in building an online platform for youth (18–35) with RMDs. However, they face the challenges of lack of experience, know-how and access to best practices on how to prepare and implement such a platform. For more than 10 years the Netherlands has a successful online youth platform, called Youth-R-Well.com. During its long-term existence the Dutch youth group has obtained in-depth experience regarding how to build and maintain such an online community.
**Objectives:** For many countries who want to build an online youth platform it is hard to initiate, build and maintain a successful platform. Youth-R-Well.com wants to support other countries through the development and dissemination of a practical guide. This guide instructs youth groups to build and maintain attractive and lively online platforms for young people with RMDs.
**Methods:** The guide for building online youth communities is based on our own experiences and the content of the current and previous online platforms of Youth-R-Well.com. The guide includes our best practices and addresses the challenges we faced on the way to establish the platform and to make it sustainable. The guide helps with tips and tricks and includes information about what an online platform is and what the basic principles are, especially for youth with RMDs. It covers topics about how to start, what kind of resources you need and how to involve people at your platform. The guide is already tested in practice by three different countries and can be used by other youth groups. In addition to the guide, Youth-R-Well.com conducted two knowledge transfer programs funded by EULAR PARE with Romania, Poland and Italy to implement the guide. These working days focused on sharing knowledge, experience and best practices related to the online platforms. We helped the participating countries in setting up their online youth platform and we received valuable feedback to improve our guide. By giving presentations and workshops, all the participating countries had a concrete plan at the end of the program to start an online youth platform.
**Results:** The main result of this project is a tested guide to establish and maintain online youth platforms. The guide can be used by patient organizations in any European country. Other outcomes are trained youth experts in several countries and a growing number of online platforms in the future. Each participating country (Romania, Poland and Italy) has made a promising start and will hopefully within a few years have developed a successful platform. The countries are satisfied with the guide as support in building an online platform for youth with RMDs.
**Conclusions:** The guide is a successful method to start an online youth platform. Within the upcoming years the guide can be used in more countries. In the future the guide can be used to get a national online youth platform in every European country.

### OP0117-PARE ILOA ELÄMÄÄN – PEER SUPPORT AND NETWORKING EVENT FOR CHILDREN, YOUTH AND FAMILIES WITH MSD DISEASE

M. Ekroth, T. Pakkala. *The Finnish Rheumatism Association, Helsinki, Finland*

**Background:** Rheumatism can be difficult and enduring disease for the individual and their family. The day-to-day life is challenging and hard for the entire family. Furthermore, finding joy and positive energy can seem impossible at times. Networking and peer support along with positive feeling such as joy are important factors for sustaining good mental health inside the family and to support them in their everyday challenges with MSD diseases in the family.
**Objectives:** The Finnish Rheumatism Association wanted to continue the successful Iloa Elämään (joy/happiness to life) campaign. The Iloa Elämään campaign's objective is to increase mental wellbeing mainly through events targeted for individuals with MSD. The event focus group was mainly on children from ages three to fifteen with MSD and to their families. The main instalment of Iloa Elämää campaign is a recreational day to create joy and experiences through fun activities focused towards the children. Simultaneously, bringing new energy into the families challenging lives with illness. The event was also a gateway for networking; meeting other individuals with the same challenges in their lives and to get in touch with organisations looking after their interests.
**Methods:** The Finnish Rheumatism Association planned to create the event in cooperation with Haaga-Helia University of applied sciences and their degree programme student group. The promoting of the events were done through contact and channels of Finnish Rheumatism Association and the resources of the student group. The Finnish Rheumatism Association funded part of the project by organizing money collections in ice-hockey matches and provided content for the event. The rest was from sponsors. Sponsors such as Hesburger, Haikko Kartano-Kokous-Spa, Haribo and Helsinki's Viihdepelit.
To measure the success of the event students planned and implemented mixed method customer satisfaction research. The event was organized with close cooperation with both organisations, The Finnish Rheumatism Association and Haaga-Helia University of applied sciences.
**Results:** The event was held at Finland Porvoo Campus 28th of November. The event lasted and had many activities throughout the whole day and had approximately 110 participants. The event peaked with a music performance with the favourite Finnish band among the teenagers, TCT.
Based customer satisfactory research 80 percent of the respondents had a family member with MSD disease, 70 percent weren't in the previous and event 93 percent though the event was successful and they enjoyed the event.
The Finnish Rheumatism Association noticed an increase in new members after the event. Moreover, it can be said some of the individuals in the event had found and joined the Finnish Rheumatism Association through the event. Many families made friends and found peer families. They have stayed in touch and supported each other still long after the event. For example a child with a rare arthritis met a peer with the same diagnosis for the first time in his life.

**Conclusions:** The event is an important service that needs to be provided to members of the Finnish Rheumatism Association and other individuals with MSD

disease. The participants enjoyed a day filled with fun activities, networking, information and support. The organizers and the participants offered support to the families living with MSD thus many were able to find new life-long friends. The event was able to reach new members and people.

## New insights into imaging

### OP0118 DEVELOPMENT OF THE EULAR RECOMMENDATIONS FOR THE USE OF IMAGING IN THE CLINICAL MANAGEMENT OF OSTEOARTHRITIS

G. Sakellariou[1], P.G. Conaghan[2], W. Zhang[3], J.W.J. Bijlsma[4], P. Boyesen[5], M.A. D'Agostino[6], M. Doherty[3], D. Fodor[7], M. Kloppenburg[8], J. Maeder[9], F. Miese[10], E. Naredo[11], M. Porcheret[12], A. Iagnocco[13]. *[1]Policlinico S. Matteo Foundation, Pavia, Italy; [2]U. of Leeds, Leeds; [3]U. of Nottingham, Nottingham, United Kingdom; [4]D. of Rheumatology & Clinical Immunology, Utrecht U. Medical Centre, Utrecht, Netherlands; [5]D. of Rheumatology, Diakonhjemmet H., Oslo, Norway; [6]U. Versailles Saint Quentin en Yvelines, AP-HP Ambroise Paré H., Boulogne, France; [7]2nd Internal Medicine D., "Iuliu Hatieganu" U. of Med. and Pharmacy, Cluj, Romania; [8]D. of Rheumatology, U. Medical Center, Leiden, Netherlands; [9]-, Zuerich, Switzerland; [10]D. of Diagnostic and Interventional Radiology, U. Duesseldorf, Duesseldorf, Germany; [11]D. of Rheumatology, H. General Universitario Gregorio Marañón, Complutense U., Madrid, Spain; [12]Res. Inst. for Primary Care and Health Sciences, Keele U., Keele, United Kingdom; [13]Ultrasound Unit, Rheumatology D., U. la Sapienza, Rome, Italy*

**Background:** The increased availability of modern imaging in clinical practice has led to its more extensive use. In the field of osteoarthritis (OA), recommendations on the use of imaging in clinical trials have been developed, but there has been less focus on routine clinical management.
**Objectives:** To develop evidence-based recommendations for the use of imaging in the clinical management of OA.
**Methods:** A task force convened by the European League Against Rheumatism including rheumatologists, radiologists, generalists, methodologists and patients from 9 countries developed recommendations based on both evidence obtained through systematic literature review (SLR) and expert opinion. The task force initially identified the areas of application of imaging in OA and developed research questions to drive the SLR. Imaging modalities included were conventional radiography, ultrasound, magnetic resonance imaging, computed tomography, radioisotope scan. Anatomical areas of interest were knee, hip, hand and foot. Based on the priorities identified by the task force, the role of imaging in making a diagnosis of OA and identifying OA features (including soft tissue, bone and cartilage involvement), in detecting alternative diagnoses, the impact of imaging on disease management, in defining prognosis (natural history of the disease and response to treatment), in the follow up of the disease and to guide treatment were addressed. Research evidence was searched systematically for each question and separately for each anatomic area using PubMed and Embase.
**Results:** The systematic review retrieved 6858 references, after the assessment of 1317 full papers, 380 studies were included. The results of the systematic review were presented to the task force, and consensus recommendations derived. These cover areas such as (exact wording not included for brevity reasons): the lack of need for imaging in diagnosis of patients who present with usual OA symptoms; role of imaging in differential diagnosis; consideration of the challenges in using imaging for routine monitoring of OA where there is no change in clinical status; what should be the feasible first choice modality and what issues were relevant to how images were acquired; how anatomical site of OA may influence use and type of imaging; and the role of imaging and intra-articular injection. Significant gaps in the literature underpinned the recommendations for future research that were also developed.
**Conclusions:** Based on the results of a SLR and expert opinion, recommendations on the use of imaging in the clinical management of OA were developed.
**Disclosure of Interest:** None declared

### OP0119 PREDICTORS OF RADIOGRAPHIC PROGRESSION IN EARLY RHEUMATOID ARTHRITIS PATIENTS TREATED BY AN AGGRESSIVE TIGHT CONTROL REGIME

N.P. Sundlisater[1], S. Lillegraven[1], I.C. Olsen[1], A.-B. Aga[1], H.B. Hammer[1], T. Uhlig[1], D. van der Heijde[2], T.K. Kvien[1], E.A. Haavardsholm[1] on behalf of the ARCTIC Study Group. *[1]Diakonhjemmet Hospital, Oslo, Norway; [2]Leiden University Medical center, Leiden, Netherlands*

**Background:** With implementation of tight control strategies and defined treatment targets in rheumatoid arthritis (RA) care, a majority of early RA patients may reach remission and traditional predictors of joint damage might no longer be present.
**Objectives:** To identify baseline parameters predictive of 2-year radiographic progression in an early RA population treated by a semi-personalized treat-to-target strategy.
**Methods:** DMARD naïve RA patients with <2 years from first swollen joint were included in the ARCTIC study. Patients were followed for 24 months with DAS, radiographs and ultrasound (32 joints, each scored 0–3 for gray-scale (GS) and power-Doppler (PD)). Patients were treated according to an aggressive algorithm with treatment target of DAS <1.6 and SJC44=0, and in half the patients, absence of ultrasound PD signal. Patients with risk factors for progressive joint destruction (ACPA or RF positive with baseline erosions, or MRI bone marrow edema) could be escalated more aggressively to biologics. Radiographs were scored by two readers using the van der Heijde-Sharp method, with cut-off ≥1 unit change/year to be classified as progression. The SDC was 1.94 units. Potential baseline predictors were analyzed for collinearity, and remaining variables (gender, age, smoking, BMI, disease duration <3 months, ACPA, RF, tender joints, 44 SJC, ESR, total GS-score, total PD-score, patient global and radiographic joint damage) assessed by univariate logistic regression. Variables with p<0.25 from the univariate analysis were included in the multivariate model building, and a p-value of <0.05 was required to remain in the model.
**Results:** Mean [SD] age of the 222 patients was 51.1 [13.7] years, disease duration 7.2 [5.4] months, and mean DAS 3.5 [1.2]. 63% were female, 72% RF and 82% ACPA positive. 92 (41%) had radiographic progression at 24 months, and 68% were in DAS remission at 24 months. In 16% of patients treatment was escalated more rapidly from MTX monotherapy to biologics due to baseline risk factors. Smoking, tender joints, 44 SJC, ESR, PD-score, age and gender had a univariate p-value<0.25 but did not remain in the final model. In the multivariate model, RF positivity (OR 2.27, p-value 0.022), total van der Heijde Sharp score (OR 1.08, p-value 0.017) and ultrasound GS score (OR 1.03 per unit, p-value 0.019) were independent baseline predictors for radiographic progression at 24 months (table).

Table 1. Multivariate model for baseline predictors of radiographic progression at 24 months. Model corrected for age and gender

| Baseline variables | Radiographic progression at 24 months (n=92/222) | | | |
|---|---|---|---|---|
| | Univariate | | Multivariate | |
| | OR [CI] | P-value | OR [CI] | P-value |
| US GS-score (0–96) | 1.03 [1.01, 1.05] | 0.005 | 1.03 [1.00, 1.05] | 0.019 |
| RF positivity (IgM/IgA) | 1.78 [0.96, 3.29] | 0.07 | 2.27 [1.13, 4.57] | 0.022 |
| Total van der Heijde Sharp score | 1.11 [1.06, 1.17] | <0.001 | 1.08 [1.01, 1.14] | 0.017 |

**Conclusions:** RF positivity, radiographic joint damage and ultrasound gray-scale score were independent baseline predictors of joint damage in early RA patients treated according to an aggressive regimen aiming for remission. This indicates that extensive individualization of treatment based on risk factors might be needed to optimize disease outcomes, also in treat-to-target strategies.

### OP0120 POST-PROCESSING TECHNIQUES FOR ENHANCED VISUALIZATION OF PULMONARY VASCULITIS AND PULMONARY THROMBOSIS BY MULTISLICE SPIRAL COMPUTED TOMOGRAPHY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

I. Leineman, R. Faizenberg, T. Golimbievskaya, M. Shostak, V. Mazurov. *North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation*

**Background:** Ground-glass opacification (GGO) is a common but non-specific radiological pattern on multislice spiral computed tomography (MSCT) scans which can refer to the interstitial or vascular involvement. Due to polymorphism of pulmonary pathology in patients with systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS) GGO requires a multi-stage differential diagnosis the result of which will significantly affect the treatment regimen - a choice between antibiotic or cytostatic and high-dose hormonal therapy.
**Objectives:** The aim of this study was to optimize the ability of MSCT for differentiating between interstitial and vascular involvement and detecting pulmonary thrombosis using newly developed post-processing techniques.
**Methods:** 120 patients, aged 39.5 ± 13.7, with moderate-severe lupus activity were administrated a complex of laboratory, pulmonary function and imaging tests. It is the first time when post-processing techniques (PPTs) such as MPR (Multiplanar reformations), MIP (Maximum intensity projection), mIP (Minimum intensity projection) and especially color mapping were used for evaluation of vascular involvement on native MSCT scans of patients with SLE and APS. The criteria of pulmonary vasculitis on color maps were described as enhanced peripheral vascularization (vessel caliber enlargement and increase in vessel tortuosity) and perivascular edema. The criteria of pulmonary thrombosis - areas of micro-infarctions in the peripheral regions of lungs. CT angiography and pulmonary perfusion scintigraphy were chosen as methods of gold standard. Reconstructed scans were compared with native CT scans, CT angiograms and perfusion scans done by three diagnosticians.
**Results:** Statistics showed that the mean area under the receiver operating characteristic curve value increased significantly from 0.713 without the PPTs

to 0.925 with the PPTs ($P<0.05$) in differentiating between vasculitis and pneumonic infiltration and increased significantly from 0.527 without the PPTs to 0.724 with the PPTs ($P<0.05$) in detecting thrombosis. Compared with CT angiogram and perfusion scans no differences in the involved regions were detected. Variants that were associated with enhanced peripheral vascularization on color maps in a significant manner were: rate of diffusion capacity (p=0.006), hypocomplementemia (p=0.01), hypoxemia (p=0.003), pulmonary hypertension (p=0.01). The presence of lupus anticoagulant in patients with SLE was associated with the development of pulmonary thromboembolism (p=0.001) and pulmonary vasculitis complicated with thrombosis in situ (p=0.04).

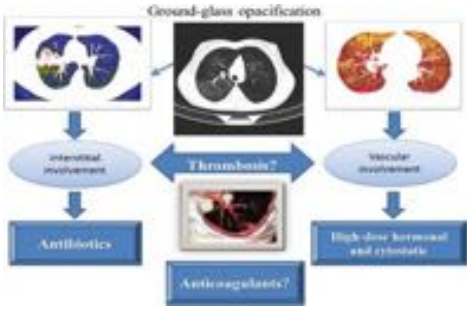

Image 1. Multi-stage differential diagnosis of GGO in patients with SLE and APS using PPTs.

**Conclusions:** PPTs are a useful addition to native MSCT scans in detecting early signs of pulmonary vasculitis, differentiating between vasculitis and pneumonic infiltration and evaluation of treatment-related changes. It equips radiologists to more easily detect areas with thrombosis especially thrombosis in situ due to pulmonary vasculitis.
**Disclosure of Interest:** None declared

## OP0121 SAFETY, TOLERABILITY AND FEASIBILITY OF MINIMALLY INVASIVE ULTRASOUND-GUIDED SYNOVIAL BIOPSY OF WRIST AND METACARPOPHALANGEAL JOINTS - AN ULTRASOUND FOLLOW-UP STUDY

L. Meric de Bellefon [1], P. Durez [1], C. Galant [2], A. Avramovska [1], A. Nzeusseu [1], B. Lauwerys [1], F.A. Houssiau [1], M.S. Stoenoiu [1]. *[1]Rheumatology; [2]Pathology, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

**Background:** Synovitis is the common feature of patients suffering from inflammatory arthropathies (IA). The development of ultrasound (US)-guided synovial biopsy will enable synovial tissue collection from small joints and will facilitate molecular studies, thus improving the understanding of mechanisms of IA as small joints are frequently involved in these diseases.
**Objectives:** To assess the safety, tolerability and feasibility to perform synovial biopsies from wrist and metacarpophalangeal (MCP) joints, using a minimally invasive US-guided technique in patients suffering from rheumatoid arthritis (RA), spondylarthropathies (SA) or undifferentiated arthritis (UA).
**Methods:** Two target joints (TJ) were biopsied: wrist and MCP. Patients with at least one clinically swollen joint at these levels, suffering from RA, SA, or UA underwent a US examination. The TJ chosen for the biopsy was the joint with the most important inflammatory changes on gray-scale (GS) US. GS synovitis and power-Doppler (PD) activity were assessed by OMERACT scores, on the day of the biopsy, as well as 2 weeks (w), 6w and 6 months (m) after the biopsy. In addition, tendon tears, hematoma, paratenonitis and tenosynovitis were searched by US. Patient-reported outcomes (PRO) included a standard questionnaire given to all patients on the day of the biopsy as well as 1w, 2w, and 6w after the biopsy. Tolerability and the patient-reported willingness to repeat the procedure was assessed using the 5-point Likert scale.
**Results:** Forty-one patients suffering from RA (27), SA (7) and UA (7) underwent US-guided biopsy of the wrists (20) and MCP (21) joints. A non-significant increase in pain was reported 24 h after the procedure. No difference in PRO of the biopsied joints was reported 2w and 6w after the biopsy, as compared to assessment before the biopsy. No infection or haemorrhage was observed after the biopsy. PRO did not differ significantly among patients suffering from RA, SA or UA. At the TJ, US scores tended to decrease 2w after the procedure. At 6w and 6m follow-up, no safety concerns were reported. Treatment response at the TJ was similar to the response of non-biopsied joints matched for the baseline US parameters.
**Conclusions:** With the exception of study of Kelly et al (Ann Rheum Dis. 2015;74:611–6117), data on safety, tolerability, feasibility and PRO using the minimally invasive US-guided biopsy technique are lacking. In this work, we confirm that US-guided biopsy of wrist and MCP joints is feasible, safe and well tolerated by RA patients. At 2w, 6w and 6m follow-up, no safety concerns were reported. Furthermore, no differences in PRO between RA, SA and UA were observed. This technique is therefore a promising approach to assess the presence and persistency of synovial inflammatory processes in patients with early and refractory IA, and to facilitate patients stratification according to transcriptomic profiles.

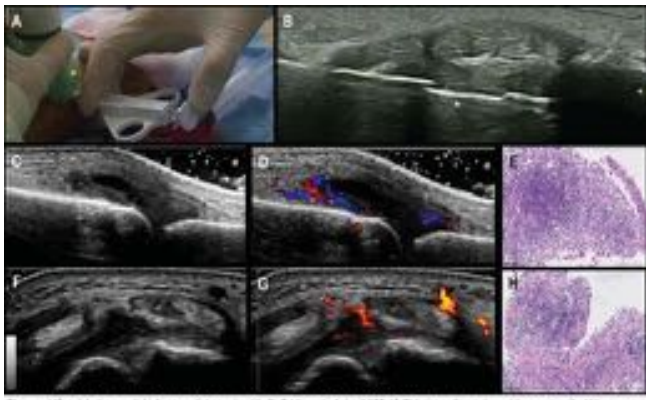

Figure. US-guided synovial biopsy of the wrist (A, B, F-H) and of the MCP (C-E) joints. Synovium biopsy needle (A) as seen with US (B) at the wrist level. A guillotine-type needle with an open throw (*) is used to cut the tissue. Prior to biopsy, MCP (C, D) synovitis is depicted by GS-US (C) and by color Doppler-US (D). Wrist synovitis (F, G) is depicted by GS-US and by PD-US (G). Histological images (E and H) of the corresponding GS-US (C and F) and Doppler US (D and G) images showing (*)oo, vessel proliferation and strong inflammatory infiltrates in the synovial sublining.

**Acknowledgement:** We acknowledge Pr C. Pitzalis and S. Kelly for giving us the opportunity to learn and further disseminate minimally invasive ultrasound-guided technique, and for fruitful discussions.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.5386

## OP0122 INTER-READER AND INTRA-READER RELIABILITY OF THE NEW OMERACT ULTRASONOGRAPHIC CRITERIA FOR THE DIAGNOSIS OF CPPD

G. Filippou [1], C.A. Scirè [2], N. Damjanov [3], A. Adinolfi [1], G. Carrara [2], V. Picerno [1], C. Toscano [1], G. Bruyn [4], M.A. D'Agostino [5], A. Delle Sedie [6], E. Filippucci [7], M. Gutierrez [8], M. Micu [9], I. Moller [10], E. Naredo [11], C. Pineda [8], F. Porta [12], W.A. Schmidt [13], L. Terslev [14], V. Vlad [15], P. Zufferey [16], B. Frediani [1], A. Iagnocco [17] on behalf of OMERACT group "US in CPPD". *[1]University of Siena, Siena; [2]SIR Epidemiology Unit, Milan, Italy; [3]University of Belgrade, Belgrade, Serbia; [4]Department of Rheumatology, MC Groep, Lelystad, Netherlands; [5]Université Versailles Saint-Quentin en Yvelines, Paris, France; [6]University of Pisa, Pisa; [7]Università Politecnica delle Marche, Jesi, Italy; [8]Instituto Nacional de Rehabilitación, Mexico City, Mexico; [9]Rehabilitation Clinical Hospital, Cluj-Napoca, Romania; [10]InstitutoPoal, Barcelona; [11]Hospital GU Gregorio Marañón, Madrid, Spain; [12]University of Florence, Florence, Italy; [13]Immanuel Krankenhaus Berlin, Berlin, Germany; [14]Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen, Denmark; [15]Sf. Maria Hospital, Bucharest, Romania; [16]Lausanne University Hospital, Lausanne, Switzerland; [17]Università la Sapienza, Rome, Italy*

**Background:** Ultrasonography (US) has been implemented recently as a possible diagnostic method for CPPD [1]. However, data on the reliability of US in CPPD diagnosis are lacking
**Objectives:** To assess the inter-reader and intra-reader reliability of US on detecting CPP deposition in fibrocartilage (FC), hyaline cartilage (HC), tendons (T) and synovial fluid (SF)
**Methods:** The OMERACT "US in CPPD" group defined firstly the US CPPD identification criteria according to methods described in an another abstract submitted in this congress. Subsequently, a two steps procedure for the assessment of the reliability has been followed. Firstly, the panel gave a dichotomous score on the presence absence of CPPD in 150 photos of FC, HC, T and SF equally distributed, on a web based platform. The assessment has

| Section | K inter-reader I round | K inter-reader II round | K intra-reader |
|---|---|---|---|
| | WEB based exercise | | |
| Fibrocartilage | 0.58 | 0.58 | 0.80 |

been carried out twice in order to calculate both inter and intra-reader reliability. In the second step, the experts met for a real life-patient based assessment of CPPD in a workshop organised in Siena-Italy. In that occasion, FC/HC/T/SF of the right knee and FC and SF of the right wrist of 8 patients were assessed twice in a day by all experts giving again a dichotomous score for CPPD. 8 US scanners (ESAOTE mylab seven) equipped with the same probe and the same preset (made ad hoc before the meeting), have been used for the workshop.
**Results:** Reliability values of the web based exercise and of the workshop are presented in table 1. Tendons and synovial fluid analysis did not reach sufficient strength of agreement neither on the web based nor in the patient based exercise regarding the inter-reader kappa and independently of the site. However, in the static exercise, both tendons and SF reached a good intra-reader reliability meaning that scanning technique of these structures is very important for CPPD identification. On the other hand, menisci (but not triangular FC of the wrist) and HC reached good kappa values for inter-reader and intra-reader agreement both on static and web-based exercise
**Conclusions:** Knee cartilage and fibrocartilage structures resulted to be reliable enough for identification of CPPD. On the other hand, CPPD identification in tendons and synovial fluid is challenging and the actual OMERACT criteria for these sites do not ensure a safe classification of patients.
OMERACT US criteria for CPPD identification in knee menisci and HC allow a reliable classification of patients and should be used when CPPD is suspected.

## OP0123 MRI-DETECTED INFLAMMATION IS ASSOCIATED WITH FUNCTIONAL DISABILITY IN EARLY ARTHRITIS

L.E. Burgers[1], W.P. Nieuwenhuis[1], H.W. van Steenbergen[1], E.C. Newsum[1], T.W.J. Huizinga[1], M. Reijnierse[2], S. le Cessie[3], A.H.M. van der Helm-van Mil[1].
*[1]Rheumatology; [2]Radiology; [3]Medical Statistics and Clinical Epidemiology, Leiden University Medical Centre, Leiden, Netherlands*

**Background:** MRI sensitively detects inflammation, but the clinical relevance of MRI-detected inflammation is undetermined in early arthritis. Therefore, this cross-sectional study investigated the association between MRI-detected inflammation of hands and feet and functional disability in early arthritis.
**Methods:** 514 early arthritis patients, consecutively included in the Leiden Early Arthritis Clinic, were studied. At baseline, unilateral 1.5T MRI of the wrist, metacarpophalangeal (MCP) and metatarsophalangeal-joints was made and functional disability was measured using the Health Assessment Questionnaire (HAQ). MRIs were scored for bone marrow oedema (BME), tenosynovitis and synovitis by two readers. The sum of these three features yielded the total MRI-inflammation score. Linear and non-linear regression analyses were performed with HAQ as dependent variable.
**Results:** The total MRI-inflammation score was associated with the HAQ-score ($\beta$=0.014, $p<0.001$), as were BME ($\beta$=0.015, $p<0.001$), tenosynovitis ($\beta$=0.046, $p<0.001$) and synovitis ($\beta$=0.039, $p<0.001$) separately. Analysing these three MRI-features in one multivariable model, revealed that only tenosynovitis was independently associated with HAQ-score ($\beta$=0.039, $p<0.001$). Also when correcting for age, gender, joint counts, acute phase reactants and auto-antibodies this association remained ($\beta$=0.034, $p<0.001$). MRI-detected inflammation at wrists or MCP-joints associated significantly with impairments in hand functioning (e.g. difficulties with opening milk cartons or jars). Exploring the relation between MRI-detected inflammation and HAQ-scores non-linear, suggested the presence of a ceiling effect, because after a certain inflammation-level, more inflammation was not associated with higher HAQ-scores.
**Conclusions:** MRI-detected inflammation, and tenosynovitis in particular, is associated with functional disability. This demonstrates the functional relevance of MRI-detected inflammation in early arthritis patients.

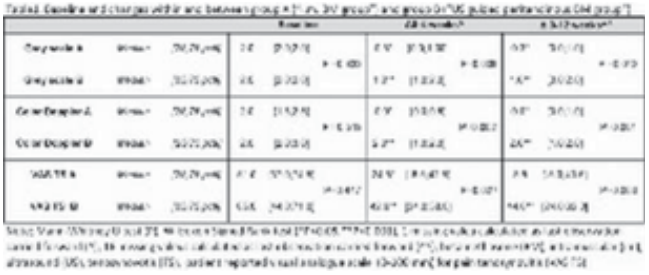
## OP0124 IMAGING REMISSION BY MUSCULOSKELETAL ULTRASOUND LEADS TO A BETTER FUNCTIONAL OUTCOME – RESULTS OF THE US IMPERA STUDY - US 7-SCORE IMPLEMENTATION STUDY IN EARLY RHEUMATOID ARTHRITIS

A.-M. Glimm[1], S. Ohrndorf[1], I. Fischer[2], J. Strunk[3], W. Schmidt[4], W. Hartung[5], H. Sattler[6], H. Kellner[7], G. Schmittat[8], G.-R. Burmester[8], M. Backhaus[8].
*[1]Department of Rheumatology and Clinical Immunology, Charité University Medicine Berlin, Berlin; [2]Biostatistik Tuebingen, Tuebingen; [3]Hospital "Porz am Rhein", Cologne; [4]Immanuel Krankenhaus Berlin, Medical Center for Rheumatology, Berlin; [5]Asklepios Klinikum Bad Abbach, Bad Abbach; [6]Parkklinik Bad Dürkheim, Bad Dürkheim; [7]Hospital Neuwittelsbach, Munich; [8]Charité University Medicine Berlin, Berlin, Germany*

**Background:** Novel treatment options together with a treat-to-target strategy present new challenges to imaging procedures in terms of therapy monitoring.
**Objectives:** To evaluate the functional outcome measured by Health Assessment Questionnaire (HAQ) as the primary outcome in patients with early rheumatoid arthritis (RA) who were treated by standard clinical care (clinical cohort) in comparison to patients in whom treatment decisions were additionally based on musculoskeletal ultrasound (US) using the US7 score (US-cohort) in a nationwide investigator initiated study in Germany.
**Methods:** Functional (HAQ), clinical (DAS28, patient's Visual Analogue Scale [VAS] for disease activity) and laboratory parameters (erythrocyte sedimentation rate [ESR], C-reactive protein [CRP]) were analyzed at seven different time points for a total of 18 months and compared between the two study cohorts. Treatment decision was made according to local standard of care (SOC) with a treatment goal of DAS28 <3.2. In the US-cohort, imaging remission criteria were defined as Gray-scale US (GSUS) <2 and Power Doppler-US (PDUS) =0 per joint level. In a subgroup analysis, US patients were analyzed separately with regard to imaging remission status and the parameters outlined above.
**Results:** Data of 313 patients (US-cohort [n=166], clinical cohort [n=147]) demonstrated a reduction of HAQ, DAS28, VAS and laboratory activity (ESR, CRP) to a low disease activity status 18 months after the beginning/change of antirheumatic therapy according to SOC (table 1). The results of functional and clinical outcome in both cohorts did not show significant differences. However, subgroup analysis of the US-cohort with imaging remission resulted in a significantly lower HAQ, DAS28 and VAS compared to patients not fulfilling these US remission criteria (table 1).

| | | HAQ | DAS28 | ESR (mm/h) | CRP (mg/l) | Patient's VAS (mm) |
|---|---|---|---|---|---|---|
| **Baseline** | | | | | | |
| Total population (n=313) | Clinical cohort (n=147) | 1.020 | 5.1 | 33.1 | 23.0 | 56.9 |
| | US-cohort in total (n=166) | 1.050 | 5.2 | 29.3 | 17.2 | 57.3 |
| | | p=0.600 | p=0.596 | p=0.194 | p=0.073 | p=0.998 |
| Subgroup analysis of US-cohort (n=166) | Non-remission group (n=87) | 1.120 | 5.3 | 32.2 | 20.6 | 57.1 |
| | Remission group (n=79) | 0.971 | 5.1 | 26.2 | 13.7 | 57.4 |
| | | p=0.200 | p=0.316 | p=0.182 | p=0.272 | p=0.945 |
| **Month 18** | | | | | | |
| Total population (n=313) | Clinical cohort (n=147) | 0.555 | 2.8 | 18.1 | 6.4 | 26.7 |
| | US-cohort in total (n=166) | 0.579 | 2.8 | 16.6 | 6.4 | 25.6 |
| | | p=0.758 | p=0.800 | p=0.174 | p=0.585 | p=0.397 |
| Subgroup analysis of US-cohort (n=166) | Non-remission group (n=87) | 0.741 | 3.4 | 18.4 | 7.8 | 33.9 |
| | Remission group (n=79) | 0.481 | 2.2 | 14.6 | 4.6 | 16.6 |
| | | p=0.002* | p=0.001* | p=0.406 | p=0.089 | p<0.001* |



*p<0.05 for significant difference

**Conclusions:** Treatment strategies by a treat to target approach in early RA patients reduced disease activity and improved functional outcome of HAQ irrespective of imaging guidance. However, patients with imaging remission by US exhibited a significantly better functional outcome and lower disease activity status. Accordingly, an additional ultrasound examination aiming at imaging remission should be strongly considered in clinical practice.

OP0125 **A RANDOMISED, DOUBLE-BLIND, CONTROLLED STUDY OF INTRAMUSCULAR VERSUS ULTRASOUND GUIDED PERITENDINOUS BETAMETHASONE INJECTION FOR TENOSYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS**

M. Ammitzbøll-Danielsen[1], M. Østergaard[1], V. Fane[1], D. Glinatsi[1], U.M. Døhn[1], L.M. Ørnbjerg[1], E. Naredo[2], L. Terslev[1]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [2]Department of Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

**Background:** Intra-articular glucocorticoid (eg. betamethasone (BM)) injections are commonly used during flares in rheumatoid arthritis (RA)[1]. Currently, evidence on the best approach to treat tenosynovitis (TS) is lacking.
**Objectives:** To compare the effect of intramuscular (im) and ultrasound (US) guided peritendinous BM injection for TS in RA patients, after 4 and 12 weeks.
**Methods:** Fifty RA patients with TS were randomised into two double-blinded groups: Group A ("i.m. BM group") received im injection of 14 milligrams (2 ml) of BM and US-guided saline injection in up to two tendon sheaths (maximum 1 ml saline for each tendon sheath) and group B ("US guided peritendinous group") received 2 ml of saline im and US guided BM injection in up to two tendon sheaths (maximum 7 milligrams (1 ml) of BM for each tendon sheath). All patients were in stable anti-inflammatory treatment prior to and during the study. Patients were excluded, and considered non-responders, if treatment changes were made during the follow-up period. TS was assessed at baseline, 4 and 12 weeks using the semi-quantitative scoring system for Grey scale (GS) (0–3) and Colour Doppler (CD) (0–3) proposed by the OMERACT US group and a patient reported visual analogue scale (0–100 mm) for pain TS (VAS TS). If two tendon sheaths were treated, the mean score was used for statistical calculation. For US assessment a GE Logiq E9 US unit with a high frequency linear 6–15 ML probe and CD settings according to published recommendations were used. The predefined primary outcome was a US-TS GS score $\leq$1 and CD score =0, at week 4, with a non-responder imputation (NRI) used for missing data. The same outcome was used at week 12, with a NRI used for missing data.
**Results:** Forty-nine patients received treatment, 24 in group A and 25 in group B. The completion rate for group A/B was 23/25 at 4 weeks and 15/18 at 12 weeks. There was no significant baseline difference between the groups, except that two tendon sheaths were injected more often in group A (10) compared to B (3). The chance of achieving the primary outcome at week 4 was 0.25 (95% Confidence limits; 0.08; 0.42) in group A and 0.64 (0.45; 0.83) in group B and for 12 weeks 0.08 (0.00; 0.19) in group A and 0.40 (0.21; 0.59) in group B (Chi-Square; 4 weeks =0.008; 12 weeks =0.020). Likewise VAS TS showed significant better response in group B versus group A (Mann-Whitney U test; 4 weeks =0.027; 12 weeks =0.003). Baseline values and 4 and 12 weeks changes for GS, CD and VAS TS are presented in table 1.

**Conclusions:** In a randomized double-blind clinical trial, RA patients with tenosynovitis responded significantly better to US guided peritendineus glucocorticoid injection compared to i.m. glucocorticoid injection, both at 4 and 12 weeks, both when assessed by US and patient-reported outcomes.

## Advancements in the imaging of PsA

OP0126 **DUAL ENERGY CT WITH IODINE MAP IS PROMISING NEW IMAGING MODALITY IN THE EVALUATION OF HAND PSORIATIC ARTHRITIS**

T. Fukuda[1], Y. Umezawa[2], S. Tojo[1], T. Yonenaga[1], A. Asahina[2], H. Nakagawa[2], K. Fukuda[1]. *[1]Department of Radiology; [2]Department of Dermatology, The Jikei University School of Medicine, Tokyo, Japan*

**Background:** Magnetic resonance (MR) imaging allows to visualize inflammatory lesions of psoriatic arthritis (PsA). However, evaluation of the small joints of the hands remains a challenge. CT has a high spatial resolution, therefore it is suitable to evaluate small structures. In spite of this advantage, CT usage in inflammatory arthritis has been limited because of its poor contrast resolution. However, iodine map, the amount of iodine distribution in each voxel, can be created by the so-called three material decomposition from imaging data obtained with Dual-Energy CT (DE-CT)[1)]. Because DE-CT with iodine map has both high spatial resolution and high iodine contrast resolution, we hypothesized this technic can be useful in evaluation of inflammatory lesions of PsA
**Objectives:** To assess the feasibility of DE-CT with iodine map in the evaluation of hand PsA
**Methods:** Materials were 16 (11 male 5 female) consecutive psoriasis patients with finger joint symptoms. All patients fulfilled CASPER criteria. The Patients were scheduled for both contrast enhanced DE-CT and contrast enhanced MR imaging within 1 month. There was no therapeutic intervention between 2 examinations. Images were evaluated by 2 radiologists independently under blinded to clinical data and other images. For evaluation of both DE-CT and MR imaging, we modified the OMERACT Psoriatic Arthritis Magnetic Resonance Imaging Scoring System (PsAMRIS)[2)]. For inflammatory lesions (synovitis, flexor tenosynovitis, and extensor peritendinitis) graded as 0–3 and bone erosion graded as 0–10, inter-reader agreement was calculated with using weighted $\kappa$. For other inflammatory lesion (periarticular inflammation) and structural change (bone proliferation), which were scored as grade 0–1, inter-reader agreement was calculated with using $\kappa$. With using consensus score, sensitivity and specificity of DE-CT for inflammatory lesions were calculated with MR imaging as gold standard. As for structural changes, we used DE-CT as gold standard and calculated sensitivity and specificity of MR imaging.
**Results:** Inter-reader agreement of inflammatory lesions were good or very good (weighted $\kappa$=0.83 and $\kappa$=0.75 in DE-CT, weighted $\kappa$=0.81 and $\kappa$=0.87 in MR imaging). Although inter-reader agreement of MR imaging for bone proliferation was moderate ($\kappa$=0.44), it was good (weighted $\kappa$=0.77) for bone erosion. Inter-reader agreement of CT for structural changes were good ($\kappa$=0.66) for bone proliferation and very good (weighted $\kappa$=0.84) for bone erosion. Sensitivity and specificity of DE-CT for inflammatory lesions were 0.78 and 0.87. However, DE-CT detected 134 various inflammatory lesions which were not observed on MR imaging, out of 1120 evaluated inflammatory items. Of these 134 lesion, 69% (93/134) was located in the DIP joints. About structural changes, MR imaging had poor sensitivity (0.30) and high specificity (0.99).

**Conclusions:** DE-CT with iodine map has found to be a useful new imaging modality to evaluate PsA of hands, and may have higher detection capability of small joint inflammatory lesions compared with MR imaging.

### OP0127 LOW FREQUENCY OF US DETERMINED EROSIONS IN EARLY PSORIATIC ARTHRITIS: RESULTS FROM THE LEEDS SPARRO COHORT

M. Merashli[1,2], G. De Marco[3], P. Helliwell[1], L. Horton[3], M.A. D'agostino[4], D. Mcgonagle[2], R. Wakefield[1], J. Freeston[2], H. Marzo-Ortega[2]. *[1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK, Leeds, United Kingdom; [3]Rheumatology, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, UK, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK, Rheumatology Department, APHP, Hôpital Ambroise Paré, and Versailles-Saint-Quentin University, Saint-Quentin en Yvelines, France., Leeds, United Kingdom*

**Background:** Ultrasound (US) is playing an increasingly important role in the early evaluation of psoriatic arthritis (PsA) being capable of detecting inflammatory changes at the enthesis, synovium and extra capsular tissues. Peri-articular radiographic erosions in PsA and rheumatoid arthritis are associated with a worse outcome. Further, US is shown to be a more sensitive imaging technique than conventional radiography (CR) to identify erosions in early RA. By contrast, there is a paucity of data in the literature on the prevalence of erosions and/or the capability of US to detect erosions in early PsA.
**Objectives:** To assess the prevalence of erosions in early PsA using CR and high resolution US.
**Methods:** We studied 860 joints of 43 patients (Table 1) with early PsA, all fulfilling CASPAR criteria from the Leeds Spondyloarthropathy Register for Research and Observation study (SpARRO) which is a prospective longitudinal observational cohort of patients with early spondyloarthritis. Radiographic and sonographic erosions of the wrists, MCPs (2, 3), PIPs (2, 3), and MTPs (1–5) bilaterally were independently evaluated. We looked at the frequency of erosions using both imaging methodologies. CR and US scoring systems used for defining erosions were the van der Heijde version of the Sharp and OMERACT respectively.
**Results:** Erosions were identified in a total of 8 patients, all negative for RF and CCP antibodies; 40% (3/8) of whom were ex-smokers. Four patients had six erosions at MTP4, MTP5, and PIP3 by CR whilst six patients had six erosions on US. The exact agreement between the 2 methods was 99%. Agreement on absence of erosions in both CR and US was 99% while agreement on their presence was 17%. The proportions of joints where the CR and US disagreed in either direction (US>XR, US

Table 1. Baseline clinical characteristics of the 43 patients

| | |
|---|---|
| Age, mean ± SD years | 42±13 |
| Female to male ratio | 1.5 |
| RF positive | 1/43 |
| CCP positive | 1/43 |
| Symptom disease duration in months, median (IQR) | 12 (6–25) |
| Disease pattern | |
| Asymmetrical | 29/43 |
| Symmetrical | 14/43 |
| Polyarthritis | 32/43 |
| Oligoarthrtis | 11/43 |
| SJC , median (IQR) | 2 (0–6) |
| TJC, median (IQR) | 7 (4–18) |
| Dactylitis at presentation | 19/43 |
| MASES at presentation, median (IQR) | 1 (0–3) |
| Nail psoriasis at presentation | 21/43 |
| PASI, median (IQR) | 2 (1–5) |
| Psoriasis at presentation | 39/43 |
| Medications at presentation | 22 (No treatment), 17 (NSAIDs only), 1 (Methotrexate), 1 (Prednisolone), 2 (Non-biologic DMARD+NSAID) |

**Conclusions:** In keeping with the emerging data in PsA, these results show a low frequency of erosions at clinical presentation on CR. Unlike studies in early RA, in this preliminary study of early PsA the burden of erosive disease detected using US was not measurably different.

## When and how to treat Raynaud's phenomenon and related complications

### OP0128 EVALUATION OF PERIPHERAL BLOOD PERFUSION BY LASER SPECKLE CONTRAST ANALYSIS IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH AMINAPHTONE

B. Ruaro, C. Pizzorni, A.C. Trombetta, S. Paolino, E. Bernero, M. Cutolo, A. Sulli. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy*

**Background:** Both primary (PRP) and secondary Raynaud's phenomenon (SRP) are characterized by impairment of the microvascular system, with clinical symptoms related to decreased peripheral blood perfusion (1,2). Different treatments are available to manage digital vasculopathy (3). Aminaphtone seems to downregulate endothelin-1 production in endothelial cells, and ameliorates RP symptoms (4,5). Laser speckle contrast analysis (LASCA) is a validated technique to assess blood perfusion (2).
**Objectives:** To evaluate short-time effects of aminaphtone treatment on blood perfusion by LASCA technique in patients affected by PRP or SRP.
**Methods:** Thirty-five patients with active RP were enrolled during routine clinical assessment in November 2015 (26 SRP, mean age 64±17 SD years, mean RP duration 10±7 years; 9 PRP, mean age 49±21 SD years, mean RP duration 5±3 years). Aminaphtone 75 mg twice daily was administered in addiction to current treatments (patients were on stable drug regimen from at least two months, and did not modify it during follow-up). Blood perfusion was assessed in all patients by LASCA at baseline (T0), after one (T1) and four weeks (T4) of treatment, at the level of fingertips, periungual areas, dorsum and palm of hands, tip of noise, zygoma, forehead, and perioral regions. Blood perfusion was calculated as perfusion units (PU) (2). Raynaud condition score (RCS), Raynaud's attach frequency and duration were also assessed at the same times.
**Results:** A progressive statistically significant increase of blood perfusion was observed from T0 to T4 in all skin areas (median PU at T0, T1, T4 respectively: fingertips 56, 93, 108; periungual areas 44, 81, 90; dorsum of hands 38, 64, 73; palm of hands 60, 85, 99; tip of noise 95, 114, 124; zygoma 134, 140, 150; forehead 113, 117, 130; perioral region 138, 144, 149; whole face 121, 132, 143. $p<0.0001$ for all areas). In particular, all patients treated with aminaphtone showed an increase of blood perfusion from T0 to T1, and 30 out of 35 patients had a further increase of blood perfusion from T1 to T4. A progressive statistically significant decrease of RCS (median at T0, T1, T4: 7, 6, 4) Raynaud frequency (median at T0, T1, T4: 2, 2, 1 attacks/day) and duration (median at T0, T1, T4: 20, 20, 10 minutes) was also observed from T0 to T4 ($p<0.0001$). The results were similar for both PRP and SRP. Two patients had to stop the drug due to headache.
**Conclusions:** This study demonstrates that the therapy with aminaphtone seems to increase in short-time and maintain skin blood perfusion, as well as seems to improve RP symptoms. Larger studies might further confirm the role of aminaphtone in the treatment of RP secondary to systemic sclerosis.

### OP0129 NAILFOLD CAPILLAROSCOPY IN RHEUMATOLOGY PRACTICE - A SINGLE CENTER EXPERIENCE

L.C. Teixeira, I. Cordeiro, J. Canas da Silva, M.J. Santos, A. Cordeiro. *Rheumatology, Hospital Garcia de Orta, Almada, Portugal*

**Background:** Nailfold capillaroscopy (NCP) is an easy, non-invasive and useful tool for the diagnosis and follow-up of Systemic Sclerosis (SSc) and other systemic rheumatic diseases.
**Objectives:** To present our single center experience with NCP, describing the main reasons for NCP request, and the major abnormalities detected in capillaroscopy.
**Methods:** Retrospective analysis of patients submitted to NCP assessment, from January 2013 to December 2015 in our center. We collected reasons for NCP request, demographic and clinical data, autoimmunity profile and NCP results.
**Results:** A total of 221 NPC, corresponding to 197 patients, 167 females (84.8%) and 30 males (15.2%) aged from 9 to 90 years were reviewed. One hundred and thirty eight (62.4%) patients had no definitive diagnosis, 53 patients (24%) had SSc, 7 (3.2%) had mixed connective tissue disease, 3 (1.4%) had dermatomyositis/polymyositis (DM/PM), and 3 (1.4%) antiphospholipid syndrome (APS).
Raynaud's phenomenon (RP) alone was the most frequent reason for requesting NCP (33% of the cases), and combined with ANA positivity accounted for another 30.8% of the requests. RP was present in 73.3% of the patients, acrocyanosis in 16.3%, livedo reticularis and puffy hands accounted for 8.6% each one.

Anti-nuclear antibodies (ANA) were positive in 59.7%, anti-centromere antibodies were present in 21.3%, anti-topoisomerase I and SSA/SSB in 5.1% of the cases. One hundred and fifty nine (71.9%) NCP were considered abnormal. The most frequent specific disease pattern was the early one (Cuttolo) in 15%. The most frequent findings were: capillary tortuosity in 112 (71.8%) cases, capillary dilatations in 95 (60.9%), and hemorrhages in 85 (54.5%). NCP was abnormal in 79.4% of patients with RP and ANA, 41.2% of them displaying specific findings of rheumatic diseases (Table 1).
In SSc patients the late and the early pattern (Cuttolo) were the most frequent, present in 15 and 13 NCP, respectively. Concerning specific NCP findings capillary dilatations (81%), hemorrhages (73.6%) and megacapillaries (71.7%) were the most frequent (Table 2).
Of the 138 cases without definitive diagnosis, 61. 6% had abnormal NCP, although mostly with non-specific patterns (50%). In 10 (7.2%) patients NCP helped to establish the diagnosis: VEDOSS (Very Early Diagnosis of Systemic Sclerosis) in 6, antiphospholipid syndrome in 3 and DM in one case.

| Reasons for requesting NCP / NCP results | Isolated RP N=73 | ANA positive N= 23 | RP + ANA N= 68 | Other reasons N= 57 |
|---|---|---|---|---|
| Normal (%) | 38.4 | 26.1 | 20.6 | 26.7 |
| Abnormal (%) | 61.6 | 73.9 | 79.4 | 73.3 |
| NCP with pathologic findings (%)* | 13.7 | 17.4 | 41.2 | 30 |

Table 1 – Relationship between the reasons why the clinicians asked a NCP (Nailfold capillaroscopy) and results of the exam. *Diseases specific NCP findings, detected in the abnormal capillaroscopy group.

| Diseases | SSc N=53 | MTCD N=7 | Sjogren S N=5 | RA N=4 | DM/PM N=3 |
|---|---|---|---|---|---|
| NCP findings | capillary dilatations (81%) | capillary dilatations (80%) | Capillary dilatations (80%) | Capillary tortuosity (75%) | Capillary dilatations (80%) |
| | Hemorrhages (73.6%) | Hemorrhages (80%) | neoagiogenesis (60%) | megacapillaries (50%) | Hemorrhages (80%) |

Table 2 – Most frequent NCP findings in Systemic sclerosis (SSc), Mixed connective tissue disease (DMTC), Primary Sjogren Syndrome (Sjogren S.), Rheumatoid arthritis (RA) and Dermatomyositis/Polymyositis (DM/PM) patients.

**Conclusions:** In our experience, NCP was helpful for the diagnosis of rheumatic systemic disease. Specific NCP findings were more frequent in patients with RP + ANA positivity, suggesting that this combination is associated with more disease incidence. Patients with isolated RF had less pathologic NCP findings than those with isolated. ANA positivity. The prospective follow up of those patients with abnormal NCP and no definitive diagnosis will help to establish the predictive value of observed alterations.

## Role of new imaging techniques as RMD outcomes -

### OP0130 RADIOGRAPHIC AND MAGNETIC RESONANCE IMAGING MARKERS PREDICT CARTILAGE VOLUME LOSS AND KNEE SYMPTOMS OVER 10.7 YEARS IN OLDER ADULTS

B.S. Eathakkattu Antony[1], X. Jin[1], X. Wang[1], W. Han[1], Z. Zhu[1], F. Cicuttini[2], C. Ding[1], G. Jones[1]. *[1]Menzies Institute for Medical Research, University of Tasmania, Hobart; [2]Epidemiology, Monash University, Melbourne, Australia*

**Background:** There are no long-term studies that describe the independent association of radiographic and magnetic resonance imaging (MRI) based markers and cartilage volume loss and knee symptoms in population-based older adults.
**Objectives:** To describe whether radiographic (joint space narrowing (JSN) and osteophytes) and MRI-based (cartilage defects, bone marrow lesions (BMLs), meniscal tears and meniscal extrusion) measures predict long-term cartilage volume loss and knee symptoms over 10.7 years.
**Methods:** 983 participants (mean age 62.8 years, 50% female) were randomly recruited from the local community of Tasmania and followed up at 2.6 years, 5.1 years and 10.7 years later. Osteophytes and JSN were assessed using OARSI atlas. A 1.5T MRI scan of the right knee was acquired at baseline (n=930), 2.6 years (n=399) and 10.7 years (n=484). Tibial and patellar cartilage volume was acquired using a manual segmentation method on the T1-weighted fat-saturated 3D GRE images. Cartilage defects were assessed on T1-weighted MRI using a modified Outerbridge scoring system (grade 0–4). BMLs were measured on T2-weigthed fat saturated FSE images using a modified Whole-Organ MRI scoring system (grade 0–3). Meniscal extrusion (grade 0–2) and meniscal tears (grade 0–3) were measured using the T1- and T2-weighted MRI. Analyses were performed using linear mixed-effects models for symptoms and linear regression for cartilage volume loss.
**Results:** After adjustment for age, sex, BMI and radiographic KOA status, cartilage defects and BMLs were associated with total WOMAC score ($\beta$=4.81, $p<0.01$ and $\beta$=2.20, $p<0.01$, respectively) and subscale (pain, stiffness and function, all $p<0.01$) scores in a dose-response pattern. Participants who had higher grades of cartilage defects, particularly grade 3 and 4, had higher WOMAC scores and remained higher over 10.7 years (Figure 1). The association of cartilage defects was independent of BMLs, meniscal pathology and effusion-synovitis, whereas the association of BMLs was dependent on cartilage defects and meniscal pathology but independent of effusion-synovitis. Tibiofemoral cartilage volume loss (not patellar) ($\beta$=1.91, $p<0.01$) and meniscal extrusion (not tears) ($\beta$=3.21, $p<0.01$) were independently associated with total WOMAC scores and pain over 10.7 years.
Baseline cartilage defects, BMLs and meniscal extrusion were significantly associated with annual loss of tibial cartilage volume over 10.7 years ($\beta$=0.27%, $p<0.01$, $\beta$=0.22%, $p<0.01$ and $\beta$=0.28%, $p<0.01$, respectively) independent of other structural abnormalities.
Radiographic osteophytes (but not JSN) were significantly associated with WOMAC score ($\beta$=8.49, $p<0.01$) over 10.7 years after adjustment for age, sex, BMI and other structural lesions. Conversely, radiographic JSN (but not osteophytes) was significantly associated with annual tibial cartilage volume loss ($\beta$=0.28%, $p<0.01$) over 10.7 years. These associations were independent of MRI structural lesions.

**Conclusions:** Baseline cartilage defects, cartilage volume loss, BMLs, meniscal extrusion, JSN and osteophytes are independent predictors of clinical and strcutural progression of knee osteoarthritis.

### OP0131 TRABECULAR THINNING IN METACARPOPHALANGEAL JOINTS OF ANTICITRULLINATED PEPTIDE ANTIBODY POSITIVE PATIENTS WITH ARTHRALGIA

K.K. Keller[1], J.S. Thomsen[2], K. Stengaard-Pedersen[1], A.W. Nielsen[1], B. Schiøtz-Christensen[3], S.G. Kjær[4], L. Svendsen[5], M. Graakjær[6], P.M. Petersen[7], B. Unger[8], B. Langdahl[9], E.-M. Hauge[1]. *[1]Department of Rheumatology, Aarhus University Hospital; [2]Aarhus University, Aarhus; [3]Spine Centre of Southern Denmark, Middelfart; [4]Silkeborg Hospital, Silkeborg; [5]Private Practice in Rheumatology, Skanderborg; [6]Clinic of Rheumatology Aarhus, Aarhus; [7]Randers Hospital, Randers; [8]Horsens Hospital, Horsens; [9]Department of Endocrinology, Aarhus University Hospital, Aarhus, Denmark*

**Background:** Rheumatoid arthritis (RA) is characterized by synovitis leading to

bone erosions and joint destruction, but little is known about bone structure in the joints of patients before they are diagnosed with RA.
High Resolution peripheral Quantitative Computed Tomography (HR-pQCT) is a new imaging technique allowing detailed automatic evaluation of bone structure.
**Objectives:** The aim was to quantify the cortical and trabecular bone structure in the metacarpophalangeal (MCP) joints of anticitrullinated peptide antibody (ACPA) positive patients with arthralgia and compare with healthy controls.
**Methods:** Using a cross-sectional study design patients were recruited from local rheumatologists and controls from a website for test subjects. All individuals underwent medical history interview, clinical examination, and biochemical screening including ACPA. Patient inclusion criteria were positive ACPA and arthralgia. Exclusion criteria were fulfillment of the 2010 ACR/EULAR criteria for RA and other rheumatologic or metabolic bone diseases. Exclusion criteria for controls were known rheumatologic or metabolic bone disease, current or prior arthralgia, arthritis, and positive ACPA.
The right hand MCP joints were imaged with HR-pQCT using an isotropic voxel size of 82 $\mu$m.
A region of 1.2 cm located proximal to the articular surface of the MCP head was evaluated in the 2nd and 3rd finger using a semiautomatic program. Volumetric bone mineral density (vBMD), bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), trabecular separation (Tb.Sp), average cortical thickness (Ct.Th), and cortical area (Ct.Ar) were evaluated. Nine patients were rescanned after repositioning and the coefficient of variation (CV) was calculated. Values are mean (SD).
**Results:** Twenty-nine ACPA positive patients without clinical arthritis (age 51 (13)) and 29 healthy controls (age 50 (14)) were included. CV of the HR-pQCT parameters was 0.64–3.53%.
The overall bone density was similar in the groups since vBMD and BV/TV did not differ. In addition, the cortical bone was not affected in patients, as we found no difference in Ct.Th and Ct.Ar between the groups. In contrast, the trabeculae were significantly ($p < 0.05$) thinner in both 2nd (87.8 (11.1) $\mu$m vs 93.9 (9.8) $\mu$m) and 3rd (84.3 (13.5) $\mu$m vs 89.8 (9.8) $\mu$m) MCP head compared with controls, whereas Tb.N and Tb.Sp did not differ.
**Conclusions:** It has earlier been demonstrated that inflammation of the synovium and bone marrow is crucial for development of erosions in RA. In the present study we demonstrate that the trabecular thickness is affected very early, i.e. before the onset of clinical arthritis. Therefore, up-regulation of bone resorption in the bone marrow may be an early feature of RA. Bone loss before clinical RA warrants earlier diagnosis and treatment.

## "Fewer words - more action" - tailored care for men with rheumatic diseases?

### OP0132-HPR AXIAL SPONDYLOARTHRITIS KNOW-HOW: WHAT ARE THE BENEFITS OF A BRIEF EXERCISE AND SELF-MANAGEMENT EDUCATION GROUP PROGRAMME? A QUALITATIVE INVESTIGATION

M. Martin[1], H. Fiddler[2]. [1]*Rheumatology, Guy's Hospital, London;* [2]*School of Health Sciences, University of Brighton, Eastbourne, United Kingdom*

**Background:** Axial Spondyloarthritis (AS), a long-term sero-negative inflammatory arthritis is associated with inflammatory back pain, reduced spinal mobility, fatigue and work incapacity. Exercise and self-management education are key recommendations of the Assessment of Spondyloarthritis Society (ASAS) management guidelines. The Axial Spondyloarthritis Know-how (ASK) programme aims to increase knowledge, exercise participation and self-management and comprises a two hour group education, gym-based exercise and hydrotherapy session for up to six people, facilitated by a specialist physiotherapist and self-management education handbook.
**Objectives:** The qualitative focus group study aims to explore the acceptability and benefit of a brief exercise and self-management group programme for adults with Axial Spondyloarthritis.
**Methods:** A purposive sample of adults with AS (ASAS,2009) who attended the ASK group programme between April-June 2014 were enrolled into the study. Focus groups were facilitated by a rheumatology specialist physiotherapist not involved in the delivery of the ASK programme and followed a topic guide developed a priori. The focus groups were audio-recorded and transcribed verbatim. Manual coding was utilised to build categories (through naturalistic inquiry as a permutation of constructivist grounded theory) resulting in the identification of a thematic framework linking the theoretical concepts. The themes were checked for resonance with participants.
**Results:** Two focus groups including nine participants (5 male) with mean age 43 years (21–74) and mean disease duration 12.2 years (1–44) were conducted. Overall, patients reported the ASK programme was an acceptable and beneficial experience. Four over-arching themes were identified: 1) Exercise Behaviours: Participants described increased knowledge and confidence to exercise following attendance. Three participants commenced exercising with local National Ankylosing Spondylitis Society groups and four adapted the content of a home exercise programme. 2) Disease Positioning: Participants reported comparing their mobility and posture with others in the ASK group and positioned themselves along a "disease severity spectrum" in relation to other group members. 3) Temporal Effects of Self-Management Education: The time between diagnosis and attending the ASK group influenced the extent of learning acquired. Newly diagnosed interviewees reported that the ASK group provided information and promoted self-management whereas those with longer disease duration, who considered themselves to be knowledgeable, reported gaining less benefit. 4) The Group Effect: Participants reported that they learned from their peers, particularly self-management strategies for dealing with flares.
**Conclusions:** The ASK programme is an acceptable and beneficial experience for adults with AS. It promotes understanding of self-management, including exercise participation and flare-up management through learning from others. It may be easily implemented into clinical practice, however, may be more appropriate for those with early disease.

## Recent advances in our understanding of macrophage biology

### OP0133 DNA DEMETHYLATION PATHWAY ANALYSIS IN RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS AND MACROPHAGES

E. Karouzakis[1], F. Sun[2], R.E. Gay[1], B.A. Michel[1], S. Ye[2], S. Gay[1], M. Neidhart[1]. [1]*University Hospital Zurich, Zurich, Switzerland;* [2]*Shanghai Jiao Tong University, Shanghai, China*

**Background:** Activated macrophages and synovial fibroblasts (SF) are found in the inflamed and hyperplastic synovial rheumatoid arthritis (RA) tissues. Our group has already reported a persistent global hypomethylation in RA tissues and RA synovial fibroblasts (RASF). Recent findings showed that the 5-methylcytosine (5-mC) modification of DNA can be converted to 5-hydroxymethylcytosine (5-hmC) through the activation of the family of Ten-Eleven-Translocation (TET1–3) enzymes which may explain the genomic hypomethylation in RA. It is known that TET enzymes require for their activation a-ketoglutarate (a-KG) which is produced from isocitrate during cell glycolysis by the enzyme Isocitrate dehydrogenase 1 (IDH-1).
**Objectives:** In the current study, we investigated the 5-hmC modification, TET1–3 and IDH-1 enzymes in RASF and monocyte derived macrophages stimulated with TNFa and LPS.
**Methods:** RASF cultures were prepared from joint replacement patients. The THP-1 cell line was differentiated into macrophages in the presence of 50nM phorbol myristate acetate (PMA). Macrophages were prepared by culturing CD14+ monocytes with macrophage colony stimulating factor (M-CSF) for 6 days. Macrophages and RASFs were transfected with siRNA for TET1 and stimulated with 100 ng/ml LPS for 2 hours or 10 ng/ml TNFa for 24 hours. Glucose uptake was measured using a colorimetric assay. The mRNA levels of TETs and IDH-1 were analyzed by quantitative Real-time PCR. The protein levels of TNFa and IL-6 were measured by ELISA. The global 5-hmC levels were determined by DNA dot blot assay. Hydroxymethylated DNA immunoprecipitation (hMeDIP) was applied to analyze the levels of 5-hmC in different promoter areas of the TNFa (TNFa 1–4) and the IL-6 locus.
**Results:** First, we screened different SF cultures and macrophages for the expression of 5-hmC using dot-blot assay and found that RASF cultures do not express 5-hmC in comparison to CD68+ macrophages. TNFa reduced the expression of TET1 and TET2 mRNA in RASF by 50% and 20% respectively. Interestingly, we observed a 40% reduction of IDH1 (n=3) and an increase of glucose uptake in RASF (n=2). Stimulation of the macrophages with LPS for 0.5h showed a significant increase of TET1 mRNA (TET1: 0.5h 1.93±0.7, fold change, n=4, p=0.03). Interestingly, LPS stimulation increased 5-hmC levels in the promoter of TNFa and IL-6 in monocyte derived macrophages (hMeDIP: TNFa 1.64±0.2, n=3, p=0.03; IL-6 1.74±0.2, n=3, p=0.03). Next, we knocked down TET1 with siRNA in THP1 differentiated macrophages and found that TNFa and IL-6 production was reduced by 46% and 44% as well as the 5-hmC levels were reduced by 25% respectively (n=4).
**Conclusions:** For the first time, we showed that TNFa reduces the glycolytic and epigenetic enzymes IDH1 and TET1 in RASF. In addition, we found that TET1 contributes to the activation of macrophages through the regulation of 5-hydroxymethylation in the promoter of pro-inflammatory cytokine genes. The IDH1 and TET1 enzymes could be promising molecular targets of RASF activation and macrophage chronic inflammation.

### OP0134 THE RHEUMATOID ARTHRITIS SUSCEPTIBILITY GENE C5ORF30 ACTS AS AN IMMUNOMODULATOR IN MACROPHAGES

E.R. Dorris[1], K. Creevey[1], C. Moran[1], M. Muthana[2], A.G. Wilson[1]. *[1]University College Dublin, Dublin, Ireland; [2]Department of Oncology & Metabolism, University of Sheffield, Sheffield, United Kingdom*

**Background:** The variant rs26232 in the first intron of *C5orf30* has been associated with both risk of developing rheumatoid arthritis (RA) and severity of tissue damage. The gene encodes a protein of 206 amino acids that is highly expressed by RA synovial fibroblasts (RASF) and macrophages. Inhibition of C5orf30 in RASF results in increased cellular invasiveness and migration *in vitro*, furthermore, inhibition in the collagen-induced arthritis model markedly accentuated joint inflammation and damage, with elevated TNF and IL-1 expression (Muthana et al, 2015). There is no published data on the biological activities of C5orf30 in macrophages.
**Objectives:** To determine the role of C5orf30 in regulating monocyte-derived macrophage biology.
**Methods:** Experiments involving both the monocyte/macrophage cell line (THP1) and primary monocyte-derived macrophages (MDM) were employed. MDMs were isolated from healthy donor PBMCs and cultured on plastic for 8 days with m-CSF. Macrophage purity was confirmed via flow cytometry. Expression of C5orf30 mRNA was assessed by quantitative PCR and protein expression via Western blot. The effects of polarization to M1 and M2a phenotypes and stimulation with TNF and LPS on C5orf30 expression were compared. C5orf30 levels were manipulated using siRNA technology and functional effects on macrophage biology was assessed using cytokine response assays, matrigel transwell invasion assays, quantitative high throughput pathogen phagocytosis assays, gene expression and intracellular signaling.
**Results:** Treatment of macrophages with either TNF or LPS significantly reduced C5orf30 expression compared to untreated cells (TNF 0.51±0.26 $p$=0.001 and LPS 0.29±0.25 $p$=0.02). Furthermore, polarization to M2a phenotype trended to increased expression (1.34±0.59 $p$=0.13) whereas polarization to M1 macrophage phenotype resulted in significantly decreased expression of C5orf30 (0.68±0.13 $p$=0.01) compared to untreated cells, indicating an anti-inflammatory effect. Knockdown of C5orf30 significantly reduced the invasive capacity of macrophages (0.54±0.04 $p$=0.003); this was intensified upon incubation with either TNF (0.29±0.16 $p$=0.02) or LPS (0.34±0.11 $p$=0.01). Phagocytosis of labeled yeast particles was increased upon C5orf30 knockdown combined with co-incubation with TNF (1.14 $p$=0.02). C5orf30 knockdown also increased activation of the JNK pathway as measured by an increase in phosphoJNK but not total JNK. All knockdown experiments compared to non-targeting (scramble) siRNA control.
**Conclusions:** C5orf30 knockdown enhanced the proinflammatory (M1-like) macrophage phenotypes of pathogen phagocytosis and JNK pathway activation whilst diminishing the tissue-clearing (M2-like) phenotype of macrophage invasion. This data combined with the observation that proinflammatory cytokine stimulation reduced *C5orf30* expression indicates an important role for C5orf30 in the immunomodulatory regulation of macrophages and is consistent with our previous findings in RASF that C5orf30 is a negative regulator of tissue damage in rheumatoid arthritis.

## Lubricants: potential as osteoarthritis treatment?

### OP0135 PREDICTIVE FACTORS OF FAILURE OF VISCOSUPPLEMENTATION IN PATIENTS WITH KNEE OSTEOARTHRITIS. RESULTS OF A POST-HOC ANALYSIS OF A DOUBLE BLIND, CONTROLLED NON INFERIORITY TRIAL

F. Eymard[1], T. Conrozier[2], X. Chevalier[1]. *[1]Rheumatology, Henri Mondor university Hospital, Créteil; [2]Rheumatology, Nord Franche Comté Hospital, Belfort, France*

**Background:** Viscosupplementation (VS) by intra-articular (IA) injections of hyaluronic acid (HA) is widely used worldwide to alleviate pain and improve function in patients with mild to moderate knee osteoarthritis (KOA). However, in most of the clinical trials, the rate of responders to treatment does not exceed 60 to 70%. One of the key points that remains to be clarified is the identification of predictive factors of success or failure to treatment.
**Objectives:** To identify clinical and radiographic predictive factors of treatment's response or failure in patients treated with VS for KOA.
**Methods:** We included in this post-hoc analysis, 166 patients, with fully available clinical and radiographic data, coming from the intent-to-treat population (n=205) of a controlled, multicentre, double-blind, randomized, clinical trial, which compared 2 HA viscosupplement in patients with symptomatic KOA. At baseline, demographic, anthropometric, clinical data (patient global assessment, WOMAC score, presence or lack of synovial effusion) radiologic data (Kellgren-Lawrence grade, OARSI score for joint space narrowing [JSN]) and all previous and present treatments for OA, previous IA steroids or HA injections were recorded. All patients received 3 weekly IA injections of HA. They were classified as Responders if they fulfilled the OMERACT-OARSI criteria, 6-month after injections. Mann-Whitney and chi-square tests were used to assess the association of quantitative or qualitative factors and OMERACT-OARSI response. Multivariate logistic regression analysis was used to identify predictors of response.
**Results:** Clinical and demographic characteristics at baseline as well as treatment effectiveness did not statistically differ between the 2 HA groups, so that the data could be pooled. The studied population consisted in 101 women and 65 men, mean age 65.2, mean disease duration 48.7, mean BMI 27.7. 47 patients were obese. Seventy three patients had grade 3 JSN. At baseline, mean WOMAC pain and function scores were 9.8 and 27.5, respectively. Before study inclusion, 95 had at least one VS or corticosteroid injection. At month 6, WOMAC pain and total scores decreased by 43.4% and 41.9% respectively. One-hundred-thirteen patients (68.1%) were classified as Responders. In univariate analysis, increased BMI and OARSI grade were significantly associated with lack of response (p=0.002 and p=0.005, respectively). Similar associations, although not statistically significant, were found with previous IA HA or steroids injection (p=0.11) and age >65 years (p=0.13). Multivariate analysis confirmed the association of obesity and radiological severity with lack of response. Finally, we found a strong cumulative impact of potential predictive factors (age >65, previous VS or steroid IA injection, obesity and severe JSN) on VS response. Thus, all patients without predictive factors were Responders, versus only 69.1% and 28.6% of those with 2 or 4 risk factors, respectively (p<0.0001).
**Conclusions:** VS should be chiefly considered in subjects with normal BMI and moderate tibio-femoral joint space narrowing. This study shows, for the first time, a strong cumulative impact of potential predictive factors of failure. This can be helpful for clinicians when they inform patients on the chance of success of VS.

## Extraarticular complications of JIA

### OP0136 ABATACEPT TREATMENT DURING 1 YEAR PERIOD IN JUVENILE IDIOPATHIC ARTHRITIS ASSOCIATED UVEITIS WITHOUT PREVIOUS BIOLOGICS THERAPY

L. Galstian, E. Zholobova, O. Loskutova, M. Nikolaeva. *I.M. mSECHENOV First Moscow State Medical University, Moscow, Russian Federation*

**Background:** Biological DMARDs have an important role in the treatment of juvenile idiopathic arthritis (JIA) associated uveitis refractory to previous standard treatment.
**Objectives:** The aim of this prospective study was assessment of Abatacept (ABA) efficacy in JIA associated uveitis.
**Methods:** Among 17 patients with JIA and eye involvement included in the study, 9 children had oligo-articular JIA, 7 children – polyarticular, 1 patient had systemic disease. Study group included 13 girls and 4 boys. Mean age was 7,10 ± 2,16 years, age of disease onset was 3,70±3,05years; mean disease duration before ABA administration was 6,40±3,21. Disease onset with initial joint damage was observed in 10 children, with eye involvement- in 7 children.
Prior to ABA administration all children received immunosuppressive drugs: 12 children (70,58%) methotrexate (MTX) 10–15mg/m$^2$ of body surface per week, 2 children (11,8%) received Sandimunne Neoral as monotherapy and with methotrexate combination – 3 patients (17,6%), 2 children received oral corticosteroids (CS), 17 children (100%) received topical treatment of uveitis.
Number of active joints was 8,7±2,6, mean ESR was 20, 0±10,32mm/h, CRP 1,18±1,05mg/dl (ref. <0,8mg/dl). RF positive was detected in 2 children, negative - in 15 children, ANA positive in 14 children (82,35%) with 1:160- 1:180 rate.
VAS physician was 73, 4±15, 0, VAS patient/parent was 68, 7±16, 2. Mean functional disability in patients before ABA administration was 1, 03 ±0, 48.
All 17 patients had active uveitis at the moment of ABA administration. 9 (53%) patients had bilateral ocular involvement, 8 patients (47%) - unilateral.
**Results:** After 6 months of ABA therapy mean ESR decreased from 20, 0±12, 32 mm/h to 17.2±4,28mm/h, CRP – from 1, 18±1, 05 mg/dl to 1,05±0,75mg/dl. ACRpedi-30 was achieved in 10 from 17 (58,82) % patients, ACRpedi-50- in 4 patients (23,52%), ACRpedi -70- in 3 children (17,64%). Uveitis remission was achieved in 22% eyes; 46% showed a significant reduction in inflammatory activity, 32% had no significant dynamic.
After 12 months of ABA therapy number of active joints decreased from 8, 7±2, 6 to 5, 63± 1, 4. Mean ESR decreased from 20, 0±12, 32 mm/h to 10,0±4,6mm/h,

CRP –0±0,31mg/dl, VAS physician decreased from 73, 4±15,0 to 42,4±13,5, VAS patient/parent decreased from 68, 7±16, 2 to 50,0 ± 14,0. ACRpedi-50 was achieved in 13 patients (76,4%), ACRpedi-80 - in 2 children (11,76%). Regarding uveitis 21% eyes had uveitis remission; 36% – sub active process. Flares were observed in 43% eyes.
**Conclusions:** Abatacept treatment during 12 months period was effective in JIA associated uveitis with 82% ANA positivity without previous biologics therapy.
**Disclosure of Interest:** None declared

### OP0137 DIABETES PREVALENCE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA)

S. Schenck[1], R.W. Holl[2,3], M. Niewerth[1], J. Klotsche[1], K. Minden[1,4], J. Rosenbauer[5], A. Thon[6]. *[1]Programmbereich Epidemiologie, Deutsches Rheuma-Forschungszentrum, Berlin; [2]Universität Ulm, Institut für Epidemiologie und medizinische Biometrie, ZIBMT, Ulm; [3]Deutsches Zentrum für Diabetesforschung, Düsseldorf; [4]Charité Universitätsmedizin, Berlin; [5]Deutsches Diabetes-Zentrum, Institut für Biometrie und Epidemiologie, Leibniz-Zentrum für Diabetes-Forschung an der Heinrich-Heine-Universität Düsseldorf, Deutsches Zentrum für Diabetesforschung, Düsseldorf; [6]Klinik für Pädiatrische Pneumologie, Allergologie & Neonatologie, Medizinische Hochschule Hannover, Hannover, Germany*

**Background:** The majority of JIA categories are considered as autoimmune diseases. Autoimmune diseases seem to cluster in children and adolescents with JIA, which is attributed to shared susceptibility genes. Studies revealed an increase in the simultaneous JIA and juvenile type 1 diabetes mellitus (T1D) occurrence and an increased JIA prevalence in patients with T1D [1]. However, the frequency of T1D in JIA patients in comparison to the general population is unknown.
**Objectives:** To determine the frequency of T1D in JIA patients and to characterize patients having both JIA and T1D.
**Methods:** Diabetes comorbidity was recorded in the national paediatric rheumatologic database (NPRD) in 2012 and 2013. Data of the North Rhine-Westphalian diabetes register and the Diabetes data acquisition system for prospective surveillance (DPV) served as reference for the diabetes prevalence in the general population. NPRD data were indirectly standardized for age and sex for the comparison with the general population. The diabetes prevalence ratio (PR) was calculated using Poisson regression models.
**Results:** 9,359 JIA patients were included in the analyses. Patient mean age was 12 years (SD 4.5), mean disease duration 4.5 years (SD 3.8). 50 patients had T1D in addition to JIA, diabetes prevalence was 0.5%. Patients with versus without T1D did not differ significantly in the JIA category spectrum. Compared to the general population, the diabetes prevalence in JIA patients was significantly increased (PR: 1.96 [CI: 1.49;2.59], $p<0.001$). The PR for diabetes for girls was 1.92 (CI: 1.35;2.73, $p<0.001$) and for boys 2.04 (CI: 1.30;3.19, p=0.002). Diabetes onset in JIA patients was slightly earlier than in the age- and sex-matched population. More than half of the patients (58%) developed diabetes before JIA. Diabetes onset was on average 60 months before the JIA onset. Patients with JIA before T1D developed T1D on average 35 months after JIA onset. The majority of these patients had not received any DMARDs before diabetes onset.
**Conclusions:** Diabetes type 1 occurs more frequently in JIA patients than in the general population. The likelihood of T1D seems to be slightly higher before JIA manifestation and in patients who were not treated with DMARDs after JIA onset. The NPRD has been funded by the German Children Arthritis Foundation (Deutsche Kinder-Rheumastiftung).

## The elephant in the room: how to avoid biases in research?

### OP0138 SIMPLE POOLING OF DATA FROM DIFFERENT STUDIES IS INCREASINGLY USED BUT NOT IN LINE WITH METHODOLOGICAL RECOMMENDATIONS: A SYSTEMATIC REVIEW OF METHODS APPLIED IN THE FIELD OF RHEUMATOID ARTHRITIS

A. Richter, J. Callhoff, L. Baganz, J. Listing. *Epidemiology, German Rheumatism Research Center, Berlin, Germany*

**Background:** Combining data from different clinical trials (observational studies) is getting more frequent for the analysis of DMARD efficacy (effectiveness) and safety. The underlying objective is plausible: the generation of data with sufficient power for the investigation of rare adverse events or different treatment strategies. However, the approach of simply pooling data from different studies within an analysis has been shown to be prone to bias which applies for both, observational and clinical trial data [1,2].
**Objectives:** To describe the agreement of recommended and applied methods in the analyses of data originating from different studies.
**Methods:** A systematic literature review with PubMed and Web of Science was independently conducted by two researchers (RA, CJ) using a common strategy. We included full text publications if: ≥2 different data bases (clinical trial/observational data) with individual patient data were used, efficacy/effectiveness or safety were investigated and if the studies were conducted in patients with rheumatoid arthritis. We excluded studies using claims data, genetic/proteomic association studies and studies of prognostic markers. Outcomes of interest were the number of data bases, the analysis-type (pooled/separated/both) and the illustration and discussion of study heterogeneity.
**Results:** After screening 2002 search results, initial consent of the eligibility of each publication for this analyses was found in 58 publications (safety: n=34 (59%), effectiveness: n=20 (34%), both: n=4 (7%)). From these 28 publications (48%) were based on observational data, 24 (42%) on clinical trials and 6 (10%) based on a mixture of study types. The No. of databases in one publication ranged from 2–42 for clinical trial data, 2–10 in observational data and 4–13 if a mixture of databases was investigated. The analysis of pooled data (n=28, 48%) was more frequent in analyses with trials (n=18) than with data from observational studies (n=8). However, the latter studies were primarily conducted in recent years (Table). In only 1/8 publications (13%) from pooled observational data the baseline characteristics were shown separately for each database. Heterogeneity of study populations was discussed in only 2/8 (25%) publications based on pooled analysis, in 8/15 publications (53%) using a separate analysis of observational studies the heterogeneity of patients was discussed.

| | | No. of publications in 5-year intervals | | | | |
|---|---|---|---|---|---|---|
| Data origin: | Analysis: | ≤2000 | 2001-2005 | 2006-2010 | 2010-2015 | Total |
| Observational | Pooled | 0 | 1 | 2 | 5 | 8 |
| | Separate | 1 | 4 | 4 | 6 | 15 |
| | Pooled + Separate | 1 | 0 | 0 | 4 | 5 |
| Clinical trial data | Pooled | 3 | 5 | 6 | 4 | 18 |
| | Separate | 0 | 1 | 1 | 2 | 4 |
| | Pooled + Separate | 0 | 0 | 2 | 0 | 2 |

Table: Summary of full text publications but excluding Meta-Analysis of summary tables from published results. Pooled=no effects/estimates of individual studies shown; Separate=results of each study and combined results shown.

**Conclusions:** Collaborative analyses of several sources of observational data or multiple clinical trials may deliver superior results than individual studies but only if an appropriate analysis is applied. The approach of simply pooling the data neglects existing heterogeneity of patient cohorts, assessment of risk factors/events, missing data and dropouts. The use of individual patient data from multiple clinical trials could be superior to meta-analysis of published results but loses this advantage if the data are simply pooled. Regarding the considerable differences between observational studies, e.g. European register [3], the utility and the recent increase of pooled analyses from observational studies is disputable.

## Digital applications for the benefit of the patient

### OP0139-PARE THE FIRST SERIOUS GAME EDUBIOT: A MODERN THERAPEUTIC EDUCATIONAL TOOL FOR ADULT PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASE, TREATED WITH BIOTHERAPY

L. Grange[1,2], J.D. Cohen[3], S. Trope[4], D. Poivret[5], C. Bonnet[6], B. Allenet[7,8], C. Stadelmann[9], G. Chales[10,11], J.N. Dachicourt[12]. *[1]University Clinic for Rheumatology, Locomotion, Rehabilitation Cluster, Hôpital Sud, CHU Grenoble, Grenoble; [2]President, AFLAR, Paris; [3]University Clinic for Rheumatology, CHU Montpellier; [4]Director, ANDAR, Montpellier; [5]Service de Rhumatologie, CH Metz Thionville, METZ; [6]1University Clinic for Rheumatology, CHU Limoges, Limoges; [7]University Clinic of Pharmacy, CHU Grenoble; [8]ThEMAS TIMC-IMAG (UMR CNRS 5525), University of Grenoble-Alpes, Grenoble; [9]Member, AFLAR, Paris; [10]University Clinic for Rheumatology, Locomotion, Rehabilitation Cluster, Hôpital Sud, CHU Rennes, RENNES; [11]Vice President; [12]Director, AFLAR, Paris, France*

**Background:** Democratization of biotherapy for chronic inflammatory rheumatic disease has created new challenges in terms of therapeutic education for patient. Our goal has been to create the first modern serious game for adult patients with chronic inflammatory rheumatic disease treated with biotherapy.
**Objectives:** Our specification is based on the minimum self-care safety skills, a patient with a biotherapy must have acquired (issued by the SFR- Therapeutic Education section)[1].
**Methods:** An expert board was formed, with 5 rheumatologists, 1 pharmacist and 2 patients. Each game scenario was tested by patients.

It helps to promote the self-care safety skills in biotherapy by creating sequences increasingly complicated during the progress of the game. A "guardian" mode with password access, unlocks all the scenarios available in the game for use in a group of educational validated program. This free game will be available online on www.ludomedic.com. An update is planned after launching the application for the increment of new scenarios play.
A statistics module is also set up to quantify many indicators, such as number of players, the most frequent errors. These Statistics can guide the objectives of a therapeutic educational program patient at the individual level and the game will provide national statistics on the strengths and weaknesses of the level of knowledge of "patient players" in biotherapy.
**Results:** We opted for a video game called Serious Game. The principle is that the patient player must evolve an avatar having chronic inflammatory rheumatic disease treated by biotherapy. Different events disrupt the daily management of its biotherapy (fever, infections, pregnancy, surgery, travel etc.).
The player must take the right decisions and allowing it to gain or lose points on his influential level of quality of life, influenced in terms of its decisions and actions. 5 themes have been made (fever and infection management, parenting desire, surgical and dental care, information, prevention, and logistics and injection technique).
**Conclusions:** This is the first serious game dealing with the management of a biological therapy in adult patient treated by a biotherapy in France. A study of its impact on the level of knowledge of patients and the most common mistakes will be investigated after broadcast. It is the result of two years of a unique collaboration between two associations of patient and French rheumatologists to offer a unique and innovative patient education tool.

## OP0140-PARE SELF-MANAGEMENT ONLINE: FROM CONCEPT TO DELIVERY, LIVING WELL WITH ARTHRITIS ONLINE

G. O'Leary. *Arthritis Ireland, Grand Canal Quay, Ireland*

**Background:** Over the past 10 years Arthritis Ireland has pioneered the development of services that enable people with arthritis to learn about self-management and put self-management tools into practice in their daily lives. Over the past 2 years we have embarked on a significant journey to bring these vital tools to even more people with arthritis through the development of an online education programme – *Living Well with Arthritis Online*.
**Objectives:** The objectives of the project were to 1)Compare and contrast the pros/cons of conventional class based self-management programmes with that of an online offering; 2) Develop a model of online delivery to attract large numbers of people with arthritis in an engaging format; 3) Develop comprehensive content to improve understanding of the various types of RMDs,the various self-management tools that could form part of a tool kit for daily living and the various medications that are now used to treat RMDs; 4) Develop appropriate mechanisms for reviewing and evaluating the impact of the programme; 5)Develop a comprehensive framework to promote and recruit participants to the programme.
**Methods:** Our journey with self-management began in earnest back in 2006 with the launch of the 6-week "*Living Well with Arthritis*" Stanford University self-management programme. Since that time we have delivered the programme to over 5,000 people across Ireland in community class settings.
Despite the myriad of benefits to the programme Arthritis Ireland recognises that not everyone approaches learning in the same way so it is important to provide alternative learning formats. We investigated the benefits and challenges of conventional self management courses with an online model. A number of reasons became apparent to us that impacted participation in class-cased programmes - time constraints; unsuitable course hours; location too far away; stigma of attending an "arthritis" course; not feeling comfortable talking about arthritis in a group; face to face course was less appealing to younger people.
In response to these challenges and to meet the growing challenge of how to reach greater numbers of people, Arthritis Ireland developed an online self-management programme – "*Living Well with Arthritis Online".* The programme was researched, developed and implemented by Arthritis Ireland during 2014 and 2015. It is designed to 1)improve a person's understanding of their arthritis 2) introduce them to key self-management tools that can be used on a daily basis and 3) improve understanding of the various medications now available to manage arthritis. The programme is highly interactive and learning take place through various video lessons with additional reading material available within each module.
**Results:** By the end of January 2016, over 800 people had registered for the programme within the first 3 months of operation. Results will be collated and findings reported at the 6-month stage.
**Conclusions:** What is clear so far is online education offers a unique learning opportunity to many people who would not otherwise attend a face to face class, at a reduced cost, with minimal ongoing financial outlay.
**Disclosure of Interest:** None declared

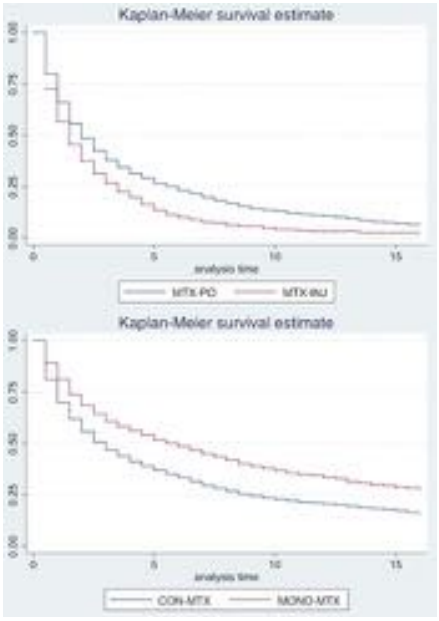
# Optimization of MTX in RA treatment

## OP0141 WHICH STRATEGIES IN RHEUMATOID ARTHRITIS PATIENT WITH INADEQUATE RESPONSE TO METHOTREXATE MONOTHERAPY: THE STRATEGE STUDY

R.-M. Flipo[1], C. Gaujoux-Viala[2], C. Hudry[3,4], E. Zinovieva[5], E. Leutenegger[6], H. Herman-Demars[5]. *[1]Rheumatology Department, Roger Salengro Hospital, Lille; [2]Rheumatology Department, Carémeau hospital, Nîmes; [3]Rheumatology Institute; [4]Rheumatology Department, Cochin Hospital; [5]Medical Department, Nordic Pharma, Paris; [6]Epidemiology Department, Gecem, Montrouge, France*



**Background:** Current EULAR and SFR (French Rheumatology Society) guidelines consider MTX as initial gold standard treatment for patients (pts) with RA. They also propose various strategies for MTX inadequate responders, among which the most frequent are optimization of MTX therapy (alone or in combination with other csDMARDs) or biological treatment.
**Objectives:** To explore the strategies applied in daily practice in RA pts with inadequate response to MTX.
**Methods:** STRATEGE is a prospective, observational, multicenter study, conducted in France. Main inclusion criteria were: confirmed RA diagnosis (ACR 1987 or ACR/EULAR 2010 criteria) and treatment by MTX monotherapy with clinical, structural, functional and/or therapeutic evolution leading to therapeutic management modification. Data presented here show the baseline pts characteristics and the therapeutic strategies chosen during the inclusion visit.
**Results:** Between Sept 2014 and July 2015, 176 rheumatologists, mainly with private (49.3%) or mixed private/public (42.1%) practice included 850 pts. Pts baseline characteristics were: mean age: 57.9 yrs (±13.7); RA duration: 5.4 yrs (±6.6); extra-articular manifestations: 10.4%; structural damage: 39.5%; mean DAS28: 3.98 (±1.35), with the following distribution: $<$2.6 for 12.4%, $>$3.2 for 75.8% and $>$5.1 for 17.1%; and mean HAQ: 1.1 (±0.84). All pts were receiving MTX monotherapy and for 83.8% it was the first-line treatment. 67.8% of pts were treated by oral MTX at a mean dose of 14.2 mg/wk (± 4.1), while parenteral mean dose was 16.4 mg/wk (± 3.8). 51.5% of pts treated with parenteral MTX were performing injections by themselves. 15.6% of pts had experience MTX dose tapering before the inclusion. Concomitant treatment included corticosteroids for 44.8% of pts and folic acid for 89.7%. After the inclusion visit, MTX prescription has been identically maintained (dose and route) for 26.2% of pts, interrupted for 2.9% and modified for 70.9% of them. Changes included dose increasing for 47.1%, dose tapering for 6.1% and a route modification for 20.3% (83% oral -> parent). Biologic treatment was initiated for 14.2%, in association with MTX for 95.8%. Other csDMARD treatment was initiated for 1.1% in monotherapy and for 3.8% in association with MTX. The mean dose of MTX after inclusion visit was 16.8 mg/wk (±4.2), with 10.6%, 35.3% and 34.9% pts receiving 10, 15 and 20 mg/wk respectively. The reasons for treatment modification were mainly high disease activity (70.2%), worsening of clinical and biologic parameters (30.8%), remission not achieved (13.1%), radiographic progression (14.1%), steroid dependence (11.4%), and MTX intolerance 4.8%.
**Conclusions:** Consistently with the recent European and National recommendations, first data of the large observational French study STRATEGE, revealed an important place held by initial MTX treatment optimization before initiation of a biotherapy.

## OP0142 METHOTREXATE USE IN RA: WHAT 17 YEARS AND 22,621 PATIENTS CAN TEACH US

K. Michaud[1,2], S. Pedro[2]. *[1]University of Nebraska Medical Center, Omaha; [2]National Data Bank for Rheumatic Diseases, Wichita, United States*

**Background:** Methotrexate (MTX) remains the gold standard treatment for rheumatoid arthritis (RA), yet most recent research refers to it only as a referent or placebo without context of dose or form of administration.
**Objectives:** To examine the real-world use trends of MTX in the US since 1998.
**Methods:** Using a large observational cohort, the National Data Bank for Rheumatic Diseases (NDB), we characterized patients with RA who initiated MTX from 1998 through 2015. Baseline characteristics were assessed by MTX

administration route, injectable (INJ) and oral (PO), and by mono- vs. concomitant DMARD therapy. Discontinuation, described using Kaplan-Meier survival curves, was defined as either ending MTX or adding another DMARD. Sensitivity analyses were performed with alternative discontinuation definitions. GEE were also used to model change on MTX dose over time.
**Results:** In our study of 22,621 RA patients, MTX had widespread use with 73.5% ever being exposed, 59.4% using it during our study, and 11.4% initiating without any prior DMARD. The MTX-exposed baseline mean age was 59±13 years, 79% female, and 14±12 years RA duration. Of these, 21% used MTX-INJ and had worse disease severity and higher weekly doses compared to MTX-PO (PAS: INJ 4.1±2.2 vs. PO 3.6±2.2; Dose: INJ 16.2±4.2 vs. PO 13.8±5.5 mg). When initiating MTX, 42.8% took mono-therapy, and concomitant use was split 53/47% on synthetic/biologic DMARDs with trends of being younger, more employed, and more private insurance (34% vs 27% on mono-therapy). Overall median (IQR) survival time after initiating MTX was 2.5 (1–6) years per patient with 24,823 p-yr followup. Sensitivity analysis of discontinuation requiring ending MTX had 8 (2.5-.) years per patient, 38,290 p-yr followup. By route, the median (IQR) survival was 1.5 (0.5–3.5) years for INJ and 2 (1–5.5) years for PO with 16.2% of patients switching between routes. Also, survival was 6 (1.5–...) years for mono-therapy and 3 (1–9) years for concomitant therapy. MTX doses increased by 0.01 (95% CI 0.01 – 0.02) mg/yr/patient with 50% of patients increasing MTX dose a median (IQR) of 5 (2.5–10) mg and 3.3% of patients decreasing their dose.

**Conclusions:** Patients who tolerate MTX early tend to use it for several years even while adding concomitant DMARDs. We showed notable differences between patients by MTX route, with trends of increasing dose over time.

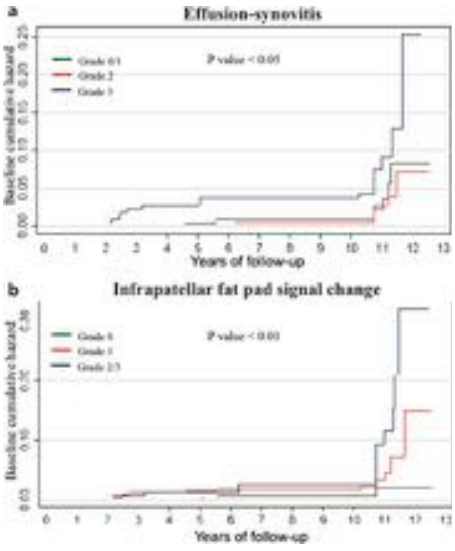
## Joint replacement in OA: friend or foe?

### OP0143 THE EFFECT OF PHYSICAL ACTIVITY ON THE RISK OF TOTAL JOINT REPLACEMENT FOR SEVERE KNEE OR HIP OSTEOARTHRITIS: A POPULATION-BASED PROSPECTIVE COHORT STUDY



D. Aitken[1], I. Munugoda[1], F. Cicuttini[2], M. Callisaya[1], G. Jones[1]. *[1]Menzies Institute for Medical Research, University of Tasmania, Hobart; [2]Monash University, Melbourne, Australia*

**Background:** Studies examining physical activity and joint health are conflicting – with some showing a detrimental effect and others showing either no effect or a beneficial effect.
**Objectives:** To explore the association between physical activity and knee or hip osteoarthritis leading to knee or hip joint replacement surgery.
**Methods:** 536 community-dwelling adults aged 51–79 years were assessed at baseline, 2.7, 5 and 10 years. Physical activity was measured by pedometer (steps/day). The incidence of knee or hip replacement surgery was reported at each follow-up. Log-binomial regression was used to examine the association between steps/day with incident knee and hip replacement adjusted for age, sex, BMI, x-ray disease severity, and pain.
**Results:** Over 10 years, 36 participants reported having a knee replacement and 27 reported having a hip replacement. For every 1000 steps/day increase at baseline, there was a 0.84 times (95% CI 0.72 to 0.99) lower risk of hip replacement (P=0.036). There was no significant association between steps/day and knee replacement (RR 1.00 95% CI 0.9999 to 1.00, P=0.778). Baseline BMI significantly predicted knee replacement (RR per SD increase in BMI 1.42 (95% CI 1.03 to 1.97, P=0.032)) but not hip replacement (RR 1.00 95% CI 0.91 to 1.10, P=0.984).
**Conclusions:** Higher physical activity levels were protective against hip replacement while being overweight or obese increased the risk for knee replacement. This suggests different causal pathways for each site with regard to habitual activity and body composition.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3065

### OP0144 INFRA PATELLAR FAT PAD SIGNAL INTENSITY ALTERATIONS AND EFFUSION-SYNOVITIS PREDICT KNEE PAIN, CARTILAGE VOLUME LOSS AND TOTAL KNEE REPLACEMENT OVER 10.7 YEARS IN OLDER ADULTS

B.S. Eathakkattu Antony[1], X. Jin[1], X. Wang[1], W. Han[1], F. Cicuttini[2], C. Ding[1], G. Jones[1]. *[1]Menzies Institute for Medical Research, University of Tasmania, Hobart; [2]Epidemiology, Monash University, Melbourne, Australia*

**Background:** There are no long-term studies that describe the independent association of infrapatellar fat pad (IPFP) signal intensity alterations and effusion-synovitis with knee osteoarthritis (KOA) severity and progression.
**Objectives:** To describe the associations between baseline IPFP signal intensity alterations and effusion-synovitis and long-term knee pain, knee dysfunction, tibial cartilage volume loss and total knee replacement (TKR) over 10.7 years.
**Methods:** Participants (n=983, mean age 62.8 years, 50% female) were selected randomly from the local community of Tasmania and followed up at 2.6 years, 5.1 years and 10.7 years later. MRI was acquired at baseline and 10.7 year follow-up. Effusion-synovitis was measured on T2-weigthed MRI using a modified WORMS system (grade 0–3) at suprapatellar pouch, central portion, posterior femoral recess and subpopliteal recess. IPFP signal intensity alteration was assessed on T2-weighted MRI and was defined as discrete areas of increased signal within IPFP, and was graded as follows: grade 0 = none; grade 1 = $<$10% of the region; grade 2 = 10% to 20% of the region; grade 3 = $>$20% of the region. Cartilage volume at baseline and 10.7 years was measured using manual segmentation of T1-weighted MRI. Clinical symptoms and TKR data were recorded at each follow-up visit. Multivariable analyses were performed using linear mixed-effects models for clinical symptoms, linear regression for cartilage volume loss and cox proportional hazards for TKR.
**Results:** After adjustment for age, sex, BMI, radiographic KOA status, baseline IPFP signal intensity alteration was associated with total WOMAC score ($\beta$=2.19, 95% CI = 0.29, 4.09), WOMAC pain and WOMAC function scores (all $p<0.01$) over 10.7 years. However, these associations became borderline significance after further adjustment for cartilage defects, BMLs or effusion-synovitis. Baseline IPFP signal intensity alteration was independently associated with tibial cartilage volume loss ($\beta$=0.08 mm$^3$, 95% CI = 0.14, 0.02) and TKR (HR=1.89, 95% CI = 1.31, 2.74) over 10.7 years.
Baseline total effusion-synovitis and suprapatellar pouch effusion-synovitis were independently associated with total WOMAC score ($\beta$=2.08,95%CI=0.16,4.16) and pain and dysfunction scores (all $p<0.05$) over 10.7 years. However, there was no significant association between effusion-synovitis and cartilage volume loss. Total (HR=1.58,95%CI=1.01,2.49), sub popliteal recess (HR=1.53, 95%CI=1.11,2.

11) and suprapatellar pouch (HR=1.90,95%CI=1.25,2.89) effusion-synovitis was associated with TKR over 10.7 years. However, these associations were dependent of other structural pathologies except grade 3 suprapatellar effusion-synovitis.
**Conclusions:** Signal intensity alterations of IPFP at baseline were significantly associated tibial cartilage volume loss and TKR over 10.7 years independent of other structural pathologies. Effusion-synovitis (especially at suprapatellar pouch) was independently associated with knee pain and TKR. These results suggest that effusion-synovitis was associated with clinical progression and IPFP signal intensity alteration was associated with structural progression and TKR, and can be used as independent markers of progression of KOA.

## How to identify and follow patients with inflammatory back pain?

### OP0145 AN EVALUATION OF INFLAMMATORY BACK PAIN IN THE COMMUNITY – A NOVEL WAY OF USING SOCIAL MEDIA (FACEBOOK)

A. Moorthy[1], G.M. Crawford[2], A.G. Wade[3], A. Goyal[4]. [1]*Rheumatology, University Hospitals of Leicester NHS trust, Leicester;* [2]*Patients Direct, Glasgow, United Kingdom;* [3]*Director, Patients Direct, Glasgow;* [4]*Abbvie, London, United Kingdom*

**Background:** In the management of Spondyloarthropathy, early diagnosis is the key. Previous UK studies show an average delay in diagnosis of IBP of up to 8 years. This is partly due to a failure of individuals with IBP symptoms to present to their GP and partly to a failure of GPs to recognize the IBP patient subgroup. IBP classification criteria have recently been developed and used in clinical practice. We applied a novel recruitment method using Facebook to identify IBP sufferers in the community. This may help to raise awareness toreduce the delay in diagnosis of Spondyloarthropathy.
**Objectives:** Evaluate a novel way of recruiting potential patients with IBP, using social media.
Determine which of the two criteria sets for IBP, ie. ASAS or Calin, is fulfilled by more patients.
**Methods:** A novel recruitment method using Facebook was applied in a cross-sectional survey carried out in the UK over 5 months to identify adults ($\geq$18 years) with symptoms suggestive of IBP. Other methods, principally newspaper advertising, were used to generate a second group of participants for comparison. Online questionnaire-based surveys were completed to assess each group for IBP using the ASAS and Calin criteria. Data about previous diagnoses, GP, hospital consultations and back pain-related investigations, were also collected.
**Results:** Of the 585 participants, 455 (77.8%) were recruited through Facebook and 130 (22.2%) by a Non-Facebook method. Of the Non-Facebook group, 90 (15.4%) were recruited by a newspaper advert and 40 (6.8%) by another method. The mean age of the Facebook group was typical of IBP at 41.5 years, and the mean age of the Non-Facebook group was higher at 59.4 years. Most participants were female: 447 (76%).
Proportions of those previously diagnosed with Ankylosing Spondylitis, told that their back pain was associated with "inflammation", and were IBP positive on the questionnaire respectively, are shown in Table 1. In total 122 survey participants (21%) met the ASAS, and 292 (50%) met the Calin criteria for IBP at the time of the survey.
The majority of patients from each group reported consulting their GP, however few patients from either group had seen a rheumatologist (Table 1). The reason for non-referral to secondary care is unclear. Regarding further investigations, 45% (204) of the Facebook group reported having an MRI scan and 45% (205) an X-ray, whereas 50% (65) of the Non-Facebook group reported having an MRI scan and 59% (77) said they had been for an X-ray.
**Conclusions:**
– Facebook advertising recruited a younger group of respondents of whom more fulfilled the criteria for IBP, suggesting this may be a cost-effective way of identifying patients earlier.
– Most patients with chronic back pain had consulted their GP, but few who met the criteria for IBP had been referred to a rheumatologist indicating the need for additional GP education.
– In our study group the ASAS IBP criteria were fulfilled by fewer patients than the Calin criteria.

### OP0146 PATTERNS OF CLINICAL ASSESSMENT OF GENERAL PRACTITIONERS WHEN FACING A PATIENT SUSPECTED FOR SPONDYLOARTHRITIS; A STUDY WITH UNANNOUNCED STANDARDIZED PATIENTS IN DAILY PRACTICE

M. Van Onna[1], S. Gorter[1], B. Maiburg[2], G. Waagenaar[2], A. van Tubergen[1]. [1]*Department of Rheumatology, Maastricht University Medical Center +;* [2]*Department of General Practice, Maastricht University, Maastricht, Netherlands*

**Background:** Timely recognition and referral of patients with spondyloarthritis (SpA) is challenging due to the insidious disease onset and frequent unawareness of the clinical picture by general practitioners (GPs). In a previous intervention study, we demonstrated that an educational programme targeted at recognition of SpA clearly improves referral of patients suspected for SpA.[1]
**Objectives:** To evaluate (1) the clinical assessment patterns of GPs and GP-residents when facing a patient suspected of having spondyloarthritis (SpA) and (2) the influence of an educational intervention on these clinical assessment patterns.
**Methods:** Alongside the intervention study, data were collected for this present qualitative study. GP (residents) were visited in 2 rounds by standardised patients (SPs) simulating either axial or peripheral SpA. In between, an educational intervention on SpA for half of the GP residents was organized. The other half and all GPs served as controls. Participants were visited by the SPs during their regular outpatient clinic and were unaware of the nature of the medical problem and study purpose. After the visit, SPs completed a case-specific checklist inquiring about disease-related items. These items were categorized into four subgroups: questions regarding (1) differentiation between a mechanical or inflammatory origin of the complaint, (2) presence of swollen joints, back pain or entheseal complaints (3) presence of extra-articular manifestations and (4) family history. Differences in patterns of clinical assessment were explored for the education versus the control group. Descriptive analyses were used to analyse demographic data.
**Results:** Sixty-eight (38 GP-residents (mean age 27.9 yrs, 32% male) and 30 GPs (mean age 52.5 yrs, 80% male) participated. Both rounds of SP-encounters were completed by 61 (90%) and 59 (87%) participants for the axial and peripheral SpA case, respectively.
Axial SpA case (Figure): participants who received education were in round 2, as compared to round 1, somewhat more likely to ask questions about the specific inflammatory character of the complaint. However, the most noticeable gain was seen in questions regarding the presence of extra-articular manifestations and family history of SpA. Despite that controls also tended to ask more questions regarding the inflammatory character of the complaint and family history of SpA in round 2, an evident increase in questions belonging to other subgroups (e.g. extra-articular manifestations) was not observed.
Peripheral SpA case (data not shown): in round 2, GP residents who received the educational intervention asked more questions regarding extra-articular complaints and family history of SpA. However, the observed gain was less evident as compared to the axial SpA case. In the control group, no difference was observed between both rounds.

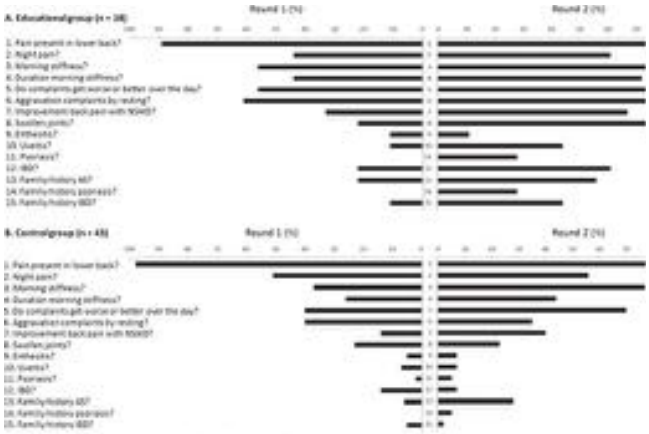

Figure. History taking pattern of GP (residents) facing a patient with axial SpA in round 1 and 2.

**Conclusions:** Targeted education can help GPs to improve their history taking and hence pattern recognition of patients suspected for SpA. Focusing on history taking alone already increases the chance of referral to the rheumatologist and targeted education should therefore be offered to all GPs to maximize a successful implementation of a referral strategy in primary care.

## Physical activity assessment - what do we know, what do we do, how does it work?

### OP0147-HPR AEROBIC CAPACITY OVER 16 YEARS IN PATIENTS WITH RHEUMATOID ARTHRITIS; RELATIONS TO RISK FACTORS FOR CARDIOVASCULAR DISEASE

K. Hörnberg, B. Sundström, S. Wållberg Jonsson. *Dpt of Public health and clinical medicine/Rheumatology, University of Umeå, Umeå, Sweden*

**Background:** Patients with rheumatoid arthritis (RA) suffer from increased mortality due to cardiovascular disease (CVD) (1). Aerobic capacity ($VO_2$ max) is inversely and strongly related to cardiovascular disease in the general population (2). RA patients have shown very low levels of $VO_2$ max compared to normative values of healthy adults (3), which may be of importance for the increased CVD incidence in RA.
**Objectives:** To analyse the change of $VO_2$ max over time from disease onset and associated potential risk- and health factors in patients with RA.
**Methods:** 25 patients (20 f/ 5 m), diagnosed with RA 1995–2002 were tested at disease onset (<12 months from symptom onset) and after a mean of 16.2 years. Applied measurements were: sub-maximal ergometer test for $VO_2$ max, functional ability, joint- and muscle function, self-efficacy, ESR, CRP, number of tender and swollen joints and patient's global health. At follow-up, the risk of CVD was measured as blood levels of lipids, insulin and glucose, Body mass index (BMI), waist circumference and body composition measured by Dual-energy X-ray absorbtiometry (DXA). Pulse wave analysis (PWA), was used to register early endothelial dysfunction, arterial stiffness and systolic blood pressure in aorta besides peripheral blood pressure. Carotid Intima-Media Thickness (IMT) was measured by ultrasonography. Additionally, Fatigue Severity Scale was used at follow-up.
**Results:** All measures reflecting disease activity decreased significantly during the follow-up period. $VO_2$ max was (median (IQR)) 32.3 (14.2) ml $O_2$/kg x min at disease onset, and 33,2 (10.5) at follow-up ($p>0.05$). Aerobic capacity at inclusion was associated with follow-up values for age (r=-.469, p=.018), $VO_2$ max (r=.557, p=.004), BMI (r=-.401, p=.047), body weight (r=-.409, p=.043), waist circumference (r=-.498, p=.011) and periferal pulse pressure (r=-.415, p=.039). Variables at disease onset associated with $VO_2$ max at follow-up were $VO_2$ max (r=.557, p=.004) and self-efficacy for function, (r=.544, p=.029).
**Conclusions:** In patients with RA followed for 16 years from disease onset, $VO_2$ max was maintained. High aerobic capacity at disease onset was associated with favourable measures of $VO_2$ max and body weight at follow-up. The variables at disease onset that best correlated with a high $VO_2$ max at follow-up were high $VO_2$ max and self-efficacy for function. Our results may be important for preventive strategies in RA.

## How cell death shapes immunity and tolerance

### OP0148 FIRST IN CLASS THERAPEUTIC ACPA REDUCES INFLAMMATION BY INHIBITION OF NETOSIS

R.G. Chirivi[1], J.W. van Rosmalen[2], G. Schmets[2], H. van Es[3], J.M. Raats[1]. *[1]Preclinical Development, Citryll and ModiQuest BV; [2]Preclinical Development, ModiQuest BV; [3]Citryll BV, Oss, Netherlands*

**Background:** Neutrophils together with aberrant Neutrophil Extracellular Trap (NET) formation contribute to the induction and propagation of inflammation. A growing number of studies indicate that Peptidyl Arginine Deiminases (PADs) mediated conversion of arginine to citrulline residues in proteins are essential for NETosis, generation of auto-antigens, autoimmunity, and the breaking of tolerance in rheumatoid arthritis (RA). In RA patients, enhanced NETosis is observed in circulating and synovial neutrophils, and NET components are observed in blood and joints.
**Objectives:** Our objective is to develop a novel first in class NET-inhibiting therapeutic anti-citrullinated protein antibody (tACPA) treatment for RA and other auto-immune diseases in which aberrant NET formation adds to the severity of the disease.
**Methods:** Human neutrophils from blood donors have been used in order to visualize the NETosis inhibiting properties of tACPA. Furthermore, collagen antibody-induced (CAIA) as well as collagen-induced (CIA) arthritis mouse models have been used in order to test the therapeutic properties of tACPA.
**Results:** In human neutrophils, NETosis induction with calcium ionophore A-23187 or physiological stimuli like human synovial fluid is strongly inhibited by tACPA treatment (40–90% NET reduction compared to non-treated cells (n>40 different donors)). This observation has been confirmed by Myeloperoxidase and Neutrophil Elastase activity as well as immunohistochemistry read-outs. In both CAIA and CIA mouse models, NET-inhibiting tACPAs are able to prevent the onset and/or exacerbation of inflammation, and prevent or strongly reduce joint damage. Histological analysis of tACPA-treated inflamed mouse joints revealed a significant decrease in neutrophil influx. We identified the epitopes recognized by tACPA to be citrullinated domains of histones 2A and 4.
**Conclusions:** We have identified antibodies directed against a citrullinated epitope in murine and human histones 2A and 4. In RA mouse models, we demonstrate that tACPAs strongly prevents the occurrence of swelling and joint damage. We propose that the therapeutic effect of tACPA acts through the inhibition of NET and auto-antigen formation, clearance of formed NETs and toxic histones. In RA patients extinguishing auto-antigen production offers an orthogonal approach for treating this destructive autoimmune disease, potentially without impacting systemic immunity.
Citryll and ModiQuest are developing tACPAs as treatment for diseases where NETs and NETosis are driving or contributing to disease progression.

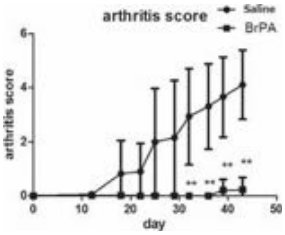
## "Smoke a joint to protect the joint". Cannabidoids & neuropeptides in pain and inflammation

### OP0149 DOPAMINE PATHWAY AND BONE METABOLISM IN RHEUMATOID ARTHRITIS

S. Capellino[1], K.W. Frommer[1], M. Rickert[2], J. Steinmeyer[3], S. Rehart[4], U. Müller-Ladner[1], E. Neumann[1]. *[1]Dept. of Internal Medicine and Rheumatology, Justus Liebig University Giessen, Bad Nauheim; [2]Dept. of Orthopedics and Orthopedic Surgery; [3]Dept. of Orthopedics, Justus Liebig University Giessen, Giessen; [4]Dept. of Orthopedics and Orthopedic Surgery, Agaplesion Markus Hospital, Frankfurt, Germany*



**Background:** A body of studies demonstrates the influence of the nervous system on the immune response. We recently described that dopamine, a neurotransmitter of the sympathetic nervous system, is locally produced by synovial fibroblasts of rheumatoid arthritis (RA) patients and influences *in vitro* cytokine release and inflammation (1). In addition, *in vivo* evidence confirmed the involvement of dopamine receptors (DR) in arthritis (2), and a subtype of DR was described to be expressed by *in vitro* differentiated human osteoclasts (3). These studies, together with the clinical evidence of an increased risk of osteoporosis in patients affected by Parkinson's disease, suggest an involvement of dopamine in joint destruction during RA. The aim of this study is therefore not only to investigate the role of the dopamine pathway on bone remodeling in RA patients, but also to unravel new pathways involved in joint destruction.
**Objectives:** The aim of this study is therefore not only to investigate the role of the dopamine pathway on bone remodeling in RA patients, but also to unravel new pathways involved in joint destruction.
**Methods:** Bone tissue was obtained from osteoarthritis (OA, n=6) and RA (n=4) patients during knee joint replacement surgery. Osteoblasts were isolated from the bone spongiosa. Immunohistochemistry of paraffin-embedded bone samples and immunocytochemistry of isolated osteoblasts were performed using antibodies against the five subtypes of DR (D1 to D5). Isolated osteoblasts were treated with specific DR agonists for 24 h or 7 d. IL-6 and IL-8 were quantified after 24 h stimulation by ELISA. Expression of tyrosine hydroxylase (TH), the rate limiting enzyme for dopamine production, was quantified in untreated isolated osteoblasts by real-time PCR. Mann Whitney test was used for statistical data analysis.
**Results:** Dopamine receptors D1, D3 and D4 could be detected by immuno-histochemistry in the bone remodeling zone of RA patients while OA samples did not express these receptors in the bone remodeling zone. Dopamine receptor subtypes D1, D2, D3 and D5 were present on isolated osteoblasts, with stronger expression in RA compared to OA. Stimulation of D1-like DR induced a significant dose-dependent increase of IL-6 release in RA compared to the untreated control (+79 ±43%, $P<0.005$). In contrast, no significant effects were detectable for OA osteoblasts. IL-8 release was not significantly altered in both RA and OA osteoblasts. TH was expressed in osteoblasts from 5 of 6 OA and from 2 of 4 RA patients, with expression levels even higher than in synovial fibroblasts (up to +50% in RA osteoblasts).
**Conclusions:** Dopamine receptors are upregulated in the bone remodeling zone of RA patients and their activation seems to have proinflammatory effects and to inhibit osteoblast activation. Expression of TH in osteoblasts suggests autocrine/paracrine effects of dopamine locally synthesized in the bone. These data underline the key involvement of the dopamine pathway in bone remodeling and joint erosion in RA.

### OP0150 3-BROMOPYRUVATE AMELIORATES AUTOIMMUNE ARTHRITIS BY EXERTING A DUAL EFFECT ON BOTH TH17 AND TREG CELL DIFFERENTIATION AND DENDRITIC CELL ACTIVATION

T. Okano, J. Saegusa, K. Nishimura, S. Takahashi, S. Sendo, Y. Ueda, A. Onishi, A. Morinobu. *Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan*

**Background:** Recent studies have shown that cellular metabolism plays an important role in regulating immune cell function. In the process of cell differentiation, both interleukin-17-producing T (Th17) cells and dendritic cells (DCs) show increase of glycolytic activity by upregulating glycolytic enzymes, such as hexokinase-II (HK-II). Blocking glycolysis by 2-deoxyglucose has recently been demonstrated to inhibit Th17 cell differentiation while promote regulatory T (Treg) cell generation, and then ameliorate experimental autoimmune encephalitis model.
**Objectives:** The aim of this study is to verify the effect of 3-bromopyruvate (BrPA), a specific inhibitor of HK-II, on the differentiation and function of immune cells and on experimental arthritis in SKG mice.
**Methods:** Arthritis was induced in SKG mice by Zymosan A injection. BrPA (5 mg/kg) was administered subcutaneously once daily. CD4+ T cells from splenocytes of unimmunized SKG mice were cultured with anti-CD3/anti-CD28, anti-IFN-γ, anti-IL-4, IL-6, TGF-β, and IL-2, with or without BrPA for 5 days, and then analyzed by flow cytometry. Bone marrow (BM) cells from unimmunized SKG mice were cultured with GM-CSF and IL-4 (for 3 days), and with LPS (for 1 day) with or without BrPA, and then analyzed by flow cytometry.
**Results:** Treatment with BrPA significantly ameliorated arthritis of SKG mice (Figure). Histological scores of arthritis in BrPA-treated mice were significantly reduced compared with those in control mice. Flow cytometric analysis revealed that significant increase of Treg cells, decrease of Th17 cells, and decrease of CD40+CD86+CD11b+CD11c+ activated DCs were observed in the splenocytes from BrPA-treated mice. BrPA did not affect IFN-γ-producing Th1 cells nor IL-4-producing Th2 cells. *In vitro*, BrPA facilitated the differentiation of Treg cells, while it inhibited the development of Th17 cells. In addition, treatment of BM cells with BrPA inhibited the differentiation of activated DCs and the production of TNF-α and IL-6 from DCs.

**Conclusions:** BrPA facilitates the differentiation of Treg cells, and inhibits the development of Th17 cells and the activation of DCs, and ameliorates arthritis in the SKG mice.

## Teaching clinical skills

### OP0151 A STUDY ON MEDICAL STUDENTS LEARNING ULTRASOUND IN RHEUMATOID ARTHRITIS (ASMSLURA)

A. Sukhdeo[1], F. Joshua[2], A. Damodaran[3], B. Shulruf[4]. *[1]Rheumatology, John Hunter Hospital, New Lambton Heights; [2]Rheumatology, Prince of Wales Hospital; [3]Prince of Wales Clinical School, University of New South Wales; [4]Medical education, University of New South Wales, Randwick, Australia*

**Background:** Rheumatoid arthritis (RA) affects ~ 0.5% of the adult population worldwide. The current "standard" of teaching consists of didactic lectures and bedside teaching. It has been shown that musculoskeletal teaching is inadequate and needs improvement.[1–3] Ultrasound is safe and increasingly taught to postgraduates in specialties such as rheumatology and orthopaedics to improve their clinical skills. Literature suggests that ultrasound teaching may be beneficial for medical students.[4]
**Objectives:** This study aimed to assess whether the incorporation of ultrasound in teaching improved medical students' knowledge of rheumatoid arthritis and interest in musculoskeletal medicine.
**Methods:** This study was a single site, randomised, prospective, open, cross over trial comparing RA teaching in medical students, assisted with ultrasound, versus teaching via standard methods. The study included 3rd and 4th year students enrolled in the University of New South Wales 6 year undergraduate medical program. Students were randomised into 2 groups, and underwent both sets of teaching in different order. A written multiple-choice exam, was held before any teaching began, and after the first and second sets of teaching. An evaluation survey was administered at the conclusion of the two sets of teaching. Results from the MCQ exam was statistically analysed and the survey was qualitatively analysed.
**Results:** A total of 20 students completed the study (11 students from group 1 and 9 from group 2). The exam scores improved significantly ($p \leq 0.01$) for both groups after they undertook standard teaching. However, the exam scores did not improve for either group after ultrasound teaching. We also found that exam scores improved significantly ($p \leq 0.01$) for both groups at the conclusion of the entire teaching period. The order in which the students underwent teaching did not result in significantly different scores. The questionnaire revealed that most students thought ultrasound was of educational value and helped them improve their knowledge of anatomy. However they were equivocal about whether it helped their learning of RA. Both groups rated standard teaching highly.
**Conclusions:** This crossover trial demonstrates significant improvement in students' knowledge of RA after undergoing standard teaching as opposed to ultrasound teaching. Factors which may have contributed to this result and which deserve further exploration include using different assessment methods for ultrasound teaching, using different learning levels and using different teachers.

## What is done for people with rare diseases? Can we do more?

### OP0152-PARE STARTING A DISEASE SPECIFIC YOUTH GROUP ON A NATIONAL LEVEL

J. Andersen[1,2,3]. *[1]EULAR Young PARE, Kilchberg, Switzerland; [2]Lupus Europe, Romford, Essex, United Kingdom; [3]Gigtforeningen, Gentofte, Denmark*

**Background:** A high proportion of individuals living with lupus (SLE) are young women, aged 25 to 35. At this age, they are getting ready to "begin" life with partners, children, education and careers. For most of them, this all stops at the time of diagnosis. They have to adjust to a lifelong struggle with pain, fatigue, headaches, cognitive problems and strong medications. As a result of this autoimmune disease, it is for instance, no longer risk-free to bear a child. This has to be done in close co-operation with various health professionals, and for some women, it is not an option at all.
**Objectives:** To help these young people to understand their disease and inspire them to live a full life, despite of coping with this incurable disease. A better understanding of the disease makes it easier to take control of treatment, and thereby having a more fulfilling life.
**Methods:** The goal was to start a youth group within our mother organisation. Although we already have a working and active SLE group in Denmark, that has existed for 22 years, we found out, that the young people were not joining in. The issues of a lupus patient changes considerably from when you are in your 20s, to your 50s (where most of our members were at that time). As a young person, you may not be comfortable with talking about your sex life with "older" ladies. We started with a theme day about sex and partnership, only for young people, and their spouses – and this was a great success.
**Results:** Out of this day, a Facebook group for young people (ages 18–35) was created, where the young people can discuss everything they want to. There are no taboos and people support each other with good advice or a shoulder to cry on. Besides the Facebook group, we now have a youth day with changing themes on our schedule every year. We have one person dedicated to the youth activities and this person also has a seat in our mother organisation, whereby youth issues are implemented in all our activities.
**Conclusions:** We now have a well functioning and active youth group, where young people with lupus can support each other and raise the issues important to them.

OP0153-PARE **REUMAMAMA'S EN –PAPA'S: INFO SESSIONS FOR (FUTURE) PARENTS WITH RMDS AND FOR PARENTS WITH CHILDREN WITH JUVENILE ARTHRITIS**

A. Marchal, I. De Keyser on behalf of ReumaNet vzw - ORKA. *ReumaNet vzw, Mol, Belgium*

**Background:** When diagnosed with a rheumatic condition (RMD), the first concern is managing and controlling the disease. More specific topics such as how you deal with a diagnosis as a parent of a child with an RMD or how to take care of children as a young parent with an RMD are less discussed with the rheumatologist. A lot of questions and concerns about heredity and pregnancy stay unanswered too.
**Objectives:** ReumaNet wants to offer tailor made information for young people with an RMD and a child wish and for parents of a child with an RMD.
**Methods:** ReumaNet, the Flemish organisation for people with RMDs, organised two info sessions in September-November 2015. The two target groups were 1) young (future) parents with an RMD and 2) parents with a child with an RMD. Both target groups first met informally for sharing their personal stories, concerns, experiences and expectations. During this first meeting, they noted down several questions and concerns regarding the topic. During the second session, different specialists such as a rheumatologist, a psychologist, a gynecologist, a pediatrician, ... tried to answer these specific questions and they gave more information on pregnancy and RMD's in the first group, and RMD's in children in the other group.
**Results:** Both sessions were well attended, although more people showed up during the second session. People obviously feel more safe when they mainly have to listen to information, instead of participating in a discussion.
(Future) parents with an RMD received information regarding heredity, pregnancy, delivery, (breast)feeding and practical tips and tricks regarding taking care of children. Parents with children with an RMD received not only practical information concerning juvenile arthritis (the diagnosis, the disease, future perspectives and impact in school), but also information regarding the psychological impact of receiving and dealing with the diagnosis as a parent.
**Conclusions:** There is a great need for information for either young parents with an RMD as well as for parents of a child with an RMD. Furthermore, these two groups will always be renewed throughout the years. This means the need for this kind of information will be ongoing. Along with organising ReuMaMaMa's, ReumaNet is also developing three brochures on these topics: "Pregnancy and heredity", "How to take care of infants", for parents with a RMD' and "Juvenile Arthritis". The live sessions will be repeated every two years.

**THURSDAY, 9 JUNE 2016**

## The Health Professionals' approach to pain management in inflammatory arthritis and osteoarthritis

OP0154-HPR **SPINAL MOBILITY IS IMPAIRED IN PATIENTS WITH CHRONIC BACK PAIN OF SHORT DURATION, BUT DOES NOT DISCRIMINATE BETWEEN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND OTHER FORMS OF CBP**

C. Fongen[1], H. Dagfinrud[1], I.J. Berg[1], S. Ramiro[2], F. van Gaalen[3], R. Landewé[2], R. Ramonda[4], M. van Oosterhout[5], D. van der Heijde[3], K.M. Fagerli[1]. *[1]Diakonhjemmet Hospital, Oslo, Norway; [2]AMC, Amsterdam; [3]LUMC, Leiden, Netherlands; [4]University of Padova, Padova, Italy; [5]GHZ, Gouda, Netherlands*

**Background:** Ankylosing spondylitis is associated with reduced spinal mobility. Little is known about the spinal mobility in early axial spondyloarthritis (axSpA) and how it compares to patients with other forms of chronic back pain (CBP).
**Objectives:** The aim was to compare spinal mobility in patients with CBP of short duration with reference mobility curves from the general population and to examine whether frequently used spinal mobility measures (SMM) can discriminate between axSpA and other forms of CBP.
**Methods:** The SPACE-cohort includes patients with CBP ($\geq$3 months, $\leq$2 years, onset $<$45 years) recruited from 5 centres in Europe. The CBP patients were classified as axSpA (fulfilling the ASAS criteria), possible axSpA (possSpA) (not fulfilling ASAS criteria but $\geq$1 axSpA feature) or not having SpA (noSpA).
Spinal mobility was assessed with lateral spinal flexion (LSF), chest expansion (CE), intermalleolar distance (IMD), modified Schober (MS), cervical rotation (CR) and occiput-to-wall distance (OWD).
SMM, except OWD, were defined as impaired if below the 5th percentile reference curve from general population, given their age and for CE and IMD also height, following the equations of mobility curves for each measures[1]. OWD $>$0 was considered impaired. The proportion of patients with impaired spinal mobility for each measure was compared across the patient groups using Chi square.
**Results:** In total 393 CBP-patients were included: 142 axSpA, 139 possSpA and 112 noSpA. Some characteristics of patients with axSpA were statistically significant different compared to possSpA and noSpA: a larger proportion (%) was male 48/28/27, reported less back pain (NRS 0–10) median 4.0/6.0/6.0 and patients with axSpA were taller (cm) than patients with possSpA mean 177/173/174.
In all CBP patients, the most frequently impaired mobility measure was LSF 40% followed by CE 22%, CR 18%, IMD 17%, MS 15% and OWD 11% (table 1). No statistically significant differences in proportion of patients with impaired spinal mobility were found between the CBP subgroups.

Table 1. Proportion of patients categorised with impaired[α] spinal mobility

| Measure | All chronic back pain (n=393) | axSpA (n=142) | possSpA (n=139) | noSpA (n=112) | p-value |
|---|---|---|---|---|---|
| Lateral spinal flexion (393) | 158 (40) | 50 (35) | 57 (41) | 51 (46) | 0.24 |
| Chest expansion[β] (374) | 80 (22) | 27 (20) | 31 (24) | 23 (21) | 0.79 |
| Cervical rotation (390) | 69 (18) | 21 (15) | 30 (22) | 18 (16) | 0.26 |
| Intermalleolar distance (371) | 63 (17) | 16 (12) | 28 (22) | 19 (18) | 0.13 |
| Modified Schober (394) | 57 (15) | 17 (12) | 20 (14) | 20 (18) | 0.42 |
| Occiput to wall[γ] (393) | 42 (11) | 18 (13) | 18 (13) | 6 (5) | 0.10 |

Values are number (percent). [α]Below the 5th percentile compared with age- (height) specific mobility curves [1], [β]the derivation of reference value included height, [γ]$>$0 categorised as impaired.

**Conclusions:** Among patients with CBP of short duration, between15–40% had a spinal mobility below the 5th percentile in the general population depending on the measurement used. The most affected SMM was LSF. Impaired spinal mobility was equally prevalent in patients with axSpA and other causes of CBP. Our findings suggest that the SMM recommended for axSpA may be of little differential diagnostic value.

## News from kinase inhibitors

OP0155 **DEVELOPMENT OF A JAK3 SPECIFIC INHIBITOR CLINICAL CANDIDATE: FUNCTIONAL DIFFERENTIATION OF JAK3 SELECTIVE INHIBITION OVER PAN-JAK OR JAK1 SELECTIVE INHIBITION**

J.-B. Telliez[1], L. Wang[1], J. Jussif[1], T.H. Lin[1], L. Li[1], E. Moy[1], W. Li[1], Y. Zhao[1], K. Crouse[1], P. Symanowicz[1], M. Hegen[1], M.E. Banker[2], F. Vincent[2], J.D. Clark[1], A. Thorarensen[3]. *[1]Inflammation & Immunology, Pfizer, Cambridge; [2]PDM, Pfizer, Groton; [3]Chemistry, Pfizer, Cambridge, United States*

**Background:** Janus kinase (JAK) inhibitors targeting multiple JAK isoforms, JAK1 and 2, or selective against JAK1 are currently utilized in clinical practice or being developed for the treatment of various inflammatory and oncological diseases. No truly JAK3-selective inhibitor has reached the clinic. JAK3 signal in pairs with JAK1 to transduce signal elicited from six known cytokines (IL-2, IL-4, IL-7, IL-9, IL-15 & IL-21) binding to the gamma-common (g-c) chain cytokine receptors. JAK1 in addition to be required for g-c chain cytokine receptors signaling can also signal in pair with JAK2 or TYK2 and is required for other cytokine receptors signaling such as type I and II interferons and IL-6 and IL-10 families of cytokines. Other cytokines such as IL-12 and IL-23 are signaling via JAK2 and TYK2. Additionally, hematopoietic cytokines such as EPO and TPO as well as cytokines such as IL-3 and IL-5 signal via homodimers of JAK2.
**Objectives:** Develop a JAK3 selective inhibitor that will inhibit signaling from the g-c chain cytokine receptors at therapeutic dosing without inhibiting signaling by other cytokines such as hematopoietic cytokines, type I and II interferons and IL-6, IL-12 and IL-10 families of cytokines.
**Methods:** A JAK3-specific covalent ATP competitive inhibitor was assessed functionally *in vitro* and *in vivo*. Functional differentiation of JAK3 selective inhibition as compare to pan-JAK inhibition (tofacitinib) or JAK1 selective inhibition was also assessed.
**Results:** The inhibitor showed JAK3 selective inhibition in biochemical and cellular assays. It inhibits Th1 and Th17 cell differentiation and function. Importantly, sparing JAK1 inhibition, through the selectivity of this inhibitor, preserved anti-inflammatory functions such as the differentiation of alternatively activated M2a macrophages. Unlike pan-JAK or JAK1-selective inhibitors, JAK3 selective inhibition also preserved IL-10-dependent suppression of the production of pro-inflammatory cytokines following LPS treatment in macrophages while maintaining the suppression of TNF and IL-1 responses in IL-27-primed macrophages. Further characterization of this compound in the rat adjuvant-induced arthritis (AIA) demonstrated efficacy at reducing disease pathology.
**Conclusions:** We have identified the first trully selective JAK3 inhibitor with potency and properties that make it suitable for further clinical development.

### OP0156 DECIPHERING THE IN VITRO THERAPEUTIC POTENTIAL OF JAK INHIBITORS IN ANKYLOSING SPONDYLITIS

A. Hammitzsch, L. Chen, H. Al-Mossawi, D. Simone, A. Ridley, P. Bowness.
*Botnar Research Centre, NDORMS, University of Oxford, Oxford, United Kingdom*

**Background:** In Ankylosing Spondylitis (AS) therapeutic options include blocking of TNF and IL-17, but are expensive and limited compared to other rheumatic diseases. In addition there is no convincing evidence that either of these therapies is able to block new bone formation, the hallmark of AS. Small molecule inhibitors of Janus kinases (JAK) are potent inhibitors of other inflammatory diseases including Rheumatoid Arthritis (RA), and inhibit new bone formation in murine Spondyloarthritis[1,2].
**Objectives:** We evaluated the ability of 4 different JAK family inhibitors to reduce IL-17A production in vitro using blood and synovial fluid samples from patients with AS, Psoriatric Arthritis (PsA) and RA. We choose to study Tofacitinib, as it shows relative specificity to JAK3, Ruxolitinib (JAK1), CEP-33779 (JAK2) and Bayer-18 (TYK2), in order to decipher the most potent inhibitor for this disease.
**Methods:** CD4 T cells were isolated from PBMC of AS (n=43), PsA (n=13), RA patients (n=10) and Healthy controls (HC, n=15) and stimulated for 3 days under Th17-promoting conditions in the presence of JAK inhibitors. Cytokine secretion (IL-17A for all samples, IL-17F, IL-22, GM-CSF and IFN$\gamma$ for a representative subgroup) was assessed using ELISA, measured in pg/m, and expressed as relative to control. Cytotoxicity and proliferation were measured with Annexin V/7-AAD staining and CFSE dilution on Flow cytometry. TYK2 was silenced in primary human CD4 T cells with siRNA and effects were analysed using ELISA and Western Blot.
**Results:** All JAK inhibitors tested reduced secretion of IL-17A in CD4 T cells from AS, PsA, RA patients and HC (see Fig. 1 for data on AS and HC). In a small subset of 10 AS patients Tofacitinib showed statistically significant inhibition of IL-17F, IL-22, GM-CSF and IFN$\gamma$ secretion, and CEP-33779 of IL-22 and GM-CSF secretion. At the same time cytotoxicity and anti-proliferative capacity of the inhibitors was low. No correlation between inhibitory capacity of the different small molecules and clinical parameters was observed. Bayer-18 did not significantly reduce Th17 cytokine secretion, but siRNA-mediated knock down of TYK2 in primary human CD4 T cells inhibited IL-17A, IL-22 and IL-17F secretion, when knock-down efficacy exceeded 70%.

Fig. 1. JAK inhibitors reduce in vitro IL-17A production by CD4 T cells from AS patients and controls

**Conclusions:** All JAK inhibitors tested reduce IL-17A secretion from CD4 T cells in vitro. Despite the fact that our study does not address the specificity of the different JAK inhibitors, we find no clear evidence that targeting any one JAK family member is superior in reducing in vitro Th17 responses. Our siRNA knock-down data suggest that TYK2 is still a valuable target for developing new treatments in AS, even though blockade of its kinase activity was not efficacious in reducing IL-17A secretion. One explanation is that the IL-17A-inducing activity of TYK2 was not inhibited by Bayer-18 in our assays or that the scaffold function of TYK2 is more important in this pathway.

## Crystal arthritis

### OP0157 PREVALENCE AND SIGNIFICANCE OF MEFV GENE MUTATIONS IN PATIENTS WITH GOUTY ARTHRITIS

S. Kobak[1], A. Karaarslan[2], I. Kaya[3], N. Intepe[2], M. Orman[4], A. Berdeli[5].
*[1]Rheumatology; [2]Ortopedics; [3]Genetics, Sifa University Faculty of Medicine; [4]Statistics; [5]Genetics and Molecular Medicine, Ege University Faculty of Medicine, Izmir, Turkey*

**Background:** Gouty arthritis is a chronic erosive autoinflammatory disease. Pyrin has anti-inflammatory effects in the regulation of inflammasome and is encoded by the MEFV gene. MEFV gene mutations trigger inflammatory cascade and cause familial Mediterranean fever The relationship between different rheumatic diseases and the MEFV gene mutations was demonstrated.
**Objectives:** The aim of this study was to determine the frequency of MEFV gene mutation in patients with gouty arthritis and identify a possible correlation with disease phenotype.
**Methods:** Ninety-three patients with gouty arthritis and 102 healthy controls, compatible with age, gender and ethnicity, were included in the study. MEFV gene was investigated by PCR method.
**Results:** Out of 93 patients with gouty arthritis, 36 (38.7%) showed MEFV gene mutation carriage, whereas 20.6% in healthy control group. Distribution of mutations identified in patients with gouty arthritis was as; R202Q in 18 (19.3%), E148Q in 5 (5.4%), K695R in 4 (4.3%), M680I in 2 (2.1%), V726A in 2 (2.1%), P369S in 2 (2.1%), R408Q in 2 (2.1%), M694V in 1 (1.1%), respectively. Three patients were identified with compound heterozygosity. Distribution of MEFV gene mutation carriage in healthy controls was; E148Q in 11 (10.7%), M694V in 2 (1.9%), M694I in 1 (0.9%), M680I in 2 (1.9%), V726A in 1 (0.9%), A744S in 1 (0.9%), K695R in 2 (1.9%), and P369S in 1 (0.9%) pateints, respectively. Higher MEFV gene mutation carrier frequency was observed in patients with gouty arthritis, compared with the control group (p=0.009). Heterozygous R202Q was the most common mutation detected in patients with gouty arthritis while heterozygous E148Q in healthy control group. Statistically significant difference was not detected between clinical findings of gouty arthritis and the MEFV gene mutations ($p>0.05$).
**Conclusions:** We determined higher prevalence of MEFV gene mutation in patients with gouty arthritis compared with the healthy control group. The most frequently detected mutation was heterozygous R202Q wheras E148Q in healthy controls. High carriage rates of MEFV gene mutation in gouty arthritis suggests that it may play an important role in the pathogenesis of the disease and predisposition to the disease. In this regard, prospective studies are needed with larger series of patients.

### OP0158 MITOCHONDRIAL GENETIC VARIATION AND SUSCEPTIBILITY TO GOUT IN POLYNESIANS

T.R. Merriman[1], A. Gosling[1], J. Boocock[1], N. Dalbeth[2], L. Stamp[3], E. Stahl[4], H. Choi[5], L. Matisoo-Smith[6]. *[1]Biochemistry, University of Otago, Dunedin; [2]Medicine, University of Auckland, Auckland; [3]Medicine, University of Otago, Christchurch, New Zealand; [4]Mount Sinai School of Medicine, New York; [5]Harvard Medical School, Boston, United States; [6]Anatomy, University of Otago, Dunedin, New Zealand*

**Background:** Mitochondria appear to play a central role in the induction of an NLRP3 inflammatory response, an immune response critical for the development of gouty pathology. Mitochondria are in part self-encoding, possessing a 16.5 kB circular genome which encodes 36 genes. Therefore mitochondrial genetic variation may contribute to susceptibility to gout.
**Objectives:** The objective of this study was to test whether mitochondrial genetic variation and copy number among New Zealand Polynesians may be contributing to susceptibility to gout. The Māori and Pacific (Polynesian) populations of New Zealand exhibit a high prevalence of gout (6 and 8%, respectively).
**Methods:** 439 whole mitochondrial genomes belonging to Māori and Pacific men from New Zealand (327 cases, 112 controls) were sequenced to explore whether mitochondrial DNA (mtDNA) variation may contribute risk to gout. mtDNA copy number variation was also investigated by looking at relative read depth using Next Generation Sequencing data produced from whole genome sequencing and resequencing of urate loci. Quantitative PCR was undertaken for replication in an extended sample set of 540 Polynesian male and female cases and 530 controls.
**Results:** Within Polynesia, there is relatively little mitochondrial genetic diversity, with around 96% of those sequenced in this study belonging to the B4a1a and derived sub-lineages. A lineage-specific heteroplasmy in hypervariable region I was found to associate with a greater than three-fold higher risk of gout among the mitochondrial sequenced sample set (e.g. heteroplasmy at position 16179: OR 3.28, $P$=0.009; heteroplasmy at position 16181: 3.86, $P$=9x10$^{-5}$; heteroplasmy at position 16182: 3.43, $P$=0.005).
Quantitative PCR of mtDNA from the 1070 Polynesian gout cases and controls showed that individuals with gout possess less mtDNA, on average than healthy controls. With each unit increase in $\Delta$Ct (which reflects a decrease in mtDNA

content), there was a 33% increase in gout risk (OR 1.33, *P*=0.003). The effect was stronger when looking at those participants who possessed urate levels exceeding 0.40 mmol $L^{-1}$ (n=422, OR 1.69, *P*=0.0005).

**References:**

[1] It is unclear whether the reduced mtDNA copy number in gout is a result of the gouty pathology directly (i.e. the reduced mtDNA copy number is caused by the inflammatory processes underlying gout) or whether the reduced mtDNA copy number contributes to the risk of gout. The latter possibility is supported by the increase in risk using hyperuricemic controls suggesting that reduced mtDNA copy number plays a role in inflammation. Given emerging research is showing that mitochondria play a central role in the induction of the NLRP3 inflammasome, in particular with the co-localisation of the NLRP3 and ASC sub-units, a process essential for the generation of IL-1β, these observations may be significant. Exploring mitochondrial genetic variation may further elucidate the inflammatory processes underlying gout.

## New pathways to treatment

### OP0159 IMPROVING B-CELL DEPLETION IN RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS: RESISTANCE TO RITUXIMAB AND THE POTENTIAL OF OBINUTUZUMAB

V. Reddy[1], C. Klein[2], D. Isenberg[1], G. Cambridge[1], M. Cragg[3], M. Leandro[1]. *[1]Rheumatology, University College London, London, United Kingdom; [2]Roche Pharmaceutical Research & Early Development, Oncology Discovery & Translational Area Cancer Immunotherapy Discovery, Zurich, Switzerland; [3]Antibody & Vaccine Group, Southampton University, Southampton, United Kingdom*

**Background:** In patients with Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE), who have poor responses to standard doses of rituximab (RTX), enhanced B-cell depletion and improved clinical responses can be achieved with higher doses of RTX. Defects in complement, NK cell function and CD11b polymorphisms associated with SLE may impair the effector mechanisms evoked by RTX whilst high BAFF levels may confer B cells some resistance to apoptosis. Obinutuzumab (OBZ, a Type II anti-CD20 monoclonal antibody [mAb] with afucosylated Fc portion and enhanced affinity for Fcγ receptor III) is more efficient than Rituximab (RTX, a Type I mAb) at inducing malignant B cell cytotoxicity and has recently entered Phase II clinical trials in SLE.

**Objectives:** To compare the effects of RTX and OBZ against B cells from patients with RA and SLE in vitro and dissect any differences between the two mAbs in evoking effector mechanisms in RA and SLE.

**Methods:** We used flow cytometry to perform: in vitro whole blood B cell depletion assays to compare the efficiency of OBZ and RTX in depleting target B cells; surface fluorescence-quenching assays to determine the extent of mAb internalization; complement dependent cellular cytotoxicity (CDC) assays to assess the ability to recruit complement and lyse target cells; NK cell degranulation assays assessing surface expression of CD107a as a measure of antibody-dependent cellular cytotoxicity (ADCC); and neutrophil activation assays assessing the surface expression of CD62L and CD11B. Annexin V positivity represented cell death in direct cell death (DCD) assay. OBZ-gly (OBZ with Fc glycosylation similar to RTX) was used to assess the effects of afucosylation. All mAb were used at 1μg/mL except for the CDC and DCD assays (10μg/mL).

**Results:** OBZ was >2 fold more efficient than RTX at inducing cytotoxicity in B cells from patients with RA (n=31) and SLE (n=34) in whole blood assays. It was also internalized by isolated B cells from SLE patients (n=6) to a significantly lower extent than RTX with a median surface accessible mAb of 75% and 59%, respectively, after 6 hours of incubation. OBZ was at least twice as efficient at inducing NK cell activation, in RA (n=13) and SLE (n=19); and also activated neutrophils more efficiently than RTX in SLE (n=15) (Figure 3). In contrast, RTX was significantly more efficient than OBZ at evoking CDC of isolated B cells (SLE, n=6). OBZ was also more efficient at inducing direct cell death in CD19+ B-cells as a whole and in naïve (IgD+CD27-); and switched (IgD-CD27+) memory B-cells, a higher frequency of which is associated with poor clinical response after RTX.

**Conclusions:** Obinutuzumab is more efficient than rituximab at inducing B cell cytotoxicity in vitro in both RA and SLE samples. Enhanced direct cell death, reduced CD20 internalization and superior FcR-mediated effector mechanisms are observed, while complement mediated cytotoxicity is reduced. These data provide a mechanistic basis for considering Obinutuzumab as an alternative B cell depleting agent in RA and SLE, in particular.

### OP0160 CHARACTERIZATION OF SYSTEMIC LUPUS ERYTHEMATOSUS SUBGROUPS WITH FEATURES OF ANTIPHOSPHOLIPID OR SJÖGRENS'S SYNDROME UTILIZING AFFINITY PROTEOMICS

H. Idborg[1], A. Zandian[2], J.T. Gustafsson[1], I. Gunnarsson[1], E. Svenungsson[1], P. Nilsson[2], P.-J. Jakobsson[1]. *[1]Rheumatology Unit, Department of Medicine, Karolinska Institutet; [2]Affinity Proteomics, Science for Life Laboratory, School of Biotechnology, KTH – Royal Institute of Technology, Stockholm, Sweden*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disease that covers a wide range of phenotypes, from subtle symptoms to life-threatening conditions. The heterogeneous presentation of SLE is a major obstacle in clinical trials and the lack of biomarkers also hampers accurate diagnosis and choice of treatment.

**Objectives:** In this study we explored biochemical pathways in two suggested subgroups of SLE utilizing affinity proteomics in order to characterize subgroups and identify biomarkers for personalized medicine.

**Methods:** We have utilized Karolinska SLE cohort consisting of 320 well-characterized SLE patients and 320 individually matched population based controls in a cross-sectional study. SLE subgroups were defined only based on patients' autoantibody profile: an Antiphospholipid Syndrome-like (APS-like, n=55) and a Sjögren's Syndrome-like (SS-like, n=58) subgroup. Based on literature and clinical knowledge we have made a targeted selection of 281 proteins targeted by in total 367 antibodies from the Human Protein Atlas. Antibodies were covalently coupled to color-coded magnetic beads. EDTA-plasma samples were labeled with biotin and screened in a 384 bead array format. The read-out was made by adding a streptavidin fluorophore and using suspension bead arrays.

**Results:** We identified differences in protein profiles comparing APS-like and SS-like SLE subgroups: The top most significantly different proteins were Integrin beta 1 (p=9.8e-8, Log2 fold change=1,5), renin (p=2.7e-5, Log2 fold change=0.5), glutamic-oxaloacetic transaminase 1 (p=2.9e-5, Log2 fold change=0,5) and Apolipoprotein M (p=3.4e-5, Log2 fold change=0,3) that all were increased in SS-like SLE, while Apolipoprotein H (β2-GPI, p=6.6e-5, Log2 fold change=-0,3) were increased in the APS-like subgroup.

**Conclusions:** The two suggested SLE subgroups were defined exclusively on autoantibody profile as the APS-like and the SS-like subgroups. Our results demonstrate that the two subgroups differ in their protein profiles and that these observations indicate underlying pathogenic differences between SS-like and APS-like SLE. A common etiology of the presence of β2-GPI in both APS and in APS-like SLE is suggested. Therefore, we believe that stratification of SLE patients should be further explored towards personalized medicine.

**Disclosure of Interest:** None declared

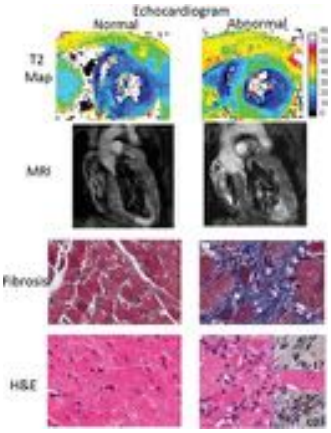
### OP0161 CARDIAC MAGNETIC RESONANCE IMAGING OF LUPUS NEPHRITIS-INDUCED CARDIOVASCULAR DISEASE CORRELATES WITH MYOCARDITIS, FIBROSIS, AND ENHANCED PRO-INFLAMMATORY CYTOKINE EXPRESSION IN A MOUSE MODEL

N.A. Young[1], J. Hampton[1], A. Kalyanasundaram[2], A. Bratasz[3], J. Pyles[3], S. Aqel[1], W. Jarjour[1], S. Ardoin[1]. *[1]Rheumatology and Immunology; [2]Physiology and Cell Biology; [3]Small Animal Imaging Core, The Ohio State University Wexner Medical Center, Columbus, United States*



**Background:** Epidemiological data shows a bimodal pattern of mortality in lupus. The most deadly complications are associated with systemic lupus erythematosus (SLE) disease activities, including kidney disease and infections, in the first 10 years; subsequently, the primary cause of morbidity and mortality is cardiovascular disease (CVD). Previously, we used cardiac magnetic resonance imaging (CMR) with quantitative T2 mapping in human SLE and observed enhanced T2 signals in active patients during flares, which suggested sub-clinical levels of cardiac inflammation.

**Objectives:** Since patients may significantly benefit from non-invasive monitoring of CVD, we used CMR to examine the NZM2410 animal model of lupus nephritis (LN), which develops severe lupus-like glomerulonephritis at 22–40 weeks of age.

**Methods:** Myocardial edema was measured with T2 CMR mapping on the BioSpec 94/30 microMRI imaging system. Mice were monitored for cardiac abnormalities and physiological cardiac function using a high-frequency ultrasound echocardiogram (EC). Blood urea nitrogen (BUN) levels were measured to assess kidney function and ELISA was performed on cardiac tissue homogenates and serum. Heart tissue was collected for H&E, immunhistochemistry, and Masson's trichrome staining to measure tissue fibrosis.

**Results:** As NZM2410 mice aged, a significantly enhanced expression of IL-1β, IL-2, IL-6, IL-10, CXCL1, and TNF-α was detected in both the serum and cardiac tissue. CMR T2 mapping was performed at 20–25 weeks of age and EC was used to monitor for cardiac abnormalities. When ECs indicated increased left ventricular diameter and residual volumes as well as significantly decreased ejection fractions

relative to baseline, CMR with T2 mapping was performed again. Despite BUN levels and weight measurements showing no signs of end-stage renal disease, T2 signals were elevated and the myocardium thickened significantly to produce a prominent left ventricular hypertrophy upon MRI analysis. In addition, expression of IL-10, IL-2, IL-6, CXCL1, and TNF-α was significantly up-regulated in the serum of these mice. Histopathological examination revealed robust infiltrates in cardiac tissue with significant fibrosis. While immunohistochemical staining showed little to no detection of B-cells, neutrophils, or macrophages, IL-17 and CD3+ T-cells were observed in cardiac infiltrates.

**Conclusions:** Our results demonstrate that myocarditis is associated with pro-inflammatory cytokine expression and LN disease progression in NZM2410 mice prior to end-stage renal disease. Consequently, our data establish CMR as a novel non-invasive technique to explore the contribution of SLE-mediated inflammation on CVD and to develop therapeutic strategies to pharmacologically inhibit cardiac damage. Future work will identify biomarkers associated with cardiac damage and will further develop CMR with quantitative T2 mapping as a clinical tool to assess CVD in patients with SLE.

## OP0162 TOLL-LIKE RECEPTOR 7-, BUT NOT TOLL-LIKE RECEPTOR 9-, MEDIATED INTERFERON-α PRODUCTION FROM PLASMACYTOID DENDRITIC CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS

K. Sakata[1,2], S. Nakayamada[2], Y. Miyazaki[2], S. Kubo[2], K. Nakano[2], Y. Tanaka[2]. *[1]Mitsubishi Tanabe Pharma Corporation, Yokohama; [2]The First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyusyu, Japan*

**Background:** Characteristic induction of interferon (IFN) signature is known to play a pivotal role in patients with SLE and plasmacytoid dendritic cells (pDC) are major source of Type I IFN. However, mechanisms of Type I IFN production from pDC in the pathogenesis of SLE remain unclear.

**Objectives:** To elucidate the function of pDC in SLE, we shed light upon Toll-like receptor (TLR) 7 and TLR9-mediated signaling during Type I IFN production from pDC in patients with SLE or healthy controls (HC).

**Methods:** Peripheral blood mononuclear cells (PBMCs) in 68 SLE patients without hydroxychloroquin treatment, 37 RA patients and 24 HC were analyzed in the presence of a TLR7 agonist loxoribine and a TLR9 agonist CpG 2216. The IFN-α production in Lin-HLA-DR+CD123+CD11c- pDCs was detected by flow cytometry.

**Results:** The spontaneous production of IFN-α in pDCs was marginal, but the TLR7 agonist markedly up-regulated IFN-α production from pDCs in SLE patients compared to that in HC. Such an up-regulation of IFN-α was not observed in pDCs in RA. On the other hands, TLR9-mediated IFN-α production from pDCs in SLE was down-regulated compared to that in HC. Furthermore, TLR7- and TLR9-mediated IFN-α production from pDCs in SLE patients were positively and negatively correlated with SLEDAI and dsDNA-ab titers, respectively. The expression of TLR7 and TLR9 on pDCs was comparable among SLE, RA and HC, indicating that the difference of TLR response was not depend on alterations of TLR expression levels. By in vitro experiments under pre-treatment with multiple cytokines, both Type I and Type II IFN up-regulated the TLR7-mediated IFN-α production from pDCs, but they down-regulated the TLR9-mediated IFN-α production, suggesting that up-regulation of TLR7 responses and down-regulation of TLR9 responses of pDCs in SLE patients were regulated by Type I and Type II IFNs.

**Conclusions:** This is the first report demonstrated the differential regulation of TLR7 and TLR9 by type I IFN in pDCs in SLE patients, namely, TLR7 and TLR9 response were regulated by Type I and Type II IFNs. Taken together, TLR7-mediated pDC response plays a pivotal role in the increase in IFN-signature in SLE patients and could be a potential therapeutic target for SLE.

## OP0163 MESENCHYMAL STEM CELLS PREVENT PODOCYTE INJURY IN LUPUS PRONE MICE VIA EDUCATING MACROPHAGE INTO AN ANTI-INFLAMMATORY PHENOTYPE

Z. Zhang, L. Niu, X. Tang, R. Feng, G. Yao, W. Chen, W. Li, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Macrophage infiltration is a hallmark of severe lupus nephritis, contributing to podocyte injury. Mesenchymal stem cell (MSC) transplantation could alleviate lupus nephritis in both lupus mice and patients. However, the underlying mechanisms remain largely unknown.

**Objectives:** The study was designed to investigate the modulatory effect of MSCs on macrophage polarization and explore its role in preventing podocyte injury.

**Methods:** B6.MRL-Fas$^{lpr}$ (B6.*lpr*) mice were injected with umbilical cord MSCs (UCMSCs), while the control groups were administered with PBS or Fibroblasts. A 24-hour urine specimen was collected by putting mice in metabolic cages over a full 24-hour period every three weeks. 9 weeks later, all the mice were sacrificed. Histopathology scores of kidney were evaluated by hematoxylin-eosin (HE) staining. IgG and C3 deposits in glomeruli were assessed by immunofluorescence. Podocyte foot processes were observed under the transmission electron microscope. Mouse peritoneal macrophages were co-cultured with or without UCMSCs for 2 days, and further co-cultured with mouse podocytes for another 2 days. The expression of TNF-α, MCP-1, IL-1β and CD206 in macrophages and synaptopodin in podocytes were determined by real-time PCR. Flow cytometry was used to analyze podocyte apoptosis.

**Results:** UCMSCs treated B6.*lpr* mice showed lower levels of proteinuria, reduced glomerular deposition of IgG and C3, decreased renal histopathology scores and less foot process fusion. Besides, UCMSCs decreased macrophages infiltration while increased the expression of CD206 and synaptopodin in the kidney of B6.*lpr* mice. *In vitro* study demonstrated that macrophages co-cultured with UCMSCs expressed lower levels of inflammatory cytokines including TNF-α, MCP-1 and IL-1β, while higher levels of CD206. Moreover, UCMSCs treated macrophages induced less podocyte injury, with higher expression of synaptopodin and lower apoptotic rate.

**Conclusions:** UCMSCs prevented podocyte injury in lupus nephritis via educating macrophage into an anti-inflammatory phenotype, thus rescuing renal function.

**Disclosure of Interest:** None declared

## OP0164 BLOCKADE OF IMMUNE COMPLEX-MEDIATED GLOMERULONEPHRITIS BY HIGHLY SELECTIVE INHIBITION OF BRUTON'S TYROSINE KINASE

S.A. Chalmers[1], J. Doerner[1], T. Bosanac[2], S. Khalil[2], D. Smith[2], C. Harcken[2], J. Dimock[2], E. Der[1], L. Herlitz[3], D. Webb[2], E. Seccareccia[2], D. Feng[2], J.S. Fine[2], M. Ramanujam[2], E. Klein[2], C. Putterman[1]. *[1]Albert Einstein College of Medicine, Bronx; [2]Boehringer Ingelheim, Ridgefield; [3]Cleveland Clinic, Cleveland, United States*

**Background:** Lupus nephritis (LN) causes significant morbidity and mortality in SLE patients. Autoantibody-containing immune complexes (ICs) can activate complement cascades and Fc receptors on resident and infiltrating cells within the kidney, thus promoting inflammation. Bruton's tyrosine kinase (BTK) is a tyrosine kinase important for B cell development, Fc receptor signaling, and macrophage polarization.

**Objectives:** To assess the role of BTK in the pathogenesis of nephritis in an inducible model of LN, and to evaluate the therapeutic potential of BTK inhibition.

**Methods:** A novel, highly selective, and potent (mouse whole blood CD69 $IC_{50}$=13±2 nM) BTK inhibitor, BI-BTK-1 (Boehringer Ingelheim), was tested in female 129 sv/J mice (10 weeks of age) injected with nephrotoxic serum (NTS), an experimental model which closely mimics LN. Mice pre-immunized with rabbit IgG (Day 0) were administered NTS containing rabbit anti-mouse glomerular antibodies (Day 5), inducing a severe IC-mediated crescentic glomerulonephritis. Mice that did not receive the NTS transfer were used as healthy controls. Mice were treated once daily with vehicle alone or BI-BTK-1 (0.3–10 mg/kg, n=16/group), before the transfer of NTS as a prophylactic assessment, or after the transfer of NTS as a therapeutic assessment.

**Results:** NTS-challenged mice treated with BI-BTK-1 exhibited a statistically significant, dose responsive protection from kidney disease. Compared to

vehicle treated mice, NTS-challenged mice treated with 10 mg/kg BI-BTK-1 had significantly less proteinuria (1220 mg/dl vs 10 mg/dl, respectively, $p<0.0005$), serum creatinine (0.74 mg/dl vs 0.48 mg/dl, respectively, $p<0.03$), and BUN (82 mg/dl vs 25 mg/dl, respectively, $p<0.03$) at the end of study (Day 11). Histology assessment confirmed marked renal protection in the BI-BTK-1 treatment groups. BI-BTK-1 treatment resulted in decreased recruitment of inflammatory monocytes from the splenic reservoir, and a decrease in infiltrating IBA-1+ cells as well as C3 deposition within the kidney. RNA-seq revealed that more than 500 genes were modulated by BTK treatment, with further analysis highlighting many of the modulated pathways being related to inflammation and glomerular injury in LN. Serum profiling and selective kidney gene expression analyses by Q-PCR revealed that BTK inhibition was associated with a significant decrease in the levels of key LN-relevant inflammatory cytokines and chemokines. Importantly, delayed treatment with 3 mg/kg of BI-BTK-1in mice with established proteinuria was able to reverse proteinuria and improve renal histopathology.

**Conclusions:** Our results further confirm the important role for BTK activation in the pathogenesis of immune complex-mediated nephritis, and highlight BTK as a valuable therapeutic target. Taken together with previously published studies and our preliminary results in spontaneous lupus models, these findings further strengthen the rationale for selective BTK inhibition as a promising approach to the treatment of LN.

## OP0165 BENEFICIAL EFFECTS OF AN ANTI-IFNAR1 MONOCLONAL ANTIBODY ON IMMUNE CELL DYSREGULATION AND COMPLEMENT SYSTEM ABNORMALITIES OF SYSTEMIC LUPUS ERYTHEMATOSUS: AN EXPLORATORY ANALYSIS OF PHASE IIB CLINICAL TRIAL OF ANIFROLUMAB

X. Guo, L. Wang, G. Illei, P. Brohawn, B.W. Higgs, W.I. White. *MedImmune, Gaithersburg, United States*

**Background:** Anifrolumab is a fully human $IgG_1$ κ monoclonal antibody directed against subunit 1 of the type I interferon alpha receptor (IFNAR1). A Phase IIb randomized clinical trial of adult patients with systemic lupus erythematosus (SLE) has been conducted for anifrolumab.

**Objectives:** To assess downstream effects of anifrolumab on peripheral biomarkers and pathophysiologic pathways in patients with SLE.

**Methods:** In the MUSE study, 305 patients with moderate to severe SLE were randomized in a 1:1:1 ratio to receive a fixed intravenous dosage of placebo or anifrolumab (300 or 1,000 mg), in addition to standard of care medications, every 28 days for 1 year. Patients were stratified by IFN gene signature status (high vs. low) based on a 4-gene expression assay. Selected proteins were measured in sera of SLE patients procured at baseline, 85, 169, and 365 days post-administration along with 30 healthy controls (HCs) using a multiplex luminex immunoassay.

**Results:** Serum concentrations of 134 proteins were measured for 30 HCs and 304 SLE patients at baseline (missing sample for one patient), of which 229 had a high IFN signature (IFN-high) and 75 did not (IFN-low). Mann-Whitney U test identified 55 proteins with higher levels and 12 proteins with lower levels in IFN-high patients than IFN-low patients and/or HCs ($p<0.05$). Anifrolumab compared with placebo induced significant suppression of 15 proteins which were elevated at baseline, and up-regulation of 4 proteins with reduced baseline levels at more than one time point post-administration ($p<0.05$). Anifrolumab-driven suppression of T cell-targeting chemokines (CXCL10 & CXCL11), B cell-targeting chemokine (CXCL13), B-cell activator (TNFSF13B/BAFF), endothelial cell markers (VCAM1 & VWF & ANGPT2), and other lymphocyte-associated chemokines (CCL2 & CCL8 & CCL19) indicates reduction in T-cell, B-cell, and endothelial cell activation/movement after anifrolumab administration compared with placebo. Further, decreased concentration of FCN3, an initiator of the lectin pathway of complement, indicates inhibition of complement system activation, consistent with upregulation of complement C3 concentration by anifrolumab. In contrast, proteins upregulated by anifrolumab included; IL1R2 – a decoy receptor for IL-1 that is highly expressed in neutrophils, and TNFRSF10C – a decoy anti-apoptotic receptor for TRAIL that has been reported to be associated with SLE neutropenia. Cellular enumeration data demonstrated upregulation of both lymphocyte and neutrophil counts after administration of anifrolumab but not placebo. Suppression of lymphocyte-related chemokines and upregulation of neutrophil-associated proteins suggests different mechanisms for anifrolumab-induced upregulation of peripheral lymphocytes and neutrophils.

**Conclusions:** Our results demonstrate a distinct proteome profile of IFN-high patients compared with IFN-low patients and HCs. Anifrolumab administration elicits a widespread impact on peripheral biomarkers of patients with SLE. Beneficial effects on both immune cell dysregulation and complement system abnormalities may be key contributors to the mechanism of action of anifrolumab in SLE.

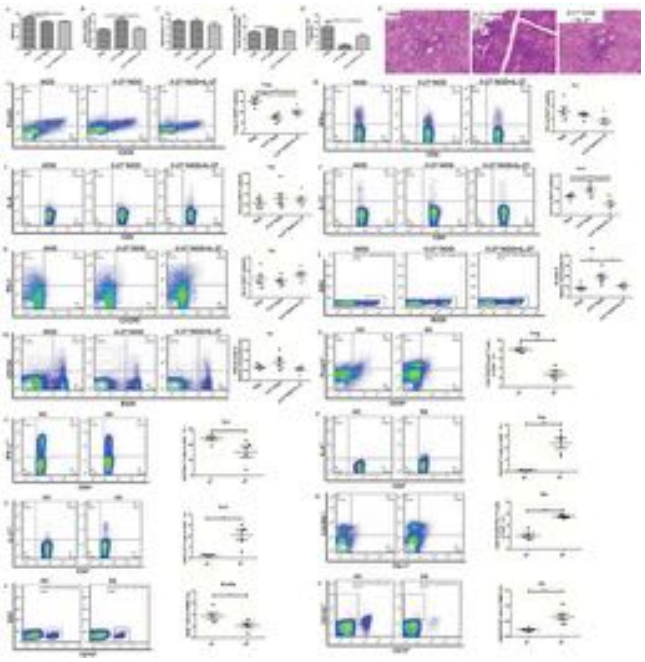
## OP0166 IL-27 PARTICIPATES IN SJOGREN'S SYNDROME BY REGULATING LYMPHOCYTE SUBSETS



J. Qi, B. Shi, Z. Zhang, R. Feng, W. Chen, G. Yao, Y. Hou, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Primary Sjogren's syndrome (pSS) is a chronic, systemic autoimmune disorder characterized by inflammation of exocrine glands and functional impairment of the salivary and lacrimal glands [1]. The pathogenesis of pSS is complicated with many respects remaining elusive. Interleukin-27 (IL-27) is a new member of the IL-12 cytokine family. It is largely secreted by activated antigen-presenting cells, such as macrophages and dendritic cells (DCs). IL-27 participates in multiple autoimmune diseases by regulating T lymphocyte subsets. Recent studies showed that IL-27 was involved in anti-inflammatory functions in SS [2]. However, the underlying mechanism of IL-27 in SS is still unknown.

**Objectives:** In the present study, the changes of lymphocyte subsets were studied in Il-27 knock-out and wild-type pSS models and pSS patients for the purpose to explore the specific mechanism of IL-27 in pSS and provide the basis for clinical treatment.

**Methods:** The NOD mice, Il-27 knockout (*Il-27*$^{-/-}$) mice, Il-27 knockout mice with recombinant IL-27 treatment were studied. The saliva flow rates, weight, weight of submandibular glands and spleens were detected. Murine submandibular glands were fixed and paraffin sections were used for hematoxylin and eosin staining. The lymphocyte subsets of spleens from experimental mice and the peripheral blood from pSS patients were measured by flow-cytometric assay.

**Results:** Compared to WT NOD mice, the saliva flow rates decreased significantly, and the indexes of submandibular glands and spleens increased significantly in *Il-27*$^{-/-}$ mice (Fig 1A-E). The histological results showed that the number of lymphocytic infiltrates in submandibular glands of WT NOD was lower than *Il-27*$^{-/-}$ mice (Fig 1F). The splenic-Treg cells decreased significantly, but the levels of splenic Th17 and B cells increased significantly in *Il-27*$^{-/-}$ mice. After IL-27 treatment, the saliva flow rates, submandibular glands, Treg and Th17 cells were partially reversed in *Il-27*$^{-/-}$ mice (Fig 1G-M). Consistent with above observations, the changes of Terg and Th17 cells in pSS patients showed similar pattern. The Th2, Tfh and plasma cells increased significantly, whilst the B cells decreased significantly in pSS patients (Fig 1N-T). Compared with healthy control, the serum IL-27 decreased in pSS patients.

**Conclusions:** In general, these findings indicated that IL-27 deficiency dete-

riorated the disease symptoms of pSS and resulted in changes of Th17/Treg balance. In addition, pSS patients showed similar lymphocyte imbalance. Our data suggested that IL-27 might play an important role on the development and pathogenesis of pSS through regulating lymphocyte subsets, and targeting IL-27 and Th17/Treg balance may be a new direction of pSS treatment.

## Epidemiology of RMDs

### OP0167 PREVALENCE OF RHEUMATIC DISEASE IN LATIN AMERICAN INDIGENOUS POPULATION: A COMMUNITY BASED STUDY

I. Pelaez-Ballestas[1], Y. Granados[2], A. Silvestre[3], F. Julian-Santiago[4], N. Santana[5], C. Rosillo[6], J. Alvarez-Nemegyei[7], A. Loyola-Sanchez[8], R. Quintana[9], M.V. Goycochea-Robles[10], C. Pacheco-Tena[11], M. Goñi[12], C. Garcia-Garcia[1], L. Cedeño[6], B. Pons-Estel[9] on behalf of GLADERPO.
*[1]Rheumatology, Hospital General de Mexico, Mexico, Mexico; [2]Hospital "Dr. Manuel NuñezTovar", Maturin, Venezuela, Bolivarian Republic Of; [3]Ministerio Salud Provincia de Santa Fe, Rosario, Argentina; [4]Universidad Nacional Autonoma de Mexico, Mexico; [5]Instituto Mexicano del Seguro Social, Chihuahua, Mexico; [6]Hospital "Dr. Manuel NuñezTovar", Maturin, Venezuela, Bolivarian Republic Of; [7]Research Unit, HRAE, Merida, Mexico; [8]Calgary University, Calgary, Canada; [9]Hospital Provincial de Rosario, Rosario, Argentina; [10]Research Unit, IMSS, Mexico; [11]Universidad Autónoma de Chihuahua, Chihuahua, Mexico; [12]Centro Especialidades Medicas Ambulatorias, Rosario, Argentina*

**Background:** GLADERPO group (Latin American Study Group on Rheumatic Diseases in Indigenous Peoples) is an organization aimed to conduct studies on indigenous populations with the purpose of closing the gap of information about rheumatic diseases and develop culturally-sensitive interventions.
**Objectives:** Estimate the prevalence of musculoskeletal disorders and rheumatic diseases in eight Latinoamerican indigenous communities using the COPCORD methodology.
**Methods:** A cross-sectional, house-by-house, community-based census study was performed. Bilingual staff members, who received standardized training, administered a cross-culturally validated version of the COPCORD questionnaire to adult indigenous population with the assistance of bilingual translators. Individuals with musculoskeletal pain, stiffness or swelling in the last 7 days and/or at any point during their lifetime were evaluated by participating physicians (general physicians and rheumatologist) to classify or diagnosed any rheumatic disease according to specific criteria.
**Results:** We surveyed 6,155 indigenous people having a mean age of 41.2 years (SD 17.6; range 18 to 105); 3,757 (61.0%) were women. Mean education was 5.0 years (SD 4.1); and 4,668 (75.8%) work for living.
MSK pain in the past and during the last 7 days occurred in 2,778 (45.1%; 95% CI 43.8–46.3) and 2,127 individuals (34.5%, 95% CI 33.3–35.7%), respectively. Of these, 1,195 (56.2%, 95% CI 54.1–58.3%) individuals associated pain to trauma. Pain was severe in 15.8% and according to localization, pain originated from the spine (26.7%), the knees (17.6%), shoulders (15.3%), and hands (10.6%) more frequently.
Point-prevalence of main rheumatic diseases was: low back pain (LBP) in 821 (13.3%; 95% CI: 12.4–14.2); osteoarthritis (OA) in 598 (9.7%; 95% CI: 8.9–10.4); rheumatic regional pain syndromes in 368 (5.9%; 95% CI: 5.3–6.6); rheumatoid arthritis (RA) in 85 (1.3%; 95% CI: 1.1–1.7); systemic lupus erythematosus in 7 (0.1; 95% CI: 0.004–0.2); nonspecific arthritis in 13 (0.2%; 95% CI: 0.1–0.3); spondyloarthritis in 12 (0.1; 95% CI: 0.1–0.3); and scleroderma in 3 (0.04%; 95% CI: 0.01–0.1).
There were marked variations in the prevalence of each rheumatic disease among the different communities, i.e.: RA prevalence was 2.4% in Qom (Argentina) and 0.4% in Mixtecos (Mexico).
**Conclusions:** The overall prevalence of MSK disorders in indigenous community of Latin-American was 35.4%. Low back pain and OA were the most prevalent rheumatic conditions, but wide variations according to population groups occurred.

### OP0168 FIRST RESULTS FROM THE PROSPECTIVE GERMAN PREGNANCY REGISTER RHEKISS

A. Strangfeld[1], C. Bungartz[1], J. Richter[2], A. Zink[1,3], M. Schneider[2], J. Listing[1], R. Fischer-Betz[2]. *[1]German Rheumatism Research Centre, Berlin; [2]Policlinic of Rheumatology, Hiller Research Unit, University Clinic Duesseldorf, Heinrich-Heine-University, Düsseldorf; [3]Charité University Medicine, Berlin, Germany*

**Background:** There is limited evidence regarding the safety of pharmacologic treatments during pregnancy. With the increasing number of new medications available for the treatment of rheumatic and autoimmune diseases, there is a growing need for systematic collection of prospective real-world data on drug safety in pregnancy and lactation.
**Objectives:** To determine the safety of various drug treatments during pregnancy and the influence of the underlying rheumatic disease on outcome and child development.
**Methods:** The Rhekiss register is designed as a prospective nationwide, web-based longitudinal observational cohort study. Pregnant patients with confirmed diagnose of inflammatory rheumatic disease are eligible to be enrolled until the 20th week of pregnancy regardless of drug treatment. Rheumatologists as well as patients report three times during pregnancy (each trimester) and semi-annually after birth until the child's 2nd birthday. Patients can use the online documentation system remote or in the practice.
Information on all given drug treatments, details on the course of the maternal disease, the development of the pregnancy, maternal or fetal complications during pregnancy, pregnancy outcomes, and child development during the first two years of life are collected. At baseline, sociodemographic parameters, prior pregnancies, and comorbidities are reported.
The register is designed as uniform platform with specific modules for various inflammatory rheumatic diseases. Only pseudonymized data are used, data security issues conform with regulatory authorities have been implemented.
It can be easily extended and translated to other languages.
**Results:** The register started on 15th of September 2015. Until end of January 2016, 106 rheumatologists in outpatient clinic or private practices signed up for participation. Among these, 28 units recruited patients so far. 99 patients were enrolled until end of January. Of these, 26 had rheumatoid arthritis, 26 systemic lupus erythematosus, 17 other connective tissue diseases, 9 juvenile idiopathic arthritis, 8 spondyloarthritis, 7 psoriatic arthritis, 4 autoinflammatory syndromes and 2 systemic vasculitis.
Mean age of the patients was 31.1 (± 5.1) years, mean disease duration 6.5 (± 8.2) years. Mean disease activity, assessed by the rheumatologist on a numeric rating scale from 0–10, was 2.6 (± 2.1) over all diagnoses. On a disease severity scale ranging from 1 to 5 (highest grade), two thirds of the patients were reported as grade 2 or 3.
**Conclusions:** The German pregnancy register Rhekiss was initiated to fill the knowledge gap on the course and outcomes of pregnancies in patients with rheumatic diseases as well as on the current use and the safety of treatments during pregnancy and lactation. The fast uptake of patients shows that there is a substantial need for and a high interest in real-life data to guide treatment decisions. Rhekiss can be easily extended and translated to other languages.
At the time of the EULAR congress, data on the first seven months of the register will be available for presentation.
**Disclosure:** Rhekiss is a collaborative project of the DRFZ Berlin and the Rheumazentrum Rhein-Ruhr e.V. Düsseldorf, jointly funded by both institutions.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3860

### OP0169 ASSOCIATION BETWEEN USE OF DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS AND DIABETES IN PATIENTS WITH ANKYLOSING SPONDYLITIS, RHEUMATOID ARTHRITIS, OR PSORIASIS/PSORIATIC ARTHRITIS: NATIONWIDE, POPULATION-BASED COHORT STUDY OF 84,989 PATIENTS

H.-H. Chen[1], C.-C. Lin[2], Y.-M. Chen[1], K.-L. Lai[3], C.-H. Lin[1], D.-Y. Chen[4]. *[1]Department of Medical Research, Taichung Veterans General Hospital; [2]Institute of Biomedical Science, Chung-Hsing University; [3]Division of Allergy, Immunology and Rheumatology; [4]Department of Medical Education, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China*

**Background:** Previous studies suggested anti-tumor necrosis factor (TNF) agents and hydroxychloroquine (HCQ) may inhibit the development of insulin resistance.
**Objectives:** Investigate the association between use of disease-modifying antirheumatic drugs (DMARDs) and diabetes mellitus (DM) in patients with ankylosing spondylitis (AS), rheumatoid arthritis (RA), or psoriasis (PSO)/psoriatic arthritis (PSA).
**Methods:** This retrospective cohort study used a nationwide, population-based administrative database to enroll 84,989 cases with AS, RA, or PSO/PSA who initiated treatment with anti-TNFs or nonbiologic DMARDs. Multivariable analysis was used to estimate effect of different therapies on risk of DM.
**Results:** There were 36,329 patients with AS, 33,112 patients with RA, and 15,638 patients with PS or PSA. All enrolled patients initiated treatment with an anti-TNF agent or a nonbiologic DMARD. We categorized patients into 4 mutually exclusive groups based on DMARD use: *(i)* anti-TNF agent with or without

another DMARD (n=6824); *(ii)* cyclosporine (CSA) without an anti-TNF agent or HCQ (n=1084); *(iii)* HCQ without an anti-TNF agent or CSA (n=27,033); and *(iv)* other nonbiologic DMARD without an anti-TNF agent, CSA, or HCQ (n=50,048), hereafter referred to as the reference group.The incidence rates of DM per 1000 person-years were 8.3 for users of anti-TNFs, 13.3 for users of cyclosporine (CSA), 8.4 for users of HCQ, and 8.1 for users of other nonbiologic DMARDs. Compared with users of nonbiologic DMARDs, the multivariate adjusted hazard ratios (aHRs) for DM were significantly lower for users of anti-TNFs with HCQ (aHR: 0.49, 95% CI: 0.36–0.66) and those who used HCQ (aHR: 0.70, 95% CI: 0.63–0.78), but not in those who used anti-TNFs without HCQ (aHR: 1.23, 95% CI: 0.94–1.60) or CSA (aHR: 1.14, 95% CI: 0.77–1.70).

Table 1. Univariate (crude HR) and multivariate (adjusted HR) analysis of factors associated with DM

| DMARD group | Crude HR (95% CI) | P-value | Adjusted HR (95% CI) | P-value |
|---|---|---|---|---|
| Other non-biologic DMARDs | Reference | | Reference | |
| Anti-TNF+HCQ | 0.73 (0.55, 0.97) | 0.028* | 0.49 (0.36, 0.66) | <0.001* |
| Anti-TNF alone | 1.52 (1.20, 1.92) | <0.001* | 1.23 (0.94, 1.60) | 0.125 |
| CSA | 1.64 (1.11, 2.41) | 0.013* | 1.14 (0.77, 1.70) | 0.510 |
| HCQ | 1.03 (0.95, 1.12) | 0.445 | 0.70 (0.63, 0.78) | <0.001* |

HR: hazard ratio; CI: confidence interval. *P<0.05 indicates a significant association with DM. Adjusted by age, sex, disease group, disease duration, pre-treatment Charlson comorbididy index and corticosteroid dose.

**Conclusions:** The aHR for DM was lowest for RA and PSO/PSA patients who initiated treatment with an anti-TNF agent with concomitant HCQ, followed by HCQ users.

## OP0170 LOW INCOME IS ASSOCIATED WITH LOWER FUNCTIONAL CAPACITY AND HIGHER DISEASE BURDEN IN RA PATIENTS YOUNGER THAN 65

J. Callhoff[1], K. Albrecht[1], F. Hoffmann[2], A. Luque Ramos[2], A. Zink[1].
*[1]Epidemiology, German Rheumatism Research Centre, Berlin; [2]Department of Health Services Research, Carl von Ossietzky University, Oldenburg, Germany*

**Background:** Low socioeconomic status is known to be a risk factor for unfavourable outcomes in rheumatoid arthritis (RA).

**Objectives:** The aim of this analysis was to assess the influence of low income on functional capacity and disease burden.

**Methods:** Patients with a diagnosis of RA (ICD-10 codes M05 or M06) in at least two quarters in 2013 from a large statutory health insurance in Germany (Barmer GEK) were randomly selected, stratified by age (18–49/50–64/65–80), sex and diagnosis (M05/M06). They were contacted by mail and asked to complete a questionnaire regarding self-reported diagnosis (for validation of claims diagnosis), sociodemographics, health behaviour, impact of RA on employment, the RA Impact of Disease questionnaire (RAID, 0: no impact, 10: highest impact) and the physical function questionnaire FFbH (0: total impairment-100: full function). General linear models were used to assess the association of income and other sociodemographic factors with the FFbH and the RAID.

**Results:** Of the 6,195 patients who were contacted, a total of 3,212 completed the questionnaire and 2,585 (80%) reported to have RA. Among those, 2,406 patients reported their household income. 31% of these had a low (<1,500 Euro), 54% a medium (1,500–3,200 Euro) and 15% a high (>3,200 Euro) household income.

Patients with a low income had a mean FFbH of 67 (standard deviation 23) and a mean RAID of 4.8 (2.3), patients with a medium income had a mean FFbH of 74 (22) and a RAID of 4.1 (2.3) and those with a high income had a mean FFbH of 83 (18) and a RAID of 3.5 (2.3). In patients <65 years (n=1353), FFbH and RAID differed between patients with low and medium/high income (table 1) while education and lifestyle (smoking, being stressed) were not associated, insufficient exercise was only associated with FFbH. This analysis was controlled for the following work-related parameters that were strongly associated with functional capacity and disease burden: being less efficient at work, being on sick leave >6 weeks, having applied for disability pension and fear of not being able to work until retirement.

Table 1. Results from two separate multivariable general linear models for patients <65 years. Parameters that are associated with functional capacity/disease burden are shown

| Parameter | Reference | Estimated effect on FFbH | Confidence interval (FFbH) | Estimated effect on RAID | Confidence interval (RAID) |
|---|---|---|---|---|---|
| Age | per 10 years | –2.8 | –3.9, –1.7 | 0.12 | 0.00, 0.23 |
| Body mass index | per unit | –0.41 | –0.61, –0.22 | 0.034 | 0.013, 0.056 |
| Male sex | female | 4.9 | 2.9, 6.8 | –0.46 | –0.67, –0.24 |
| Household income 1500–3200€ | <1500€ | 4.0 | 1.6, 6.3 | –0.51 | –0.78, –0.24 |
| Household income >3200€ | | 9.8 | 6.9, 12.6 | –1.03 | –1.34, –0.71 |
| Less efficient at work | | –7.9 | –9.9, –5.9 | 1.2 | 0.95, 1.4 |
| On sick leave >6 weeks | | –8.8 | –13.7, –3.8 | 1.1 | 0.54, 1.6 |
| Having applied for disability pension | | –22.5 | –25.7, –19.4 | 1.9 | 1.6, 2.3 |
| Fear of not being able to work until retirement | | –5.8 | –7.9, –3.8 | 1.0 | 0.77, 1.2 |
| Getting enough exercise | | 3.5 | 1.2, 5.8 | –0.08 | –0.34, 0.18 |

**Conclusions:** In patients with RA aged below 65, low income was strongly associated with higher disease burden und poorer function. The effect of income on function and overall disease burden remained after controlling for factors like considering or applying for disability pension, presenteism and absenteism.

## OP0171 PROGNOSIS OF STROKE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A POPULATION-BASED COHORT STUDY

M. Rossides[1], J.F. Simard[1,2], E. Svenungsson[1,3], M. von Euler[4,5], E.V. Arkema[1]. *[1]Dept of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden; [2]Dept Health Research and Policy AND Dept of Medicine, Stanford School of Medicine, Stanford, United States; [3]Rheum. Clinic, Karolinska University Hospital; [4]Clinical Science and Education, Södersjukhuset; [5]Stroke Research Network, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden*

**Background:** Stroke is a severely disabling complication that occurs at a much earlier age in patients with systemic lupus erythematosus (SLE) compared to the general population.[1] Individuals with SLE have also a greater risk of stroke compared to the general population. However, it remains unclear if stroke patients with SLE have higher mortality after stroke.

**Objectives:** To assess the mortality after first-ever stroke in SLE patients compared to the general population.

**Methods:** In a prospective cohort of adult SLE patients (≥2 SLE visits, ≥1 with a specialist in the National Patient Register, NPR) and general population comparators identified from the Total Population Register, we identified those with first-ever stroke via the NPR (ischaemic, intracerebral haemorrhage, and unspecified), from 1998 to 2013. We linked them to the Swedish Stroke Register (Riksstroke) and followed them from occurrence of stroke until end of follow-up (death or the end of the study (Nov 2014)). We used age-adjusted Cox models to estimate the hazard ratio (HR) for all-cause mortality and stroke-specific mortality (defined using ICD codes from the Cause of Death Register) for SLE compared to non-SLE. For all-cause mortality, we estimated HRs for death within the first 30, 90, or 180 days after stroke. We additionally adjusted for comorbidities (hypertension, diabetes, congestive heart disease, atrial fibrillation and renal disease). In patients with Riksstroke records we further adjusted for smoking, aspirin and statin use at baseline (and thrombolysis for ischaemic stroke).

**Results:** We identified 467 individuals with SLE and 1775 non-SLE comparators with a first-ever stroke. SLE patients were younger than non-SLE at inclusion (mean age 66 yrs vs. 77 yrs). During follow-up, we identified 1293 deaths in both groups. After adjusting for age, stroke patients with SLE had a 50% higher rate of all-cause death for all stroke types compared to non-SLE, with the highest observed for intracerebral haemorrhage (HR=2.0; 95% CI=1.3–3.1). The HRs were similar after adjusting for comorbidities. Restricting to patients registered in Riksstroke, the HRs for mortality were similar, except for unspecified stroke. The hazard of death within the first 30 days was higher in the SLE group only for intracerebral haemorrhage (HR 1.99). Within 90 and 180 days, SLE patients are at higher risk of death compared to non-SLE for all stroke types. The stroke-specific mortality HR was 1.3 (95% CI=1.0–1.7) for all stroke types.

Table 1. All-cause mortality rate for stroke patients with SLE compared to non-SLE

| Stroke type | No. of deaths (%) SLE/non-SLE | HR (95% CI) | | |
|---|---|---|---|---|
| | | Age-adj. | Comorbidities-adj. | Riksstroke only |
| All | 243/1050 (52/59) | 1.7 (1.3–2.0) | 1.6 (1.3–1.8) | 1.6 (1.3–2.0) |
| Ischaemic | 178/822 (48/57) | 1.7 (1.4–2.0) | 1.5 (1.3–1.8) | 1.6 (1.2–2.1) |
| Intr. haemorrhage | 35/125 (66/63) | 2.0 (1.3–3.1) | 1.8 (1.1–2.9) | 2.0 (0.9–4.7) |
| Unspecified | 30/103 (75/74) | 1.9 (1.2–3.0) | 1.9 (1.1–3.1) | 5.7 (1.2–26.7) |

**Conclusions:** The rate of any cause and stroke-specific death after stroke is greater in patients with SLE than the general population, despite controlling for factors affecting mortality.

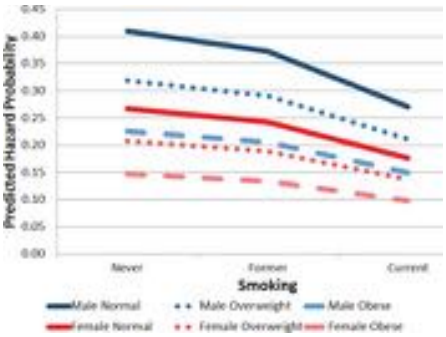
OP0172 **A COST-EFFECTIVENESS ANALYSIS OF DIFFERENT INTENSIVE COMBINATION THERAPIES FOR EARLY RHEUMATOID ARTHRITIS: 1 YEAR RESULTS OF THE CARERA TRIAL**



D. De Cock[1], A. De Saedeleer[2], K. Van der Elst[2,3], V. Stouten[1], J. Joly[3], R. Westhovens[1,3], P. Verschueren[2,3]. *[1]Skeletal Biology and Engineering Research Center, KU Leuven Department of Development and Regeneration; [2]Skeletal Biology and Engineering Research Center, KU Leuven Department of Public Health and Primary Care, KU Leuven; [3]Rheumatology, University Hospitals Leuven, Leuven, Belgium*

**Background:** The (Care in Early RA) CareRA trial compared different treatment strategies in patients with early Rheumatoid Arthritis (ERA) with or without markers of poor prognosis. No significant differences were shown between the treatment arms in terms of remission rate and functionality at 16 and 52 weeks. The differential cost-effectiveness of these therapeutic strategies could aid in determining the optimal approach for ERA.
**Objectives:** To compare the cost-effectiveness of different therapeutic strategies used in the CareRA trial during the first treatment year in patients with early Rheumatoid Arthritis.
**Methods:** The CareRA trial is a 2-year investigator-initiated randomized pragmatic superiority trial comparing remission induction regimens in a treat-to-target approach. DMARD naïve ERA patients were stratified into a high- or low-risk group based on prognostic markers. High-risk patients were randomized to a COBRA Classic (Methotrexate (MTX) + Sulphasalazine + prednisone step-down from 60mg), COBRA Slim (MTX + prednisone step-down from 30mg) or COBRA Avant-Garde (MTX + Leflunomide + prednisone step-down from 30mg) scheme. Low-risk patients were randomized to MTX tight step-up (MTX-TSU) or COBRA-Slim. The direct costs for each patient in the trial were calculated by summing the cost of a rheumatology consultation, per protocol CareRA study medication and RA-related medication such as biologicals and extra glucocorticoids not stipulated in the protocol. The incremental cost-effectiveness ratio (ICER) was calculated using these costs and the treatment efficacy as observed in CareRA. Efficacy parameters investigated were the proportion of patients in remission (DAS28(CRP) $<2.6$) and the proportion with a clinically meaningful improvement of Health Assessment Questionnaire (HAQ change $>0.22$) at week 52.
**Results:** 349 out of 379 patients had sufficient cost information to be evaluated at week 52. Remission was achieved in 65,6% Classic, 61.7% Slim (high-risk) and 64.1% Avant-Garde patients; and in 56.8% MTX-TSU and 70.0% Slim (low-risk) patients. A clinically meaningful HAQ response was reached in 66.7% Classic, 70.2% Slim (high-risk) and 75.6% Avant-Garde patients; and in 58.3% MTX-TSU and 60.0% Slim (low-risk) patients. Mean ±SD total costs during year one were €1044.3 ± €871.0 €859.7 ±€431.3 and €1267.7 ±€632.7 for the Classic, Slim (high-risk) and Avant-Garde respectively; and €880.6 ±€917.4 and €867.5 ±€364.0 for MTX-TSU and Slim (low-risk) patients. In MTX-TSU patients, the high average cost ±SD of €268.6 ±€876.5 was remarkable. Cost-effectiveness analysis in the high-risk arm showed a higher ICER for Classic (€47.3/1% remission) and Avant-Garde (€170.0/1% remission) compared to Slim (high-risk); In the low-risk arm, the cost-effectiveness of MTX-TSU was shown to be comparable to Slim (low-risk), with an ICER of €-0.99/1% remission.
**Conclusions:** Cobra Slim, a combination of MTX with a moderately dosed glucocorticoid remission induction showed favorable cost-effectiveness in both ERA patients with or without poor prognosis.

OP0173 **HOW MUCH OF A BARRIER IS EXCESS WEIGHT AND SMOKING FOR ACHIEVING SUSTAINED REMISSION IN EARLY RA? RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT**

S.J. Bartlett[1,2], O. Schieir[3], E. Schulman[4], S.M. Goodman[4], M. Zhang[4], D. Lin[5], K.M. Andersen[4], G. Boire[6], B. Haraoui[7], C. Hitchon[8], S. Jamal[9], E. Keystone[5], J. Pope[10], D. Tin[11], J.C. Thorne[11], V.P. Bykerk[4,5] on behalf of CATCH Investigators. *[1]Johns Hopkins School of Medicine, Baltimore, United States; [2]McGill University, Montreal; [3]University of Toronto, Toronto, Canada; [4]Hospital for Special Surgery, New York, United States; [5]Mt. Sinai Hospital, Toronto; [6]Universite de Sherbrooke, Sherbrooke; [7]Universite de Montreal, Montreal; [8]University of Manitoba, Winnipeg; [9]University of British Columbia, Vancouver; [10]Western University, London; [11]Southlake Regional Health Center, Newmarket, Canada*

**Background:** Relatively little is known about whether and to what extent modifiable lifestyle factors such as excess weight and smoking impact the likelihood of achieving sustained remission (SR).
**Objectives:** To explore the independent and combined effects of excess weight and smoking on achieving SR in early RA.
**Methods:** We examined the first 3 years of data of ERA patients enrolled in the Canadian Early Arthritis Cohort (CATCH), a multicenter prospective cohort study. Participants met 1987 or 2010 ACR/EULAR criteria for RA, had $<12$ months of symptom duration, were not in remission at entry, and had BMI and at least 2 consecutive DAS28 scores available. SR was defined as DAS28$<2.6$ at two consecutive visits. Independent effects of BMI class (normal weight: 18.5–24.9, overweight: 25–2.9, obese: 30+) and smoking on time to SR were estimated using Cox proportional hazards, adjusting for age, sex, ethnicity, education, comorbidities, smoking (current, former/never), symptom duration, disease activity, and treatment. Potential joint effects of smoking and weight class were tested using an interaction in the model. Higher order interactions with other covariates were also examined.
**Results:** The sample included 1,008 patients with a mean (SD) age of 53 (15), symptom duration of 5 (3) months, DAS28 of 5.3 (1.3); 728 (72%) were female and 813 (81%) were white. Among males, 131 (47%) were overweight, 93 (33%) obese, and 55 (20%) smoked. Among females, 220 (30%) were overweight, 241 (33%) obese, and 109 (15%) smoked. At entry, 741 (74%) patients were treated with MTX (mono or combination therapy), relatively few 28 (3%) with a biologic, and 522 (52%) with steroids. The proportion in SR rose steadily; at 3 years 408 (38%) had achieved SR with a median (IQR) time to SR of 11.3 (11.2) months. In fully adjusted Cox survival analyses, BMI class (p=0.003) and smoking (p=0.046) were significantly associated with SR, as was a 3-way interaction for BMI class, smoking, and gender (p=0.02). Figure 1 depicts the combined impact of smoking and BMI class on the probability of achieving SR in a prototypical male and female patient: 53-years old, white, with some postsecondary education, 5 months symptom duration, 2 comorbidities, DAS28 of 5, and initial treatment with MTX and steroids. A non-smoking male with a healthy BMI and these characteristics would have a 41% probability of achieving SR within 3 years vs. only 15% for an obese male smoker. A non-smoking female with a healthy BMI and these characteristics would have a 27% probability of achieving SR within 3 years vs. only 10% for an obese female smoker.

**Conclusions:** In this large "real-world" early RA cohort, two potentially modifiable lifestyle factors – smoking and excess weight – were prevalent and had significant independent and combined effects on the likelihood of achieving SR.

OP0174 **THE DEVELOPMENT OF THE MODIFIED DAS28-CRP TO IMPROVE AGREEMENT WITH DAS28-ESR AND ENSURE APPROPRIATE DISEASE ACTIVITY STRATIFICATION IN RA**

P.D.H. Hamann[1], K. Hyrich[2], A. Jobling[1], N. McHugh[1], G. Shaddick[3], J. Pauling[4]. *[1]Department of Pharmacy & Pharmacology, University of Bath, Bath; [2]Centre for Musculoskeletal Research, University of Manchester, Manchester; [3]Department of Mathematical Sciences, University of Bath; [4]Rheumatology Department, Royal National Hospital for Rheumatic Diseases & Royal United Hospitals, Bath, United Kingdom*

**Background:** Disease activity in rheumatoid arthritis (RA) has traditionally been measured using the 28-joint count disease activity score (DAS28) using ESR. Use of DAS28 with CRP in place of ESR is increasing. Evidence suggests these scores are not truly interchangeable and agreement varies dependant on disease activity. This study uses the BSRBR-RA to investigate agreement between these scores, proposing an optimised method to calculate the estimated DAS28-ESR using CRP (mDAS28-CRP) that offers higher interscore agreement than currently.
**Objectives:** To investigate and optimise agreement between the DAS28-ESR and DAS28-CRP scores using the BSRBR-RA.
**Methods:** Patients with concurrent measures of ESR and CRP were identified from the BSRBR-RA, enabling paired calculation of DAS28-ESR and DAS28-CRP using existing formulae. A non-linear regression model enabled prediction of ESR from CRP. Resulting values were used in the existing DAS28-ESR formula to calculate estimated disease activity (mDAS28-CRP). A Bayesian approach was used to acknowledge the uncertainty associated with the predictions and correctly propagate it through to mDAS28-CRP. Inference, including constructing credible intervals for predicted ESR and mDAS28-CRP, was performed using Markov-Chain-Monte-Carlo. Bland-Altman analysis and agreement matrices were used to compare agreement levels between mDAS28-CRP, DAS28-CRP and DAS28-ESR.
**Results:** 5457 patients (mean age 56 yrs, 76% female) with 31,084 data entries were identified where paired DAS28-ESR/DAS28-CRP scores could be calculated. Mean DAS28-ESR was 0.3 points greater than DAS28-CRP (4.4 (SD 1.7), 4.1 (SD 1.6) respectively) compared with mean mDAS28-CRP of 4.6

**Abstract OP0174** – Table 1. Comparison of agreement between DAS28-ESR, DAS28-CRP and mDAS28-CRP scores

| | | DAS28-ESR | | | | |
|---|---|---|---|---|---|---|
| | | Remission (<2.6) 15.6% (n=4857) | LDA (2.6 to ≤3.2) 11.1% (n=3440) | MDA (3.2 to ≤5.2) 38.0% (n=11810) | HDA >5.2 35.3% (n=10977) | Totals 100% (31084) |
| Remission (<2.6) | DAS28-CRP | **66.7% (4041)** | 25.4% (1541) | 7.9% (481) | 0 | 19.5% (6063) |
| | mDAS28-CRP | **84.6% (2720)** | 13.9% (446) | 1.6% (51) | 0 | 10.3% (3217) |
| LDA (2.6 to ≤3.2) | DAS28-CRP | 15.8% (646) | **32.0% (1303)** | 52.2% (2128) | 0 | 13.1% (4077) |
| | mDAS28-CRP | 42.1% (1487) | **39.2% (1384)** | 18.7% (662) | 0 | 11.4% (3533) |
| MDA (3.2 to ≤5.2) | DAS28-CRP | 1.4% (170) | 4.9% (591) | **73.7% (8881)** | 20.0% (2414) | 38.8% (12056) |

| HDA >5.2 | DAS28-CRP | 0 | 0.1% (5) | 3.6% (320) | **96.3% (8563)** | 28.6% (8888) |
| | mDAS28-CRP | 0 | 0.1% (9) | 10.4% (1181) | **89.5% (10140)** | 36.4% (11330) |

LDA, low disease activity; MDA, moderate disease activity; HDA, high disease activity.

(SD 1.6; Fig 1). mDAS28-CRP had superior agreement with DAS28-ESR across remission, low and moderate disease activity, with only a 6.8% reduction in agreement at high disease activity when compared with the DAS28-CRP (Table 1).

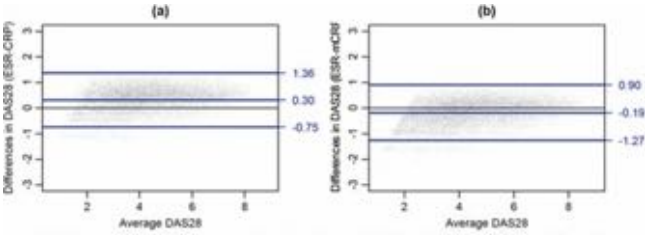

Figure 1. Reduction in interscore difference between DAS28-ESR and DAS28-CRP (a) and optimised mDAS28-CRP (b)

**Conclusions:** The mDAS28-CRP (online calculator pending) allows calculation of a disease activity score, using the same component parts of the DAS28-CRP, and has higher agreement levels with the original validated DAS28-ESR, than the current DAS28-CRP in this cohort. Disease activity scores are fundamental in clinical trials and practice, forming a central role in guiding availability of therapeutic agents. It is therefore essential that scores used are both valid and, if used interchangeably, have high agreement levels.

## Prognosis and outcome in RA

### OP0175 RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS PATIENTS TAPERING TNF INHIBITORS IS PRIMARILY DRIVEN BY MEAN DISEASE ACTIVITY OVER TIME, NOT SO MUCH BY FLARING OR LOWER TNF INHIBITOR EXPOSITION

C. Bouman[1], A.A. den Broeder[1], A. van der Maas[1], F.H. van den Hoogen[1,2], R. Landewe[3], N. van Herwaarden[1]. *[1]Rheumatology, Sint Maartenskliniek; [2]Rheumatology, Radboud University Medical Center, Nijmegen; [3]Rheumatology, Academic Medical Center Amsterdam, Amsterdam, Netherlands*

**Background:** The Dose REduction Strategies of Subcutaneous tumor necrosis factor inhibitors (TNFi) study (DRESS), a randomized controlled strategy trial (RCT) investigating disease activity guided tapering of etanercept and adalimumab compared to usual care in rheumatoid arthritis (RA) patients, indicated that minimal radiographic progression is more frequent in patients that attempted TNFi tapering (1). Possible explanations include higher mean disease activity, higher incidence of flaring, and/or lower TNFi use in the tapering group.

**Objectives:** To investigate possible causes of a difference in minimal radiographic progression between patients that attempted tapering compared to patients that did not attempt to taper TNFi.

**Methods:** Eighteen months data were used. Mean change (Δ) in Sharp van der Heijde score (SvdH) and percentage of minimal radiographic progression, defined as >0.5 ΔSvdH, were calculated and used as outcome. Mean time weighted disease activity using DAS28-CRP (MTW-DAS28-CRP), occurrence and number of (major) flares per patient (flare: DAS28-CRP increase >1.2, or >0.6 and current DAS28-CRP ≥3.2; major flare: lasting >12 weeks), and TNFi use (normalized percentage of the defined daily dose) during the study were used in univariate and multivariate analyses. Thereafter, linear regression modeling was done with ΔSvdH as dependent variable and the above mentioned disease activity measures and TNFi use as independent variables, controlled for possible confounders (including age, sex, BMI, smoking, baseline SvdH, DAS28-CRP, CRP, RF and ACPA status, and concomitant synthetic DMARD). To check for effect modification by randomization group (tapering or usual care), all models were also done for both groups separately.

**Results:** All patients with 18 months data available (n=175) were included. Mean ΔSvdH was 0.75 and 0.15, and minimal radiographic progression was found in 39/121 (32%) and 9/59 (15%) patients in the tapering and usual care group respectively (both p<0.05, number needed to harm [NNH]=6). Mean DAS28-CRP and cumulative incidence of (major) flares were 2.3 (standard deviation [SD] 0.5) versus 2.1 (0.6) and 73% (12%) versus 27% (10%) in tapering and usual care (p<0.05). MTW-DAS28-CRP, but not incidence or number of (major) flares, was independently associated with radiographic progression. Effect modification was present for randomization group (p=0.01) (table 1). No significant confounding was present.

**Table 1:** linear regression model with effect modification

| Total group | Beta | P-value | 95% Confidence Interval (CI) |
|---|---|---|---|
| MTW-DAS28-CRP | 0.51 | 0.005 | 0.15 to 0.86 |
| constant | -0.4 | | |
| | | | |
| **Tapering group** | **Beta** | **P-value** | **95% CI** |
| MTW-DAS28-CRP | 0.64 | 0.013 | 0.14 to 1.14 |
| constant | -0.73 | | |
| | | | |
| **Usual care group** | **Beta** | **P-value** | **95% CI** |
| MTW-DAS28-CRP | 0.17 | 0.47 | -0.29 to 0.62 |
| constant | -0.20 | | |

**Conclusions:** The TNFi tapering strategy used in DRESS leads to higher risk for radiographic progression after 18 months than usual care. This is mainly caused by somewhat higher mean time weighted disease activity, but not so much by flaring after dose reduction attempts or lower TNFi use itself. Effect modification by randomization group was present. Dose tapering of TNFi still seems a safe long-term approach, but long term disease activity should be kept on the lowest possible level using treat to target, and radiologic progression should be checked regularly.

### OP0176 FIVE YEAR OUTCOMES OF REMISSION STEERED TREATMENT INCLUDING DRUG TAPERING STRATEGIES IN EARLY ARTHRITIS PATIENTS

G. Akdemir[1], L. Heimans[1], R.J. Goekoop[2], M. van Oosterhout[3], J.B. Harbers[4], C. Bijkerk[5], G.M. Steup-Beekman[6], L. Lard[7], P.B.J. de Sonnaville[8], B.A.M. Grillet[9], T.W.J. Huizinga[1], C.F. Allaart[1]. *[1]Rheumatology, LUMC, Leiden; [2]Rheumatology, Haga Hospital, The Hague; [3]Rheumatology, GHZ, Gouda; [4]Rheumatology, Franciscus, Roosendaal; [5]Rheumatology, RdGG, Delft; [6]Rheumatology, Bronovo, The Hague; [7]Rheumatology, MCH, Leidschendam; [8]Rheumatology, ADRZ, Goes; [9]Rheumatology, Zorgsaam, Terneuzen, Netherlands*

**Background:** The window of opportunity hypothesis suggests that early initiation of treatment targeted at remission in early arthritis patients may avoid chronicity of inflammation and may result in early drug-free remission (DFR).

**Objectives:** To assess clinical outcomes of induction therapy followed by 5 years DAS-remission targeted therapy including rapid drug tapering strategies in early arthritis patients.

**Methods:** The IMPROVED study included 610 early rheumatoid arthritis (RA, 2010 criteria) or undifferentiated arthritis (UA) patients starting with methotrexate (MTX) and tapered high dose of prednisone. Patients in early DAS-remission (ER) (disease activity score (DAS)<1.6 after 4 months) stopped prednisone and if remission persisted at t=8 months also MTX. Patients not in ER (DAS≥1.6) were randomized to MTX+sulfasalazine+hydroxychloroquine+low dose prednisone (arm 1) or MTX+adalimumab (arm 2), 50 patients were not randomized and were treated "outside of protocol" (OP). Four monthly treatment adjustments aimed at DAS<1.6; if DAS<1.6 taper/stop medication and if DAS≥1.6 restart/intensify medication. Percentages of patients in (drug free) DAS-remission after 5 years were compared between RA and UA patients and the different treatment strategies. Logistic regression analysis was used to identify predictive factors of DAS-remission and DFR after 5 years.

**Results:** After 5 years mean±SD DAS decreased and functional ability improved in all treatment groups without differences between arm 1 and 2. 295/610 (48%) patients were in DAS-remission: 220/387 (57%) in the ER group, 31/83 (37%) in arm 1, 29/78 (37%) in arm 2 (p=0.768 arm 1 vs arm 2) and 15/50 (30%) in OP. 134/610 (22%) patients were in DFR: 105/387 (27%) in the ER group, 9/83 (11%) in arm 1, 12/78 (15%) in arm 2 (p=0.374 arm 1 vs arm 2) and 8/50 (16%) in OP. DAS-remission was achieved in similar percentages in RA and UA

patients and autoantibody positive (+) vs negative (–) patients. More UA than RA patients were in DFR at year 5 (33% vs 19%, p<0.001), and the same was true for anti-citrullinated protein antibodies (ACPA)– vs ACPA+ patients (31% vs 15%, p<0.001) and rheumatoid factor (RF)– vs RF+ positive patients (28% vs 17%, p<0.001). Between anti-carbamylated antibodies (anti-CarP)+ and – patients there was no difference in DFR rates.
Predictors of DAS-remission were age (OR 0.97 (95% CI 0.96–0.99)), symptom duration (0.99 (0.98–0.99)), baseline tender joint count (0.95 (0.90–1.00)) and achieving ER (1.95 (1.23–3.10)) (figure). Predictors of DFR were symptom duration (0.99 (0.97–1.00) and ER (2.67 (1.48–4.84)). ACPA+ was mostly associated with less DFR.

Figure: Multivariable logistic regression analysis with outcome DAS-remission and drug free remission at 5 years.

**Conclusions:** After 5 years of DAS-remission steered treatment, 48% of early RA and UA patients were in DAS-remission and 22% in DFR. Remission results were better for patients who achieved ER and who had a shorter symptom duration. Remission results were similar for RA and UA patients, randomization arms and autoantibody status, but more UA than RA patients and more autoantibody? than + patients were in DFR.

## OP0177 ULTRASOUND IN THE MANAGEMENT OF RHEUMATOID ARTHRITIS: RESULTS FROM THE RANDOMIZED CONTROLLED ARCTIC TRIAL

E.A. Haavardsholm[1], A.-B. Aga[1], I.C. Olsen[1], S. Lillegraven[1], H.B. Hammer[1], T. Uhlig[1], H. Fremstad[2], T.M. Madland[3], Å.S. Lexberg[4], H. Haukeland[5], E. Rødevand[6], C. Høili[7], H. Stray[8], A.N. Bendvold[9], I.J.W. Hansen[10], G. Bakland[11], L.B. Nordberg[1], D.V.D. Heijde[12], T.K. Kvien[1]. *[1]Diakonhjemmet Hospital, Oslo; [2]Ålesund Hospital, Ålesund;[3]Haukeland University Hospital, Bergen; [4]Drammen Hospital, Drammen; [5]Martina Hansens Hospital, Sandvika; [6]St Olavs Hospital, Trondheim; [7]Hospital Østfold HF Moss, Moss; [8]Haugesund Rheumatism Hospital, Haugesund; [9]Rheumatology Clinic Dovland/Bendvold; [10]Sørlandet Hospital HF, Kristiansand; [11]University Hospital of North Norway, Tromsø, Norway; [12]Leiden University Medical Center, Leiden, Netherlands*

**Background:** Application of ultrasound (US) in the management of patients with rheumatoid arthritis (RA) is rapidly growing.
**Objectives:** The randomized controlled ARCTIC trial (ClinicalTrials.gov NCT01205854) examined if the use of a treatment strategy based on structured US assessment[1] would lead to improved outcomes in RA, compared to a conventional strategy based on clinical and laboratory assessments alone.
**Methods:** Newly diagnosed DMARD naïve RA patients were randomized 1:1 to A) an ultrasound tight control (UTC) strategy targeting clinical and imaging remission (no ultrasound power-Doppler signal) or B) a conventional tight control (CTC) strategy targeting clinical remission. Patients in both arms were treated according to the same DMARD escalation strategy, starting with MTX, then triple therapy MTX/SSZ/HCQ, then biologic DMARD if target was not reached. The primary endpoint was the proportion of patients with a combination between 16 and 24 months of clinical remission, no swollen joints and non-progression of radiographic joint damage.
**Results:** A total of 238 patients were randomized, and patients with at least one follow-up visit were included in the full analysis set (UTC n=118, CTC n=112). Twenty-six patients (22.0%) in the UTC arm and 21 patients (18.8%) in the CTC arm reached the primary endpoint (mean difference 3.3%; 95%CI -7.1% to 13.7%). No significant differences were found between the groups for the components of the primary outcome, and secondary endpoints were similar (table).
**Conclusions:** The implementation and systematic use of ultrasound in the follow-up of early RA patients treated with an aggressive treat-to-target strategy is not justified based on the results of the ARCTIC trial.

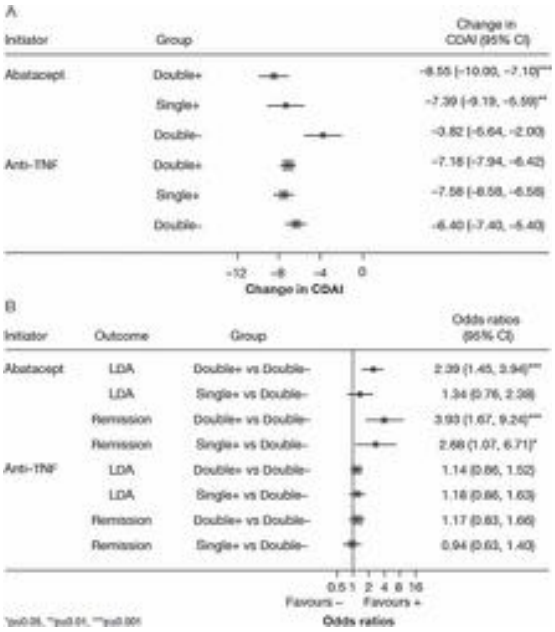
## OP0178 IMPACT OF ANTI-CYCLIC CITRULLINATED PEPTIDE AND RHEUMATOID FACTOR STATUS ON RESPONSE TO ABATACEPT THERAPY: FINDINGS FROM A US OBSERVATIONAL COHORT

L.R. Harrold[1], H.J. Litman[2], S.E. Connolly[3], S. Kelly[3], W. Hua[2], E. Alemao[3], L. Rosenblatt[3], S. Rebello[2], J.M. Kremer[4]. *[1]University of Massachusetts Medical School, Worcester; [2]Corrona, LLC, Southborough; [3]Bristol-Myers Squibb, Princeton; [4]Albany Medical College and The Center for Rheumatology, Albany, United States*



**Background:** It is unclear whether anti-cyclic citrullinated peptide (anti-CCP) and rheumatoid factor (RF) status are predictive of response to rheumatoid arthritis (RA) therapy.
**Objectives:** To assess whether baseline anti-CCP/RF status is associated with treatment response in patients with RA initiating abatacept (ABA) or a tumour necrosis factor-alpha inhibitor (TNFi).
**Methods:** Patients who initiated ABA or a TNFi within the Corrona RA registry between June 2002 and January 2015 were eligible if they had: anti-CCP and RF testing at or prior to initiation; a follow-up visit 6 months after initiation (±3 months); and Clinical Disease Activity Index (CDAI) measured at or within 4–6 months prior to initiation and after 6 months' treatment. Seropositivity was identified for anti-CCP (≥20 U/mL) and RF (≥40 U/mL). At 6 months, the primary

outcome was ΔCDAI, with secondary outcomes being achievement of remission (CDAI ≤2.8 in those with low, moderate or high baseline disease activity) and low disease activity (LDA; CDAI ≤10 in those with moderate or high baseline disease activity). Unadjusted and adjusted linear and logistic regression analyses were performed by baseline anti-CCP/RF status: double positive (anti-CCP+/RF+), single positive (anti-CCP+/RF– or anti-CCP–/RF+) and double negative (anti-CCP–/RF–). Adjusted models controlled for baseline age, sex, BMI, CDAI score, co-morbidity index and number of prior biologic DMARDs.

**Results:** 566 patients starting ABA (244 double positive; 167 single positive; 155 double negative) and 1715 starting a TNFi (774 double positive; 470 single positive; 471 double negative) were identified. Most patients were female (ABA: 79–83%; TNFi: 74–80%) and middle-aged (mean age 57–58 years in ABA, 54–57 years in TNFi), with established disease (mean disease duration 9–11 years in ABA, 6–8 years in TNFi) and moderate disease activity (mean CDAI 18–23 in ABA, 18–19 in TNFi). For patients who initiated ABA, double positive status was associated with a significantly greater response compared with double negative status on all outcomes (ΔCDAI –8.9 vs –4.5, p=0.002; LDA 43% vs 26%, p=0.002; remission 15% vs 5%, p=0.001). Additionally, single positive status was associated with a greater likelihood of remission as compared with double negative status for ABA users (12% vs 5%, p=0.018). Conversely, there were no significant differences in responses between anti-CCP/RF groups in the TNFi users (double positive vs double negative: ΔCDAI –7.5 vs –6.8, p=0.46; LDA 39% vs 35%, p=0.20; remission 16% vs 14%, p=0.38). In adjusted models, there are significant differences in the outcomes based on anti-CCP/RF status among ABA users but not TNFi users (Figure).

**Conclusions:** These real-world data demonstrate that baseline anti-CCP+/RF+ is associated with better clinical response to ABA, with the strongest association observed for double seropositivity. In contrast, no relationship was evident between anti-CCP/RF status and response to a TNFi, suggesting that the predictive value of autoantibodies is dependent on drug mechanism of action.

## OP0179 COMPARING INITIAL TREATMENT STRATEGIES WITH METHOTREXATE ON FIRST USE OF BIOLOGIC THERAPY: RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT

S. Gottheil[1], J. Pope[2], O. Schieir[3], G. Hazlewood[4], E. Keystone[5], S. Jamal[6], C. Barnabe[4], G. Boire[7], C. Hitchon[8], C. Thorne[9], V. Bykerk[5], D. Tin[9], P. Haraoui[10] on behalf of CATCH Investigators. *[1]London Health Sciences Centre; [2]St. Joseph's Health Care, London; [3]University of Toronto, Toronto; [4]University of Calgary, Calgary; [5]Mount Sinai Hospital, Toronto; [6]University of British Columbia, Vancouver; [7]Sherbrooke University, Montreal; [8]University of Manitoba, Winnipeg; [9]Southlake Regional Health Centre, Newmarket; [10]University of Montreal, Montreal, Canada*

**Background:** Optimal treatment of early rheumatoid arthritis (ERA) involves a treat-to-target strategy aiming for remission. Initial use of combination DMARDs is associated with an increased likelihood of remission in ERA patients. Research suggests that combinations DMARDs can provide equivalent outcomes at lower costs than biologic DMARDs.

**Objectives:** To compare effects of initial treatment with methotrexate (MTX) monotherapy vs MTX combination therapy on time to first use of biologic DMARDs in a large multi-centre ERA cohort.

**Methods:** The Canadian Early Arthritis Cohort (CATCH) is a multi-centre prospective cohort study of patients with early RA diagnosed and treated by a rheumatologist. The present study included participants who met 1987 or 2010 ACR criteria for RA, with ≤12 months symptom duration, moderate or high disease activity based on the DAS28 at baseline and treated with MTX. Patients treated with a biologic at baseline were excluded. Patients were followed until they started a biologic or they were censored due to loss to follow up or the end of the 3-year study period. Cox proportional hazards survival analysis was used to estimate effects of oral MTX monotherapy, subcutaneous MTX monotherapy, and MTX combination therapy adjusting for age, gender, education level, symptom duration, comorbidities, seropositivity, baseline erosions, baseline DAS28, and corticosteroid use.

**Results:** 1214 patients were included with 212 first events of biologic use. At baseline, 865 (71.3%) were female with mean (sd) age of 54.4 (14.9) years, symptom duration of 5.5 (2.8) months, and DAS28 of 5.5 (1.2). Oral MTX monotherapy was used as initial treatment in 230 (19%), subcutaneous MTX monotherapy in 226 (19%), and MTX combination therapy in 730 (62%). In fully adjusted Cox regression models, patients treated with subcutaneous MTX monotherapy were half as likely to require biologics as patients treated with oral MTX monotherapy (HR =0.47, p=0.015). There was no difference between MTX combination therapy and oral MTX monotherapy (HR =0.95).

**Conclusions:** Treatment with subcutaneous MTX monotherapy was associated with a reduced use of biologics. This may be due to increased treatment efficacy compared to oral MTX. Combination DMARD therapy was not associated with longer time to biologic initiation, potentially due to funding models in Canada specifying that combination DMARD therapy must be used before biologics can be considered. This study suggests that early use of subcutaneous MTX can potentially delay the need for more expensive biologic therapies.

## OP0180 OCCURRENCE OF REPAIR OF EROSIONS DURING EIGHT YEARS IN A LARGE INCEPTION COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS – A BARFOT-STUDY

K. Forslind[1], K. Eberhardt[2], B. Svensson[2]. *[1]Department of Clinical Scienses, Section of Rheumatology, Lunds University, Helsingborg; [2]1Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund, Sweden*

**Background:** Bone erosion is a central pathophysiological process in rheumatoid arthritis (RA) leading to joint destruction and functional limitations. Measurement of the degree of joint damage represents an important tool to assess disease progression and effectiveness of current treatments. Repair of existing bone erosions have been described but the extent and significance of this is so far unclear.

**Objectives:** The aim of this study was to examine the incidence of repair of erosions in patients with early RA during eight years and to look for possible factors linked to repair.

**Methods:** 473 patients from the BARFOT (Better Anti-Rheumatic FarmacOTherapy) inception RA cohort were included into the study71% were women, mean age 55 years, 63% were rheumatoid factor (RF)-positive and 59% current or previous smokers. All patients had radiographs of hands and feet at inclusion into the study (baseline), 1, 2, 5, and 8 years.

Erosion scores were measured by the Sharp-van der Heijde scoring (SHS) method. Sustained remission was defined as a DAS28 <2.6 at all follow-up visits. Repair was defined as complete healing or reduction in size of the erosion.

**Results:** After one year, presence of repair was found in 82 patients (17%), after two years in 140 (30%), after 5 years in 179 (38%) and after 8 years in 203 (51%). At 1, 2, 5 and 8 years these patients had 153, 260, 424 and 717 erosions with repair, respectively.

The number of repairs at the follow-up visits correlated weakly or moderately with the erosion scores, r=0.2–0.4, p=0.001.

The sum of the number of erosions showing repair recorded at each follow-up visit (*total repairs*) was 1.554 and the corresponding sum of erosion scores (*total erosion scores*) was 10.867. The *total repairs* correlated strongly with *total erosion scores*, r=0.7, p=0.001. The mean *total repairs* was associated with RF positivity, p=0.001 but not with gender, p=0.23.

The mean number of repairs was significantly higher in RF-positive patients at 2 and 8 years, 0.62 vs 0.37, (p=0.010) and 2.16 vs 1.18, (p=0.001). Presence of repair was significantly associated with RF-positivity at 2, 5, and 8 years and with gender at 8 years, 61% in men vs 47% in women (p=0.011).

The mean *total repairs* was significantly lower in patients in sustained remission compared with the rest of the patients, 2.3 vs 3.7, p=0.008.

There was no significant correlation between number of repairs and baseline DAS28 at any follow-up visit. Treatment with a combination of conventional DMARDs was associated with presence of repair after 1 (p=0.048) and 5 (p=0.001) years. After 8 years biologic DMARD therapy was more common in patients with some repair (p=0.011). Prednisolone treatment did not significantly influence repair.

**Conclusions:** In this cohort of patients with early RA, repair was more common than previously described. Repair of erosions occurred with increasing frequency during the 8 year study and was associated with rheumatoid factor positivity. Patients in sustained remission showed fewer repairs.

**Disclosure of Interest:** None declared

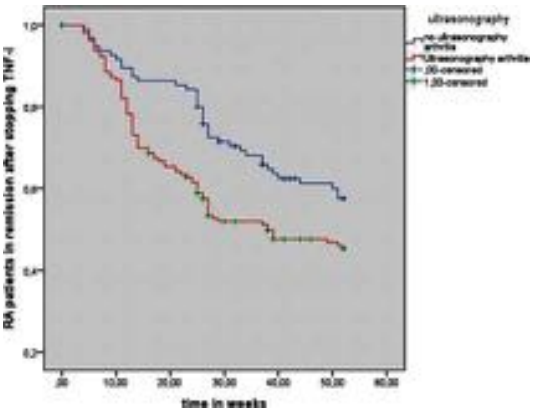
## OP0181 PREDICTION OF FLARE AFTER STOPPING TNF-INHIBITOR BY BASELINE ULTRASONOGRAPHY AND PATIENT CHARACTERISTICS IN RHEUMATOID ARTHRITIS PATIENTS WITH LOW DISEASE ACTIVITY: 12-MONTH RESULTS

F.B.G. Lamers-Karnebeek[1,2], J. Luime[3], P. van Riel[1,4], J. Jacobs[5], T. Jansen[4,6]. *[1]Rheumatology, Bernhoven Hospital, Uden; [2]Rheumatology, Radboud University Nijmegen Medical Center, Nijmegen; [3]Rheumatology, Erasmus Medical Center, Rotterdam; [4]IQ healthcare, Radboud University Nijmegen Medical Center, Nijmegen; [5]Rheumatology, University Medical Center Utrecht, Utrecht; [6]Rheumatology, Viecuri Medical Center, Venlo, Netherlands*

**Background:** A significant number of rheumatoid arthritis (RA) patients can reach low disease activity (LDA) by using TNF-inhibitors (TNF-i), but this therapy can cause serious side-effects and is expensive. Therefore it could be expedient to stop in case of LDA, unless a relapse can be predicted. Ultrasonography of joints seems to be a predictor in this respect in smaller studies.

The Dutch POET (Potential Optimalisation of Expediency of TNF-i (TNF-inhibitor)) study, is a multicenter randomized prospective cohort study investigating if in patients with RA with LDA on TNF-i and conventional DMARD, the TNF-i can be stopped. Patients were randomized to continue or stop TNF-i. Part of this study is the POET-ultrasonography (US) study.



**Objectives:** To investigate whether US, at the time of stopping TNF-i in RA patients with LDA, is an additive predictor for flare besides clinical data.

**Methods:** Data were analysed of 251 patients who stopped TNF-i in the POET study. Participating patients had RA according to ACR 1987 criteria, >6 months a DAS28 <3.2 (LDA) and treatment with TNF-i >1 year next to a conventional DMARD, with no dose change 6 months prior to randomisation. Nineteen trained ultrasonographers performed at baseline of the study US (with different US machines) of 20 joints: MCP 1–5 dorsal and volar, wrist and MTP 2–5 dorsal aspect, all bilaterally. The joints were graded on grayscale (GS; 0–3) and power Doppler (PD; 0–3). US signs of arthritis were defined as GS>1 and/or PD>0. Trial visits were performed every 3 months during 12 months and intercurrently when flare was suspected. Flare was defined as DAS28 >3.2 and at least >0.6 increase compared to the baseline DAS28. Univariate and multivariate Cox-regression was performed guided by clinical factors described in the literature and US.

**Results:** The Kaplan Meier curve for patients with US signs of arthritis in one or more joints shows greater/higher risk of flare and shorter relapse-free period compared to the curve for patients without US signs of arthritis, p= (figure). At multivariate analysis (table), correcting for potentially clinical predictors, US detected arthritis stayed a statistically significant predictor of flare; HR 1.69; 95% CI 1.11 to 2.53. The predictive value of US seems not that strong that it can be used in individual patients.

| | Regression Coefficient | Hazard ratio (95% CI) |
|---|---|---|
| IgM RF (+) | –0.51 | 0.60 (0.35–1.05) |
| Anti-CCP (+) | 0.25 | 1.29 (0.76–2.17) |
| Erosiveness (+) | 0.23 | 1.26 (0.82–1.95) |
| Disease duration (years) | 0.24 | 1.27 (0.97–1.67) |
| Sex (male) | 0.06 | 1.06 (0.71–1.59) |
| BMI | 0.01 | 1.01 (0.97–1.06) |
| csDMARD (number) | –0.04 | 0.96 (0.72–1.27) |
| TNF-inhibitor (number) | –0.01 | 0.99 (0.89–1.11) |
| US (+)* | 0.52 | 1.69 (1.11–2.53) |

*P-value <0.05.

**Conclusions:** The presence of US arthritis is associated with an earlier flare and a higher flare rate compared to those with negative US taking into account demographic and clinical patient characteristics.

## OP0182 PREVENTION OF RHEUMATOID ARTHRITIS BY B CELL DIRECTED THERAPY IN THE EARLIEST PHASE OF THE DISEASE: THE PRAIRI STUDY

D. Gerlag[1,2], M. Safy[1], K. Maijer[1], M. de Hair[1], S. Tas[1], M. Starmans-Kool[3], A. van Tubergen[4], M. Janssen[5], P.-P. Tak[1,6]. *[1]Amsterdam Rheumatology and Immunology Center, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; [2]GlaxoSmithKline, Cambridge, United Kingdom; [3]Department of Rheumatology, Atrium Medical Centre, Heerlen; [4]Department of Rheumatology, Maastricht University Medical Center, Maastricht; [5]Department of Rheumatology, Rijnstate Hospital, Arnhem, Netherlands; [6]GlaxoSmithKline, Stevenage, United Kingdom*

**Background:** Systemic autoimmunity may precede the development of clinical signs and symptoms of seropositive rheumatoid arthritis (RA), which offers a

window of opportunity to delay or prevent clinically manifest arthritis by targeted intervention. This could represent a paradigm shift from treatment to prevention[1].
**Objectives:** To explore if a single infusion of rituximab (anti-CD20 antibody) can prevent or delay the onset of clinically manifest arthritis in individuals at risk of developing autoantibody positive RA.
**Methods:** Eighty-two subjects with arthralgia who had never had clinically manifest arthritis and never used disease-modifying antirheumatic drugs were included in a multicentre, randomised, double-blind, placebo-controlled clinical trial. They were positive for both anti-citrullinated protein antibodies (ACPA) and rheumatoid factor and they had CRP levels ≥3 mg/l and/or subclinical synovitis on ultrasound or MRI of the hands. Subjects were randomized to receive a single iv infusion of either 1000 mg rituximab or placebo after 100 mg methylprednisolone premedication in each group. Subjects were prospectively followed to assess development of clinically manifest arthritis. We performed Kaplan-Meier survival analysis, Cox regression analysis and determined Treatment*Time Cox proportional hazards.
**Results:** Eighty-one individuals (52 females; mean age 53 (IQR 13.5) years) received treatment, which was generally well tolerated. One patient withdrew before treatment. The median follow up was 27.0 months (IQR 25.0), during which 30 subjects developed arthritis: 16/40 (40%) in the placebo group and 14/41 (34%) in the rituximab group, after a median period of 11.5 (interquartile range [IQR] 12.5) months in the placebo group versus 16.5 (IQR 19.0) months in the rituximab group. Whereas the risk for development of arthritis in the placebo group was 40%, we found a reduction of 53% of this risk in the rituximab group at 18 months follow up (HR (95%CI)=0.475 (0.190–1.191)). At the 25% quartile (75% free of arthritis) of the cumulative arthritis-free survival, there was a delay in the development of arthritis of 12.0 months (12 months in the placebo group versus 24 months in the rituximab group. As expected, this effect attenuated over time. Treatment*Time Cox proportional hazard analysis showed that the beneficial effect of rituximab was statistically significant (P<0.0001)
**Conclusions:** A single infusion of 1000 mg rituximab significantly delays the development of arthritis in subjects at risk of developing RA. This is the first study evaluating the effects of a biopharmaceutical in this population, and the results strongly support the rationale for future clinical trials aimed at prevention of RA by a targeted intervention.

## SLE, Sjögren's and APS: clinical aspects (other than treatment)

### OP0183 HYPOCOMPLEMENTEMIA ASSOCIATES WITH THROMBOSIS IN SLE PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES

L. Durcan[1,2], W. Fu[2], M. Petri[2]. [1]*Rheumatology, University of Washington, Seattle;* [2]*Rheumatology, Johns Hopkins, Baltimore, United States*

**Background:** Low complement is common in systemic lupus erythematosus (SLE) and is considered in classification criteria and disease activity indices. Recent evidence supports the hypothesis that the activation of complement is also important in the antiphospholipid syndrome (APS), coating platelets and contributing to thrombus formation. The successful treatment of catastrophic APS with the terminal complement inhibitor, eculizumab, has been reported, supporting this hypothesis.
**Objectives:** This work was undertaken to evaluate the relationship between hypocomplementemia and thrombotic outcomes in SLE patients with antiphospholipid antibodies (APL).
**Methods:** As part of a longitudinal lupus cohort, the presence of antiphospholipid antibodies (lupus anticoagulant and anticardiolipin) and thrombotic events, both venous and arterial, were updated quarterly. Statistical analysis included only patients who were found on longitudinal follow up to have one or more APL, i.e. antibodies to cardiolipin, or the presence of the lupus anticoagulant (LAC). Patients were then categorized by thrombotic event, the presence of hypocomplementemia (low C3, low C4 and both low C3 and C4) and type of APL. Those with low complement were compared to those without and the odds ratio for each thrombotic outcome calculated.
**Results:** 2399 patients were included, 1140 (47.5%) had antibodies to cardiolipin and 624 (26.0%) a positive LAC. The relationship between the antiphospholipid antibodies, thrombotic outcomes and low C3, low C4 or both in combination is outlined in Table 1.
**Conclusions:** In patients with anticardiolipin antibodies, the presence of hypocomplementemia (both low C3 + C4) associates strongly with DVT and stroke. Hypocomplementemia in the setting of the LAC was also associated with stroke whilst low C4 alone associated with digital gangrene. These findings are supportive of the robust mechanistic data involving the complement system in APS. They also raise the question as to whether hypocomplementemia should be considered a further risk factor for thrombosis in SLE patients with positive antiphospholipid antibodies in whom to date many traditional risk factors have been implicated.
**Disclosure of Interest:** None declared

### OP0184 CLINICAL SPECTRUM AND THERAPEUTIC MANAGEMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED MACROPHAGE ACTIVATION SYNDROME. DATA FROM A FRENCH NATIONWIDE STUDY OF 81 EPISODES IN 67 ADULT PATIENTS

P.-E. Gavand[1], I. Serio[2], C. Larroche[3], J. Carvelli[4], A. Dossier[5], L. Terriou[6], J. Sibilia[1], C. Bloch-Queyrat[3], L. Arnaud[7], Z. Amoura[7], T. Martin[1]. [1]*CHRU Strasbourg, Strasbourg, France;* [2]*S. Orsola-Malpighi Hospital, Bologna, Italy;* [3]*CHU Avicenne, Bobigny;* [4]*CHU Marseille, Marseille;* [5]*CHU Bichat, Paris;* [6]*CHRU Lille, Lille;* [7]*Pitié-Salpêtrière Hospital, Paris, France*

**Background:** Macrophage activation syndrome (MAS) is a potentially life-threatening hyperinflammatory syndrome that can occur during systemic lupus erythematosus (SLE). In SLE, MAS can mimic a disease flare. This overlap in clinical presentations can hinder the recognition of incipient MAS and delay the selection of the most appropriate treatment. Data on MAS in adult SLE patients are very limited (1).
**Objectives:** Description of clinical, laboratory and pathological features, treatment strategies and prognosis of a large series of SLE-associated MAS
**Methods:** We conducted a nationwide retrospective study that included 81 episodes of MAS in 67 adult patients with SLE seen between 1990 and 2015. All patients fulfilled the 1997 ACR revised criteria for SLE and had at least one episode of MAS diagnosed according to Henter's criteria (2).
**Results:** No patient had familial history of MAS. Median age at first MAS episode was 32 (18–74) years. Median duration of follow up was 40 months. MAS was inaugural in 36 patients (44.4%). For the remaining patients median delay between the diagnosis of SLE and the first episode of MAS was 82 months. Eleven patients relapsed (2 had >2 relapses).
Patients had the following features: fever (100% episodes; mean ± SD: 39.5°C ± 0.57), splenomegaly (52%), increased serum levels of aspartate aminotransferase (AST) (96%; mean: 192UI/l ±167), LDH (96%; mean: 1155 UI/l ±863), CRP (96%; mean: 75.8 mg/l ±72), ferritin (94%; mean: 11497 ng/l ±20511), lymphopenia (mean: 0.49 G/l ±0.35). thrombocytopenia $<100\times10^9$/l was found in 90% of the cases, neutropenia $<1000\times10^9$/l in 65% and anemia <8 g/dl in 45%. Procalcitonin (PCT), measured in 32 episodes was found high in 85% of the cases. A concomitant infection was documented in 34/81 (42%) episodes (including 3 EBV infections).
Visceral complications included myocarditis (16 episodes), acute lung injury (15), seizures (8) pancreatitis (4). In 23 episodes, patients required hospitalization in an intensive care unit and 3 died (multiple organ failure).
80 episodes (98%) were treated with high dose steroids. In 38 cases additional treatments were required: immunoglobulins (n=21), cyclophosphamide (n=18), mycophenolate mofetil (n=8) Etoposide (n=7) and Rituximab (n=7). Etoposide

| | Digital Gangrene | 4.21 (0.98, 18.04) | 0.0529 | 5.47 (1.06, 28.19) | 0.0421 | 2.25 (0.61, 8.28) | 0.222 |

and cyclophosphamide based regimens had a higher efficacy than immunoglobulins and conventional immunosuppressants.
**Conclusions:** This is the largest ever published case-series on SLE-associated MAS. It is a severe complication of SLE (28% ICU admissions) and is often inaugural. High fever and high levels of AST, LDH, CRP ferritin and PCT should be considered as red flags for early diagnosis. High dose steroids are often not sufficient to control disease.

## OP0185 CHARACTERISTICS OF PRIMARY SJÖGREN'S SYNDROME PATIENTS WITH IGG4-POSITIVE PLASMA CELLS IN LABIAL SALIVARY GLANDS

C. Liu, H. Zhang, G. Yao, W. Chen, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Primary Sjögren's syndrome (pSS) is a systemic autoimmune disease affecting predominantly exocrine glands such as salivary and lacrimal glands. Immunoglobulin G4 (IgG4)-related disease (IgG4-RD) is a new clinical concept of multi-organ diseases, which is characterized pathologically by the infiltration of IgG4-bearing plasma cells into involved organs. However, some pSS patients showed infiltration of IgG4+ plasma cells in exocrine glands.
**Objectives:** We aim to investigate the characteristics of primary Sjögren's syndrome (pSS) patients with IgG4+ plasma cells in labial salivary glands (LSGs).
**Methods:** 336 patients with pSS were enrolled. The LSG tissues from pSS patients were stained with monoclonal antibodies to IgG4 and IgG. Patients were divided into three subgroups according to histopathologic infiltration degree of $IgG4^+$ plasma cells. The clinical and serological characteristics of patients were compared.
**Results:** 336 patients were divided into three groups according to infiltration degree of $IgG4^+$ plasma cells: slight-IgG4 group (n=194), moderate-IgG4 group (n=106) and high-IgG4 group (n=36). The results showed that the higher $IgG4^+$ plasma cells expression, the lower positive rates of serum anti-SSA, anti-SSB, anti-nuclear antibodies (ANA) and rheumatoid factor (RF). The comparison of extraglandular manifestations of three groups indicated that patients in high-IgG4 expression group showed a highest frequency of interstitial lung disease (30.6%) and tubulointerstitial nephritis (13.9%), whereas a lowest frequency of leucopaenia (13.9%), thrombocytopaenia (11.1%) and abnormal thyroidal function (0%).
**Conclusions:** The results showed that a considerable proportion of pSS patients could manifest abundant IgG4+ plasma cells infiltration in LSGs. These patients have unique laboratory and clinical characteristics. These findings may help further understand pSS, IgG4-RD, and the role of $IgG4^+$ plasma cells in autoimmune diseases.

## OP0186 IMMUNE COMPLEX BOUND U1 AND Y1 RNA CORRELATES WITH INTERFERON-STIMULATED GENE EXPRESSION AND DISEASE ACTIVITY: AN OBSERVATIONAL STUDY OF SYSYTEMIC LUPUS ERYTHEMATOSUS PATIENTS

J. Doedens[1], W. Jones[2], K. Hill[3], M. Mason[4], P. Linsley[5], P. Mease[6], M. Dall'Era[7], C. Aranow[8], R. Martin[9], S. Cohen[10], R. Fleischmann[10], A. Kivitz[11], D. Burge[1], D. Chaussabel[12], K. Elkon[13], J. Posada[1,14], C. Gabel[1].
*[1]Resolve Therapeutics, Seattle; [2]EA Genomics/Q2 Solutions, Durham; [3]PlasmaLab International; [4]Sage Bionetworks; [5]Benaroya Research; [6]Swedish Medical Center, Seattle; [7]University of California San Francisco, San Francisco; [8]Feinstein Institute for Medical Research, Manhasset; [9]Michigan State University, East Lansing; [10]Metroplex Clinic al Research Center, Dallas; [11]Altoona Center for CInical Research, Duncansville, United States; [12]Sidra Medical and Research Center, Doha, Qatar; [13]Rheumatology, University of Washington; [14]Rheumatology, Resolve Therapeutics, Seattle, United States*

**Background:** Immune complexes (ICs) containing RNA are thought to play a central role in driving interferon (IFN) production and systemic inflammation in systemic lupus erythematosus (SLE) via activation of intracellular Toll-Like Receptors (TLRs). However, quantitation of IC-bound RNAs in SLE patient plasma has not previously been performed.
**Objectives:** To quantify IC-associated U1 and Y1 RNA and relate the findings to the interferon (IFN) signature and SLE clinical activity.
**Methods:** Medications and SLEDAI measurements were completed on 228 SLE patients. Autoantibodies were quantified by a Bioplex assay. Peripheral blood transcript profiles for 186 selected genes were quantified by a dynamic array QPCR analysis. ICs were isolated from plasma by protein A bead capture and associated RNA quantified by QPCR using primer/probes designed to detect small, noncoding U1 and Y1 RNA transcripts.
**Results:** The autoantibodies anti-SmRNP and anti-Ro60 displayed the strongest associations with IC-bound U1 and Y1 RNA levels, respectively. When patients were grouped into 4 categories based on the presence of ICs containing U1 and/or Y1 RNA, blood gene expression changes in the U1-/ Y1- group were significantly lower than observed in the three groups possessing U1 alone, Y1 alone, or both RNA molecules. Within the U1 RNA-positive groups, the top 10 up-regulated genes were increased 10–48 fold compared to healthy volunteers (associated p values exceeding $10^{-15}$) and corresponded to known IFN-inducible transcripts. IC-bound U1 and Y1 RNA levels showed significant correlations with each other and also with disease activity (SLEDAI) ($p<0.0003$).
**Conclusions:** The enhanced expression of IFN-inducible transcripts in blood from patients possessing IC-bound U1 and/or Y1 RNA lends further support to the hypothesis that these RNA molecules are involved in triggering TLR7 and stimulating interferon production in SLE patients.
Therapeutic strategies that seek to reduce the quantities of RNA associated with ICs may be an attractive approach to blocking downstream IFN production and immune system activation.
**Disclosure of Interest:** None declared

## OP0187 ALL-CAUSE AND SPECIFIED CAUSES OF MORTALITY IN SYSTEMIC LUPUS ERYTHEMATOSUS: SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL TRIALS

A. Souto[1], A. Castelo[2], J.R. Maneiro[3], E. Cervantes[1], A. Mera[1], J. Gomez-Reino[1]. *[1]Rheumatology Unit and Fundacion Ramon Dominguez, Complejo Hospitalario de Santiago Compostela; [2]Medicine, University of Santiago de Compostela, Santiago de Compostela; [3]Rheumatology Unit, Complejo Hospitalario de Pontevedra, Pontevedra, Spain*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease with a broad spectrum of clinical manifestations. Increased morbidity and mortality were observed despite early and aggressive treatment. A changing pattern of mortality has been observed recently.
**Objectives:** To summarize the incidence rate (IR) of all-cause and specified causes of mortality in SLE in clinical trials (CT).
**Methods:** A systematic review was performed by searching the Medline, Embase and Cochrane databases. The search strategy identified all synonyms of disease and was limited to CTs. Data from randomized CTs and open-label studies were combined to assess the IR of all-cause and specified causes of mortality using a random effects model.
**Results:** The search identified 2168 articles. After selection, 140 studies met the inclusion criteria (13,409 patients and 18,028.71 patients-year of exposure) and were included in the analysis. A total of 283 SLE patients died. IR of all-cause of mortality was 1.73 per 100 patients-year. IRs of specific causes are showed in the table. Stratified analysis showed higher IR for patients treated with higher dose of glucocorticoids ($\geq$1 mg/kg/day of prednisone) [IR was 3.13 (2.15–4.28) vs 1.22 (0.92–1.55)] and for studies with lower percentage of women (less than

## OP0188 THE DOSE OF GLUCOCORTICOIDS TAKEN AT ONE YEAR, BUT NOT THE INITIAL DOSE PRESCRIBED, IS AN INDEPENDENT PREDICTOR OF DAMAGE ACCRUAL IN LUPUS NEPHRITIS

A. El Mourad, S. Nieuwland-Husson, G. Depresseux, F.A. Houssiau.
*Rheumatology Department, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium*

**Background:** Several studies have demonstrated the pivotal role of glucocorticoids (GC) in damage accrual in lupus patients but very few studies were selectively performed in the subgroup of patients suffering from lupus nephritis (LN).
**Objectives:** To define the predictors of damage accrual in a LN population.
**Methods:** We reviewed the files of the 146 patients with biopsy-proven LN included in the Louvain Lupus Nephritis Cohort. The following data were retrieved: demographics, renal pathology, standard renal parameters at baseline and last followup, treatment, renal relapses and SLICC/ACR-DI over time.
**Results:** After a mean followup period of 124 months, 76/146 patients (52%) had some damage, *i. e.* a SLICC/ACR-DI $\neq 0$. The renal, musculoskeletal, cardiovascular and ocular items were the most represented. By univariate analyses, patients with a SLICC/ACR-DI $\neq 0$ were older, had a longer followup, took more GC at one year [methylprednisolone (MP): 8.8 mg/d *vs* 5.7], had suffered from more renal relapses and had develop more renal impairment, including end-stage renal disease. Similar data were obtained if a different SLICC/ACR-DI cutoff value was used ($>1$ *vs* $\leq 1$). In a multivariate analysis, using the logistic likelihood ratio test, only 3 variables independently predicted damage, namely the length of followup, the presence of renal relapses and the MP daily dose taken at one year. By contrast, gender, ethnicity, age of onset, standard renal parameters, renal pathology, starting oral MP daily dose, use of IV MP or IV CY did not predict damage. Time to first SLICC/ACR-DI point was statistically shorter, by Kaplan-Meier survival curves, in patients taking $\geq 4$ mg/d of MP after one year of treatment compared to $<4$ mg/d. Again the initial dose of MP was not influential. Every additional mg/d of MP taken at one year increased the risk of having a SLICC/ACR-DI $\neq 0$ by 26% (HR: 1.26; CI: 1.02–1.55).
**Conclusions:** We confirm that more than half of LN patients develop damage over time according to the SLICC/ACR-DI. Interestingly, the dose of GC taken at one year (and not the initial dose prescribed) is an independent predictor of damage accrual.
**Disclosure of Interest:** None declared

## OP0189 RATE OF CERVICAL NEOPLASIA IN SYSTEMIC LUPUS ERYTHEMATOSUS: A NATIONWIDE COHORT-STUDY

H. Wadström [1], E.V. Arkema [1], C. Sjöwall [2], J. Askling [1], J.F. Simard [3]. *[1] Dept. of Medicine, Solna, Karolinska Institutet, Stockholm; [2] Faculty of Health Sciences, Linköping University, Linköping, Sweden; [3] Dept. of Health Research and Policy, Dept of Medicine, Stanford School of Medicine, Stanford, United States*

**Background:** Systemic lupus erythematosus (SLE) or its treatment might increase the risk of cervical neoplasia as evidenced by previous studies, although inconclusive. Cervical screening can detect subclinical cervical intraepithelial neoplasias and, in turn, offers effective protection against cervical cancer.
**Objectives:** To examine the risk of cervical neoplasia among women with SLE and across different treatment exposures incorporating findings from cervical screening.
**Methods:** By linking national Swedish registers we assembled a cohort of women with SLE and matched general population comparators. SLE patients were identified using the National Patient Register. Using the Prescribed drug register, two SLE subcohorts were defined by use of antimalarials and other immune-suppressive treatments (with or without antimalarials). Data on cervical screening came from the Swedish National Cervical Screening Registry, which gathers data on all Pap smears. A composite outcome of cervical dysplasia and invasive cervical cancer during follow-up (2006–2012) was defined using the Cervical Screening Registry and the Swedish Cancer Register. Secondary outcomes considered CIN 1, 2–3, and invasive malignancy separately. Cox models estimated hazard ratios (HR) adjusted for age, sex, education level, healthcare utilization, number of children, marital status, family history of cervical cancer, and prior cervical screening.
**Results:** Compared to the general population, there was a doubled rate of cervical dysplasia or invasive cancer among women with SLE (HR=2.12 95%CI 1.65–2.71). The rate was higher among those treated with systemic immune-suppressives than among those with only antimalarials (Table). Among women with SLE, immunosuppressive treatment was associated with an increased rate of cervical dysplasia or neoplasms compared to those on antimalarial therapy without additional immunosuppressive treatment (HR=1.83 95% CI 1.15–2.91). Results were generally similar for the secondary outcomes, however limited due to number of events and follow-up time, particularly in the antimalarial treated group.

Table 1

| Outcome definition | Cohort | Subjects | Number of events | Total follow-up, years | Adjusted[#] HR (95% CI) |
|---|---|---|---|---|---|
| Composite outcome of cervical dysplasia and cancer | Full SLE | 4550 | 121 | 23136 | 2.12 (1.65–2.71) |
| | Antimalarials* | 1783 | 26 | 6564 | 1.52 (1.00–2.33) |
| | Immune-suppressives* | 1981 | 73 | 9002 | 2.72 (2.01–3.67) |
| | General population | 28113 | 336 | 155543 | REF |

*Subsets of "Full SLE". Data on exposure from the Prescribed Drug Register 2006–. [#]Adjusted for level of education, healthcare utilization, number of children, marital status, family history of cervical cancer, prior cervical screening during the last 5 years before start of follow-up, and start year.

**Conclusions:** SLE is a risk factor for cervical neoplasia, even after adjusting for important risk determinants such as previous cervical screening. The clinical implication of our findings is that SLE patients treated with immune-suppressives are at increased risk of cervical neoplasia and should be adequately monitored, regardless of whether the risk increase is due to disease severity or treatment.

## OP0190 INCREASED SERUM LEVELS OF IFN-Λ CORRELATE WITH TH17 AXIS CYTOKINES AND INDEPENDENTLY TO IFN-α IDENTIFY PATIENT GROUP WITH HIGHER ORGAN DAMAGE

V. Oke [1], S. Brauner [1], A. Larsson [2], J. Gustafsson [1], A. Zickert [1], I. Gunnarsson [1], E. Svenungsson [1]. *[1] Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm; [2] Department of clinical Chemistry and Pharmacology, Uppsala University, Uppsala, Sweden*

**Background:** Type I interferons (IFN), particularly IFN-αs, are considered to have a pivotal role in SLE. Recently, increased levels of type III IFNs (IFN-λs) have been described to be also associated with SLE.
**Objectives:** We measured circulating levels of IFN-λ, IL-17, IL-23, IP-10 and also IFN-α, in a cohort of SLE patients and investigated their association with clinical and laboratory manifestations of the disease. Population controls were investigated as comparators.
**Methods:** 261 SLE patients and 276 population controls, identified through the population registry and matched for age, sex, and region of living, were included. All participants were examined by clinician rheumatologist and assessed for current organ manifestations and disease related organ damage. Sera were collected at inclusion and stored at -70* C until analysis. Serum levels of IFN-α, IFN- λ, IL-17, IL-23 and IP-10 were measured in sera by commercial ELISA.
**Results:** IFN-λ was detected in 76 (29,1%) patients and IFN-α in 115 (44%). In 108 patients (41.4%) neither of the cytokines was detected. Both IFN-λ and IFN-α were detected more often and in higher levels in patients. IFN-λ levels did not correlate to the levels of IFN-α, and only in 38 (14.5%) patients had detectable levels of both. Levels of IL-17, IL-23 and IP-10 correlated with each other and with IFN-λ. In comparison, only a weak correlation between levels of IFN-α and IL-23 was observed. Detectable levels of IFN-λ were associated with lower incidence of fever, photosensitivity and also arthritis. Patients with detectable IFN-α had active mucocutaneous disease, serositis and lower levels of C3 and C4, and also presence of anti-Ro/SSA and anti-La/SSB. Incidence of nefritis and DVT was lower in this group. Co-detection of IFN-α and IFN-λ was significantly associated with lymphadenopathy, serositis, cortical dysfunction and presence of antiphospolipid antibodies. IFN-α was associated with overall lower disease damage. However, IFN-λ was associated with lower incidence of musculoskeletal, but higher frequency of cerebrovascular damage. The triple detection of IFN-λ, IL-17 and IL-23 was significantly associated with overall higher disease damage score, and particularly higher incidence of renal damage.
**Conclusions:** Our study demonstrates that in SLE patients the levels of IFN-α and IFN-λ do not correlate, but rather dissect patient's groups with different target organs. Triple positivity for IFN-λ, IL-17 and IL-23 is associated with the higher disease damage, in particular kidney damage.

### OP0191-HPR USABILITY STUDY OF A NEW AUTO-INJECTOR IN THE MANAGEMENT OF RHEUMATOID ARTHRITIS

C. Hudry[1,2], A. Lebrun[1,2], B. Moura[1,3], O. Backers[4], H. Herman-Demars[5].
*[1]Rheumatology Institute; [2]Rheumatology department, Cochin Hospital, Paris; [3]Rheumatology department, Ambroise Paré Hospital, Boulogne-Billancourt, France; [4]Disphar International, Baarn, Netherlands; [5]Medical Department, Nordic Pharma, Paris, France*

**Background:** Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease, for which the introduction of injectable treatments has had a major impact on quality of life. However, patients with RA may suffer from reduced manual dexterity, meaning that administering self-injections can be physically problematic.
**Objectives:** The primary objective of this French multicenter study was to evaluate the usability of a new auto-injector, based on the device design and instructions for use (IFU).
**Methods:** Three groups of subjects were enrolled in the trial: i/ professional nurses or caregivers; ii/ patients with established RA diagnosis with moderate to severe and iii/ from mild hand disability to normal hand function (assessed by Cochin scale above or fewer than 20, respectively). Injections (inj.) were performed with a water-filled device on a foam pad mimicking skin behavior. Each subject performed three inj. in different conditions (first phase (one inj.): just after reading the IFU without further instructions; second phase after explanations upon user's request (two inj.): first in an optimum environment then in a "worst case" environment (noise, dimmed light etc.)). The usability of the auto-injector was assessed by a questionnaire (success: $\geq$75% of positive responses) and by a score card reflecting injection performances, assessed by an independent observer (success: execution of $\geq$75% of handling steps).
**Results:** 42 subjects were enrolled in the study between November 2014 and March 2015. There were no major differences in subject profiles (group size, age, sex) between the 3 user groups. During the first phase, the great majority of subjects succeeded in the usability questionnaire (90.5%) and in the inj. performance (95.2%) with no major differences between the user groups. In the second phase, all subjects from all 3 user groups succeeded in the usability questionnaire and had a positive rate of device handling, regardless of the environment and of the user group. No safety concerns were raised during the study.
**Conclusions:** This study found a very high level of usability and subject acceptance of the auto-injector, regardless of the hand disability. The high performance rate in the first phase showed an intuitive device handling. The study also emphasized the importance of instructions provided to the patient for a 100% understanding and handling success.

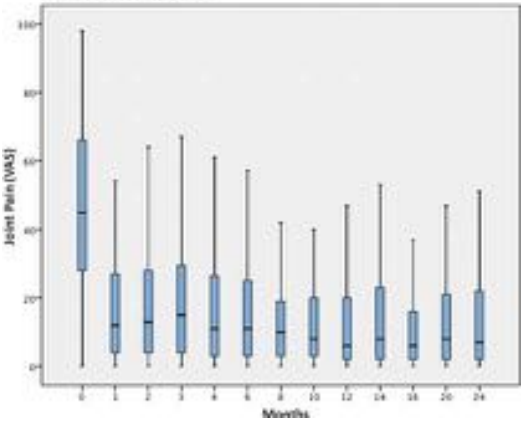
### OP0192-HPR TEACHING METHOTREXATE SELF-INJECTION TECHNIQUE TO THE PATIENTS IN A ROUTINE RHEUMATOLOGY OUT-PATIENT CLINIC: FACTORS FAVOURING OR COUNTERING ACCEPTABILITY

R. Rawat, S.S. Baghel, R. Thakran, C. Messi, S. Kapoor, S. Garg, A.N. Malaviya.
*Rheumatology, Indian Spinal Injuries Centre, New Delhi, India*



**Background:** In recent years, early aggressive targeted treatment for inflammatory joint diseases such as rheumatoid arthritis (RA) is recommended. Low dose Methotrexate (LD-MTX) is the "anchor drug" for RA and other inflammatory arthritidies. The administration of LD-MTX using subcutaneous route increases its therapeutic efficacy, ensures the maximum bioavailability and reduces gastrointestinal adverse effects. Therefore, it is preferred over the oral route. However, the acceptability of the injectable form of LD-MTX has several hurdles including fear of discomfort associated with the injection. This study tried to find out the factor(s) that directly influence the learning capabilities of patients with rheumatological diseases.
**Objectives:** To find out the factors influencing the learning ability of self-injection technique among patients with inflammatory rheumatic diseases.
**Methods:** This retrospective study included patients who were prescribed injectable LD-MTX for their treatment. Besides the demographic information (age, gender) and disease characteristics (diagnosis, duration, prior treatment), the patients were interviewed and counselled regarding the virtues of LD-MTX self-injection. Various other aspects including family and social support, educational background that could influence the learning ability of self-injection techniques were also discussed. Data were analysed statistically with appropriate tests.
**Results:** One hundred (n=100) consecutive patients who were advised weekly LD-MTX injections and taught the self-injection technique were enrolled in this study. On follow-up visit it was found that among them 57 patients ($n_1$) learned and started taking the subcutaneous injection of LD-MTX (either by self or by the attendant who had learnt techniques at the clinic) while the other 43 ($n_2$) did not. The various parameters were statistically analysed to find out which one of them were associated with acceptability for learning injection technique and which ones were impeded. Of the various variables studied, the family support was the only factor that proved to be highly significantly ("p" value 0.0001) associated with the acceptance to learn the self-injection technique. No other variable showed any influence on the learning of LD-MTX self-injection.
**Conclusions:** Among all the variable studied only family support showed a strong association ("p" =0.00001) with learning capabilities for the technique of subcutaneous injection of LD-MTX. Therefore, this preliminary study indicates that for the success of this route of self-administration of LD-MTX and making the patient independent, family support needs to be harnessed. This would improve drug efficacy and disease control

### OP0193-HPR AIMING FOR REMISSION IN EARLY RA: IMPACT ON PAIN DURING THE FIRST 2 YEARS OF TREATMENT

E. Moholt, A.-B. Aga, I.C. Olsen, H.B. Hammer, T. Uhlig, A.K. Kongtorp, H. Lunøe, E.M. Styrmoe, S. Lillegraven, T.K. Kvien, E.A. Haavardsholm on behalf of the ARCTIC study group. *Diakonhjemmet Hospital, Oslo, Norway*

**Background:** Pain is the symptom people with rheumatoid arthritis (RA) have prioritized highest for improvement [1]. Treating to target and aiming for remission in early RA may reduce pain, but there is limited knowledge about the impact of modern treatment strategies on pain in RA patients classified using the 2010 ACR/EULAR criteria.
**Objectives:** The objective of this study was to explore and describe changes in the levels of pain in early RA during the first two years after starting DMARD treatment.
**Methods:** Patients with symptom duration of less than 2 years from first swollen joint who fulfilled the 2010 ACR/EULAR classification criteria for RA, and were DMARD naïve with indication for DMARD treatment were recruited from 11 rheumatology centres and followed for 2 years in the ARCTIC trial. The treatment target was remission, and DMARDs were prescribed using an algorithm developed according to international recommendations. Swollen joints and joints with ultrasound power Doppler synovitis were injected with intra-articular corticosteroids. Pain was recorded on a Visual Analogue Scale (VAS 0–100 mm) at every visit, and categorised according to Jensen et al. with cut points for no pain set at 0–4 mm, mild 5–44 mm, moderate 45–74 mm and severe pain 75–100 mm [2]. Short Form-36 (SF-36) bodily pain was recorded, and transformed to a scale from 0–100, with high scores indicating low bodily pain.
**Results:** A total of 205 early RA patients were included: 61.5% female, 82.4% ACPA positive, and mean (SD) age 52.2 (13.4) years. At initiation of DMARD treatment the mean (SD) 44-swollen joint count was 10.2 (7.2), Ritchie Articular Index 8.14 (6.5), ESR 24 (19) mm/hr and Patient Global Assessment 49 (24) mm. The mean (SD) DAS value was 3.4 (1.1); 20.1% were in low disease activity, 47.1% in moderate disease activity and 32.8% in high disease activity according to DAS. VAS pain at baseline was median (IQR) 45 (27–68) mm, and decreased

Figure: VAS pain 0–100 mm (box-and-whiskers plot including median and 25–75 percentiles)

to 12 (4–27) mm after 1 month, after 1 year to 6 (2–20) mm and after 2 years VAS pain was 7 (2–23) mm; see figure for details. Mean (SD) SF-36 bodily pain at baseline was 40 (21), and increased after 12 months to 73 (23) and 24 months to 74 (24). At baseline less than 3% of the patients reported no pain, after 3/6/12/24 months this proportion increased to 27/32/41/41%, respectively. In the interval 12 to 24 months more than 87% of patients reported exclusively either no or mild pain.

**Conclusions:** In this cohort of early DMARD-naïve RA patients treated according to modern treatment strategies aiming for remission, there was a substantial and significant reduction of pain after 1 month. Pain levels decreased further during the first year, and this reduction was sustained during the first 2 years of follow-up. Early intervention and treating to target in this population fulfils the patients' prioritised goal of minimising pain, leading to a decreased burden of pain in RA.

## OP0194-HPR NURSING TRIAGE IN RHEUMATOLOGY: THREE MONTHS EXPERIENCE IN AN OUTPATIENT CLINIC OF THE UNIVERSITY OF FLORENCE (ITALY)

G. Piemonte[1], K. El Aoufi[2], F. Braschi[2], M. Poli[2], S. Guiducci[2], S. Bellando Randone[2], L. Rasero[1], M. Matucci Cerinic[2]. *[1]Clinical and Experimental Medicine; [2]Clinical and Experimental Medicine - Div. Rheumatology, University of Florence, Florence, Italy*

**Background:** At present patients with rheumatic diseases are mainly assisted in outpatient settings. In our centre more than 150 patients with SSc (Systemic Sclerosis) and more than 100 patients with SPA (Spondyloathritis) are treated monthly. Rheumatic diseases are chronic conditions associated with disability, reduced quality of life and emotional and social consequences. Nurses' role is crucial in improving rheumatic patients' global health providing educational support, promoting self-management and helping accessing appropriate services when needed.

**Objectives:** To describe nursing triage in rheumatology – A nurse led service focused in monitoring disease activity, symptoms and complications and providing educational and clinical support. Nursing triage takes place before rheumatologists' assessment. Period of observation: 1/12/2013 – 28/2/2014

**Methods:** All SSc and VEDOSS patients were evaluated for Raynaud Condition Score (RCS), sHAQ, SScQoL, HAMIS, Cochin, Borg, IIEF5. DUs and other skin lesions were assessed. All SPA patients were evaluated for MASES, BASMI, BASDAI, BASFI, swollen and tender joints, tender points and sacroiliac joint pain. BP, BMI were available for all patients. A severity index based on the previous tests' scorings was obtained both for SSc and SPA patients. Severity index for SSc/VEDOSS was based on DUs presence, sHAQ, HAMIS, Cochin, Borg, RCS and ranges between 0 and 7 (0=lowest severity; 7=highest severity). Severity index for SPA was based on all the previous evaluations and ranges between 0 and 10 (0= lowest severity; 10= highest severity).

**Results:** 264 patients were treated in SSc/VEDOSS outpatient clinic (51 VEDOSS, 71 SSc, 7 primary RP, 98 secondary RP whose diagnosis had to be confirmed). DUs occurred in 29,41% of SSc patients, in 4,08% of patients with secondary RP, no DUs were found in VEDOSS patients. DUs were significatively associated with global and hand impairment and with reduced QoL ($p<0,05$). In SSc patients severity index, RP severity, overall and hand disability were more severe than VEDOSS patients ($p<0,05$). SPA patients had a mean severity index of 3,85; ds 2,67. The overall disability was low (BASFI mean value 2,32; ds 2,56), the disease activity was high (BASDAI mean value=4,09; ds 2,62).

**Conclusions:** SSc and VEDOSS patients with severity index=0 and SPA patients with severity index$\leq$1 may be followed mainly by nursing staff with interventions based on lifestyle modifications and non-pharmaceutical therapies. Adequate protocols must be approved by rheumatologists staff. In this context a nurse led helpline may be effective to select the most appropriate site and level of care for acute conditions in rheumatic diseases.

## OP0195-HPR COMPARISON OF EDUCATIONAL MODELS FOR MAINTAINING OPTIMAL SAFETY IN THE SELF-MANAGEMENT OF BIOTHERAPY AMONGST RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS PATIENTS

F. Fayet[1], M. Rodere[1], C. Savel[1], B. Pereira[2], M. Soubrier[1], M. Couderc[1]. *[1]Rheumatology; [2]Biostatistic Unit, Clermont Ferrand Universitary Hospital, Clermont-Ferrand, France*

**Background:** Biotherapies prescribed in patients with rheumatoid arthritis (RA) and spondyloarthritis (SpA) are associated with risks that patients must be aware of. Patient education offers them to learn how to manage such treatments on a day-to-day basis. In our department, patients can benefit from 3 different educational models: individual informational consultation (Model 1), individual consultations including the 4 recommended steps (educational diagnosis, objectives, education and assessment) (Model 2) and individual consultations with group workshops (Model 3).

**Objectives:** To assess which educational model appears the most appropriate for maintaining optimal safety in the self-management of biotherapy.

**Methods:** This is an observational, monocentric, retrospective study on routine care. All patients on biotherapy with at least one educational consultation between 2009 and 2013 were subsequently divided up according to the undergone educational model (Models 1, 2, or 3). During normal management, patients filled out the BIOSECURE questionnaire, meant to assess their theoretical and practical knowledge (clinical cases), prior to consultation with an education nurse. The overall BIOSECURE score, its theoretical and practical subsections, the different dimensions of the questionnaire and the behaviors in risk situations were compared based on the 3 models.

**Results:** In total, 222 patients were included (67% women, age 53.9 years, disease duration: 10 years, RA n=137, SpA n=77 and uncategorized rheumatism n=8, anti-TNF 89.6%, rituximab 3.2%, abatacept 3.6%, and tocilizumab 3.6%. As regards the educational model, 106 patients (47.8%) benefited from Model 1, 88 (39.6%) from Model 2, and 28 (12.6%) from Model 3.

The overall BIOSECURE score was 76.6/100 without any significant difference depending upon the educational model (Model 1: 75.1, Model 2: 76.7, Model 3: 81.8; p=0.07). The BIOSECURE score was significantly higher amongst women (p=0.007), young people ($p<0.001$), working patients (p=0.005), higher education degree holders ($p<0.001$), patients whose diagnosis was most recent (p=0.008), as well as patients on etanercept (p=0.04) and those on intravenous biotherapies (p=0.004). Model 3 patients displayed a significantly higher practical score (clinical cases) than Model 1 ($p<0.001$) and 2 (p=0.003) patients. There was also a significant difference in BIOSECURE score in favor of Model 3 in certain skill areas, such as "Patient behavior in case of fever" (p=0.03) and "Behavior when faced with injuries, prevention of infectious complications and vaccination" (p=0.03). In terms of the implementation of acquired knowledge in risk situations, 64.5% of patients displayed appropriate behavior in the event of signs of infection, 68% in the case of surgical intervention, and 65% in the event of dental avulsion, without anydifference depending upon the model.

**Conclusions:** The educational model involving group workshops showed no significant variation from the overall BIOSECURE score amongst patients treated with a biotherapy for RA or SpA when compared to the models based solely on individual consultations. However, patients having participated in group workshops exhibited improvement in practical scores and certain skill areas.

**Disclosure of Interest:** None declared

## OP0196-HPR DOSE REDUCTION OF BIOLOGIC DRUGS IN AXIAL SPONDYLOARTHRITIS IN CLINICAL PRACTICE

L. Van Rossen[1], C. Harris[2], R. Withrington[1], A. Keat[2]. *[1]East Kent Hospitals University Foundation Trust, Canterbury; [2]Northwick Park Hospital, Harrow, United Kingdom*

**Background:** The practice of reducing the dose of anti-TNF agents during the treatment of patients with axial spondyloarthritis (axSpA) is often applied in clinical practice; it is not unusual for patients with axSpA to reduce the dose of anti-TNF agents despite the lack of supporting evidence from clinical trials or real-world investigations. Reasons for dose reduction include patient preference (fewer injections or infusions when the patient feels well) and cost reduction. The 2010 update of the ASAS recommendations for the use of anti-TNF agents in patients with axSpA does not consider dose reduction, nor do the 2015 draft BSR guidelines on the topic of biologics in axSpA. However, limited studies have indicated positive results.[1–3] Real-life data regarding dose reduction are therefore valuable and may inform further studies, potentially enabling a rational approach to dosing in clinical practice to be adopted in the future.

**Objectives:** To report the results of anti-TNF dose reduction in axSpA patients attending rheumatology practices in the UK.

**Methods:** In this retrospective study in SpA clinics at two UK hospitals, patients with axSpA who met NICE response criteria after 12 weeks of anti-TNF treatment,[4] and remained stable for at least 6 months, were considered for dose reduction. Dose reduction could have been suggested by either patient or practitioner. Dose reduction decisions were made on an individual basis and implemented by extending the interval between anti-TNF administration, reducing the dose of

each administration, or both. Dose reduction was calculated as a percentage of the standard recommended dose. Outcomes reported include BASDAI, BASFI and BASMI. Observed case data are reported.
**Results:** 47 patients had their dose reduced between June 2005 and December 2015 (25 adalimumab, 14 etanercept, 7 infliximab and 1 golimumab). Most patients (79%) were male and the mean age was 50.2 years (SD±10.5). At the time of anti-TNF initiation, mean BASDAI was 6.4 (SD±1.7), which improved to a mean of 1.8 (SD±1.4) at the time of dose reduction. BASFI and BASMI scores also improved from anti-TNF initiation to time of dose reduction (Table). The mean time interval between initiation of anti-TNF therapy and dose reduction was 3.8 years (SD±2.8).
At the time of analysis 39/47 (83%) remained on a reduced dose and were stable, with maintained efficacy up to 24 months post dose-reduction (Table). In these patients, the mean dose reduction was 36% (SD±16). 8 patients (17%) reverted to their original dose after a mean of 20.2 months (SD±18.7) of treatment with a mean dose reduction of 38% (SD±16).

**Table:** BASDAI, BASFI and BASMI scores at time of anti-TNF initiation, at time of dose reduction, and up to 24 months post-dose reduction in all patients (n=47) and in those in whom dose reduction was successful (n=39)

| | At anti-TNF initiation | | At dose reduction | | Post-dose reduction | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | 6 months | | 12 months | | 24 months | |
| | n | Mean (SD) | n | Mean (SD) | n | Mean (SD) | n | Mean (SD) | n | Mean (SD) |
| **BASDAI** | | | | | | | | | | |
| All patients (n=47) | 46 | 6.4 (1.7) | 46 | 1.8 (1.4) | 40 | 2.1 (1.8) | 28 | 2.0 (1.4) | 25 | 2.3 (2.0) |
| Completers (n=39) | 38 | 6.5 (1.7) | 38 | 1.6 (1.3) | 33 | 1.6 (1.4) | 22 | 1.8 (1.4) | 19 | 1.9 (1.3) |
| **BASFI** | | | | | | | | | | |
| All patients (n=47) | 44 | 4.9 (1.9) | 46 | 2.3 (2.1) | 39 | 2.3 (2.1) | 27 | 2.2 (1.7) | 24 | 2.2 (1.6) |
| Completers (n=39) | 37 | 4.9 (1.9) | 38 | 2.0 (1.9) | 32 | 2.1 (2.0) | 21 | 2.1 (1.6) | 19 | 2.3 (1.6) |
| **BASMI** | | | | | | | | | | |
| All patients (n=47) | 40 | 4.4 (1.8) | 37 | 3.7 (1.8) | 29 | 3.6 (1.8) | 16 | 3.2 (1.6) | 21 | 3.4 (1.5) |
| Completers (n=39) | 33 | 4.3 (1.7) | 33 | 3.6 (1.7) | 25 | 3.5 (1.7) | 14 | 3.5 (1.6) | 18 | 3.4 (1.6) |

Completers: patients who were successful on dose reduction.

**Conclusions:** In this study, patients responding well to anti-TNF therapy successfully had their dose reduced while maintaining treatment response in real-life clinical practice in the UK. This approach to treatment may lead to cost savings in the care of these patients.

## OP0197-HPR PSYCHOSOCIAL PREDICTORS OF DMARD ADHERENCE IN THE FIRST THREE MONTHS OF TREATMENT FOR EARLY ARTHRITIS

A. Pasma[1], J.M. Hazes[2], J.J. Busschbach[3], W.H. van der Laan[4], C. Appels[5], Y. de Man[6], D. Nieboer[7], R. Timman[8], A. van 't Spijker[8]. *[1]Rheumatology, Erasmus MC, Nijmegen; [2]Rheumatology; [3]Psychiatry, Erasmus Medical Center, Rotterdam; [4]Rheumatology, Sint Maartenskliniek, Nijmegen; [5]Rheumatology, Amphia, Breda; [6]Rheumatology, St. Antonius hospital, Nieuwegein; [7]Public Health; [8]Psychiatry, Erasmus MC, Rotterdam, Netherlands*

**Background:** To induce disease remission, early arthritis patients should adhere to their disease-modifying antirheumatic drugs (DMARD) in the first months after diagnosis.[1] It remains unknown why some patients do not adhere to their therapy.
**Objectives:** In this study we aimed to identify which patients are at risk for non-adherence in the first 3 months of treatment.
**Methods:** Adult DMARD-naïve early arthritis patients who started synthetic DMARDs were recruited for a cohort study. At baseline, patients filled out items on potential adherence predictors. These items were based on a literature review and focus group interviews.[2] Items included amongst others questions on coping with pain and the disease, anxiety and depression, and beliefs and expectations about medication. Adherence was in the first 3 months of treatment continuously measured with electronically monitored pill bottles. Items were reduced and clustered using principal component analysis. Per cluster of items, latent trait models were constructed to extract the most discriminating items. Per DMARD and per day non-adherence was defined as not opening the pill bottle when it should have been. We conducted a multilevel multivariable logistic regression model to find predictors for non-adherence.
**Results:** 301 patients agreed to participate of which 259 completed follow-up. Adherence was high and declined over time. Principal component analysis led to 7 dimensions, while the subsequent latent trait models analyses led to 15 dimensions. Of these dimensions, "information seeking" and "having positive expectations about the disease" were associated with adherence and the dimension "adjusting to the pain" was associated with non-adherence (see table 1).

Table 1. Results of the initial multivariable generalized linear mixed model and the results of the multivariable final model after backward selection and correction for over-optimism

| | Initial model | | | | Final model |
|---|---|---|---|---|---|
| Factor | OR | 95% CI | Regression coefficient | p | Regression coefficient |
| 1. Negative feelings | 1.92 | (0.66, 5.62) | 0.65 | 0.24 | |
| 2. Disability | 1.06 | (0.41, 2.72) | 0.05 | 0.91 | |
| 3. Depression | 1.11 | (0.40, 3.10) | 0.11 | 0.84 | |
| 4. Anxiety | 0.49 | (0.18, 1.29) | -0.72 | 0.14 | |
| 5. BMQ specific- necessity | 1.05 | (0.48, 2.38) | 0.05 | 0.91 | |
| 6. Modelling | 0.92 | (0.33, 2.57) | -0.09 | 0.87 | |
| 7. Adjusting / limiting activities | 1.20 | (0.43, 3.35) | 0.19 | 0.72 | 0.11 |
| 8. Information seeking | 0.70 | (0.40, 1.23) | -0.36 | 0.22 | -0.17 |
| 9. Not speaking about it | 1.97 | (0.91, 4.27) | 0.68 | 0.09 | |
| 10. Distancing | 0.90 | (0.35, 2.32) | -0.10 | 0.83 | |
| 11. BMQ - general harm/general overuse | 1.01 | (0.40, 2.55) | 0.01 | 0.98 | |
| 12. BMQ - specific concerns | 1.44 | (0.60, 3.46) | 0.37 | 0.41 | |
| 13. Internal locus of control | 1.36 | (0.53, 3.54) | 0.31 | 0.52 | |
| 14. Active coping | 1.31 | (0.57, 3.02) | 0.27 | 0.53 | |
| 15. Positive expectations | 0.35 | (0.14, 0.84) | -1.06 | 0.02 | -0.30 |

Abbreviations: OR: odds ratio, 95% CI: 95% confidence interval, BMQ: beliefs about medication questionnaire

**Conclusions:** Our findings suggest that patients who experience autonomy through information seeking behavior and having positive expectations about the course of the disease are more prone to be adherent than patients who feel less autonomous and become passive because of pain: these patients are at risk for non-adherence.

## OP0198-HPR EXPLORING FACTORS WHICH INFLUENCE ANTI-TNF TREATMENT DECISIONS FOR RHEUMATOID ARTHRITIS IN ENGLAND – A QUALITATIVE ANALYSIS

S. Gavan[1], G. Daker-White[2], A. Barton[3], K. Payne[1]. *[1]Manchester Centre for Health Economics; [2]NIHR Greater Manchester Primary Care Patient Safety Translational Research Centre; [3]Centre for Musculoskeletal Research, The University of Manchester, Manchester, United Kingdom*

**Background:** Clinical guidance produced by the National Institute for Health and Care Excellence (NICE) recommends that patients in England with rheumatoid arthritis should be treated with the lowest cost anti-TNF[a]. In practice, however, it is possible that a number of factors may influence treatment choice.
**Objectives:** To explore the factors which influence consultant rheumatologists when prescribing anti-TNF therapies in England.
**Methods:** Individual semi-structured telephone interviews were conducted with a purposive sample of consultant rheumatologists (n=11) from hospitals across England between January and September 2015. The telephone interviews (mean duration =31 minutes) were recorded and transcribed verbatim. Interviewees were asked to discuss the influences on key treatment decisions, including: the decision to begin anti-TNF therapy; the choice of first-line anti-TNF; treatment decisions in remission. Interview transcripts were analysed by thematic framework analysis. Ethical approval was obtained from The University of Manchester's Research Ethics Committee (Project: 14147).
**Results:** Interviewees' responses clustered around six main themes. Cost was rarely a factor which influenced the participants' choice of first-line anti-TNF, unless their local service commissioners imposed the use of the least-expensive anti-TNF. In contrast, cautious optimism was expressed towards using biosimilar anti-TNF agents first-line on the grounds of potential cost savings. Patient involvement in decision making was viewed to be sacrificed in those units where using the cheapest anti-TNF was enforced. The interpretation of NICE guidance varied between interviewees with some claiming that the guidance was too restrictive whereas others saw benefits in the flexibility it provided. Interviewees tried to maintain clinical autonomy by careful manipulation of the DAS28 measure in patients with insufficient disease activity to receive anti-TNF therapy according to NICE guidance if they believed it to be clinically appropriate. Negotiated local exceptions to NICE guidance also facilitated clinical autonomy, while the use

(and success) of individual funding requests for treatments apparently varied between interviewees. Often advances in the clinical evidence were used to justify deviations from guidelines. However the influence of evidence had a lesser role in dose-optimisation decisions in remission, where the evidence to guide such decisions is limited.
**Conclusions:** The results suggest that a range of factors, other than just cost, may influence anti-TNF prescribing decisions including the emergence of evidence, the interpretation of clinical guidelines, patient involvement in decision making, a desire for clinical autonomy and the influence of clinical service commissioners. Such factors generate variability in the treatment received by patients with rheumatoid arthritis across England. Further research could explore whether the variation in deviations from NICE guidance leads to differences in patient outcomes or the cost-effectiveness of care.

## Novel insights into B and T cell immunity in rheumatic disease

### OP0199 IMMUNE RESPONSES TO PREVOTELLA COPRI IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Pianta[1], E.E. Drouin[1], S. Arvikar[1], Q. Wang[2], C.E. Costello[2], A.C. Steere[1]. *[1]Center for Immunology and Inflammatory Diseases, Massachusetts General Hospital, Harvard Medical School; [2]Center for Biomedical Mass Spectrometry, Boston University School of Medicine, Boston, United States*

**Background:** Recently, Scher et al. showed that *Prevotella copri*, an intestinal microbe, was over-expanded in stool samples from patients with new-onset RA (NORA). However, it has been unclear whether over-expansion of *P. copri* is simply a marker for dysbiosis in the bowel, or whether the organism itself actually has a pathogenic role in RA.
**Objectives:** To determine whether *P. copri* may have a pathogenic role in RA, we investigated whether patients had T and/or B cell responses to the organism and looked for *P. copri* DNA in synovial fluid (SF).
**Methods:** To identify immunogenic proteins of *P. copri*, we identified microbial HLA-DR-presented peptides (T cell epitopes) in patients' synovial tissue, SF or peripheral blood (PB), using tandem mass spectrometry. The identified peptides were synthesized and tested for T cell reactivity with the matching patient's PBMC by IFN-g ELISpot assay. Immunoreactive peptides or source proteins were then tested for T and B cell responses using cells and sera from our cohort of DMARD-naive NORA patients, chronic RA (CRA) patients, and controls. All RA patients met the 2010 ACR/EULAR criteria for RA. Available serum and SF samples were analyzed for the presence of 16S rDNA of *P. copri* by nested PCR.
**Results:** From the HLA-DR-presented peptides isolated from the PB of one RA patient (HLA-DRB1*0401/0101), we identified an immunogenic T cell epitope derived from bacterial signal sequence of a 27-kDa protein of *P. copri* (*Pc*-p27), implying that this organism or components of it were present in this patient's circulating phagocytic cells. When testing was done in additional patients, 24 of 40 (60%) NORA patients had T cell reactivity with epitopes of *Pc*-p27 compared with none of 10 patients with Lyme arthritis (P=0.0007) and none of 15 healthy control subjects (P<0.0001). In addition, 10 of 78 NORA patients (13%) and 10 of 49 CRA patients (20%) had IgG antibodies to *Pc*-p27; 8 of 78 NORA patients (10%) and 6 of 49 CRA patients had IgA antibodies to this protein. Only 2 patients had both IgG and IgA antibody responses. Overall, 31 of 127 NORA or CRA patients (24%) had IgG or IgA antibody responses to *P. copri*, whereas low-level antibody responses to the organism were found in only 2 of 131 patients with Lyme arthritis, spondylarthropathy or lupus (P<0.0001) and in 2 of 50 healthy control subjects (P=0.001). Finally, synovial fluid yielded positive results for *P. copri* 16S rDNA in 3 of 5 RA patients with IgG antibody responses to *P. copri*, but in none of 13 patients with IgA *P. copri* antibodies or no response to the organism (P=0.01).
**Conclusions:** A subgroup of RA patients had *P. copri*-specific IgA or IgG antibody responses early or late in the disease, whereas patients with other types of arthritis rarely did, implying specificity of these responses in RA. IgA responses may occur because of interactions between host and immune cells in the gut mucosa, whereas IgG responses may be a sign of systemic spread of the organism to joints. These observations suggest that *P. copri* is more than a bystander in gut dysbiosis, and implies that the organism itself may have a pathogenic role in RA patients, creating a new paradigm to consider in RA pathogenesis.

### OP0200 CIRCULATING, AUTO-REACTIVE B CELLS SPECIFIC FOR CITRULLINATED ANTIGENS IN PATIENTS WITH RHEUMATOID ARTHRITIS DISPLAY AN ACTIVATED, PROLIFERATIVE PHENOTYPE

H. Kristyanto[1], P.F. Kerkman[1], E. van der Voort[1], H. Spits[2], D. Baeten[3], T.W. Huizinga[1], R.E. Toes[1], H.U. Scherer[1]. *[1]Department of Rheumatology, Leiden University Medical Center, Leiden; [2]Department of Cell Biology and Histology; [3]Amsterdam Rheumatology & Immunology Center, Division of Clinical Immunology and Rheumatology, Academic Medical Center, Amsterdam, Netherlands*

**Background:** Rheumatoid arthritis (RA) is characterized by the formation of autoantibodies against citrullinated antigens (CA). Intriguingly, depletion of CD20+ B cells leads to significant clinical improvement in the majority of patients, despite the persistence of high titer autoantibodies. This indicates that the CD20+ B cell compartment, potentially more than the autoantibodies themselves, contributes to the pathogenesis and/or chronicity of RA. Auto-reactive B cells within this compartment could be the main drivers of this effect, but evidence for this hypothesis is lacking. We recently developed the technology to visualize and characterize CA-specific B cells in patients and demonstrated that a large proportion has a CD20+ memory phenotype[1].
**Objectives:** To study the phenotype of CA-specific B cells in comparison to tetanus-toxoid (TT)-specific B cells in peripheral blood of individual patients.
**Methods:** Differentially labeled CA and their arginine control variants were used as tetramers to identify CA-specific B cells in peripheral blood of patients with RA. TT-specific B cells were identified in the same samples using differentially labeled TT. Both antigen-specific cell populations were enumerated and phenotypically characterized by flow cytometry.
**Results:** CA-specific B cells and TT-specific B cells were detected in peripheral blood in comparable frequency (median 0.012% vs. 0.014%). Both CA- and TT-specific B cells displayed mainly markers of class-switched memory B cells. Intriguingly, CA-specific memory B cells showed remarkable overexpression of co-stimulatory molecules and markers of active proliferation.
**Conclusions:** This is the first phenotypic analysis of auto-reactive, CA-specific memory B cells in comparison to recall antigen-specific memory B cells in individual patients with RA. CA-specific memory B cells overexpress co-stimulatory molecules and proliferation markers, indicative of an active immune response against CA in these patients. These data support the hypothesis that CA-specific memory B cells contribute to RA pathogenesis and fuel efforts for their antigen-specific depletion.

### OP0201 SAFETY, TOLERABILITY, AND FUNCTIONAL ACTIVITY OF MGD010, A DART® MOLECULE TARGETING CD32B AND CD79B, FOLLOWING A SINGLE DOSE ADMINISTRATION IN HEALTHY VOLUNTEERS

N. Pandya[1], W. Chen[1], J. Lohr[1], X.-T. Yao[1], R. Burns[1], H. Li[1], H. Li[1], J. Muth[1], R. Goldwater[2], E. Bonvini[1], S. Johnson[1], P. Moore[1], J. Wigginton[1]. *[1]MacroGenics, Rockville; [2]Parexel, Baltimore, United States*

**Background:** MGD010, a bi-specific Dual-Affinity Re-Targeting, or DART®, molecule, inhibits activated B-cells by delivering a negative signal via simultaneous co-ligation of the inhibitory checkpoint molecule, CD32B (FcγRIIb), with the BCR component, CD79B. This novel-therapeutic approach leverages a physiologic B-cell inhibitory loop leading to signal suppression without B-cell depletion, while targeting all activated B cells rather than subsets, such as those dependent on BLyS for survival. MGD010 is being developed for the treatment of autoimmune disorders.
**Objectives:** A single ascending dose study among healthy volunteers was conducted to assess the safety, tolerability, pharmacokinetics, and functionality of MGD010.
**Methods:** This was a first-in-human, double-blind, placebo-controlled study in which 48 evaluable healthy volunteers were intravenously (IV) administered a single dose of MGD010. Eight (8) subjects were randomized [6:2 MGD010:Placebo] in each of the six (6) dose levels [0.01, 0.1, 0.3, 1.0, 3.0, and 10.0 mg/kg] and followed for safety evaluation. B-cell binding and functional assessment, as measured by ex-vivo calcium ($Ca^{2+}$) flux, was determined by flow cytometry in peripheral blood samples. Quantitation of immune cell populations, phenotyping of B-cell subsets, immunoglobulin levels and cytokines were also serially evaluated.
**Results:** MGD010 was well tolerated at all dose levels. All related adverse events (AEs) were ≤ Grade 2 and no serious AEs (SAEs) were reported. No subjects

had premature discontinuations or infusion reactions, systemic hypersensitivity reactions or injection site reactions. No clinically relevant changes in laboratory parameters, vital signs, or ECG parameters occurred. No substantial decrease in peripheral B-cell counts was observed at any dose level. MGD010 demonstrated linear pharmacokinetic and dose-dependent binding to circulating B lymphocytes. Consistent with its anticipated mechanism of action, administration of MGD010 was associated with a reduction in *ex vivo* BCR-induced $Ca^{2+}$ mobilization in B lymphocytes. Furthermore, a selective dose-dependent, prolonged downregulation of surface IgG BCR expression among circulating $CD27^{+}$ memory B cells was also observed, supporting a preferential effect on activated memory B cells.
**Conclusions:** These data demonstrate that MGD010 has an acceptable safety profile following a single-dose IV administration of up to the maximal tested dose level and showed pharmacodynamic activity consistent with its design. The results support continued development of MGD010 in patients with autoimmune disorders.

## OP0202 LONG-LIVED CD19-NEGATIVE HUMAN PLASMA CELLS ARE GENERATED AT THE PLASMABLAST TO PLASMA CELL TRANSITION

G. Arumugakani[1], S. Stephenson[2], G. Doody[2], A.C. Rawstron[3], P. Emery[1], D. McGonagle[1], R. Tooze[4]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]Section of Experimental Haematology, Leeds Institute of Cancer and Pathology, University of Leeds; [3]HMDS, St. James's Institute of Oncology; [4]Section of Experimental Haematology, Leeds Institute of Cancer and Pathology, St James's University Hospital, Leeds, United Kingdom*

**Background:** B-cells are key mediators in a wide variety of autoimmune disorders as evidenced by the clinical response to B-cell depletion. Lack of response in a proportion of patients could be due to long-lived plasma cells (PCs) that are resistant to B-cell depletion therapy. Thus long-lived PCs in addition to their central role in humoral immunity are also involved in autoimmunity. Absence of CD19 expression, a feature of neoplastic PCs, identifies a minor subpopulation of normal human bone marrow PCs potentially linked to long-lived cells [1]. Whether $CD19^{neg}$ PCs are "aged" cells that have gradually lost CD19 expression, or derive from a distinct differentiation decision is not established.
**Objectives:** We sought to ascertain whether human $CD19^{neg}$ PCs are derived at the plasmablast to PC transition or are established by gradual loss of CD19 expression with increasing PC age.
**Methods:** We performed a sensitive flow cytometric analysis of CD19 expression during the human acute immune responses to flu vaccination, and tracked the generation and maintenance of CD19-negative PCs using CD40:CD40L and TLR mediated in vitro human PC differentiation systems [2].
**Results:** Using intracellular staining for IRF4 alongside conventional surface markers such as CD27, CD38, CD95 and CD20, we robustly identify a $CD19^{neg}$ plasmablast population present in steady state peripheral blood. The $CD19^{neg}$ plasmablasts expanded during the acute plasmablast response to flu vaccination (p=0.063) but the degree of expansion was smaller compared to $CD19^{pos}$ plasmablasts. Influenza specific $CD19^{neg}$ plasmablasts were detectable 6 days after vaccination in the peripheral blood by ELISpot. $CD19^{neg}$ state was established at the plasmablast to PC transition in both CD40:CD40L and TLR mediated B-cell differentiation in vitro. $CD19^{neg}$ PCs increase as a percentage of surviving PCs with time in vitro at all the three subsequent time points compared to the previous time point (p=0.0009, 0.0015 and 0.0179). Flow-cytometrically sorted $CD19^{neg}$ PCs can be maintained independent of $CD19^{pos}$ PCs.
**Conclusions:** $CD19^{neg}$ PCs are independently established as an early event during human PC differentiation and predominantly do not derive by age-associated conversion from $CD19^{pos}$ PCs. Absence of CD19 expression does not provide evidence of PC age, but may identify PCs with greater potential for longevity in humans. Understanding the plasmablast to PC transition is vital in determining strategies for depletion of long-lived PCs and stages of immune response at which they can be employed for treatment of autoimmune disorders.

## OP0203 IN RHEUMATOID ARTHRITIS SYNOVITIS IS NOT DOMINATED BY POLYMORPHIC LOCAL, BUT RATHER BY UNIFORM SYSTEMIC T CELL RESPONSES

A. Musters[1], P.L. Klarenbeek[1,2], M.E. Doorenspleet[1,2], R.E. Esveldt[1,2], B.D. van Schaik[3], A. Jongejan[3], S.W. Tas[1], A.H. van Kampen[3], F. Baas[4], N. de Vries[1,2]. *[1]Clinical Immunology and Rheumatology, Amsterdam Rheumatology and immunology Center | Academic Medical Center; [2]Laboratory of Experimental Immunology; [3]Bioinformatics Laboratory, Department of Clinical Epidemiology, Biostatistics and Bioinformatics; [4]Laboratory for Genome Analysis, Academic Medical Center, Amsterdam, Netherlands*

**Background:** Genetic and immunological evidence clearly points to a pathogenic role of T cell clones in rheumatoid arthritis (RA). Previous studies of T cell receptor (TCR) repertoires in the synovial tissue (ST) of individual inflamed joints showed highly expanded T cell clones; however, these clones had background frequencies in peripheral blood (PB)[1].
**Objectives:** To gain more insight into the potential role of these expanded T cell clones in RA, and to study whether single ST biopsies and synovial fluid (SF) samples are representative for the clonal T-cell disturbances observed, we analyzed the distribution of these highly expanded T cell clones in ST and SF samples from different joints in the same patient at the same time point.
**Methods:** In 7 RA-patients we simultaneously obtained ST biopsies from two inflamed joints via mini-arthroscopy together with paired PB and SF samples. ST biopsies were obtained from ankle or from the infrapatellar region of the knee. In 6 patients we took additional independent suprapatellar (SP) biopsies within the same knee joint. Samples were processed for RNA-based next generation sequencing. T cell clones were identified by their unique TCR β-chain sequence, the degree of expansion being expressed as a percentage of the total number of reads. To test for dissimilarity between different sites the Morisita index was used. This index originates from the field of biodiversity and gives a value between 0 and 1, values near 0 resemble no overlap between two locations while values close to 1 indicate similarity[2]. A One-tailed Mann-Whitney test was performed where applicable.
**Results:** We identified 1,114,386 clones in 7,890,571 TCR-sequences. Only a small proportion of the clones present in ST were retrieved in the same proportion in SF (Morisita Index 0.07, SD 0.20) and PB (0.006, SD 0.14). In contrast, considerable overlap was seen if we analyzed cellular infiltrate in ST biopsies from different regions of the same joint: 0.55 (SD 0.28). An identical overlap was seen if we analyzed ST from different joints in the same patient: 0.54 (SD 0.26). This overlap was significantly different from that between ST and PB ($p<0.005$) and ST and SF ($p<0.05$).

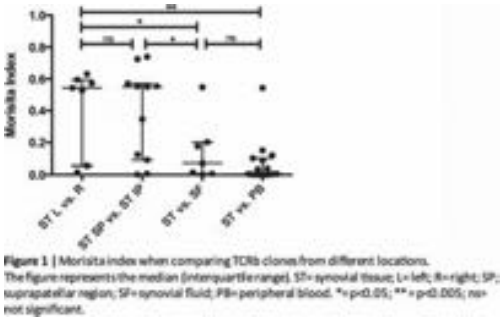

Figure 1 | Morisita index when comparing TCRb clones from different locations. The figure represents the median (interquartile range). ST= synovial tissue; L= left; R= right; SP; suprapatellar region; SF= synovial fluid; PB= peripheral blood. *= p<0.05; **= p<0.005; ns= not significant.

**Conclusions:** SF and PB T cells do not fully reflect the repertoire of dominant clones in the ST, suggesting that analysis of biopsies rather than SF or PB is preferred. ST biopsies taken from different locations within the same joint show substantial overlap suggesting that single biopsies, e.g. taken by ultrasound, show a representative snapshot of the ST T cell infiltrate. Interestingly, ST biopsies from different joints also show substantial overlap of the most dominant T cell clones in patients with active RA. This indicates that in individual patients a limited number of T cell clones dominate the adaptive immune response in the ST. Detailed cellular characterization of these clones seems warranted, and may help to devise more selective strategies for therapeutic targeting.

## OP0204 CLONAL EXPANSION OF CD4+ CYTOTOXIC T LYMPHOCYTES IN IGG4-RELATED DISEASE

H. Mattoo[1], V. Mahajan[1], T. Maehara[2], E. Della Torre[3], V. Deshpande[4], W. Zachary[5], M. Kulikova[6], J.H. Stone[5], S. Pillai[1]. *[1]Ragon Institute of MGH, MIT and Harvard, Massachusetts General Hospital, Boston, United States; [2]Section of Oral and Maxillofacial Oncology, Division of Maxillofacial Diagnostic and Surgical Sciences, Fukuoka, Japan, Fukuoka, Japan; [3]Unit of Medicine and Clinical Immunology, IRCCS, Ospedale San Raffaele, Milan, Italy; [4]Department of Pathology; [5]Rheumatology Unit; [6]Massachusetts General Hospital, Boston, United States*

**Background:** IgG4-related disease (IgG4-RD) is a systemic condition of unknown etiology, characterized by highly fibrotic lesions with dense lymphoplasmacytic infiltrates rich in IgG4+ plasma cells and CD4+ T cells (1). Given the longstanding history of atopy that characterizes a proportion of patients with IgG4-RD, it has been suggested that TH2 cytokines contribute to the pathogenesis of this condition (2). However, we recently demonstrated that allergic manifestations are not increased in patients with IgG4-RD compared to the general population (3). Similarly, CD4+TH2 cells are expanded only in the peripheral blood of IgG4-RD patients with concomitant atopy, questioning the hypothesis of IgG4-RD as a TH2 driven condition (4).
**Objectives:** We aimed to characterize CD4+ T cell subsets in IgG4-RD subjects.
**Methods:** We used flow cytometry to identify CD4+ effector/memory T cells as well as Th1, Th2, and T regulatory cells in a cohort of 101 IgG4-RD patients. Gene expression analysis was used to further characterize expanded cells. Results were validated by flow cytometry. Next-generation sequencing of the T cell receptor β chain gene was performed on CD4+ T cells in a subset of patients to identify their clonality. Tissue infiltration by specific T cells was examined using quantitative multi-color imaging.
**Results:** CD4+ effector/memory T cells with a cytolytic phenotype (cytotoxic T lymphocytes (CTLs)) were expanded in IgG4-RD patients compared to healthy controls. Next-generation sequencing revealed prominent clonal expansions of these CD4+CTLs but not of CD4+GATA3+ memory TH2 cells in subjects with IgG4-RD. The dominant T cells infiltrating a range of inflamed IgG4-RD tissue sites were clonally expanded CD4+CTLs that expressed granzyme A and perforin. Clinical remission induced by rituximab-mediated B cell depletion was associated with a reduction in disease-associated CD4+ CTLs.
**Conclusions:** IgG4-RD is prominently linked to clonally-expanded CD4+ CTLs in peripheral blood as well as in inflammatory tissue lesions. A TH2 signature might be primarily linked to a concomitant atopic diathesis. CD4+ CTLs might be of pathogenic importance in other fibrotic conditions including IgG4-RD.

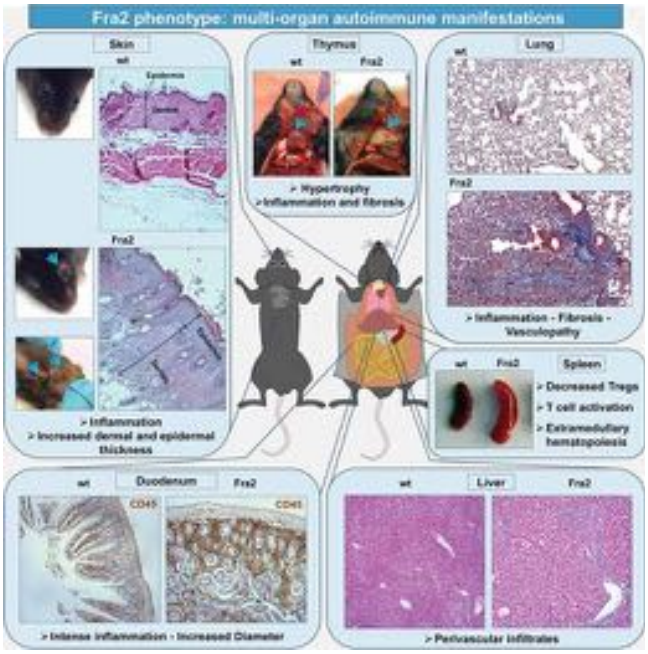
## OP0205 CLINICAL AND PRECLINICAL ASSESSMENT OF THE ANTI-MCAM MONOCLONAL ANTIBODY PRX003, A POTENTIAL NOVEL TREATMENT FOR TH17-MEDIATED INFLAMMATORY DISEASES



M. Koller[1], K. Flanagan[1], M. Skov[1], R. Goldblum[2], S.G. Griffith[3], R.M. Barbour[1], N. Ehsani-Chimeh[4], M.P. Marinkovich[4], W. Zago[1], T.A. Yednock[1], G.G. Kinney[1], D. Ness[1]. *[1]Prothena Biosciences Inc., South San Francisco; [2]Carlsbad Pharmaceutical Consulting, Inc.; [3]ClinPharma Services, Inc., San Diego; [4]Stanford University School of Medicine, Palo Alto, United States*

**Background:** Melanoma cell adhesion molecule (MCAM; CD146) is expressed on the surfaces of a small population of T cells that have the capacity to produce a multitude of cytokines; further, expression of MCAM is a defining characteristic of TH17 cells. As such, MCAM is hypothesized to be central to the pathogenesis of numerous autoimmune disorders, including psoriasis and psoriatic arthritis. Laminin α4 (LAMA4), the primary MCAM ligand, promotes T-cell transmigration into sites of inflammation. Thus, inhibition of MCAM/LAMA4 binding may limit cell infiltration and subsequent pathogenic inflammation. PRX003, a monoclonal antibody designed to bind an MCAM epitope critical for LAMA4 interactions, blocks adhesion of MCAM-expressing cells to LAMA4 rather than targeting an individual cytokine, thus preventing the infiltration of cells responsible for disease pathogenesis.
**Objectives:** Study objectives were twofold: (1) to demonstrate preclinical proof of concept for anti-MCAM antibodies in mice overexpressing RAC1, an aggressive transgenic model of psoriasis and (2) to evaluate the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and immunogenicity of PRX003 in healthy human subjects.
**Methods:** The effects of anti-MCAM antibodies (murine homolog of PRX003) on the MCAM expression of circulating immune cells and on disease progression were assessed in RAC1 mice treated 3×/week with anti-MCAM antibodies (0.1 or 10 mg/kg) or isotype control from postnatal day 7 (when disease progression is evident) through postnatal day 34. In a first-in-human, randomized, double-blind, placebo-controlled, phase 1, single ascending dose-escalation study (NCT02458677), PRX003 was administered by intravenous infusion over approximately 60 minutes. Five escalating dose cohorts received 0.3, 1.0, 3.0, 10, or 30 mg/kg of PRX003 or placebo (6 subjects randomized to PRX003 and 2 to placebo per cohort) and were subsequently monitored in an inpatient unit for 24 hours and by periodic follow-up for 12 weeks. PD measurements in humans included MCAM expression on circulating T-lymphocytes and serum soluble MCAM.
**Results:** Anti-MCAM antibodies demonstrated target-mediated binding to circulating immune cells after administration to RAC1 transgenic mice. Furthermore, anti-MCAM antibody-treated mice experienced marked reductions in MCAM expression levels on circulating cells, resulting in diminished (by 40% to 60%) psoriatic disease progression, as evidenced by less erythema, scaling, and skin thickness than were observed in RAC1 transgenic mice treated with an isotype control antibody. PRX003 may thus have a beneficial impact on inflammatory diseases in humans. Data on the safety, tolerability, serum PRX003 PK, and immunogenicity of PRX003 in healthy human subjects, including PK/PD modeling of markers of target engagement, will be presented for the first time.
**Conclusions:** The results of these studies and of previously published reports support further examination of PRX003 in patients with inflammatory disease. A phase 1 multiple ascending dose trial of PRX003 in patients with plaque psoriasis (NCT02630901) is planned.

## OP0206 FRA2 IS PLAYING A KEY ROLE IN THE CONTROL OF TREG DEVELOPMENT AND AUTOIMMUNITY

F. Renoux[1], M. Stellato[1], E. Pachera[1], D. Impellizzieri[2], C. Dees[3], J. Distler[3], G. Kania[1], O. Boyman[2], O. Distler[1]. *[1]Division of Rheumatology; [2]Division of Clinical Immunology, University Hospital Zurich, Zurich, Switzerland; [3]Internal Medicine 3, University of Erlangen, Erlangen, Germany*

**Background:** Decreased number or altered function of regulatory T cells (Tregs) has been reported in many inflammatory rheumatic diseases, and Tregs are considered promising therapeutic targets for autoimmune diseases. It is thus of high importance to delineate the pathways controlling Tregs biology and the onset of autoimmunity. Fra2 is a transcription factor belonging to the Fos family proteins which takes part in the AP-1 transcription complex. The role of Fra2 in Tregs is so far unknown.
**Objectives:** To characterize the potential role of Fra2 in controlling Tregs and autoimmunity in Fra2 transgenic mice.
**Methods:** Fra2 transgenic mice were generated, in which the Fra2 transcription factor is ubiquitously overexpressed under the control of an MHCI promotor. T lymphocyte populations were analyzed by flow cytometry, and pathological manifestations in multiple organs by histology. Bone marrow cells were transferred into lethally irradiated recipients to create Fra2-wt chimeric mice.
**Results:** At 3 weeks of age, Fra2 mice showed a striking decrease of the Treg population ($CD4^+CD25^+FoxP3^+$ in wt and Fra2 littermates spleens: 11.35 and 5.75% of $CD4^+$, respectively, p=0.0005, Mann-Whitney test, n=6). The strong decrease in Tregs was stable over time and also observed in $CD4^+$ single positive thymocytes, indicating that Fra2 mice have a defect in natural Treg development. Interestingly, from 7 weeks on, we could also detect the appearance of activated T cells ($CD4^+$ and $CD8^+$, with $CD62L^{high}CD44^{high}CD127^{low}$ profile) which represented up to 60% of total T cells by 16 weeks of age. While the phenotype of young mice was limited to decreased Tregs, macroscopic and histological observations in 16 week-old mice showed the presence of an extensive multi-organ autoimmune phenotype (see figure). Perivascular inflammatory infiltrates, containing T cells, B cells and numerous granulocytes were observed in the lung and liver. Extensive inflammation and fibrosis were observed in the thymus. Spleens were also enlarged with pronounced extramedullary haematopoiesis. Fra2 mice also developed dermatitis on eyelids and back-skin, with an increase in dermal and epidermal thickness. Finally, duodenum was enlarged due to acute inflammation and reactive hyperplasia.
To understand whether the effect of Fra2 is T cell intrinsic or extrinsic, we also performed bone marrow transfer experiments in which irradiated wt recipient mice received Fra2 transgenic bone marrow. Interestingly, chimera mice displayed a

decreased percentage of Tregs in blood, spleen, but also thymus, confirming an intrinsic role of Fra2 in natural Treg development.
**Conclusions:** These data suggest that Fra2 overexpression inhibits natural Treg development, resulting in 1: diminished Tregs, 2: activation of effector T cells and 3: development of inflammation in multiple organs. This is the first evidence for a role of Fra2 in controlling Treg development and autoimmunity. This murine model also provides a unique opportunity to delineate the function of the Fra2 pathway in T cells and Tregs and its impact on autoimmunity.

## An inflammatory update!

### OP0207 TRANSMEMBRANE TNF-ALPHA REVERSE SIGNALING LEADING TO TGF-BETA PRODUCTION IS SELECTIVELY ACTIVATED BY ANTI-TNF-ALPHA TARGETING MOLECULES

A. Pallai[1], B. Kiss[1], G. Vereb[2], M. Armaka[3], G. Kollias[3], Z. Szekanecz[4], Z. Szondy[1]. *[1]Department of Dental Biochemistry; [2]Department of Biophysics and Cell Biology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary; [3]Institute for Immunology, Biomedical Sciences Research Center "Alexander Fleming", Vari, Greece; [4]Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary*

**Background:** Tumor necrosis factor (TNF)-a, a potent pro-inflammatory cytokine, is generated in a precursor form called transmembrane (m)TNF-a that is expressed on the surface TNF-a producing cells. TNF-a was shown to act both as a ligand by binding to TNF-a receptors, as well as a receptor that transmits outside-to-inside (reverse) signals back into the mTNF-a bearing cells. Anti-TNF-a targeting molecules which neutralize TNF-a with the same efficiency show disease specific effectiveness.
**Objectives:** The aim of the present study was to characterize mTNF-a signaling and to test whether known anti-TNF-a targeting molecules trigger mTNF-a signaling in human macrophages.
**Methods:** TNF-a expression and localization was studied in mouse bone marrow derived macrophages by RT-QPCR or FACS analysis and confocal microscopy. mTNF-a signaling was triggered by coated anti-TNF-a antibodies and tested by a Phospho-MAPK array. The cytokine induced was determined by RT-QPCR analysis and ELISA. The effect of mTNF-a signaling on lipopolysaccharide (LPS)-induced pro-inflammatory cytokine formation was tested with a cytokine array.
**Results:** Non-activated macrophages express basal levels of mTNF-a and respond to anti-TNF-a antibodies by triggering the mitogen-activated protein kinase kinase 4 signaling pathway leading transforming growth factor (TGF)-b production. Exposure to LPS further induced the expression of mTNF-a, and mTNF-a signaling suppressed the LPS-induced pro-inflammatory response via TGF-b. Since apoptotic cells downregulate their TNF receptors, they do not trigger mTNF-a for TGF-b production. Etanercept, a soluble TNF-a receptor, does not, while golimumab and infliximab, which are anti-TNF-a antibodies, do trigger TGF-b production in human macrophages.
**Conclusions:** Induction of TGF-b production by mTNF-a or by receptors triggered by apoptotic cells could be considered in the therapy of inflammatory diseases and may, in part, also account for differences in the actions of various TNF-a inhibitors.
**Disclosure of Interest:** None declared

### OP0208 EMERGING ROLE OF IL-33/ST2 AXIS IN ENDOTHELIAL CELL INJURY OF LUPUS NEPHRITIS

S. Yu, C.-H. Huang, W.-H. Huang, C.-H. Huang, Y. Huo, Y. Tao. *Rheumatology, The Second Affiliated Hospital of Guangzhou Medical University, Guangzhou, China*

**Background:** "Alarmins" are prototypic endogenous pro-inflammatory factors as they are released from necotic cells and provoke local damage or systemic inflammation. Evidences are accumulating to support the inclusion of "Alarmins" as targets of autoreactivity as well as inducers in the pathogenesis of Systemic Lupus Erythematosus (SLE). Interleukin (IL)-33 is a novel member of the family of "Alarmins" because of its characteristics and functions in mediating host immune responses. On this background, we sought to determine the role of IL-33/ST2 axis in lupus pathogenesis. The role of IL-33/ST2 axis has not previously been described in lupus nephritis.
**Objectives:** We sought to determine the role of IL-33/ST2 axis in lupus pathogenesis. The role of IL-33/ST2 axis has not previously been described in lupus nephritis.
**Methods:** This project will study the followings: (1) To determine whether IL-33 was present in renal glomerular endothelial cells; (2) To assess the functional and intracellular signal transuction mechanisms regulating the link between IL-33/ST2-mediated innate immunity and inflammation in $CD4^+$ T cells-endothelial cells co-culture system of lupus patients.
**Results:** Immunofluorescence (IF) for IL-33 in the kidney were performed in both $MRL^{lpr}$ lupus mice and C57BL/6J mice. On double staining for IL-33 and lectin, IL-33 was clearly seen in glomeruli and also in peritubular areas. To determine whether the IL-33 staining in glomeruli and peritubular areas was in endothelium, double IF staining for IL-33 and von Willebrand factor (vWF) was performed. IL-33 co-localized with vWF in glomeruli and in peritubular areas. The increased levels of IL-33 mRNA transcripts were detected in kidney of $MRL^{lpr}$ lupus mice compared with C57BL/6J mice. Expression of cell-surface ST2 was increased on the $CD4^+$ T cells of lupus patients when compared with healthy controls. Serum sST2 level was significantly higher in SLE patients with *flare* than those without *flare* ($p<0.05$).
**Conclusions:** As a result of external stimuli or infection, renal glomerular endothelial cells undergo cellular death and release the "Alarmin", IL-33, to alert the lupus immune system. Released IL-33 interact with their target cells, $CD4^+$ T cells via their specific receptor ST2 to subsequently induce innate and adaptive responses, activate inflammatory pathways in the pathogenesis of lupus nephritis.

### OP0209 ELEVATED GITRL IS ASSOCIATED WITH MULTI-ORGAN INVOLVEMENT AND INCREASED DISEASE ACTIVITY OF PRIMARTY SJOGREN'S SYNDROME AND PROMOTES PATHOGENIC TH17 DIFFERENTIATION

Y. Gan, X. Sun, L. Li, J. He, Z. Li. *Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China*

**Background:** Accumulating data has showed that Glucocorticoid-induced Tumor Necrosis Factor Receptor Family-related Protein (GITR), with its ligand (GITRL), plays an important role in promoting T-cell-mediated immunity and exacerbating autoimmunity in animal models, including transient inhibition of Tregs[1] and enhancement of Th17 cells[2]. But its pathogenesis role in primary Sjögren syndrome (pSS) remains unclear.
**Objectives:** Our study aimed to evaluate whether GITRL is related to disease severity and multi-organ involvement in pSS patients and explore the possible mechanisms.
**Methods:** 78 pSS patients and 44 healthy controls were recruited, and the serum level of GITRL was measured by ELISA, and the serum levels of interleukin (IL) -17A, IL-17E, IL-17F, IL-1β, IL-22 and IL-23 were tested by Luminex. $CD4^+$ T lymphocytes were isolated from PBMCs of 5 healthy donors by $CD4^+$ T Cell isolation kit and cultured in TexMACS™ GMP medium with anti-CD3

monoantibody (mAb), anti-CD28 mAb and rhIL-2. For Th17 cell differentiation and the pathway exploration of pAkt, pS6, pSTAT3 and pSTAT5, $CD4^+$T cells were treated either with recombinant human GITRL protein or without the protein for 5 days. Surface marker, intracellular cytokine and signal proteins were detected by flow cytometry. Clinical and laboratory data were also collected.

**Results:** *S*erum level of GITRL was significantly higher in pSS patients than in HC (Figure 1). There is a negative correlation between elevated levels of serum GITRL and WBC, Neutrophils%, PLT, $C_3$ and $C_4$, and positive correlation with Lymphocytes%, IgG and RF (Table 1). Interestingly, pSS patients with overt hypothyroidism showed higher level of serum GITRL comparing to those with subclinical hypothyroidism and normal thyroid function (Figure 2). Patients with pulmonary involvement had higher serum GITRL level (Figure 3), and patients of moderate to high disease activity (ESSDAI$\geq$5) also showed higher serum level of GITRL (Figure 4). Moreover, *S*erum GITRL level was positively correlated with IL-17A, IL-17E, IL-17F, IL-1β, IL-22 and IL-23 (Table 2). After GITRL treatment, we found an obvious expansion of $CD4^+IL\text{-}17A^+$T (Th17) cells and there might be a dose-dependent effect (Figure 5). We also found the mean fluorescence intensity (MFI) of pAkt, pS6, pSTAT3 and pSTAT5 increased after GITRL stimulation (Figure 6).

**Conclusions:** Our results identified the function of GITRL in exacerbating disease activity in pSS patients, and enhancing the differentiation of Th17 cells and the secretion of Th17-related cytokines, and the possible mechanisms might be through the pathways of pAkt, pS6, pSTAT3 and pSTAT5. This finding might provide the theoretical basis of anti-GITRL mAb[3] as a novel therapeutic tageting on Th17 cells in the treatment for pSS patients.

## OP0210 APOLIPOPROTEIN E AGGRAVATES INFLAMMATION AND JOINT DESTRUCTION IN MURINE ANTIGEN-INDUCED ARTHRITIS

G. Ascone, I. Di Ceglie, W. de Munter, B. Walgreen, A. Sloetjes, P. van Lent, P. van der Kraan. *Radboud Institute for Molecular Life Sciences, Nijmegen, Netherlands*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by severe bone destruction which has been associated with altered lipid metabolism. Apolipoprotein E (Apo E) is a lipoprotein crucial in lipid metabolism, mainly produced by macrophages. Moreover ApoE has been recently described as an important anti-inflammatory mediator regulating innate immunity and bone turnover.

**Objectives:** In the present study we investigated the role of Apo E in inflammation and bone destruction during antigen-induced arthritis (AIA).

**Methods:** Experimental arthritis (AIA) was induced by injection of 60 μg mBSA into the right knee joint of $ApoE^{-/-}$ and wild type (WT) control mice previously immunized with mBSA/CFA.

Joint swelling was measured by uptake of $^{99m}$Technecium ($^{99m}$Tc) and expressed as a ratio of the uptake in right (injected) and the left (non injected) knee joint. Humoral immunity (mBSA antibody titer) was measured by ELISA. Joint inflammation and bone erosion were measured by histological analysis using an arbitrary scale from 0 to 3. $TRAP^+$ cells were determined using immunohistochemistry.

**Results:** $ApoE^{-/-}$ mice showed significantly less joint swelling at day 1, 3 and 7 after AIA induction compared to WT controls (21%, 17%, 18% lower, respectively). Serum mBSA antibody levels (total IgG, IgG1, IgG2a and IgG2b) are comparable between the two immunized mouse strains. At day 21, histology of the knee joints showed less infiltration of inflammatory cells (25% lower) and decreased bone erosion in the $ApoE^{-/-}$ mice compared to WT controls (25% lower from 1.5±0.2 to 1.1 ±0.1). In line with that, $ApoE^{-/-}$ mice showed a reduction of the number of osteoclasts present at the area of resorption within the arthritic knee joints (36% lower from 20±4 osteoclasts/section in WT mice to 12±5 in $ApoE^{-/-}$ mice), as measured by image analysis of TRAP staining.

**Conclusions:** ApoE aggravates bone destruction within the knee joints during AIA by increasing influx of inflammatory cells within the synovium and elevating the number of resorbing osteoclasts on the bone surface.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3937

## OP0211 REPROGRAMMING OF METABOLIC PATHWAYS INHIBITS TLR2-INDUCED INFLAMMATION IN RA

T. Mcgarry, M. Biniecka, D. Veale, U. Fearon. *Centre for Arthritis and Rheumatic Diseases, St Vincent's University Hospital, Dublin, Ireland*

**Background:** Recent studies have emphasized a tight link between the metabolic state and phenotype of immune/inflammatory cells. Metabolic turnover of the inflamed synovium may induce a cellular switch in energy production, characterised by a glycolytic flux, suppression of mitochondrial function and potentiation of inflammation. The role of Toll-like receptors (TLRs) in immune responses is well documented, however emerging evidence suggests they also play a role in metabolism.

**Objectives:** In this study, we examine mitochondrial function, cellular metabolism and synovial inflammation in response to TLR2 activation.

**Methods:** RA synovial explant cultures and RA synovial fibroblasts (RASFC) were cultured with TLR2-ligand Pam3CSK4 (1μg/ml). Mitochondria DNA (mtDNA) mutations were assessed using a Random Mutation Capture assay and reactive oxygen species (ROS), mitochondrial membrane potential (MMP) and ATP levels were quantified using fluorescent probes. Mitochondrial and glucose metabolism gene arrays were quantified by RT-PCR and the mitochondrial ultrastructure assessed by transmission electron microscopy (TEM). Surrogate markers of glycolysis PKM2, GLUT1, ATP5B and GAPDH were quantified in RA/OA synovium by immunohistochemistry. PKM2 was also assessed by western blotting and immunofluorescence. Finally, we examined the effect of glycolytic inhibitor 3-(3-pyridinyl)-1-(4-pyridinyl)-2-propen-1-one (3PO) (20μM) on TLR2–induced cytokine production, invasion/migration and signalling components NFκBp65, Notch-1IC and p-STAT3.

**Results:** Pam3CSK4 significantly induced mtDNA mutation frequency, ROS, and inhibited the MMP. In parallel, Pam3CSK4 differentially regulated key mitochondrial genes SOD2, BNIP3 and BBC3 (all $p<0.05$) and markedly altered the ultrastructure of mitochondria. Consistent with this, we demonstrated altered metabolic activity in RASFC, with induced PKM2 nuclear translocation, increased ATP levels and differential regulation of metabolic genes FBP1/2, PGAM2 and ACo2 (all $p<0.05$), resulting in metabolic shift in favour of glycolysis. This change in metabolic activity was mirrored *in-vivo* where expression of PKM2, GLUT1 and ATP5B were significantly higher in RA synovium compared to OA ($p<0.05$). Finally, reprogramming of metabolism using 3PO significantly inhibited TLR2-induced cytokine production, cell migration/invasion and transcriptional regulation of NFκBp65 and p-STAT3.

**Conclusions:** Reprogramming of metabolic activity in RA resulted in resolution of inflammation. These results show close interactions between innate immunity, metabolism and inflammation, further elucidation of these interactions may provide new insights to new therapeutic approaches in RA.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2016-eular.3455

## OP0212 PHOSPHOLIPID TRANSFER PROTEIN (PLTP): A LINK BETWEEN INFLAMMATION AND LIPIDS IN RHEUMATOID ARTHRITIS?

R. Audo[1,2,3], V. Deckert[4,5,6], C. Daien[1,2,3], H. Che[1,2,3], J. Elhmioui[2], J.-P. Pais de Barros[4,5,6], S. Lemaire[4,6,7], C. Desrumaux[3,6,8], M. Hahne[2,3], B. Combe[1,3], L. Lagrost[4,5,6,7], J. Morel[1,2,3]. *[1]Department of rheumatology, Teaching hospital Lapeyronie; [2]UMR5535, CNRS; [3]Montpellier University, Montpellier; [4]LNC UMR866, INSERM; [5]University Bourgogne Franche-Comté; [6]LipSTIC LabEx, Fondation de Coopération Scientifique Bourgogne-Franche Comté; [7]University Hospital of Dijon, Dijon; [8]U710, INSERM, Montpellier, France*

**Background:** Rheumatoid arthritis (RA) is associated with an increased risk of cardiovascular events related to inflammation. In early RA, there is an imbalance between inflammation and lipids. The LXR (Liver X receptors) pathway regulates lipid metabolism and inflammation and it was recently shown to be the most upregulated pathway in RA synovial fluid macrophages compared to blood monocytes (1). Plasma phospholipid transfer protein (PLTP) is one of the LXR's upregulated targets genes. PLTP has been shown to be involved in lipids metabolism, atherosclerosis and, more recently, in the inflammatory response. PLTP was alternatively described as a proinflammatory factor when expressed in cells or as an anti-inflammatory agent through its ability to bind and neutralize LPS.
**Objectives:** We investigated PLTP expression in RA and its effects on synovial fibroblasts from RA (RAFLS).
**Methods:** PLTP expression was examined in FLS from RA patients by qPCR, WB analysis and immunochemistry. ABCA1 expression was analysed by flow cytometry. The effect of recombinant human PLTP on IL-8, IL-6, VEGF and MMP3 production, and on cell proliferation was assessed by ELISA and $^{3}$H-Thymidine incorporation, respectively. Inactivation of lipid transfer activity of PLTP was obtained by heating PLTP for 2 hours at 65°C. Lipid transfer activity of PLTP and pro-inflammatory cytokines were measured in synovial fluid (SF) from RA patients and controls (osteoarthritis (OA) patients).
**Results:** PLTP mRNA was increased in RAFLS (n=11) compared to OAFLS (n=5) but not statistically significant (p=0.08) whereas PLTP protein levels were significantly higher in RAFLS (p=0.04). RA synovial tissues showed higher PLTP staining than OA. ABCA1, a putative receptor of PLTP, was found on RAFLS both at the cell surface and at the intracellular level (n=5). Native PLTP and heat-inactivated recPLTP were able to significantly increase the production of inflammatory cytokines (IL-6 and IL-8), of the VEGF angiogenic mediator and of the MMP3 metalloproteinase in RAFLS. PLTP and heat-inactivated PLTP also significantly increased RAFLS proliferation (by 3.3±.1.2 and 5.5±2.1 fold, respectively). These effects were markedly impaired after treatment with anti-PLTP antibodies or glyburide (*i.e.* a chemical inhibitor of the ABCA-1 transporter). SF of RA patients were found to display elevated levels of PLTP activity compared to OA patients (p=0.0009). PLTP activity levels in RASF correlated with IL-6 and IL-1b (r=0.53, p=0.0086, and r=0.58, p=0.018, respectively), as well as with some lipid parameters.
**Conclusions:** It is shown for the first time that PLTP is highly expressed in the joint of RA patients. It is able to directly trigger inflammation and FLS proliferation, independently of its lipids transfer activity.

## OP0213 CD40-MEDIATED ACTIVATION OF NONCANONICAL NF-κB SIGNALLING IN DENDRITIC CELLS INDUCES EXTRATHYMIC AUTOIMMUNE REGULATOR (AIRE) EXPRESSION, WHICH IS IMPAIRED IN PRIMARY SJÖGREN'S SYNDROME

L. Huitema[1], B. Helder[1], A.-R. Noort[1], C. Lebre[2], S. Tas[1]. *[1]Amsterdam Rheumatology & immunology Center/ Experimental immunology; [2]Experimental Immunology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

**Background:** The nuclear factor (NF)-κB family of transcription factors has a key role in the regulation of inflammation. We have previously demonstrated that activation of noncanonical NF-κB signalling in dendritic cells (DC) via CD40 stimulation is important for the induction of the immunoregulatory enzyme indoleamine 2,3-dioxygenase (IDO) [1]. This pathway is also involved in the expression of Autoimmune Regulator (AIRE) in the thymus, which is essential central tolerance. Peripheral extrathymic AIRE-expressing cells (mainly antigen presenting cells, including DC) can also induce tolerance. However, stimuli that induce extrathymic AIRE expression in DC are unknown. Therefore, we studied whether activation of noncanonical NF-κB signalling induces AIRE expression in monocyte-derived DC (moDC) and whether this induction is altered in moDC derived from patients with autoimmunity, using primary Sjögren's syndrome (pSS) as a prototypic systemic autoimmune disease.
**Objectives:** To study whether activation of non-canonical NF-κB signalling induces AIRE expression in moDC from healthy donors and pSS.
**Methods:** MoDC were generated by culturing monocytes for 6 days with GM-CSF and IL-4. Maturation was induced by addition of the non-canonical NF-κB stimulus anti-CD40 for 48 hours. Cleavage of p100 into p52, IDO and AIRE protein was analyzed by Western blot. Immunofluorescence staining for RelB was performed on cytospins of moDC. RelB protein was visualized by confocal microscopy. siRNA-mediated silencing of NF-κB-inducing kinase (NIK), the main activating kinase of the noncanonical pathway, was accomplished by neo electroporation.
**Results:** Anti-CD40 stimulation of moDC from healthy donors induced cleavage of p100 into p52 and nuclear translocation of RelB, which is indicative of noncanonical NF-κB signalling. This was accompanied by upregulation of IDO and AIRE expression, which was inhibited by siRNA-mediated silencing of NIK. Anti-CD40 stimulation of moDC derived from pSS patients also resulted in activation of noncanonical NF-κB signalling and upregulation of IDO. However, AIRE expression was to a much lesser extent upregulated in moDC derived from pSS patients compared to healthy donor DC.
**Conclusions:** Extrathymic AIRE expression can be induced in moDC via CD40-stimulation and is regulated by noncanonical NF-κB signalling. This is impaired in pSS patients. The functional consequences of this potentially defective immunoregulatory program are currently investigated.

## OP0214 S100A8/A9 PRODUCED LOCALLY DURING EXPERIMENTAL OSTEOARTHRITIS INDUCES LOCAL AND SYSTEMIC CHANGES IN MONOCYTE POPULATIONS

N. Cremers, E. Geven, A. Blom, A. Sloetjes, I. DiCeglie, S. van Dalen, G. Ascone, W. de Munter, M. van den Bosch, P. van Lent. *Experimental Rheumatology, Radboudumc, Nijmegen, Netherlands*

**Background:** The etiology of osteoarthritis (OA) is multi-factorial, and is mainly driven by an activated synovium wherein inflammation plays an important role. In response to pro-inflammatory cytokines, monocytes can be recruited from the bone marrow (BM) to the site of inflammation. In mice, two functionally distinct monocyte populations are described: pro-inflammatory Ly6C-high monocytes (C-C chemokine receptor type 2 (CCR2)$^{high}$) and patrolling Ly6C-low monocytes (CCR2$^{low}$). In the BM, monocyte chemoattractant protein-1 (MCP-1) is a key molecule that drives monocyte efflux via binding with CCR2.
**Objectives:** The objectives of our study are to investigate the systemic effects of locally induced OA on BM monocyte populations and their recruitment to the OA joint in collagenase induced OA (CiOA), and the role of the alarmins S100A8/A9 in that.
**Methods:** CiOA was induced by unilateral-articular collagenase-injection in C57BL/6 mice. At day 7, 21 and 42, mice were sacrificed together with age-matched naive mice (n=6/group), and synovial mRNA expression of several pro-inflammatory cytokines were measured. During CiOA and control conditions, the absolute amount of cells in the BM per femur was measured and the mRNA expression of BM MCP-1 and CCR2 was determined. Cells from BM, blood and synovial tissue were isolated and analyzed by FACS. Monocyte subsets were identified as (B220/CD90/CD49b/NK1.1/Ly6G)$^{low}$CD11b$^{high}$(F4/80/MHCII/CD11c)$^{low}$ and further distinguished by their Ly6C expression. In addition, we investigated synovitis in S100A9$^{-/-}$ mice during CiOA.
**Results:** Expression of the pro-inflammatory cytokines IL-1β, IL-6, TNF-α, S100A8 and S100A9 in the synovium were increased at day 7, but only expression of S100A8 and S100A9 remained high until day 21. Local induction of CiOA resulted in systemic effects within the BM as shown by the decrease in cell numbers at day 7 and 21 (15% and 14% respectively). Concurrently, the expression of MCP1 at day 7 in BM was increased (3.3-fold), suggesting an increased efflux of BM-cells. Relative number of BM-Ly6C-high monocytes was increased at day 7 (164%), being reflected by increased CCR2 expression (2.8-fold). This suggests a specific regulation of BM Ly6C-high monocytosis and recruitment during CiOA and emphasizes the systemic effects following CiOA. During the course of CiOA increased numbers of Ly6C-high monocytes were also observed in the synovium: 398% at day 7 and 510% at day 42, compared to naïve mice. These effects may be caused by the sustained S100A8/A9 levels; we therefore investigated synovitis in S100A9$^{-/-}$ mice during CiOA. The number of cell layers and cell influx in the synovium of S100A9$^{-/-}$ mice was decreased compared to C57BL/6 mice.
**Conclusions:** Local induction of OA induces systemic release of BM-derived cells and increased Ly6C-high monocyte populations systemically and locally in the synovium, a process that may be regulated by the sustained release of S100A8/A9 from the synovium.

Gaslini Pediatria II Reumatologia and University of Genova, Genova, Italy*

**Background:** IV abatacept (ABA) 10 mg/kg every 4 weeks is safe and effective in reducing signs and symptoms of polyarticular forms of juvenile idiopathic arthritis (pJIA) in children and adolescents.[1] SC ABA 125 mg weekly has therapeutically equivalent efficacy and comparable safety to IV ABA in adult RA, but similar data in pJIA are lacking.
**Objectives:** To assess the PK, efficacy and safety of SC ABA in children and adolescents with active pJIA.
**Methods:** This single-arm, open-label (OL), Phase III study (NCT01844518) enrolled patients (pts) aged 2–17 years (yrs) with pJIA and an inadequate response/intolerance to ≥1 DMARD. Pts received SC ABA weekly OL for 4 months (M), based on body weight tier (10–<25 [50 mg ABA], 25–50 [87.5 mg ABA] and >50 kg [125 mg ABA]). JIAACR criteria 30 (JIAACR30) responders at 4M could enter a 20M OL extension; JIAACR30 non-responders could continue SC ABA for 3M more and discontinued if JIAACR30 was not achieved by M7. The primary endpoint was steady-state blood trough concentration ($C_{minss}$) of ABA at 4M in the 6–17-yr-old pJIA pts (n=173); we report PK, efficacy and safety from the initial 4M OL phase for these pts.
**Results:** Baseline characteristics of the 173 pJIA pts were: mean age (SD) =12.3 (3.1) yrs; mean number of active joints (SD) =12.4 (8.3); 78.6% of patients used MTX (mean dose: 12 mg/m$^2$/week) and 26.6% failed prior biologic treatment. The target therapeutic $C_{minss}$ of 10 μg/mL was achieved (Figure); at 4M, mean (SD) $C_{minss}$ was 42.1 (14.7) μg/mL and was consistent across all three weight groups. Robust JIAACR responses were seen at 4M (Figure): JIAACR30, 80.9%; inactive disease, 29.5%. Biologic-naïve pts had a numerically higher JIAACR30 response than biologic-experienced pts at 4M. The number of pts with serious AEs and those who discontinued study drug due to AEs during the initial 4M were low (n=5 and n=3 [fatigue, exanthematous rash and ovarian germ cell teratoma] pts, respectively). AEs of interest reported included infections (31.8%) with 1 case of sepsis, injection-site reactions (5.2%) and malignancy (0.6%). No laboratory abnormalities or unexpected safety concerns were reported.

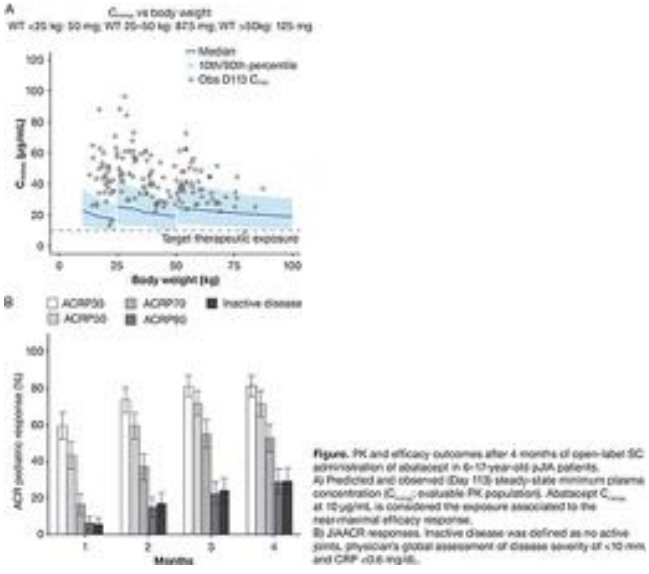

**Figure.** PK and efficacy outcomes after 4 months of open-label SC administration of abatacept in 6-17-year-old pJIA patients. A) Predicted and observed (Day 113) steady-state minimum plasma concentration ($C_{minss}$) evaluable PK populations. Abatacept $C_{minss}$ at 10 μg/mL is considered the exposure associated to the near-maximal efficacy response. B) JIAACR responses. Inactive disease was defined as no active joints, physician's global assessment of disease severity of <10 mm, and CRP <0.6 mg/dL.

**Conclusions:** The target therapeutic exposure for SC abatacept was achieved in pts aged 6–17 yrs with pJIA irrespective of weight group. The exposures for SC abatacept were within the range for IV abatacept in pJIA and comparable with SC abatacept in adult RA. Robust efficacy was observed with SC abatacept with no new safety concerns after 4M of treatment.

### OP0216 SAFETY OF TOCILIZUMAB, INTERLEUKIN-1 INHIBITORS AND ETANERCEPT IN 262 SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS PATIENTS

G. Horneff[1], A.C. Schultz[1], A. Hospach[2], G. Ganser[3], I. Foeldvari[4], A. Thon[5], R. Trauzeddel[6], F. Weller[7], K. Minden[8], J.P. Haas[9]. *[1]Asklepios, Sankt Augustin; [2]Olga Hospital, Stuttgart; [3]St Josef Stift, Sendenhorst; [4]Cenre Ped Rheum, Hamburg; [5]MMH, Hannover; [6]Helios Clinic, Berlin; [7]Prof Hess Clinic, Bremen; [8]Charite, Berlin; [9]Centre Ped Rheumatology, Garmisch-Partenkirchen, Germany*

**Background:** Since the approval of first biologics for treatment of JIA, surveillance in Germany is monitored prospectively by the BIKER registry.
**Objectives:** To evaluate the safety of Tocilizumab (TOC), IL-1 inhibitors (Anakinra & Canakinumab) and Etanercept (ETA).
**Methods:** Safety assessments were based on adverse events reports.
**Results:** 205 sJIA pts received 269 treatment courses with biologics (TOC 71, Anakina 36, Canakinumab 19, ETA 143 and 57 pts. received MTX only. Median age was lower In the MTX cohort (4.8y) than with ETA (8.2); TOC (9.6); IL-1i (8.2) as was the disease duration. ETA was started in 80% of pts before 2008 while in the TOC cohort all pts and in the IL-1i cohort 74% started therapy after 2008. Pre-treatment consisted of systemic steroids in 75% starting MTX and in all patients starting biologics. Initial concomitant treatment with systemic steroids was significantly less frequent with TOC (44%, p<0,001) and IL-1i (44%, p<0.001) compared to 83% with ETA and 82 in MTX cohort. There were 30 adverse events (AE) in the MTX cohort, 71 in the ETA, 118 in the TOC and 81 in the IL-1i cohort. Rate of AE (per patient-year) was significantly higher in the TOC (RR 4.64; p<0.0001) and IL-1i-group (RR 3.04; p<0.01) (Table) and serious AE were also more frequent upon TOC (RR 5.5; p<0.01) and IL1i (6.39; p<0.01) but not upon ETA compared to the MTX cohort. There were 13 reports about Macrophage activation syndrome. Rates were not different. Of 125 infections, 13 were reported as serious. The infection rate was significantly higher in the TOC cohort (RR 4.3; p<0.001)and IL-1i cohort (RR 2.93; p<0.001) and significantly lower with ETA (RR 0.39; p<0.01) than in the MTX cohort. Hodgkin's lymphoma, Crohn's disease and demyelination occurred once in the ETA cohort, one case with a depression with suicidal thoughts occurred with IL-1i. Intolerance led to discontinuation of ETA in 3.5%, TOC in 8.3% and IL-1i in 2%. 2 pts died (septic shock & MAS) not related to biologics.
**Conclusions:** Higher rates of safety signals, especially infections were noted upon treatment with TOC and IL-1i. Beside infections, disease reactivation and

## OP0217 ADJUDICATION OF INFECTIONS IN THE PHARMACOVIGILANCE IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS (PHARMACHILD) TREATED WITH BIOLOGIC AGENTS AND/OR METHOTREXATE

J. Swart, G. Giancane, F. Bovis, E. Castagnola, A. Groll, G. Horneff, H.-I. Huppertz, D. Lovell, T. Wolfs, M. Hofer, E. Alekseeva, V. Panaviene, S. Nielsen, J. Anton, F. Uettwiller, V. Stanevicha, M. Trachana, F. De Benedetti, L.M. Ailioaie, E. Tsitsami, S. Kamphuis, T. Herlin, P. Dolezalova, G. Susic, B. Flato, F. Sztajnbok, A. Pistorio, A. Martini, N. Wulffraat, N. Ruperto. *PRINTO, Genova, Italy*

**Background:** The Pharmachild study is aimed at observing children with JIA undergoing treatment primarily with biologics±methotrexate (MTX). It is conducted by the participating centres of over 60 countries belonging to PRINTO and PReS.
**Objectives:** Primary endpoint of the study is safety in JIA patients undergoing immunosuppressive therapy. A preliminary analysis of infections has been performed by an independent Safety Ajudication Committee of 6 experts (3 pediatric rheumatologists and 3 pediatric infectious disease specialists).
**Methods:** The centres were asked to report all infections encountered by the patients followed for JIA. Data were checked by PRINTO and the medical monitor based on MedDRA dictionary. Upon completion of these steps, all eligible cases for adjudication, represented by serious/severe/very severe infections, were submitted to the expert Committee. The experts were asked to answer 6 questions. The events with consensus of at least 4/6 experts on more than 3/6 questions were considered. An additional analysis was performed on opportunistic infections, with referral to the recommendations by Withrop *et al.*[1], and on the correlation between infections and 3 treatment phases: MTX only, first biologic±MTX and at least 2 sequential biologics±MTX after failure of the first biologic.
**Results:** 7817 patients were enrolled in Pharmachild at the time of preliminary analysis, with 27% of total safety events reported as infections. 360 events were submitted to the Safety Adjudication Committee. 94 infections (26.1%) achieved maximum consensus among the experts (6/6 questions), 237 (65.8%) consensus on 4/6 or 5/6 questions, the remaining events were discarded. 330 infections were finally retained for the analysis, mostly represented by serious infections of moderate/severe intensity. With regard to the other questions, 74.2% infections were adjudicated as common, appropriately treated, with no clear correlation to the immunosuppressive therapy. The experts achieved consensus on 18 infections adjudicated as opportunistic. Referring to the list of opportunistic infections provided by Winthrop *et al.*[1], we identified 89/330 (27%) opportunistic infections, mostly represented by EBV and herpes zoster infections. 98.8% of events were not recoded. A doubled risk of infections was found in the group of patients who were started on their first biologic±MTX or who had been treated with at least 2 sequential biologics±MTX (1.3 and 1.9 infectious events per 100 py, respectively), compared to the MTX only group (0.8 infectious events per 100 py). The same was found for serious and opportunistic infections.
**Conclusions:** Our preliminary analysis showed a significant number of infections in JIA patients on immunosuppressive therapy, with one third classified as opportunistic infection. The introduction of biologics in therapy increased the risk of opportunistic and serious infection.

## OP0218 EVALUATION OF THE ACR AND SLICC CLASSIFICATION CRITERIA IN JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL ANALYSIS

H. Lythgoe[1,2], T. Morgan[3], E. Heaf[3], O. Lloyd[3], M.W. Beresford[1,2,3] on behalf of UK JSLE Study Group. *[1]Department of Women's and Children's Health, Institute of Translational Medicine, University of Liverpool; [2]NIHR Alder Hey Clinical Research Facility; [3]Department of Paediatric Rheumatology, Alder Hey Children's NHS Foundation Trust, Liverpool, United Kingdom*

**Background:** Juvenile-onset systemic lupus erythematosus (JSLE) is a severe multi-system inflammatory disease with very varied presentation and disease course. Diverse clinical manifestations means classification of JSLE can prove challenging. The Systemic Lupus International Collaborating Clinics (SLICC) group proposed revised classification criteria for systemic lupus erythematosus (SLICC-2012 criteria)[1].
**Objectives:** This study aimed to compare the SLICC-2012 criteria with the widely used American College of Rheumatology classification criteria (ACR-1997 criteria)[2,3] in a national cohort of JSLE patients and evaluate how classification criteria that individual patients meet evolved over time.
**Methods:** Data from patients in the UK JSLE Cohort Study with a senior clinician diagnosis of probable, evolving or definite JSLE was reviewed. Patients were classified using both criteria within one year of diagnosis and at latest follow-up (following a minimum twelve month follow-up period). Sensitivity of each classification criteria was compared using McNemar's test.
**Results:** 226 patients were included. The SLICC-2012 was more sensitive than ACR-1997 at diagnosis (92.9% vs 84.1% p<0.0001) and after follow-up (100% vs 92.0% p<0.0001). Figure 1 provides an overview of our results. Of those patients meeting the SLICC-2012 criteria and not the ACR-1997 criteria 59% of patients at diagnosis and 61% of patients at follow-up, scored more than one additional point on the SLICC-2012. In particular, the inclusion of hypocomplementaemia on SLICC-2012 facilitated classification of more patients using these criteria.

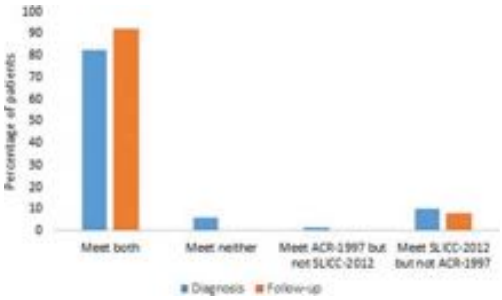

Figure 1. Summary of classification criteria met by patients at diagnosis and at follow-up

**Conclusions:** The SLICC-2012 was better able to classify patients with JSLE than the ACR-1997 and did so at an earlier stage in their disease course. SLICC-2012 should be considered for classification of JSLE patients for the purpose of observational studies and clinical trial eligibility. It may also be useful in daily practice to corroborate clinician diagnosis of JSLE.

## OP0219 UPDATE ON MALIGNANCIES IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS IN THE GERMAN BIKER REGISTRY

G. Horneff[1], A. Klein[1], A. Hospach[2], P. Oommen[3], I. Foeldvari[4], J. Kuemmerle-Deschner[5], I. Feddersen[6], K. Minden[7]. [1]*Asklepios, Sankt Augustin;* [2]*Olga Hospital, Stuttgart;* [3]*University, Duesseldorf;* [4]*Hamburg Centre Ped Rheum, Hamburg;* [5]*University, Tuebingen;* [6]*Helios Clinic, Berlin Buch;* [7]*Charite, Berlin, Germany*

**Background:** While TNFα-inhibitors improved outcome of JIA markedly, concerns have been raised about an increased risk for malignancies especially lymphoma, probably already due to the disease itself.
**Methods:** The BIKER data base was used to identify cases of suspected and confirmed malignancies
**Results:** Until 2015, 3695 pts treated with MTX and /or TNFα inhibitors were prospectively followed with 13198 observation years (OY). 12 cases of suspected malignancies, including 7 lymphoid neoplasms, have been reported. 11 pts had received MTX, 2 CSA, single patients received Sulfasalazine, Azathioprine or Leflunomide. 9 pts received Etanercept (ETA), 2 Adalimumab, and 1 case consecutively ETA, Infliximab and Abatacept. A case of myelodysplasia, with spontaneous recovery and a cervical dysplasia were labelled as suspected. Confirmed cases included 2 Hodgkin's lymphoma, 1 non-Hodgkin's lymphoma, 2 ALL and 2 lymphoproliferative disorders, who recovered after discontinuation of immunosuppressive therapy. Singular confirmed cases were thyroid carcinoma, yolk sac carcinoma, cervical dysplasia and anaplastic ependymoma. The total rate of malignancies observed in the registry (0.91/1000Y) exceeds the rate expected according to data of the German cancer registry (0.16/1000Y, $p<0.001$). The calculated risk-ratio in the MTX cohort (n=3: 1 lymphoma, 2 acute lymphatic leukaemias) was significantly increased for both all malignancies (RR 4.5; 95% CI1.5–14.0) and for haemato-lymphatic malignancies (RR 10.1; 95% CI 3.2–31.2). The risk ratio in the ETA cohort also was significantly increased (RR for all malignancies 8.1; 95% CI 4.2–15.5; RR for leukaemia/lymphoma 10.4 (3.9–27.7). No difference was found between the incidence rate of malignancies within the ETA cohort compared to the MTX cohort (p=0.39). Rates did not markedly differ if suspected malignancies (cervical dysplasia, myelodysplasia) were excluded. 6 of the 7 haemato-lymphatic malignancies occurred in ps <15 y of age. There was a higher rate within MTX (0.93/1000Y; 95%CI 0.30–2.89) than with ETA (0.56/1000Y; 95%CI 0.18–1.74). 4 of 5 solid tumours occurred after the age of 15, all in the ETA cohort. One patient never exposed to biologics but to MTX died of ALL, all other recovered.

Table 1. Risk ratios (RR) and 95% CI compared to the German Childhood Cancer Registry report 2015 (1657/2056 cancers in children <15/<18 years of age in $10.5/12.9\times10^6$ children)

| | Malignancies | N (Incidence/1000 PY) | RR (95% CI)* | P (Wald test) |
|---|---|---|---|---|
| MTX <15 y (3224 PY) | All | 3 (0.93) | 5.90 (1.90–18.3) | 0.002 |
| | Lymphoma & leukemia | 3 (0.93) | 13.74 (4.42–42.71) | <0.0001 |
| ETA <15 (5333 PY) | All | 3 (0.56) | 3.56 (1.15–11.1) | 0.028 |
| | Lymphoma & leukemia | 3 (0.56) | 8.31 (2.67–25.82) | 0.0003 |
| MTX <18 y (4182 PY) | All | 3 (0.72) | 4.50 (1.45–13.97) | 0.009 |
| | Lymphoma & leukemia | 3 (0.72) | 10.05 (3.23–31.21) | <0.0001 |
| ETA <18 Y (6998 PY) | All | 9 (1.29) | 8.07 (4.19–15.53) | <0.0001 |
| | Lymphoma & leukemia | 4 (0.57) | 8.01 (3.00–21.38) | <0.0001 |

**Conclusions:** Malignancies were more frequent than expected. Whether the increased risk is through the rheumatic disease or through treatment remains unclear. Treatment with ETA seems not to further increase the malignancy risk. Long-term observation of JIA patients treated with TNFα inhibitors into adulthood remains an important challenge.

## OP0220 PERSONAL EXPOSURE TO AIR POLLUTION INFLUENCED DISEASE ACTIVITY AND EXHALED BREATH BIOMARKERS: A PROSPECTIVE STUDY IN A CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS POPULATION

M.F.G. Goulart[1], A.G.F. Alves[1], A.L.F. Braga[2], A.M.E. Salum[1], L.A.A. Pereira[2], A.J.F. Coimbra[2], T.D.S. Carvalho[3], N.K. Nakagawa[2], C.A. Silva[1], S.C.L. Farhat[2]. [1]*Pediatric Rheumatology;* [2]*Laboratory of air polution;* [3]*Physiotherapy, University of São Paulo, São Paulo, Brazil*

**Background:** Recently, we showed that exposure to outdoors pollutants was associated with an increase of hospitalizations in paediatric rheumatic diseases (1) and higher risk of disease activity in our childhood-onset systemic lupus erythematous (cSLE) patients (2).Exhaled breath biomarkers measurements, such as exhaled breath condensate (EBC) and fractional concentration of exhaled nitric oxide (FeNO) may indicate airways inflammation related to air pollutant exposure. To our knowledge, this was the first study that showed the effects of daily exposure to $PM_{2.5}$, assessed by personal real time monitoring, on airway inflammation and increased risk of disease activity in cSLE patients.
**Objectives:** To investigate the association between daily individual real-time exposure to air pollutants and disease activity in cSLE patients.
**Methods:** A longitudinal panel study was carried-out in 108 consecutive visits of cSLE patients. During four consecutive weeks, daily personal measures of nitrogen dioxide ($NO_2$), fine particulate matter ($PM_{2.5}$), ambient temperature and humidity were obtained.This cycle was repeated every 2.5 months along one year and pH of exhaled breath condensate (EBC pH), fractional exhaled NO (FeNO) and disease activity parameters were collected weekly. Specific generalized estimation equation models were used to assess the impact of these pollutants on the risk of moderate/severe disease activity (SLEDAI-2K≥8), EBC pH and FeNO considering the fixed effects for repetitive measurements. The models were adjusted for inflammatory indicator, body mass index, infection, medication and weather variables.
**Results:** For an interquartile range increase of 18.12μg/m$^3$ in $PM_{2.5}$ daily concentration we observed an increased short-term effect in FeNO at the first three days (lag 0 to lag 2) after exposure. The 3-day moving average effect on FeNO was an increase of 0.75 ppb (95%IC: 0.38–1.29). Decreases in EBC pH were evidenced at days 7 and 10 after exposure [0.09 (95%IC: 0.15–0.02); 0.09 (95%IC: 0.17–0.01) respectively]. Regarding the risk of SLEDAI-2K ≥8, an increase of 18.12 μg/m$^3$ in $PM_{2.5}$ was associated with increases in the risk of SLEDAI-2K ≥8 at four [RR 1.45 (95%CI: 1.24–1.66)] and 11 days [RR 1.34 (95%CI: 1.05–1.62)] after exposure.

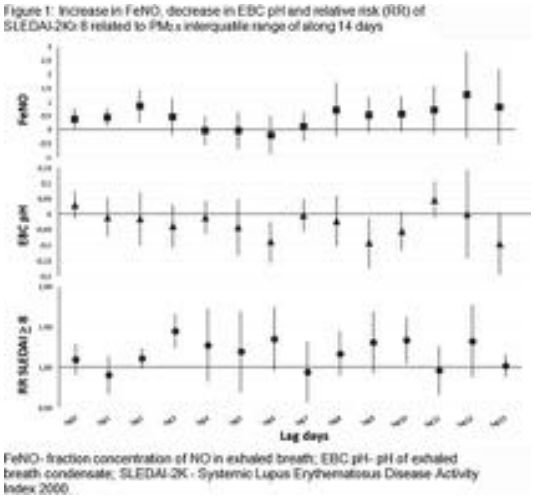

Figure 1. Increase in FeNO, decrease in EBC pH and relative risk (RR) of SLEDAI-2K≥ 8 related to $PM_{2.5}$ interquartile range of along 14 days
FeNO- fraction concentration of NO in exhaled breath; EBC pH- pH of exhaled breath condensate; SLEDAI-2K - Systemic Lupus Erythematosus Disease Activity Index 2000

**Conclusions:** Real-time exposure to air pollution may have a role in triggering disease activity and airways inflammation in cSLE patients.

## OP0221 EFFICACY AND SAFETY OF TUMOUR NECROSIS FACTOR-ALPHA ANTAGONISTS IN A LARGE COHORT OF JUVENILE DERMATOMYOSITIS PATIENTS

R. Campanilho-Marques[1,2,3,4], C. Deakin[1], S. Simou[1], L.R. Wedderburn[1,5], C. Pilkington[2] on behalf of Juvenile Dermatomyositis Research Group (JDRG). [1]*Infection, Inflammation and Rheumatology Section, UCL, Institute of Child Health;* [2]*Rheumatology, Great Ormond Street Hospital for Children NHS Trust, London, United Kingdom;* [3]*Rheumatology, Santa Maria Hospital;* [4]*Rheumatology, Instituto Português de Reumatologia, Lisbon, Portugal;* [5]*Arthritis Research UK Centre for Adolescent Rheumatology, UCL, UCLH, GOSH NHS Trust, London, United Kingdom*

**Background:** Some patients with juvenile dermatomyositis (JDM) have a disease course which is refractory to multiple drug treatments. There is evidence that prolonged disease activity is associated with increased mortality and morbidity. High levels of anti-TNFα have been reported in JDM patients with a long disease course, suggesting it may play a significant role in refractory disease. There are no published clinical trials of this therapy but some are in progress.
**Objectives:** To evaluate the efficacy and safety of anti-TNFα treatment in UK JDM Cohort and Biomarker Study patients.
**Methods:** Data were analysed from children who were recruited to the UK JDM Cohort and Biomarker Study, met Bohan-Peter criteria and were on anti-TNF treatment at the time of analysis, and had had at least 3 months of therapy. Childhood Myositis Assessment Scale (CMAS), Manual Muscle Testing (MMT8),

muscle enzymes and physicians global assessment (PGA) were recorded. Skin disease was assessed using modified skin Disease activity score (DAS).
**Results:** 66 patients with JDM actively treated with anti-TNF agents were analyzed. 41 patients were female (62%). The current mean (±SD) age of these patients was 16.8±5.6 years old, the mean age at diagnosis was 7.31±4.04 years old and the mean disease duration was of 9.6±4.6. Mean disease duration at the beginning of anti-TNF treatment was 3.49±2.80 years and mean duration of anti-TNF therapy was of 2.76±2.09 years. Muscle involvement significantly improved, with median [IQR] CMAS and MMT8 values at initiation of anti-TNF therapy of 45.50 [39.75–52.25] and 74 [59.5–79.5] respectively, and at current evaluation (or date of anti-TNF treatment completion) of 53 [50–53] and 79 [74.5–80] ($p<0.0001$ and p=0.0097; Mann Whitney test), respectively. For skin involvement the initial modified DAS was 4 [2–5] and final 1 [0–3] ($p<0.0001$; Mann Whitney test). Assessing global disease activity the initial PGA was 2.9 [1.3–4.3] and final 0.5 [0–1.45] ($p<0.0001$; Mann Whitney test). Sixteen patients (24%) switched their anti-TNF treatment. 62.5% of the switches were due to therapy failure, 25% due to adverse events and 12.5% for patient preference in subcutaneous administration. Of 21 adverse reactions registered, 7 were considered severe (anaphylactic reactions on infliximab infusion). One patient died due to small bowel perforation (not felt to be related to the use of TNF antagonists). The remaining adverse reactions were not severe and 77% (n=10) of them were due to infections causes. In 4 of the mild to moderate adverse reactions the drug had to be discontinued and switched to another TNF antagonist, while in the remaining patients temporarily withholding the drug proved sufficient. No tuberculosis case was registered.
**Conclusions:** This study is one of the largest to explore the efficacy and safety of TNF antagonist treatment in a large independent cohort of JDM patients. Both muscle and skin involvement appeared to improve after anti-TNF treatment.
**Disclosure of Interest:** None declared

## OP0222 PREGNANCY OUTCOME IN PATIENTS AFFECTED BY JUVENILE IDIOPATHIC ARTHRITIS (JIA) EXPOSED TO BIOLOGICAL AGENTS: A MONOCENTRIC EXPERIENCE IN A TERTIARY CENTRE OF MILAN

I. Pontikaki[1], M. Gerosa[2], L.M. Argolini[1], L. Trespidi[3], P.L. Meroni[2]. *[1]Unit of Pediatric Rheumatology, Department of Rheumatology; [2]Department of Rheumatology, Chair of Rheumatology, University of Milan, Gaetano Pini Institute; [3]Clinica Ostetrica L.Mangiagalli, Fondazione IRCSS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy*

**Background:** During the last sixteen years, biologics have been used in our centre in an open prospective study for the treatment of refractory JIA not only in paediatric age but also in young adults.
**Objectives:** To underline the capability to become pregnant, not negatively influenced by biologics and to describe the pregnancy outcome of our young patients who got pregnant during the biologics treatment, since this event seems to be facilitated from a low disease activity under biologics.
**Methods:** Seventeen women affected by refractory JIA became pregnant during biologic therapy. Two males affected by JIA, both treated with Adalimumab have been achieved as indirect pregnancies. All patients had a long lasting refractory polyarticular disease not responsive to DMARDs. Patients were treated with biological agents like Etanercept (9 patients), Adalimumab (4 patients), Golimumab (3 patient), Infliximab (1 patient) and Rituximab (2 patients) as monotherapy and most of the cases after multiple switches.
**Results:** 3 patients decided for an elective termination; 16 patients had a normal pregnancy resulted in live born infants, full term, with no structural abnormalities and still in good health. The median time of exposure to biologics was 48 months (min 10- max 72 months). No abnormalities were achieved neither in the live born infants nor in the fetuses of the pregnancies which ended with an elective termination. The paternal exposure did not influence conception and was not associated with negative outcome of pregnancy.
**Conclusions:** The availability of therapies like antiTNFa and other biologics has raised important questions about pregnancy outcome in female and male patients affected by JIA exposed to biologics. Other data regarding limited populations affected by Crohn's disease or Rheumatoid Arthritis treated with antiTNFa have been published. It doesn't seem to be an increased risk to pregnancy loss. Even if there is no increase in miscarriage or malformation or birth defect, as reported in letterature, TNFa inhibitors are raccomended to be discontinued after pregnancy detection. In our experience no complications or unexpected side effects on the course of pregnancy were observed.

# Developments in the treatment of RA

## OP0223 SAFETY AND EFFICACY OF ABT-494, A NOVEL SELECTIVE JAK1 INHIBITOR, IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS WITH AN INADEQUATE RESPONSE TO METHOTREXATE

M.C. Genovese[1], J.S. Smolen[2], M.E. Weinblatt[3], S. Meerwein[4], H.S. Camp[4], L. Wang[4], A.A. Othman[4], N. Khan[4], S. Jungerwirth[4]. *[1]Stanford University School of Medicine, Palo Alto, CA, United States; [2]Medical University of Vienna and Hietzing Hospital, Vienna, Austria; [3]Brigham and Women's Hospital, Boston, MA; [4]AbbVie Inc., North Chicago, IL, United States*

**Background:** ABT-494 is a novel selective JAK1 inhibitor.
**Objectives:** The safety and efficacy of ABT-494 was characterized vs placebo (PBO) in patients (pts) with moderate to severe RA and an inadequate response to stable background methotrexate therapy (MTX-IR).
**Methods:** In a phase 2b, 12-week, randomized, double-blind PBO-controlled study, MTX-IR pts with active RA on stable background MTX were randomized 1:1:1:1:1:1 to ABT-494 3, 6, 12, and 18 mg twice daily (BID), 24 mg once daily (QD), or matching PBO. The primary efficacy endpoint was ACR20 response at week 12.
**Results:** Baseline demographics and characteristics of the 299 randomized, treated pts were similar across groups. ACR20 response rates were significantly higher with ABT-494 at 6 mg BID (68%), 12 mg BID (80%), and 24 mg QD (76%) vs PBO (46%; non-responder imputation; Table 1). ACR50 and ACR70 response rates and change from baseline in DAS28(CRP) were also statistically significantly better for all ABT-494 doses (except ACR70 in 12 mg BID) vs PBO. Clinical remission by DAS28(CRP) was achieved by significantly more pts on ABT-494 (except 24 mg QD) vs PBO. Onset of action was rapid for ACR20, ACR50, and ACR70 responses, with significant ($P \leq 0.027$) differences in ACR20 observed at week 2 for all dose groups vs PBO. DAS28(CRP) $\leq$3.2 and CDAI $\leq$10 were achieved by significantly more pts on ABT-494 (except 24 mg QD for CDAI) vs PBO.
AE incidence was numerically higher with ABT-494, with a trend of dose dependence (Table 2). The incidence of infections was similar across groups. One serious infection (community acquired pneumonia) occurred with ABT-494 12 mg BID. One pt receiving ABT-494 3 mg BID and 2 pts receiving 24 mg QD had non-serious zoster infections (single dermatomes). A pt in the 6-mg BID dose group, aged 79 y and smoking 40 y, was diagnosed with lung cancer 8 days after study completion and died 3 months later. No deaths occurred during the study. ABT-494 treatment resulted in dose-dependent increases in LDL and HDL cholesterol. Liver function test elevations were sporadic, with no clear dose dependence. Mean hemoglobin values remained stable or increased at lower doses, most notably in pts with elevated CRP at baseline. Dose-dependent decreases in hemoglobin were seen at higher doses, without clinical impact.

**Conclusions:** This phase 2b study evaluated a broad dose range to understand the boundaries of JAK1 selectivity and demonstrated the efficacy of ABT-494 vs PBO in MTX-IR pts with active RA on stable background MTX. ABT-494 had an acceptable safety and tolerability profile.
**Acknowledgement:** The design, study conduct, analysis, and financial support of the clinical trial (NCT02066389) were provided by AbbVie. AbbVie participated

in the interpretation of data, review, and approval of the content. All authors had access to all relevant data. Mariana Ovnic, PhD, Katherine Groschwitz, PhD, and Michael J. Theisen, PhD of Complete Publication Solutions, LLC, provided medical writing support. This presentation contains information on the investigational product ABT-494.

## OP0224 FILGOTINIB (GLPG0634), AN ORAL JAK1 SELECTIVE INHIBITOR IS EFFECTIVE IN COMBINATION WITH METHOTREXATE IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: RESULTS FROM A 24-WEEK PHASE 2B DOSE RANGING STUDY

R. Westhovens[1], R. Alten[2], D. Pavlova[3], F.E. Enriquez Sosa[4], M. Mazur[5], M. Greenwald[6], A. Van der Aa[7], F. Vanhoutte[7], C. Tasset[7], P. Harrison[7].
*[1]Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, KU Leuven, Leuven, Belgium; [2]Innere Medizin II, Schlosspark-Klinik, Berlin, Germany; [3]Ltd M & M Centers, Carnikava, Latvia; [4]Clinstile, S.A. de C.V., Mexico City, Mexico; [5]IMSP Institul de Cardiologie, Chisinau, Moldova, Republic of; [6]Desert Medical Advances, Palm Desert, United States; [7]Galapagos NV, Mechelen, Belgium*

**Background:** Filgotinib (GLPG0634) is a novel oral selective JAK1 inhibitor that was evaluated in a 24-week phase 2B study in combination with methotrexate (MTX) in active rheumatoid arthritis (RA) with inadequate response to MTX. The primary endpoint of proportion of patients achieving ACR20 response after 12 weeks of treatment was met.

**Objectives:** To present the results of the 24-week analysis.

**Methods:** Patients with active RA on stable dose of MTX were randomized 1:1:1:1:1:1:1 in a double blinded manner to receive either placebo (PBO) or one of three doses of filgotinib (50mg, 100mg or 200mg) as once (qd) or twice daily (bid) regimen for 24 weeks (DARWIN 1 study). At Week 12, patients on placebo and 50mg dose whose tender and swollen joint counts did not improve by 20% (non-responders (NR)) were reassigned to 100mg daily.

**Results:** 594 randomized and treated patients, mean duration of RA of 7–10 years and mean DAS28(CRP) at baseline 6.0–6.2. At Week 12, statistically significant and dose dependent higher ACR20, ACR50, ACR70, DAS28(CRP) and CDAI responses versus PBO were observed in patients on filgotinib. These responses were maintained or continued to improve through 24 weeks (Table 1). Increase in filgotinib dose from Week 12 lead to improved efficacy in PBO and 50mg NR groups (at Week 24 ACR20 57% and 42% respectively). Serious Adverse Events and Treatment-Emergent Adverse Events (TEAE) were distributed over the groups including PBO: TEAE 51% PBO and 52% filgotinib groups. No opportunistic infections or cancers occurred; one death was reported. Infections occurred in 19% PBO and 25% filgotinib groups. Laboratory parameters remained stable between 12 and 24 weeks. Increase in haemoglobin was noted in patients on filgotinib.

## OP0225 THREE MONTHS' CLINICAL OUTCOMES FROM A NATIONWIDE NON-MEDICAL SWITCH FROM ORIGINATOR TO BIOSIMILAR INFLIXIMAB IN PATIENTS WITH INFLAMMATORY ARTHRITIS. RESULTS FROM THE DANBIO REGISTRY

B. Glintborg, I. Juul Sørensen, D. Vendelbo Jensen, N.S. Krogh, A.G. Loft, A. Colic, J. Espesen, J. Olsen, O. Hendricks, J. Grydehøj, I.M.J. Hansen, M.V. Sørensen, S. Chrysidis, N. Manilo, M. Klarlund, L.S. Andersen, H. Nordin, S. Kristensen, M.L. Hetland. *The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark*

**Background:** According to national guidelines issued in 2015, a non-medical switch from originator infliximab (IFX) (Remicade) to biosimilar Remsima was conducted in all Danish patients with inflammatory rheumatic diseases treated in routine care.

**Objectives:** To investigate 3 months' clinical outcomes in Remicade-treated patients (pts) with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthrits (SpA) who switched to Remsima and were monitored prospectively in the DANBIO registry.

**Methods:** Disease activity at 3 mths before switch (pre-switch), at the switch and after 3 mths (70–120 days) (post-switch) and changes over time (∆pre-switch and ∆post-switch) were calculated. Disease flare was defined as ∆DAS28≥1.2 (RA/PsA) or ∆ASDAS≥1.3 (SpA). Reasons for withdrawal (adverse events (AE), lack of effect (LOE) or other) were registered.

**Results:** 647 of 693 switching pts (300 RA, 96 PsA, 219 SpA, 32 other) had available data (52% women, age (median (IQR) 56 (45–66) yrs)). Prior Remicade treatment duration was 6.7 (4.1–9.4) yrs and in 77% it was the first biological treatment. Remsima dose was in RA+PSA 3.3 (3.0–4.8) mg/kg every 7 (6–8) wks and in SpA 4.8 (3.6–5.1) mg/kg every 6 (6–9) wks. Concomitant MTX was given in 69% (RA+PsA)/25% (SpA). Median follow-up time was 139 (98–160) days.

Disease activity remained largely unchanged 3 months prior to vs. after the switch (Table). The proportion of patients with disease flare pre-/post switch was 10%/10% (RA+PsA) (p=1.0) and 10%/0% (SpA) (p=1.0) (related samples McNemar test).

Overall, 45 ptts (7%) stopped Remsima treatment during follow-up (AE 16 (allergic 3, infection 2, rash 2, unspecific 9), LOE 20, remission 3, cancer 2, other 4). Prior Remicade treatment duration in these patients was 5.9 (3.5–9.1) yrs.

Table 1

| | Disease activity, median (IQR) | | | Delta-values, median (IQR) | | P* |
|---|---|---|---|---|---|---|

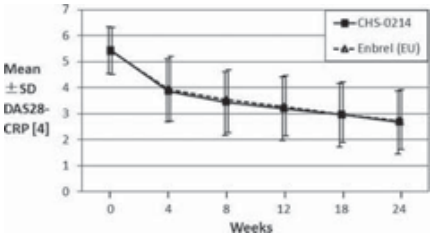
*Delta values for disease activity pre-switch vs. post-switch, Wilcoxon matched-pair signed rank test.

**Conclusions:** In 647 patients with inflammatory rheumatic diseases treated with Remicade for >4 years, disease activity was largely unaffected in the majority of patients 3 months after non-medical switch to biosimilar Remsima and comparable to the fluctuations observed in the 3 months prior to the switch. However, several patients (~6%) stopped treatment due to LOE or AE. This warrants further investigation before such a non-medical switch can be recommended.



**Disclosure of Interest:** None declared

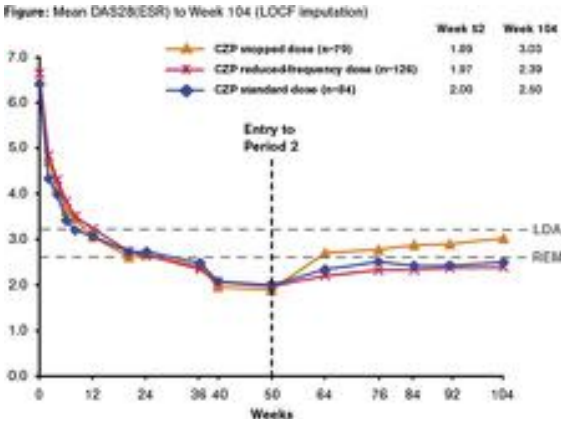
## OP0226 RANDOMIZED, DOUBLE-BLIND STUDY COMPARING CHS-0214 WITH ETANERCEPT IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS (RA) DESPITE METHOTREXATE (MTX) THERAPY

J. O'Dell[1], T. Takeuchi[2], Y. Tanaka[3], I. Louw[4], T. Tiabut[5], M. Kai[6], M. Oribe[7], S. Nakashima[8], B. Finck[9] on behalf of RApsody Study Group. *[1]University of Nebraska Medical Center, Omaha, United States; [2]Division of Rheumatology, Dept of Internal Medicine, Keio University School of Medicine, Tokyo; [3]First Dept of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan; [4]Panorama Medical Center, Cape Town, South Africa; [5]City Clinical Hospital No. 1 of Minsk, Minsk, Belarus; [6]Kai Clinic Rheumatology and Orthopedics, Miyazaki; [7]Oribe Clinic of Rheumatism and Medicine, Oita; [8]Daiichi Sankyo Co., Ltd., Tokyo, Japan; [9]Clinical Science, Coherus Biosciences, Redwood City, United States*

**Background:** CHS-0214 is a proposed biosimilar of etanercept, a fusion protein inhibiting tumor necrosis factor that is approved for several inflammatory autoimmune diseases.
**Objectives:** This Phase III multi-center study compared the efficacy, safety, and immunogenicity of CHS-0214 with etanercept for 24 weeks (Part 1) in patients with moderate/severe RA who had an inadequate response to MTX; then all patients received open-label CHS-0214 for 24 weeks with a final evaluation at Week 52 (Part 2).
**Methods:** Patients were randomized to 50 mg of CHS-0214 or etanercept subcutaneously QWx24 weeks (Part 1). The primary endpoint was the ACR20 response rate at Week 24. To establish the equivalence of CHS-0214 to etanercept, the 95% confidence interval (CI) of the treatment difference between groups had to be within [–15%, 15%]. Secondary efficacy endpoints (ACR50, ACR 70, and change in DAS28-CRP), safety, and immunogenicity were also evaluated.
**Results:** In 13 countries, 644 patients on MTX were randomized and received treatment. Baseline characteristics were comparable between treatment groups. Part 1 results are reported here. At 24 weeks, 512 patients were evaluable for efficacy. The ACR20 response rate was 91.0% (233/256) in the CHS-0214 group and 90.6% (232/256) in the etanercept group. The 95% CI of the treatment difference was [- 4.55, 5.37], which was within the pre-defined equivalence range. The response rates at 24 weeks were 67.6% vs. 63.7% for ACR50 and 38.3% vs. 37.9% for ACR70 in the CHS-0214 and etanercept groups, respectively. Mean (±SD) DAS28-CRP scores were 5.45 (± 1.00) and 5.42 (±1.00) at baseline and decreased to 2.67 (± 1.18) and 2.73 (±1.14) at 24 weeks in the CHS-0214 and etanercept groups, respectively (See Figure).
Among the 644 patients, adverse events (AEs) occurred in 60.8% and 65.0% of patients in the CHS-0214 and etanercept groups, respectively, including all infections combined in 34.3% and 32.2%, respectively. Investigator-designated treatment-related AEs occurred in 16.4% and 21.9% of patients, respectively, and most commonly included: injection site reactions (2.2% and 13.4%) and all infections combined (7.7% and 5.3%). Treatment-related serious AEs occurred in 3 (0.9%) patients treated with CHS-0214 (cholecystitis, increased blood creatinine phosphokinase, and bronchospasm) and 1 (0.3%) patient treated with etanercept (sepsis). Binding anti-drug antibodies occurred in 1.3% and 4.7% of patients in the CHS-0214 and etanercept groups.



**Conclusions:** These results demonstrated equivalence of CHS-0214 to etanercept with respect to efficacy as measured by the primary endpoint (ACR20 at Week 24) and other measures (ACR50, ACR70, and DAS28-CRP). CHS-0214 was well tolerated with no clinically meaningful differences to etanercept with regard to safety and immunogenicity.

## OP0227 A RANDOMIZED DOUBLE-BLIND TREATMENT STRATEGY STUDY EVALUATING CONTINUATION OR REDUCED-FREQUENCY DOSING OF CERTOLIZUMAB PEGOL VERSUS WITHDRAWAL TO MAINTAIN LOW DISEASE ACTIVITY IN EARLY RA PATIENTS (C-EARLY PERIOD 2)

P. Emery[1], C. Bingham[2], G.-R. Burmester[3], V.P. Bykerk[4], D. Furst[5], X. Mariette[6], D. van der Heijde[7], R. van Vollenhoven[8], B. VanLunen[9], C. Ecoffet[10], C. Cioffi[9], M. Weinblatt[11]. *[1]University of Leeds, Leeds, United Kingdom; [2]John Hopkins University, Baltimore, United States; [3]Charité - University Medicine, Berlin, Germany; [4]Weill Cornell College, New York; [5]University of California, Los Angeles, United States; [6]Université Paris-Sud, Paris, France; [7]Leiden University Medical Center, Leiden; [8]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; [9]UCB Pharma, Raleigh, United States; [10]UCB Pharma, Brussels, Belgium; [11]Brigham and Women's Hospital, Boston, United States*

**Background:** MTX plus anti-TNF therapy is an effective treatment for early RA. It is becoming increasingly important to understand whether the dose of anti-TNF can be reduced or stopped in patients (pts) receiving long-term therapy.
**Objectives:** To demonstrate that for patients (pts) who achieved sustained low disease activity (sLDA) after 1 year (yr) with CZP 200mg Q2W+optimized MTX, continuation of certolizumab pegol (CZP) as a standard (200mg Q2W) or reduced-frequency dose (200mg Q4W) is superior to stopping CZP for maintaining pts in LDA from Week (Wk) 52 through Wk104.
**Methods:** CZP+MTX-treated pts achieving sLDA (DAS28[ESR]$\leq$3.2 at Wks40 and 52) in C-EARLY Period 1 (NCT01519791)[1] entered Period 2 (NCT01521923); pts were randomized 2:3:2 to CZP standard dose (200mg Q2W+MTX), CZP reduced-frequency dose (200mg Q4W+MTX) or CZP stopped (PBO+MTX). Pts were evaluated every 8–12 wks. The Period 2 primary endpoint was the proportion of pts who maintained LDA (DAS28[ESR]$\leq$3.2) from Wk52 through Wk104 without flare, using non-responder imputation for missing values. CZP standard dose was compared with CZP stopped; if $p<0.05$ was achieved then, as per the hierarchical testing scheme, CZP reduced-frequency dose was compared with CZP stopped. The assumptions were that 455 pts would achieve sLDA in C-EARLY Period 1 and enter Period 2, with a response of 95%, 90% and 75% at Wk104 for standard, reduced-frequency and stopped dose respectively. Given $\alpha$=0.05, there would be 99% and 92% power to detect a difference between CZP standard and reduced-frequency dose vs stopped dose.
**Results:** In Period 2, 289 pts (who had achieved sLDA in Period 1) were included in the full analysis set: CZP Q2W+MTX (n=84), CZP Q4W+MTX (n=126) or PBO+MTX (n=79). From Wk52 through Wk104, a greater proportion of pts continuing CZP (either Q2W or Q4W)+optimized MTX maintained LDA vs PBO+MTX (48.8% and 53.2% vs 39.2%; p=0.112 and $p<0.05$ [nominal p value; first hierarchical test not significant]). Pts stopping CZP tended to worsen over time, as demonstrated by the increase of the mean DAS28(ESR) values from 1.89 at Wk52 to 3.03 to Wk104 (Figure). No new safety signals were observed.

**Conclusions:** Early RA pts with prognostic factors for severe disease progression achieving sLDA after 1yr of standard dose CZP+optimized MTX can taper to CZP reduced-frequency dose and maintain comparable disease activity control to CZP standard dose. Pts who stopped CZP had a tendency to have more relapses; despite this, 39.2% of these pts maintained LDA through Wk104. Further work will aim to identify the characteristics of pts who can successfully stop CZP.

## OP0228 BARICITINIB DOSE STEP-DOWN FOLLOWING DISEASE CONTROL IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Takeuchi[1], M. Genovese[2], L. Xie[3], M. Issa[3], A.L. Pinto Correia[3], T. Rooney[3], K. Emoto[3], J. Smolen[4]. *[1]Keio Univ., Tokyo, Japan; [2]Stanford Univ School Medicine, Palo Alto; [3]Eli Lilly & Co., Indianapolis, United States; [4]Medical Univ. Vienna, Vienna, Austria*

**Background:** Ph3 studies demonstrated clinical efficacy of 2 different once-daily (QD) doses of baricitinib (bari) (2mg and 4mg) in patients (pts) with active rheumatoid arthritis (RA) and an inadequate response (IR) to conventional synthetic DMARDs[1] or biologic DMARDs[2]. In general, larger, more rapid and more consistent treatment effects were observed for the 4mg dose across measures.

**Objectives:** To investigate the effects of bari dose step-down in patients who had achieved sustained low disease activity (LDA) or remission with bari 4mg QD.

**Methods:** Pts who completed a bari Ph3 Study (RA-BEGIN, RA-BEAM, RA-BUILD, or RA-BEACON) could enter a long-term extension study, RA-BEYOND. In RA-BEYOND, pts who had received bari 4mg for at least 15 months and who had achieved sustained LDA or remission (defined by CDAI score at 2 consecutive visits at least 3 months apart) were re-randomized in a double blind manner to continue receiving bari 4mg or to step down to a 2mg QD dose. Disease activity was assessed at a 12 week (wk) landmark following re-randomization.

**Results:** Among pts who achieved satisfactory and sustained disease control with bari 4mg QD, randomized, double blind dose reduction to 2mg QD was associated with modest, statistically significant increases in disease activity across measures at a subsequent 12 wk landmark assessment (Table). However, a large majority of pts (in both the continued 4mg and reduced to 2mg groups) retained the state of LDA or remission that led to their re-randomization.

| | RA-BEAM, RA-BUILD, RA-BEACON combined | |
|---|---|---|
| Efficacy measure† Wk12 | Continued bari 4 mg (N=147) | Stepped down to bari 2 mg (N=146) |
| CDAI LDA ≤10§, n (%) | 136 (92.5) | 123 (84.2)* |
| CDAI remission ≤2.8§, n (%) | 57 (38.8) | 54 (37.0) |
| ΔCDAI | 0.60 (3.44) | 2.04 (6.29)* |
| ΔTJC 68 | 0.3 (3.0) | 1.2 (3.8)* |
| ΔSJC 66 | 0.1 (1.7) | 0.8 (2.7)* |
| ΔHAQ-DI | 0.04 (0.26) | 0.06 (0.28) |
| ΔPain | 0.7 (14.7) | 2.5 (16.4) |
| ΔPtGA | 1.2 (14.3) | 2.5 (14.5) |
| ΔPhGA | –0.0 (9.6) | 2.7 (13.6)* |
| ΔCRP | 0.68 (7.16) | 1.68 (7.82) |
| ΔDAS28-CRP | 0.14 (0.70) | 0.36 (0.77)* |
| ΔDAS28-ESR | 0.10 (0.73) | 0.35 (0.89)* |
| ΔSDAI | 0.69 (3.55) | 2.19 (6.33)* |

†Values other than CDAI LDA or remission are mean change from baseline (SD) with missing data imputed using modified last observation carried forward; §Missing data imputed using non-responder imputation; RA-BEAM = MTX-IR pts; RA-BUILD = csDMARD-IR pts; RA-BEACON = bDMARD-IR pts; Δ = change from baseline; CDAI = Clinical Disease Activity Index; CRP = C-reactive protein; DAS28 = Disease Activity Score modified to include the 28 diarthrodial joint count; ESR = erythrocyte sedimentation rate; HAQ-DI = Health Assessment Questionnaire-Disability Index; PhGA = Physician's Global Assessment of Disease Activity; PtGA = Patient's Global Assessment of Disease Activity; SD = standard deviation; SDAI=Simplified Disease Activity Index; SJC = swollen joint count based on 66 joints; TJC = tender joint count based on 68 joints; *p≤0.05 vs. bari 4 mg.

**Conclusions:** Consistent with completed studies, these data indicate that 4mg QD was the most efficacious dose of bari for pts with RA in clinical studies. Most pts who had achieved sustained disease control with bari 4mg sustained LDA or remission 12 wks after randomized, blinded dose taper to 2mg QD.

## OP0229 BOTH HIGH TITER OF RF/ACPA AT BASELINE IS CLOSELY LINKED WITH HIGH LEVEL OF BASELINE PLASMA TNF LEVEL WHICH RESULTED IN LOW DRUG LEVEL AND LOW CLINICAL RESPONSE IN INFLIXIMAB TREATMENT IN RA PATIENTS: POST-HOC ANALYSIS OF A DOUBLE-BLIND CLINICAL STUDY (RISING STUDY)

T. Takeuchi[1], N. Miyasaka[2], T. Inui[3], T. Yano[3], T. Yoshinari[3], T. Abe[4], T. Koike[5]. *[1]School of Medicine, Keio University; [2]Tokyo Medical and Dental University, Tokyo; [3]Mitsubishi Tabnabe Pharma Corporation, Osaka; [4]Saitama Medical Center, Saitama Medical University, Saitama; [5]Sapporo Medical Center NTT EC, Hokkaido, Japan*

**Background:** Baseline RF or ACPA positivity is reported to be linked with clinical response of some non-TNF bDMARDs in RA. However, its impact on the efficacy of TNF inhibitors was controversy.

**Objectives:** To evaluate the influence of baseline RF and ACPA "titers" on the patients characteristics and efficacy of infliximab (IFX) in RA patients using data of the RISING study, a randomized double-blind clinical study in MTX-refractory RA (ref-1, NCT00691028).

**Methods:** In the RISING study, after patients received 3 mg/kg IFX infusion at Weeks 0, 2, and 6, they were randomly assigned to infusion of 3, 6, or 10 mg/kg IFX, every 8 weeks from Week 14 to Week 46 in a double-blind manner (n=307, all patients received 3 mg/kg treatment until Week 14). Serum IFX levels and clinical responses based on DAS28-CRP were evaluated at Weeks 14 and 54.

**Results:** Both baseline RF and ACPA titers showed significant positive correlation with baseline plasma TNF level. We hypothesized that "both RF-High and ACPA-High" was correlated with higher TNF level. Then, we stratified the patients into 3 classes using baseline RF/ACPA titers; "Low/Low" (RF: <55 U/ml, ACPA: <42 U/ml), "High/High" (RF: ≥160 U/ml, ACPA: ≥100 U/ml), and "Middle" (did not meet above criteria for either class), and compared baseline patient characteristics, serum IFX level, and DAS28-CRP among these 3 classes.

Among above 3 classes, significant difference was observed in plasma baseline TNF level, which was previously reported to be closely correlated with low serum IFX level, and low clinical response (ref-2); low TNF level in Low/Low class, high TNF level in High/High class, and intermediate value in Middle class (median: 0.73, 1.15, and 0.91 pg/ml, respectively, p<0.0001). In addition, high serum

Table. Comparison of patient characteristics, serum IFX levels and clinical responses among 3 classes stratified using baseline RF/ACPA

| Serum IFX, μg/ml | 8.1 (7.1, 13.5) | 5.2 (0.9, 8.9) | 3.8 (1.5, 8.3) | 0.1313 |
| DAS28-CRP † | 2.78 (1.91, 3.36) | 2.51 (1.78, 3.64) | 2.31 (1.48, 3.97) | 0.5540 |

Data are median (IQR).
* Spearman rank correlation coefficient, † evaluated using LOCF method.

IFX level and low DAS28-CRP in Low/Low class, low serum IFX level and high DAS28-CRP in High/High class, and intermediate values in Middle class were observed at Week 14. In Low/Low, Middle, High/High classes, median IFX levels at Week 14 were 1.5, 0.7, and 0.4 μg/ml, respectively (p=0.0004), and median DAS28-CRP at Week 14 were 3.17, 3.53, and 3.82, respectively (p=0.0256). Similar tendency was observed at Week 54 in patients who continued 3 mg/kg treatment, but not in those who received dose-escalation from 3 to 6 or 10 mg/kg after Week 14.

**Conclusions:** High titers of both RF/ACPA at baseline is correlated with high baseline plasma TNF level which might be resulted in low IFX level and low clinical response in patients with continuing 3 mg/kg treatment, but not in patients receiving 6 or 10 mg/kg treatment. Baseline RF/ACPA might be the index of dose-escalation of IFX in RA.

### OP0230 MULTI DRUG RESISTANCE (MDR) PROTEIN ACTIVITY OF ACTIVATED T LYMPHOCYTES IS A PREDICTOR OF BIOLOGICAL TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS

Z. Szekanecz[1], S. Szántó[1], G. Szücs[1], S. Szamosi[1], Á. Horváth[1], A. Domján[1], H.P. Bhattoa[2], J. Kappelmayer[2], G. Toldi[3], P. Szeremy[3], A. Apjok[3].
*[1]Department of Rheumatology; [2]Department of Laboratory Medicine, University of Debrecen, Faculty of Medicine, Debrecen; [3]MDQuest Ltd, Szeged, Hungary*

**Background:** Multi-Drug Resistance (MDR) protein function is an independent prognostic marker in certain haematological malignancies. Immune activation is also linked to the expression of MDR proteins in autoimmune disorders. Furthermore, MDR protein function may predict patient response to traditional DMARD, as well as biological treatment helping the physician to tailor the therapy. Switching the patient to biologicals is often challenging due to unpredictable drug susceptibility and high cost, especially in patients with mildly elevated DAS28 scores. However, MDR protein activity values can objectively reflect the actual disease activity of RA patients.

**Objectives:** In this observational cohort trial, we wished to assess lymphocyte MDR protein activity in RA patients on biological therapy in comparison to healthy controls in order to predict response to treatment.

**Methods:** We measured the activity of three clinically relevant MDR proteins (MRP1/ABCC1, MDR/ABCB1, BCRP/ABCG2) expressed in MDR activity factor (MAF) values in CD3+, CD4+ and CD19+ cells of 23 responder and 8 primary non-responder RA patients before (at 0 week) as well as at 2, 6 and 12 weeks after patients were switched to biological therapy according to the EULAR guideline. For this purpose, a novel flow cytometry based, CE-IVD certified diagnostic kit was applied. DAS28 scores, CRP, IL-6, aCCP and RF values were also recorded on each occasion. 35 age-matched, healthy controls were included.

**Results:** There was an inverse correlation between MAF of BCRP/ABCG2 in CD3 and CD4 cells and DAS28 at 0 week in RA patients. Multiple correlations between MAF values and inflammatory parameters were also observed. While DAS28 and IL-6 values decreased as the treatment progressed, MAF of MRP1/ABCC1 on CD3 cells was increased at 12 weeks. A positive correlation was noted between MAF of BCRP/ABCG2 on CD3 cells at 0 week and IL-6 at 12 weeks (p=0.0274, r =0.4095) in RA patients. MAF of CD3 BCRP/ABCG2 and CD3 MRP1/ABCC1 were higher in non-responders compared to responders at 0 week.

**Conclusions:** Our results suggest that low BCRP/ABCG2 and MRP1/ABCC1 MAF activities on CD3 cells may predict the need to start biological therapy in RA patients whose symptoms do not improve on classical DMARD treatment. Further decrease of CD3 BCRP/ABCG2 and increase in CD3 MRP1/ABCC1 MAF upon follow-up may indicate a good therapeutic response to biological therapy.

## Emerging concepts in genomics & genetics

### OP0231 DIFFERENTIAL TRANSCRIPTION FACTOR BINDING COULD EXPLAIN THE GENETIC ASSOCIATION OF ANKYLOSING SPONDYLITIS WITH POLYMORPHISMS IN THE IL23R-IL12RB2 INTERGENIC REGION

A.R. Roberts[1,2], M. Vecellio[1,2], L. Chen[2], C.J. Cohen[1,2], B.P. Wordsworth[1,2].
*[1]NIHR Oxford Comprehensive Biomedical Research Centre; [2]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*

**Background:** Genome-wide association studies have revealed the polygenic nature of ankylosing spondylitis (AS). More than 60 genetic influences have been identified but most of these are non-coding sequences (1–3). Protection against AS is afforded by a loss of function mutation in the cytoplasmic tail of the IL23 receptor (IL23R), but there is also a second independent association in this region (2).

**Objectives:** This study explores the functional basis for the second independent association between AS and single nucleotide polymorphisms (SNPs) in the *IL23R-IL12RB2* intergenic region.

**Methods:** We performed conditional analysis on genetic association data at *IL23R* and used epigenetic data on chromatin remodelling and transcription factor (TF) binding to identify the primary AS-associated SNP. Functional effects were tested in luciferase reporter assays in HEK293T cells and allele-specific TF binding was investigated by electrophoretic mobility gel shift assays. The involvement of candidate TFs in DNA binding was investigated by antibodies in these experiments. We measured mRNA expression levels of nearby genes in CD4+ T-cells and compared these between cases homozygous for the risk "A" allele and the protective "G" allele. The proportions of IL-17A+ and IFN-γ+ CD4+ T-cells were measured by FACS and also correlated to patient genotype.

**Results:** Conditional analysis identified *rs11209032* as the primary causal SNP within a putative enhancer between *IL23R* and *IL12RB2*. Reduced luciferase activity was seen for the risk "A" allele ($p<0.001$), and reduced H3K4me1 methylation observed in CD4+ T-cells from "A/A" homozygotes (p=0.02). Nuclear extract binding to the risk "A" allele was decreased ~3.5-fold compared to the protective allele ($p<0.001$). Reduced nuclear factor binding was observed when antibody to TWIST1 was included. The proportion of IFN-γ+ CD4+ T-cells was increased in "A/A" homozygotes (p=0.004), but neither *IL23R* nor *IL12RB2* mRNA was affected.

**Conclusions:** The *rs11209032* SNP downstream of *IL23R* forms part of an enhancer, allelic variation of which may influence Th1-cell numbers. Homozygotes for the risk "A" allele have more Interferon gamma-secreting (Th1) cells compared to those with the protective "G" allele. Further work is necessary to explain how TWIST1 contributes to these important observations.

### OP0232 C1QTNF4 MUTATION IDENTIFIED BY EXOME SEQUENCING IS ASSOCIATED WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND DYSREGULATION OF TNF-INDUCED APOPTOSIS

D. Mauro[1], M.J. Lewis[1], V. Pullabhatla[2], S. Vyse[1], M. Simpson[2], D. Cunninghame-Graham[2], A.C. Syvanen[3], C. Pitzalis[1], E. de Rinaldis[2], T.J. Vyse[2]. *[1]Experimental Medicine & Rheumatology, Queen Mary University of London; [2]Department of Medical and Molecular Genetics, King's College London, London, United Kingdom; [3]Molecular Medicine, Department of Medical Sciences, Uppsala University, Uppsala, Sweden*

**Background:** Whole exome sequencing of DNA samples from 30 UK SLE trios identified a *de novo* nonsynonymous mutation in *C1QTNF4* gene associated with juvenile onset, severe SLE. *C1QTNF4* encodes the secretory protein C1q/TNF-

related protein 4, a member of the C1q family, characterized by two highly conserved C1q domains with structural similarity to adiponectin. C1QTNF4 has been implicated in NF-κB signalling and regulation of energy metabolism.
**Objectives:** To characterize the structural and functional consequences of the *C1QTNF4* C594G mutation (p.His198Gln) on TNF signalling and NF-κB activation.
**Methods:** Whole exome sequencing of 90 individuals from 30 UK SLE trios was analysed to identify a list of *de novo* mutations associated with SLE. Resulting mutations were then filtered by likelihood of being deleterious and confirmed by Sanger sequencing of affected families. *In silico* modelling of wild type C1QTNF4 and C1QTNF4 p.His198Gln protein conformation was performed using Phyre2 and Pymol. The C1QTNF4 p.His198Gln mutation was reproduced *in vitro* by site-directed mutagenesis of pCMV6-C1QTNF4 vector, confirmed by Sanger sequencing. Secreted supernatants of C1QTNF4 and mutant C1QTNF4 p.His198Gln expressed in HEK293 cells were analysed for effects on secretion and oligomerization by chromatography and western blot. The effect of C1QTNF4 p.His198Gln on TNF-induced NF-κB activation was assessed in HEK293-NF-κB reporter cell line. The effect of the mutation on TNF-induced apoptosis was studied in L929 cells by luminescent cell titre assay.
**Results:** The G594C mutation in *C1QTNF4* results in a histidine to glutamine substitution at position 198 within the second globular C1q domain, resulting in significant change to the conformation of the second domain according to computational 3D modelling. The p.His198Gln mutation had no effect on protein secretion or oligomerization comparing C1QTNF4 and mutant C1QTNF4 p.His198Gln. Functional experiments revealed an inhibitory effect of secreted C1QTNF4 p.His198Gln on TNF signalling. Although wild type C1QTNF4 had no effect on TNF-stimulated activation of NF-kB and TNF-induced cell death, secreted C1QTNF4 p.His198Gln demonstrated significant inhibition of TNF-stimulated activation of NF-κB ($p<0.01$) and inhibition of TNF-induced apoptosis in L929 cells ($p<0.0001$).
**Conclusions:** Using exome sequencing, we have identified a novel *de novo* mutation G594C (p.His198Gln) in *C1QTNF4* associated with development of SLE, which results in a gain-of-function change in conformation of the second C1q domain of C1QTNF4. Secreted C1QTNF4 p.His198Gln inhibited both TNF mediated activation of NF-kB and TNF-induced apoptosis. Thus the association of *C1QTNF4* G594C with SLE is consistent with the known role of dysregulated apoptosis in SLE pathogenesis, and the association of TNF blockade with development of SLE-type autoimmunity.

**Background:** Systemic lupus erythematosus (SLE) is a genetically complex rheumatic disease with heterogeneous clinical manifestations. Recent studies have suggested the existence of a genetic basis for the diverse SLE clinical phenotypes. Also, there is increasing evidence indicating that a substantial part of the genetic variation associated with complex diseases is explained by small-effect genes from common genetic pathways.
**Objectives:** The objective of the present study was to identify new genetic variation associated with SLE phenotypes using a genome-wide association study at the pathway level.
**Methods:** A total of 598,258 SNPs were genotyped in a discovery cohort of n=482 SLE patients of southern European ancestry using the Illumina platform Quad610. After quality control analysis, including ancestry estimation using principal-component analysis, genome-wide pathway analysis was performed. A total of 14 clinically relevant SLE phenotypes were tested for association with n>700 reference genetic pathways. Significantly associated pathways (corrected P-value <0.05) were subsequently tested for validation in an independent cohort of n=425 SLE patients from the same ancestry. Both discovery and validation cohort patients were Caucasian European and from Spanish origin, and were recruited by rheumatology departments from n=15 Spanish university hospitals. The validated genetic pathways were functionally characterized using *in silico* analysis on cell types of relevance in SLE pathogenesis.
**Results:** In the discovery stage, two genetic pathways were significantly associated with the presence of oral ulcers and antinuclear antibodies in SLE ($P_{FDR}<0.05$). In the replication stage, we validated the association between oral ulcers and vascular endothelial growth factor (*VEGF*) genetic pathway ($P$=1.3e-2). Analyzing the transcriptional effect of the topical immunotherapies used for the treatment of oral ulcers in SLE, we found a significant differential expression of *VEGF* pathway genes ($P<0.05$).
**Conclusions:** In this work we have performed the first genome-wide association study for clinically relevant SLE phenotype using a pathway-based approach. With this new approach, we have identified and validated the association of VEGF genetic pathway with oral ulcers in SLE. These findings represent an important step towards the characterization of the genetic basis of phenotype heterogeneity in SLE.

## OP0234 RHEUMATOID ARTHRITIS SUBSETS DEFINED BY SUB-SPECIFICITIES OF ANTI-CITRULLINATED ANTIBODIES (ACPAS) HAVE UNIQUE HLA ASSOCIATIONS

B. Brynedal[1], C. Terao[2], Z. Chen[1], X. Jiang[1], H. Westerlind[1], M. Hansson[1], P.-J. Jakobsson[1], K. Skriner[3], G. Serre[4], J. Rönnelid[5], L. Padyukov[1], P. Gregersen[6], J. Worthington[7], L. Alfredsson[1], S. Raychaudhuri[2], L. Klareskog[1]. *[1]Karolinska Institutet, Stockholm, Sweden; [2]Brigham & Women's Hospital, Harvard Medical School, Boston, United States; [3]Charité Universitätsmedizin Berlin, Berlin, Germany; [4]Université de Toulouse, Toulouse, France; [5]Uppsala University, Uppsala, Sweden; [6]The Feinstein Institute for Medical Research, Manhasset, United States; [7]The University of Manchester, Manchester, United Kingdom*

**Background:** Antibodies (Ab) towards citrullinated (cit) peptides (ACPA) are specific serological markers for a subset of rheumatoid arthritis (RA) patients with distinct genetic and environmental associations [1,2]. On the autoantigen-derived peptide level, the ACPA responses in RA patients are heterogeneous. Better understanding of the relationships between immunity to defined peptides, and structural variants of HLA molecules may provide novel insights concerning HLA-driven pathology in RA.
**Objectives:** To investigate whether RA specific Ab towards cit peptides can detect subsets of patients with distinct associations to different HLA structures.
**Methods:** We used a multiplex peptide array [3] to detect reactivities in sera of patients (n=6400) and selected controls (n=12000) across cohorts from Sweden (EIRA), United Kingdom (WTCCC), and the United States (NARAC). Genetic data from the immunochip platform was used to investigate variation in the HLA region. First, we tested the association between AA-alleles of HLA molecules and Ab defined strata of RA patients. In order to quantify the similarity between different peptide reactivities we used permutation, scaled Jaccard distance metrics and hierarchical clustering. Next, we assessed genetic associations with antibody titers in RA cases, and estimated interactive effects on susceptibility to Ab-positive RA.
**Results:** Comparing 20 different ACPAs reactive with different cit peptides, we observed that reactivities to specific peptides are highly correlated across patients (>87% pairs co-occurs more than expected). The majority of Abs are highly co-expressed in patients who have high frequencies of HLA-alleles known to be associated to ACPA-positive RA. AA at positions 11/13 of HLA-DRB1 display the strongest susceptibility to 18 fine-specific ACPAs (omnibus $p \leq 9.3 \times 10^{-64}$), the exceptions being reactivities towards cit Fibrinogen (Fib) β 62–81 with citrullination at position 72 or 74. The reactivities towards two Fib peptides are not highly co-occurring with other Ab; The expression of Ab against cit Fib α peptide 36–50 is independent of HLA variants and for Ab towards cit Fib β 62–81 (72) there is even a negative association to HLA-variants previously shown to associate with ACPA-positive RA. Finally, we observed several allelic combinations showing interactive effects on fine specific ACPAs, and not or weakly with CCP2.
**Conclusions:** RA patients often co-express many different RA specific Ab, and the expressions of most of these are associated to HLA variants linked with ACPA-positive RA. However we also identified ACPAs with distinct expression profiles and HLA associations.

## OP0235 IDENTIFICATION OF NOVEL CD4+ LYMPHOCYTE EXPRESSION QUANTITATIVE TRAIT LOCI IN UNTREATED EARLY ARTHRITIS PATIENTS

A.G. Pratt[1], J. Massey[2], A.E. Anderson[1], N. Nair[2], J. Diboll[1], A. Skelton[1], D. Lendrem[1], L.N. Reynard[2], H.J. Cordell[3], S. Eyre[2], A. Barton[2], J.D. Isaacs[1]. *[1]National Institute for Health Research Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle upn Tyne; [2]Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Institute of Inflammation and Repair, University of Manchester, Manchester; [3]Institute of Genetic Medicine, Newcastle University, Newcastle upn Tyne, United Kingdom*

**Background:** Rheumatoid arthritis (RA) is a CD4+ lymphocyte-mediated disease of immune dysregulation. Genome-wide association scans (GWAS) have shown common variants at approximately 100 genetic loci to be associated with RA. However, the associated single nucleotide polymorphisms (SNPs) often lie in intergenic regions and the gene upon which they act has not been defined. Examining how RA-associated SNPs influence gene expression in relevant biological contexts will begin to address this.
**Objectives:** To map *cis* eQTLs at established RA risk loci in CD4+ lymphocytes of a well-characterised early arthritis cohort, and so gain insight into mechanisms of genetic risk.
**Methods:** Patients attending the Newcastle Early Arthritis Clinic, naïve to immunomodulatory therapy, donated high integrity RNA and DNA extracted from 98% pure CD4+ lymphocytes within 4 hours of blood draw. Detailed baseline and longitudinal clinical data were recorded for all participants, who were followed up for $\geq$1 year. Genotyping and global gene expression measurement was carried out using the Illumina Human CoreExome array, and either HT12v4 or WG6v3 BeadChip arrays, respectively, and expression data was batch-corrected and normalised using standard algorithms. Data were analysed using the R package. Variants in linkage disequilibrium (LD) with $>$100 confirmed RA- SNPs[1] ($r^2>0.8$), and probes within 4MB of these LD blocks, were included in the analysis, seeking evidence of cis-eQTLs.
**Results:** Data from 249 white Caucasian early arthritis patients were available for analysis; diagnoses (confirmed at follow-up) were RA (n=88), spondyloarthropathy/other inflammatory arthritis (n=86), osteoarthritis/other non-inflammatory arthralgia (n=70) and undifferentiated arthritis. Analysis of 1,247 SNPs and 8,023 probes identified strong evidence for cis-eQTLs at a number of RA risk loci in this population overall (experiment-wide $p<0.05$). Previously observed genes subject to eQTLs in primary human CD4+ lymphocytes replicated by our study include *BLK*, *FADS1* and *FADS2*. Genes whose expression specifically in these cells has, to our knowledge, been associated with RA risk variants for the first time include *RPS26*, *RNF167* and *IKZF3*.
**Conclusions:** We present the first detailed eQTL analysis in the pathophysiologically relevant setting of early arthritis CD4+ lymphocytes, free of confounding immunomodulatory treatment. Interactions of clinical parameters (including disease phenotype) with eQTL effects remains the subject of ongoing analyses, to be presented. Our findings have the potential to modify the biological candidate gene landscape of RA.

## OP0236 WHOLE TRANSCRIPTOME INVESTIGATION OF RESPONSE TO ANTI-TNF TREATMENT IN RHEUMATOID ARTHRITIS

J. Oliver[1], D. Plant[2], G. Orozco[1], K.L. Hyrich[3], A.W. Morgan[4], A.G. Wilson[5], J.D. Isaacs[6], A. Barton[1,2]. *[1]Arthritis Research UK, Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, The University of Manchester; [2]NIHR Manchester Muscoloskeletal BRU, Central Manchester Foundation Trust and University of Manchester, Manchester Academic Health Science Centre; [3]Arthritis Research UK, Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre, The University of Manchester, Manchester; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds; [5]UCD School of Medicine and Medical Science, Conway Institute, University College Dublin, Dublin; [6]NIHR Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle, United Kingdom*

**Background:** Despite the revolutionary impact of anti-TNF treatments on rheumatoid arthritis (RA) patients, good disease control is only achieved in 30% of patients. In current clinical practice, RA drugs are administered on a trial and error basis and there are no clinical biomarkers of response to guide treatment decisions. Whilst non-responding patients can be switched to alternative therapies at 3 months, many remain on ineffective therapy for longer periods. Identification of early predictors of response could support timely switching in patients whose disease activity is not controlled by a particular drug.
**Objectives:** To investigate gene expression levels in whole-blood collected from patients with RA, between the start of treatment (baseline) and following 3-months of treatment, to identify a biological biomarker of response to the anti-TNF drug adalimumab.
**Methods:** EULAR good responders (GR) and non-responders (NR) to adalimumab were selected from the Biologics in RA Genetics and Genomics Study Syndicate (BRAGGSS) cohort. Total RNA was isolated from Tempus™-stabilised baseline and 3-month blood samples using the MagMAX™ RNA Isolation Kit and quality assessed using the Agilent Bioanalyzer 2100. Samples with an RNA integrity number $>$4 were amplified and converted into biotinylated sense-strand DNA using the Affymetrix WT PLUS Kit and hybridised to Affymetrix GeneChip® Human Transcriptome Arrays. Quality control and differential transcription analysis was performed using the Affymetrix Expression and Transcriptome Analysis Console™.
**Results:** Whole genome expression profiling was performed on 44 patient samples (31 GR and 12 NR to adalimumab treatment). Gene level paired-analysis of variance revealed the significant downregulation of 1776 transcripts and upregulation of 943 transcripts following 3 months of adalimumab treatment in GR (FDR p-value $<$0.05, fold change $>$1.2 or $<$ -1.2) (Figure). There were no significant differences in gene expression between baseline and 3 months in NR. Pathway analysis using the Database for Annotation, Visualization and Integrated Discovery (DAVID) revealed that both differentially expressed and differentially spliced genetic variants in GR were heavily enriched for relevant processes including antigen processing and presentation, ribosome biogenesis and T- and B-cell receptor signalling. Many of the most significantly upregulated genes encoded immunoglobulin and MHC II components, which may indicate immune cell migration from the synovium into the blood in a positive response to adalimumab therapy in GR.

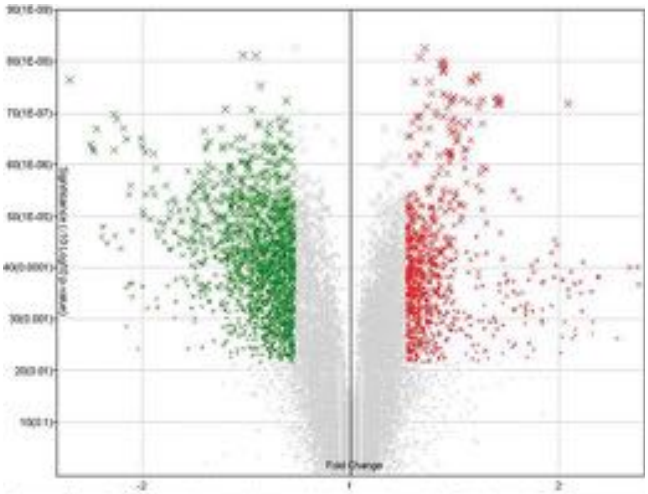

**Figure:** Differentially expressed transcripts between baseline and 3 months of adalimumab treatment in good responders. Green represents downregulated genes (FDR p<0.05, fold-change <-1.2); red represents upregulated genes (FDR p<0.05, fold-change>1.2).

**Conclusions:** A blood-based biomarker for good-response to anti-TNF treatment at 3 months could allow prompt identification of non-response, reducing the impact of long-term radiological damage and facilitating more responsible pharmacological spending. To support the promising immune signature of good-response at 3 months identified herein, subsequent work will include replication in additional patients and integration with corresponding genotype and serum microRNA data.

## OP0237 POLYMORPHISMS OF GENE IMPLICATED IN TYPE 1 INTERFERON PATHWAY ARE ASSOCIATED WITH THE CLINICAL RESPONSE OF RITUXIMAB AT 24 WEEKS IN RHEUMATOID ARTHRITIS

P.-A. Juge[1], S. Gazal[2], A. Constantin[3], X. Mariette[4], B. Combe[5], J. Tebib[6], M. Dougados[7], J. Sibilia[8], X. Le Loët[9], P. Dieude[1]. *[1]Rheumatology; [2]Hôpital Bichat, Paris; [3]Rheumatology, Hôpital Purpan, Toulouse; [4]Rheumatology, Hôpital du Kremlin Bicêtre, le Kremlin Bicêtre; [5]Rheumatology, CHU Montpellier, Montpellier; [6]Rheumatology, CHU Lyon Sud, Lyon; [7]Rheumatology, Hôpital Cochin, Paris; [8]Rheumatology, CHU Strasbourg, Strasbourg; [9]Rheumatology, CHU Rouen, Rouen, France*

**Background:** Rheumatoid arthritis (RA) treatment may target B-cells using rituximab (RTX), a chimeric monoclonal antibody directed against the B-cell marker CD20. Transcriptome of PBMCs from RA patients before RTX has suggested that responders differs from non-responders on the expression of genes regulated by type 1 interferon (IFN) (1) suggesting a possible contribution of type 1 IFN pathway genes such as interferon regulatory factor 5 (*IRF5*),

tyrosine kinase 2 (*TYK2*), signal transducer and activator of transcription 4 (*STAT4*), osteopontin (*SPP1*) and interferon regulatory factor 7 (*IRF7*).
**Objectives:** To study 8 *IRF5*, *TYK2*, *STAT4*, *SPP1* and *IRF7* variants as candidate predictors of the clinical response to RTX in RA at 6 months defined by a good or moderate EULAR response.
**Methods:** Patients from the SMART study who signed consent for genetic studies were included (2). The association between the EULAR response at 24 weeks and the polymorphism of the 8 chosen SNPs was analyzed by logistic regression. Response rates were compared across *risk* genotypes using the $\chi^2$ test or the Fisher exact test, when appropriate. Significant variables after univariate regression ($P<0.15$) were entered into a stepwise multivariate model adjusted to the sex, the age and the DAS28-CRP score.
**Results:** Among the 115 included patients, 92 were women, mean age was 56 years, 93 patients were anti-CCP positive. At M6, 30 patients were considered as good responders (26.1%), 62 as moderate responders (53.9%) and 22 as non-responders (19.1%). Univariate analysis showed that *IRF5* rs2004640 was significantly associated with a good/moderate EULAR response at week 24 ($P$=0.038) whereas *IRF7* rs1131665 and *SPP1* rs9138 were near statistical significance ($P$=0.092 and $P$=0.089, respectively). Since it was previously reported an association between *TNFSF13B* (the gene coding the BAFF cytokine) rs9514828 and RTX response in RA in the same cohort (2), this variant was also included in the multivariate analysis. The multivariate analysis with logistic regression analysis including *IRF5*, *SPP1*, *IRF7* and *TNFSF13B* revealed that a genotypic combination of *IRF5* rs2004640, *SPP1* rs9138 and *TNFSF13B* rs9514828 was strongly associated with good/moderate response to RTX at M6: $P=9.34\text{x}10^{-6}$, OR =11.37 [4.03–35.28] with a PPV of 91% and a NPV of 53% (Fig. 1).

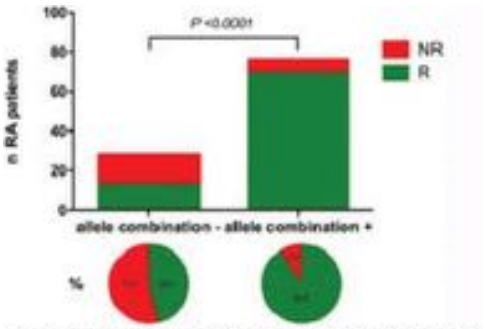

Fig.1 Number and corresponding percentages of EULAR responders and non-responders according to the genotypic combination.
R: responders, NR: non responders

**Conclusions:** We found an association between a combination of type 1-interferon genes and response to RTX treatment in RA. To further validate the magnitude of the association detected an independent replication in a larger cohort is required. If validated, our model could be helpful before the decision of initiating RTX in RA.

## OP0238 FCGR2B AND MULTIPLE HLA LOCI ARE ASSOCIATED WITH SUSCEPTIBILITY TO IGG4-RELATED DISEASE

C. Terao[1,2], M. Ota[3], M. Shiokawa[4], K. Kuriyama[4], Y. Kodama[4], K. Uchida[5], I. Yamaguchi[1], T. Kawaguchi[1], S. Kawaguchi[1], K. Higasa[1], T. Mimori[6], K. Okazaki[5], T. Chiba[4], S. Kawa[7], F. Matsuda[1] on behalf of the Japanese IgG4-related Disease Working Consortium. *[1]Center for Genomic Medicine, Kyoto University Graduate School of Medicine; [2]Center for the Promotion of Interdisciplinary Education and Research, Kyoto University, Kyoto; [3]Department of Legal Medicine, Shinshu University School of Medicine, Matsumoto; [4]Department of Gastroenterology and Hepatology, Kyoto University Graduate School of Medicine, Kyoto; [5]The Third Department of Internal Medicine, Division of Gastroenterology and Hepatology, Kansai Medical University, Osaka; [6]Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Kyoto; [7]Center for Health, Safety, and Environmental Management, Shinshu University School of Medicine, Matsumoto, Japan*

**Background:** IgG4-related disease (IgG4RD) is an emerging concept of an autoimmune disease entity including autoimmune pancreatitis, IgG4-related sialadenitis and IgG-related kidney disease (Ref 1–3). Comprehensive genetic landscape of IgG4RD is unknown.
**Objectives:** To perform a genome-wide association study of IgG4RD to detect susceptibility loci and uncover the pathophysiology underlying IgG4RD.
**Methods:** We conducted a two-staged genome-wide association study composed of a total of 850 cases and 2,082 controls by genotyping 2,310,564 single nucleotide polymorphisms (SNPs). Allele frequencies were compared between cases and controls by logistic regression analysis and followed by meta-analysis with use of inverse-variance method. Comprehensive analysis in the *HLA* region using imputation of amino acid residues of classical *HLA* alleles in combination with direct sequencing was also performed. The associations between clinical manifestations and correlates especially genetic components were analyzed.
**Results:** We identified *FCGR2B* and the *HLA* region as susceptibility loci to IgG4RD ($p\leq1.2\text{x}10^{-11}$). We also found evidence that the *HLA* region contained at least two independent associations in *HLA-DRB1* and *HLA-A* regions. The amino acid position 11 in the HLA-DRB1 peptide-binding groove, the strongest susceptibility position to other autoimmune diseases, was strongly associated with IgG4RD ($p=1.3\text{x}10^{-22}$). We also found a significant synergistic effect in combination of the two SNPs in *FCGR2B* and *HLA-DRB1* loci ($p\leq0.024$). The susceptibility SNP in *FCGR2B* was in linkage disequilibrium with a functional missense variant of *FCGR2B* and showed an association with the decreased gene expression ($p\leq1.0\text{x}10^{-10}$). None of rare or coding variants found by direct sequencing in the *FCGR2B* region and copy number variations could explain the association. The SNP in *FCGR2B* and age at diagnosis were independently associated with recurrence of IgG4RD ($p\leq0.013$). When we assessed common genetic architectures between IgG4RD and other autoimmune diseases, SLE-susceptibility loci showed a trend of opposite directions in IgG4RD susceptibility in contrast to RA, which showed a trend of common directions with IgG4RD ($p$=0.027).
**Conclusions:** A total of three susceptibility markers to IgG4RD were identified. *FCGR2B* may play critical roles in developing and the progression of IgG4RD. HLA-DRB1 amino acid position 11 is important for IgG4RD. Common molecular pathways are suggested to underlie IgG4RD and other autoimmune diseases.

# Novel clues solved in RA development

## OP0239 DISSECTING THE MOLECULAR BASIS OF IMMUNE CELL ACCUMULATION IN THE INFLAMED JOINT USING A MURINE MODEL OF RHEUMATOID ARTHRITIS

C.T. Prendergast, R.A. Benson, I.B. McInnes, J.M. Brewer, P. Garside. *Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom*

**Background:** The molecular control of the “ebb and flow” of inflammatory cells into and out of the joint during the initiation, maintenance and resolution of inflammation in Rheumatoid Arthritis (RA) remains unclear.
**Objectives:** To characterise the ingress and egress of immune cells into inflamed joints, and identify the key molecular pathways regulating their migration in real time *in vivo*.
**Methods:** We developed a “breach of self tolerance” murine model of articular inflammation [1]. Using this model in conjunction with mice expressing the photoswitchable fluorescent protein kaede [2], we characterized the migration of cells from the inflamed joint (after photoswitching) to the draining lymph nodes. Flow cytometry of excised lymph nodes allowed the identification and phenotypic characterization of photoswitched cells that could only have originated from the inflamed joint. Using the same approach we identified and sorted cells that migrated to the draining lymph nodes and those that remained in the joint. RNA-seq analysis of these populations identified genes differentially regulating cellular retention in, and egress from, the inflamed joint to the draining lymph node.
**Results:** The key populations identified exiting the inflamed joint and entering the draining lymph node were $CD4^+$ and $CD8^+$ T cells, $FoxP3^+$ Treg, B cells and $CD11c^+$ DCs. The populations present in the inflamed joint comprised mainly $CD4^+$ T cells, $CD11c^+$ DCs and $Ly6G^+$ neutrophils. Analysis of RNA-seq data revealed pathways and genes previously highlighted as characteristic of RA in patient studies. More specifically focusing on cell migration, adhesion and movement pathways has indicated genes associated with the egress of immune cells from the inflamed joint.
**Conclusions:** We have identified key gene expression profiles that may be important for the migration of cells from the inflamed joint, which may provide targets for therapeutic manipulation.

## OP0240 SYNOVIAL LYMPHOCYTIC AGGREGATES ASSOCIATE WITH HIGHLY ACTIVE RA AND PREDICT EROSIVE DISEASE PROGRESSION AT 12 MONTHS: RESULTS FROM THE PATHOBIOLOGY OF EARLY ARTHRITIS COHORT

F. Humby[1], M. Dicicco[1], S. Kelly[1], M. Bombardieri[1], R. Hands[1], V. Rocher[1], L. Zou[2], L. Myles[1], K. Blighe[1], N. Ng[1], N. Ramamoorthi[3], J. Hackney[3], N. Zuckerman[4], M. Townsend[3], R. Landewe[5], A. Van der Helm van Mihl[5], D. van der Heijde[5], C. Buckley[6], P. Taylor[7], I. McInnes[8], C. Pitzalis[1]. *[1]Experimental Medicine and Rheumatology, Queen Mary University of London; [2]Experimental Medicine and Rheumatology, Barts and the London School of Medicine, London, United Kingdom; [3]Research and Early Development, Genentech, San Francisco; [4]Research and Early Development, Genentech, California, United States; [5]Medical Centre, Leiden University, Leiden, Netherlands; [6]Centre for Translational Inflammation Research, University of Birmingham, Birmingham; [7]Kennedy Institute of Rheumatology, University of Oxford, Oxford; [8]School of Medicine, University of Glasgow, Glasgow, United Kingdom*

**Background:** The synovial cellular infiltrate in RA has for some time been recognised to organise into lymphocytic aggregates with a number observations suggesting they are immunologically competent and can support chronic inflammation. However, their clinical significance has been controversial with conflicting publications reporting diverse associations with disease outcome.
**Objectives:** The aim of this study was to examine in a cohort of therapy naïve, early RA patients whether baseline synovial pathotype: i)associated with specific clinical phenotypes, ii)predicted response to DMARD therapy, and iii)predicted joint damage progression
**Methods:** 135 DMARD-naïve early RA patients were recruited as part of the Pathobiology of Early Arthritis Cohort at Barts Health NHS Trust. Following pre-treatment synovial biopsy clinical data was collected at baseline and 12 months. Following immunohistochemical staining the degree of synovial infiltration by CD20+B cells, CD3+T cells, CD68+macrophages and CD138+plasma cells was determined. Patients were then categorised into synovial pathotypes: lymphoid, myeloid or fibroid according to the degree of immune cell infiltration. Samples also underwent nanostring analysis of 238 genes. Significant differences in clinical parameters at baseline and progression in radiographic damage at 12 months between synovial pathotypes was determined.
**Results:** At baseline a lymphoid pathotype significantly associated with ACPA+ve (0.017) and highly active disease (DAS28, CRP, ESR and swollen joint count, $p<0.01$). Furthermore a significantly higher number of patients with a baseline lymphoid pathotype (vs myeloid/fibroid) developed radiographic progression (9/26 vs 5/53, p=0.026). A cohort of 79 genes were identifed from the nanostring analysis that were differentially upregulated in patients with joint damage progression. Logistic regression analysis was used to develop a clinical model for predicting radiographic progression (final model ESR, RF and ACPA) with an AUC of 0.86. Integration of synovial gene expression profiles into the clinical model improved the AUC to 0.96.
**Conclusions:** The demonstration in this early RA cohort of a significant association between a lymphoid pathotype and a severe clinical phenotype/sero positivity for ACPA supports a direct role for synovial lymphoid structures in disease pathogenesis. Furthermore patients with a lymphoid pathotype were significantly more likely to develop radiographic damage. Integration of synovial gene expression profiles into a clinical model of radiographic progression enhanced performance. This data strongly supports a role for integration of synovial biomarkers into clinical prediction models of radiographic progression in early RA with critical implications for future patient stratification.

## OP0241 REPETITIVE PROLONGED PHYSICAL WORKLOAD IS ASSOCIATED WITH INCREASED RISK OF DEVELOPING RHEUMATOID ARTHRITIS: RESULTS FROM THE SWEDISH EIRA-STUDY

P. Zeng[1], L. Klareskog[2], L. Alfredsson[1], C. Bengtsson[1]. *[1]Institute of Environmental Medicine; [2]Department of Medicine, Karolinska Institute, Stockholm, Sweden*

**Background:** Physical workloads and physical activities/exercises differ in quantity, intensity and duration of mechanical stress exerted on the joint and synovia. There are various types of repetitive prolonged physical workload (RPPW) that have been hypothesized to provide stress to the joints and possibly influence the development of arthritis. To our knowledge, there is no study that investigates the association of various types of RPPW and risk of rheumatoid arthritis (RA).
**Objectives:** To investigate the association between exposure to 7 different types of RPPW and risk of rheumatoid arthritis; to study the potential interactions between different RPPWs and the genes in the human leukocyte antigen (HLA) region.
**Methods:** Data from the Swedish Epidemiological Investigation of Rheumatoid Arthritis (EIRA), a population-based case-control study involving incident cases of RA (3680 cases and 5935 controls), were analyzed. Information on different types of self-reported RPPW exposures (see figure 1), anti-citrullinated protein antibody (ACPA) status and *HLA-DRB1* genotypes of cases and controls were retrieved. RPPW exposed subjects were compared with that of unexposed subjects. Odds ratios (ORs) with 95% confidence intervals (CI) of RA (overall), ACPA-positive RA and ACPA-negative RA associated with various RPPW exposures were estimated using an unconditional logistic regression model. Age, sex, residential area, smoking status, alcohol consumption, body mass index and education were considered as potential confounders and added as covariates in the statistical model. RPPW-HLA interactions were evaluated using the principle of departure from additivity of effects, by calculating the attributable proportion (AP) due to interaction.
**Results:** As shown on figure 1, the estimated ORs of developing RA associated with various RPPW exposures ranged from 1.3 (95% CI, 1.1–1-4) to 1.8 (95%CI, 1.6–2.0). No major difference in the ORs between ACPA-positive and ACPA-negative RA was found. Significant interactions between RPPW exposures and *HLA-DRB1* shared epitope genes were observed among ACPA-positive RA (AP values ranging from 0.3 (95% CI, 0.1–0.5) to 0.4 (95%CI, 0.2–0.6)).

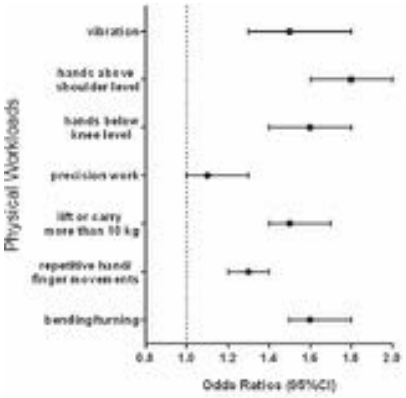

**Figure 1** Odds ratios of developing rheumatoid arthritis among subjects exposed to repetitive prolonged physical workload 5 years before diagnosis compared with unexposed subjects

**Conclusions:** Repetitive prolonged physical workload (RPPW) is associated with the risk of both ACPA-positive and ACPA-negative RA. The interactions between some RPPWs and *HLA-DRB1* shared epitope may be involved in the etiology of ACPA-positive RA.
**Acknowledgement:** The authors thank the investigators and participants from the EIRA study. The authors also thank Marie-Louise Serra and Lena Nise for data collection and Lena Israelsson for performing ELISA analysis.

## OP0242 SELECTIVE DELETION OF FAP EXPRESSING CELLS ATTENUATES SYNOVIAL INFLAMMATION AND PROTECTS AGAINST INFLAMMATORY BONE CHANGES

A.P. Croft[1], J. Campos[1], M. MacKenzie[1], A. Filer[1], D. Fearon[2], G. Desanti[1], F. Barone[1], C. Buckley[1]. *[1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham; [2]Deparment of Medicine and Cancer Research UK, Cambridge Institute, Cambridge, United Kingdom*

**Background:** Despite their role as key effector cells driving synovial inflammation and joint damage, fibroblast like synoviocytes (FLS) have yet to be targeted therapeutically. Fibroblast activation protein (FAP) is a cell surface serine protease, known to be expressed at a low level in resting FLS but up-regulated during inflammation (1). Genetic deletion of FAP has been shown to protect against cartilage damage despite no protective effect on inflammation or bone erosion (2). The pathogenic role of FLS expressing FAP is currently unknown.
**Objectives:** To determine the role of FAP expressing FLS in a murine model of autoantibody mediated inflammatory arthritis.
**Methods:** We utilized a transgenic mouse in which FAP expressing cells were conditionally ablated (FAP-DTR) by administration of diphtheria toxin (3) in either in a prophylactic or therapeutic regime. Inflammatory polyarthritis was induced by the passive transfer of K/BxN serum into naïve mice. Mice were scored for clinical signs of arthritis and flow cytometry of digested synovial tissue was performed to determine the expression of fibroblast subsets. In addition, MicroCT

was performed on hind-limbs of mice 15 days following induction of arthritis to evaluate inflammatory bone changes.
**Results:** We found that FAP expression in the human synovium predicts disease persistence in patients with early synovitis.FAP was dynamically expressed by FLS during inflammatory arthritis and defined a population of activated fibroblasts that co-express the lining layer marker Podoplanin (gp38). Therapeutic deletion of FAP+ cells during either the induction or peak phases of inflammatory arthritis significantly attenuated synovial inflammation leading to a reduction in the clinical severity of arthritis reduced inflammatory cell infiltration and protection against inflammatory bone changes as measured by micro CT. In contrast, prophylactic deletion of FAP expressing cells led to a delayed onset of inflammatory arthritis, but did not impact on subsequent clinical severity.
**Conclusions:** These data support a pathogenic role for FAP expressing FLS in inflammatory arthritis and provide a rationale for the selective targeting of FAP+ fibroblasts as a novel therapeutic approach.

## OP0243 SINGLE NUCLEOTIDE POLYMORPHISMS (SNP) IN THE IL-4 RECEPTOR, IL-4, AND CD40 LOCI AND OUTCOME PREDICTION IN PATIENTS WITH EARLY IMMUNE-MEDIATED INFLAMMATORY POLYARTHRITIS

G. Sauvageau[1], N. Carrier[2], A.J. de Brum-Fernandes[3], P. Liang[3], A. Masetto[3], C. Daniel[1], G. Boire[3]. *[1]Institut national de la recherche scientifique - Institut Armand-Frappier, Laval; [2]Centre hospitalier universitaire de Sherbrooke; [3]Department of Medicine/Division of Rheumatology, Universite de Sherbrooke, Sherbrooke, Canada*

**Background:** Clinicians need reliable biomarkers of disease progression contributing additional information sufficient to personalize treatments in patients with early immune-mediated inflammatory polyarthritis (EPA) and rheumatoid arthritis. Some single nucleotide polymorphisms (SNP) in immune-related genes impact the expression of encoded proteins.
**Objectives:** To determine whether SNP in the Interleukin (IL)-4 Receptor (IL-4R), IL-4, and CD40 genes are associated with EPA disease outcomes.
**Methods:** We studied patients from the Early Undifferentiated PolyArthritis (EUPA) cohort. These patients were evaluated early (median 3.8 months), treated to remission and followed up at pre-specified intervals. Radiographs were scored according to Sharp/van der Heijde (SvH); significant damage was $\geq$5. SNPs were genotyped using an allele-specific primer extension (ASPE) assay and Luminex 100 analyzer. HLA-DR alleles were determined using the LABType rSSO assay (One Lambda). SNP and HLA-DR alleles were correlated to total (SvH $\geq$5) or erosive (Erosion $\geq$5) joint damage, functional incapacity (Modified Health Assessment Questionnaire (M-HAQ) $\geq$1.0) and remission according to Simplified disease activity index (SDAI $\leq$3.3) using generalized estimating equation (GEE) with repeated measures over 5 years. Results were presented with relative risk (RR) and 95% confidence intervals (CI). General linear model (GLM) with repeated measures was used for continuous outcomes.
**Results:** The allelic distribution for the SNPs is presented in Table. IL-4 SNPs rs2243250 and rs2070874 were strongly correlated (r2=0.99); only rs2243250 is presented.
The (G) allele at rs1801275 (IL-4R) was significantly associated with decreased radiographic damage (GLM: Estimate (standard error): 0.035 (0.017), p=0.043).
A (T) allele at rs2243250 (IL-4) was positively associated with erosive damage (GEE: RR 1.26 (1.02–1.55), p=0.034) and functional incapacity (M-HAQ $\geq$1.0; GEE: RR 1.25 (1.00–1.55), p=0.048).
A (T) allele at rs4810485 (CD40) was associated with a higher likelihood of reaching SDAI remission (GEE: RR 1.36 (1.13–1.64), p=0.001).
As previously published[1], the presence of at least one copy of the DERAA protective alleles was significantly associated with decreased erosive damage (GEE: RR 0.75 (0.58–0.96), p=0.02), a trend to decreased functional incapacity (GLM: M-HAQ $\geq$1.0; RR: 0.79 (0.61–1.02), p=0.07) and increased chance of SDAI remission (GEE: RR 1.19 (1.01–1.4), p=0.04).
Combined presence of at least one copy of the DERAA alleles and two copies of rs2243250 (C) allele of IL-4 further reduced erosive damage (GEE: RR 0.67 (0.51–0.90), p=0.007), functional incapacity (GLM: RR 0.75 (0.56–1.00), p=0.051) and slightly increased the chance for SDAI remission (GEE: RR 1.21 (1.02–1.44), p=0.03).

| Allelic distribution of EUPA patients | | |
|---|---|---|
| | Total | n (%) |
| rs1801275 (IL-4R) [A;G] | | |
| A/A | 663 | 391 (59.0) |
| A/G | | 240 (36.2) |
| G/G | | 32 (4.8) |
| rs2243250 (IL-4) [C;T] | | |
| C/C | 662 | 474 (71.6) |
| C/T | | 172 (26.0) |
| T/T | | 16 (2.4) |
| rs1883832 (CD40) [C;T] | | |
| C/C | 559 | 320 (57.2) |
| C/T | | 135 (24.2) |
| T/T | | 104 (18.6) |
| rs4810485 (CD40) [G;T] | | |
| G/G | 559 | 322 (57.6) |
| G/T | | 132 (23.6) |
| T/T | | 105 (18.8) |
| Shared epitope | | |
| -/- | 560 | 308 (55.0) |
| -/+ | | 200 (35.7) |
| +/+ | | 52 (9.3) |
| Protective epitope DERAA | | |
| -/- | 615 | 450 (73.2) |
| -/+ | | 151 (24.6) |
| +/+ | | 14 (2.3) |
| DERAA -/+ or +/+ AND rs2243250 (IL-4) C/C | 610 | 128 (21.0) |

**Conclusions:** Genotyping the SNP rs1801275 (IL-4R), rs2243250 (IL-4), rs1883832/rs4810485 (CD40) and determining the HLA-DR allele of EUPA patients provided a set of stable genetic predictors of disease progression, both clinically and on radiographs. Their association together and with other stable predictors may contribute to develop reliable biomarker signatures suggesting significant associations with poor disease outcomes.

## OP0244 SUSTAINED SUPPRESSION OF RHEUMATOID ARTHRITIS DISEASE MARKERS BY MAVRILIMUMAB BUT NOT GOLIMUMAB IN ANTI-TUMOR NECROSIS FACTOR-INADEQUATE RESPONDERS: AN EXPLORATORY ANALYSIS IN THE PHASE IIB EARTH EXPLORER 2 CLINICAL TRIAL

X. Guo[1], S. Wang[1], A.C. Bay-Jensen[2], M.A. Karsdal[2], A. Godwood[3], D. Close[3], P.C. Ryan[1], L.K. Roskos[1], W.I. White[1]. *[1]MedImmune, Gaithersburg, United States; [2]Nordic Bioscience, Herlev, Denmark; [3]MedImmune, Cambridge, United Kingdom*

**Background:** Treatment of rheumatoid arthritis (RA) patients by anti-tumour necrosis factors (anti-TNFs), such as golimumab, has substantially improved patient outcomes. However, unmet therapeutic needs exist for the significant proportion of patients who do not respond to current biologics treatment. Mavrilimumab is a fully human monoclonal antibody which inhibits the granulocyte-macrophage colony-stimulating factor receptor $\alpha$ (GM–CSFR-$\alpha$). Recently, a Phase IIb study has been completed to evaluate the efficacy and safety of mavrilimumab and golimumab in both disease-modifying antirheumatic drug (DMARD)-inadequate responder (IR) and anti-tumor necrosis factor-inadequate responders (anti-TNF-IR) patients (EARTH EXPLORER 2, NCT01715896).
**Objectives:** To assess peripheral biomarkers and pathophysiological pathways modulated by mavrilimumab in comparison with golimumab in both DMARD-IR and anti-TNF-IR RA patients.
**Methods:** In total, 75 DMARD-IR and 63 anti-TNF-IR patients were randomized in a 1:1 ratio to receive subcutaneous 100 mg mavrilimumab (n=70) every other week (Q2W) or 50 mg golimumab (n=68) Q2W alternating with placebo, in combination with methotrexate (7.5–25.0 mg/week) for 24 weeks. Serum levels of 18 RA-associated proteins as well as 3 protease-derived protein fragments were measured in 71 DMARD-IR and 61 anti-TNF-IR RA patients at baseline and 4 time points post-administration. Transcriptome sequencing was used to measure gene expression changes in whole blood of RA patients at baseline and day 169 post-administration.
**Results:** Serum levels of CCL22 and CCL17 were suppressed by mavrilimumab but not golimumab, while CXCL13 and ICAM1 levels were suppressed by golimumab but not mavrilimumab. Those four proteins may be specific pharmacodynamic markers for the two biologics respectively. More interestingly, both mavrilimumab and golimumab demonstrated early and sustained suppression of multiple inflammatory markers in DMARD-IR patients, including CRP, SAA, MMP1, MMP3, IL6, VEGF, IL2R, and CD163. However, golimumab-induced early changes rapidly returned towards baseline levels in anti-TNF-IR patients, while serum protein suppression by mavrilimumab was maintained through day 169 in anti-TNF-IR patients. Similarly, mavrilimumab administration was associated with durable suppression of extracellular matrix markers, C1M, C3M, and P4NP7S, while golimumab only induced a transient change of the three markers in anti-TNF-IR patients. Furthermore, RNA sequencing results demonstrated significant regulation of 1547 transcripts at day 169 after mavrilimumab administration while golimumab had no impact on whole blood gene expression in anti-TNF-IR patients. In contrast, significant changes of 1042 and 2058 transcripts were observed in DMARD-IR patients at day 169 after mavrilimumab and golimumab administration respectively.
**Conclusions:** Our study demonstrated sustained suppression of RA disease markers by mavrilimumab but not golimumab in anti-TNF-IR patients, suggesting the potential of greater long-term disease control by mavrilimumab than golimumab in this population of RA patients.

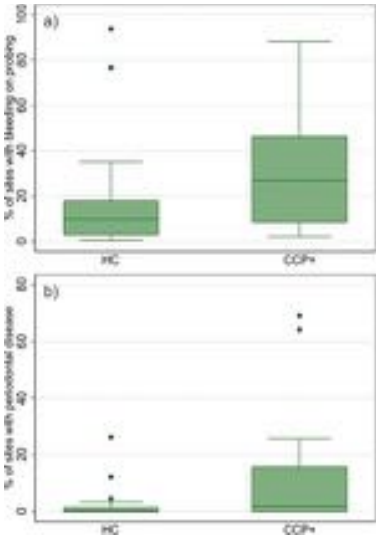
## OP0245 HS1,2A ENHANCER POLYMORPHISM IN RHEUMATOID ARTHRITIS DETERMINES HIGH DISEASE ACTIVITY, HIGH NF-KB ACTIVITY IN B CELLS AND LEADS TO A DIFFERENTIAL RESPONSE TO THERAPY



G. Di Sante[1], B. Tolusso[2], A.L. Fedele[2], S. Canestri[2], L. Petricca[2], S. Alivernini[2], C. Di Mario[1], E. Gremese[2], G. Ferraccioli[2]. [1]*Institute of General Pathology;* [2]*Institute of Rheumatology, Catholic University of the Sacred Heart, Rome, Italy*

**Background:** Several autoimmune chronic inflammatory diseases have been associated with a polymorphism of the HS1,2A enhancer located in the 3' regulatory region of the locus for the immunoglobulin heavy chain (IgH 3'RR-1) (1,2). Its main biologic role resides in the immunoglobulin isotype switching and somatic hypermutation, but the interest in the regulatory region relies also on the demonstration that the allele*2 has a binding site for NF-kB, not present in allele*1.
**Objectives:** To study the HS1,2A enhancer polymorphism as a possible biomarker of disease, disease activity and of response to therapy in the earliest phases of Rheumatoid Arthritis (ERA). To evaluate whether the polymorphism is related to a different NF-kB pathway activation on B cells of ERA patients carrying 2/2 or 1/1 genotypes.
**Methods:** Three-hundred and twenty nine ERA patients, treated according to a tight control strategy were enrolled in the study. At each visit, clinical improvement and remission were evaluated according to ACR/EULAR criteria (3). ERA patients were genotyped for HS1,2A enhancer polymorphism, as previously described (4). At diagnosis, circulating B cells were isolated from PB of 8 naïve RA patients (4 with the 2/2 genotype and 4 with the 1/1 genotype) and analysed for specific genes expression through Real-Time PCR (PCR Array). The Ingenuity Pathway Analysis (IPA) software was used to examine biological networks associated with the polymorphism and to identify functionally related genes that correspond to specific canonical pathways.
**Results:** Twenty-eight percent of ERA patients had the HS1,2A enhancer 2/2 genotype and 10.9% the 1/1 genotype, comparable with the already published data on RA (1). ERA patients carrying the 2/2 genotype had more active disease at baseline compared to 1/1 genotype (in terms of ESR, CRP, circulating IL6 and DAS), reaching less likely a good-EULAR response and remission at 3 months FU (good-EULAR response: 35.9% vs 56.4%, OR (95%CIs): 0.43 (0.24–0.78); EULAR-remission: 14.1% vs 34.6%, OR (95%CIs): 0.31 (0.14–0.67), respectively). Moreover, at 6 months FU, a higher percentage of subjects carrying the 2/2 genotype needed TNF-blockers addition compared to patients without the 2/2 genotype (26.1% vs 12.2%, p=0.01). Finally, we performed the IPA analysis of PB derived B cells from ERA patients carrying the 2/2 and 1/1 genotypes, finding that the focus genes were mapped to 3 networks related mainly to cell death and survival, immunological disease and cell-to-cell signaling and interaction. Moreover, the 2/2 genotype was linked to the top canonical pathway "NF-kB signaling" with TNF-alpha, CD40 and CD40 ligand as top upstream regulators.
**Conclusions:** We demonstrate that carrying allele*2 of HS1,2A enhancer influences the disease activity and the response to therapy in RA already at the earlier phases of the disease and that this genetic background is strongly related to NF-kB activation. Based on these findings we suggest that the enhancer HS1,2A polymorphism is a genetic biomarker that should be included in an individual matrix able to define a possible personalized therapy in RA.

## OP0246 INCREASED PREVALENCE OF PERIODONTAL DISEASE IN ANTI-CCP POSITIVE INDIVIDUALS AT RISK OF PROGRESSION TO INFLAMMATORY ARTHRITIS: A TARGET FOR PREVENTION?

K. Mankia[1], L. Hunt[1], E. Hensor[1], J. Nam[1], V. Clerehugh[2], A. Speirs[2], A. Tugnait[2], T. Do[2], D. Devine[2], P. Emery[1]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine;* [2]*Leeds Dental Institute, Leeds, United Kingdom*

**Background:** The prevalence of periodontal disease is increased in rheumatoid arthritis (RA) patients (1) but has not been reported in seropositive at risk individuals. Comprehensive periodontal examination requires expert evaluation of six sites per tooth for bleeding on probing (BOP), clinical attachment loss (CAL) and pocket depth (PD). Periodontal disease is associated with *Porphyromonas gingivalis*, which, through its unique ability to citrullinate arginine residues (2) may trigger RA-related mucosal autoimmunity. Salivary IgA anti-CCP antibodies have been reported in RA patients (3) but their presence in at risk individuals has not been described.
**Objectives:** To investigate the prevalence of periodontal disease and to describe evidence of RA-related mucosal autoimmunity in anti-CCP positive subjects at risk of progression to inflammatory arthritis.
**Methods:** Anti-CCP positive individuals with no evidence of synovitis (CCP+), healthy controls (HC) and anti-CCP positive RA patients were recruited. All patients underwent periodontal examination by a dentist; six sites per tooth were assessed for BOP (present/absent), CAL (mm) and PD (mm). Dentists later agreed a consensus clinical diagnosis for each case, blinded to patient group. Unstimulated saliva and serum samples were collected. CAL$\geq$2mm and PD$\geq$4mm at the same site signified periodontal disease (PDD). The % of evaluable sites with BOP (%BOP) and % with PDD (%PDD) were calculated per patient. Anti-CCP antibodies (anti-CCP2; immunocap assay, Phadia) were measured in paired saliva & serum samples. IgA anti-CCP titres exceeding the 95th centile in HCs were considered positive. Mann-Whitney U tests were used to compare groups. Spearman rho is reported for associations.
**Results:** We recruited 31 CCP+, 20 HC and 12 RA patients. Groups were balanced for sex, smoking and number of missing teeth. Dentists classified 77% of CCP+ and 45% of HC as having clinical periodontal disease. %BOP was higher in CCP+ than HC (CCP+=26.9 [8.6, 46.3], HC=9.8 [3.1, 17.9]; p=0.033) (fig 1a). %PDD was higher in CCP+ compared to HC (CCP+=1.9 [0.0, 15.7], HC=0.3 [0.0, 1.4]; p=0.050) (fig 1b). PDD was recorded at $\geq$1 site in 65% of CCP+ and 50% of HC. Similar results were obtained for percentage of sites with both PDD and BOP present. 4 patients (CCP+ n=3, RA n=1) had positive saliva IgA anti-CCP results ($>$6$\mu$g/L). 21% of CCP+ (n=6) and 17% of RA (n=2) had positive serum IgA anti-CCP results ($>$15$\mu$g/L); these were not associated with periodontal disease measures. RA patients were slightly older (mean age CCP+=52, HC=50, RA=62) and on disease-modifying treatments; the latter may account for similar %BOP and lower %PDD in this group compared to HC. Age was not associated with %BOP (rho=0.05, p=0.714) or %PDD (rho=0.03, p=0.833).

**Conclusions:** We provide preliminary evidence of both an increased prevalence of periodontal disease and the presence of salivary IgA anti-CCP antibodies in anti-CCP positive individuals at risk of arthritis development. These findings support the concept that periodontal inflammation precedes joint inflammation as a potential trigger or early target of RA-related autoimmunity.

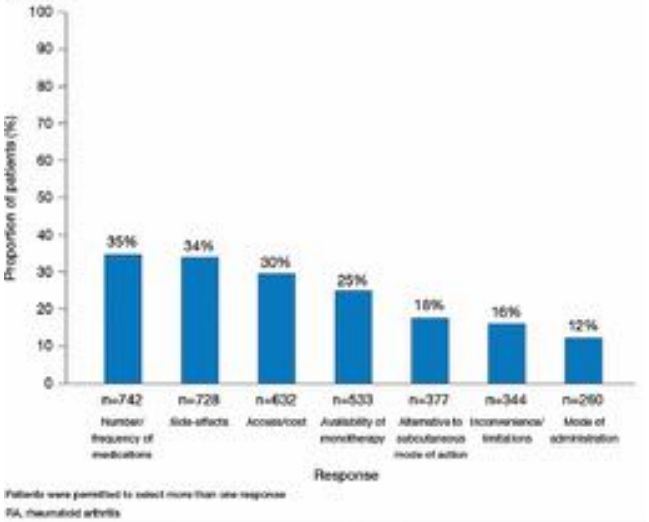
**FRIDAY, 10 JUNE 2016**

## PARE abstract session

### OP0247-PARE SURVEY: WHAT DO PATIENTS THINK ABOUT THEIR CARE, CARETAKERS AND THE ROLE OF PATIENT ORGANISATIONS?

N. Caeyers on behalf of ReumaNet vzw. *ReumaNet vzw, Mol, Belgium*



**Background:** When diagnosed with a rheumatic condition (RMD), we turn to rheumatologists and other specialists for the best treatment possible. We rely on medication and exercise to minimize the impact of our conditions. While living with a chronic disease, people develop a certain expertise themselves. An expertise that differs from what rheumatologists know, but nevertheless is extremely valuable.
**Objectives:** ReumaNet wanted to know what patients think about their care and how they believe things can be improved. By communicating the results to health care providers, policy makers and industry, ReumaNet wants to start a unique collaboration between professionals and patient experts to improve care for people with RMD's.
**Methods:** ReumaNet, the Flemish patient organisation for people with RMDs, developed a survey together with its partners (= rheumatologists, health professionals, industry). The survey was launched in February 2015 and ran until June 2015. It contained 40 online questions for people with an RMD and covered the following items: information, treatment, research, relation with Health Professionals (rheumatologist, physiotherapist, general practitioner and pharmacist), communication between these care takers and the role of patient organisations (POs).
**Results:** 711 people completed the questionnaire. Most people completed the questionnaire online, 50 surveys were filled in on paper by people not familiar with a pc. The majority had RA (48%), but also AS, PsA, JIA, CTD, fibromyalgia, OA and osteoporosis or a combinations of different RMD's were represented. The results were analysed in different ways: conditions, age, gender, time of diagnosis. A part of the survey was also analysed based on medication.
Only 48% considered themselves well informed about their condition and only 34% were well informed about their treatment and medication. Specially people with a diagnosis of less than 6 months are in great need of more info. A fear of side effects are the main reason not to take medication as prescribed (51%).
Fatigue and heredity are the most important issues that should be on the research agenda, according to patients. Rheumatologists score 7/10 on the question: "How satisfied are you with your rheumatologist". Not listening to the patient and not taking him or her seriously are the biggest concerns. Communication between rheumatologist and GP only scores a low 6/10. Most patients do not even know if there is some form of communication and if there is, this obviously is not satisfying for all parties involved.
Other HP's score around 80%, which means people with RMD's are happy with their interactions.
Spreading information among patients is the biggest task for POs (82%). Young people have the greatest need to meet with peers, but 21% of the same group does not even know a PO exists.
**Conclusions:** The results were presented during the World Arthritis Day Symposium of ReumaNet, where the different target groups were present. A debate started the first discussions on these important topics. Health care providers, industry and policy makers were asked how they would tackle the issues in the next five years. ReumaNet is currently meeting with all stakeholders to work together towards better care for all people with RMD's. Opening a 'Reuma Expertise Huis', a place where all expertise on RMD's can come together, was a first step.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.2087

### OP0248-PARE UNDERSTANDING THE IMPORTANCE OF A PATIENT'S ROLE IN THE MANAGEMENT OF RA: RESULTS FROM A PATIENT-BASED SURVEY DEVELOPED BY THE RA NARRATIVE GLOBAL ADVISORY PANEL

C. Koehn[1], A. Dikranian[2], A. Maniccia[3], E. Bananis[4]. *[1]Arthritis Consumer Experts, Vancouver, Canada; [2]San Diego Arthritis Medical Clinic, San Diego; [3]Pfizer Inc, New York; [4]Pfizer Inc, Collegeville, United States*

**Background:** Rheumatoid arthritis (RA) is a chronic, debilitating disease for which there is no cure.
**Objectives:** To identify and better understand the perspective of patients (pts) regarding pt/healthcare provider (HCP) interactions, RA treatment and RA management, based on results from a pt-based survey developed by the RA NarRAtive global advisory panel.
**Methods:** The RA NarRAtive initiative comprises an advisory panel of 39 RA experts (including rheumatologists and pt advocacy group leaders [many with RA themselves]) from 17 countries. A pt-based survey designed by the working group was fielded online across 13 countries between Sept 2014 and Jan 2015. Results are presented for all respondents who consented to the survey.
**Results:** Total of 3649 pts responded to the survey: mean age 52.8 yrs (SD ±15), 59% female. Median time since diagnosis of RA (pt-reported) was 7 yrs. Only 34% of pts (n=1251) described their current overall health as excellent/good. Respondents represented a wide spectrum of self-reported disease activity from mild (39%) to moderate to severe (30%) to severe (8%). Overall, 93% and 50% of pts were under the care of an HCP or rheumatologist/RA specialist, respectively. In total, 59% (2139) of pts were receiving prescribed RA medication, including pain relievers (70%), disease-modifying antirheumatic drugs (DMARDs) (38%), steroids/corticosteroids (32%), and biologic DMARDs (16%). Of these, 38% were not taking their medication as prescribed. Overall, 78% of pts currently taking RA medication were satisfied with their treatment regimen, however 70% desired fewer medications, 57% were worried their medications would fail and 56% wanted more medication choices. The number or dosing frequency of medications was the most frequently cited aspect that pts would most like to change with respect to their current prescribed medications (Figure). Almost half of pts under HCP care (48%) acknowledged that dialogue with the HCP would optimise management of their RA. However, 62% of respondents felt uncomfortable raising treatment/disease concerns to their HCP. Of those currently seeing an HCP to manage their RA, 34% strongly/somewhat agreed that if they ask too many questions, their HCP will consider them a difficult pt and this may affect the quality of care they receive. The current treatment goal for physicians is to achieve clinical remission or low disease activity.[1] However, successful treatment was most commonly defined by pts as a reduction of pain and/or joint swelling/inflammation (81%) and improvements in quality of life (77%).

Figure: Aspects of current, prescribed treatment for RA that patients (n=2139) would most like to change

**Conclusions:** This pt-based survey highlights the importance of treatment conversations between pts and HCPs. Although many pts are satisfied with their RA treatment, non-adherence persists and many would like to discuss and/or change their currently prescribed treatment. Further understanding the responses from this survey will be important to facilitate communication between pts and HCPs, with the aim of improving treatment outcomes.

### OP0249-PARE 25 YEARS OF CAMP FREEDOM - A 6 DAY CAMP FOR CHILDREN 7-17 YEARS OLD WITH ARTHRITIS

K. Mace. *Arthritis & Osteoporosis WA, Shenton Park, Australia*

**Background:** Camp Freedom was developed by the Arthritis Foundation of Western Australia in conjunction with Princess Margret Hospital for Children in 1990 for children with arthritis, with a camp manual having been produced as a guide into the preparation and development of each camp.
**Objectives:** The aim of Camp Freedom is to empower young people with all forms of Arthritis to make informed choices with regards to lifestyle, education and disease management. The camp is designed to offer friendship, fun and exciting activities as well as educational workshops. This also provides respite for the family.
**Methods:** Preparation for camp begins with the selection of the campsite, forming

an enthusiastic team is our next step, our team consists of a Camp Coordinator and our volunteers are a Pediatric Rheumatology Nurse Specialist, a Pediatric Rheumatologist and 7–10 Peer leaders over the age of 21, most having been previous campers.
A programme is created to keep the children occupied most of the time during the 6 day camp, with confidence building a prime outcome to most of our activities, with abseiling, flying fox, sports and fun actvities planned.
Our education sessions are undertaken in two sections, for our junior and senior campers, the subjects and methods are very different, with our health professionals providing age appropriate information and subject matter. Junior camper topics are generally related to understanding the mechanics of their joints,how Arthritis affects them and how to handle bullying. Whereas with the senior campers more detailed interactive subjects such as Transition, peer pressure and social issues are discussed, generally in two sessions, the first with peer leaders and the second with our Health professionals in attendance to answer the questions from the previous session.
**Results:** At the end of each camp we ask the participants to fill in a feedback form to make sure we are providing them with activities and information they need and to give us information to change and improve our programme. We think the biggest accolade is that the parents allow their children to attend camp year after year, if they didn't think they benefited from camp they wouldn't allow them to attend.
Seeing the change that has happened to many of the campers, arriving as shy, negative, closed children who hate their difference to their other friends, at the end of camp to be kids who are vibrant outgoing young people who have made lifelong friends all because they just "get each other". They don't have to explain why they take medications, or why they have a limp today but not yesterday, or why they have to sit down for a while after exercise, they are all in the same boat, although at different levels. Camp gives the kids the chance to discuss their condition with someone just like them, to know they aren't alone and can share their experiences, without having to explain themselves.
**Conclusions:** Many of our outcomes are not measurable on a piece of paper but having been involved with Camp Freedom for 18 years seeing the campers grow up and now returning as adult peer leaders is a very rewarding outcome. Camp Freedom is very successful and growing due to the caring and nurturing nature of the week. The kids are allowed to be kids; they don't have well meaning but overprotective parents around to stop them from "having a go".
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4998

## OP0250-PARE SHARED DECISION MAKING IN RHEUMATOID ARTHRITIS - PATIENTS/DOCTORS WORKSHOP

E. Kritza on behalf of the Arthritis Foundation of Crete. *The Arthritis Foundation of Crete, Heraklion, Crete, Greece*

**Background:** As in most countries in Greece, medical consultations for RA are too short especially in public hospitals. Therefore there isn't enough time for doctors to educate patients about their disease, to discuss treatment options, to review the side effects and finally to adjust treatment strategies according to their patient's life and priorities.
**Objectives:** After campaigning for change for so many years, we wanted answers to our main questions: a. Do doctors and patients view the importance of Shared Decision Making in the same way b. Is shared decision making possible within the current social, economic and cultural climate?
**Methods:** Two full day mixed workshops were organized to discuss the realities of SDM in Greece today, to share ideas and explore solutions. One in Heraklion on 6/6/2015 involving 30 experienced patients and 6 Healthcare Professionals (4 rheumatologists, 1 GP, 1 nurse, 1 Anesthesiologist specializing in chronic pain).
The second workshop took place in Chania on 29/11/2015 involving 25 patients and 4 Healthcare Professionals (1 rheumatologist, 1 GP, 1 orthopedic, 1 nurse).
After a short introduction the participants were divided into two groups: a doctors' group facilitated by a patient and a patients' group facilitated by a doctor. Both groups were asked to rate the degree of implementation of SDM in clinical practice, its usefulness for patients and to justify their ratings.
*The patient Sub Group* rated the usefulness of SDM 10 out of 10 but, the rate of its implementation was only 5 out of 10.They believe that SDM is more likely to occur after the 1st year of diagnosis and depends on: levels of mutual respect and doctor/patient trust, available time, patient preparation before the visit, level of education and information both patients and doctors have, and the weaknesses within the healthcare system.
*The HCP Sub Group* rated the usefulness of SDM 8–9 out of 10 but, the rate of its implementation was only 5 out of 10.The HCPs felt that the implementation of SDM depends on: the patients' age, educational level, willingness to participate and the doctors' attitude
Then the participants were split into three mixed groups and asked to explore the same topics such as: FEASIBILITY, BARRIERS, and SOLUTIONS and propose PRACTICAL STEPS
**Results:** The implementation of SDM is very difficult under current conditions in the healthcare system. As main barriers were identified: lack of time, breakdown in the doctor/patient relationship, weakness in hospital systems & structures and lack of personal responsibility for decision making among some patients.To overcome these barriers a lot of interesting ideas were put forward such as: allow more time during the first consultation, prepare patients before their consultation for better use of time, recruit trained nursing staff who will be in more active contact with patients and the management of their disease, exploit new technologies for patient data transfer to doctors and vice versa, educate patients and doctors to appreciate the benefits of SDM.
**Conclusions:** SDM allows the patient, to be an equal partner in their health care, working with their doctor, nurse or other health professional to make an informed decision about their treatment. However to be implemented in clinical practice doctors and patients need to be educated.
**Disclosure of Interest:** E. Kritza Grant/research support from: Bristol-Myers Squibb Greece
**DOI:** 10.1136/annrheumdis-2016-eular.3951

## OP0251-PARE PATIENT AND PUBLIC INVOLVEMENT IN DESIGN, ANALYSIS AND REPORTING OF A PUBLIC PRIORITY SETTING EXERCISE FOR RESEARCH IN OSTEOPOROSIS

C. Jinks[1], W. Mahmood[1], P. Jayakumar[2], S. Gwilym[2], S. Blackburn[1], A. Worrall[1], Z. Paskins[1,3] on behalf of Research Institute for Primary Care and Health Sciences Research User Group and National Osteoporosis Society.
*[1]Research Institute for Primary Care & Health Sciences, Keele University, Keele; [2]Oxford University Hospitals NHS Trust, Oxford University, Oxford; [3]Haywood Rheumatology Centre, Haywood Hospital, Burslem, United Kingdom*

**Background:** Patient and public involvement (PPI) in identifying topics for research ensures relevant, impactful research questions and is expected by research funders. We have undertaken a two-stage national priority setting exercise to identify public views on research priorities in osteoporosis. Four focus groups were undertaken with members of the National Osteoporosis Society (NOS) and a research cohort of people who had experienced fracture. A national e-survey was sent to members of the NOS. PPI was embedded throughout to inform study design, analysis and reporting.
**Objectives:** To describe the role and impact of a Research User Group in co-designing priority setting methods for osteoporosis research.
**Methods:** Three face-to-face advisory group meetings were held with members of the Research Institute's Research User Group (RUG). All members have bone and muscle pain. Meeting 1 occurred before the focus groups. A draft topic guide was discussed. Meeting 2 occurred after all focus groups were completed and before the e-survey went live. Before this meeting researchers undertook some analysis of focus group data to identify specific research questions or uncertainties about treatments and produced a draft e-survey. Each section and question was discussed with the RUG alongside relevant data from the focus groups to clarify concepts and wording. Meeting 3 focussed on e-survey results and co-design of recommendations on research priorities.
**Results:** Five RUG members participated. In meeting 1 RUG members advised on general topics to include in the focus group discussion and the order of questions to be asked. The group had innovative ideas about how best to ask participants to prioritise topics discussed and suggested using "post-it" notes which the researchers subsequently implemented. In meeting 2 researchers presented how emerging themes from the focus groups could be turned into questions for the e-survey. Some themes were felt to be "straightforward", and for these RUG members advised on question wording. Some themes were less well crystallised (e.g. support, confidence), and for these, the RUG members interpreted meaning from quotes. Discussions led to clarity about what the question should be about and wording amended. The RUG identified overlap between questions and the need to simplify the introduction to the e-survey. Researchers redrafted and re-circulated the survey. RUG members fed back further comments by email, particularly regarding the order of presented questions and suggesting reordering in line with patient experiences. This meant moving the questions about diagnosis to an earlier part of the questionnaire. The final meeting was held after the e-survey closed. Summary results from the e-survey were presented and RUG members discussed how results should be presented in a final report.
**Conclusions:** Patient and public involvement was integral to the design and analysis of this UK osteoporosis research priority setting exercise at three key points. This iterative process enabled active involvement throughout and impacted on focus group and e-survey design and the development of research strategy recommendations.
**Acknowledgement:** We would like to thank the PPI team at Keele who helped to set up the RUG groups and the focus group participants and people who responded to the e-survey.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.3302

## OP0252-PARE INCREASING THE INTEREST IN RESEARCH IN RHEUMATOLOGY

K. Blidberg. *Reumatikerförbundet, Stockholm, Sweden*

**Background:** The Swedish Rheumatism Association has a research fund which distributes money to research in rheumatology but also research on pain, osteoarthritis and other conditions related to musculoskeletal disease. Our long term commitment is to reduce the burden of rheumatic disease, increase the

quality of life for people with rheumatic disease and ultimately prevent the onset of rheumatic disease and its consequences. The fund distributes about 20 million Swedish krona yearly. In 2015 the Swedish Rheumatism Association published a report on the research that is financed by their fund.
**Objectives:** The report had several objectives 1) to increase the awareness of the Swedish Rheumatism Association's function as a funder of research 2) to interest decision makers in different parts of society in the field 3) to be used for fundraising.
**Methods:** The Swedish Rheumatism Association worked together with a content agency (OTW, Stockholm, Sweden) in the production of the report. The report was based around six major areas of research, rheumatoid arthritis, juvenile arthritis, juvenile idiopathic arthritis, systemic autoimmune rheumatic disease, pain, osteoarthritis and life style. Each theme contained a number of articles on different projects that the Swedish Rheumatism Association has helped to fund. The different articles were written by, or in collaboration with, the principal investigator.
**Results:** The report contains 18 articles on research. It addition, it contains four cases where four patients tell their story. The report was printed and first released to the public during a research seminar arranged by the Swedish Rheumatism Association. The report is also distributed as a PDF via the Swedish Rheumatism Association's webpage and a few of the individual articles have been reworked to suit the web better.
**Conclusions:** The Swedish Rheumatism Association have published a report on the research they finance in order to use it both for lobbying purposes and for fundraising. For the coming year a series of activities will be arranged around the report. For example it will be used at a research seminar that is arranged for young medical students in order to interest them in research as a career path. It will also be used in different meetings with various decision makers as well as for fundraising purpose.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4039

## OP0253-PARE "SAMEN REUMA"- A CLOSED GROUP ON FACEBOOK FOR PEOPLE WITH RHEUMATIC DISEASES

A.M. Zimmerman, N. Lopuhaä. *Dutch Arthritis Foundation, Amsterdam, Netherlands*

**Background:** With a website with 250.000 visitors monthly, a fanpage on Facebook with over 17.000 fans and a Twitteraccount with about 2.400 followers the Dutch Arthritis Foundation is in touch with a very large group of people with rheumatic diseases. We noticed there is a demand for an online place to meet for people with RMDs in the Netherlands. A place to share their feelings and to ask each other questions. Nowadays there are a lot of social communities on the internet. Although we do have a Fanpage on Facebook, where we share our extensive knowledge about all kinds of rheumatic diseases, the page is accessable for everybody and less suited for more personal conversations. For this reason we started a closed Facebook group for people with RMDs where they can get in touch with peers in a more private setting (within the possibilities of Facebook) to exchange tips, give support and to find answers to more private matters.
**Objectives:** Many people with rheumatic diseases would like to be able to get in touch with peers. On the other hand the Dutch Arthritis Foundation would like to stay in touch with patients and get more insight into what is going on in the community. For that reason we've created a private community on Facebook where patients can meet each other and can exchange knowledge amongst themselves and with us.
**Methods:** In the beginning of 2015 we developed a plan to start an online community on Facebook. As not only the support of the patient community is important, but also the support from the organisation we tried to involve both as much as we could. Our goal was to reach 200 members within half a year and to have activity in the community 3 to 4 times a week.) After we set up the group on Facebook (without any members yet) we made a list of rules and in June started to ask patients to help us find members. About ten people were interested in helping and invited their friends to the group. When somebody had a question they made sure that the question got answered. In this way we started the group low profile. In July we asked two key members of the group if they would like to be a moderator, which they agreed to do. For moderation purposes we created a secret (untraceable) group on Facebook. In August we announced the group on all of our media channels (Facebook public fanpage, Twitter, website, newsletter etc) after which the group grew rapidly.
**Results:** Our goal at six months was to have at least 200 members, by the end of 2015 we counted more than 1.700 members!
The group is very active and the amount of subjects is enormous. At least every two hours somebody posts a question or reacts on someone else's question, if not more often. The converstation contains subjects like medical problems, health insurance and solutions for daily activities. The members introduce themselves, ask questions, support each other en share their experiences and knowledge.
**Conclusions:** As the group got off at a tremendous pace, we can conclude that it satisfies the (online) needs of people with rheumatic diseases. People are positive about the group and are likely to stay and help each other. It is still a quest for the Dutch Arthritis Foundation to decide what topics we can contribute to. While we do believe in the power of peer to peer conversations, we also think people with RMDs can benefit from our knowledge. The big question for us at this moment however is when and how often to contribute ourselves.
**Disclosure of Interest:** None declared
**DOI:** 10.1136/annrheumdis-2016-eular.4009

## OP0254-PARE RHEUMATOID ARTHRITIS PATIENT CHARACTERISTICS AND WILLINGNESS TO PARTICIPATE IN RESEARCH AMONG MEMBERS OF THE CREAKYJOINTS ARTHRITIS PATIENT COMMUNITY: RESULTS FROM A PATIENT SURVEY

W.B. Nowell[1], N. Gerber[1], J.R. Curtis[2], B. Johnson[2], K. Saag[2], M. Safford[2], J. Willig[2], S. Ginsberg[1]. *[1]Global Healthy Living Foundation, Upper Nyack; [2]University of Alabama at Birmingham, Birmingham, United States*

**Background:** CreakyJoints (CJ) is an international online arthritis patient community offering support, blogs, education, advocacy and the opportunity to participate in research.
**Objectives:** To identify willingness to participate in research among rheumatoid arthritis (RA) patients in an online community.
**Methods:** CJ patient community completed an online form preparatory to launch of a PCORI-funded research network (ArthritisPower.org). The online survey captured self-reported demographic, diagnosis, treatment, and willingness to participate in research.
**Results:** As of January 2016, a total of 8923 patients had registered. Among respondents, 2147 identified themselves as patients who had RA; a subgroup of 970 completed the survey on willingness to participate in research. *Demographics (N=2147):* Respondents were mostly female (93%) and white, non-Hispanic (85%) with mean age of 51.7 years (SD 11.6). *Conditions & Treatments (N=2147):* The most frequent concomitant conditions reported by RA respondents were osteoarthritis (32%), fibromyalgia (31%), and osteoporosis (13%). A majority reported taking a classical DMARD (e.g. MTX) (59%) or a biologic (50%) including anti-TNF biologics (33%); only 23% indicated they were taking neither. *Willingness to Participate in Research (N=970):* Most patients (68%) had never taken part in research. Among U.S. respondents, a majority (75%) would refuse to participate in research that requires sharing Social Security Number (SSN) and 50% for the last 4 digits of SSN compared with only 20% for email and 34% for medical records. Top 3 reasons patients would not be interested in being part of medical research were: project not recommended by doctor (30%), individual results may not be kept private/confidential (28%), and project will take a lot of time (25%). Table 1 shows percentage of patients interested in research based on the source of the invitation.

Table 1. Interest in research participation by source of invitation

| | Not Interested | Somewhat Interested | Very Interested |
|---|---|---|---|
| Your own doctor | 7% | 27% | 66% |
| Medical school or hospital | 13% | 40% | 47% |
| Non-profit | 21% | 46% | 33% |
| Government (e.g., U.S. NIH) | 27% | 42% | 31% |
| Drug company | 36% | 45% | 18% |
| Private company (e.g., food or retail) | 50% | 38% | 12% |
| Insurance company | 54% | 34% | 12% |

**Conclusions:** Results from this patient community survey indicate substantial willingness to participate in rheumatology research yet identify a number of potential barriers. Considering patients as unique stakeholders is vital to maximize the relevance and patient-centeredness of future research endeavors.

# Cormobidities

## OP0255 RHEUMATOID ARTHRITIS COMORBIDITY INDEX: DEVELOPMENT AND VALIDATION OF A NEW SPECIFIC TOOL FOR CLASSIFYING PROGNOSTIC COMORBIDITY IN RHEUMATOID ARTHRITIS PATIENTS

Y. El Miedany[1], M. El Gaafary[2], S. Youssef[3], S. Bahlas[4], I. Ahmed[5], M. Hegazi[6]. *[1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; [2]Community and Public health; [3]Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt; [4]Rheumatology, King Abdel Aziz University, Jeddah, Saudi Arabia; [5]Medicine, Cairo University, Cairo, Egypt; [6]Medicine, Adan Hospital, Kuwait, Kuwait*

**Background:** Rheumatoid arthritis patients are clinically complex, and the interplay of their prognostically important conditions leads to morbidity as well as

mortality. Separate patterns of comorbidity are identified in patients with different rheumatic diseases. These patterns include the type of comorbid variables reported and their associations with age and disease duration. The available comorbidity tools face some tough challenges particularly most of them are non-specific and were developed before the era of biologic therapy, early inflammatory arthritis as well as Treat to Target concepts.
**Objectives:** 1. identify comorbidities with greatest impact on Rheumatoid Arthritis (RA) patients' health status. 2. develop and validate a prospectively applicable comorbidity index for classifying RA patients according to their comorbid conditions which might alter their risk of hospitalization and mortality.
**Methods:** This was a retrospective multicenter cohort analysis of RA patients in a rheumatology clinical registry assessing the effect of different comorbidities measured at patients' visits over 10-years period, on predicting future death and hospitalization. A weighted index that takes into account the number and seriousness of comorbid disease was developed in a cohort of 2029 patients with early RA monitored over 10-years. Logistic and Cox Regression analyses were implemented to estimate the risk of mortality. Regression coefficients were used to develop the morbidity index score. ROC curve for the invented index was used to evaluate the discriminating ability of the index and identify different cutoff values that can delineate patients at different stages for risk of death. Disease activity parameters were considered.
**Results:** Comorbidities (18 conditions) were strongly associated with the 10-year death risk, and composed the RA-comorbidity index. These include Cardiovascular (7 comorbidities), infection, osteoporotic fractures, falls risk, Depression/anxiety, functional status (HAQ >2), diabetes mellitus, steroid therapy >5mg, DAS-28 >3.2), renal/liver/lung disease and tumors. A comorbidity index weighted according to the regression coefficient of the variables extracted through the logistic regression analysis was developed. The score ranges from 0 to 40. A cut off point of 20 was associated with a sensitivity of 90.2% and a specificity of 89.3%. Validation using ROC curve revealed AUC of 97%.

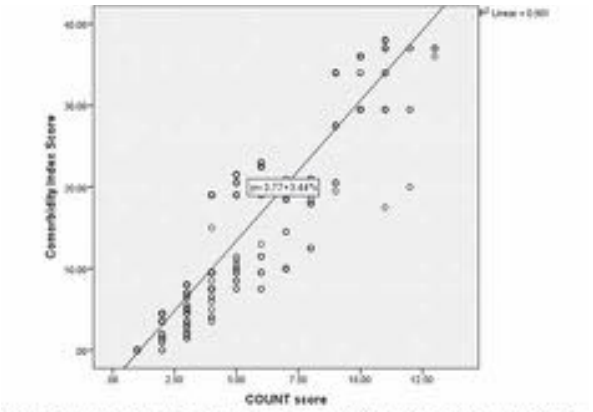

Figure Scatterplot displaying correlation between COUNT score and Comorbidity Index

**Conclusions:** The RA-comorbidity index is a valid method for estimating risk of death in RA patients. It enables the clinicians to include comorbidities assessment and management in their standard practice. It can be used to predict resource utilization, identify targets for reducing high costs, by prospectively identifying RA patients at high risk.

## OP0256 PRESENCE OF RISK FACTORS FOR CARDIOVASCULAR DISEASE PREDATES THE ONSET OF SYMPTOMS OF RHEUMATOID ARTHRITIS

H. Kokkonen, S. Rantapää-Dahlqvist. *Public Health and Clinical Medicine, Rheumatology, UMEÅ UNIVERSITY, Umeå, Sweden*

**Background:** Patients with rheumatoid arthritis (RA) are at increased risk of developing cardiovascular (CV) comorbidity compared with the general population. Contradictory results concerning CV disease prior to onset of RA have been reported. Of the known CV risk factors, a more atherogenic lipid profile and smoking have been presented prior to RA onset.
**Objectives:** In this study, lifestyle factors, lipid levels, presence of hypertension, and diabetes were evaluated in individuals prior to onset of symptoms of RA and matched population controls from northern Sweden.
**Methods:** A nested case-control study was based on information from The Västerbotten Intervention Programme (VIP) and the WHO Multinational Monitoring of Trends and Determinants in Cardiovascular Disease (MONICA). Data were collected by questionnaire (socioeconomic and lifestyle factors), assessments by a nurse (body mass index;BMI, waist and blood pressure), and blood sampling (lipids and glucose loading). The registers of patients with RA (ARA criteria) attending the Department of Rheumatology, Umeå was co-analysed with the registers from VIP and MONICA. This study included 547 pre-symptomatic individuals (mean age 51.5years; 372f/175m, median (IQR) predating time 5.0 (7.0) years), and 1654 controls (mean age 51.6years; 1123f/531m). CV risk factors were defined as: hypertension (systolic≥140 mmHg, diastolic≥90 mmHg), ApoB/ApoA1 ratio (females ≥0.7, males ≥0.8), BMI≥25, diabetes, and ever smoker.
**Results:** Lower levels of ApoA1 (OR=2.0 (95%CI1.25, 3.25) and increased ApoB/ApoA1 ratio (OR=2.25 95%CI1.25, 4.06) were associated with RA development, particularly in females besides smoking, BMI and waist range. Plasma glucose at baseline was related to disease development, particularly in males (OR=1.18 95%CI1.01, 1.37). Blood pressure did not differ between the groups. Conditional logistic regression models identified elevated ApoB/ApoA1 ratio (OR=1.25 95%CI1.01, 1.56), being ever smoker (OR=2.00 95%CI1.63, 2.47), BMI≥25 (OR=1.33 95%CI1.09, 1.63) and diabetes (OR=1.98 95%CI1.06, 3.68) but not hypertension (OR=0.89 95%CI 0.72–1.11) to be associated with RA development. The pre-symptomatic individuals had significantly higher frequency of these risk factors, 32.3% of these individuals had ≥3 of these factors compared with 23.2% of the matched controls (OR=2.52 95%CI1.67, 3.83).
**Conclusions:** Several of the CV risk factors are present in individuals already years before onset of symptoms of RA. One third of the pre-symptomatic individuals had at least 3 of these factors present. These results urge early CV prevention in patients with RA.

## OP0257 RHEUMATOID ARTHRITIS-SPECIFIC CARDIOVASCULAR RISK CALCULATORS ARE NOT SUPERIOR TO RISK CALCULATORS ESTABLISHED FOR THE GENERAL POPULATION: A VALIDATION ANALYSIS IN A COHORT OF RA PATIENTS FROM 7 COUNTRIES

C.S. Crowson[1], S.E. Gabriel[2], A.G. Semb[3], P.L. van Riel[4], G. Karpouzas[5], P.H. Dessein[6], C. Hitchon[7], V. Pascual Ramos[8], G.D. Kitas[9] on behalf of A Trans-Atlantic Cardiovascular Consortium for Rheumatoid Arthritis (ATACC-RA). *[1]Mayo Clinic, Rochester, MN; [2]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, United States; [3]Diakonhjemmet Hospital, Oslo, Norway; [4]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [5]Harbor UCLA Medical Center RHU, torrance, CA, United States; [6]Witwatersrand University, Johannesburg, South Africa; [7]University of Manitoba, Winnipeg, Manitoba, Canada; [8]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubir, México City, Mexico; [9]Dudley Group NHS Foundation Trust, West Midlands, United Kingdom*

**Background:** Cardiovascular disease (CVD) risk calculators developed for the general population do not accurately predict CVD events in patients with rheumatoid arthritis (RA).
**Objectives:** To externally validate risk calculators recommended for use in patients with RA including the European League Against Rheumatism (EULAR) 1.5 multiplier, the Expanded Cardiovascular Risk Prediction Score for Rheumatoid Arthritis (ERS-RA) and QRISK2.
**Methods:** Seven RA cohorts from United Kingdom, Norway, Netherlands, United States, South Africa, Canada and Mexico were combined. Data on baseline CVD risk factors, RA characteristics and CVD outcomes (including myocardial infarction, ischemic stroke and cardiovascular death) were collected using standardized definitions. Performance of QRISK2, EULAR multiplier and ERS-RA was compared to other risk calculators (ACC/AHA, Framingham Adult Treatment Panel III [FRS-ATP] and Reynolds Risk Score) using c-statistics and net reclassification index (NRI).
**Results:** Among 1796 RA patients without prior CVD (mean age: 54.0 [SD: 14.0] years, 74% female), 100 developed CVD events during a mean follow-up of 6.9 years (12430 person-years). Estimated CVD risk by ERS-RA (mean: 8.8%, SD: 9.8%) was comparable to FRS-ATP (mean: 9.1%, SD:8.3%) and Reynolds (mean: 9.2%, SD: 12.2%), but lower than ACC/AHA (mean: 9.8%, SD: 12.1%) and QRISK2 (mean: 15.5%, SD: 13.9%) estimates. Discrimination was not improved for ERS-RA (c-statistic=0.69), QRISK2 or EULAR multiplier applied to FRS-ATP and ACC/AHA (c-statistic=0.72 for all) compared to ACC/AHA and FRS-ATP (c-statistic=0.72 for both). The NRI for ERS-RA were low (-0.8% vs. ACC/AHA and 2.3% vs. FRS-ATP). The NRI for QRISK2 compared ACC/AHA was low (-2.4%). The NRI for QRISK2 compared to FRS-ATP was higher, but not significant (NRI: 25.0%, 95% CI: -9.4–34.7%). The EULAR multiplier only reclassified 6 patients above the 7.5% treatment threshold for the ACC/AHA calculator and 3 patients above the 20% treatment threshold for the FRS-ATP calculator, so the NRI was negligible.
**Conclusions:** The QRISK2, EULAR multiplier and ERS-RA algorithms did not predict CVD risk more accurately in patients with RA than CVD risk calculators developed for the general population.

## OP0258 OPTIMIZING THERAPY IN INFLAMMATORY ARTHRITIS: PREDICTION OF RELAPSE AFTER TAPERING OR STOPPING DMARDS/ BIOLOGIC AGENTS BY ULTRASONOGRAPHIC ASSESSMENT IN RHEUMATOID ARTHRITIS PATIENTS WHO ACHIEVED CLINICAL REMISSION

Y. El Miedany[1], M. Maha El Gaafary[2], S. Youssef[3], D. Palmer[4], A. Nasr[5]. *[1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; [2]Public Health and community; [3]Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt; [4]Rheumatology, North Middlesex University Hospital, London, United Kingdom; [5]Radiology, Ain Shams University, Cairo, Egypt*

**Background:** In contrast to initiation of biologic therapy, guidelines regarding stopping of this treatment are missing. As a result, the decision of discontinuation is still a challenging aspect in the use of biologic therapy. Currently this is typically based on an estimated, case-by-case, benefit-risk ratio.
**Objectives:** To assess whether joint ultrasonography can predict disease relapse in RA patients in sustained remission, either continuing, tapering or stopping Disease modifying drugs (DMARDs) or biologic therapy in a prospective randomized study.
**Methods:** 157 RA patients in clinical remission, (Disease Activity Score in 28 joints [DAS-28] $<$2.6 for more than 6-months) receiving treatment with DMARDs and biologic therapy, were randomized into four arms: Arm 1: continue full dose DMARDs and taper biologic therapy by 50% (31 patients); Arm 2: taper both DMARDs and biologic therapy dose by 50% (32 patients); Arm 3: taper DMARDs by 50% and stop biologic therapy (31 patients); Arm 4: stop both DMARDs and biologic therapy (31 patients). Patients' joints were assessed ultrasonographically (Gray scale and Power Doppler) at 40 joints (DAS28 joints + ankles + metatarsophalangeal joints) and were prospectively followed up bi-monthly for 12-months. Control group (32 RA patients) continued their DMARDs and biologic therapy at the same doses. Physicians who evaluated the patients during the study period were blinded to the baseline ultrasound findings. The primary endpoint was sustained remission during 12 months. Patients were considered as having a relapse when the DAS-28 score was $>$3.2 and anti-rheumatic treatment was escalated.
**Results:** The incidence of relapses was related to study arms: Arm 1: relapse 41.9%, arm 2: 59.3%; arm 3: 67.7%; Arm 4: 77.4%. Kapler-Meier Analysis revealed that time to relapse also varied in the 4 study subgroups: Arm 1: 6.8 ± 2.46; Arm 2: 5.3 ± 2.6; Arm 3: 4.7 ± 2.2; Arm 4: 3.9 ± 2.1 months. Relapse rates were significantly higher in patients whose total ultrasound scores at discontinuation were high than in those whose total ultrasound scores were low ($P<0.001$ for both total gray-scale and power Doppler scores). Positive and negative predictive values were 84.7% and 71.2% for the total Gray-scale score and 89.8% and 73.5% for the total power Doppler score, respectively. Multivariate logistic regression identified anti-citrullinated protein antibodies (ACPA) positivity (p=0.027) and treatment reduction (in comparison to continuation) as predictors for relapse (arm 1: p 0.004, arm 2: p=0.002; arm 3: p=0.003, arm 4: p=0.001).
**Conclusions:** Less than 40% of the patients remained in remission after tapering or stopping DMARDs and biological therapy. In RA patients in clinical remission, residual synovial inflammation determined by joint ultrasonographic assessment predicted relapse within a short term after discontinuation of the treatment. Relapses occurred mainly in the first 6 months after treatment reduction or stoppage and were associated with the presence of ACPA. This data endorse the establishment of ultrasound-based strategies before optimizing biologic/ DMARs therapy in RA is considered.

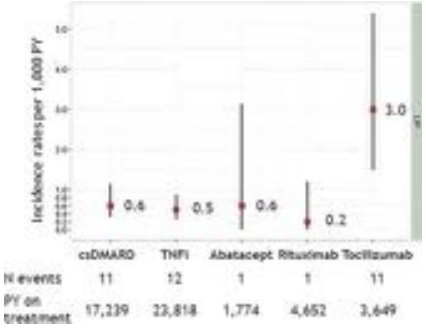
## OP0259 IMPACT OF SUSTAINED REMISSION ON RISK FOR INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS ENROLLED IN A US REGISTRY

J.R. Curtis[1], M. Liu[2], S. Rebello[2], M. Trivedi[3], T. Lesperance[3], Y. Li[4], N. Accortt[3]. *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Corrona, LLC, Southborough, MA; [3]Amgen, Inc., Thousand Oaks, CA; [4]University of Massachusetts, Worcester, MA, United States*

**Background:** High disease activity has been shown to be associated with increased risk of infection in patients with rheumatoid arthritis (RA).[1] The potential benefit of lower disease activity on the risk of serious infection has not been examined.
**Objectives:** This study was conducted to assess the impact of sustained remission on infection risk.
**Methods:** We identified patients in the Corrona registry with at least two Clinical Disease Activity Index (CDAI) measures, at least 1 follow-visit, and met the criteria based on CDAI for sustained remission or sustained low disease activity (two incident consecutive visits in remission [CDAI $\leq$2.8] or LDA [CDAI between 2.8 and 10] and following the second visit (index visit) had an average disease activity in remission or LDA over follow-up using the area under the curve method based on the trapezoidal rule. Patients were followed until the earliest of: first serious infection (infection requiring either hospitalization or treatment with IV antibiotics) or last follow-up visit. Covariates identified at the index date included demographic and clinical characteristics. The incidence rates (IR) per 100 patient-years of serious infections in patients in sustained remission vs sustained LDA were calculated and crude incidence rate ratios (IRRs) calculated.
**Results:** There were a total of 3355 RA patients in the sustained remission group and 3912 in the sustained LDA group. The majority of patients were female (75%) with mean age of 60 years, with an average disease duration of RA of 9.9 years for the sustained remission patients and 12.1 years for the sustained LDA patients ($P<0.001$). During follow-up, the sustained remission and sustained LDA groups reported 115 and 260 serious infections, respectively. Incidence rates between the two disease activity groups differed significantly, with the sustained LDA group having a nearly twofold (crude IRR=1.8 [1.45, 2.24]) higher rate of infections (IR=2.01 [1.78, 2.27]) than the sustained remission group (IR=1.12 [0.93, 1.34]).

Table 1. Incidence rate and incidence rate ratio between sustained LDA vs sustained remission cohorts



| | Sustained remission | Sustained LDA | p |
|---|---|---|---|
| Serious infections, N | 115 | 260 | |
| Person-yrs follow-up | 10282 | 12909 | |
| Incidence Rate [95% CI] (per 100 person-year) | 1.12 [0.93, 1.34] | 2.01 [1.78, 2.27] | $<$0.001 |
| Crude Incidence rate ratio (IRR) | Ref. | 1.80 [1.45, 2.24] | $<$0.001 |

**Conclusions:** Patients in sustained remission have a lower risk of serious infections compared to those in sustained LDA. These findings may help motivate those who only attain LDA to strive to reach remission if possible.

## OP0260 LOWER INTESTINAL PERFORATIONS ARE MORE FREQUENT AND PRESENT UNTYPICALLY IN PATIENTS TREATED WITH TOCILIZUMAB COMPARED TO OTHER BIOLOGIC OR CONVENTIONAL SYNTHETIC DMARDS

A. Strangfeld[1], A. Richter[1], B. Siegmund[2], P. Herzer[3], K. Rockwitz[4], W. Demary[5], M. Aringer[6], A. Zink[1,2], J. Listing[1]. *[1]German Rheumatism Research Centre; [2]Charité University Medicine, Berlin; [3]Scientific Advisory Board, Munich; [4]Rheumatologist, Goslar; [5]Rheumatologist, Hildesheim; [6]University Medicine, Dresden, Germany*

**Background:** During randomized controlled trials with tocilizumab, an IL-6 inhibitor, perforations of the lower intestinal tract (LIP) occurred only in the exposed patient population, not in the control group. The relevance of this finding for daily practice is unclear because we know little about the background risk for LIP in rheumatoid arthritis (RA) patients on different treatments.
**Objectives:** To examine the incidence of LIP and their appearance in RA patients treated with different biologics (bDMARDs) or conventional synthetic DMARDs (csDMARDs).
**Methods:** We used data from the prospective longitudinal German biologics register RABBIT with 14,300 RA patients included since May 2001 starting a csDMARD or bDMARD. All serious gastrointestinal adverse events reported until 30th April 2015 which were possibly associated with perforations (including haemorrhages) were filtered (n=137). All events were validated (twice, with additional external validation) based on medical records or specific queries. Reviewers were blinded for treatment exposure. Only events with a definite, non-traumatic and non-iatrogenic perforation of the lower intestinal tract were selected for the analysis. Treatment exposure was defined as treatment given in the last three months before occurrence of the event.

**Results:** In total, 36 LIPs (colon/sigma: 31, appendix: 4, terminal ileum: 1) were observed in 48,102 patient years (PY). In total, 27 of the 36 patients with LIP had concomitant GCs, with a daily dose of ≥7,5mg in 12 patients. In the multivariate analysis higher age, GC use and treatment with TCZ were significantly associated with a higher risk of LIP (hazard ratio (HR) 1.3 per 5mg increase in GC dose [95%CI=1.2, 1.4], and HR 1.5 [1.3, 1.8] per 5 years increase in age). Compared to csDMARDs, treatment with TCZ was associated with a 5 times higher risk for LIP (HR 5.2 [2.4,11.6]) whereas no association was found for TNF inhibitors, abatacept or rituximab.
None of the patients with LIP had a history of diverticulitis known to the treating rheumatologist. In patients treated with TCZ the presentation of LIP events was untypical: acute and localized pain was only reported by some patients, diffuse abdominal pain was more frequent. CRP was completely suppressed or only slightly elevated. In total, 11 (31%) of the patients died after LIP: 2 of 11 csDMARD, 3 of 12 TNFi and 6 of 11 TCZ treated patients.
**Conclusions:** This first comparative analysis of all bDMARDs available for the treatment of RA showed a significant risk of LIPs in patients treated with TCZ. It confirms a signal detected in clinical trials and specified the localization to lower GI tract only. TCZ patients with LIP present untypically. In order to ensure timely intervention, patients should be advised that symptoms of LIP might be mild and that CRP is not a valid diagnostic marker in their case.

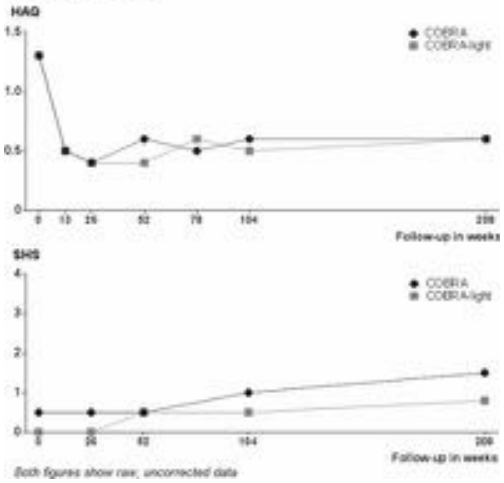
## OP0261 7-YEAR TOLERABILITY PROFILE OF GLUCOCORTICOIDS USE IN EARLY RHEUMATOID ARTHRITIS: DATA FROM THE ESPOIR COHORT

C. Roubille[1], N. Rincheval[2], M. Dougados[3], R.-M. Flipo[4], J.-P. Daures[5], B. Combe[1]. *[1]Department of Rheumatology, Lapeyronie Hospital; [2]Statistiques, Institut Universitaire de Recherche Clinique, Montpellier; [3]Rheumatology, Cochin Hospital, Paris; [4]Rheumatology, Roger Salengro Hospital, Lille; [5]Statistiques, Institut Universitaire de Recherche Clinique, Montpellier, France*



**Objectives:** To explore the 7-year tolerability profile of glucocorticoids (GC) use in patients with early rheumatoid arthritis (RA).
**Methods:** Six-hundred and two RA patients from the early arthritis ESPOIR cohort (less than 6 months disease duration) were included. They were stratified in two groups, based on whether they received or not GC treatment during their follow-up. The group "with GC" comprised RA patients who took a systemic GC therapy at least once during their entire follow-up, while the control group "without GC" included RA patients who had never taken GC. The main outcome was a composite of death, cardiovascular diseases (including myocardial ischemia, cerebrovascular accident and heart failure), severe infections and fractures. We used Cox proportional-hazard model, adjusting for confounding factors and propensity score (Inverse Probability of Treatment Weighting).
**Results:** Among the 602 RA patients (476 women, mean age of 48 ± 12 years), the group "with GC" included 386 patients (64.1%) and the group "without GC" comprised 216 patients. RA patients in the group "with GC" received low dose prednisone treatment during their follow-up (mean dosage 3.1 mg/day ±2.9), most of them starting GC during the first six months (n=263, 68.1%). Compared to patients "without GC", RA patients "with GC" significantly received more DMARDs and biological agents, more NSAIDs, and were more frequently diabetics and smokers. Additionally, RA patients "with GC" suffered from a more active disease, with significantly higher DAS-28 CRP and HAQ scores, and higher CRP and ACPA levels. Among a total of 65 events (7 deaths, 14 cardiovascular diseases, 19 severe infections and 25 fractures), 21 (9.72%) occurred in the "without GC group", and 44 (11.4%) in the "with GC group". No significant difference was found between groups in univariate analysis (p=0.520). However, a trend toward more infections was evidenced in RA patients "with GC" (p=0.09). Propensity score included baseline HAQ, and DAS-28 CRP scores, baseline ACPA level, history of diabetes and baseline modified Sharp score. Cox model adjusted on propensity score, age, gender, and history of hypertension, showed no significant difference between groups (p=0.628).
**Conclusions:** This 7-year data analysis of the ESPOIR cohort did not show any significant difference with regards to major safety events in RA patients exposed to GC treatment compared to RA patients who had never received GC. These data support the good safety profile of short term low-dose GC therapy in early RA.
**Disclosure of Interest:** None declared

## OP0262 SIMILAR CLINICAL AND RADIOLOGICAL OUTCOME IN THE COBRA AND COBRA-LIGHT TREATMENT GROUP 4 YEARS AFTER INITIATION OF THE COBRA-LIGHT TRIAL

N. Konijn[1], L. van Tuyl[1], M. Boers[1,2], D. den Uijl[1], M. ter Wee[1,2], P. Kerstens[3,4], A. Voskuyl[1], D. van Schaardenburg[3,5], M. Nurmohamed[1,3], W. Lems[1,3]. *[1]Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical Center; [2]Epidemiology & Biostatistics, VU University Medical Center; [3]Rheumatology, Amsterdam Rheumatology and immunology Center, Reade, Amsterdam; [4]Rheumatology, Westfriesgasthuis, Hoorn; [5]Rheumatology, Amsterdam Rheumatology and immunology Center, Academic Medical Center, Amsterdam, Netherlands*

**Background:** COBRA and COBRA-light combination therapy are equally effective treatments for early rheumatoid arthritis (RA) after 26 and 52 weeks [1,2], but the long-term effect of start with COBRA-light therapy is unknown.
**Objectives:** To investigate the efficacy of initial COBRA and COBRA-light combination therapy after a 4 year follow-up period. A detailed analysis of long-term safety will be presented separately.
**Methods:** In the COBRA-light trial, 164 patients with recent-onset RA were randomized to either COBRA (prednisolone 60 mg/day, tapered to 7.5 mg/day in 6 weeks; MTX 7.5 mg/week and sulfasalazine 2 g/day; n=81) or COBRA-light therapy (prednisolone 30 mg/day, tapered to 7.5 mg/day in 8 weeks and MTX escalated to 25 mg/week in 8 weeks; n=83). In the period of 26 to 52 weeks; treatment intensification of MTX and addition of etanercept was protocollized (treat-to-target). After 52 weeks, treatment was continued without protocol. Four years after trial initiation, all patients who had initiated therapy (n=162) were invited to participate in the COBRA-light extension study. Main outcomes were: Disease Activity Score in 44 joints (DAS), Health Assessment Questionnaire (HAQ), Sharp – Van der Heijde radiographic Score (SHS) and ACR/EULAR Boolean remission. Longitudinal mixed modeling (DAS), TOBIT (HAQ), and GEE analyses (SHS: log negative binomial; Boolean remission: logit binomial) were performed in STATA.
**Results:** A total of 149 out of 162 original trial patients participated in the extension study (77 COBRA and 72 COBRA-light patients); 2 COBRA vs. 3 COBRA-light patients had died, 1 vs. 5 patients were not able or willing to participate, and 1 vs. 1 patient were in drug-free remission and out of care. After the 52 weeks trial period, 43% COBRA vs. 42% COBRA-light patients used prednisolone for ≥90 days, 34% vs. 44% patients switched to other DMARDs, and 39% vs. 28% patients used biologicals during the follow-up period. After mean 4 years follow-up, 49% COBRA vs. 47% COBRA-light patients had DAS<1.6, 50% vs. 48% had HAQ≤0.5, and 29% vs. 36% had SHS=0. Boolean remission occurred significantly more in the COBRA-light group (12% COBRA vs. 26% COBRA-light; p=0.04). Longitudinal data analyses showed equal effects of both COBRA and COBRA-light therapy on DAS, HAQ, SHS and Boolean remission over time. HAQ and SHS, both indicators of long-term efficacy, showed equal progression in both treatment groups during the 4 year follow-up period (Fig. 1).

Figure 1. HAQ and SHS during the 4 year follow-up period of the COBRA-light extension trial (n=149)

**Conclusions:** Early RA patients initially treated with COBRA or COBRA-light therapy showed similar outcome over a 4 year follow-up period.

## Biomarkers: powerful or powderpuff?

### OP0263 SYNOVIAL B-CELL GENE SIGNATURE PREDICTS RESPONSE TO RITUXIMAB THERAPY

A. Mahto, F. Humby, S. Gregoriadou, N. Ng, K. Blighe, L. Zou, M. Lewis, M. Bombardieri, S. Kelly, C. Pitzalis. *Experimental Medicine and Rheumatology, Queen Mary University, London, United Kingdom*

**Background:** Predicting response to biologic therapies in RA remains a clinical challenge. The anti-CD20 monoclonal antibody Rituximab effectively depletes peripheral blood B-cells, however response rates are approximately 60%. We hypothesized that expression of CD20 in diseased tissue may be an important predictor of response, since up to 40% of patients have few/no B-cells present in the synovium.
**Objectives:** To ascertain whether a synovial B-cell gene signature can enhance prediction of responsiveness to Rituximab therapy and identify genes involved in response/non-response to treatment.
**Methods:** Synovial tissue was obtained using ultrasound-guided synovial biopsies from 20 patients with active RA who were treated with Rituximab therapy after failure of conventional DMARD and anti-TNF therapy. High-throughput quantitative real-time PCR for 190 genes was performed in collaboration with MedImmune (MedImmune, LLC) using the Fluidigm platform. Samples were classified as B-cell "rich" or "poor" according to levels of MS4A1 expression. Using an empirical Bayes statistical model, a further 17 significant ($p<0.05$) genes were identified to create a baseline B-cell gene expression signature. Hierarchical clustering and receiver operating characteristic curve analysis was used to assess ability to predict EULAR criteria response at 16 weeks. Gene expression was compared pre- and post-treatment in responders versus non-responders and correlated with delta DAS-28. Logistic regression with backward and forward selections using AIC was applied to identify further predictive models.
**Results:** Seventeen genes were identified that clustered with MS4A1 expression to create the B-cell signature. Fifteen of these are directly involved in B-cell and plasma-cell signaling or differentiation pathways and immunoglobulin synthesis. Two genes identified within this signature play a pivotal role in antigen presentation and TH17 differentiation. The baseline B-cell signature had an area under ROC curve (AUC) of 0.87 (95%CI 0.76–1.0) to predict response to Rituximab therapy at 16 weeks. Three additional genes were identified segregating responders from non-responders; that when combined with the baseline B-cell signature the AUC improved to 0.95. Additionally, ten genes were identified that significantly correlated with delta DAS-28. High expression of genes involved in the formation of ectopic lymphoid structures and the TH17 lineage correlated with non-response to Rituximab therapy (all $p<0.05$).
**Conclusions:** This study shows that a B-cell rich gene signature has high sensitivity to predict response to Rituximab therapy. High expression of TH17 related genes correlates with non-response to B-cell depletion, indicating that in a subset of patients, these pathways may play a more pivotal role in disease pathogenesis. The observed high expression of ELS associated genes in non-response may relate to variable synovial B-cell depletion; disruption of these follicles may be the key to response, particularly with repeat cycles. These findings warrant confirmation in a larger cohort of patients; however they strongly support the notion that a stratified approach to treatment relies upon the identification of biomarkers, both in the synovium and peripheral blood that reflect heterogenous molecular disease pathways in RA.
**Disclosure of Interest:** None declared

### OP0264 RELATIVE FREQUENCIES OF CIRCULATING T FOLLICULAR HELPER AND T FOLLICULAR REGULATORY CELLS IN AUTOIMMUNE PATIENTS AND HEALTHY CONTROL DONORS AND THE EFFECT OF DISEASE MODULATING THERAPY

A.J. Macdonald[1], K. Cerosaletti[2], J. Chen[2], T.-S. Nguyen[2], S. Posso[2], G. Marchesini[2], M. Abashian[1], A.P. Martin[1], D. De Rosa[1], T. Samanta[1], J. Poorbaugh[1], R.J. Benschop[1], J. Buckner[2]. *[1]ELI. LILLY & Co, Indianapolis; [2]Benaroya Research Institute, Seattle, WA, United States*

**Background:** T follicular helper cells are critical in the formation of autoantibody-producing ectopic germinal centers in seropositive autoimmune diseases and have attracted interest as potential biomarkers of autoimmune disease activity. A further subset with regulatory properties (Tfr) has also been described but, as yet, not well characterized in autoimmune diseases.
**Objectives:** The purpose of this study was to (1) determine the frequencies of Tfh in a range of autoimmune diseases by flow cytometry and a new commercially available Tfh epigenetic marker assay, (2) ascertain if Tfr frequencies vary among AI diseases, (3) determine effect of treatment on Tfh/Tfr frequencies in the autoimmune groups.
**Methods:** Patients were recruited from the Rheumatology or Neurology clinics at the Virginia Mason Clinic in Seattle WA. Healthy controls were recruited from the Seattle community. AI samples were selected regardless of length of disease or therapy; healthy control samples were matched with AI samples for age, gender and race. Cryopreserved peripheral blood mononuclear cells (PBMC) from 50 each of systemic lupus erythematosus (SLE), systemic sclerosis (SSc), multiple sclerosis (MS), rheumatoid arthritis (RA) and healthy volunteers (HV) were analyzed by multicolor flow cytometry for Tfh and Tfr frequencies. Tfh frequencies were also analyzed by a PCR-based assay from Epiontis GmbH, Germany. Initial experiments established that results obtained from fresh versus frozen PBMC were not significantly different. Relative frequencies of Tfh and Tfr were compared among disease/control groups, and in relation to disease activity and concurrent therapies – none, DMARDs, depleting (biologics, Cytoxan, MMF)
**Results:** Elevated frequencies of Tfh were seen in SSc, MS and RA compared with healthy controls, but not in SLE. TFh counts by flow cytometry and Epiontis epigenetic assay were significantly correlated within groups and globally. Tfr percentages were increased in RA, SSc and SLE compared with healthy controls, and the ratio of Tfh/Tfr was reduced in SLE compared with the other study groups. Tfh frequencies were positively correlated with inflammation (ESR) in SLE. Depleting therapy reduced Tfh and/or Tfr frequencies in patients with SLE and SSc.
**Conclusions:** A novel epigenetic marker assay to count Tfh proved to be robust and correlated well with flow cytometry counts. This supports the use of the PCR-based epigenetic marker assay as a replacement for multi-color flow cytometry. This would facilitate standardization of Tfh counts in clinical trials and studies where multiple sites are involved. A range of Tfh and Tfr frequencies were observed in the peripheral blood of patients with autoimmunity, but levels were significantly elevated in SSc, MS and RA patients. In SLE patients, Tfh levels correlated with ESR values and may be indicative of ongoing inflammation. Tfh and/or Tfr levels in SLE and SSc may be modulated though the use of biologics or cytotoxic therapies and further longitudinal studies are indicated.

## The role of nuclear medicine in rheumatology

### OP0265 FEVER OF UNKNOWN ORIGIN (FUO) AND INFLAMMATION OF UNKNOWN ORIGIN (IUO): IS 18F-FDG-PET/CT A USEFUL FIRST LINE DIAGNOSTIC STRATEGY?

V. Schoenau[1], K. Vogel[1], M. Engelbrecht[1], D. Schmidt[2], T. Kuwert[2], B. Manger[1], G. Schett[1]. *[1]Rheumatology; [2]Nuclear Medicine, University Clinic Erlangen, Erlangen, Germany*

**Background:** Fever of unknown origin (FUO) and inflammation of unknown origin (IUO) are rare but diagnostically challenging clinical problems. Because of the abundance of differential diagnoses, a generally accepted diagnostic guideline has not yet been established. Besides a thorough medical history, physical examination, and laboratory testing, imaging techniques are important tools in the diagnostic workup of FUO and IUO. In the last few years, $^{18}$F-FDG-PET/CT has been found to be a suitable diagnostic tool for FUO/IUO, as it is able to detect inflammatory and malignant processes with a high spatial resolution.
**Objectives:** The present study is carried out at to quantify the utility of $^{18}$F-FDG-PET/CT for the diagnosis of FUO and IUO. The study, moreover, evaluates special clinical markers, that increase the possibility of diagnosing FUO or IUO with a $^{18}$F-FDG-PET/CT.
**Methods:** All patients presenting with FUO or IUO at the University Clinic of Erlangen between 2007 and 2015 were clinically documented and subjected to $^{18}$F-FDG-PET/CT scanning. $^{18}$F-FDG-PET/CT scans were considered positive when a focal uptake of the tracer was detected additionally to the standard areas of physiological tracer uptake. $^{18}$F-FDG-PET/CT results were compared to the final diagnosis and classified as helpful or non-helpful in establishing the final diagnosis. Multivariate logistic regression was used to identify clinical parameters that correlated with a helpful $^{18}$F-FDG-PET/CT in patients with and without FUO as well as in patients with and without IUO.
**Results:** Of the 240 patients enrolled 72 presented with FUO, 142 with IUO and 26 did not fulfill FUO or IUO criteria. 235 patients were included in the multivariate logistic regression model. Final diagnosis was established in 190 patients (79.2%). In 136 (56.7% of all patients and 71.6% of the patients with a diagnosis), the $^{18}$F-FDG-PET/CT was helpful in finding the diagnosis. The chance was higher in patients without fever (p=0.003), those aged >50 years (p=0.002; p=0.005, respectively) and those with a CRP level >30 mg/dl (p=0.003; p=0.008, respectively).

| Category | N (%) FUO patients in category | N (%) IUO patients in category | N (%) non-FUO/IUO patients in category |
|---|---|---|---|
| Infection | 11 (15.3%) | 17 (12.2%) | 0 (0%) |
| Malignancy | 5 (6.9%) | 11 (7.9%) | 2 (8.0%) |
| Chronic inflammatory diseases | 35 (48.6%) | 86 (61.9%) | 10 (40.0%) |
| Miscellaneous | 1 (1.4%) | 2 (1.4%) | 6 (24.0%) |
| No diagnosis | 20 (27.8%) | 23 (16.5%) | 7 (28.0%) |
| Total | 72 (100%) | 142 (100%) | 26 (100%) |

**Conclusions:** Our study shows that if the standard diagnostic tests (laboratory, chest x-ray and abdominal ultrasound) did not identify the cause of FUO/IUO, $^{18}$F-FDG-PET/CT scanning should be applied in the early stage of the diagnostic

process. An early use of an $^{18}$F-FDG-PET/CT is especially helpful to establish a final diagnosis in patients with an elevated C-reactive protein and age over 50 years.

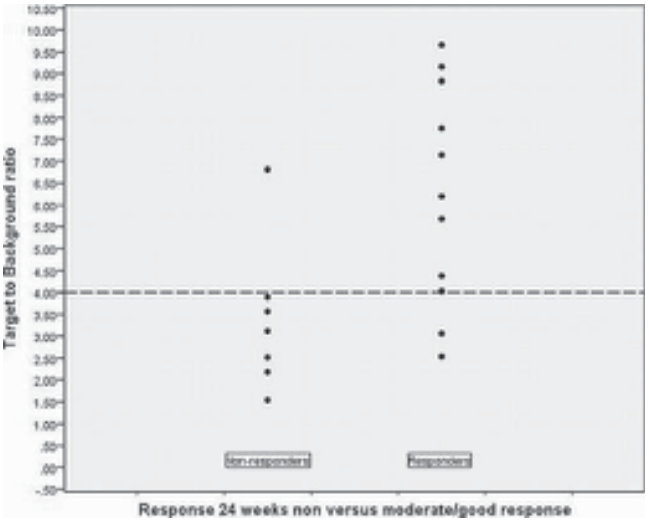
### OP0266 BASELINE 89ZR-RITUXIMAB PET MAY PREDICT THERAPEUTIC RESPONSE 24 WEEKS AFTER INITIATION OF RITUXIMAB TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS



S.T.G. Bruijnen[1], M. Tsang-A-Sjoe[1], H. Raterman[1], T. Ramwadhdoebe[2], D. Vugts[3], G. Van Dongen[3], M. Huisman[3], O. Hoekstra[3], P. Tak[4], A. Voskuyl[1], C. Van der Laken[1]. *[1]VU University Medical Center; [2]Academic Medical Center, Amsterdam Rheumatology and immunology Center; [3]Department of Radiology & Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands; [4]GlaxoSmithKline, Stevenage, United Kingdom*

**Background:** Rituximab (RTX) is an effective treatment of rheumatoid arthritis (RA) after failure or intolerance to TNF blockers. Nevertheless, still 30–50% of RA patients does not respond. Therefore, identifying patients with favourable response to RTX is important in order to further optimize treatment for the individual patient. *In vivo* imaging of biodistribution of radiolabelled RTX in RA by Positron Emission Tomography (PET) might provide a tool to fulfil this unmet clinical need.

**Objectives:** To investigate the association of *in vivo* biodistribution of Zirconium-89 (89Zr-)RTX in RA patients starting with RTX treatment and clinical response at 24 weeks post injection (p.i.).

**Methods:** We included 20 anti-B cell therapy naïve RA patients (female18/20; age 53±11; DAS28 5.4±1.2) who started RTX treatment according to standard clinical protocol (without methylprednisolone). The first RTX infusion (1000 mg) was directly followed by infusion of 10 mg-18 MBq 89Zr-RTX. Whole body and PET-CT images of wrists/hands (n=22 joints/patient) were performed three days p.i. After 24 weeks of therapy, response was defined according to the EULAR response criteria (DAS28 at endpoint $\leq$5.1 and/or deltaDAS28$>$0.6) (1). 89Zr-RTX uptake was assessed visually (blinded for clinical data) and quantitatively by drawing volumes of interest (VOI) on PET positive tissues/joints. Standardized uptake values (SUVs) were calculated and background ROIs were drawn on metacarpal bone to calculate target-to-background (T/B) ratios.

**Results:** At 24 weeks 13/20 patients were moderate to good responders to RTX. Whole body PET images showed 89Zr-RTX distribution in liver, spleen, kidneys, blood pool, lymph nodes (LN) (9/20pts) and in shoulders/elbows (9/20pts), without statistically significant SUV differences between responders and non-responders. Detailed hand images showed PET positive joints in 18/20 patients (ranging 1–20 joints/patient). Clinical responders had significantly higher 89Zr-RTX uptake in visually positive joints than non-responders (SUV: 3.2±1.4 vs 2.1±1.1 [p=0.04]; T/B ratios 6.2±2.5 vs. 3.4±1.7 [p=0.015], respectively). Using a T/B cut-off value of 4.0, positive predictive value and negative predictive value for response were respectively 90% and 75%, at a sensitivity of 82% and specificity of 86% (Fig 1). In contrast, no association was found between any clinical disease or serological (including a-CCP/RF) parameters and clinical response at 24 weeks.

**Conclusions:** 89Zr-RTX PET-CT clearly visualizes arthritic joints in RA patients. Significant differences in baseline quantitative 89Zr-RTX uptake in PET positive hand joints were found between responders and non-responders to RTX treatment at 24 weeks. Our data point at a promising clinical value of 89Zr-RTX PET to predict at baseline the therapeutic response to RTX and therefore has potential for stratification of RTX treatment in RA. Further validation is required in larger cohorts.

## PROMs/PROs in rheumatological research - time for a critical appraisal?

### OP0267-HPR A SURVEY OF PATIENT REPORTED EXPERIENCE, PATIENT REPORTED OUTCOME AND WORK IN PATIENTS WITH INFLAMMATORY ARTHRITIS SEEN IN NURSE LED RHEUMATOLOGY CLINICS IN THE UK

D. Homer on behalf of The West Midlands Rheumatology Nurse Specialist Network. *Community rheumatology service, Modality Partnership, Birmingham, United Kingdom*

**Background:** Measuring patient experience (PREMs) and Patient reported outcomes (PROs) in the health care setting have become a priority in health care in the past 5 years. Collection of these measures enables quality, safety and value of care delivered to be demonstrated. In response to a need to collect patient outcomes both the National Rheumatoid Arthritis Society and the British Society for Rheumatology in the UK have devised PREMs and PROs questionnaires to support the commissioning, provision and performance of rheumatology services. Additionally the British Society for Rheumatology is piloting these questionnaires across the UK as part of the Health Quality Improvement Programme (HQIP).

**Objectives:** The WMRNSN piloting PREMS, PROs and Work questionnairs in clinic practice. To demonstrate quality of care provided and identifying gaps quality of patient care.

**Methods:** The format of the questionnaire following approval by a local rheumatology patient group and research and development approval obtained from 7 hospital Trusts across the West Midlands. The questionnaire was then used to survey 309 inflammatory arthritis patients seen in rheumatology nurse led clinics during May – July 2015. Patients completed and submitted the questionnaire anonymously following a clinic visit and the author extracted and analysed the data.

**Results:** The WMRNSN have shown 309 patients with inflammatory arthritis seen in rheumatology nurse led clinics had a positive experience of care in the past year. Negative experiences were patients reporting not being aware of the following:

1. Referral to other members of the multidisciplinary team was available
2. Information available was available about UK based national support groups
3. There was opportunity to attend a self- management course
4. Family members could attend consultations to help them make treatment decisions
5. They could discuss personal and intimate issues.

Patient reported if appointments were suddenly cancelled or if they needed to be seen sooner they wait 4 weeks or more to be seen. A third of patients reported poor disease control preventing them from managing day to day which was concordant with the PROs visual analgoue scores which were on average 4.9 or great for pain, sleep, fatigue, physical disability, emotional wellbeing, physical well being and pain. The work questionnaire reported unhelpful data in that; the age ranges do not reflect working ages within the UK nor identify the nature of work e.g. Studying, working from home, raising children, homemakers or retired. Additionally it does not capture hours worked or the difficulties experienced by patients regarding work. A fact sheet has been developed by the WMRNSN to provide patient information on these issues.

**Conclusions:** We suggest collection of PROMS and work data is more useful to patients when used individually during their appointment. The Trusts who took part have their results and as evidence for nurses' revalidation. Finally PREMS, PROs and Work data we recommend routinely collecting this data to demonstrate quality, improve patient experience and health outcome. Resources and IT needs to be available to facilitate this.

OP0268 **THE EULAR OUTCOME MEASURE LIBRARY, AN EVOLUTIONAL DATABASE OF VALIDATED PATIENT-REPORTED OUTCOMES: USE AND DISSEMINATION IN THE FIRST TWO YEARS**

I. Castrejon[1], L. Gossec[2], L. Carmona[3]. *[1]Rheumatology, Rush University Medical Center, Chicago, United States; [2]Rheumatology, Pitié Salpêtrière Hospital, Paris, France; [3]Rheumatology, Instituto de Salud Musculoesquelética, Madrid, Spain*

**Background:** Patient reported outcomes (PROs) are being more frequently used in rheumatology to evaluate treatment response and to guide clinical decisions. In order to standardize and enhance the use of these measures a structured database including the main cross-culturally validated PROs in rheumatic and musculoskeletal diseases was developed: the EULAR Outcomes Measure Library (OML)[1]. This is an in-progress library led by rheumatologists freely available online since November 2013 (http://oml.eular.org/) and connected to the main EULAR website.
**Objectives:** To evaluate the use and dissemination of the EULAR OML during the first two years of functioning.
**Methods:** The EULAR OML includes to date 138 measures covering any domain of health identified through systematic reviews. The PROs are generic (across diseases) or specific, being the most represented diagnosis rheumatoid arthritis (RA) (33 instruments), osteoarthritis (OA) (27), spondylarthritis (23), fibromyalgia (21), systemic lupus (20), low back pain (15), osteoporosis (12), and juvenile idiopathic arthritis (6). The PROs search can be performed by disease, domain, or language. All PROs are validated at least in English but versions in other languages are also included being the most frequent cross-validated versions in French (54 instruments), Spanish (53), Dutch (49), and German (46). A glossary with validation aspects is available for educational support. The OML is regularly updated using search strategy alerts in PubMed and based on a network of volunteers, who may propose the inclusion of new instruments. A summary of the statistics of the website is presented.
**Results:** Over the first two years, the OML has been increasingly used with an accumulated 41,641 page views and 25,926 visits (Figure). The mean of visits per month is 571 with a mean of 333 new visitors per month. Tuesdays and Wednesdays are the peak days for visits. The PROs being downloaded most frequently are: the evaluation of ankylosing spondylitis quality of life (EASI-QOL) (11.6%), the multidimensional health assessment questionnaire (MDHAQ) (8.8%), the RA quality of life scale (RAQoL) (7.4%), and the Western Ontario McMaster OA index (WOMAC) (3.4%). The devices more frequently used are iPad (42%), android (31%), and iPhone (26%). The European countries with most users are France and Germany (15% each), The United Kingdom (13.7%), Ukraine (9.4%), and Spain (6.7%). Other non-European countries are also users of the Library, in particular the United States of America (19.8%), and China (12.5%).

**Conclusions:** The use of the EULAR OML freely available website is increasing over time. This website includes a detailed description of each instrument, recommendations for use, information about validation, and versions in different languages. There are many instruments that still need to be included. We expect that unified access to this information will contribute to a better use of PROs. We invite everyone to contact us if willing to contribute to keep the EULAR OML updated and useful.

## Collaboration for success. User-centred design for improvement of health services

OP0269-HPR **PATIENT PARTICIPATION IN MULTIDISCIPLINARY TEAM CARE: VIEWS OF PATIENTS AND HEALTH CARE PROFESSIONALS**

E. Kuijpers, J.W. Luites, J.E. Vriezekolk. *Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

**Background:** A hallmark feature of multidisciplinary team care is patient-centeredness; every aspect of patient's health status is systematically evaluated and the treatment goals and plans for interventions are jointly set, evaluated, attuned.[1] But the perceptions and values of patients and health care professionals (HCPs) about the role and degree of active involvement of patients in team care has received little attention.
**Objectives:** To explore patients' and HCPs views on the meaning and role of patient participation in team care, and to explore the experiences of patient membership in team conference.
**Methods:** This study was conducted before and after the introduction of patients in team conference. To explore the views about patient participation semi-structured face-to-face interviews were held with 10 patients with rheumatic diseases eligible for or participating in multidisciplinary treatment and 12 HCPs. After the introduction of patients' membership in the team conference, telephone interviews with 8 patients and a focus group (n=5) with HCPs were held. The interviews and the focus group were audiotaped and described verbatim. Thematic content analysis of the interviews were performed by two researchers independently and discussed until consensus was reached. Similarly, data of the telephone interviews and focus group were analysed and identified topics were discussed by a rheumatology nurse and a researcher.
**Results:** Participants described patient participation in terms of an active participatory behaviour of the patient (e.g. willingness to change, motivation, asking questions, expressing their own opinions, treatment adherence), an open respectful dialogue between patients and HCPs based on trust and equality, and (shared) responsibility of treatment. Participants indicated that patients' involvement in team care varied, from passive receiver to meaningful exchange between patients and HCPs. Opportunities for improvement were identified: improving information about the treatment, facilitating patient involvement in goal-setting, planning and evaluation of treatment, and stimulating patient's responsibility of care. After the introduction of patients in team conference, the evaluation of patient membership revealed that although some patients felt tense the atmosphere felt safe and they experienced a honest, transparent and respectful interaction between themselves and HCPs. Patients felt they were taken seriously and that their needs were taken into account, the treatment goals were set in mutual agreement and the resulting therapeutic interventions were clear and satisfactorily. HCPs valued patient's membership in team conference, although they needed to get used to it. HCPs experienced an open, honest and truthful team dialogue and a truly shared treatment plan leading to more patient commitment to treatment. The limited time, prior to team conference, to formulate a draft treatment plan to be discussed during the team conference, was seen as a disadvantage, especially in complex cases.
**Conclusions:** Patients and HCPs highly valued patient's membership in the multidisciplinary team conference. Treatment plans were developed in partnership between patients and HCPs, and team interaction was based on mutual trust and respect. This study underscores the value of stimulating partnership in team care.

## ER stress & rheumatic disease

OP0270 **TARGETING IL-23 CAN ATTENUATE PROGRESSION OF SPINAL ANKYLOSIS IN ANKYLOSING SPONDYLITIS**

S. Jo[1], B.S. Koo[2], B.S. Koo[2], I.-H. Sung[3], I.-H. Sung[3], Y.-S. Park[4], Y.-S. Park[4], C.-B. Choi[1], C.-B. Choi[1], T.-H. Kim[1], T.-H. Kim[1]. *[1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Disease, Seoul; [2]Division of Rheumatology, Department of Internal Medicine, Konkuk University College of Medicine, Chungju; [3]Department of Orthopaedic Surgery, Hanyang University Hospital for Rheumatic Disease, Seoul; [4]Department of Orthopaedic Surgery, Hanyang University Hospital for Rheumatic Disease, Guri, Korea, Republic Of*

**Background:** IL-23 has been implicated in the development of ankylosing spondylitis (AS). The role of IL- 23 in AS pathogenesis has emerged as a therapeutic target. This study aimed to clarify that anti IL-23 blockade can prevent progression of bony ankylosing in AS patients.
**Objectives:** We investigated endoplasmic reticulum (ER) stress and IL-23 cytokine could play a role in human bone-derived osteoblast cells and blocking it leads to regulation of bone-related genes and/or preventing bone ankylosis in AS.
**Methods:** Primary human osteoblast cells were isolated from diced bones of facet joints which were taken from surgical operation of 8 AS patients and 8 healthy controls (HC). The tissues of facet joints in AS were stained and compared with those of HC. Osteoblast differentiation- and ER stress-related genes were determined by quantitative RT-PCR, immunoblotting, immunofluorescence, and immunohistochemistry. Osteoblast activity of all bones-derived osteoblast cells was confirmed by Alkaline Phosphatase activity (ALP) and Alizarin Red (ARS) staining. The ER stress by BIX, selective BIP inducer X, in the regulation of IL-23 expression and secretion was evaluated by quantitative RT-PCR and ELISA.
**Results:** We found that elevated RUNX2, BIP, and IL-23 protein expressions were observed at osteoblast cells in human AS compared to HC. In addition, mRNA levels of bone differentiation (ALP, BMP2, COL1A, RUNX2, C/EBPβ, OPG, and OCN) and ER stress (BIP and CHOP)-related genes were highly expressed in human AS. In particular, IL-23 and RUNX2 expressions were

significantly increased in AS. BIX-mediated ER stress stimulated induction of osteoblast activity and IL-23 secretion via modulating RUNX2 and C/EBPβ genes. Intriguingly, RUNX2 Knockdown by shRNA impeded ER stress-induced effects. Moreover, osteoblast activity and RUNX2 expression in AS were significantly reduced by IL-23 blockers, but not TNFα blockers.
**Conclusions:** This is the first report to show that ER stress, osteoblastic activity, and IL-23 expression in AS were increased compared to HC, suggesting that sustained ER stress induces osteoblast activity and IL-23 expression. Notably, these effects in AS were reduced by IL-23 blockade. Taken together, our results supported that blocking IL-23 may represent a promising therapeutic target to assist and prevent bony progression in AS.

### OP0271 PERK PATHWAY CHARACTERIZATION IN LABIAL SALIVARY GLANDS OF SJÖGREN SYNDROME'S PATIENTS: COULD IT BE AN ADAPTIVE RESPONSE?

V. Bahamondes[1], S. Aguilera[2], J. Cortés[1], I. Castro[1], M.-J. Barrera[1], U. Urzúa[1], S. González[3], C. Molina[3], C. Leyton[1], M.-J. González[4]. *[1]ICBM, Facultad de Medicina, Universidad de Chile; [2]Reumatología, Clínica INDISA; [3]Patología Oral, Universidad Mayor; [4]Programa Biología Celular y Molecular, ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Chile*

**Background:** Labial-salivary-glands (LSG) of Sjögren's syndrome (SS) patients show an altered exocytic route that can induce endoplasmic reticulum (ER)-stress and activate the unfolded-protein-response (UPR)[1,2]. UPR helps to recover and preserve cellular homeostasis, reducing the load of unfolded proteins in the ER, through various mechanisms of cell survival. UPR is mediated by the activation of IRE1α, PERK and ATF6 sensors.Chronic activation of ER-stress sensors exhibits a time course-kinetics with attenuation of IRE1α pathway and sustained signaling of PERK and ATF6 pathways[3]. We have observed in SS-patients a decrease of IRE1α pathway activity[4] and an increase of ATF6 pathway activity[5].
**Objectives:** Considering that PERK pathway reduces levels of unfolded proteins by increasing expression of pro-survival or pro-apoptotic components, here our purpose was to evaluate the expression of PERK pathway components and its relation with an adaptive response of LSG from SS-patients.
**Methods:** RNA and proteins were extracted from LSG of 11 SS-patients and 12 controls. Expression of PERK pathway components was determined by q-PCR and Western-blot. Localization was addressed by immunofluorescence.
**Results:** Compared to controls, LSG of SS-patients showed a significant increase of pPERK/PERK ratio but no changes of peIF2α/eIF2α ratio. Also, an increase of ATF4 and CHOP protein levels were observed, which correlated with clinical parameters including scintigraphy and serology. On the contrary, significantly decreased expression of ERO1α, PDIA1 and PDIA4 (proteins involved in protein folding), and NRF2 (transcription factor) protein levels, an additional PERK substrate involved in the response to oxidative stress, were detected. Interestingly, SS-patients showed a significant increase of expression of Xc- system subunits, which is involved in glutathione synthesis. PERK, ERO1α, PDIA1, PDIA4, eIF2α and peIF2α were located in the basal cytoplasm of acinar cells, while eIF2α and peIF2α were also observed in the nucleus. NRF2 localized in cytoplasm and lateral plasma-membrane, next to E-cadherin.
**Conclusions:** PERK pathway is activated in LSG of SS-patients and controls; indicating that both are developing UPR. Considering that ATF4 mediates an integrated response to cellular stress[6], its increased expression in SS-patients and its correlation with clinical data and $Xc^-$ expression, suggest that ATF4 could be part of an adaptive response against cellular stress. In addition, expression of ERO1α, PDIA1 and PDIA4 suggests alterations of the protein folding process. Finally, NRF2 protein levels and its location suggest an altered oxidative stress response.

## Joint EULAR - EFIS session: Do stromal cells house and cure immune cells?

### OP0272 IDENTIFICATION OF NEW INHIBITORS OF ANGIOGENESIS IN A NOVEL 3D MODEL OF RHEUMATOID ARTHRITIS SYNOVIAL ANGIOGENESIS

C.X. Maracle[1], P. Kucharzewska[2], B. Helder[1], H. Olsson[2], S.W. Tas[1]. *[1]Amsterdam Rheumatology and immunology Center | Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands; [2]Astra Zeneca, Gothenburg, Sweden*

**Background:** Angiogenesis contributes to rheumatoid arthritis (RA) pathogenesis, however, many models focus solely on endothelial cells (EC). We developed a 3D-spheroid model including both EC and RA fibroblast-like-synoviocytes (FLS) to study angiogenesis associated with RA and to test the efficacy of several inhibitors targeting this process. Previous work demonstrated a role for the non-canonical NF-κB pathway and its main regulator, NF-kB inducing kinase (NIK), in pathological angiogenesis and thus we aim to use the 3D model to further characterize its contribution to neovascularization.
**Objectives:** Generate a representative 3D *in vitro* model of RA synovial angiogenesis and screen the effects of targeting the non-canonical NF-κB pathway using siRNA or small molecule pharmacological inhibitors.
**Methods:** Human primary EC were co-cultured with RA FLS after pre-incubation with cell tracker dyes and incubated overnight to form spheroids. Subsequently, spheroids were plated in collagen gel and stimulated with 10% RA SF, growth factors (GF) or well-known activators of non-canonical NF-kB signaling (lymphotoxin beta (LT) or LIGHT). To establish NIK dependency, EC were pre-transfected with NIK-targeting siRNA before incorporation into spheroids. Furthermore, several pharmacological inhibitors were screened for their ability to block sprout formation. Spheroids were imaged by confocal microscopy and quantified using Leica QWin Plus software.
**Results:** We established a robust 3D model of angiogenesis containing both EC and RA FLS. LT, LIGHT, RA SF and GF stimulations led to significant increases in sprout formation as compared to basal conditions ($p<0.05$). The LT and LIGHT induced sprout formation proved to be NIK dependent as spheroids containing EC transfected with NIK targeting siRNA had significant reductions in vessel formation as compared to the non-targeting controls ($p<0.05$). Sprouting promoted by GF and RA SF was significantly blocked by the angiogenesis inhibitor Anginex ($p<0.05$). Finally, targeting of the non-canonical pathway using a small molecule pharmacological NIK inhibitor significantly reduced sprout formation caused by LT and LIGHT, and importantly also RA SF-induced sprout formation ($p<0.05$).
**Conclusions:** We developed a novel 3D model that incorporates essential elements of synovial inflammation, namely EC, RA FLS and RA SF, which proves to be an effective tool for studying synovial angiogenesis. Using this system, we have further demonstrated a role for the non-canonical NF-kB pathway, and its central regulator NIK, in neovascularization associated with RA. Moreover, we have shown that the 3D model is useful for testing small molecule inhibitors of angiogenesis and found that targeting non-canonical NF-kB signaling is an effective method to block pathological angiogenesis.
**Disclosure of Interest:** None declared

### OP0273 EFFECTS OF TUMOR NECROSIS FACTOR ALPHA ON CYTOKINE SECRETION OF SYNOVIAL FLUID-DERIVED MESENCHYMAL STEM CELL-LIKE CELLS

Z. Vereb[1], A. Váncsa[2], M. Pilling[1], G. Petrovski[1], Z. Szekanecz[2]. *[1]Department of Ophthalmology, University of Szeged, Szeged; [2]Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary*

**Background:** Rheumatoid arthritis is characterized by painful joint swelling, cartilage and bone destruction, chronic inflammation of the synovium (synovitis) with the accumulation of synovial fluid into the joint cavity. Within the synovial fluid the number of MSC-like cells (SYF-MSC) is increasing during the active phase of the disease. MSC are able to mediate immunosuppression via cell-cell contact and secreted factors respectively.
**Objectives:** Our goal was to screen the secreted proteins by SYF-MSCs under pro-inflammatory conditions.
**Methods:** Synovial fluid was harvested from patients with active RA (according to the Guidelines of the Helsinki Declaration). The isolated fluid/cells were cultured *in vitro,* their expression of well-known MSC markers as well as their differentiation potential was tested. SYF-MSCs were treated with human recombinant TNF alpha (TNFa) for 24 hour than the secreted cytokines were determined by high throughput protein array.
**Results:** SYF-MSCs secreted aggrecan, angiogenin, chitinase 3 like-1, Dkk-1, DPPIV, EMMPRIN, FGF-19, GM-CSF, IGFBP-3, IL-6, IL-17A, MCP-1, PDGF-AA, Pentraxin-3, Resistin, SDF-1α and Thrombospondin-1 under normal condition. Treatment by TNFa decreased the level of the secreted chitinase 3 like-1 (544003±56200.85; Pixel density, Mean±SD) and Dkk-1 (388062.5±10488.51) compared to untreated controls (721671.5±10434.77 and 705830±16013.14).

Beside this phenomenon the pro-inflammatory provocation increased the secretion of IL-6 (from 79140±6940.96 to 615191±73256.26), MCP-1 (283985.5±25964.25 to 846348±81354.05), furthermore induced the release of IL-(8743315±71580.42) IL-24 (32189±29555.65) and RANTES (641698±26383.57). Unlike untreated cells no resistin, empirin and SDF-1 could be detected after TNFa exposure.
**Conclusions:** The *in vitro* data suggest that TNFa is able to turn SYF-MSCs to a pro-inflammatory phenotype, which may play a role in the inflammatory processes of RA prolonging the active phase of the disease.
**Disclosure of Interest:** None declared

## Role of imaging in childhood-onset rheumatic diseases

### OP0274 QUANTIFICATION OF DYNAMIC MRI EXAMINATIONS IN JUVENILE IDIOPATHIC ARTHRITIS

N. Tzaribachev[1], R. Hagoug[2], P. Louka[2], C. Trentin[2], O. Kubassova[2], M. Hinton[2], M. Boesen[3]. *[1]PRI - Pediatric Rheumatology Research Institute, Bad Bramstedt, Germany; [2]Image Analysis Ltd, London, United Kingdom; [3]Department of Radiology, Copenhagen University, Copenhagen, Denmark*

**Background:** In chronic inflammatory conditions, the need for a more objective measurement of disease activity has been identified. Imaging biomarkers based on the automated quantification of dynamic contrast enhanced magnetic resonance images (DCE-MRI) have been studied in adult patients with rheumatoid arthritis (RA)[1]. In children with juvenile idiopathic arthritis (JIA) similar knowledge is very limited.
**Objectives:** To compare treatment changes of clinical scores in patients with JIA and automated DCE-MRI quantitative parameters analysed with a dedicated software - Dynamika[tm].
**Methods:** In 8 Caucasian patients (7 girls, median age 13,6 years) with polyarticular JIA, who underwent standardized DMARD treatment, DCE-MRI of the metacarpophaleangeal (MCP) 2–5 joints in the most affected hand were performed at 3 time points: baseline (BL), month 3 and 6 of treatment using 0.2 Tesla Esaote C-Scan. Clinical scores included active joints (AJ), swollen joints (SJ), tender joints (TJ) and joints with limited range of motion (LJ) divided into 3 levels: joint level (the MCP), region level (the hand) and global level (all joints). DCE-MRI were analyzed using a region of interest covering synovium of MCP 2–5. Output parameters included DEMRIQ-ME (Maximum Enhancement) and -IRE (Initial Rate of Enhancement). DEMRIQ is a perfusion/inflammation imaging biomarker and combines the volume of synovial inflammation (GD-map based statistics) and the degree of perfusion (ME-map or IRE-map based statistics), either as volume (classified pixels) or intensity (ME/IRE) or a combination of both (DEMRIQ score).
Differences in DEMRIQ scores between visits, were analyzed using the t-test ($p<0.05$ = statistically significant, $p<0.25$ = clinically meaningful). Correlations were also assessed using the Pearson's Correlation Coefficient.
**Results:** At 3 months all patients showed statistically significant and/or clinically meaningful changes mainly in DEMRIQ-ME, 6 patients in parallel with clinical improvement. Two patients worsened in DEMRIQ-ME despite clinical improvement. At 6 months, six patients continued clinical improvement. In all but one, DEMRIQ-ME persisted or worsened (compared to previous examinations) and patients had a clinical flare within 2 to 6 months after last DCE-MRI. One patient had persistent clinical activity with corresponding DEMRIQ-ME score. Another patient showed clinical worsening and improvement in DEMRIQ-ME, where clinical improvement followed later during disease course. Thus a persistent/rising DEMRIQ-ME compared to previous examinations predicted clinical flare in a timeframe between 2 and 6 months after last DCE-MRI, despite of global clinical improvement.
**Conclusions:** Dynamika based scores (mainly DEMRIQ-ME) show to be useful for depicting disease activity in JIA. In particular, the DEMRIQ-ME correlated with clinical activity over time especially after 3 months. Moreover, persistence or worsening of Dynamika based scores could predict clinical flares (in this study within 2–6 months) despite of global clinical improvement. Dynamika based DCE-MRI calculations could be of high importance for disease management and a supportive tool in treatment decisions in pediatric rheumatology.

### OP0275 PREVALENCE OF ULTRASOUND-DETECTED FINDINGS IN FOOT IN JUVENILE IDIOPATHIC ARTHRITIS VERSUS HEALTHY CHILDREN: ASSOCIATION TO PAEDIATRIC FOOT POSTURE

P. Collado[1], M.L. Gonzalez[2], M. Alcalde[1], C. Calvo[3], R. Diaz-Delgado[3], R. Morales-Lozano[2]. *[1]Rheumatology, Hospital Universitario Severo Ochoa; [2]Podiatry, Clínica Universitaria de Podología, UCM; [3]Paediatric, Hospital Universitario Severo Ochoa, Madrid, Spain*

**Background:** Foot problems have been reported in several JIA categories, even though children rarely complain symptoms. Besides synovitis, peri-articular manifestations have been associated with reduced joint ranges-of-motion and deformities. Musculoskeletal ultrasound (US) is more sensitive than clinical examination for detecting signs of inflammation. It becomes an accessible tool with an ongoing role on the foot care in JIA. Consequently, the clinical relevance of what is considered as a normal or pathological US finding needs to be more precisely clarified.
**Objectives:** 1. To determine and to compare prevalence of US-detected findings in JIA patients and healthy children. 2. To examine associations of foot US-findings to foot abnormalities using objective podiatry assessment.
**Methods:** Eighty-four children (168 feet), 29 children with a definitive diagnosis of JIA (ILAR criteria) and history of foot/ankle complains were recruited from the outpatient paediatric rheumatology clinic at our Hospital as well as 55 healthy children. The participants underwent clinical, podiatrist and US assessment. The sonographer, who was blinded to the clinical and podiatrist details, performed gray- scale and power Doppler (PD) bilateral evaluation at each site of study (8 joints, 8 tendons and 2 entheseal insertions per foot). Joint recess distension, tenosynovitis, abnormal echogenicity or thickening of entheseal insertion, and PD signal were assessment (dichotomous score: absence or presence). The podiatry assessment included the following measures: 1) footprint evaluation on podoscope, 2) the calcaneus relaxed position test (RCSP), 3) the foot postural index (FPI-6), 4) the standing heel-rise test (SHRT) the Jack test or Hubscher maneuver.
**Results:** The JIA group included 17 girls and 12 boys (mean age, 9.3 ± 4.6 years old), oligoarthritis was the commonest category and disease duration was 53.4 ± 49 months. No statistical differences were found for demographic characteristics between the two groups.
Forty-six children had at least one US abnormality (20, JIA and 26, control). Distension of the dorsal recess in the first metatarsophalangeal (MTP1) was the most frequently detected finding (32 JIA feet and 46 controls; 52% and 41.8% of feet in each group respectively) without statistical differences ($p>0.05$). The presence of distension of the anterior tibiotalar joint (TA) and anterior subtalar joint was always associated with the presence of disease. The presence of tenosynovitis and enthesitis was associated as well.
The podiatry assessment showed several findings: joint hypermobility of MTF1was frequently detected in the study population, mostly in JIA ($p=0,001$), and the association between abnormal FPI/ footprint and US findings (distension of the anterior subtalar and MTP2 joints) ($p<0.05$).
**Conclusions:** This study describes the prevalence and location of US findings in the paediatric foot. Distension of the MTP1 joint was quite common in childhood and it was associated to joint hypermobility. FPI seems to be associated with the presence of anomalies of TA, subtalar and MTP2 joints in children with JIA. Further studies are needed to confirm these results.

## Physician-patient relationship in the era of interactive media

### OP0276 POSTGRADUATE RHEUMATOLOGY EDUCATION FOR HEALTH PROFESSIONALS IN RHEUMATOLOGY: AVAILABILITY, NEEDS AND BARRIERS

T.P. Vliet Vlieland[1], C. Van Den Ende[2] on behalf of Educational Subcommittee of the EULAR Standing Committee of Health Professionals in Rheumatology. *[1]Orthopedics, LUMC, Leiden; [2]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

**Objectives:** To explore the availability of postgraduate education for rheumatology health professionals (HPs) in Europe, to define HPs' educational needs, including Eular's role and its activities across Europe, and to identify potential barriers.
**Methods:** An interview guide to obtain information from national representatives of rheumatology HPs' organisations and an online survey for individual HPs were prepared by a team of HPs from multiple disciplines, two rheumatologists and a patient representative (Educational subcommittee of the Eular Standing Committee of Health Professionals in Rheumatology). The interviews were conducted by telephone or in person by members of the team. The English online survey was translated into Czech, Danish, French, German, Portuguese, Spanish, Swedish and Turkish. The interviews and survey comprised questions on: availability of postgraduate education, familiarity with Eular and its educational offerings, needs regarding the contents and mode of delivery of education and

potential barriers to participate in education (0–10 scales). Access information for (translated versions of) the online survey was circulated to national representatives of rheumatology HPs' organisations for dissemination among their contacts, to individual HPs who had once visited the Eular annual congress, and was announced on the EULAR Website and in the Eular HPs' newsletter.
**Results:** Interviews with representatives from 17 countries were conducted. Overall, the number of countries where postgraduate rheumatology education was reported to be available was 13/17 for nurses, 8/17 for physical therapists and 7/17 for occupational therapists, and 3 or less countries for other disciplines. There were 1041 responses to the online survey (216 English and 824 translated version), from 19 European countries. The mean (SD) age of the respondents was 41 (11) years, 897 (86%) were female. 545 (56%) were familiar with Eular, 201 (21%) had once or more attended the Eular annual conference, and 137 (14%) were familiar with Eular online courses. Educational need scores were highest for "Inflammatory arthritis" (6.5 SD 2.8) and "Connective Tissue Diseases" (6.5 SD 2.7) regarding content and for "Courses in English organised in own country" (5.7 SD 3.5) and "Eular online course" (5.7 SD 3.4) concerning mode of delivery. The most important perceived barriers to participate in educational offerings included "Lack of resources" (7.2 SD 2.8), "Lack of time" (5.8 SD 2.9) and "Lack of mastery of the English Language" (5.8 SD 3.4; Participants in translated survey only).
**Conclusions:** With the exception of education for nurses, there is a lack of postgraduate rheumatology education for HPs in the majority of countries. There are opportunities to raise familiarity with Eular and its educational offerings, with considerable interest in online courses and courses provided in HPs' own country with lack of English language skills being an important aspect to take into account.
**Acknowledgement:** This project was financially supported by Eular.
**Disclosure of Interest:** None declared

### OP0277-PARE PATIENT RESEARCH PARTNERS INVOLVED IN A PROJECT TO ENHANCE DISEASE-ASSOCIATED COMMUNICATIONS SKILLS OF RHEUMATOID PATIENTS

J. Clausen[1], P. Böhm[2], E. Farin-Glattacker[3], A. Thyrolf[4]. *[1]Deutsche Rheuma-Liga Bundesverband e.V., Bonn; [2]Deutsche Vereinigung Morbus Bechterew Berlin-Brandenburg e. V., Berlin; [3]Institut für Qualitätsmanagement und Sozialmedizin, Universitätsklinikum Freiburg, Freiburg; [4]Institut für Rehabilitationsmedizin, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany*

**Background:** Patients with chronic diseases often have to conduct conversations that are associated with their disease, either to pursue their own interests or to justify their personal restrictions. The ability to communicate with confidence may be considered a precondition for social participation. Because social participation is one of the key concerns of the Deutsche Rheuma-Liga (DRL), the DRL has funded a research project for enhancing the communication skills of people suffering from rheumatic diseases. The project involved key participation by DRL's- patient research partners (PRPs), who related their own communication limitations as well as providing input to the design of a novel programme of communication skill training. The experience gained and the various contributions of the PRPs will be presented.
**Objectives:** The aim of the project was the inclusion of PRPs in a scientific study that identifies, and subsequently seeks to enhance, those areas of life in which patients with rheumatic diseases experience the most problems during conversations.
**Methods:** PRPs were trained during a two-day interactive training course based on EULAR recommendations. Obstacles during disease-associated conversations were identified via an online questionnaire. The results of this analysis fed into a new programme of communication skills training.
**Results:** The PRPs felt they were being treated on equal terms and that they were being taken seriously by the researchers. Their proposals were implemented by the researchers, if possible, and they took part in all substantial meetings of the research project. The PRPs were actively involved in: i) the preparation of the information leaflet describing the online questionnaire; ii) the preparation of the online questionnaire itself; iii) designing the course of the interviews; iv) disseminating information about the study. Thereafter, the PRPs participated in: v) designing the various modules of the communication skill training; vi) the training handbook's preparation; vii) the information leaflets promoting and describing the skill training. Moreover, the PRPs will operate the first test runs of the skill training. Altogether, the participation in the research project was acclaimed as interesting and enriching by the PRPs.
**Conclusions:** The implementation of the patient's perspective through inclusion of the PRPs was successful and gave important impetus. The usefulness and effectivity of the new training programme will be evaluated in a future randomised, controlled trial.
**Acknowledgement:** The authors wish to thank the following patient research partners for participating in the study: R. Choijnacki, U. Garske and I. Kimmerle. We also thank the following investigators: J. Lamprecht, W. Mau, M. Schlöffel and A. Schöpf.
**Disclosure of Interest:** None declared

**FRIDAY, 10 JUNE 2016**

## It's in your hands

### OP0278-PARE PATIENT EMPOWERMENT: NATIONAL ACTION WEEK WITH INFORMATIVE LECTURES IN LAYMAN'S TERMS FOR THOSE WHO ARE AFFECTED BY RHEUMATISM

E.S. Rösch. *Rheumaliga Schweiz, Zürich, Switzerland*

**Background:** Rheumatic diseases can cause significant restrictions for sufferers in virtually all aspects of everyday life. Those who are affected often feel like they are on their own with their symptoms. Information about their illness, treatment options and the responsibilities of corresponding specialists is often not issued in layman's terms. Studies have shown that patients who have received adequate information handle their illness better and are able to positively influence the progression of their illness [1].
**Objectives:** Patient Empowerment should be achieved by providing the patient with information about a) their illness, b) treatment options and c) specialists and contacts. Those who are affected should feel empowered as responsible patients to be able to participate in decision-making processes regarding the types of treatment available and to have a discussion with a doctor on an equal footing. Those who are affected should also be able to carry out movement exercises independently and integrate joint protection strategies into their everyday lives. What is more, a platform should be created for those who are affected, so that they can directly contact specialists, health professionals and others who are affected.
**Methods:** Rheumaliga Schweiz organises a National Action Week on a specific topic in September every year in several cities throughout Switzerland. Specialists (rheumatologists, surgeons, physiotherapists, occupational therapists, psychologists and others) offer information on specific symptoms and the treatment options available in layman's terms. The events are free of charge. The national office provides its member organisations with a concept for the event that has been compiled by a specialist group. The lectures are compiled by experts in their field and are adapted accordingly so that they are suitable for the general public. In this way, it is guaranteed that both up-to-date and technically flawless contents are presented at all events. Speakers are even on hand to offer personal advice to visitors during the breaks. Other specialists present their offerings at information stands. Emphasis is placed on regional roots both in terms of the speakers and the information stands.
**Results:** The National Action Week has become a fixed series of events for people who are affected by rheumatism in recent years. In the meantime, we have been able to organise approximately 15 events each year with the support of our member organisations. On average, each individual event is attended by 150 participants. This means that on the whole, over 2,200 people across Switzerland can benefit from an information event every year. In a survey carried out, 94% of participants stated that they had benefited considerably from the event.
Focussing the event in a period of a single week makes it possible to use resources sparingly on the one hand, whilst also facilitating media work.
**Conclusions:** Rheumaliga Schweiz will continue to hold an annual action week for people affected by rheumatism in the future. There is a good balance between the expenses incurred for this by Rheumaliga Schweiz and the benefits gained by those who are affected.

## The EULAR School of Rheumatology - a new era of education

### OP0279 DEVELOPING AND RUNNING A RHEUMATOLOGY EMERGENCY SIMULATION COURSE

A. Sabanathan[1], G. Fent[2], M. Purva[3]. *[1]Rheumatology Department, Leeds Teaching Hospitals NHS Trust, Leeds; [2]Simulation; [3]Medical Education, Hull Institute of learning and Simulation, Hull, United Kingdom*

**Background:** The UK Joint Royal College Of Physicians 2010 rheumatology curriculum states that "trainees should be able to diagnose, choose appropriate investigations, formulate an appropriate management plan, communicate effectively and involve appropriate specialities where necessary" [1].
However rheumatology emergencies are rare, and trainees may not get adequate exposure to be able to develop these competencies. A survey performed in the Yorkshire region (UK) showed that up to 62.5% of trainees were not confident in dealing with some emergency presentations.
Currently there are no simulation courses covering this aspect of training for rheumatology trainees.
**Objectives:** Our objective was to develop and run a pilot simulation course

for rheumatology trainees that will provide education in the identification and management of rheumatology emergencies, and aid development of non-technical skills.

**Methods:** Scenarios were developed and mapped against the curriculum requirements. They were run in a simulated ward environment using a high fidelity simulator. Faculty included one actor acting as ward staff, 2 senior simulation fellows, 1 technician, and 3 senior rheumatology Consultants.

5 scenarios were used in the pilot one day course run on the 1st May 2015. These were; Scleroderma renal crisis, methotrexate pneumonitis, acute lupus myocarditis, catastrophic antiphospholipid syndrome and ANCA positive vasculitis presenting with pulmonary haemorrhage. The running of the scenarios lasted 20 minutes, with debriefing taking between 30–40 minutes.

Delegates were provided with a reading pack at the end of the course, consisting of literature. Post course questionnaires assessing confidence scores, session rating, as well as general feedback were used to assess the course.

**Results:** Post course feedback was provided using a 5 point Liket scoring sheet, with a rating of 5 – extremely confident in managing independently, and 1 – unable to manage:

Delegates rated between 3–5 in their overall ability to identify and manage rheumatological emergencies (50% giving a rating of 5, and 40% rating a 4, 10% rating a 3), and between 3–5 in their ability to manage the five emergency scenarios. With the majority rating a 4, one delegate rated a 3 in two scenarios, while one delegate rated a 5 in four of the scenarios.

All delegates felt that the session had added to their knowledge and rated the course as either very good or excellent.

**Conclusions:** The pilot course was felt to overall improve trainee confidence in identifying and managing these rheumatology emergencies. It also highlighted non-technical skills and was felt to be a satisfactory teaching method by all the participants and trainers.

This course has obtained training programme director support for the Yorkshire and Humber region (UK) as well as funding and will run on a yearly basis in the region.

## Advances in large vessel vasculitis

### OP0280 IMPROVED SURVIVAL IN GIANT CELL ARTERITIS: A POPULATION-BASED STUDY

L.M. Belvedere[1], H.K. Choi[1,2], N. Dehghan[3], E.C. Sayre[1], J.A. Avina-Zubieta[1,3]. *[1]Arthritis Research Canada, Richmond, Canada; [2]Department of Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, United States; [3]Division of Rheumatology, University of British Columbia, Vancouver, Canada*

**Background:** Giant cell arteritis (GCA) is associated with significant morbidity and mortality, but previous studies on mortality in GCA have yielded conflicting results. Furthermore, mortality trends are largely unknown, particularly in the general population.

**Objectives:** To address this knowledge gap, we evaluated mortality trends in individuals with GCA in a general population-context from January 1, 1997 – December 31, 2012.

**Methods:** Using an administrative health database from the province of British Columbia, Canada (population approximately 4.5 million), we identified all incident cases of GCA and up to 10 non-GCA sex-, age- and entry-time-matched controls. The case definition for GCA included at least one prescription of oral glucocorticoids between one month before and six months after the index date. Study cohorts were divided into two sub-groups based on the year of diagnosis (i.e., 1997–2004 and 2005–2012). Mortality rates were calculated, as well as hazard ratios (HR) using a Cox proportional hazard model. HRs were adjusted for potential confounders (e.g., Charlson's comorbidity index, number of outpatient visits and hospitalizations, cardiovascular drugs, glucocorticoids, cox-2 inhibitors, NSAIDs within 12 months prior to index date).

**Results:** The early cohort (i.e., 1997–2004) of GCA patients had considerably higher mortality rates than the late cohort (i.e., 2005–2012) (i.e., 373.7 vs 87.5 cases per 1000 person-years), while the non-GCA cohort experienced a much smaller improvement in mortality rates between the two time periods (i.e., 70.9 vs 52.0 cases per 1000 person-years). The resulting HRs for mortality for the early and late cohorts were 4.58 (95% CI, 3.70–5.67) and 1.46 (95% CI, 1.16–1.84), respectively. Testing for difference between incident cohorts via an interaction term were all significant.

**Conclusions:** This population-based study shows that survival of GCA patients has improved in recent years, suggesting that new treatment strategies and improved management of GCA and its associated complications has led to significant improvements in GCA-associated mortality.

**Acknowledgement:** This study was funded by the Canadian Arthritis Network, The Arthritis Society of Canada/the British Columbia Lupus Society (Grant 10-SRP-IJD-01) and The Canadian Institutes of Health Research (THC-135235).

Table 1. Incidence rates and hazard ratios (HR) for associations between giant cell arteritis and death according to sub-cohort

| | 1997–2004 | | 2005–2012 | |
|---|---|---|---|---|
| | GCA Cohort | Non-GCA Cohort | GCA Cohort | Non-GCA Cohort |
| **Overall** | 349 | 714 | 652 | 1304 |
| Number of deaths | 235 | 172 | 135 | 196 |
| Mean follow-up Time (person-years) | 1.80 | 3.40 | 2.36 | 2.89 |
| Death rate (deaths per 1000 person-years) | 373.74 | 70.92 | 87.50 | 52.04 |

### OP0281 SURVIVAL OF BIOPSY-PROVEN GIANT CELL ARTERITIS IN ITALY DURING A 26-YEAR PERIOD: CORRELATION WITH HISTOLOGICAL PATTERN

P. Macchioni[1], L. Boiardi[1], M. Catanoso[1], F. Muratore[1], A. Cavazza[2], P. Mancuso[3], G. Restuccia[1], C. Salvarani[1]. *[1]Rheumatology Unit; [2]Pathology; [3]Epidemiology Service, Arcispedale S Maria Nuova IRCCS, Reggio Emilia, Italy*

**Background:** No study have evaluated if there is a correlation between histological pattern of temporal artery biopsy and survival in patients with biopsy-proven giant cell arteritis (GCA).

**Objectives:** To investigate the relationship between histological pattern of temporal artery biopsy and survival in patients with biopsy-proven GCA in a defined area of Northern Italy.

**Methods:** All patients with incident temporal artery biopsy-positive GCA diagnosed between 1986 and 2012 living in the Reggio Emilia area were identified using pathology register and by reviewing all histopathological specimens. Patients were followed from the time of diagnosis until either their death or until December 31st, 2013. On the basis of the localization of the inflammation, positive TABs were classified into 4 categories: transmural inflammation (TMI), (229 cases, 81.8% of the positive biopsies); inflammation limited to adventitia (ILA), (14 cases, 5% of the positive biopsies); vasa vasorum vasculitis (VVV), (13 cases, 4.6% of the positive biopsies); and small vessel vasculitis (SVV), (24 cases, 8.6% of the positive biopsies). A semiquantitative 4 grade scale was used to describe the severity of mural inflammation (no mural inflammation, 81 cases, 28.9%, mild mural inflammation, 43 cases, 15.4%, moderate mural inflammation, 75 cases, 26.8%, severe mural inflammation, 81 cases, 28.9%). For each case, we identified one control from the same geographic area matched for age and gender. Mortality rates and specific causes of death were reported and compared between cases and controls and between cases with different histological pattern. TAB histological pattern and severity of mural inflammation entered in a Cox proportional regression analysis along with demographical, clinical and laboratory data at disease onset.

**Results:** There were 280 incident cases of biopsy-proven GCA (205 women, mean age at disease onset 74.3 + 7.5 y, mean duration of follow-up 95 + 58 months) during the 26-year study period with complete clinical, laboratory and survival data. During the follow- up period 159 (56.8%) patients died (mean survival time from disease onset 101 + 60 months). Patients with histological pattern ILA and VVV had reduced hazard ratio mortality as compared to TMI type (0.38 and 0.12 respectively). Survival of patients with different histological TAB pattern of GCA was not different from controls. The most frequent causes of death were cardiovascular diseases, cancer, and respiratory diseases. No significant differences in causes of death were observed comparing the 4 pattern of histological TAB involvement.

**Conclusions:** The histologic spectrum of inflammatory lesions in TAB positive GCA have correlation with survival.

## When and how to diagnose and treat vitamin D deficiency?

### OP0282 EXPRESSION OF VITAMIN D RECEPTOR ASSOCIATED GENES IN THE AORTA OF CORONARY ARTERY DISEASE PATIENTS WITH AND WITHOUT RHEUMATOID ARTHRITIS

I. Oma[1], J.K. Andersen[2], S. Holm[3], O.K. Olstad[4], I. Fostad[5], T. Lyberg[4], S.M. Almdahl[6], Ø. Molberg[7], I. Hollan[3,8,9]. *[1]Innlandet Hospital Trust, Lillehammer; [2]Norwegian University of Science and Technology, Gjøvik; [3]Lillehammer Hospital for Rheumatic Diseases, Lillehammer; [4]Department of Medical Biochemistry, Oslo University Hospital; [5]Department of Oral Biology, University of Oslo, Oslo; [6]University of North Norway, Tromsø; [7]Department of Rheumatology, Dermatology and Infectious Diseases, University of Oslo, Oslo, Norway; [8]Division of Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital; [9]Harvard Medical School, Boston, United States*

**Background:** Vitamin D has an important role in the immune system, and has been linked to inflammation, rheumatoid arthritis (RA) and coronary artery disease (CAD)[1, 2]. However, the exact mechanisms how vitamin D is involved in these processes are still unclear.
**Objectives:** To compare expression of vitamin D receptor (VDR) associated genes in the aortic adventitia of CAD patients with and without RA.
**Methods:** RNA was isolated, and Affymetrix microarray was used to determine the gene expression profile in specimens from the ascending aorta in 8 patients with CAD and 8 patients with CAD and RA from the Feiring Heart Biopsy Study. Partek Genomics Suite software was used to identify differentially expressed genes by one-way ANOVA ($p<0.05$; FC>1.1), and differences in expression of VDR associated genes were determined by Ingenuity Pathway Analysis.
**Results:** Among the 15586 transcripts that were identified, pathway analysis determined two genes within the VDR signaling pathway, Growth arrest and DNA-damage-inducible protein 45 alpha (GADD45A) ($p=0.006$; FC=1.474) and Nuclear Receptor Corepressor 1 (NCOR1) ($p=0.005$; FC=1,210), that where both up-regulated in RA patients.
**Conclusions:** We found that GADD45A and NCOR1 were upregulated in the aorta of RA patients. GADD45A induces cell cycle arrest, DNA repair and apoptosis in response to various environmental stresses [3], while NCOR1 has an important role as a gene-specific integrator of positive and negative signals that control inflammation [4]. Based on this finding, we hypothesize that the accelerated atherosclerosis in RA might be related to the up-regulation of GADD45A and NCOR1 through the VDR signaling pathway.

### OP0283 A RANDOMIZED DOUBLE-BLIND COMPARATIVE CLINICAL TRIALS TO EVALUATE EFFICACY OF VITAMIN D IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS

W. Lomarat, R. Rattapol Pakchotanon, S. Chaiamnuay, P. Narongroeknawin, P. Asavatanabodee. *Rheumatology, Phramongkutklao Hospital, Bangkok, Thailand*

**Objectives:** To assess the efficacy and safety of ergocalciferol in combination with standard care in patients with systemic lupus erythematosus (SLE)
**Methods:** A randomized, double-blinded, placebo-comparative study was conducted in SLE with mild-moderate disease activity. The patients were randomized to receive either high doses of vitamin D (100,000 IU of ergocalciferol weekly for 4 weeks followed by 40,000 IU of ergocalciferol weekly for 20 weeks) or placebo. All patients received 800 unit of cholecalciferol daily for 24 weeks. Concurrent medications could be adjusted as clinically required. Efficacy measures were SLE disease activity index (SLEDAI) score, SLE Flare Index (SFI), inflammatory markers, and dosage of immunosuppressive drugs. The study was approved by the ethic committee and institutional review board
**Results:** Of the 104 patients enrolled, 88 patients completed the study. Baseline characteristics were similar. At 24 weeks, the mean ± standard difference (SD) of serum 25(OH)D in patients who received high doses of vitamin D was significantly higher than placebo group (41.2 ± 14.4 vs. 27.2 ± 10.1, $p<0.001$). There was no difference between patients who received high doses of vitamin D and placebo in respect of SLEDAI, SFI, inflammatory markers, and dosage of immunosuppressive drugs. However, at 12 and 24 weeks, the number of patient who can reduce prednisolone dosages in patients who received high doses of vitamin D were significantly greater than that of the placebo (39.6% vs.17.6%, p=0.008) and (43.4% vs. 23.5%, p=0.013). Adverse reactions in both groups were similar. Serum calcium levels did not change within and between groups of treatment.
**Conclusions:** This study could not demonstrate the efficacy of high dose ergocalciferol in controlling SLE disease activity. However, high dose ergocalciferol could be an adjunctive therapy that safe and has a corticosteroid-sparing effect on patients with SLE

## Data harmonization across (rheumatoid arthritis) clinical cohorts and registers

### OP0284 COMPARABILITY OF THE HEALTH ASSESSMENT QUESTIONNAIRE BETWEEN COUNTRIES: PSYCHOMETRIC EXAMINATION OF CROSS-NATIONAL MEASUREMENT EQUIVALENCE

S. Norton[1], M. Hifinger[2], S. Ramiro[3], P. Putrik[4], T. Sokka[5], A. Boonen[2]. *[1]Psychology, King's College London, London, United Kingdom; [2]Rheumatology, Maastricht University Medical Center, Maastricht; [3]Clinical Immunology & Rheumatology, Amsterdam Rheumatology Center, Amsterdam; [4]Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands; [5]Rheumatology, Jyväskylä Central Hospital, Jyväskylä, Finland*

**Background:** The HAQ disability index is the most widely used measure of function in rheumatological conditions. Translated versions of thr original HAQ and several revisions are increasingly used to make comparisons between countries in epidemiological studies. Such comparisons assume cross-national measurement equivalence. That is, total scores are not biased due to responses to individual items being influenced by subtle differences in interpretation across languages or cultures. Despite its wide use, this measurement property has not been tested across a wide range of countries.
**Objectives:** To examine the cross-national measurement equivalence of four versions of the HAQ: modified HAQ (MHAQ), multidimensional HAQ (MDHAQ), functional HAQ (FNHAQ) and HAQ-II.
**Methods:** Data are from the QUEST-RA cross-sectional survey of 10,150 patients with RA from 34 countries (74% female, mean age 55 years). Respondents completed an item pool of 33 items, excluding devices, relating to the original HAQ and four revisions. Item response theory (IRT) models were estimated. Likelihood ratio tests compared models for each HAQ version fixing IRT parameters to be the same across all countries (equivalent) or estimating separate parameters for each country (non-equivalent). Further analysis with Bayesian multiple-group IRT models identified items with non-equivalent IRT parameters for each country using an alignment method.
**Results:** All versions of the HAQ exhibited good psychometric properties with a single latent disability variable explaining around two-thirds of the variance in item responses. Compared to other versions, the HAQ-II exhibited greater precision (i.e. reliability) in differentiating between people with low levels of disability. For each version of the HAQ the non-equivalent model provided a significantly better fit compared to the equivalent model (all $p<0.001$), indicating comparisons of scores across countries are biased. Further analysis indicated this non-equivalence across countries was generally due to differences in the level of disability required to respond positively to an item, rather than variation

in an items ability to discriminate level of disability. Examining the aligned means for each country using the limits of agreement method (Figure) indicated that the overall impact of non-equivalence was likely to be minimal for most countries and that scores for the MHAQ were least affected. Scores for Russia, Serbia and Morocco were overestimated, and Egypt underestimated.
**Conclusions:** All versions of the HAQ have good psychometric properties. Due to differences in item interpretation across translations, caution should be taken when drawing inferences about disability levels across countries. For most countries such inferences are likely to be valid due to the relatively low level of bias introduced by individual items. Although measurement properties at the individual level are more favourable for the HAQ-II, it is more prone to bias in cross-national comparisons where the MHAQ may be favoured.

### OP0285 THE EULAR TASK FORCE FOR STANDARDISING MINIMUM DATA COLLECTION IN RHEUMATOID ARTHRITIS OBSERVATIONAL RESEARCH: RESULTS OF A HIERARCHICAL LITERATURE REVIEW

K. Chatzidionysiou[1], E. Nikiphorou[2], L. Gossec[3], K. Hyrich[4], C. Filip[5], Y. van Eijk-Hustings[6], P. Williamson[7], W. Dixon[4], J. Askling[1], H. Radner[8] on behalf of the EULAR Task Force for Standardising Minimum Data Collection in Rheumatoid Arthritis Observational Research. *[1]Karolinska Institute, Stockholm, Sweden; [2]Whittington Hospital NHS Trust, London, United Kingdom; [3]Université Paris, Paris, France; [4]University of Manchester, Manchester, United Kingdom; [5]Romanian League Against Rheumatism, Bucharest, Romania; [6]Maastricht University Medical Centre, Maastricht, Netherlands; [7]University of Liverpool, Liverpool, United Kingdom; [8]Medical University Vienna, Vienna, Austria*

**Background:** There is considerable variation in the type of information used in rheumatoid arthritis (RA) observational studies. This, in turn, makes collaborative RA observational research challenging. As part of a larger initiative (EULAR Task Force) a step-wise approach was designed in order to achieve a consensus on a standardized minimum core dataset (MCD) with items (i.e. "what to collect") and instruments (i.e. "how to collect").
**Objectives:** To undertake a literature review designed to construct a comprehensive list of items and instruments currently collected across observational RA studies in Europe. This will ultimately inform the development of a MCD for collaborative RA research.
**Methods:** A hierarchical literature review of published articles that were I) observational cohorts or registers II) including RA patients and III) were initiated in Europe, was performed. Results were compared and cross-checked with EULAR recommendations for data reporting in RA clinical trials and trial extension studies for management of RA, The EULAR outcome measures library (OML) and the results of an initial survey undertaken by our group[1]. The latter was a web-survey involving a smaller sample of RA registers and clinical cohorts. The current literature review expanded to involve all existing RA registers and cohorts in published literature. From the literature, information of what is collected (item) and how (instrument) was extracted and the frequency of data collection was calculated.
**Results:** Published articles from 67 different European RA registers and cohorts were included. The number of patients recruited in each register ranged from 130 to more than 50,000. A total of 40 different items were identified comprising >100 different instruments Most studies included a measure of disease duration, disease activity, current DMARD use or physical function although the choice of instrument within each item varied widely in many cases (table 1). For example, 8 different composite scores of disease activity are being captured. Relative agreement on specific items did not always, however, entail agreement in terms of instruments.

Table 1. Commonly captured items in the literature, their frequency and the number of different instruments (i.e. how) used to collect the information

| Item | Frequency of collection | Number of instruments |
|---|---|---|
| Age | 67/67 (100%) | 1 |
| Gender | 67/67 (100%) | 1 |
| Current DMARD | 63/67 (94%) | 7 |
| Disease Duration | 62/67 (93%) | 1 |
| Composite Score of Disease Activity | 61/67 (91%) | 8 |
| Serology | 60/67 (90%) | 4 |
| Tender Joint Count | 58/67 (87%) | 5 |
| Swollen Joint Count | 58/67 (87%) | 5 |
| Acute phase reactants | 58/67 (87%) | 2 |
| Physical Function | 55/67 (81%) | 5 |
| Steroids | 53/76 (79%) | 5 |
| Patient Global | 52/67 (78%) | 6 |
| Pain | 48/67 (72%) | 4 |

**Conclusions:** Information captured in registers is heterogeneous. The frequency of collection of items and instruments informed voting in the first face-to-face meeting, alongside the expert panel survey.

## Telemedicine and e-health in community care

### OP0286-HPR THE EFFICACY OF MOTIVATIONAL COUNSELLING AND SMS-REMINDERS ON DAILY SITTING TIME IN PATIENTS WITH RHEUMATOID ARTHRITIS: A RANDOMISED CONTROLLED TRIAL

T. Thomsen[1], M. Aadahl[2], N. Beyer[3], M.L. Hetland[1], K.B. Loeppenthin[1], J. Midtgaard[4], R. Christensen[5], B.A. Esbensen[1]. *[1]DANBIO and Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases VRR, Rigshospitalet; [2]Research Centre for Prevention and Health, Glostrup Hospital, Glostrup; [3]Musculoskeletal Rehabilitation Research Unit, Bispebjerg and Frederiksberg Hospitals; [4]University Hospitals Centre for Health Research, Rigshospitalet; [5]Musculoskeletal Statistics Unit, The Parker Institute, Bispebjerg and Frederiksberg Hospitals, Copenhagen, Denmark*

**Background:** Patients with rheumatoid arthritis (RA) are more sedentary than the general population, which can have serious health consequences. Reducing sedentary behaviour (SB) and increasing light intensity physical activity is advocated as a potentially more achievable health promotion focus in patients with chronic diseases and mobility problems. Intervention studies have shown that behavioural approaches are effective in reducing SB in healthy populations. Whether this applies to patients with RA is yet to be determined.
**Objectives:** To test the efficacy of a 16-week individually tailored, behavioural intervention in reducing daily sitting time, pain and fatigue and improving health-related quality of life, self-efficacy, physical function and cardio-metabolic disease risk in patients with RA.
**Methods:** Parallel-group, observer-blinded randomised controlled trial (N=150). RA patients >18 years of age, self-reported daily sitting time >5 hours and Health Assessment Questionnaire (HAQ) score <2.5 were consecutively recruited from a rheumatology outpatient clinic. The intervention group (n=75) received three individual motivational counselling sessions with a health professional and text messages aiming at improving motivation for light intensity physical activity through reduction of SB. The control group (n=75) was encouraged to maintain usual lifestyle. Primary outcome was change from baseline in daily sitting time measured objectively by ActivPAL, analysed using ANCOVA with a factor for group and adjustment for the outcome level at baseline. Primary analyses were based on the intention-to-treat population. Secondary outcomes included patient-reported outcomes and cardio-metabolic biomarkers (blood pressure, cholesterol levels, blood glucose, body weight and waist circumference).
**Results:** After 16 weeks, three participants were lost to follow-up. There was a mean decrease in daily sitting time of 1.61 hours (h)/day with the intervention and an increase of 0.59 h/day in the control group; between-group difference was -2.20 h/day (95%CI: -2.72 to -1.69; p<.0001) in favour of the intervention group. Most of the secondary outcomes were also in favour of the intervention; VAS-pain: -22.36 (-29.27 to -15.44); VAS-fatigue: -26.80 (-34.32 to -19.30), physical function (HAQ): -0.42, (-0.54 to -0.30) and total cholesterol: -0.37 (-0.50 to -0.24) mmol/l.
**Conclusions:** An individually tailored, behavioural intervention effectively reduced daily sitting time by on average more than two hours in patients with RA and additionally improved patient-reported clinical outcomes and cholesterol levels. The results may be important for clinical practise and physical activity recommendations for patients with RA and can most likely be generalised to other populations with chronic disease and mobility limitations.

## Inflammasome as therapeutic target in inflammatory diseases

### OP0287 CALCIUM PYROPHOSPHATE DIHYDRATE CRYSTALS INDUCE IL-1β PRODUCTION BY MONOCYTES THROUGH A POTASSIUM EFFLUX-DEPENDENT PATHWAY

L. Campillo-Gimenez[1,2], F. Renaudin[1,2], P. Bobé[3], M. Gosset[4], C. Combes[5], M. Cohen-Solal[1,2,6], F. Lioté[1,2,6], H.-K. Ea[1,2,6]. *[1]INSERM UMR1132; [2]Paris Diderot University, Paris; [3]Paris Sud University, INSERM UMRS757, Orsay; [4]EA2496, Paris Descartes University, Montrouge; [5]ENSACIET, Toulouse; [6]Rheumatology Department, AP-HP, Lariboisière Hospital, Paris, France*

**Background:** Osteoarthritis (OA) is the most common adult rheumatic disease characterized by cartilage degradation, synovial inflammation and subchondral bone remodeling. Risk factors associated with OA are age, genetics, mechanical overload and presence of calcium-containing microcrystals. Calcium pyrophosphate crystals including monoclinic and triclinic dihydrate phases (m- and t-CPPD) are found in 40% of end-stage OA patients. Frequently asymptomatic, it can

give rise to synovitis contributing to OA lesion worsening. CPP crystal-induced inflammation is orchestrated mainly by interleukin (IL)-1β. Secretion of IL-1β required a cytokine maturation process which depends on the NLRP3 inflammasome activation. This intracellular multiprotein complex can be stimulated by ATP-dependent potassium ($K^+$) efflux, reactive oxygen species (ROS) generation, lysosomal or mitochondrial alterations.
**Objectives:** The objectives were to identify intracellular pathways induced by CPPD crystals and leading to NLRP3 activation and IL-1β production.
**Methods:** The effects of CPPD crystals were assessed in human THP-1 cell line and bone marrow-derived macrophages (BMDM) from wild type (wt), NLRP3 (*nlrp3*$^{-/-}$) or P2X7 receptor (*p2x7*$^{-/-}$) knock out mice. Cells were primed before stimulation with synthetic m- and t-CPPD crystals in presence or absence of $K^+$-enriched media (KCl 50mM – to block $K^+$ efflux), N-acetyl-L-cystein (NAC 50mM – an intracellular ROS scavenger) or oxidized ATP (oxATP 200μM – an antagonist of ATP). NLRP3 expression was determined by western blotting, IL-1β and extracellular ATP (ATPe) concentrations were measured in cell culture supernatants whereas ROS production and mitochondrial membrane potential were evaluated using fluorescent probes (DFDA and JC-1, respectively).
**Results:** First, IL-1β production induced by CPPD crystals was lacking in *nlrp3*$^{-/-}$ BMDM but important in wt BMDM. Second, we showed that m-CPPD crystals induced a higher NLRP3 expression and IL-1β production than t-CPPD suggesting a differential modulation of NLRP3 activation. We observed that CPPD-induced IL-1β secretion was completely abrogated when $K^+$ efflux or intracellular ROS were inhibited. Moreover, we demonstrated a stronger decrease in mitochondrial membrane potential following m-CPPD than t-CPPD crystal stimulation, combined with a *de novo* ROS generation. These two latter effects were inhibited when $K^+$ efflux was blocked. Finally, we found that m- and t-CPPD crystals differentially brought on an ATP release and that IL-1β production was partially inhibited by oxATP. However, although ATPe can trigger $K^+$ efflux through P2X7 receptor opening, crystal-mediated IL-1β production was similar between wt and *p2x7r*$^{-/-}$ BMDM.
**Conclusions:** IL-1β production triggered by m- and t-CPPD crystals occurred through a modulation of ROS production and mitochondrial disruption. Interestingly, $K^+$ efflux, associated with ATP release, could be the initial signal of CPPD-induced IL-1β maturation, independently of P2X7 receptor involvement. These results highlight a new molecular pathway of crystal-dependent OA inflammation.

Kania[1]. *[1]Division of Rheumatology, University Hospital Zurich; [2]Center of Molecular Cardiology, University of Zurich, Zurich, Switzerland; [3]Department of Molecular Pathology; [4]Division of Rheumatology, University Hospital Teubingen, Teubingen; [5]Insitute of Pathology, Ludwig Maximilians University, Munich, Germany*

**Background:** Heart involvement in patients with systemic sclerosis (SSc) resembles the inflammatory dilated cardiomyopathy (iDCM) phenotype with predominance of inflammation, fibrosis, vasculopathy and heart dysfunction. Animal studies of iDCM indicated bone marrow originated cells as a major source of pathological myofibroblasts. MicroRNAs are key regulators of immune cell function and are involved in many cardiac pathological processes. However, their roles in monocyte differentiation and fibrogenesis are unclear.
**Objectives:** To determine the role of circulating monocytes and microRNAs in the onset and progression of myocardial fibrosis in SSc, we examined monocyte differentiation and their microRNAs expression profile in SSc.
**Methods:** Endomyocardial biopsies from SSc/iDCM patients and healthy controls were screened by immunohistochemistry. $CD14^+$ monocytes isolated from peripheral blood of SSc patients and healthy donors were differentiated towards the myofibroblast phenotype by stimulation with TGF-β1, IL-4, IL-10 and IL-13. In addition, $CD14^+$ monocytes were co-cultured with dermal fibroblasts originated from SSc patients and healthy subjects. After 7 days, myofibroblast gene expression and cytokines secretion profile were evaluated. MicroRNA candidates were selected using DIANA-TarBase v7.0 and TargetScan Release 7.0 and further analysed by qPCR.
**Results:** Myocardium of SSc/iDCM patients (n=10) revealed extensive fibrosis and accumulation of inflammatory cells including $CD14^+$ monocytes. Moreover, fibrotic myocardium from SSc patients exhibited the presence of $CD14^+$/$Fra\text{-}2^+$ monocyte-derived fibroblast-like cells. Bioinformatical analysis indicated several potential microRNAs being involved in monocyte differentiation, and qPCR confirmed predicted candidates. We observed decreased basal levels of let-7i (Mann-Whitney U test, p=0.005), miR-10b (p=0.005), miR-21 (p=0.005), miR-29a (p=0.005), miR-155 (p=0.002), miR-199a (p=0.008) and miR-544a (p=0.002), and increased levels of miR-29b (p=0.03) in circulating $CD14^+$ monocytes isolated from SSc patients (n=10) compared to healthy controls (n=4). Stimulated monocytes acquired a myofibroblast-like phenotype with increased expression of collagen I, fibronectin, α smooth muscle actin and Fra-2 in comparison to untreated cells. Similarly, $CD14^+$ monocytes exposed to dermal fibroblasts acquired myofibroblast features. $CD14^+$ monocytes from SSc patients were characterised by higher production of IP-10, MIP-3α, LIF and NT-3. The process of monocyte to myofibroblast differentiation employed Fra-2/TGF-β signalling. Inhibition of the canonical SMAD-dependent pathway with TGFβR1 inhibitors resulted in the abrogation of monocyte-to-myofibroblast differentiation.
**Conclusions:** Here we demonstrated the capability of peripheral blood monocytes to differentiate towards the myofibroblast phenotype, indicating these cells as one of the potential sources of pathological tissue myofibroblasts in SSc. Different miRNA expression profiles in SSc monocytes indicate a primary activation state. Further studies of miRNAs regulation pathways might lead to novel treatment strategies, particularly for heart involvement.

### OP0290 OX40L BLOCKADE PROTECTS AGAINST SKIN AND LUNG INFLAMMATION-DRIVEN FIBROSIS

M. Elhai[1,2], J. Avouac[1,3], A.-M. Hoffmann-Vold[4], J. Sadoine[5], T. Guilbert[1], H. Akiba[6], V. Heissmeyer[7], A. Subramaniam[8], R. Resnick[8], G. Chiocchia[9], Y. Allanore[1,2]. *[1]INSERM U1016 Cochin Institute; [2]Rheumatology A department; [3]Cochin Hospital, Paris, France; [4]Oslo University Hospital, Oslo, Norway; [5]UFR Odontologie, Montrouge, France; [6]Department of Immunology Juntendo, Tokyo, Japan; [7]Institute for Immunology, Munich, Germany; [8]Immune Mediated Diseases, Sanofi Genzyme, Framingham, United States; [9]Inserm, U1173, Saint-Quentin-En-Yvelines, France*

**Background:** Systemic sclerosis (SSc) is a severe fibrotic disease with no effective treatment. The OX40-OX40L axis is emerging as a new potential target in autoimmune diseases offering the advantage of a targeted approach on co-stimulatory signals with limited impact on the whole immune response and very preliminary data suggested its involvement in SSc.
**Objectives:** To investigate the contribution of OX40L in SSc
**Methods:** We assessed the expression of OX40L in fibrotic skin and in the serum of SSc-patients. The efficacy of a targeted therapy against OX40L *in vivo* was evaluated using complementary experimental mouse models.
**Results:** Expression of OX40L protein was higher in fibrotic skin of SSc-patients as compared to healthy controls (p=0.003), particularly in diffuse cutaneous forms. Soluble OX40 levels were significantly higher in SSc-patients (n=177) than in healthy controls (n=100). Longitudinal analyses of our cohort showed that high level of serum OX40L at baseline was highly predictive of worsening of dermal and lung fibrosis during the follow-up (HR: 8.28 [2.11–32.50] and 4.60 [1.52–12.18], $P<0.001$). This was confirmed in a replication Norwegian cohort (n=241) dedicated to lung fibrosis analysis. In this cohort, in multivariate analyses, OX40L was a strong predictor of lung fibrosis including known risk factors for lung fibrosis.

Invalidation of OX40L prevented dermal fibrosis in the bleomycin mouse model with a decrease in dermal thickness, hydroxyprolin content and myofibroblasts count. OX40L invalidation was associated with a decrease in T cell, B cell and macrophage infiltrates and in cytokine release (IL-6, TNF-α) in lesional skin of mice. A transcriptomic approach identified two main pathways regulated by OX40L blockade: NF kappa B and AP 1 signaling. Then pharmacologic approaches, using a monoclonal anti-OX40L antibody, demonstrated that the blockade of OX40L not only prevented dermal fibrosis, but also induced regression of established fibrosis. Thereafter, the use of this monoclonal antibody demonstrated in the fra-2 transgenic mouse model marked protection from fibrosing alveolitis (measured by CT-scan (Figure) and histology) and vessel remodeling leading to pulmonary arterial hypertension.

**Conclusions:** Altogether, our results show that OX40L is as an attractive target in inflammation-driven fibrosis. OX40L appears as a very promising biomarker in SSc and an appealing potential therapy to reduce both skin and lung fibrosis.

**Disclosure of Interest:** None declared

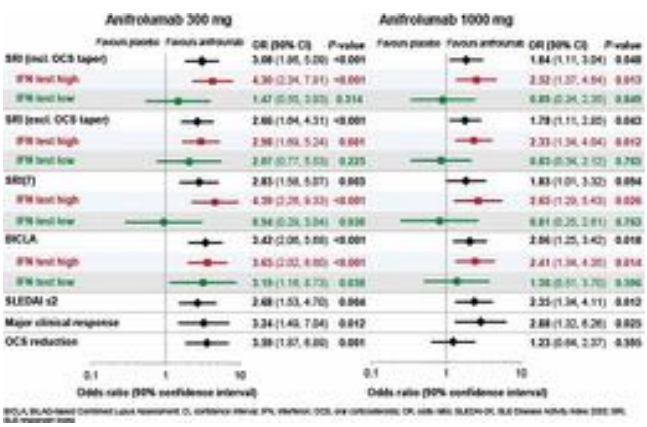
## SLE: What will it be and how will it be treated 5 years from now

### OP0291 ANIFROLUMAB, AN ANTI-INTERFERON-ALPHA RECEPTOR MONOCLONAL ANTIBODY, IN MODERATE TO SEVERE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)



R. Furie[1], J.T. Merrill[2], V.P. Werth[3], M. Khamashta[4], K. Kalunian[5], P. Brohawn[6], G. Illei[6], J. Drappa[6], L. Wang[6], S. Yoo[7]. *[1]Northwell Health, Great Neck; [2]Oklahoma Medical Research Foundation, Oklahoma City; [3]Philadelphia VA Medical Center and University of Pennsylvania, Philadelphia, United States; [4]Graham Hughes Lupus Research Laboratory Division of Women's Health, London, United Kingdom; [5]UCSD School of Medicine, La Jolla; [6]MedImmune, Gaithersburg; [7]Regenx Bio, Rockville, United States*

**Background:** Increased activity of the type I interferon (IFN) pathway is central to the pathogenesis of SLE. Blocking the type I receptor may reduce SLE activity more effectively than inhibiting IFN-α alone.

**Objectives:** Efficacy and safety of anifrolumab were assessed in a Phase IIb, randomized, double-blind, placebo-controlled study of adults with moderate to severe SLE (the MUSE study).

**Methods:** 305 patients were treated for 48 weeks with intravenous anifrolumab (300 mg or 1000 mg) or placebo, in addition to standard-of-care medications. Randomization was stratified by SLE Disease Activity Index 2000 (SLEDAI-2K) score (<10 or ≥10), oral corticosteroid (OCS) dose (<10 or ≥10 mg/day), and IFN gene signature status (high vs. low) based on a 4-gene expression assay. The primary endpoint was the percentage of patients achieving an SLE Responder Index [SRI(4)] response at Day 169 with sustained reduction of OCS (<10 mg/day and ≤Day 1 dose from Day 85 to 169).

**Results:** The primary endpoint was met by more anifrolumab-treated patients [placebo vs. 300 mg vs. 1000 mg: 17.6%, 34.3% ($p$=0.014), 28.8% ($p$=0.063)] with greater effect sizes observed in the 75% of patients who had a high baseline IFN signature [13.2%, 36.0% ($p$=0.004), 28.2% ($p$=0.029)]. At Day 365 more anifrolumab-treated patients achieved SRI(4) responses [40.2%, 62.6%, ($p$<0.001), 53.8%, ($p$=0.043)], BILAG-based Composite Lupus Assessment (BICLA) [25.7%, 53.5% ($p$<0.001), 41.2% ($p$=0.018)], modified SRI(6) [28.4%, 49.5% ($p$=0.002), 44.7% ($p$=0.015)], and SLEDAI-2K ≤2 [17.6%, 35.4% ($p$=0.004), 32.7% ($p$=0.012)]. Major clinical response (BILAG "C" or better in all domains at Day 169 maintained to Day 365) was achieved by 6.9%, 19.2% ($p$=0.012), and 17.3% ($p$=0.025) of patients. BILAG "A" flares were reported in more placebo- vs. anifrolumab-treated patients (16.7%, 9.1%, 10.6%). In patients with baseline Cutaneous Lupus Erythematosus Disease Area and Severity Index activity score ≥10, more anifrolumab-treated patients attained a ≥50% reduction by Day 365 [30.8%, 63.0% ($p$=0.013), 58.3% ($p$=0.077)]. In patients with ≥8 swollen and ≥8 tender joints at baseline more anifrolumab-treated patients achieved ≥50% decrease in joint count [48.6%, 69.6% ($p$=0.038), 64.6% ($p$=0.156)]. Although steroid tapering was not mandated, OCS reduction to ≤7.5 mg/d at Day 365 was achieved by 26.6%, 56.4%, and 31.7% of patients. The observed benefits were driven by results in the IFN-high subpopulation (figure). Median suppression of 21 IFN-regulated genes was ~90% for both doses of anifrolumab. Patients in the placebo group had the lowest incidence of *Herpes zoster* (2.0%, 5.1%, 9.5%) and cases reported as influenza (2.0%, 6.1%, 7.6%); there were no differences in the incidence of serious adverse events (18.8%, 16.2%, 17.1%). The incidence of infusion-related reactions was similar (5.9%, 2.0%, 3.8%).

**Conclusions:** Anifrolumab significantly reduced disease activity across all clinical endpoints. Enhanced effects in IFN-high patients support the pathobiology of this treatment strategy.

## Clinical outcomes for PMR/GCA

### OP0292 INTERSPINOUS BURSITIS EVALUATION BY ULTRASOUND IS VERY USEFUL FOR DIAGNOSIS OF POLYMYALGIA RHEUMATICA EXTENSION STUDY

K. Kume[1], K. Amano[1], S. Yamada[1], T. Kanazawa[1], K. Hatta[2]. *[1]Rheumatology, Hiroshima Clinic, hiroshima; [2]Rheumatology, hatta clinic, kure, Japan*

**Background:** Polymyalgia rheumatica (PMR) is a common inflammatory disease of the elderly, and 2012 provisional classification criteria were suggested, however it is provisional and not meant for diagnosis purpose[1)]. Ultrasound (US), MRI and other modalities were often detected interspinous bursitis in patients with PMR[2)]. To develop 2012 provisional classification criteria, adding interspinous bursitis evaluation by US. We reported the usefulness of interspinous bursitis evaluation by US at 2015 American college of rheumatology annual meeting.

**Objectives:** In this time, we compared 2012 provisonal classification criteria to adding interspinous bursitis evaluation by US, and checked the association between US evaluation of conventional (shoulder and hip) bursitis and interspinous bursitis.

**Methods:** This is a prospective cohort study. Candidate criteria were evaluated 161 patients with new onset untreated PMR, and 174 patients non-PMR comparison subjects with conditions mimicking PMR. We compared the diagnosis ability of 2012 provisional classification criteria with 2012 provisional classification criteria, adding interspinous bursitis evaluation by US. US evaluation was checked cervical and lumbar spine added conventional shoulder and hip. In PMR patients, we evaluated the prevalance of interspinous bursitis without hip or shoulder bursitis, the association between interspinous bursitis and shoulder or hip bursitis.

**Results:** 2012 provisional classification criteria scoring system had 66% sensitivity and 82% specificity. Adding interspinous bursitis by US had significantly increased sensitivity to 89%,and not significantly decreased specificity to 77%.(ROC anaylysis: p<0.05)

PMR patients without hip or shoulder bursitis were 56 patients. Surprisingly, PMR patients without hip or shoulder bursitis had interspinous bursitis with high prevalence. (85%, 48 patients) No correlation was found between interspinous bursitis and shoulder or hip bursitis (r=0.09, $P$=0.36).

**Conclusions:** Interspinous bursitis by US is important evalution in patients with PMR. Interspinous bursitis by US should be added classification criteria for PMR. If patients were suspected of PMR, interspinous bursitis by US might be performed despite hip and shoulder bursitis.

OP0293 **PATIENT PRIORITIES FOR PMR RESEARCH: A PRIMARY CARE SURVEY**

S. Hider[1], C. Morton[1], S. Muller[1], J. Belcher[1], K. Gilbert[2], M. Bucknall[1], C. Mallen[1]. *[1]Primary Care Sciences, Keele University, Keele; [2]Trustee, PMRGCAuk, London, United Kingdom*

**Background:** Polymyalgia rheumatica (PMR) is a common inflammatory disorder of older (>50 years) adults, frequently managed in primary care. PMR remains under-researched despite the significant impact this condition has on patient's quality of life. Existing research is typically focused in secondary care settings and as such may not be generalizable to the wider PMR patient population. The importance of involving patients in research is increasing recognised as best practice, yet to date patient priorities for PMR research have not been examined.
**Objectives:** To identify patient priorities for PMR research.
**Methods:** All adults aged ≥50years registered with 150 English general practices who had a first Read code for PMR in their medical records in the preceding 3 years were mailed a self-completion questionnaire (n=704). Survey items included questions on patient demographics and PMR symptoms. Questions regarding patient priorities for PMR research were developed in collaboration with patient members of the leading UK patient group (PMRGCAuk). Patients were asked to indicate what their priorities for research were from a predefined list of 8 items and an additional free-text option.
**Results:** 550 patients responded (78%). The mean (SD) age was 74.2 (8.4) years and 365 (66%) were female. Non-responders did not differ significantly from responders in terms of age (mean age 75 (9.2) vs 74.2 (SD 8.4), p=0.21) or gender (73% vs 66% females, p=0.14).Priorities areas for research were focused on how to manage pain, stiffness and fatigue (440, 80%), improving the diagnosis of PMR (391, 71%), steroid management (341, 62%) and improving self-management (330, 55%). The development of giant cell arteritis (74, 13%), a key concern for clinicians, was the item rated as least important by participants for future research.
**Conclusions:** Meaningful involvement of patients in the research process is essential if we are to generate evidence that improves outcomes for those suffering with this painful and disabling condition. This survey of PMR patients in primary care suggests that symptom management and managing medication are key areas for patients for future research. Researchers and funding organisations should be aware of these priorities if we to generate research findings that are relevant to the widest range of stakeholders.

## Getting active against rheumatoid arthritis fatigue —

OP0294-HPR **SLEEP QUALITY, SLEEP DISTURBANCES AND PHYSICAL ACTIVITY: A NATIONAL SURVEY OF IRISH PEOPLE WHO HAVE INFLAMMATORY ARTHRITIS**

S.G. McKenna, N. Kennedy. *Department of Clinical Therapies, University of Limerick, Limerick, Ireland*

**Background:** Restorative sleep has an important role in maintaining health with disrupted or lower levels of sleep being related to serious outcomes such as increased risk of morbidities and reduced levels of physical activity. Sleep disturbances and poor sleep quality are prevalent complaints in people with Inflammatory Arthritis. Poor sleep quality and disturbances may exacerbate pain in this population, which may further lead to reduced levels of physical activity. Due to a dearth of information in this area, establishing same among Irish People with Inflammatory Arthritis is important.
**Objectives:** To investigate sleep quality, sleep disturbances and physical activity among Irish people who have Inflammatory Arthritis
**Methods:** Members from Arthritis Ireland were invited to participate in a cross-sectional survey hosted on SurveyMonkey(R)TM. Ethics approval was received through the University of Limerick. Descriptive statistics, Chi-square tests/Fisher's exact tests were used to analyse the data using SPSS v22.
**Results:** Ninety (90) people with Inflammatory Arthritis responded and report an average of 5.7 (SD 1.46) hours sleep per night. Results found 77% of respondents were female, with a mean number of years with inflammatory arthritis to be 10.09 (SD 9.92). Over half had a third level qualification (54%), while a third (33%) were in full-time employment. A majority (61%) report their sleep quality as fairly bad/very bad, with 31% having taken medications at least once a week to help their sleep, over the previous month. Ninety three percent (93%) reported arthritis pain in the previous week, while 23% were limited a lot and 62% limited a little with moderate activities. A large majority report "pain" (95%), "waking up in the middle of the night or early morning" (97%) and "cannot get to sleep within 30 minutes" (91%), as sleep disturbances. There was a statistically significant association between longer years with symptoms (p=0.004), taking medication at least once a week (p=0.009) and limited in their activities (p=0.004), when rating their sleep quality as bad. When using the SQUASH questionnaire, patients' physical activity levels were a low 1,210 minutes per week, compared to other physical activity surveys from their healthy counterparts, even-though 72% believe it is important to measure physical activity.
**Conclusions:** Irish people with Inflammatory Arthritis fall far below the "sleep needs spectrum" with those having symptoms longer, taking medications regularly and having limitations with their activities, reporting poorer sleep quality. More research is needed with regards to investigating poor sleep quality and disturbances in order to promote health and well-being in people with Inflammatory Arthritis. In addition the effects of physical activity interventions on poor sleep needs to be examined to show if it is a positive non-pharmacological treatment approach for the management of poor sleep in patients with Inflammatory arthritis.

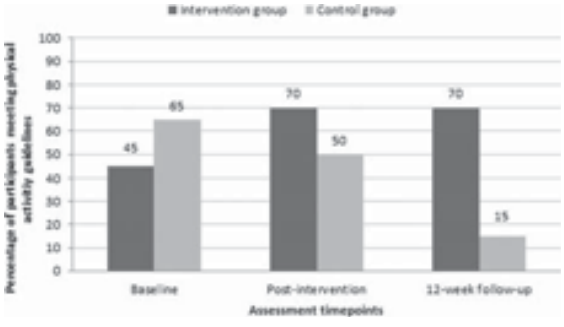
OP0295-HPR **INCREASING PHYSICAL ACTIVITY IN ANKYLOSING SPONDYLITIS (INPACT-AS): A RANDOMISED CONTROLLED TRIAL**



T. O'Dwyer[1], A. Monaghan[1], J. Moran[1], F. Wilson[1], F. O'Shea[2]. *[1]Physiotherapy, Trinity College Dublin; [2]Rheumatology, St. James's Hospital, Dublin, Ireland*

**Background:** The numerous benefits of physical activity (PA) are well established, and guidelines recommend adults obtain ≥150 minutes of moderate-intensity PA per week in bouts lasting ≥10 minutes ($PA_{BOUTS}$)[1]. PA, including exercise, is a key component of the management of ankylosing spondylitis (AS), however participation in PA in this cohort is low[2,3].
**Objectives:** The INPACT-AS trial explored the effects of a PA behaviour change intervention on habitual PA of adults with AS; secondary aims explored effects on spinal mobility and AS-related features.
**Methods:** This single-blind, parallel-group randomised controlled trial recruited adults diagnosed with AS. Exclusion criteria were the presence of comorbidities limiting PA, or recent changes in medication usage. Forty participants (26 males) were randomised to an intervention group (IG) or a control group (CG). Over a 12-week period, the IG had individual consultations with a physiotherapist, aiming to optimise habitual PA. The CG continued with 'usual care'. Blinded outcome assessments were conducted at baseline, post-intervention, and 12-week follow-up. Habitual PA was measured during waking hours with ActiGraph GT3x accelerometers. Questionnaires administered included the Bath AS Disease Activity Index, Bath AS Functional Index, and the AS Quality of Life questionnaire (ASQoL). The Bath AS Metrology Index (BASMI) measured spinal mobility. An intention-to-treat analysis was performed.
**Results:** Mean (SD) age was 38.9 (7.6) years in the IG and 44.8 (9.7) years in the CG. Mean symptom duration was 17.7 (9.5) years in the IG and 24.4 (13.6) years in the CG. Other baseline socio-demographic, AS, medication, and PA-related features were similar across groups ($p>0.05$). No adverse effects were reported during the study. Median number of IG consultations was 5 (IQR 1). Post-intervention, there were significant between-group differences in health-related PA, of large effect size (Tab. 1). After follow-up, significantly more participants in the IG met PA guidelines than in the CG [$\chi^2(1)=12.379$, $p<0.0005$] (Fig. 1). BASMI score changes significantly favoured the IG [ANOVA: $F(2, 76)=5.691$, $p=0.005$]. ASQoL scores significantly improved in the IG [Friedman's test, $\chi^2(2)=8.400$, $p=0.015$].

Table 1. Health-enhancing physical activity

| Variable | Group | Baseline | 12-weeks | 24-weeks | *p*-value[a] | Effect size[b] |
|---|---|---|---|---|---|---|
| Moderate/vigorous intensity PA, min/week | IG | 238 (310) | 309 (278) | 296 (269) | **<0.0005** | **0.205** |
| | CG | 302 (283) | 298 (244) | 197 (128) | | |
| $PA_{BOUTS}$, min/week | IG | 124 (226) | 192 (188) | 198 (171) | **<0.0005** | **0.281** |
| | CG | 173 (188) | 142 (144) | 69 (74) | | |

Median (interquartile range). [a]Mixed-design repeated measures ANOVA. Significant *p*-value <0.05. [b]Partial $\eta^2$: small >0.01, medium >0.06, large >0.14.

**Conclusions:** This was the first behaviour change intervention targeting PA in an AS cohort. Health-enhancing PA, spinal mobility and quality of life were significantly improved after the intervention, and improvements were maintained at three-month follow-up.

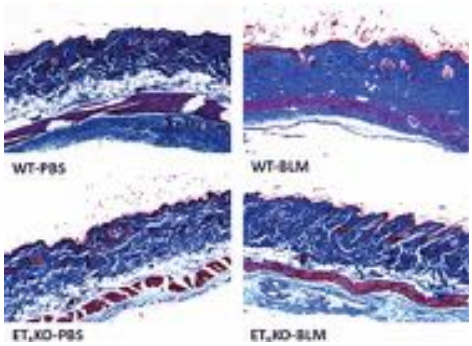
## Endothelial to mesenchymal transition and angiogenesis as driving mechanisms in systemic sclerosis.

### OP0296 COMPARISON OF BOSENTAN AND MACITENTAN EFFECTS ON ENDOTHELIAL-TO-MESENCHYMAL TRANSITION PROCESS INDUCED BY ET-1 IN CULTURED HUMAN MICROVASCULAR ENDOTHELIAL CELLS



S. Soldano, P. Montagna, A.C. Trombetta, R. Brizzolara, A. Sulli, C. Pizzorni, S. Paolino, M. Cutolo. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy*

**Background:** In systemic sclerosis (SSc), the damage of microvascular endothelial cells (ECs) and their phenotype alteration are considered early events responsible for myofibroblast activation and the development of fibrosis (1). Endothelin (ET)-1 and transforming growth factor (TGF)β1 induce ECs to acquire features of extracellular matrix-producing myofibroblasts through the induction of the endothelial-to-mesenchymal transition process (EndoMT) (2).
**Objectives:** To compare the ability of ET-1 receptor antagonists ($ET_{A/B}$RAs), bosentan and macitentan, to support the *in vitro* endothelial damage repair and to contrast the EndoMT induced by ET-1 in cultured human microvascular ECs (HMVECs).
**Methods:** HMVECs, at 3rd culture passage, were grown in endothelial cell medium (EGM2-MV). A part of these cultured HMVECs was untreated or treated with either ET-1 (100nM) or TGFβ1 (10ng/mL) for 6 days. Another part of cultured cells was treated for 1hr with bosentan (10μM) or macitentan (1μM) and then stimulated with ET-1 for 6 days (2,3). At the end of treatments, cultured HMVECs were scraped with a 200μL tip to create a linear injury, whose area was determined at baseline and after 24hrs of culture in EGM2-MV by ImageJ analysis software, to evaluate the *in vitro* endothelial damage repair. The gene expression of specific markers of the EndoMT, such as α-smooth muscle actin (α-SMA), fibroblast specific protein-1 (S100A4), fibronectin (FN), platelet endothelial cell adhesion molecule (CD31), and vascular endothelial (VE)-cadherin was evaluated by quantitative real time polymerase chain reaction (qRT-PCR). Statistical analysis was performed by Man-Whitney non-parametric *U*-test.
**Results:** ET-1 treated HMVECs showed a significantly lower ability to promote the *in vitro* endothelial damage repair compared to untreated cells ($p<0.05$). A similar effect was observed in TGFβ1-treated cells ($p<0.01$). On the contrary, cultured HMVECs treated with $ET_{A/B}$RAs significantly improved the *in vitro* endothelial damage repair compared to ET-1-treated cells ($p<0.05$ for bosentan and macitentan). ET-1 significantly up-regulated the gene expression of α-SMA, S100A4, and FN ($p<0.0001$ for all proteins) and down-regulated that of CD31 and VE-cadherin compared to untreated cells ($p<0.05$, $p<0.01$) as observed by qRT-PCR.
Bosentan contrasted the up-regulation of α-SMA as well as significantly contrasted the up-regulation of S100A4 and FN induced by ET-1 ($p<0.01$, $p<0.05$ vs. ET-1 treated cells). Macitentan significantly reduced the ET-1-induced increase in α-SMA, S100A4, and FN ($p<0.01$; $p<0.01$; $p<0.05$), as well as it antagonized the down-regulation of CD31 and VE-cadherin compared to ET-1 treated cells ($p<0.05$ for both proteins), as observed by qRT-PCR.
**Conclusions:** Both macitentan (at very low concentration) and bosentan seem to allow *in vitro* endothelial damage repair and to efficiently contrast the EndoMT induced by ET-1 in cultured HMVECs. Therefore, $ET_{A/B}$ receptor antagonism might contrast the damage of ECs and their phenotype transition that seems to contribute the early phases of the fibrotic process in SSc.

### OP0297 KNOCKOUT OF ENDOTHELIN TYPE B RECEPTOR SIGNALING ATTENUATES BLEOMYCIN-INDUCED SKIN SCLEROSIS IN MICE

K. Akashi, J. Saegusa, S. Sendo, K. Nishimura, K. Tsuda, I. Naka, T. Okano, S. Takahashi, M. Nishida, Y. Ueda, A. Morinobu. *Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan*

**Background:** Endothelin-1 (ET-1) is important in the pathogenesis of systemic sclerosis (SSc). It has been reported that plasma concentration of ET-1 are higher in SSc patients, and that endothelin receptor expression are also increased in lungs and skins in the patients. ET-1 binds two receptors, endothelin type A ($ET_A$) and endothelin type B ($ET_B$). Dual $ET_A$/$ET_B$ receptor antagonists and a selective $ET_A$ receptor antagonist are used clinically to treat SSc, and the effect of these antagonists on fibroblast activation has been described. However, the role of $ET_B$ receptor signaling in fibrogenesis is less clear.
**Objectives:** This study was conducted to evaluate the profibrotic function of $ET_B$ receptor signaling in a murine model of bleomycin (BLM)-induced scleroderma.
**Methods:** We used $ET_B$ receptor–knockout ($ET_B$KO) mice, which are genetically rescued from lethal intestinal aganglionosis by an $ET_B$ receptor transgene driven by the human dopamine β-hydroxylase (Dβ H)-gene promoter, and wild-type mice with DβH-ETB (WT). BLM or phosphate-buffered saline (PBS) was administered subcutaneously by osmotic minipump, and skin fibrosis was assessed by dermal thickness, subcutaneous fat atrophy, and alpha-smooth muscle actin (αSMA)-expressing myofibroblast count in the dermis. Dermal fibroblasts isolated from $ET_B$KO and WT mice were cultured *in vitro*, stimulated with BLM or ET-1, and the expression of profibrotic genes was compared by quantitative PCR.
**Results:** Dermal thickness, subcutaneous fat atrophy, and myofibroblast counts in the dermis were significantly reduced in $ET_B$KO mice compared to WT mice, after BLM treatment. Compared with wild-type, dermal fibroblasts isolated from $ET_B$KO mice showed lower gene expressions of *αSMA* and *collagen 1α1* in response to BLM or ET-1 stimulation *in vitro.*

**Conclusions:** ET-1–$ET_B$ receptor signaling is involved in skin sclerosis and in collagen synthesis by dermal fibroblasts.

## Cell-cell interaction in joint inflammation

### OP0298 ANTI-CITRULLINATED PROTEIN ANTIBODIES PROMOTE SYNOVIAL FIBROBLASTS MIGRATION AND ADHESION THROUGH A PEPTIDYLARGININE DEIMINASES (PAD) DEPENDENT PATHWAY

M. Sun[1], V. Joshua[2], A. Haj Hensvold[2], S.B. Catrina[3], C. Ospelt[4], V. Malmström[1], K. Amara[1], M. Engström[1], H. Wähämaa[1], B. Rethi[1], A.I. Catrina[1]. *[1]Rheumatology unit, Department of Medicine; [2]Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [3]Department of Molecular Medicine and Surgery, Diabetes Center Karolinska, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; [4]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zürich, Zürich, Switzerland*

**Background:** Synovial fibroblasts (SFs) contribute to rheumatoid arthritis (RA) pathogenesis by growing into the synovial space and by producing pro-angiogenic and tissue remodelling factors, chemokines and inflammatory cytokines that recruit and stimulate various immune cells. We have recently demonstrated that anti-citrullinated proteins antibodies (ACPAs) promote osteoclast development. In the present work we investigated whether ACPAs can also modulate SFs.
**Methods:** SFs were isolated from synovial tissue of RA patients by enzymatic digestion. Polyclonal ACPA and others non-ACPA IgGs were separated from plasma of RA patients by affinity purification on cyclic citrullinated peptide (CCP)-2 column. Monoclonal ACPAs were generated from synovial B-cells. Antibodies were tested in scratch-assays for SF migration and the results were evaluated

by NIH ImageJ software. SF adhesion was analyzed by xCELLigence System Real-Time Cell Analyzer (ACEA bioscience). ACPA-induced signalling pathways were examined using inhibitors of phosphoinositide 3-kinase (PI3K), phosphatase and tensin homolog (PTEN), G-protein coupled receptors, focal adhesion kinase (FAK) and peptidylarginine deiminases (PAD) in the migration assays. Protein phosphorylations were monitored by western blot.
**Results:** Polyclonal ACPAs but not others IgGs induced both SFs migration (a fold increase of 2.6±0.5, mean±SD, $p<0,05$) and SFs adhesion (a fold increase of 1.3±0.1 at 6 hours, $p<0.05$). Similar effects were observed with two (D10 and B02) out of three tested monoclonal ACPAs, with a fold increase of the migration index of 2.4±0.4 for D10 antibody and 2.2±0.4 for B02 antibody ($p<0.05$ for both). IL-8, a chemokine that is upregulated in developing ostecolasts by ACPAs, synergistically increased the ACPA-induced SF migration. Inactivation of the PAD enzymes completely abolished the ACPA-induced SFs migration. GPCR and PI3K blocking completely abolished ACPAs effects, indicating an important role for GPCR and PI3K but not for FAK in the ACPA effects.
**Conclusions:** ACPAs promote SFs migration and adhesion acting synergistically with IL-8 through a PAD-dependent pathway. Our findings suggest that SFs may have a potential role in the ACPA-dependent disease propagation from the bone marrow to synovial tissue.

## OP0299 SUSCEPTIBILITY TO ANKYLOSING SPONDYLITIS IS INFLUENCED INDEPENDENTLY BY TWO CLOSELY ADJACENT RUNX3 SNPS, THAT SHOW STRONG FUNCTIONAL EFFECT IN DIFFERENT CELL TYPES

M.L. Vecellio, A.R. Roberts, B.P. Wordsworth. *Nuffield Dept. of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*

**Background:** More than 60 genes are associated with ankylosing spondylitis (AS), many of which (*RUNX3, EOMES, TBX21, ZMIZ1, IL23R, IL6R, ERAP-1, IL7 and IL7R)* are involved in diverse immunological processes.[1] To understand the functional basis for these genetic associations is one of the greatest scientific challenges in complex polygenic diseases. For example, the association between AS and the single nucleotide polymorphism (SNP) *rs4648889* located in a 2kb regulatory *locus* upstream the promoter of *RUNX3* can be explained by allele-specific effects on transcription factor (TF) recruitment (including IRF4) that alter gene expression, specifically in CD8+ T-cells.[2]
**Objectives:** 22 SNPs in the *RUNX3* locus were initially found to be associated with AS. Here we focus on an independently associated SNP adjacent to *rs4648889* which affects gene regulation in CD14+ monocytes.
**Methods:** We used the Encyclopedia of DNA Elements (ENCODE) data to dissect the epigenetic and transcriptional landscape of the RUNX3 locus; we performed *in silico* analysis and *in vitro* functional studies to characterize the effects of this particular genetic variant, providing critical functional evidence for its role in AS.
**Results:** (1) Conditional analysis on 4230 AS cases and 9700 matched controls established the primacy of *rs4648889* association ($1.3\times10^{-14}$) with AS in this region. However, there was also an independent second signal ($1.7\times10^{-7}$) with *rs4265380*, adjacent to *rs4648889*, highlighting the importance of this *locus* and a likely functional role for *rs4265380*. (2) ENCODE data on CD14+ monocytes, revealed a robust peak for DNA accessibility (DNase1 Hypersensitivity) and TFs ChIP-seq overlapping *rs4265380*. There was also a strong overlying peak for histone modification H3K4Me1, normally associated with active regulatory region. (3) The effect of the *rs4265380* dimorphism on TF binding was evaluated by electrophoretic mobility shift assays (EMSA) using nuclear extract from U937 and THP-1 (monocyte-derived cell lines) focusing on specific TFs involved in monocyte regulation, inflammation and chromatin modifiers (C-Fos, p300 i.e.). (4) Analysis of the expression of inflammasome-related genes revealed some striking differences (i.e CARD6 and IL-6, upregulated of 5 and 177 fold, respectively) influenced by the *rs4265380* genotype.
**Conclusions:** We have identified functional differences in the transcriptional regulation of *RUNX3* associated with AS-associated SNPs at this locus. Two individual adjacent SNPs exert their independent effects in two separate cell types (CD8+ T-cells and monocytes). These observations are critically important not only in identifying cell types that play a pathogenic role in AS but also in defining potential therapeutic drug targets.

# Transition of care

## OP0300 DO DEPRESSIVE SYMPTOMS AT DISEASE ONSET ASSOCIATE WITH FUTURE DISEASE ACTIVITY FOR ADOLESCENT PATIENTS WITH JIA? RESULTS FROM THE CHILDHOOD ARTHRITIS PROSPECTIVE STUDY (CAPS)

L. Hanns[1], L. Cordingley[2], J. Galloway[3], S. Norton[3], L.A. Carvalho[1], D. Christie[1], D. Sen[1], R. Carrasco[2], A. Rashid[2], H. Foster[4], E. Baildam[5], A. Cheing[6], J. Davidson[7], L. Wedderburn[8], K. Hyrich[2], W. Thomson[2], Y. Ioannou[1] on behalf of Childhood Arthritis Prospective Study (CAPS).
*[1]University College London, London; [2]University of Manchester, Manchester; [3]Kings College London, London; [4]University of Newcastle, Newcastle; [5]Alder Hey Children's Foundation NHS Trust Liverpool, Liverpool; [6]Royal Manchester Children's Hospital, Manchester; [7]Royal Hospital for Children Glasgow, Glasgow; [8]University of Manchester, London, United Kingdom*

**Background:** Adolescents with rheumatic disease have a four times higher incidence of depression than healthy peers. Studies in adults have shown an association between depression and worse disease in rheumatoid arthritis, yet this association has never been explored in detail for patients with JIA or in a purely adolescent population.
**Objectives:** This study investigates the association between depressive symptoms and 1) disease activity at onset and 2) future disease activity.
**Methods:** Data are from JIA patients in the Childhood Arthritis Prospective Study, a nationwide inception cohort of childhood onset arthritis. Patients are recruited within 6 months of disease onset and the first study visit is identified as "baseline". Patients were included in this analysis if they were aged 11–16 at baseline. Depressive symptoms were assessed using the Mood and Feelings Questionnaire (MFQ). Associations at baseline were analysed using Spearman's correlation. Separate piecewise linear mixed-effect models for change in active joint count and disability (Childhood Health Assessment Questionnaire (CHAQ)) over 48 months was estimated. A change point at 12 months allowed for different rates of change between 0–12 months and 12–48 months. MFQ score at baseline was included as a covariate
**Results:** 102 patients were included. At baseline, mean age was 12.7 years (SD1.4) and 15.7% were taking DMARDS. 56.7% were female, 52.0% had persistent oligoarticular arthritis, 30.4% had polyarticular arthritis and 17.6% had enthesitis related arthritis. 14.7% scored over the MFQ cut-off for probable depression (>27) at baseline. At baseline, depressive symptoms significantly associated with disability ($r=0.51$, $p<0.000$) and active joint count ($r=0.32$, $p=0.001$). Longitudinal analysis showed that depressive symptoms, active joint count and disability rapidly decreased during the first 12 months after baseline and then stabilised. After 12 months, baseline depressive symptoms no longer associated with active joint count whereas disability for those with high baseline depressive symptoms continued to be higher than those with low depressive symptoms (Figure 1).

**Conclusions:** At disease onset, 14.7% adolescents with JIA have significant depressive symptoms. Those with more depressive symptoms have higher numbers of inflamed joints and more disability. In the 12 months after disease onset, a reduction in disease activity is mirrored by improvements in mental health. After the first year, baseline depression no longer associates with subsequent disease activity but remains associated with higher disability. This highlights the importance of psychological health assessment for adolescent patients with JIA and underlines the need for psychological support fully integrated into their routine care.
**Disclosure of Interest:** None declared

### OP0301 ADOLESCENT AND YOUNG ADULT CARE IN ADULT RHEUMATOLOGY: HOW WELL DO WE KNOW OUR HEEADDSS?

E. Bruce[1], J. Fox[1], A. Samsudeen[2], P. Watson[1], R. Gorodkin[2], J. McDonagh[3,4]. *[1]Rheumatology, University Hospital of South Manchester; [2]Rheumatology, Central Manchester University Hospitals; [3]Paediatric Rheumatology, Royal Manchester Childrens Hospital; [4]Centre for Musculoskeletal Research, Manchester University, Manchester, United Kingdom*

**Background:** Most rheumatology departments will have a significantly larger cohort of older adolescents and young adults (AYAs) that enter adult services de-novo than will have transitioned from paediatric services. The current move towards a hub and spoke model of care makes it increasingly important that both secondary and tertiary care services are aware of AYA specific needs.
**Objectives:** Our aim was to evaluate AYA care within two different adult Rheumatology clinics, in particular focusing on use of the HEEADDSS psychosocial interview.
**Methods:** A review of clinical correspondence for 120 patients aged 16–25yrs attending adult rheumatology clinics at a secondary and tertiary care hospital in Greater Manchester, UK.
Data collected focussed on evaluating the documentation of components of the HEEADDSS screen.
**Results:** At both sites the "did not attend" rate was equal at 13%. The tertiary hospital had significantly more AYAs with Juvenile Idiopathic Arthritis (JIA) (22 patients) than the secondary care hospital (4 patients).
There were differences in recording of the HEEADDSS criteria. The three most frequently documented at the tertiary hospital were drugs, education, home (41%, 36%, 19% respectively), least documented was sleep (5%). The three most often documented at the secondary care hospital were, education, exercise, activities (24%, 15%, 13% respectively), least documented was sex (1%).
**Conclusions:** There were significantly more AYAs with JIA in the tertiary hospital. Documentation of HEEADDSS criteria varied between the two hospitals, documentation of any component was achieved in less than 50% of AYAs.
A hub and spoke model of healthcare requires all adult rheumatologists to have an understanding the unique needs of AYAs.

## New approaches to understanding and managing chronic musculoskeletal pain

### OP0302-PARE SUPPORTING PEOPLE WORKING WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES (RMDS)

G. O'Leary. *Arthritis Ireland, Grand Canal Quay, Ireland*

**Background:** Work is proven to be good for your health and it is important to people with rheumatic and musculoskeletal diseases (RMDs), both financially and for their quality of life and wellbeing. There is also an enormous social cost. In Ireland, RMDs account for 7 million days in absenteeism - half of the total. That amounts to €750 million each year. €295 million is paid out in illness benefit. Arthritis Ireland is working to improve the supports available to people with RMDs so that they can continue in their jobs or get back to work.
**Objectives:** The objectives of the project were to 1) develop succinct informative guides to working with RMDs for both employees and employers 2) develop an online educational programme to provide information, guidance and support to employees, employers and healthcare professionals on working with RMDs.
**Methods:** In 2011, Arthritis established Fit for Work Ireland – a coalition of stakeholders including employer and employee representatives and health professionals with the key goal of improving employees' ability to work with RMDs and reducing the impact of RMDs on workplace absenteeism.
Arthritis Ireland has developed a number of educational tools to support people with RMDs in the workplace as part of our Fit for Work Programme. 2014 saw the development of two comprehensive guides for employees and employers to help address these challenges. 1) "*Working with arthritis, back pain & related conditions: A guide for employees*" provides up to date and accurate information and advice to make sure an individual can find the help they need to stay in their job. If a person is worried or concerned following a recent diagnosis of an MSD, they can find more information about what kind of support they are entitled to. This guide also discusses the options of re-training or moving to different types of jobs within an organisation. 2) "*Arthritis, back pain & related conditions: A guide for employers*" provides a practical source of information and guidance for employers to help them to understand what MSDs are; understand how MSDs may affect employees and support employees working with MSDs.
In 2015 Arthritis Ireland developed an online education programme "*Fit for Work Online*" which focuses on the tripartite relationship between the employee, employer and healthcare professional.
**Results:** The two published guides for employees and employers have been distributed widely to rheumatology clinics, physiotherapy clinics and GP surgeries. The guides are also available for order or for download on the Arthritis Ireland website. The information has been positively received but employees, employers and healthcare professionals alike.
"*Fit for Work Online*" will launch formally in February 2016.
**Conclusions:** Despite the staggering incidence and the fact that RMDs are the leading cause of work absence in Ireland, these conditions often remain overlooked by policy makers and employers. This project has aimed to improve employee's ability to work with RMDs through the provision of clear and quality information and support.

### OP0303-PARE RAISING PUBLIC AWARENESS ON OSTEOARTHRITIS THROUGH AN EDUCATIONAL CAMPAIN

N. Avielle, K. Blidberg, B. Svanberg. *Reumatikerförbundet, Stockholm, Sweden*

**Background:** The Swedish Rheumatism Association has in collaboration with Netdoktor.se, Sweden's leading public portal for health issues, developed an online test with the aim of improving public awareness of osteoarthritis. There are many myths surrounding osteoarthritis that we need to address, for example that osteoarthritis is just something one needs to accept rather than it being treatable.
**Objectives:** There is a lack of knowledge in the Swedish society about osteoarthritis. With this online test we want to improve the understanding of the condition. Without basic knowledge it is hard for a patient to demand one's right in the health care system.
**Methods:** The Swedish Rheumatism Association has in collaboration with Netdoktor.se put together a team of experts to review all information in the test. The experts have different backgrounds from both the medicine, IT and PR.
**Results:** This far the test has been very successful, a total of 9 720 individuals have completed the whole test and 35 388 have visited the website for more information.
The test shows that among women with symptoms of osteoarthritis, who had sought medical advice, only 40% have received any explanation on what may cause their joint pain. And out of these women, 23% use naturopathic drugs for their condition. The numbers are almost the same for men; only 41% have received an explanation on what may cause their joint pain and 20% uses naturopathic drugs.
Out of the category which already has been diagnosed with osteoarthritis, 62% have not been invited to join an evidence based supportive osteoarthritis self-management program lead by a physiotherapists. The program helps the patient to gain knowledge to improve their health condition, a program which the Swedish Rheumatism Association recommends.
**Conclusions:** The Swedish Rheumatism Association is able to use the different statistic that the test generates to raise awareness about osteoarthritis. Approximately 800 000 Swedes suffer from osteoarthritis in one or more joints. It is in other words a huge public health issue and more needs to be done for a better care of this patient group. Our aim is that the health care system will increasingly recommend their patients to the supportive osteoarthritis self-management program.

## Picking knowledge from other medical disciplines for SSc

### OP0304 ESTROGENS INHIBIT THE PROFIBROTIC EFFECTS OF TGF-BETA AND PROTECT FROM THE DEVELOPMENT OF EXPERIMENTAL DERMAL FIBROSIS

J. Avouac[1], L. Baudoin[2], A. Cauvet[2], B. Ruiz[2], M. Elmerich[2], Y. Allanore[1]. *[1]INSERMU1016 and Rheumatology A department, Paris Descartes University, Cochin Hospital; [2]INSERM U1016, Cochin Institute, Paris, France*

**Background:** Systemic sclerosis (SSc) primarily affects postmenopausal women. This sex bias could partly be explained by the action of estrogens on the immune system and/or fibrogenesis. Since little is known about their direct role in fibrogenesis.
**Objectives:** Our aim was to evaluate the effects of estrogens i) on the pathological activation of dermal fibroblasts induced by transforming growth factor-b (TGF-β) and ii) in the development of experimental dermal fibrosis.
**Methods:** Effects on estrogen inhibition by gene inactivation (knockout mice for the estrogen receptor-α, ERKOα) or targeted molecular strategy (tamoxifen, a selective estrogen receptor modulator that display anti-estrogenic properties) were evaluated in the mouse model of bleomycin-induced dermal fibrosis and in the tight skin (Tsk-1) mouse model.
SSc dermal fibroblasts were stimulated with TGF-β and incubated with different concentrations of 17-β-estradiol and/or tamoxifen. Collagen release from fibroblasts was evaluated by mRNA levels of col1a1 and col1a2 and by measuring the concentrations of collagen in cell culture supernatants with the SirCol collagen assay. Differentiation of fibroblasts into myofibroblasts was assessed by the ex-

pression of alpha smooth muscle actin (α-SMA). Activation of the TGF-β pathway was evaluated by the expression of phospho-smad-2/3.
**Results:** Estrogen inhibition increased the activation of canonical TGF-β signaling and exacerbated skin fibrosis both in the bleomycin model and in Tsk-1 mice. Upon bleomycin injections, ERKO-α mice treated with tamoxifen had a significant increase of dermal thickness (17%, p=0.03 and 20%, p=0.04), hydroxyproline content mice (16%, p=0.02 and 36%, p=0.003, respectively) and number of myofibroblasts (22%, p=0.01 and 20%, p=0.04 respectively) compared to control mice. In Tsk-1 mice, treatment with tamoxifen led to significantly enhanced skin fibrosis, with a 31±8% increase of hypodermal thickening (p=0.03) and a 17% increase of hydroxyproline content (p=0.01) compared to control mice.
In SSc dermal fibroblasts, treatment with 17-β-estradiol significantly decreased the stimulatory effects of TGF-β on collagen synthesis and myofibroblast differentiation, decreased activation of canonical TGF-β signaling, and markedly reduced the expression of TGF-β target genes. Tamoxifen reversed the inhibitory effects of estrogens by restoring Smad2/3 phosphorylation and TGF-β-induced collagen synthesis.
**Conclusions:** Our results demonstrate a beneficial effect of estrogen in experimental dermal fibrosis. Estrogens reduce TGF-β dependent activation of SSc dermal fibroblasts and estrogen inhibition leads to a more severe experimental dermal fibrosis. These findings may partly contribute to the occurrence of SSc in postmenopausal women and the greater severity of the disease in men and open avenue to potential hormonal therapies.

## OP0305 PSYCHOLOGICAL PROFILE OF SCLERODERMA PATIENTS DESCRIBED BY MULTIDIMENSIONAL MINNESOTA MULTIPHASIC PERSONALITY INVENTORY (MMPI II) AND BECK DEPRESSION INVENTORY TESTS (BDI II)

A. Smržová[1], L. Hubáčková[2], S. Kreiselová[2], M. Schubertová[1], M. Skácelová[1], A. Petráčková[3], E. Kriegová[3], Z. Heřmanová[3], F. Mrázek[3], P. Horák[1]. *[1]3Rd Department of Internal Medicine – Nephrology, Rheumatology and Endocrinology; [2]Department of Psychology; [3]Department of Immunology, Faculty of Medicine and Dentistry, Palacký University Olomouc, Olomouc, Czech Republic*

**Background:** Scleroderma is a systemic multiorgan autoimmune disease with high mortality and morbidity rates. In serious disease with organ manifestation, quality of life and perception of health is deeply influenced in these patients. The face changes and fibrosis of skin, digital ulceration contribute to the psychological trauma of these patients. Only little is known about the objective evaluation of systemic scleroderma psychological impact.
**Objectives:** The aim of study is detection of psychological profile and manifestation of depression in scleroderma patients.
**Methods:** From March 2015 to January 2016 we examined 42 patients with scleroderma Patients were evaluated by MMPI-II (The Minnesota Multiphasic Personality Inventory test, standardized psychometric test of adult personality and psychopathology) and BDI-II tests (Beck Depression Inventory test of depression). The data obtained from the multidimensional pachological testing were correlated with the clinical and laboratory pheonotype of the disease (smoking status, BMI, arterial hypertension, diabetes, lipid profile, family history of cardiovascular event, lung manifestation, pulmonary hypertension, digital ulceration, damage of gastrointestinal tract, myositis, renal crisis, autoantibody profile, and presence of cardiovascular events) Statistical tests (descriptive statistic, Student t-test, Spearman test, ANOVA) were performed and p-value $\leq$0.05 was considered as significant.
**Results:** In this study42 patient were included (6 men, 36 women. mean of age – 57,8±9.4y., duration of disease 8,6±8.2y. duration of Raynauds phenomenon 13,4±11,2y.), 12 patient have diffuse form and 30 patient limited form of scleroderma. Subjective perceived depression detected by BDI II test was present in 16 patients (32.1%, mild 7, moderate 7 and 2 severe). BDI-II correlated with anticentromer antibodies (p=0.05), total cholesterol (p=0.008), LDL (p=0.05) and, gastrointestinal manifestation (p=0.002). Scale L, F and K in MMPI-II test in typical sequence for depressive score was detected in 38 patients (90%). The main scales of MMPI-II test were detected in followed percentage values: – Hypochondria (54.7%), Depression (33.3%), Converse hysteria (28.6%), Psychopathic (14.3%), Masculinity/Felinity (7.1%), Paranoia (9.5%), Psychastenia (26.2%), Schizophrenia (21.4%), Hypomania (11.9%) and Social introverse (33.3%).
**Conclusions:** The limitation of these data is fact, that these tests showed some of trends of symptoms typical for psychological and personal manifestation; they could not be regarded as a diagnostic test. Patients with scleroderma have high prevalention of subjective perceived depression. In this study we detected high prevalence of depression, social introversion and trend toward somatisation. It will be very useful to be aware of this subjective perception of scleroderma patient and cooperated with psychologist or psychiatrist to improve quality of life and sometimes also morbidity of these seriously ill patients.

## OP0306 TEN YEARS OF DENOSUMAB TREATMENT IN POSTMENOPAUSAL WOMEN WITH OSTEOPOROSIS: RESULTS FROM THE FREEDOM EXTENSION TRIAL

H. Bone[1], M. Brandi[2], J. Brown[3], R. Chapurlat[4], S. Cummings[5,6], E. Czerwinski[7], A. Fahrleitner-Pammer[8], D. Kendler[9], K. Lippuner[10], J.-Y. Reginster[11], E. Vittinghoff[6], N. Daizadeh[12], A. Wang[12], P. Dakin[12], R. Wagman[12], S. Papapoulos[13]. *[1]Michigan Bone and Mineral Clinic, Detroit, MI, United States; [2]University of Florence, Azienda Ospedaliera Careggi, Florence, Italy; [3]Laval University and CHU de Québec Research Centre, Quebec City, QC, Canada; [4]Hôpital Edouard Herriot, Lyon, France; [5]San Francisco Coordinating Center, CPMC Research Institute; [6]University of California, San Francisco, San Francisco, CA, United States; [7]Krakow Medical Centre, Krakow, Poland; [8]Medical University Graz, Graz, Austria; [9]University of British Columbia, Vancouver, BC, Canada; [10]Bern University Hospital, Bern, Switzerland; [11]University of Liège, Liège, Belgium; [12]Amgen Inc., Thousand Oaks, CA, United States; [13]Leiden University Medical Center, Leiden, Netherlands*

**Background:** Osteoporosis is an important chronic disease, requiring prolonged treatment. Long-term efficacy and safety data are therefore of great importance. Denosumab (DMAb) is used in over 80 countries or administrative districts worldwide for the treatment of postmenopausal women with osteoporosis. The effects of DMAb treatment for up to 10 years have been evaluated in the 3-year FREEDOM study and its 7-year extension.
**Objectives:** Report results through the final year of the FREEDOM extension, representing up to 10 years of continued DMAb treatment.
**Methods:** During the extension, all subjects were to receive 60 mg DMAb every 6 months and calcium and vitamin D daily. In this analysis, the long-term group received 10 years of DMAb treatment (3 years in FREEDOM and 7 years in the extension), and the cross-over group received 7 years of DMAb treatment (3 years of placebo in FREEDOM and 7 years of DMAb in the extension).
**Results:** Of the 4,550 subjects who entered the extension, 2,784 (61%) continued to participate at the beginning of year 10. Of these, 2,212 (80%) have completed their final 10-year visit, 120 (4%) discontinued, and 452 (16%) were ongoing at the time of this submission. In the long-term group, further significant increases in BMD occurred with mean cumulative 10-year gains of 21.6% (lumbar spine) and 9.1% (total hip) from FREEDOM baseline. The cross-over group had mean cumulative 7-year gains of 16.3% (lumbar spine) and 7.3% (total hip) from the extension baseline (Figure 1; all $P<0.0001$ compared with FREEDOM baseline, extension baseline, and previous measurement). Similar and sustained reductions in bone turnover markers were observed in both groups, with the characteristic attenuation of effect at the end of the dosing period. Yearly rates of new vertebral and nonvertebral fractures remained low. Overall incidence rates of adverse events (AEs) and serious AEs were consistent with data reported previously in the extension study.

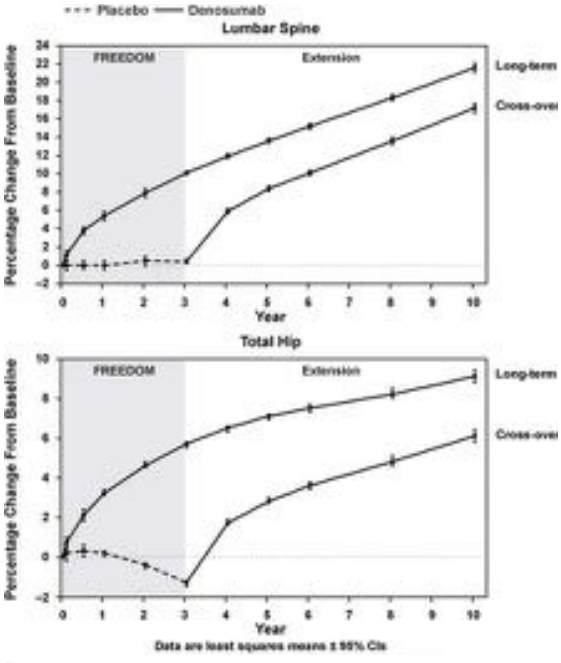

Figure 1

**Conclusions:** DMAb treatment for up to 10 years was associated with persistent reduction of bone turnover, continued increases in BMD without therapeutic

plateau, and low fracture incidence. The benefit/risk profile for DMAb in an aging population of postmenopausal women remains favorable.

### OP0307 NO LONG-TERM EFFECT ON DISEASE ACTIVITY AND PAIN OF PHYSICAL ACTIVITY FOUND IN PROSPECTIVE OBSERVATIONAL STUDY OF EARLY RHEUMATOID ARTHRITIS

M.E. Sandberg[1,2], H. Westerlind[3], S. Saevarsdottir1[3], P. Frumento[3], L. Klareskog[3], L. Alfredsson[3]. *[1]Inst. of Environmental Medicine, Karolinska Institutet, Stockholm; [2]Epidemiology and Register Centre South, Skane University Hospital, Lund; [3]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*

**Background:** Physical activity was once perceived as potentially harmful for patients with rheumatoid arthritis (RA), but intervention trials in the past decade have shown that physical activity on the contrary is well tolerated in established RA. [1] Further, small, short-term intervention studies have in addition shown potential positive effects of physical activity/exercise on the symptoms of RA [2].

**Objectives:** Prospectively investigate the long-term effect of physical activity on the prognosis of rheumatoid arthritis (RA) in terms of disease activity, measured as DAS28, and pain, measured on the VAS-scale.

**Methods:** We used incident RA cases from the population-based EIRA-study with clinical follow-up in the Swedish Rheumatology Quality Register (2006–2010). We investigated the effect of self-reported physical activity 1 year after diagnosis (>150 min. of moderate/intense or >75 min intense activity/week), on the probability of remission (DAS28<2.6) and remaining pain (CRP<10mg/l and VAS-pain>20mm) after 3 years, using modified Poisson regression, adjusted for sex, age at diagnosis, BMI, education, smoking, physical activity before diagnosis and baseline level of DAS28/pain, respectively. Further, we estimated the longitudinal effect from assessment of physical activity, using mixed models, and also the effect of the combination of physical activity 5 years before/1 year after diagnosis in four groups (low-low, low-high, high-low and high-high).

**Results:** 555 RA-patients were included in this study, the mean age at diagnosis was 54 years and 74% was female. One year after diagnosis, when physical activity was assessed, the mean DAS28 was 2.92 and the mean VAS-pain was 30. We could not detect any effect of physical activity after diagnosis; the adjusted risk ratio for remission was 1.07 (95%CI:0.74–1.53) and for remaining pain 1.12 (95%CI:0.75–1.67). Similarly, no effect was found using longitudinal analysis (p-value for difference in DAS28, comparing active and non-active patients: 0.32, corresponding p-value for difference in VAS-pain: 0.71) or when we investigated the combination pattern of physical activity 5 years before RA-diagnosis and 1 year after.

**Conclusions:** In this prospective cohort study we did not find evidence of an effect of self-reported physical activity on the prognosis of RA, either measured as pain or disease activity. Such lack of improvement could e.g. occur if the effect of physical activity would be short-lasting. There is no reason to doubt the beneficial effect of physical activity on the general health of RA-patients, similar to the effect for the general population.

## Intimate life and sexual relations in RA

### OP0308-HPR PRECIPITATING, PREDISPOSING AND MAINTENANCE FACTORS ASSOCIATED WITH SEXUAL DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Villarreal[1], P. Santos-Moreno[2], J. Bello[2], N. Palacio[3], C. Castro[4], D. Buitrago-Garcia[4]. *[1]Psychology; [2]Rheumatology; [3]Nursing; [4]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Sexuality is an important dimension of personality and human body, therefore any involvement in this area should be considered as important. Sexual disturbances in rheumatoid arthritis (RA) patients are poorly described in literature.

**Objectives:** The aim of this study using CIE-10 was to describe different type of factors that may influence the prevalence and worsening of sexual disturbances in patients with RA and relationship with disease activity.

**Methods:** A descriptive cross-sectional study was performed in a specialized clinic dedicated to Ra patients care. Patients seen by the area of psychology, information was collected through semi-structured interviews and non-probability sampling. Descriptive epidemiology was done, using averages and percentages for categorical and qualitative variables; we used chi2 test to study a possible relationship between the level of disease activity with precipitating, predisposing and maintenance factors.

**Results:** Total sample of patients was 1298, 1048 (80%) were women and 250 (19%) were men. Patients had a DAS28 2.6 in average ± 1.1; mean age was 55.1 ± 8.8 years; 451 (40%) women reported no sexual activity, while 627 (60%) reported sexual activity. 77 (31%) of men reported no sexual activity, while 173 (69%) reported sexual activity. 377 (36%) of women and 85 (34%) men referred to have any sexual disturbances (lack of sexual desire, non-satisfactory sexual life, dyspareunia, orgasmic dysfunction, premature ejaculation). The relationship between having a sexual disturbance and the disease activity was not statistically significant. *precipitating factors:* In women 110 (33%) manifested infidelity, 107 (32%) insecurity in sexual role, biological or physical causes 56 (17%) while in men 42 (16%) manifested insecurity in sexual role, 38 (15%) inadequate information, 15 (6%) infidelity, and 7 (3%) biological or physical causes. *predisposing factors:* Of those who had any predisposing factor, in woman 155 (14%) were related to image changes (14%), infidelity 135 (13%), anxiety 23 (2%) and loss of attraction 15 (1.4%), while in men 53 (21%) were related to image changes, 24 (10%) loss of attraction, 18 (7%) infidelity, and 5 (2%) anxiety. *maintenance factors:* In women, 120 (11%) reported maintenance factors related with biological causes followed by 100 (9%) infidelity, 93 (9%) general alteration of couple relationship, 37 (3%) partner's sexual dysfunction and 20 (1.9%) depression and anxiety; while in men, 47 (19%) general alteration of couple relationship followed by 39 (15%) reported maintenance factors related with biological causes, 14 (5%) depression and anxiety, 10 (4%) infidelity and 2 (0.8%) partner's sexual dysfunction. The relationship between precipitating, predisposing or maintenance factors and disease activity was not statistically significant.

**Conclusions:** According to these findings sexual disorders are present in a half of patients with RA both men and women. There are many factors that may influence the prevalence and worsening of sexual disturbances; however the sexual disturbances do not affect disease activity.

## Bone and heart: common molecular mechanisms in osteoporosis and atherosclerosis

### OP0309 ASSOCIATION OF BONE MINERAL DENSITY AND CAROTID ATHEROSCLEROSIS IN PATIENTS WITH DIABETES TYPE 2

V. Vasilkova[1], T. Mokhort[2], E. Naumenko[3]. *[1]Gomel State Medical University, Gomel; [2]Belarusian State Medical University, Minsk; [3]The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus*

**Background:** Many epidemiological studies have shown that low bone mineral density (BMD) and atherosclerosis appear to be related. However, their precise correlation is not completely understood [1,2].

**Objectives:** The aim of this study was to examine the relationship between bone mass and carotid measurements in patients with diabetes type 2 (DT2).

**Methods:** 105 patients both sexes with type 2 diabetes aged 54.69±11.07 years were studied. Control group included 84 healthy subjects the same age. Osteoporosis was defined as a femoral neck BMD T score below -2.5. Carotid intima media thickness (cIMT) and carotid plaque occurrence were determined by B-mode ultrasound and BMD by dual-energy X-ray absorptiometry. The plaques were measured in both common and internal carotid arteries.
**Results:** BMD and cIMT were inversely associated both in patients and controls. The correlation was stronger in females than in males, and in females, the correlation was stronger after menopause. Patients with DT2, with carotid plaque had higher cIMT at low BMD than at normal BMD, p=0.020. Multiple linear regression analysis reveals that age ($p<0.001$), smoking (p=0.016), and osteoporosis (p=0.001) were significantly associated with increased cIMT. In women, cIMT was significantly related to age (p=0.01) and osteoporosis (p=0.03). In men, though there was no significant relationship, a trend toward old age and having osteoporosis was observed in increased cIMT (p=0.054, p=0.075).
**Conclusions:** The association between carotid atherosclerosis and bone metabolism has become an increasing focus of interest in recent years [3], and accumulating evidence has shown that atherosclerosis and osteoporosis frequently co-exist. We found inverse association between BMD and carotid measurements in both diabetic patients and controls. Diabetes type 2 patients, especially postmenopausal women, with decreased BMD may have a higher risk of developing coronary atherosclerosis.

### OP0310 ASSOCIATION OF NEUTROPHIL EXTRACELLULAR TRAPS WITH ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS

N. Barbarroja[1], P. Ruiz-Limón[1], C. Perez-Sanchez[1], Y. Jimenez-Gomez[1], M.C. Abalos-Aguilera[1], I. Arias de la Rosa[1], P. Segui[2], P. Font[1], M.A. Aguirre[1], J. Calvo[1], R. Ortega[1], M.C. Castro[1], R. Gonzalez-Conejero[3], C. Martinez[3], E. Collantes-Estevez[1], A. Escudero[1], C. Lopez-Pedrera[1]. *[1]Rheumatology service; [2]Radiology service, IMIBIC/University of Cordoba/Reina Sofia Hospital, Córdoba; [3]Regional Centre of Blood Donation, University of Murcia, Murcia, Spain*

**Background:** Neutrophil extracellular traps (NETs) have recently been implicated in vascular damage and atherothrombosis. Extruded DNA fibers containing multiple proinflammatory and thrombotic molecules induce the activation and recruitment of monocytes and dendritic cells to the vessel wall. Enhanced NETosis occurs in rheumatoid arthritis (RA), which has been shown related to the pathogenesis of this disorder. However, the relevance of this abnormality in the development of atherosclerosis has not been elucidated yet.
**Objectives:** To evaluate the association of netosis-derived products with the development of atherosclerosis in RA.
**Methods:** One hundred RA patients and 30 healthy donors were included. Carotid intima media thickness (CIMT) was used as atherosclerosis marker. Inflammatory and prothrombotic molecules, nitric oxide (NO), total antioxidant capacity (TAC) and protein nitration (NTyr) were analyzed in plasma. Neutrophils were isolated from RA patients and controls. Spontaneous and induced NETs formation from RA and control neutrophils was assessed in vitro through fluorescence microscopy. Oxidative stress status (JC1 and DCFH) and myeloperoxidase (MPO), neutrophil elastase (NE) protein expression were measured in neutrophils through flow cytometry. Cell-free DNA plasma levels were analyzed using Sytox staining. mRNA expression of peptidyl arginine deiminase 4 (PAD4) was analyzed in neutrophils by RT-PCR. Receiver operator characteristic (ROC) curves were calculated.
**Results:** Induced NETosis was increased in RA patients alongside MPO and NE protein expression in neutrophils. Cell-free DNA plasma levels were found significantly increased in RA patients. ROC curve analysis showed an area under the curve (AUC): 84, with a high sensitivity (69%) and specificity (86%). Those DNA levels strongly correlated with clinical parameters such as evolution time, DAS28, CRP and ESR and autoimmunity state (RF and anti-CCPs levels). In addition, high levels of cell-free DNA were associated with elevated levels of IL-6, MCP-1, spSelectin and tPA in plasma. Moreover, high levels of cell-free DNA correlated with increased NTyr and TAC and decreased NO. At cellular level, cell-free DNA plasma levels correlated with increased oxidative status in RA neutrophils (JC1 and DCFH) and mRNA expression of PADI4. Those patients having pathologic CIMT showed increased cell-free DNA plasma levels (ROC curve analysis: AUC 77, sensitivity 60%, specifity 72%).
**Conclusions:** 1) Elements associated with the extrusion of NETs are significantly enhanced in RA compared with healthy controls. 2) NETosis-derived products, such as cell-free DNA strongly correlated with clinical parameters, inflammatory and oxidative status in RA patients. Thus, NETosis-derived products demonstrated diagnostic potential for atherosclerosis, which might be a complementary tool to discriminate between normal and pathologic CIMT in RA patients.

## Adiposity as a driver of arthritis through inflammatory mechanisms

### OP0311 SYNOVIAL LIPODYSTROPHY INDUCED BY HYPERCHOLESTEROLEMIA AGGRAVATES SYNOVITIS IN AN EXPERIMENTAL MODEL OF OSTEOARTHRITIS IN RABBITS

R. Largo[1], A. Larranaga-Vera[2], S. Perez-Baos[2], I. Prieto-Potin[2], G. Herrero-Beaumont[2]. *[1]Joint and Bone Research Unit, RETICEF; [2]Joint and Bone Research Unit, Rheumatology Dept., IIS-Fundación Jiménez Díaz, Madrid, Spain*

**Background:** Metabolic syndrome (MetS) is a risk factor for osteoarthritis (OA). While obesity contribution is well characterized, less known is the effect of each component of this syndrome on its own. Particularly interesting is the role of hypercholesterolemia, given the high incidence of cardiovascular events and atherosclerosis in OA patients.
**Objectives:** To study the effect of hypercholesterolemia without any other component of MetS in the synovial inflammation in knee OA.
**Methods:** 16 New Zeland rabbits were fed with a high fat diet (HFD, 0.5% cholesterol+4% peanut oil). Six weeks later, OA was induced by anterior cruciate ligament transection and partial medial meniscectomy, in 10 of these animals (OA+HFD group), and in 10 regular chow fed rabbits (OA group). 10 healthy rabbits fed with regular chow were simultaneously followed (Control group). Twelve weeks after OA induction, animals were euthanized and SM isolated for histological and molecular biology studies.
**Results:** HFD, OA and OA+HFD animals gain significantly less weight than control rabbits at the end of the study. We did not find significant differences in systolic blood pressure, serum glucose or oral glucose tolerance between the groups. HFD fed rabbits showed higher total serum cholesterol, triglycerides and C-Reactive Protein levels than rabbits fed a normal diet. Synovitis score was increased in HFD and OA rabbits, and particularly in OA+HFD group, with the more severe score. Synovitis in OA+HFD was characterized by a massive infiltration of foam RAM11+ cells, with higher presence of multinucleated foam cells and stromal fibrosis than in OA. A huge decrease in the adipose tissue area (%ATA)t ogether with a marked decrease in the adipocyte size was observed in the SM of OA+HFD in comparison to OA and control animals. Furthermore, perilipin1a synthesis was significantly decreased in OA+HFD in comparison to OA and control rabbits. In comparison to controls, synovial leptin and adiponectin gene expressions were markedly decreased in HFD and OA rabbits, and especially in OA+HFD animals ($p<0.01$ vs OA), and positively correlated with %ATA in these animals. By contrast, serum leptin was increased in HFD and OA+HFD in comparison to control rabbits. We did not find significant differences in the SM gene expression of the proinflammatory cytokines IL-1$\beta$, COX-2 or MCP-1, between OA and OA+HFD animals. However, TNF SM expression was significantly increased in OA+HFD vs. OA, and significantly correlated with the presence of RAM11+ cells in the SM of these rabbits.
**Conclusions:** Our data show that hypercholesterolemia is an aggravating factor for OA synovitis, inducing an increased infiltration of macrophages and the disappearance of adipose tissue in the SM. Hypercholesterolemia induced a profound decrease in the adipocyte content in the OA SM, together with a remarkable increase in synovial TNF expression. HFD induced a decrease in the synovial expression of leptin and adiponectin in OA rabbits. However, high levels of serum leptin, probably due to systemic synthesis such as that derived from the liver were found in HFD fed animals. Our data indicate that synovial adipocytes and dyslipemia could play pivotal roles in OA joint deterioration in patients with MetS, and support the concept that the link between obesity and OA transcends mechanical loading
**Disclosure of Interest:** None declared

### OP0312 DIABETES-ACCELERATED EXPERIMENTAL OSTEOARTHRITIS IS PREVENTED BY AUTOPHAGY ACTIVATION

B. Carames[1], M. Ribeiro[1,2], P. Lopez de Figueroa[1], U. Nogueira-Recalde[1], A. Centeno[3], A.F. Mendes[2], F.J. Blanco[4]. *[1]Cartilage Biology Group. Rheumatology Division, Biomedical Research Institute of A Coruña, a Coruña, Spain; [2]Centre for Neuroscience and Cell Biology and Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal; [3]Unidad de Cirugía Experimental; [4]Rheumatology Division, Biomedical research Institute of A Coruña, a Coruña, Spain*

**Background:** Type 2 Diabetes (T2D) is a risk factor for Osteoarthritis (OA) (1). Autophagy, an essential mechanism in articular cartilage, is defective in T2D and OA (2). However, how T2D may influence OA progression is still unknown.
**Objectives:** We aimed to determine how diabetes affects cartilage integrity and whether pharmacological activation of autophagy has disease-modifying efficacy in diabetic mice with OA.
**Methods:** Experimental OA was performed in the right knee of 9 weeks-old C57Bl/6 male mice (Lean group, N=8) and of 9 weeks-old B6.BKS (D)-*Leprdb* male mice (db/db group, N=16) by transection of medial meniscotibial and medial collateral ligaments. Left knee was employed as control knee. Rapamycin (2 mg/kg weight/day) or Vehicle (dimethyl sulphoxide) were administered intraperitoneally 3 times a week for 10 weeks. Body weight and fasting blood glucose levels were monitorized weekly. Insulin levels in plasma were determined by ELISA at the end of the study. Histopathology in articular cartilage and synovium was evaluated by using semiquantitative scoring and synovitis grading systems, respectively. Immunohistochemistry was employed to evaluate the effect of diabetes and Rapamycin on cartilage integrity and OA biomarkers.
**Results:** Diabetic mice have increased body weight, fasting blood glucose levels and insulin levels compared to lean mice. Importantly, Rapamycin treated mice have significantly reduced body weight and blood glucose and insulin compared to control db/db mice. Moreover, rapamycin treatment significantly reduced the phosphorylation of rpS6, a direct target of mTOR and increased phosphorylation of AMPK. The results indicated that cartilage damage was significantly increased in db/db mice compared to lean group after surgical induction of OA, while no differences are observed in the control knee. mTOR inhibition protects against surgical-induced OA in db/db mice joints. Cartilage damage and OA severity was significantly reduced in the treated group. This reduction was accompanied with a significant reduction in synovium inflammation and in the expression of OA biomarkers, such as MMP-13 and ADAMTS-5 and decreased IL-12 levels. Furthermore, LC3 lipidation, a marker of autophagosome formation, was increased and cartilage cellularity was maintained after treatment, suggesting that autophagy activation protects chondrocytes against death.
**Conclusions:** Our findings indicate that diabetic mice exhibit accelerated-joint damage after experimental OA, and that autophagy activation might be an effective therapy for diabetes-accelerated OA.

## There is more than drugs

### OP0313-PARE THE SWEDISH RHEUMATISM ASSOCIATION'S BLOG ABOUT TRAINING – A NEW WAY OF LEARNING

E. Löfberg. *The Swedish Rheumatism Association, Stockholm, Sweden*

**Background:** Regardless of whether we live with a rheumatic disease or not recommendations on physical activity and training apply to all of us. For a person with rheumatic disease easily accessible knowledge and how-to-do ideas on physical activity and training is central. It contributes not only to a reduction of current symptoms but it also contributes to a higher level of sustained health over time, both physically, psychologically and socially. In synergy with the development of IT and different social media, blogging has become a tool of communication also in the public sector. A blog often approaches its reader in a readily accessible way, with updated information and often with a personal tone. By using a blog large groups of people can be reached in a cost effective way.
**Objectives:** To use a blog as a tool to support and encourage individuals with rheumatic disease in both their understanding of and their performance of physical activity and training.
**Methods:** Plan, do, study, act (PDSA) which is a method for systematic improvement of processes was applied.
*Plan:* The Swedish Rheumatism Association's training blog (SRA-tb) was initially set up as a project in 2011. The reader was invited to follow a person with rheumatic disease as she prepared for, performed and evaluated two challenges. The challenges were a cross-country ski race (30k) and a run (5k). The emphasis was placed on the perceived health in relation to disease activity rather than the results in the races. Foremost, symptoms and effects of training in relation to the disease became the focus. A physiotherapist with special competence in rheumatology was appointed editor of the blog.
*Do:* During 2011, 135 posts were made on the SRA-tb. Several of the published posts contained practical information such as examples of exercises, suggestions for self-help but also articles on the latest research on physical activity and training for people with rheumatic disease were also published.
**Results:** *Study:* In 2011 the project resulted in a total of 17351 viewings. The statistics showed that the postings that contained practical advice or was of a more instructing character (i.e. training programs) rendered most viewings. Moreover, the search terms that were used by the readers were monitored. The tool for the blog also allowed for the readers to comment or ask questions, which opened up for dialog and interaction.
**Conclusions:** *Act:* Since the start of the SRA-tb over 850 posts have been made and the blog has become a part of the Swedish Rheumatism Association's communication strategy. During 2015 the blog had 41497 viewings and 198 posts were published. The increase in viewings in relation to the number of posts can be explained by a systematic review and analysis of which topics and search terms that renders most interest. Also, the blog is now often linked to other social media published by the Swedish Rheumatism Association, mainly Facebook.
The Swedish Rheumatism Association is currently facing the challenge to use social media in a more efficient way. As a part of meeting that challenge the Swedish Rheumatism Association is building a digital health platform with the ambition that this will become a knowledge base for life style questions related to rheumatic disease and rheumatology. The blog about training will become a part of this knowledgebase. Our goal is that the digital health platform will help empower our members to influence the course of their disease and to live a healthier life.
**Disclosure of Interest:** None declared

### OP0314-PARE GROUP EXERCISE THERAPY IN ANKYLOSING SPONDYLITIS (AS): THE PATIENTS' PERSPECTIVE

F. Van Der Giesen[1], F. Van Gaalen[2], R. De Jong[3], M. Van Goeverden[4], H. Slootweg[5], T. Vliet Vlieland[1]. *[1]Orthopaedics; [2]Rheumatology, Leiden University Medical Center, Leiden; [3]Praktijk voor Mensendieck, Sassenheim; [4]Praktijk voor Fysiotherapie, Leiden; [5]Slootweg Legal Support., Noordwijk, Netherlands*

**Background:** Group exercises have been recommended for patients with AS with, some exercise classes having been instituted more than 20 years ago. Current practice may therefore not be consistent with the current needs and preferences of AS patients and new scientific insights into required components and dosage (exercises improving joint mobility, strength, cardiopulmonary fitness and neuromotor abilities) dosage (intensity x duration/repetitions, dependent on age and health status), frequency (at least 2–3 times a week).
**Objectives:** To determine to what extent patients with AS are satisfied with a long-existing group exercise programme and what their preferences are regarding the current and required features of group exercise classes.
**Methods:** A survey was administered to patients participating in a group exercise programme used in a randomised trial (1). The programme, once a week during 2.5 hours, consisted of mobility exercises, sports activities (e.g. volleyball, badminton) and hydrotherapy, addressing strength, mobility and fitness without specification of dosage, regular monitoring or home exercises. The survey investigated experiences with the dosage of the programme components (too high/too low), its subjective effects, patients' preferences regarding potentially novel elements (heart rate controlled training, regular standardized assessments of mobility, physical function and activity limitations) and increased exercise frequency (in favour/not in favour/don't know).
**Results:** 43 of 48 patients (90%) returned the survey, 31 (72%) were male, their median age was 58 years (range 33–80). Overall, there were patients finding the dosage of various programme components either high/too high or low/too low and/or deserving less or more attention. The top 3 of most frequently perceived positive effect of the programme were the prevention of deterioration (74%), moving less stiff (61%) and an improved cardiopulmonary fitness (30%). Regarding potential adaptations, the majority of patients favoured implementing

Satisfaction of 43 AS patients regarding a group exercise programme

| Patients' opinions regarding programme components | Exercise therapy | Sports | Hydrotherapy |
|---|---|---|---|
| Duration too short/too long | 4 (9)/3 (7) | 7 (16)/4 (9) | 4 (9)/1 (2) |
| Intensity too high/not high enough | 3 (7)/6 (14) | 3 (7)/9 (21) | 3 (7)/8 (19) |
| **Patients' opinions regarding exercise modalities** | **Muscle strength** | **Joint mobility** | **CP-fitness** |
| Too little attention | 10 (23) | 4 (9) | 12 (28) |
| Enough attention | 32 (74) | 37 (86) | 29 (67) |
| Too much attention | 0 | 0 | 1 (2) |

heart rate-guided cardio-vascular training (63%) and standardized and periodic assessments (74%), whereas a minority favoured increasing the frequency of exercise classes (23%).

**Conclusions:** The variety regarding patients' perception with a group exercise programme of its intensity and preferred components underlines the need for individual adaptions, according to results of regular assessments. As only a minority of patients favours group exercises more than once a week, the delivery of home-based exercises meeting minimum requirements to enhance health status in patients with AS is a future challenge.

## Adaptive immunity (T cells and B cells) in rheumatic diseases

### THU0001 TERTIARY LYMPHOID ORGANS IN TAKAYASU ARTERITIS: ARE LOCALLY MATURED B CELLS INVOLVED IN THE PATHOGENESIS?

A. Galy[1], M. Clement[1], P. Bruneval[2], F. Hyafil[1], T. Papo[1], A. Nicoletti[1], K. Sacre[1]. *[1]Paris-7 University, APHP, Bichat Hospital; [2]Paris-5 University, APHP, Bichat Hospital, Paris, France*

**Background:** Takayasu arteritis (TA) is a large vessel vasculitis involving the aorta and its major branches. T cell mediated autoimmunity is thought to play a major role in its pathogenesis while the role of B cells is still unclear.
**Objectives:** To study the presence of tertiary lymphoid organs (TLOs) in the aortic wall of TA patients and analyzing if their presence could be associated with the activity of the disease.
**Methods:** Hematoxylin and eosin–stained sections from aorta specimens from patients with TA were screened for tertiary lymphoid organs (TLOs). The presence of B cell aggregates (CD20), follicular dendritic cells (FDCs, CD21), and high endothelial venules (HEVs, PNAd) was investigated by immunohistochemistry. Immune cells from the adventitial layer of one patient were characterized by flow cytometry. Demographic, medical history, laboratory, imaging, treatment and follow up data were extracted from medical records.
**Results:** Aorta specimens from Bentall procedures were available from 7 patients (five female, aged 22 to 57 years) with TA in whom surgery was performed between 2009 and 2014. Surgical treatment was performed at TA diagnosis (n=4) or at a median of 108 [84–156] months after TA diagnosis. Disease was active at surgery in four patients according to NIH score. B cell aggregates-TLOs containing HEVs were observed in the adventitia of all but one patient. Ectopic follicles containing FDCs were found in 5 patients and appeared associated with aortic FDG uptake assessed by PET. In addition, flow cytometry analysis confirmed the accumulation of memory/germinal center–like B cells in the adventitial layer and showed the presence of antigen-experienced T follicular helper cells (Tfh).
**Conclusions:** Apparently functional ectopic lymphoid neogenesis takes place in the aortic wall of a subset of patients with TA. Our data suggest that the B cells play a key role in the pathogenesis of TA.

### THU0002 PREVALENCE OF MONOCLONAL B-CELL DISORDERS IN PATIENTS WITH AUTOIMMUNITY IN THE UK

G. Arumugakani[1], J. Thompson[2], F. Khukhar[2], R.M. de Tute[3], R. Tooze[4], P. Emery[1], D. McGonagle[1], A.C. Rawstron[2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]HMDS, St. James's Institute of Oncology; [3]HMDS, St.James's Institute of Oncology; [4]Section of Experimental Haematology, Leeds Institute of Cancer and Pathology, St James's University Hospital, Leeds, United Kingdom*

**Background:** Persistent inflammation as seen in patients with autoimmune disorders can potentially lead to the development of monoclonal B-cell disorders. The incidence of non-Hodgkin's lymphoma is more than 2-fold higher in RA patients compared to the general population [1]. Monoclonal B-cell lymphocytosis (MBL) refers to the asymptomatic presence of monoclonal B-cells in the peripheral blood with a risk of progression to lymphoproliferative disease. MBL includes CLL-type (CD5 positive) MBL (5.1%), which is more common in the UK and less common non-CLL type (CD5 negative) MBL (1.8%) [2].
**Objectives:** To assess whether the prevalence of monoclonal B-cell disorders is higher in autoimmune disorders compared to the native general population.
**Methods:** Peripheral blood B-cells from patients with autoimmune disorders were analysed using a panel of CD19 PerCP-Cy5.5, CD20 APC-H7, Kappa BV421, Lambda FITC, CD45 BV510, CD305 PE and CD5 PE-Cy7. The presence of MBL was defined according to standard criteria [3], briefly the detection of a monoclonal B-cell population in the peripheral blood with an overall kappa:lambda ratio $>$3:1 or $<$0.3:1, or greater than 25% of B cells lacking or expressing low level surface immunoglobulin, or the presence of a disease-specific immunophenotype in the absence of any other feature diagnostic of a B-lymphoproliferative disorder.
**Results:** Peripheral blood from a total of 128 patients with autoimmune disorders were analysed by flow cytometry for the presence of monoclonal B-cells. This included 101 RA patients, 11 patients with SLE, 7 patients with GPA and 8 patients with other autoimmune disorders. The patient group was predominantly females with female to male ratio of 2.7:1 (93:35). The median age of the patients was 57 years (18–85). 45 patients were between 40 – 60 years old and 55 patients were between 60 – 80 years old. 23 patients were less than 40 years old and 5 patients were more than 80.
The presence of a monoclonal B-cell population was detected in 10.1% (13/128) of the patients. One of these patients was already known to have CLL. The prevalence of CLL type MBL was 2.4% (3/127) and non-CLL type MBL was 7.1% (9/127). Of these 12 patients, 7 patients had RA, 2 patients had GPA, 2 patients had SLE and one patient had an overlap of RA and Sjogren's syndrome. Five patients were between 60–80 years old, three in their 30s, three in their 80s, and one in their 50s.
**Conclusions:** Non-CLL type MBL may be more common in patients with autoimmune disorders compared to the general population in the UK. The apparent relative increase in CD5neg MBL could be associated with the effective control of the inflammatory disease process or the direct effect of therapies used for the treatment of autoimmune diseases on B-cells. More extensive studies are required to understand the implications of current treatment strategies on the selective pressure for expansion of monoclonal B-cell populations.

### THU0003 MOUSE B CELL CYTOKINE PRODUCTION REQUIRES OXIDATIVE PHOSPHORYLATION MEDIATED BY GLYCOLYSIS AND FATTY ACID OXIDATION

D. Wu[1], M. Dunlap[2], D. Huang[2], E. Pearce[3], A.H. Kim[2]. *[1]Immunobiology; [2]Rheumatology, Washington University School of Medicine, Saint Louis, MO, United States; [3]Immunometabolism, Max Planck Institute of Immunobiology and Epigenetics, Freiburg im Breisgau, Germany*

**Background:** B cells contribute to disease pathophysiology through several mechanisms, including cytokine secretion. A wide variety of stimuli can activate B cells to produce cytokines including B cell receptor (BCR) and Toll-like receptor (TLR) engagement. Recently, numerous observations have established the role of metabolic pathways in the diverse array of immune cell functions. It is unknown though how these metabolic pathways influence B cell cytokine production.
**Objectives:** Delineate the array of cytokines generated by B cells and their metabolic requirement following activation.
**Methods:** B cells were isolated from the spleens of C57Bl/6J mice and activated overnight individually by the following agents: anti-$\mu$ antibody (B cell receptor), anti-CD40 agonist antibody, poly(I:C) (TLR3), LPS (TLR4), ssPolyU (TLR7/8), and CpG (TLR9). Supernatants were collected and analyzed for the quantification of cytokines using the Milliplex Multiplex cytokine kit (EMD Millipore). Real-time analysis of extracellular acidification rates (ECAR) and oxygen consumption rates (OCR) of activated B cells were performed using the XF-96 Extracellular Flux Analyzer (Seahorse Bioscience). Three or more consecutive measurements were obtained under basal conditions and after the sequential addition of 1 $\mu$M oligomycin, to inhibit mitochondrial ATP synthase; 1.5 $\mu$M FCCP (fluoro-carbonyl cyanide phenylhydrazone), a protonophore that uncouples ATP synthesis from oxygen consumption by the electron-transport chain; and 100 nM rotenone plus 1 $\mu$M antimycin A, which inhibit the electron transport chain. To assess 3-carbon sources for oxidative phosphorylation, inhibitors to fatty acid oxidation (etomoxir, which irreversibly inhibits carnitine palmitoyltransferase-1), pyruvate transfer to mitochondria (UK-5099), and glutamine usage (BPTES, which inhibits mitochondrial glutaminases) were used.
**Results:** Both LPS and CpG activation of B cells independently generated the highest levels of cytokine secretion. In addition, these stimuli generated high OCR and ECAR values, reflecting the need for oxidative phosphorylation and lactate production respectively. Both LPS and CpG required free fatty acids and glucose as a carbon sources, as addition of etomoxir and UK-5099 abrogated both cytokine secretion and oxidative phosphorylation.
**Conclusions:** We catalogued the breadth of cytokines secreted by B cells via various stimulatory agents. High-dose LPS and CpG required free fatty acids and glucose for the elaboration of LPS or CpG-induced cytokine production. These data suggest that B cell cytokine secretion can be manipulated by altering the local metabolic environment, and may represent an interesting therapeutic approach for modulating B cells in autoimmune diseases.

## THU0004 ACTIVATED PLASMACYTOID DENDRITIC CELLS (PDCS) ALTER THE COMPOSITION OF THE BLOOD B CELL SUBSETS

O. Berggren, L. Rönnblom, M.-L. Eloranta. *Dept. Medical Sciences, Rheumatology, SciLife Laboratory, Uppsala University, Uppsala, Sweden*

**Background:** Many autoimmune rheumatic diseases, such as systemic lupus erythematosus (SLE), display multiple aberrations in their B cell functions together with a continuous type I interferon (IFN) production by plasmacytoid dendritic cells (pDCs). Type I IFN has a broad range of immunomodulatory effects but less is known about the impact of direct B cell and pDC interactions.
**Objectives:** We asked whether the peripheral blood B cell phenotype is affected by interactions with pDCs and SLE-related immune complexes (IC).
**Methods:** B cells and pDCs were isolated from peripheral blood of healthy individuals and stimulated with immune complexes consisting of IgG from SLE patients and U1snRNP particles (RNA-IC). The cells were cultivated alone or in cocultures for 6 days. Expression of activation markers, cell surface molecules and proliferation were analyzed by flow cytometry and the production of IL-6, IL-10 and IFN-$\alpha$ were analyzed by immunoassays.
**Results:** Both B cells and pDCs displayed an increased expression of activation markers in the cocultures compared to cultures of B cells or pDCs alone. No increased proliferation of the B cells was detected in the RNA-IC-stimulated cocultures. The production of IL-6 was enhanced in the stimulated cocultures compared to the single cultures of B cells or pDCs, in a similar manner as we earlier have described for IFN-$\alpha$ production by pDCs. Cocultivation of B cells with pDCs resulted in a 7-fold increased frequency of $CD24^{hi}CD38^{hi}$ B cells, independently of RNA-IC. This B cell subset is considered to have a regulatory character, however, the IL-10 production was low in the stimulated cultures. Interestingly, we found a highly increased frequency of double negative $CD27^{-}IgD^{-}$ B cells, from 7% among fresh B cells to 37% in the RNA-IC-stimulated cocultures. This was accompanied by a decreased frequency of memory and naïve B cells. In addition, $CD95^{+}$ expression was induced in a small fraction (1.4%) of the double negative B cells in the RNA-IC-stimulated cultures. We could also confirm a higher frequency of the double negative $CD27^{-}IgD^{-}$ B cells in SLE patients compared to healthy individuals.
**Conclusions:** The pDCs and SLE-related ICs are able to alter the composition and activation of the peripheral blood B cell subsets. Notably, a prominent enrichment of double negative $CD27^{-}IgD^{-}$ B cells, resembling those found in SLE, required presence of both pDCs and SLE related ICs. The functional role of the double negative B cells in SLE is so far unknown, but their presence are reported to correlate with anti-dsDNA autoantibodies and nephritis. Thus, activated pDCs may contribute to the regulation and expansion of potentially pathogenic B cell subpopulations, especially in patients with circulating interferogenic ICs and an ongoing type I IFN production.

## THU0005 DRUG RE-PURPOSING WITH A COMMERCIALLY AVAILABLE CHEMICAL LIBRARY IDENTIFIES NOVEL B-CELL INHIBITORY COMPOUNDS

K. Matsumoto, K. Bieber, S. Ghorbanalipoor, S. Ibrahim, D. Zillikens, R. Ludwig. *Lübeck Institute of Experimental Dermatology, Universität zu Lübeck, Lübeck, Germany*

**Background:** Self-reactive antibodies produced by B-cell derived plasma cells play a crucial role in the pathogenesis of autoimmune disorders. By targeting the source of these pathogenic antibodies, B-cell modulation is one treatment option. However, newly emerging therapeutics directed at specific molecules are not universally available and the current therapies of autoimmune diseases still rely on the systemic use of corticosteroids. Hence, a development of new treatment strategies is required.
**Objectives:** We investigated a hypothesis that some drugs, which are already used for other treatment purposes, might possess unknown B-cell modulatory effects. By using a drug library consisting of 1,200 commercially available, off-patent compounds, an *in vitro* screening evaluating the drug effect on human B cell proliferation was performed. Afterwards, the selected drugs were tested *in vivo* to confirm their effect on adaptive immunity and potential use as therapeutic agents in autoimmune diseases.
**Methods:** Human B cells were obtained from healthy donors. Under the stimulation with IL-21 and anti-CD40 antibody, isolated B-cells were cultured for five days in the presence or in the absence of 1$\mu$M drugs from the library, and the drug effect on cell proliferation was assessed by 5-Bromo-2'-Deoxyuridine (BrdU) ELISA. Dose-dependency and cytotoxicity test with candidate drugs inhibiting B cell proliferation were performed as validation. IgM and IgG production in the culture supernatant was measured by ELISA. For *in vivo* validation, further selected drugs were tested in an experimental animal model of epidermolysis bullosa acquisita (EBA), an autoimmune skin blistering disease characterized by antibody production against type VII collagen which triggers the blister formation [1]. One day prior to the disease induction by immunizing B6.S mice with vWFA2, a subdomain of the pathogenic antigen in EBA [1], drug or vehicle treatment was initiated and continued for eight weeks. Disease severity was recoded weekly, and the antigen-specific B cell as well as plasma cell numbers in the draining lymph nodes were evaluated by flow cytometric analysis.
**Results:** Out of 1,200 drugs, BrdU ELISA screening identified 48 compounds inhibiting human B cell proliferation and the validation narrowed the number of candidates to six. Immunoglobulin production was negatively affected in the presence of these compounds with a dose-dependent manner. Experimental EBA mice treated with the selected drugs showed >50% less disease development compared to the vehicle-treated group. Furthermore, mice treated with one of the candidate drugs had significantly fewer numbers of B cells as well as antigen-specific B cells in the draining lymph nodes ($p<0.05$).
**Conclusions:** The present results suggest unknown properties of "old" drugs in B cell biology as well as the subsequent adaptive immunity and their potential "new" roles in the treatment of autoimmune diseases. In addition, such a drug screening method would save time and be more cost efficient than the conventional approach used to develop new therapeutic agents.

## THU0006 NOVEL CHANGES IN B AND T-CELL PHENOTYPES WITH BELIMUMAB IN AN AUTOANTIBODY MEDIATED DISEASE

C. Barrett[1], R.B. Henderson[1], N. Galwey[1], S. Flint[2], A. Gibson[1], C. Savage[1]. *[1]GlaxoSmithKline, Stevenage; [2]Addenbrookes Hospital, Cambridge, United Kingdom*

**Background:** Belimumab is a B-lymphocyte stimulator (BLyS)-specific inhibitor indicated for the treatment of adult patients with active, autoantibody-positive, systemic lupus erythematosus. Belimumab has also been shown to reduce anti-phospholipase A2 receptor (PLA2R) autoantibodies and proteinuria in a mechanistic study in primary membranous nephropathy (PMN)[1]. Here we report an interim analysis of B and T cell phenotypes in PMN subjects treated with belimumab to further elucidate the mechanism of action in autoantibody mediated disease.
**Objectives:** To characterize changes in B and T lymphocyte phenotypes in PMN patients treated with belimumab, as a comparison with known pharmacodynamic (PD) effects in SLE[2], and to assess correlation with anti-PLA2R autoantibody.
**Methods:** 14 anti-PLA2R autoantibody positive PMN patients received 10mg/kg iv belimumab every 4 wks (or 2 wks) for up to 100 wks. 11 of these completed at least 28 wks treatment. Whole blood was collected at baseline, Wks 8, 16 and 28 for analysis of B and T-cell phenotypes by flow cytometry. Serum levels of anti-PLA2R antibodies were measured by ELISA (Euroimmun). Statistical analysis to identify PD-induced changes in lymphocyte subsets was carried out by paired t-test (2 tailed) against baseline.
Correlations between anti-PLA2R antibody and B and T-cell subsets, either at a specific time point or in the linearised trend over time, were calculated using Pearson's correlation coefficient (r).
**Results:** There was a significant reduction (-63%, p=0.002) in absolute numbers of naive B cells (CD19+ CD27-) at Wk 8 which was sustained through to Wk 28. There was a significant increase in absolute numbers of memory B cells (CD19+ CD27+) at Wk 8 (70%, p=0.023) which increased further through to Wk 28. Plasmablasts (or SLE subset, CD19lo CD38hi CD27hi) showed a trend at Wk 8 to decrease (-64%, p=0.20) but with high variance and low cell numbers.
In addition, the expression (mean fluorescence intensity) of BAFF-R (B-cell activating factor receptor) on B-memory cells increased through Wk 28, while expression of TACI (transmembrane activator and calcium modulator and cyclophylin ligand interactor) decreased. Activated cells as identified by surface CD95 expression, decreased as a proportion of B-memory cells through Wk 28. No clear trend was seen in T-regulatory or T-activated cells.
There was a significant negative correlation between decrease in absolute numbers of naive B-cells and immunological efficacy defined as level of anti-PLA2R antibody remaining at Wk 28 (r=-0.87, p=0.0005). Correlations were also seen between antibody and changes in proportion of B-memory CD95+ cells.
**Conclusions:** This mechanistic trial of belimumab in PMN has enabled a novel analysis of PD endpoints, confirming but also extending the PD effects previously reported in studies of SLE. Changes in B-cell subsets were associated with improvements in levels of autoantibody in PMN which in turn correlates with proteinuria. Further analysis of longer term anti-PLA2R antibody kinetics as related to early changes in B and T cell phenotypes may also be informative.

## THU0007 ENHANCED IGG4 PRODUCTION BY FOLLICULAR HELPER TYPE 2 T CELLS IN IGG4-RELATED DISEASE

M. Akiyama[1], H. Yasuoka[1], K. Yamaoka[1], K. Suzuki[1], Y. Kaneko[1], H. Kondo[1], Y. Kassai[2], K. Koga[2], T. Miyazaki[2], R. Morita[3], A. Yoshimura[3], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; [2]Inflammation Drug Discovery Unit, Pharmaceutical Research Division, Takeda Pharmaceutical Company Limited; [3]Department of Microbiology and Immunology, Keio University School of Medicine, Tokyo, Japan*

**Background:** IgG4-related disease (IgG4-RD) is characterized by elevated serum IgG4 and increased circulating plasmablasts[1]. The high degree of somatic hypermutation and emergence of distinct plasmablast clones at disease relapse suggests the de novo recruitment of naïve B cells into T-cell–dependent responses[1]. Follicular helper T (Tfh) cells play a major role in T-cell–dependent B cell responses, and their counterparts and subsets (Tfh1, Tfh2 or Tfh17 cells) have only been recognized in peripheral blood[2]. We previously reported that Tfh2 cells were increased in IgG4-RD[3], although the functional role of Tfh2 cells remains to be elucidated.
**Objectives:** To elucidate the function of Tfh2 cells and involvement in the pathogenesis of active, untreated IgG4-RD.
**Methods:** Active, untreated IgG4-RD (n=17) were compared to healthy controls (HC) (n=12), patients with primary Sjögren syndrome (pSS) (n=20) and multicentric Castleman's disease (MCD) (n=5). Tfh2 cells (CD3+CD4+CD45RA-CXCR5+CXCR3-CCR6-cells), activated Tfh2 cells ($CCR7^{lo}PD\text{-}1^{hi}$ subset in Tfh2 cells) and plasmablasts (CD19+CD20-CD27+CD38+cells) were detected by flow cytometry. The function of Tfh2 cells was evaluated by co-culture with autologous naïve B cells in vitro. Disease activity was evaluated by IgG4-RD Responder Index (IgG4-RD RI) score.
**Results:** The percentage of Tfh2 cells was significantly increased in IgG4-RD compared to pSS, MCD or HC, and correlated with serum IgG4 levels ($\rho$=0.7377, $P$ =0.0011) or the percentage of plasmablasts ($\rho$=0.6127, $P$=0.0104). In vitro, Tfh2 cells induced a greater percentage of differentiation of naïve B cells into plasmablasts in IgG4-RD and HC compared to Tfh1 and Tfh17 cells. Of note, while IgG production in culture supernatants of Tfh2 cells were comparable between IgG4-RD and HC, IgG4 production was significantly higher in IgG4-RD compared to HC. Accordingly, IgG4/IgG ratio in culture supernatants was also significantly higher only with Tfh2 cells from IgG4-RD. In addition, the percentage of activated Tfh2 cells was significantly increased in IgG4-RD (8.0 ± 1.6%) compared to pSS (1.4±0.2%, $P<0.0001$), MCD (1.6±0.5%, $P<0.0001$) or HC (1.2±0.2%, $P<0.0001$), and correlated strongly with IgG4-RD RI score ($\rho$=0.7984, $P$=0.0002). In particular, the percentage of activated Tfh2 cells associated with the number of affected organs ($\rho$=0.8152, $P$=0.0001), and decreased with glucocorticoid treatment in parallel with disease improvement. Of note, the percentage of activated Tfh2 cells was re-elevated at disease relapse.
**Conclusions:** Tfh2 cells, but not Tfh1 or Tfh17 cells, induce the differentiation of naïve B cells into plasmablasts and IgG4 production in patients with active, untreated IgG4-RD. This increase in activated Tfh2 cells is linked to disease activity, suggesting that Tfh2 cells play a pivotal role in the pathogenesis of IgG4-RD.

## THU0008 LEUCINE-RICH ALPHA 2 GLYCOPROTEIN PROMOTES THE DIFFERENTIATION OF TH17 AND DETERIORATES COLLAGEN INDUCED ARTHRITIS THROUGH ENHANCEMENT OF TGF BETA SIGNALING

H. Urushima, M. Fujimoto, T. Mishima, T. Ohkawara, H. Honda, S. Serada, T. Naka. *National Institute of Biomedical Innovation, Health and Nutrition, Ibaraki, Japan*

**Background:** We have identified leucine-rich alpha 2 glycoprotein (LRG) as a disease marker of rheumatoid arthritis (RA) [1)]. Although LRG is produced in site of inflammation such as synovial tissues, its function is still unclear. Recently, LRG is reported to bind with TGF-β and enhance of Smad2 phosphorylation [2)]. TGF-β is essential for differentiation of Th17. Th17 plays important roles in the pathogenesis of RA, for example, by regulating osteoclast differentiation. In collagen induced arthritis (CIA), a mouse model of RA, phosphorylation of Smad2 in CD4 T cells is important for the Th17 differentiation and the induction of arthritis [3)]. Thus, LRG may be involved in the pathogenesis of RA through the regulation of T lymphocyte differentiation.
**Objectives:** In this study, we aimed to elucidate the function of LRG on T lymphocyte differentiation and to examine the involvement of LRG in the pathogenesis of RA.
**Methods:** Naïve T lymphocyte were isolated from WT or LRG KO mice to examine the effects of LRG on the differentiation into Th17 and Treg in the absence or presence of recombinant LRG. Male C57BL/6 mice and LRG KO mice were subjected to collagen-induced arthritis (CIA).
**Results:** In the presence of TGF-β alone, the differentiation of Treg was promoted by LRG. However, in the presence both TGF-β and IL6, LRG enhanced the differentiation into Th17 by increasing both Smad2 and STAT3 phosphorylation. The phosphorylation of p38 was also increased by LRG. In addition, the expression of IL6 receptor in naïve T cells was significantly lower in LRG KO mice than in WT mice. In CIA model, arthritis score was significantly lower in LRG KO mice than in control group. The numbers of Th17 in regional lymph nodes and serum levels of IL17 were significantly lower in LRG KO mice than in WT mice.
**Conclusions:** LRG promoted TGF-β-induced Smad2 phosphorylation under Th17 differentiation condition. Since Smad2 signal increases the expression of IL6 receptor in naïve T cells [4)], LRG might increase the expression of IL6 receptor through Smad2 signal, leading to enhanced the phosphorylation of STAT3 which is an essential transcription factor in the differentiation of Th17 [4)5)]. LRG also enhanced phosphorylation of p38 MAPK which is involved in the proliferation of helper T cells. In addition, recent study reported that p38 MAPK plays an important role in the production of IL17 [6)7)]
Taken together, our study suggested that LRG promotes both the proliferation and Th17 differentiation of naive T cells under inflammatory state, leading to deterioration of arthritis.

## THU0009 ADIPONECTIN-ADIPOR1-STAT3 DEPENDENT PATHWAY IS A CRITICAL REGULATOR OF TH17 CELL DIFFERENTIATION IN COLLAGEN-INDUCED ARTHRITIS

M. Zhang. *Rheumatology Department, The First Affiliated Hospital of Nanjing Medical University Jiangsu Province hospital, Nanjing, Jiangsu province, China*

**Background:** We previously showed that adiponectin (AD) acts to promote Th17 cell differentiation, suggesting that AD plays an important role in mediating joint inflammation and damage in collagen-induced arthritis (CIA).
**Objectives:** The aim of this study was to investigate whether STAT3 expression is regulated by AD, and if so, whether knockdown AdipoR1 could inhibit STAT3 and Th17 expression and prevent disease progression in CIA.
**Methods:** Expression of Th17, AD and STAT3 in joint tissue of CIA was detected by real-time PCR and flow cytometry. STAT3 promoter activity was analyzed using a Dual-Luciferase Reporter Assay. The effect of AD on STAT3 expression in *vitro* and *vivo* was assessed using histological analysis, real-time PCR and flow cytometry.
**Results:** Expression of STAT3 was up-regulated and positively correlated with highly expressed AD in joint tissue of CIA. Moreover, AD treatment markedly enhanced STAT3 expression both in *vitro* and *vivo*. Moreover, we found that the anti-Th17 differentiation effect of STAT3 inhibitor can be stimulated by addition of exogenous AD partly. Mechanistically, we showed AD activated STAT3 transcription by binding to the promoter region of the STAT3 gene. Further, using the CIA model, we showed that treatment with the AdipoR1 RNA interference led to reduction of STAT3 levels, decrease of Th17 response, and attenuation of inflammation and disease progression in *vivo*.
**Conclusions:** Our results not only reveal a new role of AD in promoting Th17 development via upregulation of STAT3 expression. Our study also suggests that the pro-Th17 cell differentiation effect of AD is mediated through AdipoR1.

## THU0010 LACK OF CRP RESPONSE IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS - WHAT ARE THE IMMUNOLOGICAL CAUSES, AND HOW CAN WE HARNESS THIS DATA TO IMPROVE DISEASE OUTCOMES

C.M. Bradford[1], H.Y.J. Mak[1], L. Kidd[2], V. Howard[2], R. González-Serrano[1], C. Cuirtin[2], E.C. Jury[1], J.J. Manson[2]. *[1]Rheumatology, University College London; [2]Rheumatology, University College London Hospital, London, United Kingdom*

**Background:** Using musculoskeletal ultrasound (US) to assess joint erosions and disease activity in patients with rheumatoid arthritis (RA) an atypical subgroup was identified with active disease demonstrated by significant Power Doppler, but normal C-reactive protein (CRP) levels. We questioned whether this presentation was associated with delayed diagnosis or relative under treatment, risking worse disease outcome and/or disability. We hypothesized that understanding the underlying immune pathology in this atypical subset of patients could directly influence therapeutic targeting in patients whose needs are not currently met.

**Objectives:** Define the immunological and clinical phenotype of RA patients with active disease and either normal or high CRP levels. Investigate whether lack of CRP response is associated with altered inflammatory cytokine signaling and exploit the immunological and clinical phenotype of this patient subgroup to propose a more appropriate treatment algorithm.
**Methods:** 44 RA patients with active synovitis were recruited, defined by ≥1 joint with Power Doppler detected by US, 29 had normal (n)CRP (≤5mg/L) and 15 had high (h)CRP (>5mg/L) levels. Peripheral blood mononuclear cells (PBMCs) and serum as well as detailed clinical and disease activity scores were collected. Blood from 18 age and sex matched healthy donors was obtained. Multicolour flow cytometry was used to perform in depth PBMC immunophenotyping and serum cytokines were assessed using a Cytometric Bead Array.
**Results:** The erosion accrual rate was elevated in patients with nCRP compared to hCRP suggesting more disease-associated joint damage, while no significant differences were detected between patient groups in terms of autoantibody levels, ESR and disease activity scores. Inflammatory cytokine levels were elevated in both the nCRP and hCRP patients including IL1β ($p$=0.0364; 0.0233) and IL6 ($p$=0.0009; 0.0007) which are known to trigger CRP production. This suggested that nCRP patients could have defects in downstream IL6 signaling, or alternatively, the disease mechanism may not be IL6-dependent in the nCRP group. Since IL6 is known to support T-cell and T-follicular helper-cell (Tfh) activation and differentiation we compared the T-cell phenotype in the two patient groups. As expected, $CD4^+$ T-cells from hCRP patients with RA were activated compared to healthy donors ($p$=0.0054) and had increased central memory (p=0.0380, T-CM) and Th17 populations. Similarly, only Tfh-cells in hCRP patients were activated compared to nCRP ($p$=0.0026). In contrast, nCRP patients had a less inflammatory phenotype characterized by the highest level of regulatory T-cells (T-reg) compared to healthy donors ($p$=0.0036) and hCRP ($p$=0.0303) and raised serum IL10 suggesting increased immune modulation in these patients. This was supported by a significant correlation between Treg and TCM populations in the nCRP ($p$=0.05) but not the hCRP patients.
**Conclusions:** Overall, this supports altered immunological mechanisms in nCRP compared to hCRP patients which could have therapeutic implications.
**Disclosure of Interest:** None declared

## THU0011 CD32+ B LYMPHOCYTES AND IL21R+ T LYMPHOCYTES ARE ASSOCIATED WITH DISEASE ACTIVITY AND INCREASED LEVELS OF PROINFLAMMATORY CYTOKINES IN PATIENTS WITH RHEUMATOID AND PSORIATIC ARTHRITIS

A. Sucur[1], Z. Jajic[2], M. Artukovic[3], D. Flegar[1], D. Grcevic[1]. [1]*Department of Physiology and Immunology, University of Zagreb Medical School;* [2]*Department of Rheumatology, Physical Medicine and Rehabilitation, Clinical Hospital Center "Sisters of Mercy", University of Zagreb Medical School;* [3]*Department of Clinical Immunology and Allergology, University Hospital "Sveti Duh", Zagreb, Croatia*

**Background:** Autoimmunity is presumed to be a major driving force in the pathogenesis of chronic rheumatic diseases, including rheumatoid arthritis (RA) and psoriatic arthritis (PSA). Although these forms of arthritis differ in their clinical features, both are marked by persistent inflammation and osteoresorption underpinned by aberrant lymphocyte populations and disturbed cytokine network.
**Objectives:** Various subpopulations of both T and B lymphocytes have been implied in RA and PSA, but their relevance to disease onset and progression remains largely unclear. The aim of our study was to define the association of T, B and NK cell subpopulations with cytokine levels and clinical parameters in RA and PSA patients.
**Methods:** Mononuclear cells were isolated from peripheral blood of healthy controls (n=35), RA (n=36) and PSA (n=13) patients, after obtaining Ethical approval and informed consent. Flow cytometry was applied to discriminate between T lymphocyte subpopulations: Th1/2 (CD3+CD4+CCR6-), Th17 (CD3+CD4+CCR4+CCR6+), Tfh (CD3+CD4+CXCR5+), Tc (CD3+CD8+) and memory Tc (CD3+CD8+CCR4+); B lymphocyte subpopulations: naïve (CD19+IgD+CD27-), unswitched memory (CD19+IgD+CD27+), class-switched memory (CD19+IgD-CD27-) and plasmablasts (CD19+IgD+CD27hiCD38+); and NK cells (CD3-CD19-CD56+). Markers of lymphocyte maturation (CD32), activation (CD86, IL21R, CD25) and migration (CD11b) were also analyzed. Frequencies of lymphocyte subpopulations were correlated with clinical parameters, including DAS28 (for RA and PSA) and BASDAI (for PSA with spondylitis). Finally, serum levels of various cytokines (TNF, IL4, IL6, IL10, IL17, CCL2, CCL3, CCL4, CCL5) were measured by flow cytometry bead based assay.
**Results:** Several subpopulations were found to be significantly expanded: CD32+ naïve (Ctrl 1.8%, RA 5.8%, PSA 6.0%) and memory B lymphocytes, both class-switched (Ctrl 1.8%, RA 5.3%, PSA 3.8%) and unswitched (Ctrl 4.0%, RA 16.8%, PSA 13.7%); memory Tc lymphocytes (Ctrl 4.8%, RA 6.8%, PSA 9.1%); and CD11b+ B lymphocytes (Ctrl 15.1%, RA 20.9%, PSA 20.2%). Significant correlations between lymphocyte subpopulations and clinical parameters included: positive association of IL21R+ T lymphocytes with DAS28 in RA (ρ=0.45) and negative with BASDAI in PSA (ρ=-0.86); negative association of class-switched memory B lymphocytes with DAS28 in RA (ρ=-0.52), but positive with BASDAI in PSA (ρ=0.71). Correlation of lymphocyte subpopulations with cytokine levels showed: significant positive association of CD32+ naïve B lymphocytes with TNF and CCL5 (ρ=0.55 and 0.54); CD32+ class-switched and unswitched memory B cells with TNF (ρ=0.47 and 0.55) and CCL4 (ρ=0.47 and 0.54); CD11b+ B lymphocytes with CCL4 (ρ=0.47); and IL21R+ T lymphocytes with TNF, CCL3 and CCL4 (ρ=0.42, 0.47 and 0.49).
**Conclusions:** Our results indicate novel T and B lymphocyte subpopulations induced in both RA and PSA. CD32+ B lymphocytes, as well as IL21R+ T lymphocytes, may be of particular interest as possible therapeutic targets, since their frequency is associated with disease activity and increased levels of proinflammatory and proresorptive cytokines.

## THU0012 REGULATORY T- CELLS IN PERIPHERAL BLOOD OF DMARD-NAIVE PATIENTS WITH VERY EARLY RHEUMATOID ARTHRITIS: ASSOCIATION WITH DISEASE ACTIVITY AND SYSTEMIC DISEASE MANIFESTATIONS

A. Avdeeva[1], Y.P. Rubtsov[2], D.T. Dyikanov[2], T.V. Popkova[1], E.N. Aleksandrova[1], V.A. Tkachuk[2], E.L. Nasonov[1]. [1]*Nasonova Research Institute of Rheumatology;* [2]*Lomonosov Moscow State University, Moscow, Russian Federation*

**Background:** Regulatory T (Treg) cells play a critical role in the regulation of peripheral immune tolerance.The ability of Tregs to suppress T-cell responses,and thereby to regulate immune reactions,points to their key role in the pathophysiology of autoimmune diseases
**Objectives:** To investigate the percentage and absolute number of Treg cells in peripheral blood of healthy donors and DMARD-naive very early rheumatoid arthritis (VERA) patients (pts) by immunocytometry and to analyze the association between Treg cells subsets and RA activity
**Methods:** Peripheral blood of 20 healthy donors and 39 VERA DMARD-naive pts (34F/5M, Me;IQR age 50; 32–58 years, disease duration 5.0; 4.0–6.0 months, DAS28 5.1; 4.3–5.8, RF positive-66.7%, anti-CCP positive-87.2%) were assessed for Treg-cell subpopulations. Human blood mononuclear cells were isolated from whole venous blood by Ficoll–Hypaque centrifugation and subjected to multicolor flow cytometry analysis. Tregs were stained for different surface markers, and proportions of marker-positive subsets (FoxP3+CD25+; CD152+surface; CD152+intracellular; FoxP3+CD127-; CD25+CD127-; FoxP3+ICOS+; FoxP3+CD154+; FoxP3+CD274+) between healthy controls and pts were compared
**Results:** We found the lower percentage of FoxP3+CD25+T-cells in pts with VERA,compared to healthy donors: 5.5% (4.1–6.5) vs 6.9% (5.8–7.9); the percentage and the absolute number of FoxP3+ICOS+T-cells: 6.9% (2.1–11.5) vs 10.8% (9.3–13.7); 0.0035 (0.0013–0.0067) vs 0.0068 (0.0039–0.009);the percentage and the absolute number of FoxP3+CD154+T-cells: 0.47% (0.19–0.83) vs 1.5% (1.12–2.08); 0.0002 (0.0001–0.0005) vs 0.0009 (0.0005–0.0014); the percentage and the absolute number of FoxP3+CD274+-cells: 0.6% (0.3–1.5) vs 1.9% (1.2–2.2); 0.0003 (0.0002–0.0007) vs 0.001 (0.0006–0.0016), $p<0.05$ for all cases. We found a negative correlation between the percentage of FoxP3+CD25+ T-cells and CRP in pts with VERA (r=-0,4), ESR (r=-0,43); the percentage of CD152+ intracellular T-cells and DAS28 (r=-0,4), ESR (r=-0,52), CRP (r=-0,55); the percentage of FoxP3+CD127- T-cells and ESR (r=-0,41), CRP (r= -0,48); the percentage of CD25+CD127-T-cells and DAS28 (r=-0,53), SDAI (r=-0,5), CDAI (r=-0,44), ESR (r=-0,56), CRP (r=-0,53), $p<0.05$ for all cases. Low percentage of CD25+CD127–cells compared to pts with low/moderate disease activity was observed in the group of pts with high disease activity (DAS28>5.1 SDAI>26 CDAI>22, n=27) (5.1% (4.9–5.6) vs 6.9% (6.4–7.9), $p<0.05$). A lower percentage of FoxP3+CD127- T cells: 4.2% (2.8–5.4) vs 6.4% (4.9–7.3) and the percentage of CD25+CD127- cells: 5.1% (3.5–5.1) vs 6.6 (5.6–7.9) was found in pts with systemic disease manifestations (n=7), $p<0.05$ for all cases
**Conclusions:** VERA pts have demonstrated the lower frequency of FoxP3+CD25+regulatory T cells and the percentage and the absolute number of FoxP3+ICOS+, FoxP3+CD154+, FoxP3+CD274+ cells in comparison to healthy donors. These markers characterize activated Treg cells, capabale of effective immunosuppression, thus lower levels of these markers on Treg surface and reduced numbers of marker-positive cells, suggest that Treg function is reduced in VERA pts. Diminished T-reg cell counts are associated with higher disease activity and systemic disease manifestations

## THU0013 NORMAL CD19-NEGATIVE PLASMA CELLS ARE BIOLOGICALLY DISTINCT FROM OTHER NORMAL PLASMA CELLS AND LIKELY TO BE INVOLVED IN LACK OF RESPONSE TO B-CELL DEPLETION FOR AUTOIMMUNE DISORDERS

G. Arumugakani[1], R.M. de Tute[2], D.J. Newton[3], G.J. Morgan[4], J.A. Child[5], R. Owen[2], P. Emery[1], A.S. Jack[6], D. McGonagle[1], R. Tooze[3], A.C. Rawstron[6]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [2]HMDS, St.James's Institute of Oncology; [3]Section of Experimental Haematology, Leeds Institute of Cancer and Pathology, St James's University Hospital, Leeds, United Kingdom; [4]Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, United States; [5]University of Leeds; [6]HMDS, St. James's Institute of Oncology, Leeds, United Kingdom*

**Background:** Plasma cells (PCs) are heterogeneous in terms of function and lifespan. Long-lived PCs are not depleted by B-cell depletion therapy for autoimmune disorders and therefore likely to be responsible for lack of clinical response in a significant proportion of patients. Until recently [1], the phenotype of long-lived PCs was not known. Understanding the biological features of long-lived PCs could greatly facilitate identification of therapeutic targets. Long-lived PCs contribute to humoral memory, and may represent the cell of origin for myeloma while neoplastic PCs are generally distinguished by lack of CD19 expression. However, polyclonal $CD19^{Neg}$ PCs constitute approximately 15–35% of total PCs in people aged over 50 years. Here we further characterize normal $CD19^{Neg}$ PC populations in the context of normal and therapeutically perturbed bone marrow.
**Objectives:** To establish the phenotypic and functional differences between normal $CD19^{Pos}$ and $CD19^{Neg}$ human PCs
**Methods:** Extensive phenotyping of surface and intracellular proteins of normal and myeloma PCs were performed by flow cytometry. The regeneration of normal PCs was monitored following bone marrow ablation for myeloma [2] and B-cell depletion with alemtuzumab [3] in a series of clinical trials. The immunoglobulin heavy chain variable (IGHV) region of normal $CD19^{Pos}$ and $CD19^{Neg}$ human PCs were sequenced as described previously [4] to identify phylogenetic relationships.
**Results:** $CD19^{Neg}$ PCs are phenotypically distinct from normal $CD19^{Pos}$ plasma cells with weaker CD95 ($p<0.0001$) and stronger ($p<0.0001$) BCL2 expression. Normal $CD19^{Neg}$ PCs share some characteristics with neoplastic PCs including variable expression of CD28, CD56, and CD45, but neoplastic PCs are reliably distinguished from normal $CD19^{Neg}$ PCs by differential expression of CD27, CD81 and CD117 as well as CD56 in some cases. After effective myeloablation for myeloma $CD19^{Pos}$ PCs recovered in 74 out of 80 samples, while $CD19^{Neg}$ PCs remained at less than 1% of total PCs in 30 out of 80 samples. Therapeutic B-cell depletion with alemtuzumab for chronic lymphocytic leukaemia results in loss of $CD19^{Pos}$ PCs ($p<0.0001$) whereas $CD19^{Neg}$ PCs persist. There was little overlap between the IGHV repertoire with only 2.1 to 3.7% of unique IGHV@ rearrangements shared between the $CD19^{Pos}$ and $CD19^{Neg}$ fractions, suggestive of a largely discrete immunoglobulin repertoire in the two fractions at steady state.
**Conclusions:** $CD19^{Pos}$ and $CD19^{Neg}$ PCs are biologically distinct with different immunoglobulin repertoires and production kinetics consistent with $CD19^{Neg}$ PCs having greater potential lifespan. Identifying the developmental pathway of normal $CD19^{Neg}$ PC is likely to allow selectively targeting PC compartments for autoimmune disorders.

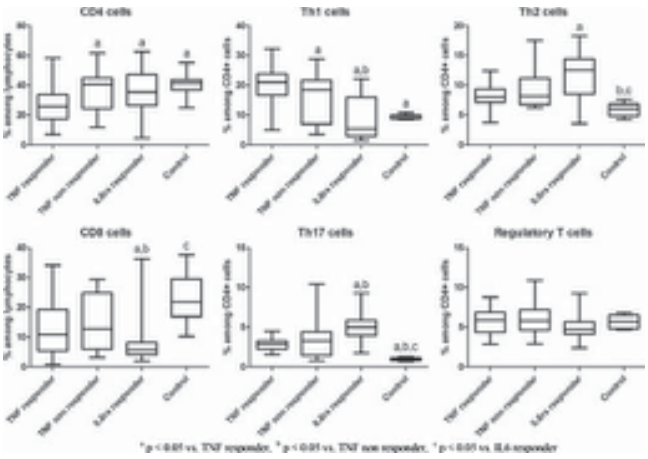
## THU0014 CCR6 EXPRESSION REGULATES ARTHRITIS IN A T CELL DEPENDENT MANNER



M. Bonelli[1], A. Puchner[2], L. Goeschl[2], S. Hayer[2], B. Niederreiter[1], J.S. Smolen[1], C. Scheinecker[2], S. Blueml[2]. *[1]Devision of Rheumatology; [2]Medical University of Vienna, Vienna, Austria*

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease, characterized by synovial infiltration of various inflammatory cells. Chemokines are involved in controlling the recruitment of different cell types into the synovial membrane. Increased production of MIP-3-a and accumulation of CCR6 expressing mononuclear cells can be found in joints of RA patients. CCR6 expression has also been reported on $CD4^+$ T cells, in particular regulatory as well as Th17 cells. Recent data suggest that $CD25^-Foxp3^+$ T cells upregulate CCR6 and promote arthritis.
**Objectives:** In this study, we investigated the role of CCR6 in the pathogenesis of arthritis using different arthritis models.
**Methods:** Clinical as well as histological signs of arthritis were investigated in the collagen-induced arthritis (CIA), K/BxN serum transfer arthritis and in the human tumor necrosis factor (hTNFtg) arthritis model, comparing *wt* and *CCR6–/–* mice. We analyzed the phenotype of lymph node cells by flow cytometry and cytokine concentrations in serum. Anti-collagen antibodies and cytokines were measured by enzyme-linked immunosorbent assay.
**Results:** Since CCR6 is an important component of the innate immune system we compared the development of arthritis in *CCR6–/–* mice in 2 different arthritis models known to be T cell independent, the K/BxN serum transfer arthritis and hTNFtg arthritis. In both models, we did not detect any significant differences in clinical signs of inflammation or histological severity of arthritis between wt and CCR6–/– mice. In additon, we could not detect differences in bone density between *wt* and *CCR6–/–* mice. To investigate the role of CCR6 as part of the adaptive immune system in the development of arthritis we induced CIA in *wt* and *CCR6–/–* mice. *CCR6–/–* mice were almost completely protected from CIA. Analyses of T cell subsets by flow cytometry revealed a significant reduction of $CD25^-Foxp3^+$ T cells.
**Conclusions:** These data suggest that CCR6 is not crucially involved in innate immunity driven arthritis, but is necessary for the development of autoimmune arthritis. Importantly, CCR6 is necessary for the generation of pathogenic $CD25^-Foxp3^+$ T cells in CIA, suggesting an important function of CCR6 on T cells in the development of autoimmune arthritis.

## THU0015 THE IMPACT OF BIOLOGIC THERAPIES ON CD4+ AND CD8+ CELL SUBSETS IN RHEUMATOID ARTHRITIS: A LONG TERM FOLLOW-UP STUDY

S. Dulic[1], G. Toldi[2], Z. Vásárhelyi[2], A. Balog[1]. *[1]Department of Rheumatology, Faculty of Medicine, Albert Szent-Györgyi Health Center, University of Szeged, Szeged; [2]First Department of Obstetrics and Gynecology, Faculty of Medicine, Semmelweis University, Budapest, Hungary*

**Background:** Rheumatoid arthritis (RA) is characterized by abnormal prevalence of Th1, Th2, Th17, and regulatory (Treg) subsets. Some data suggest that these subsets are influenced by anti-RA agents. Biologic therapies target different elements in autoimmune process. These agents are regarded as therapeutically equivalent clinical alternatives in RA. However, there are still some slight differences in their action, individual responses, and side effect profile. Follow-up studies monitoring T cell phenotype in response to biologic therapies are limited. We investigated the alteration of CD4+ and CD8+ T cell subset distribution during long term follow-up of anti-TNF and IL-6 receptor antagonist (IL6ra) therapies.
**Methods:** We enrolled RA patients including 28 anti-TNF responders, 38 IL6ra responders and 19 secondary anti-TNF non responders. Blood was taken at least half year after the initiation of biologic therapies. Ten volunteers served as controls. The T cell phenotype was assessed with flow cytometry.
**Results:** In anti-TNF responders, CD4+ prevalence was lower than in anti-TNF non responders, IL6ra responders and controls (Figure). CD4/CD45RA prevalence was lower in all RA groups than in controls. CD4/CD69 prevalence was higher in IL6ra responders than in anti-TNF responders and anti-TNF non responders. CD4/HLADR prevalence was higher in anti-TNF and IL6ra responders than in controls. CD4/CD25 prevalence was lower in all RA groups than in controls and CD4/CD25 prevalence was higher in IL6ra responders than in anti-TNF responders. In IL6ra responders, Th1 prevalence decreased, while Th2 prevalence increased compared to anti-TNF treated groups and controls; and anti-TNF responders and controls, respectively. Th17 prevalence was higher in all RA groups than in controls and Th17 prevalence was also higher in IL6ra responders compared to anti-TNF treated groups. Treg prevalence normalized in all RA groups (Figure) (1). CD8+ prevalence was lower in IL6ra responders than in anti-TNF treated groups and controls (Figure). CD8/CD45RA and CD8/CD45RO prevalence were lower in all RA groups than in controls. CD8/CD69 prevalence was higher in IL6ra responders than in anti-TNF treated groups and controls. CD8/HLADR prevalence was higher in anti-TNF responders than in controls.

**Conclusions:** Biological therapies exhibit marked effects on all the cell populations investigated; some significant differences in this action exist between anti-TNF and IL6ra therapies. This study on peripheral blood samples has provided

comprehensive information regarding the long term impact of biologic therapies on CD4+and CD8+ cell distributions.

## Cartilage, synovium and osteoimmunology

### THU0016 HEPARANASE IS ACTIVE IN HUMAN OSTEOARTHRITIC CARTILAGE AND DRIVES CATABOLIC RESPONSES IN PRIMARY HUMAN CHONDROCYTES

G. Gibor[1], N. Ilan[2], S. Journo[1], A. Sharabi[1,3], O. Elkayam[1,3], I. Vlodavsky[2], U. Arad[1,3]. *[1]Rheumatology, Tel Aviv Medical Center, Tel-Aviv; [2]Cancer and Vascular Biology Research Center, Technion, Haifa; [3]Sackler Faculty of Medicine, Tel Aviv University, Tel-Aviv, Israel*

**Background:** Osteoarthritis (OA) affects hundreds of millions of people worldwide, resulting in significant morbidity. Articular cartilage homeostasis is governed by resident chondrocytes that can either contribute to cartilage anabolism by producing tissue constituents or drive catabolic events by secreting aggrecanases and collagenases. The chondrocytes' pericellular matrix (PCM) acts as a mechanosensor by sequestering growth factors that are bound to heparan sulfate (HS) proteoglycans, such as perlecan.
Heparanase is the sole mammalian enzyme with HS degrading activities. Heparanase enzymatic activity releases HS-bound growth factors, cytokines, chemokines and other ligands stored within the extracellular matrix. Through both enzymatic and non-enzymatic activities, heparanase influences the expression of a number of important genes and has been implicated in numerous processes involved in cancer progression, inflammation and remodeling of the ECM. Little is known about whether heparanase plays a role in cartilage homeostasis.
**Objectives:** To ascertain whether heparanase may have a role in modulating the anabolic or catabolic responses of human articular chondrocytes.
**Methods:** Heparanase enzymatic activity was measured in collagenase digests of osteoarthritic articular cartilage using solid-phase-bound radiolabeled heparan sulfate as substrate. Primary human chondrocytes obtained from OA patients undergoing joint replacement surgery, were incubated with or without recombinant human pro-heparanase. In some experiments, the heparanase inhibitor, PG545, was also added. Heparanase was also added together with fibroblast growth factor 2 (FGF-2) or interleukin 1 (IL-1). The association of pro-heparanase with the chondrocytes and its conversion to active heparanase was evaluated by Western blot. Induction of the catabolic genes *MMP13*, *ADAMTS4* and *ADAMTS5* and the anabolic genes *ACAN* (encoding the aggrecan core protein) and *COL2A1* (encoding the alpha chain of type II collagen), was analyzed by real time reverse-transcriptase PCR. MMP13 enzymatic activity in the culture medium was measured with a specific fluorescent assay. ERK phosphorylation was evaluated by Western blot.
**Results:** The collagenase-digested cartilage (but not the collagenase blend alone), liberated small fragments compatible with HS-degradation products, indicated active heparanase is present in osteoarthritis cartilage. Cultured chondrocytes rapidly associated with the inactive 62-kDa pro-heparanase, which was then cleaved to the active 50-kDa enzyme. Addition of heparanase to cultured human chondrocytes activated the catabolic genes *MMP13* and *ADAMTS4* by 4 hours and reduced the expression of anabolic genes *ACAN* and *COL2A1* by 20 hours. Heparanase also induced human chondrocytes to secrete active MMP13 to the culture medium by 20 hours and induced intracellular ERK phosphorylation by 30 minutes. A synergistic effect was observed between heparanase and FGF-2, but not between heparanase and IL-1. PG545, a heparan sulfate mimetic, reversed the effects of heparanase.
**Conclusions:** Heparanase is active in osteoarthritic cartilage and induces catabolic responses in cultured primary human chondrocytes. This response seems to be due, at least in part, to the release of heparan sulfate-bound growth factors such as FGF-2.

### THU0017 DEFEROXAMINE SUPPRESSES COLLAGEN CLEAVAGE IN CULTURED HUMAN OSTEOARTHRITIC ARTICULAR CARTILAGE VIA A PROCESS INVOLVING DOWNREGULATION OF PROTEASE ACTIVITY, PROINFLAMMATORY CYTOKINES AND TYPE X COLLAGEN EXPRESSION AND UPREGULATION OF AMPK AND CITRIC ACID CYCLE GENES

E.V. Tchetina[1], G.A. Markova[1], A.R. Poole[2]. *[1]Immunology & Molecular Biology, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; [2]Surgery, McGill University, Montreal, Canada*

**Background:** Osteoarthritis (OA) involves degenerative changes in articular cartilage, remodelling of subchondral bone and limited synovial inflammation. Osteoarthritic changes in articular cartilage are associated with progressive proteolytic degradation of the extracellular matrix (ECM), which is composed mainly of type II collagen and aggrecan. Their destruction leads to eventual cartilage loss that is accompanied by phenotypic hypertrophy-related changes in chondrocytes.
**Objectives:** Here we studied the effects of the iron chelator deferoxamine (DFO) on collagen cleavage, inflammation and chondrocyte hypertrophy in relation to energy metabolism-related gene expression in OA articular cartilage. We hypothesised that DFO treatment of human OA articular cartilage explants might decrease collagen cleavage activity, generation of pro-inflammatory cytokines and recover an often-altered chondrocyte phenotype by changing the cellular energy balance in favour of improving of mitochondrial function and restoring an anabolic matrix phenotype. We tested this hypothesis in cultured OA cartilage while also examining and comparing whole-body AMPK expression by peripheral blood mononuclear cells (PBMCs) in OA versus normal patients.
**Methods:** Full-depth explants of human OA knee articular cartilage from arthroplasty were cultured with exogenous DFO (1–50$\mu$M). Type II collagen cleavage and phospho-adenosine monophosphate activated protein kinase (pAMPK) concentrations were measured using ELISAs. Gene expression studies in the knee articular cartilage employed real-time PCR and included AMPK analyses in PBMCs.
**Results:** In OA explants collagen cleavage was frequently downregulated by 10–50 $\mu$M DFO. PCR analysis of five OA patient cartilages revealed that 10 $\mu$M DFO suppressed expression of MMP-1, IL-1b and TNFa, and a marker of chondrocyte hypertrophy, COL10A1. No changes were observed in the expression of glycolysis-related genes. In contrast, expressions of genes associated with the mitochondrial citric acid cycle (TCA) and AMPK were upregulated. Gene expressions of HIF1$\alpha$ and COL2A1 were also upregulated in individual patients but not significantly in the whole group. AMPK gene expression was reduced in OA cartilage and increased in PBMCs from the same patients compared to healthy controls.
**Conclusions:** Our studies demonstrate that DFO is capable of suppressing excessive collagenase-mediated type II collagen cleavage in OA cartilage and reversing phenotypic changes. The concomitant upregulation of pro-anabolic TCA-related gene expressions points to a potential for availability of energy generating substrates required for matrix repair by end-stage OA chondrocytes. This might normally be prevented by high whole-body energy requirements indicated by elevated AMPK expression in PBMCs of OA patients.

### THU0018 REGULATION OF XYLOSYLTRANSFERASE-1 EXPRESSION BY FIBRONECTIN FRAGMENT IN HUMAN ARTICULAR CHONDROCYTES

C.M. Lee[1], G.H. Park[1], S.Y. Lee[2], K.M. Son[3], H.S. Lee[4], M.H. Lee[5], H.S. Hwang[1], H.A. Kim[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Hallym University Sacred Heart Hospital, Kyunggi, 431–070; [2]Division of Rheumatology, Department of Internal Medicine, Hallym University Sacred Heart Hospital, Anyang; [3]Division of Rheumatology, Department of Internal Medicine, Hallym University Chuncheon Sacred Heart Hospital; [4]Division of Rheumatology, Department of Internal Medicine, Hallym University Chuncheon Sacred Heart Hospital, Chuncheon; [5]Division of Rheumatology, Department of Internal Medicine, Hallym University Sacred Heart Hospital, Kyunggi, 431–070, Korea, Republic Of*

**Background:** Xylosyltransferase-1 (XT-1), encoded by *xylt1* gene, is an essential anabolic enzyme to catalyze the initial and rate-determining step in glycosaminoglycan chain synthesis. The effect of fibronectin fragments (FN-fs), generated by proteolytic cleavage of FN and known as damage-associated molecular pattern (DAMP) molecules, on cartilage metabolism was poorly characterized.
**Objectives:** In this study we examined 29-kDa amino-terminal fibronectin fragment (29-kDa FN-f)-mediated XT-1 expression mechanism and its signaling pathway, determining the role of 29-kDa FN-f in cartilage matrix synthesis.
**Methods:** Human articular chondrocytes were enzymatically isolated from articular cartilage and cultured in monolayer. In 29-kDa FN-f-stimulated chondrocytes, the relative levels of mRNA and protein for XT-1 were analyzed by real-time quantitative reverse transcription-polymerase chain reaction and Western blot analysis, respectively. In order to investigate the effects of 29-kDa FN-f on XT-1, human chondrocytes were transfected with small interfering RNAs (siRNAs) targeting TLR-2.
**Results:** The level of aggrecan and XT-1 in human osteoarthritis cartilage was significantly decreased compared to normal cartilage. XT-1 expression in cultured primary articluar chondrocytes showed a periodic oscillation in both mRNA and protein level. 29-kDa FN-f significantly suppressed the mRNA and protein levels of XT-1 at 14 h and 24 h, respectively. Knockdown of toll like receptor-2 (TLR-2) using small interference RNA revealed that the decrease of XT-1 expression by 29-kDa FN-f is mediated by TLR-2 signaling pathway. Inhibition of mitogen activated protein kinase (MAPK) and nuclear factor-$\kappa$B (NF- $\kappa$B) signaling pathway restored 29-kDa FN-f-inhibited XT-1 expression. In addition, reduction of XT-1 expression by 29-kDa FN-f- was associated with activation of activator protein 1 (AP-1) signaling pathway. Finally, 29-kDa FN-f enhanced the expression of Sp3

and inhibited the expression of Sp1. Knockdown and overexpression experiments confirmed that XT-1 expression was modulated by Sp3 and Sp1, which are ubiquitous transcriptional proteins and compete for the same DNA binding site.
**Conclusions:** These results demonstrated that 29-kDa FN-f plays a detrimental role in the regulation of cartilage extracellular matrix formation including XT-1 expression.

## THU0019 AGE-RELATED HISTOLOGICAL CHANGES IN CALCIFIED CARTILAGE AND SUBCHONDRAL BONE PLATE IN COMPLETE HUMAN FEMORAL HEADS

A.W. Nielsen[1], L.B. Hartlev[1], R. Klose-Jensen[1], L.W. Boel[2], K.K. Keller[1], E.-M. Hauge[1]. *[1]Department of Rheumatology, Aarhus Universitetshospital; [2]Department of Forensic Medicine, Aarhus Universitet, Aarhus, Denmark*

**Background:** Age is the most important risk factor for osteoarthritis (OA). However, the pathogenesis of OA is not fully understood, but the subchondral bone plate may be thickened in osteoarthritis. How aging of the joint corresponds to OA changes is poorly elucidated, but preliminary OA alterations may occur in healthy old individuals and progress into symptomatic OA.
**Objectives:** The objective was to investigate the age-related changes in different tissue compartments of the femoral head hypothesizing that a positive correlation with age would be found for 1) volume of the femoral head; 2) volume and thickness of the subchondral bone plate and calcified cartilage.
**Methods:** Sixty-one femoral heads from 29 females (median, range) (49, 20–74 years) and 32 males (47, 23–78 years), who had accidently died, were obtained by autopsy from the Institute of Forensic Medicine. Individuals were excluded in case of known bone or joint diseases, or macroscopic cartilage erosions.
Design-based stereological methods using systematic uniform random sampling were applied to estimate absolute volume. The femoral heads were randomly rotated around a vertical axis and sawn in 5–8 slabs with a thickness of 7 mm. The slabs were halved and alternating right or left half were embedded in methylmethacrylate from where 7-μm thick sections were cut. The sections were stained with Masson-Goldner trichrome or May-Grünwald toluidine blue. The total absolute volume of the femoral head, calcified cartilage, and the subchondral bone plate were estimated using the Cavalieri estimator. Orthogonal thicknesses of the calcified cartilage and the subchondral bone were measured in uniform randomly selected sampling points and related to the overlying articular cartilage alterations using the OARSI score of histological osteoarthritis. Linear regression was used to test the effect of age on the parameters and t-tests were applied for comparing men and women.
**Results:** The volume and thickness of the subchondral bone did not correlate with age (Table 1). Calcified cartilage volume and thickness correlated positively with age only in women. The volume of the femoral head correlated positively with age only in men. Women and men did not differ in OARSI-stage or grade.

| | Mean Values ± SD | | | Changes per 10 years | | |
|---|---|---|---|---|---|---|
| | All | Women | Men | All | Women | Men |
| Femoral Head volume ($cm^3$) | 34.3 ± 10.4 | 25.8 ± 3.7 | 41.9 ± 8.3§ | 1.3 | 0.1 | 1.9* |
| Calcified cartilage volume ($mm^3$) | 276 ± 121 | 282 ± 149 | 271 ± 89 | 34** | 51*** | 19 |
| Subchondral bone plate volume ($mm^3$) | 681 ± 252 | 585 ± 258 | 767 ± 211§ | -13 | -27 | -6 |
| Calcified cartilage thickness (μm) | 88 ± 34 | 100 ± 40 | 76 ± 21§ | 8* | 15*** | 2 |
| Subchondral bone plate thickness (μm) | 222 ± 61 | 216 ± 69 | 229 ± 52 | -7 | -9 | -6 |
| Mean OARSI-grade | 0.34 ± 0.29 | 0.35 ± 0.34 | 0.33 ± 0.23 | 0.08*** | 0.08 | 0.09*** |
| OARSI-stage (%) | 18.1 ± 13.4 | 19.4 ± 15.6 | 16.9 ± 11.1 | 4.5*** | 4.3* | 4.7*** |
| -OARSI-grade 0 | 81.9 ± 13.4 | 80.6 ± 15.6 | 83.1 ± 11.1 | -4.5*** | -4.3* | -4.7*** |
| -OARSI-grade 1 | 9.0 ± 7.2 | 9.9 ± 7.9 | 8.1 ± 6.3 | | | |
| -OARSI-grade 2 | 4.6 ± 5.4 | 5.6 ± 6.5 | 3.7 ± 4.0 | | | |
| -OARSI-grade =3 | 4.6 ± 5.5 | 3.9 ± 5.6 | 5.1 ± 5.3 | | | |

Data is represented as mean±SD and changes per 10 years.
Linear regression was used to check for statistical correlation with age and is denoted as * p<0.05, ** p<0.01 and ***p<0.001.
Students T-test or Mann-Whitney Rank Sum test was applied for comparing men and women and a statistical difference is denoted as § p<0.05.

**Conclusions:** In complete human femoral heads obtained from a cross-sectional population without macroscopic OA changes, we found no correlation with age for the volume or thickness of the subchondral bone plate. Surprisingly, the two genders differed in the effect of age on volume of the femoral head and volume and thickness of the calcified cartilage even though they had corresponding damage of the articular cartilage.

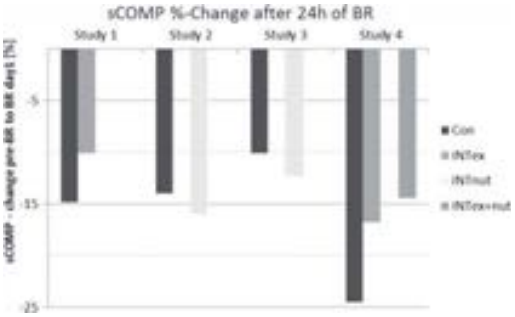
## THU0020 IMMATURE DENDRITIC CELL ARE POTENT OSTEOCLASTS PRECURSORS IN RA AND ARE TARGETED BY RA-SPECIFIC ANTIBODIES

A. Krishnamurthy[1], M. Sun[1], B. Rethi[1], V. Joshua[1], N. Tarasova[2], H. Wähämaa[1], K. Amara[1], V. Malmström[1], J. Ytterberg[2], A. Catrina[1]. *[1]Medicine, Rheumatology Unit; [2]Medicinal Biophysics and Biochemistry, Karolinska Institutet, Stockholm, Sweden*



**Background:** We have recently shown that the immature dendritic cells (iDC) developing in dense cultures in presence of high lactic acid levels can efficiently differentiate into osteoclasts (OC).
**Objectives:** We aimed to investigate influence of Anti-citrullinated protein antibodies (ACPA) on iDC differentiation to OC in rheumatoid arthritis (RA).
**Methods:** CD14+ monocytes from PB of ACPA+ RA patients and healthy individuals were first used to generate iDC and MΦ and these cells were then differentiated to OC with RANKL and M-CSF. Mass spectrometry analysis was performed on different stages of differentiation of iDC and MΦ derived OC. ACPA positive and negative polyclonal IgGs were isolated from synovial fluid (SF, n=26) and peripheral blood (PB, n=38) samples of RA patients and the effects of these antibodies was tested in OC cultures. Cytokines were measured by CBA in cultures supernatants. Immunoflourescence was done on OCs with monoclonal ACPAs derived from single SF derived B cells. The effect of IL-8 and PAD inhibition was tested on OC differentiation.
**Results:** Principal component analysis confirmed distinct proteomics profiles in sparse or dense DC cultures and in MΦ but both DC and MΦ precursors differentiated into OC with similar protein composition. Citrullinated-actin was identified during iDC-OC maturation and citrullinated-vimentin in matured OC. With immunofluorescent staining we demonstrated the presence of citrullinated proteins on the surface of both iDC precursors and iDC-derived mature OCs. PAD2 and PAD4 showed faint staining in CD14 monocytes with increased staining intensity in both iDC precursors and more mature OCs with PAD activity present both in dendritic cells and osteoclasts. Polyclonal ACPAs enhanced osteoclastogenesis and bone resorption from iDC (fold increase 1.6±0.2 for OC number and 2.0±0.3 for bone resorption area). Similar effect was observed when the iDC were derived from ACPA+ RA patients (fold increase of 2.3±0.9 for OC number and 2.6±0.1 for bone resorption area). Monoclonal ACPA's with certain specificities were able to induce osteoclastogenesis. The importance of citrullination and PAD enzymes for ACPA mediated iDC transdifferentiation to OC was confirmed by a dose-dependent inhibition of OC differentiation using the PAD inhibitor Cl-Amidine. Increased osteoclastogenesis was associated with significantly higher levels of IL-8 levels in ACPA treated culture supernatants (fold increase of 2.4±0.5). Neutralization of IL-8 blocked ACPA induced osteoclastogenesis.
**Conclusions:** Our results shows iDC can efficiently transdifferentiate in to OC in RA and this process is enhanced by ACPA. We provide evidence on the importance of the IL-8 and PAD enzyme in ACPA mediated osteoclastogenesis.

## THU0021 IMPACT OF IMMOBILIZATION ON SERUM LEVELS OF CARTILAGE OLIGOMERIC MATRIX PROTEIN AND IMPLICATIONS FOR CLINICAL PRACTICE IN MUSCULOSKELETAL DISORDERS

A.-M. Liphardt[1,2], G.-P. Brüggemann[1,3], F. Zaucke[4], F. Eckstein[5], W. Bloch[6], A. Mündermann[7], J. Mester[8], G. Schett[9], J. Rech[9], A. Niehoff[1,3]. *[1]Biomechanics and Orthopaedics, German Sport University Cologne, Köln; [2]Rheumatology & Immunology, University Erlangen-Nürnberg (FAU), Erlangen; [3]Cologne Center for Musculoskeletal Biomechanics, Medical Faculty; [4]Center for Biochemistry, Medical Faculty, University of Cologne, Köln, Germany; [5]Institute of Anatomy, Paracelsus Medical University, Salzburg, Austria; [6]Cardiovascular Research and Sport Medicine, Dep. of Molecular and Cellular Sport Medicine, German Sport University Cologne, Köln, Germany; [7]Dep. of Orthopaedics, University Hospital Basel, Basel, Switzerland; [8]Training Science and Sport Informatics, German Sport University Cologne, Köln; [9]Rheumatology and Immunology, University Erlangen-Nuremberg, Erlangen, Germany*

**Background:** Healthy articular cartilage is important for proper joint function. The impact of unloading due to disease or injury on healthy and diseased articular cartilage is not well understood and bed rest (BR) studies offer a unique and well-standardized model to study the effects of immobilization. Cartilage oligomeric matrix protein (COMP) is a structural protein found in cartilage and is a marker of cartilage turnover [1]. Increased serum concentrations (sCOMP) have been associated with cartilage degradation in osteoarthritis [2] and rheumatoid arthritis [3] but also physiological loading [4, 5]. sCOMP decreases with with immobilization [6].
**Objectives:** To investigate the impact of duration of immobilization (CON) and effectiveness of exercise (INT ex) and nutrition interventions (INTnut) on sCOMP concentration in healthy male subjects during medium-term BR-studies.
**Methods:** Four BR-studies were conducted, each in cross-over design: study 1 (INTex; N=8) had a 14-days of BR, Study 2 (INTnut; N=7), Study 3 (INTnut; N=9) and Study 4 (INTex+nut; N=8) had 21 days of BR. Blood samples were taken after overnight fast. sCOMP concentration was analyzed using commercial enzyme immunoassays (COMP® ELISA, AnaMar Medical AB, Lund, Sweden). Statistical

analysis (IBM SPSS Statistics, 19.01) was performed using repeated measures ANOVA ($p<0.05$).
**Results:** BR lead to a reduction in sCOMP after 24h for all interventions and the control condition (Fig.1). sCOMP recovered to baseline after the end of BR for all conditions (study 1: INTex: +26%, CON: +28.6%; study 2: INTnut: +25%, CON: +25%; study 3: INTnut: +28.9%, CON: + 28.6%; study 4: INTex: +35.0%, INTex+nut: +33.2%, CON: +32.8%). INTnut and INTex did not affect the results. COMP data of 24 individuals from studies 1–3 were re-analyzed for the adaptation of sCOMP during BR. Baseline values of sCOMP decreased by -16% after 24h of BR and further by -5% until BRday 14.

**Conclusions:** sCOMP concentration is sensitive to immobilization. After the distinct initial decrease in sCOMP during the first 24hrs of BR, sCOMP is significantly lowered at BR day 14 compared to the first 24h of BR. These results suggest that beside a reduced diffusion of molecules from the joint, cartilage turnover is decreased during prolonged immobilization. This presumably also negatively affects tissue properties. Thus the combined effects of disease and immobilization on cartilage health in arthritis patients need to be considered and require further investigation. High standardization of blood sampling with regards to mechanical loading is essential for data quality when evaluating sCOMP concentration.

## THU0022 HYPERGLYCEMIA-RELATED ADVANCED GLYCATION END-PRODUCTS IS ASSOCIATED WITH THE ALTERED PHOSPHYTIDYLCHOLINE METABOLISM IN OSTEOARTHRITIS PATIENTS

W. Zhang, G. Sun, S. Likhodii, E. Randell, A. Furey, G. Zhai. *memonial university of newfoundland, St. John's, Canada*

**Background:** Accumulating evidence suggests an independent association between osteoarthritis (OA) and type 2 diabetes mellitus (DM). Our recent work [Zhang, *et al.* Metabolomics, 2015] found phosphatidylcholine acyl-alkyl C34:3 (PC ae C34:3) and phosphatidylcholine acyl-alkyl C36:3 (PC ae C36:3) were associated with both OA and DM. Both synovial and plasma concentrations of these two metabolites were reduced in knee OA and DM patients, and OA patients with DM had lowest concentration of these two metabolites, suggesting the altered unsaturated phosphatidylcholine metabolism may be responsible for the association between OA and DM.
**Objectives:** We hypothesized hyperglycemia-related production of advanced glycation end-products (AGEs) was involved in the altered phosphatidylcholine metabolism in OA patients and tested this hypothesis in the current study.
**Methods:** Synovial fluid and plasma samples were collected from OA patients with and without DM. Hyperglycemia-related AGEs including methylglyoxal (MG) and methylglyoxal-derived hydroimidazolone (MG-H1) levels were measured in both synovial fluid and plasma samples using UPLC/MS method. The correlation between MG, MG-H1, and PC ae C34:3 and PC ae C36:3 were examined.
**Results:** 84 knee OA patients, including 46 with DM and 38 without DM, were included in the study. We did not find a significant difference in plasma MG-H1 concentration between OA with and without DM. However, we found that log transformed synovial concentrations of MG-H1 in the groups of OA with diabetes were 2.56±0.27 ng/ml which was significantly higher than that in the group of OA without diabetes (2.39 ±0.25 ng/ml, P=0.012). Similarly, synovial concentration of MG was 2.05±0.11 ng/ml in the group of OA with diabetes which was significantly higher than 1.99±0.11 ng/ml in the group of OA without diabetes (P=0.046). The significance remained after adjusting the age, BMI and sex. The correlation between MG-H1 and PC ae C34:3, MG-H1 and PC ae C36:3, MG and PC aeC34:3, and MG and PC ae C36:3 were -0.15, -0.32, -0.23 and -0.06, respectively.
**Conclusions:** We demonstrated that both MG-H1 and MG concentrations in synovial fluid were elevated in OA patients with DM and associated with the levels of PC ae C34:3 and PC ae C36:3, suggesting that hyperglycemia-related AGEs may be responsible for the altered phosphotidylcholine metabolism in OA.

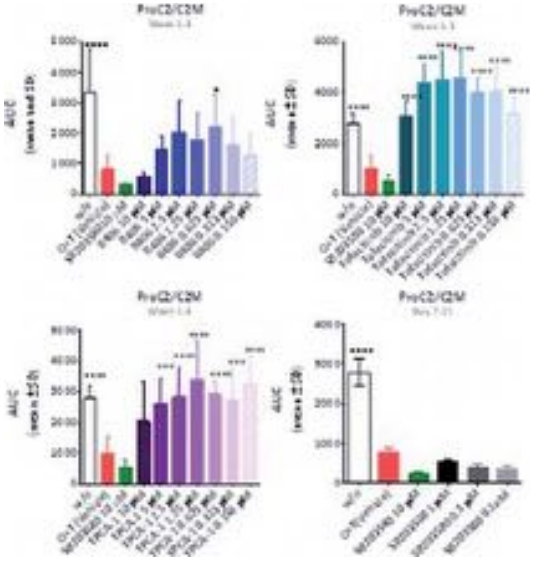
## THU0023 EXPRESSION OF OSCAR IN THE SYNOVIUM OF EARLY RA PATIENTS

T.N. Crotti[1], R. Coleman[1], A.A. Dharmapatni[1], H. Weedon[2], D.R. Haynes[1], M.D. Smith[2,3], M.D. Wechalekar[2,3]. [1]*Anatomy and Pathology, University of Adelaide, Adelaide;* [2]*Rheumatology, Repatriation General Hospital, Daw Park;* [3]*Flinders University, Bedford Park, Australia*



**Background:** Osteoclast-associated receptor [OSCAR] is expressed by monocyte, endothelial and dendritic cells. OSCAR is a co-stimulation receptor involved in transducing immunoreceptor tyrosine-based activation (ITAM) signals for differentiation from monocytes into active osteoclasts (OCs). Endothelial OSCAR expression may induce monocyte adhesion increasing monocyte extravasation available for osteoclastogenesis in affected joints. Higher expression of OSCAR by endothelial and pre-OCs, as detected by immunohistochemistry, is present in active RA compared with OA and healthy synovial samples (Crotti ART 2012). Inflammation in RA may increase OSCAR expression as supported by increased monocyte (Herman ART 2012) and endothelial cell (Crotti ART 2012) OSCAR expression in response to TNF-alpha in vitro. OSCAR expression in early RA (less than 6 months post diagnosis) and cartilage pannus junction (CPJ) and non-CPJ samples from established RA has not been reported.
**Objectives:** To examine OSCAR expression in the synovium of early RA patients at diagnosis and 6 months following treatment. OSCAR was also assessed in the CPJ and non-CPJ tissues of patients with established RA.
**Methods:** Samples included synovial biopsies from 15 patients newly diagnosed for RA at 0 and 6 months. CPJ and non-CPJ samples from established RA joints were also assessed (n=14). Serial sections for both cohorts were stained for OSCAR, TRAP (to identify pre-OCs/OCs) and von Willebrand factor (to identify vessels). Positive cells were counted (TRAP) or scored semiquantitatively (OSCAR) in 6x 2mm$^2$ fields. A paired T test was used to detect significance.
**Results:** OSCAR was associated with the synovial lining cells and distributed sparsely in association with monocytes in the subsynovial tissue or lymphoid aggregates in both early and established RA. A subset of samples from both cohorts showed a very mild staining associated with the vasculature and lumen. In early RA there was no significant difference in OSCAR expression within lining, sublining and vessels (p=0.217, 0.622, 0.906 respectively) between 0 and 6 months. The expression of OSCAR in the sublining reduced in 10/15 patients by 6 months. Very few TRAP positive cells were detected at either time point. The CPJ and non-CPJ established RA cohort had higher expression of OSCAR than the early cohort. The number of TRAP positive cells was significantly higher in the CPJ versus non-CPJ (p=0.015, mean=88.5 vs 44).
**Conclusions:** OSCAR positive cells were observed in all synovial tissues, particularly in the lining, in both early RA and established RA. This has not been previously reported. Expression of OSCAR by sublining cells including OC precursors, possibly dendritic cells, macrophages and endothelial cells is consistent with previous reports. Low numbers of TRAP positive cells may relate to early disease and/or site of biopsy as distant from the actual CPJ due to limitations of arthroscopic technique. In established RA, higher numbers of TRAP and OSCAR positive cells were present in both CPJ and non-CPJ tissues. The reduced sublining OSCAR expression in the majority of patients following treatment suggests modulation of OSCAR by DMARDS and may implicate OSCAR as an inflammation and bone erosion predictive biomarker.

## THU0024 ANTI-INFLAMMATORY INHIBITORS TARGETING JAK AND IKK HAVE AN ANABOLIC EFFECT ON TYPE II COLLAGEN TURNOVER EX VIVO

C.F. Kjelgaard-Petersen[1,2], A.-C. Bay-Jensen[2], M.A. Karsdal[2], P. Hägglund[1], C.S. Thudium[2]. [1]*Systems Biology, Technical University of Denmark, Lyngby;* [2]*Biomarkers and Reseach, Rheumatology, Nordic Bioscience, Herlev, Denmark*

**Background:** Rheumatoid arthritis (RA) and a subpopulation of osteoarthritis, inflammatory OA (iOA) are degenerative joint diseases with an inflammatory

component. However, the degree of inflammation is much higher in RA than iOA. There are many signaling pathways involved with the inflammation-driven extracellular matrix (ECM) degradation in RA and iOA cartilage that have been suggested as anti-inflammatory targets. However, the results on joint structure in clinical trials have been varying. A better understanding of the intracellular signaling pathways and the downstream effect on ECM turnover could be beneficial for the selection of novel anti-inflammatory treatments for RA and iOA.
**Objectives:** The aim of this study was to investigate the direct effect of the anti-inflammatory inhibitors R406 (the active metabolite of Fostamatinib), Tofacitinib, TPCA-1 and SB203580 on the cartilage ECM turnover.
**Methods:** Full depth bovine cartilage *ex vivo* cultures were cultured for 3 weeks with OSM [10 ng/mL] and TNFα [2 ng/mL] (O+T) or together with R406, Tofacitinib or TPCA-1 at 10 μM and a two-fold dilution to 0.16 μM. SB203580 was tested at 3 μM, 1 μM and 0.3 μM. As negative control, untreated explants were included. The ECM turnover of the cartilage was assessed with the biomarkers; C2M, ProC2, AGNx1 and/or ARGS. Additionally, histology of the explants was examined with Safranin O and fast green staining.
**Results:** Aggrecanase mediated degradation of aggrecan was assessed with ARGS or AGNx1. The Syk inhibitor R406, the Jak inhibitor Tofacitinib, and the IKK inhibitor TPCA-1 inhibited the release of ARGS or AGNx1, while the p38 inhibitor, SB203580, had no effect. The turnover of type II collagen was measured by the formation of type II collagen (ProC2) and MMP-mediated degradation of type II collagen (C2M). The ratio between ProC2 and C2M was calculated for week 1–3. Tofacitinib and TPCA-1 increased the area under the curve (AUC) of ProC2/C2M significantly compared to O+T ($p<0.001$). SB203580 and R406 had no effect at 10 μM, 5 μM, 0.31 μM and 0.16 μM, but tended to increase ProC2/C2M at 2.5–0.625 μM compared to O+T (Figure 1). Safranin O and fast green staining of the explants showed that O+T, SB203580 and 0.16 μM of R406, Tofacitinib, and TPCA-1 lead to loss of proteoglycans from the cartilage explants compared to the untreated explants. R406 at 10 μM retained the proteoglycans in the deep and middle zone of the cartilage, while the proteoglycans of the superficial layer was lost. 10 μM of Tofacitinib and TPCA-1 retained the proteoglycans in all layers of the cartilage explants.

**Conclusions:** The four inhibitors tested had a positive effect on the degradation of aggrecan and type II collagen. However, only Tofacitinib and TPCA-1 had an increased anabolic effect on type II collagen turnover. The anabolic effect from Tofacitinib and TPCA-1 on top of the anti-catabolic effect indicates that the chondrocytes can repair the cartilage during treatment opposite to the p38 inhibitor that inhibits the catabolic and the anabolic response.

## THU0025 OVER-EXPRESSED PGC-1β IN CD14+ MONOCYTES OF RHEUMATOID ARTHRITIS PATIENTS AND ITS DOWN-REGULATION CAN SUPPRESS OSTEOCLASTOGENESIS AND BONE RESORPTION THROUGH INHIBITION OF CATHEPSIN K AND TRAP

J. Jing, J.-D. Ma, Y.-Q. Mo, D.-H. Zheng, D. Lie. *Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China*

**Background:** Peroxisome proliferator-activated receptor-gamma coactivator-1 (PGC-1) is a transcriptional coactivator that plays important roles in regulating energy metabolism and cytokine signaling pathways. Our previous study showed that down-regulating PGC-1β could inhibit rheumatoid arthritis fibroblast-like synoviocytes induced osteoclastogenesis by RAW264.7 (used as precursor of osteoclasts).
**Objectives:** To investigate the expression of PGC-1β in CD14+ monocytes from RA patients and its effect and underlying mechanism on osteoclastogenesis and bone resorption.
**Methods:** (1) Peripheral blood mononuclear cells (PBMCs) were collected from 3 patients with active RA and 3 healthy controls and CD14+ monocytes were selected by flow cytometry. PGC-1β expression was detected by immunofluorescence staining or flow cytometry. (2) PGC-1β in RAW264.7 was depleted by lentivirus short hairpin RNAs and then cultured with recombinant murine RANKL (50ng/ml) and M-CSF (25ng/ml). Tartrate-resistant acid phosphatase (TRAP) staining and western blot (WB) for detecting the expression of DC-STAMP, cathepsin K and TRAP were performed at day 7. Toluidine blue staining for examining resorption pits by reflected light microscopy and image analysis system was performed at day 14. (3) After PGC-1β knockdown in RAW264.7, cytoplasmic protein was extracted for WB determining the expression of JNK, p-JNK, p38, p-p38, p-ERK1/2, NFATc-1, NF-κB and IκB, while nuclear protein was extracted for WB determining the expression of PGC-1β, p- NF-κB, ERK1/2, c-jun and c-fos.
**Results:** (1) Immunofluorescence staining showed that the percentage of PGC-1β positive PBMCs in RA was significantly higher than that in healthy controls (94±3% vs. 57±7%, *P*=0.021, Figure 1A). Flow cytometric analyses showed that PGC-1β expression in CD14+ monocytes from RA patients was higher than that of healthy controls (Figure 1B) and the mean fluorescence intensity was significantly higher than that of healthy controls (274±23 vs. 167±15, *P*=0.034).(2) At day 7, the number of TRAP-positive multinucleated osteoclasts in sh-PGC-1β group was significantly lower than that in sh-GFP group (33.4 ± 3.4 vs. 192.5 ± 5.1 cells/per well, *P*=0.021, Figure 1C). At day 14, the pit area of bone resorption lacunae on the slices of sh-PGC-1β group was significantly reduced than that of sh-GFP group (13 ± 2 vs. 197 ± 15 $\mu m^2$/per slice, *P*=0.012, Figure 1C). (3) WB assay showed that the protein expression of cathepsin K and TRAP,but not DC-STAMP, were obviously suppressed in sh-PGC-1β group (Figure 1D). Further analysis of signaling pathways showed the expression of NFATc1 and phosphorylate NF-κB p65 were also significantly decreased (Figure 1E).

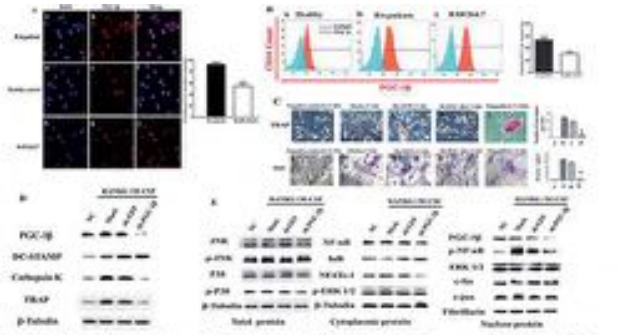

**Figure 1. A.** Elevated expression of PGC-1β in RA-PBMC. **B.** Elevated expression of PGC-1β in CD14+ monocytes. **C.** PGC-1β knockdown decreases the number of osteoclasts and resorption lacunae area induced by RANKL and M-CSF. **D.** PGC-1β knockdown inhibits the expression of cathepsin K, TRAP. **E.** PGC-1β knockdown dampens the activation of NF-κB.

**Conclusions:** Our results showed that over-expressed PGC-1β in CD14+ monocytes of RA patients and down-regulation of PGC-1β can suppress RANKL induced osteoclastogenesis and bone resorption through inhibition of cathepsin K and TRAP by NF-κB and NFATc1 pathway.

## THU0026 MICRORNA-365 REGULATES EXPRESSION OF CATABOLIC FACTORS VIA MODULATING IL-1β-INDUCED EPAS-1 EXPRESSION IN SW1353 CELLS AND HUMAN PRIMARY CHONDROCYTES

G.H. Park[1], C.M. Lee[1], S.Y. Lee[1], K.M. Son[2], H.S. Lee[2], H.S. Hwang[1], M.H. Lee[1], H.A. Kim[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, Kyunggi, 431–070; [2]Division of Rheumatology, Department of Internal Medicine, Hallym University Chuncheon Sacred Heart Hospital, Chuncheon, Korea, Republic Of*

**Objectives:** Endothelial PAS domain protein-1 (EPAS-1/HIF-2α), encoded by *EPAS1* gene, is a catabolic transcription factor to regulate osteoarthritis (OA) cartilage destruction. In this study we examined whether microRNA-365 (miR-365) can regulate interleukin (IL)-1β-induced expression of catabolic factors in SW1353 cells and human articular chondrocytes via regulation of EPAS-1.

**Methods:** Total RNA was isolated from normal and OA cartilage tissues, human chondrocytes, and SW1353 cells. The level of miR-365 was quantified by TaqMan assay. The effects of miR-365 on expression of EPAS-1 and EPAS-1-modulated genes were measured by quantitative real-time polymerase chain reaction (qRT PCR), Western blot analysis, and enzyme-linked immunosorbent assay (ELISA). To examine the direct interaction of miR-365 with 3' untranslated region (UTR) of EPAS-1 mRNA, luciferase reporter assay was performed.
**Results:** The level of miR-365 in human OA cartilage was significantly decreased compared to normal cartilage. The overexpression of miR-365 significantly suppressed IL-1β-induced expression of EPAS-1 in both SW1353 cells and human articular chondrocytes. QRT PCR analysis using pharmacological inhibitors revealed that mitogen activated protein kinase and nuclear factor-κB signaling pathway was involved in IL-1β-induced miR-365 decrease and subsequent increase of EPAS-1 expression. Luciferase reporter assay using DNA construct containing binding site of miR-365 within 3'UTR of human EPAS-1 mRNA demonstrated that the overexpression of miR-365 significantly suppressed IL-1β-induced up-regulation of EPAS-1. Furthermore, miR-365 overexpression significantly suppressed IL-1β-induced expression of catabolic factors, including cyclooxygenase-2, inducible nitric oxide synthase, and matrix metalloproteinase-1, -3 and -13, in SW1353 cells and human chondrocytes.
**Conclusions:** MiR-365 regulates IL-1β-stimulated catabolic effects in SW1353 cells and human chondrocytes via modulating the expression of EPAS-1.
**Disclosure of Interest:** None declared

## THU0027 INDUCTION OF REGULATORY T CELLS AND ITS REGULATION WITH INSULIN-LIKE GROWTH FACTOR/INSULIN-LIKE GROWTH FACTOR BINDING PROTEIN-4 BY HUMAN MESENCHYMAL STEM CELLS

I. Miyagawa[1], S. Nakayamada[1], K. Nakano[1], K. Yamagata[1], K. Sakata[1], K. Yamaoka[2], Y. Tanaka[1]. *[1]The First Department of Internal Medicine, University of Occupational and Environmental Health, Japan, Kitakyusyu; [2]Division of Rheumatology, Department of Internal Medicine, Keio University, Tokyo, Japan*

**Background:** Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by synovitis and subsequent joint destruction. Biological agents and Janus kinase inhibitors have proven to be more effective than conventional treatments. However, no effective treatment for repairing damaged joints has yet been established. Human mesenchymal stem cells (hMSCs) are multipotent and are expected as potential therapeutic tools for promoting tissue repair at various sites, including joints in RA. Human MSCs also have the capacity to modulate immune responses, but the underlying mechanism remains elucidated.
**Objectives:** In the present study, we investigated the regulatory mechanism of induce regulatory T cells (Treg cells) induction through the growth factors released by hMSCs.
**Methods:** Human naïve $CD4^+$T cells were stimulated with anti-CD3/28 antibodies and co-cultured with hMSC culture supernatant for 48 hours. The proliferation and cytokine production of $CD4^+$T cells and surface molecule expressions on $CD4^+$T cells were evaluated.
**Results:** The proliferation of anti-CD3/28 antibody-stimulated $CD4^+$T cells was suppressed by the addition of hMSCs culture supernatant, but production of IL-10 and IL-4 from $CD4^+$T cells were induced the supernatant. The hMSCs supernatant induced $CD4^+FoxP3^+$Treg cells. The induced $CD4^+FoxP3^+$Treg cells expressed CD25, CTLA-4, GITR, and IGF (insulin-like growth factor)-1R and IGF-2R and revealed anti-proliferative activity against $CD4^+$T cells. In addition, the induction of Treg cells by the hMSCs supernatant was enhanced by addition of rhIGF-1/2 and suppressed by inhibition of IGF-1R. The MSCs supernatant include not only IGF-1 and IGF-2 but also a significant amount of IGFBP-4, an inhibitor of IGF action. After neutralization of IGFBP-4 in the hMSCs culture supernatant by anti-IGFBP-4 antibodies, the number of the Treg cells increased significantly as compared to the neutralization of IGFBP-3.
**Conclusions:** Human MSCs induced $CD4^+IGF1R^+IGF2R^+FoxP3^+$Treg cells responsive to IGF signaling thorough the secretion of soluble factors. On the other hand, hMSCs are also involved in a negative regulatory mechanism, which suppresses Treg cells proliferation by releasing IGFBP-4, indicating differential regulation of Treg cells by the MSCs: positive regulation by IGF and negative regulation by IGFBP-4. The present results also suggest that the inhibition of IGFBP-4 may be necessary for the efficient application of MSC therapy in the context of joint repair in RA

## THU0028 MICRORNA-381 AMELIORATES ARTHRITIS BY CONTROLLING FUNCTIONS OF FIBROBLAST-LIKE SYNOVIOCYTES, WHICH ARE AFFECTED BY A TO I RNA EDITING

Y. Tanaka[1], S. Takada[2], H. Iizasa[3], A. Hatzigeorgiou[4], S.-I. Miyazawa[5], T. Furumatsu[5], K. Nishida[5], H. Asahara[1]. *[1]Department of Systems BioMedicine, Tokyo Medical and Dental University; [2]Department of Systems BioMedicine, National Research Institute for Child Health and Development, Tokyo; [3]Department of Microbiology, Shimane University Faculty of Medicine, Shimane, Japan; [4]DIANA-Lab, Alexander Fleming Biomedical Sciences Research Center, Vari, Greece; [5]Department of Orthopedic Surgery, Okayama University Graduated School of Medicine, Okayama, Japan*

**Background:** MicroRNAs (miRNAs) play as regulators of rheumatoid arthritis (RA) and other diseases. MicroRNA is edited by the adenosine deaminase double-stranded RNA (ADAR) as well as mRNA and other noncoding RNA after transcription. A to I RNA editing is occurred limited variety of miRNAs. MicroRNA-381 (MiR-381) is one of limited miRNAs and was down regulated in synovium derived from patients with RA. However, the function of miR-381 and A to I RNA editing against RA is not clear.
**Objectives:** To clarify a role of miR-381 and A to I RNA editing in synovium derived from RA or OA.
**Methods:** 1) RNA was purified from the synovium derive from patients with RA (n=6) or OA (n=6) and analyzed with next generation sequencing (NGS). MiRNA editing was annotated containing 2 nucleotide mismatch. 2) The expression of wild type (WT) and edited miR-381 of synovium derived from RA (n=10) was compared to OA (n=10) with real time PCR. 3) Fibroblast-like synoviocytes (FLS) purified from RA synovium (n=3) were treated TNFα and IL-1β to clear miR-381 expression mechanism. 4) FLS were transfected with WT or edited miRNA expression vectors. These migration, proliferation and MMP production were analyzed. The target genes was predicted and determined by luciferase assay. 5) Male DBA/1 mice were intraperitoneally injected anti-collagen antibodies (collagen antibody-induced arthritis, CAIA) on day0 and LPS on day3. MiR-381 mimic was injected intra articular space on day0 and 3 after antibody injection. Arthritis was evaluated by arthritis score and histological score.
**Results:** 1) Two types of A to I RNA editing were detected in miR-381 seed sequence using NGS (edit1/edit2). 2) These expression of both WT, edit1 and edit2 miR-381 in RA synovium were lower than OA ($p<0.05$). 3) The expression of series of miR-381s were decreased by TNFα and IL-1β stimulation. 4) Overexpression of WT and edit1 miR-381 reduced the migration of FLS ($p<0.01$). Overexpression of edit1 and 2 miR-381 repressed proliferation of FLS ($p<0.01$), which may be caused by reducing CUL3 mRNA expression. CUL3 was regulator of cell cycle and was a direct target gene of edited miR-381s by luciferase assay. All types of miR-381 reduced MMP13 expression ($p<0.05$). 5) Treatment with miR-381 mimic increased expression of miR-381 in synovium but not in other tissues and significantly reduced arthritis score (scramble vs. miR-381 mimic: 11.5±0.76 vs. 8.4±2.06) and cartilage destruction.
**Conclusions:** These findings suggested that miR-381 was added functions by A to I RNA editing and controls FLS and arthritis.

# Rheumatoid arthritis - prognosis, predictors and outcome

## THU0029 PREDICTING DAS28-CRP <2.6 AND LOW DISEASE ACTIVITY STATUS AT 6 MONTHS BASED ON EARLY CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

J.S. Smolen[1], X. Wang[2], I. Sainsbury[2], A. Kavanaugh[3]. *[1]Medical Univ. of Vienna, Vienna, Austria; [2]AbbVie, N. Chicago; [3]Univ. of California San Diego, La Jolla, United States*

**Background:** For patients (pts) with rheumatoid arthritis (RA), early attainment of remission or low disease activity (LDA) predicts better long-term outcomes. Predicting non-response to therapy early in the disease course may avoid additional exposure to ineffective treatments and reduce a patient's potential risk of adverse events.
**Objectives:** To develop an instrument for predicting clinical outcomes for individual RA pts at 6 months based on observed 3-month responses.
**Methods:** A 3-step method was used to predict DAS28-CRP (28-joint disease activity score based on C-reactive protein) <2.6 and LDA (<3.2) at 6 months, using data from the OPTIMA trial in early RA pts: First, baseline (BL) and post-BL candidate predictors including demographics, laboratory assessments and genetic assays, were screened using the Least Absolute Shrinkage and Selection Operator (LASSO) method (1). To obtain an individual prediction score

of achieving Week (wk) 26 DAS28-CRP <2.6 or LDA, logistic regression was performed using predictors chosen based on LASSO results and clinical feasibility. Lastly, cutoff values were established by applying the Recursive Partitioning and Regression Tree (2) (RPART) method on the individual predictive score. Prediction rules were recommended based on satisfactory positive and negative predictive values (PPV/NPV), and validated using data from the DE013, DE019, MUSICA and CONCERTO trials in patients with early or established RA. Responders and non-responders (NR) are defined based on attainment of DAS28-CRP <2.6 or LDA at 6 months.

**Results:** Wk 12 DAS28-CRP, physician global assessment of arthritis, and health-assessment questionnaire-disability index (HAQ-DI) were selected from the final list of predictors to calculate the individual prediction score (Table footnote). Individual prediction scores were calculated for 866 pts in OPTIMA, who had both Wk 26 DAS28-CRP <2.6 status and Wk 12 predictors. The prediction rule was applied to 541/866 (62%) pts based on their Month 3 prediction score. Out of 427 predicted NR at Wk 26, 401 predictions were correct (NPV of 94.61%) (Table). Out of 114 predicted responders at Wk 26, 97 predictions were correct (PPV of 85.19%). For the 38% of pts in the hard-to-classify category, the treatment outcome at Wk 26 was unclear due to lack of proper early response indicators; however, a higher prediction score corresponded to a higher rate of DAS28-CRP <2.6. Similarly, for DAS28-CRP LDA, the NPV was 90.80% and the PPV was 90.15%. Prediction accuracy in the validation datasets was consistent with that in OPTIMA; for MTX NR, accuracy was consistently >90% in all the trials.

**Table 1**

| Summary of Prediction Rule for DAS28-CRP <2.6 in OPTIMA | | | | |
|---|---|---|---|---|
| **Score Cutoff** | **N [%]** | **Prediction** | **PPV** | **NPV** |
| <0.1726 | 427 (5.39) | Non-Responder | | 94.61 |
| ≥0.1726, <0.4421 | 202 (28.22) | Hard-to-classify | | |
| ≥0.4421, <0.7072 | 123 (60.16) | Hard-to-classify | | |
| ≥0.7072 | 114 (85.19) | Responder | 85.19 | |
| **Summary of Prediction Rule for DAS28-CRP LDA in OPTIMA** | | | | |
| <0.2467 | 348 (9.20) | Non-Responder | | 90.80 |
| ≥0.2467, <0.4497 | 146 (29.45) | Hard-to-classify | | |
| ≥0.449, <0.7234 | 169 (60.95) | Hard-to-classify | | |
| ≥0.7234 | 203 (90.15) | Responder | 90.15 | |

Equation for logit of prediction score of DAS28 <2.6: Logit = 3.719 - 1.126*DAS28_wk12 - 0.623*HAQ_wk12 - 0.16*PhGA_wk12. Equation for logit of prediction score of LDA: Logit =4.626 - 1.121*DAS28_wk12 - 0.636*HAQ – 0.143*PhGA_wk12; Logit is the natural logarithm of the odds of DAS28 <2.6 (or LDA) status respectively, at Wk 26. Individual prediction score is $\frac{\exp(\text{Logit})}{1+\exp(\text{Logit})}$. N=number of pts in subgroup defined by score cutoff, % = percentage of pts achieving DAS28 <2.6/LDA at Wk 26. LDA, low disease activity; PPV=positive predictive value; NPV=negative predictive value; HAQ, health assessment questionnaire; PhGA, physician's global assessment of arthritis activity

**Conclusions:** Using this instrument derived from clinical study data, DAS28-CRP <2.6 or LDA at 6 months could be individually predicted for about 60% of RA pts based on clinical outcomes at 3 months. This instrument-based predictive capability may provide quantified guidance for switching non-responders to more effective therapy as early as 3 months.

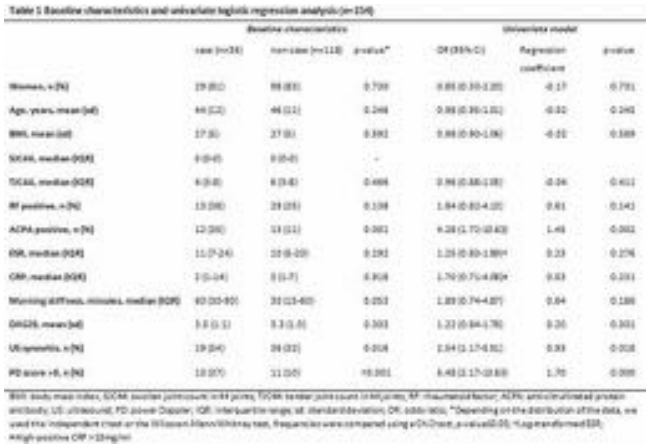
## THU0030 ULTRASOUND INFLAMMATION IN ARTHRALGIA PATIENTS PREDICTS THE DEVELOPMENT OF ARTHRITIS



M. van der Ven[1], M. van der Veer-Meerkerk[2], D. Ten Cate[1], N. Rasappu[1], M. Kok[3], D. Csakvari[4], M. Hazes[1], A. Gerards[5], J. Luime[1]. *[1]Rheumatology, Erasmus MC, University Medical Center, Rotterdam; [2]Rheumatology, Zuyderland Medical Center, Heerlen; [3]Rheumatology, Maasstad Hospital, Rotterdam; [4]Rheumatology, Reumazorg Zuid West Nederland, Roosendaal; [5]Rheumatology, Vlietland Hospital, Schiedam, Netherlands*

**Background:** To decrease burden of disease of rheumatoid arthritis (RA) we need to identify patients at risk for RA as early as possible, preferably as no clinical apparent synovitis could be detected yet. Previous studies suggest that this should be in the arthralgia phase or even before that. Up to now it has been fairly difficult to identify those arthralgia patients who develop inflammatory arthritis (IA), but recent studies in ultrasound (US) suggest that earlier detection is possible [1].

**Objectives:** We aim to identify which arthralgia patients will develop clinical apparent IA within a year using US to detect subclinical synovitis at first consultation.

**Methods:** In a multi-centre prospective cohort study we followed arthralgia patients with ≥2 painful joints of hands, feet or shoulders without clinical apparent synovitis. Patients had a symptom duration of <1 year which could not be explained by other conditions (e.g. fibromyalgia). We collected data at baseline, 6 months and 12 months follow-up, which included physical examination, laboratory variables (ESR, CRP, auto-antibodies), diagnosis and medication used (including DMARDs at 6 and 12 months). At baseline we examined patients by US, which included 26 joints (MCP2–5, PIP2–5, wrists, MTP2–5) graded on greyscale (GS; 0–3) and power Doppler (PD; 0–3) according to a semi-quantitatively scoring system of Naredo et al. US synovitis was defined as GS grade 2 or 3 and/or PD grade 1, 2 or 3. After one year follow-up we determined the incidence of IA (clinical soft tissue swelling or start of DMARD treatment). We performed a complete-case analysis. For univariate logistic regression we tested demographic characteristics, clinical characteristics, and ultrasound findings and their association for development of IA. For multivariate logistic regression we selected the strongest variables ($p<0.2$).

**Results:** In total, 196 patients were included of whom 154 completed the 12 months follow-up. At baseline 72 (38%) arthralgia patients had US synovitis and in 29 (15%) patients a positive PD signal was detected. At 12 months follow-up 36 (23%) patients had developed IA of whom 22 patients initiated DMARD treatment. Table 1 shows baseline characteristics of cases and non-cases and the results of the univariate analysis. Strongest variables were ACPA, RF, morning stiffness >30 minutes and PD signal. In the multivariate logistic regression positive ACPA (OR 4.56: 95% CI 1.26–16.46) and the presence of PD signal (OR 5.79: 95% CI 1.75–19.19) at baseline were associated with the development of IA during one year follow-up.

**Conclusions:** In this early arthralgia cohort 38% of patients showed US synovitis at baseline. At 12 months 23% of the patients developed IA. In a multivariate analysis positive PD signal and positive ACPA were significantly associated with the development of IA after one year.

## THU0031 BASELINE CHARACTERISTICS AND TREATMENT OUTCOMES OF PATIENTS WHO ACHIEVE DEEP REMISSION IN RHEUMATOID ARTHRITIS

Y. Tanaka[1], J. Smolen[2], H. Jones[3], A. Szumski[4], L. Marshall[3], P. Emery[5]. *[1]University of Occupational & Environmental Health, Kitakyushu, Japan; [2]Medical University of Vienna, Vienna, Austria; [3]Pfizer, Collegeville; [4]InVentiv Health, Princeton, United States; [5]University of Leeds, Leeds, United Kingdom*

**Background:** It is unclear which patients with rheumatoid arthritis (RA) may benefit from treatment discontinuation or dose reduction without diminished therapeutic effect. Previously, deep remission (DAS28-ESR ≤1.98) has been demonstrated as a good indicator of sustained remission upon anti-TNF treatment withdrawal.[1]

**Objectives:** Investigate baseline characteristics and treatment outcomes of patients with RA who achieve deep remission with etanercept (ETN).

**Methods:** Randomised patients with moderate/severe RA who participated in 3 ETN clinical trials[2–4] were included in this post-hoc analysis. Patients who achieved deep remission (DAS28-ESR≤1.98), remission (1.98<DAS28-ESR<2.6), or low disease activity (LDA; 2.6≤DAS28-ESR<3.2) during the full-dose ETN open-label (OL) period of each study were randomised into ETN tapering or withdrawal arms. Treatment outcomes (maintenance of response or non-failure) were assessed per the studies' primary endpoints (Table). Last observation carried forward (LOCF) analyses were conducted.

**Abstract THU0031** – Table 1. Sustained clinical response (LOCF) according to response category during OL period

| Study | Study primary endpoint | Randomised treatment | Patients sustaining clinical response per study primary endpoint, n/N (%) | | |
|---|---|---|---|---|---|
| | | | LDA | Remission | Deep Remission |
| PRESERVE[2] | DAS28-ESR LDA with discontinuations due to lack of efficacy treated as failures at 88 weeks | ETN 50 mg + MTX | 27/35 (77.1) | 56/65 (86.2) | 82/98 (83.7) |
| | | ETN 25 mg + MTX | 32/39 (82.1) | 52/74 (70.3) | 73/86 (84.9) |
| | | MTX | 9/39 (23.1) | 32/73 (43.8) | 43/85 (50.6)* |
| PRIZE[3] | DAS28-ESR remission at weeks 76 and 91 in patients not requiring corticosteroid boost from week 52 to 64 | ETN 25 mg + MTX | – | 13/29 (44.8) | 27/34 (79.4)* |
| | | MTX | – | 10/29 (34.5) | 16/37 (43.2) |
| | | PBO | – | 4/28 (14.3) | 11/36 (30.6) |
| EM T2T[4] | DAS28-ESR LDA at week 52 | ETN 50 mg + MTX ± DMARDs | 36/101 (35.6) | 14/37 (37.8) | 21/25 (84.0)** |
| | | MTX ± DMARDs | 8/107 (7.5) | 12/43 (27.9) | 9/18 (50.0)** |

Statistically significant trend; *P<0.01, **P≤0.0001. DMARD, disease-modifying anti-rheumatic drug; MTX, methotrexate; PBO, placebo.

**Results:** 1117 patients were included across clinical trials (n=594 PRESERVE, n=192 PRIZE, n=331 EM T2T). In PRESERVE, patients who achieved deep remission at week 36 were significantly younger at baseline (P<0.001), had lower baseline ESR (P<0.01), and lower baseline mean DAS28 (P<0.01) than those who achieved DAS28 remission or LDA. In PRIZE, demographics and disease characteristics were not significantly different across response categories at week 52. In EM T2T, the week 24 deep remission category had significantly younger patients (P<0.05), more males (P<0.05), and patients had lower mean baseline DAS28-ESR, DAS28-CRP, CDAI, SDAI, CRP, ESR, HAQ, PGA, SGA, and General Health scores (all P<0.01). Generally, patients who achieved deep remission during the OL-period were more likely to sustain their clinical response following ETN dose-tapering than those who achieved remission or LDA, across clinical trials (Table).
ClinTrials.gov:NCT00565409 (PRESERVE), NCT00913458 (PRIZE), NCT01981473 (EM T2T).
**Conclusions:** Sustained clinical response is more likely in patients who achieved deep remission prior to ETN withdrawal.

## THU0032 DIAGNOSTIC ACCURACY OF HAND AND FOOT MRI FOR EARLY RHEUMATOID ARTHRITIS

W.P. Nieuwenhuis[1], H.W. van Steenbergen[1], L. Mangnus[1], E.C. Newsum[1], J.L. Bloem[2], T.W.J. Huizinga[1], S. le Cessie[3], M. Reijnierse[2], A.H.M. van der Helm-van Mil[1]. *[1]Rheumatology; [2]Radiology; [3]Clinical Epidemiology and Medical Statistics, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Early diagnosis and treatment of rheumatoid arthritis (RA) is advocated. However, in part of the RA-patients a classifiable diagnosis cannot be made at first presentation; these patients present with unclassified arthritis (UA). The use of MRI for early diagnosis of RA is recommended, yet the evidence is limited.
**Objectives:** To assess the performance of hand and foot MRI for early diagnosis of RA.
**Methods:** Unilateral contrast-enhanced 1.5T MRI of the hand and foot was performed in 589 early arthritis patients included in the Leiden Early Arthritis Clinic, of whom 229 presented with RA, 159 with other arthritides and 201 with UA. MRI-findings observed in symptom-free controls served as reference to define an abnormal MRI. In preliminary investigations, patients that presented with RA were compared with symptom-free controls and with patients that presented with other arthritides. Thereafter, the accuracy of MRI was determined in UA-patients that were followed for 1-year on fulfilling the 1987-RA-criteria (primary outcome); the secondary outcome was start of disease-modifying drugs.
**Results:** The results of the preliminary investigations were promising and showed that MRI-detected tenosynovitis was more discriminative than other types of MRI-inflammation. Of all UA-patients, 29 (14%) developed RA and 75 (37%) started disease-modifying treatment. MRI-detected tenosynovitis was associated with RA-development independent of other types of MRI-inflammation (odds ratio (OR) 7.5 95%CI 2.4–23) and also independent of age and commonly used measures of inflammation (number of swollen joints and C-reactive protein) (OR 4.2 95%CI 1.4–12.9). Within UA-patients, the negative predictive value (NPV) of abnormal tenosynovitis was 95% and the positive predictive value (PPV) 25%. The performance was best in the subgroup UA-patients presenting with oligo-arthritis (18% developed RA): PPV was 36%, NPV 98%, sensitivity 93%, and specificity 63%. Decision curve analysis revealed a higher net benefit for a model including MRI-detected tenosynovitis.
**Conclusions:** MRI-detected inflammation, MRI-detected tenosynovitis in particular, contributes to identification of the UA-patient that will develop RA.
**Disclosure of Interest:** None declared

## THU0033 EFFECTS OF EARLY REMISSION ON WORK ABILITY AND ABSENTEEISM IN EARLY RHEUMATOID ARTHRITIS

T.H. Cheng[1], K.Y. Kwok[2], L.-S. Tam[1] on behalf of the CRYSTAL Study Group. *[1]Department of Medicine and Therapeutics, Division of Rheumatology, The Chinese University of Hong Kong; [2]Department of Medicine, Queen Elizabeth Hospital, Hong Kong, Hong Kong*

**Background:** Treatment of RA is increasingly aimed at remission. A small scale study on patients who were clinically regarded to be in remission felt that they were able to continue their normal everyday activities at home, at leisure and at work (1). However, whether achieving early disease remission by tight control treatment can predict improvement in work ability remained uncertain.
**Objectives:** To ascertain whether achieving early remission will influence work ability and absenteeism in early RA patients treated by a protocol-driven, tight-control strategy after 1 year.
**Methods:** Early RA patients with symptom onset of less than 2 years were recruited for this prospective cohort study. All patients were treated according to a tight control protocol aiming at remission. Early remission was defined as achieving Disease Activity Score (DAS) or Simplified Disease Activity Index (SDAI) remission after treatment for 3 months. Work ability was assessed by the self-perceived working ability index (WAI) compared to life time best (score from 0–10, with 10 as best). WAI was evaluated at both baseline and 1 year after treatment. The days of sick leave were also retrieved. Logistic or linear regression models were used to assess baseline clinical and demographic predictors, with the need to take sick leave and month 12 WAI during the 1-year period following RA diagnosis as outcome.
**Results:** 103 early RA patients (79 female and 24 male, mean age: 55.7±13.1 years) completed 1 year follow-up. At baseline, the mean baseline WAI was 4.97±2.9. 12/103 patients (12%) were unable to work as a result of the disease. After treatment for 3 months, 38 (36.9%) achieved DAS remission and 18 (17.5%) achieved SDAI remission. After treatment for 1 year, the WAI increased significantly to 6.45±2.6 ($p$<0.001) and 6/12 (50%) were able to go back to the work force again. Using univariate analysis, the baseline physician global assessment score (PhyGA), patient global assessment score (PatGA), tender joint count, swollen joint count, DAS-ESR, DAS-CRP, SDAI and HAQ were negatively associated with month 12 WAI. Early DAS remission ($r$=0.233, $p$=0.018) and SDAI remission ($r$=0.336, $p$=0.001) were positively associated with month 12 WAI. Using multivariate linear regression, early SDAI remission (β=2.256, 95% CI: 0.945–3.566, $p$=0.001) was an independent predictor for higher month 12 WAI after adjustment for the baseline characteristics. The working population (n=65, 15 achieved early SDAI remission and 29 achieved early DAS remission) was further analyzed. Significantly less patient required sick leave ≥1 day(s) if early SDAI remission was achieved [3 (20.0%) vs 12 (80%), $p$=0.010] but not DAS remission [12 (41.4%) vs 17 (58.6%), p=0.256]. Using univariate logistic regression, baseline PhyGA, DAS-CRP, WAI, HAQ, SF36 Physical component score were associated with ≥1 day(s) of sick leave, while patients not achieving early SDAI remission (OR=5.524, 95%CI:1.384–22.049, $p$=0.016) was more likely to require any sick leave. Using multivariate logistic regression, not achieving early SDAI remission was the independent predictor for taking sick leave (5.317, 1.314–21.516, $p$=0.019).
**Conclusions:** Early RA patients who achieved early SDAI remission had better self-perceived working ability and were less likely to require sick leave after adjustment of baseline characteristics.

## THU0034 USE OF RITUXIMAB COMPARED TO ANTI-TNF AGENTS AS SECOND AND THIRD-LINE THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS. A 6-YEAR FOLLOW-UP REPORT FROM THE RHUMADATA® CLINICAL DATABASE AND REGISTRY

J.-P. Raynauld[1], L. Bessette[2], J. Brown[2], L. Coupal[1], B. Haraoui[1], F. Massicotte[1], J.-P. Pelletier[1], M.-A. Rémillard[1], D. Sauvageau[1], É. Villeneuve[1], D. Choquette[1]. *[1]Rhumatologie, Institut de rhumatologie de Montréal, Montreal; [2]Rhumatologie, Centre d'ostéoporose et de rhumatologie de Québec, Québec, Canada*

**Background:** The order of use of biologic agents after failing a TNF inhibitor remains a question for debate. Phase III trial data in TNF-IR patients show comparable efficacy results across biologic agents, and limited head-to-head studies have been published. Prospective registries offer a unique opportunity to observe the effectiveness of these agents in a real-world clinical setting where all single diagnostic patient treated in the center are included. We report here a six-year follow-up.
**Objectives:** Our aim is to assess if patients with rheumatoid arthritis (RA) treated with rituximab (RIT) after failing a first or a second anti-TNF agent (TNF-IR) have different six-year retention rates than patients similarly prescribed anti-TNF agents (pooled adalimumab, etanercept or infliximab) and compare the treatment strategies of using RIT as second or third biologic treatment.
**Methods:** Data from TNF-IR RA patients prescribed adalimumab (ADA), etanercept (ETA), infliximab (INF) or rituximab (RIT) as second or third biologic agents on or after January 1st, 2007 was extracted and subjects taking either ADA, ETA or INF were pooled to form the anti-TNF cohort. Baseline demographics included age, disease duration, HAQ-DI, fatigue and pain visual analog scale evaluations (VAS), TJC, SJC, DAS-28(ESR) and CDAI. Six-year drug retention rates were estimated and compared using Kaplan-Meier survival estimates. Statistical analysis was performed using SAS version 9.4. RHUMADATA® is a software used in daily clinical practice at the IRM and CORQ. All patients with RA are included.
**Results:** The data from 231 RA patients was extracted, 155 and 76 having respectively failed a first and a second anti-TNF agent. No clinically significant differences in baseline variables were observed between treatment groups in second and third intention. The 6-year retention rates of second-line RIT and anti-TNF users were 80.1% and 19.1% respectively (overall survival log-rank $p<0.0001$). After two failures, subsequent use of RIT and anti-TNF agents respectively demonstrated 6-year retention rates of 53.6% and 37.2% (overall survival log-rank p=0.0473). Second versus third-line use was numerically (80.1% vs. 53.6%) and statistically better (overall survival log-rank p=0.0029). Of the censored patients treated with a second TNFi, 41%, were in remission, 27% had low disease activity (LDA), and 23% had moderate disease activity (MDA) according to DAS28(CRP) criteria. In patients treated in second intention with RIT, 23% were in remission, and 27% and 42% were respectively in LDA and MDA. Among censored patients treated with a third TNFi, 33%, 11% and 44% were in remission, had LDA and MDA respectively compared to 39%, 6% and 39% in RIT exposed patients.
**Conclusions:** As second and third-line agent used in TNF-IR patients, RIT demonstrates a better 6-year retention rate than anti-TNF agents. Second-line use showed a statistically better retention rate than third-line use. This suggests that using RIT as a second agent after failing a first anti-TNF agent is a better strategy than waiting to use it after two successive anti-TNF failures.

## THU0035 SIX YEARS TOCILIZUMAB USE IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH ONE PREVIOUS ANTI-TNF AGENT EXPOSURE: COMPARISON WITH ADALIMUMAB AND ETANERCEPT FROM THE PROVINCIAL ELECTRONIC DATABASE AND REGISTRY RHUMADATA®

L. Bessette[1], J. Brown[1], L. Coupal[2], B. Haraoui[2], F. Massicotte[2], J.-P. Pelletier[2], J.-P. Raynauld[2], M.-A. Rémillard[2], D. Sauvageau[2], É. Villeneuve[2], D. Choquette[2]. *[1]Rhumatologie, Centre d'ostéoporose et de rhumatologie de Québec, Québec; [2]Rhumatologie, Institut de rhumatologie de Montréal, Montreal, Canada*

**Background:** Tocilizumab, an intravenous agent, is approved for rheumatoid arthritis (RA) treatment in Canada since April 30th, 2010. It was the sixth approved agent after adalimumab, etanercept, abatacept, infliximab and rituximab. It has been demonstrated effective in the treatment of RA either in mono or combo therapy after non-biologic or biologic DMARDS.
**Objectives:** The goal of this analysis is to describe the six-year effectiveness of tocilizumab used in patients with RA failing a first anti-TNF agent and to compare it with adalimumab and etanercept used in the same clinical situation.
**Methods:** All patients with RA having failed a first anti-TNF agent and subsequently exposed to tocilizumab after the 1st of January 2008 were extracted from the Rhumadata® database. Three cohorts were created according to the time tocilizumab or the subsequent anti-TNF agents were introduced: One cohort of patients starting tocilizumab and two other cohorts starting either adalimumab or etanercept. Demographics and baseline characteristics including age, gender, disease duration, rheumatoid factor and anti-CCP antibodies, CRP and ESR, the number of previously failed treatments, DAS-28(ESR) and CDAI, HAQ-DI were included for each cohort. Kaplan-Meier model and were used to compare retention rates and Cox proportional hazard models were used to generate adjusted hazard ratios.
**Results:** The data from 128 patients prescribed either tocilizumab (44=34%), adalimumab (38=30%) or etanercept (46=36%) as a second biologic agent was extracted from the Rhumadata® registry and clinical database. Most subjects were female (77.3%), and the average age of cohort subjects was 54.4 (SD=13.2). 69.3% and 62.2% of patients were respectively $RF^+$ or anti-$CCP^+$. Mean CRP and ESR were respectively 14.8 (SD=21.5) mg/L and 28.6 (SD=24.2) mm/hr. No clinically significant differences at baseline were observed between groups. The six-year retention rates of tocilizumab, adalimumab, and etanercept as second-line biologic agents were respectively 54.6% (95% CI=35.9–70.0), 22.8% (9.7–39.1), 21.9% (8.9 -38.6) respectively. Kaplan-Meier survival analysis revealed significant differences in drug retention rates (log rank p=0.0007). Multivariate analysis adjusting for patient characteristics yielded hazard ratios of 2.66 (1.10–6.44), 5.33 (2.30–12.38) when respectively comparing adalimumab and etanercept to tocilizumab. Of the censored patients taking tocilizumab, 35% and 12% were in remission and had low disease activity (LDA) respectively, according to the DAS-28(CRP) criteria. In patients treated with anti-TNF agents, 50% and 17% were in remission and LDA.
**Conclusions:** In RA patient having failed their first anti-TNF agent, tocilizumab, an Il-6 inhibitor, is a more valuable alternative than cycling to a second anti-TNF agent. Similarly to previously presented analysis, in a patient having failed a first anti-TNF agent, it seems that using an agent with a different mode of action such as abatacept, rituximab or tocilizumab as opposed to a second anti-TNF agent delivers better long-term retention.

## THU0036 IDENTIFYING CLINICAL FACTORS ASSOCIATED WITH LOWER DISEASE ACTIVITY DURING PREGNANCY IN PATIENTS WITH RHEUMATOID ARTHRITIS TO SELECT THOSE PATIENTS IN WHOM MEDICATION CAN BE SAFELY TAPERED

H. Ince-Askan, J.M. Hazes, R.J. Dolhain. *Rheumatology, Erasmus Medical Centre, Rotterdam, Netherlands, Rotterdam, Netherlands*

**Background:** Pregnancy is the only natural condition in which Rheumatoid Arthritis (RA) remits spontaneously in approximately half of the pregnancies [1]. Many physicians try to taper or stop medication when a women conceives in order to prevent drug related side effects for mother and child. However, 50% of the patients still has active disease in the third trimester of pregnancy[1]. Factors that can identify patients in whom medication can be safely tapered during pregnancy are therefore needed.
**Objectives:** To determine clinical factors associated with lower disease activity in the third trimester during pregnancy in women with Rheumatoid Arthritis (RA) and thereby to identify patients in whom medication can be safely tapered during pregnancy.
**Methods:** This study is embedded in the Pregnancy induced Amelioration of Rheumatoid Arthritis (PARA)-study, a nationwide prospective cohort study. There was data available on 190 pregnancies from first trimester unto delivery. Disease activity was measured using the Disease Activity Score in 28 joints (DAS28). A multivariate linear regression analysis was performed on the DAS28 in the third trimester. Independent covariates in these models: the DAS28 in the first trimester, prednisone and sulfasalazine use in the first trimester, parity, methotrexate use in past, autoantibody status (either rheumatoid factor or ACPA positive), presence of erosions and duration of RA.
**Results:** In the multivariate linear regression model, see table 1., a higher DAS28 in the first trimester, the use of prednisone and the presence of autoantibodies were statistically significantly associated with a higher DAS28 in the third trimester (p-values $<0.001$, 0.032 and 0.014 respectively).

Table 1. Factors associated with RA disease activity in the third trimester, a multivariate linear regression model for DAS28 in the third trimester.

| N=190 | Linear regression DAS28 in the third trimester | | | |
|---|---|---|---|---|
| | Multivariate | | Multivariate* | |
| | Coeff. | P-value | Coeff. | P-value |
| DAS28 1st trimester | 0.542 | <0.001 | 0.544 | <0.001 |
| Sulfasalazine use 1st trimester | -0.184 | 0.192 | -0.186 | 0.177 |
| Prednisone use 1st trimester | 0.301 | 0.030 | 0.287 | 0.032 |
| Parity | -0.165 | 0.195 | -0.164 | 0.195 |
| MTX use ever | -0.041 | 0.760 | - | - |
| Autoantibody status | 0.410 | 0.009 | 0.367 | 0.014 |
| Presence of erosions | -0.065 | 0.658 | - | - |
| Duration RA | 0.012 | 0.291 | - | - |

DAS28 = Disease Activity Score in 28 joints, RA= rheumatoid arthritis, MTX= methotrexate.
*Multivariate model after backward selection (limit for exclusion P≥0.20)

**Conclusions:** The DAS28 in the first trimester, the autoantibody status and the use of prednisone were associated with RA disease activity in the third trimester. Female RA patients who have a lower DAS28 in the first trimester are

likely to have lower disease activity in the third trimester, especially if they are autoantibody negative and if they do not use prednisone. In these patients, it may be considered to safely taper their medication.

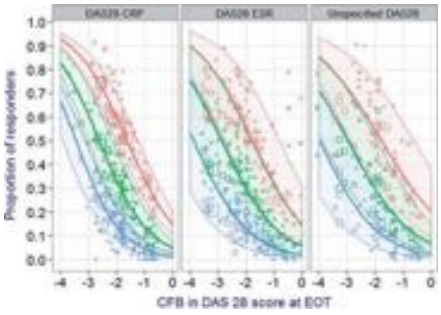
## THU0037 PERSONALITY TRAITS IN PATIENTS WITH RHEUMATOID ARTHRITIS: AN UNRECOGNIZED PREDICTOR OF MORTALITY



A.D. Crowson, R.C. Colligan, E.L. Matteson, J.M. Davis III, C.S. Crowson. *Mayo Clinic, Rochester, MN, United States*

**Background:** Psychosocial factors, such as pessimistic explanatory style, are shown to affect the course of treatments in many illnesses (Cardiovascular diseases, lung cancer, Parkinson's disease). Little is known about how pessimistic explanatory style affects rheumatoid arthritis (RA).
**Objectives:** The aim of this study was to determine if pessimistic explanatory style altered the risk for and mortality rates of RA patients.
**Methods:** The study used a subset of patients who completed the Minnesota Multiphasic Personality Inventory (MMPI) from among a population-based cohort with incident RA in 1955–2007 and an age- and sex-matched non-RA comparison cohort. Only patients who were ≥18 and fulfilled the American College of Rheumatology (ACR) 1987 criteria for RA were included. Pessimistic explanatory style was measured using the Optimism-Pessimism scale (PSM≥60). Logistic regression and Cox models were used to examine the associations between pessimistic explanatory style and development of RA or mortality rates.
**Results:** There were 148 RA and 135 non-RA subjects who completed the MMPI. Pessimistic explanatory style was associated with development of rheumatoid factor positive (RF+) RA (odds ratio [OR]:1.74; 95% confidence interval [CI]: 0.99–3.04; p=0.053 adjusted for age, sex, smoking and obesity). Among patients with RA, mortality risk adjusted for age, sex, year, smoking, and Charlson Comorbidity Index was increased with a pessimistic explanatory style (hazard ratio [HR]:2.88; 95%CI: 1.02–8.14), similar to mortality risk in RF+ RA patients (HR:2.28; 95%CI:1.10–4.73). A significant interaction between RF+ and pessimistic explanatory style indicated that having both did not confer an additive effect (p=0.037). The 10 year survival percentages were highest for those with RF-RA who were not pessimistic (93%) and were similar for patients with RF+RA who were not pessimistic (73%), those with RF-RA who were pessimistic (77%), and those who were both RF+RA and pessimistic (84%). This association did not change after adjusting for the MMPI depression scale or a history of depression prior to diagnosis of RA.
**Conclusions:** Having a pessimistic explanatory style was associated with an increased risk of developing RA and increased mortality rate in patients with RA. In these patients, the effects of RF+ and pessimistic style were not additive. The patient's psychological state strongly affects treatment decisions and outcomes and can inform about the usefulness of mindful interventions (e.g. cognitive behavioral therapy). Understanding the explanatory style is an important step in the holistic management of disease and a vital component of integrated care.

## THU0038 QUANTITATIVE ASSESSMENT OF THE RELATIONSHIP BETWEEN THE DAS28 CONTINUOUS SCORES AND THE PROPORTION OF RESPONDERS BASED ON THE ACR CRITERIA IN RHEUMATOID ARTHRITIS: A META-ANALYSIS

M. Minocha[1], J. Mandema[2], A.A. Othman[1]. *[1]Clinical Pharmacology and Pharmacometrics, AbbVie, North Chicago, IL; [2]Certara Strategic Consulting, Certara, Menlo Park, CA, United States*

**Background:** ACR scores are widely accepted binary endpoints in Rheumatoid Arthritis (RA) clinical trials to characterize response to treatment. The Disease Activity Score calculated from twenty-eight tender and swollen joints (DAS28) is often assessed as a secondary endpoint in RA trials and is believed to be a more sensitive measure of dose-response due to the continuous nature of the scale.
**Objectives:** To characterize the quantitative relationship between the change from baseline (CFB) in DAS28 score and the proportion of responders based on ACR20/50/70 criteria using summary level data available in the literature from RA trials reporting both measures of response.
**Methods:** Summary level data from RA trials reporting DAS28-CRP, DAS28-ESR or unspecified DAS28 and ACR20/50/70 variables at the primary time point (with a minimum of 20 subjects per arm) were included in the analyses. The dataset included 82 unique trials with information from more than 12,000 patients (trial durations from 4 to 104 weeks). Three separate mixed-effects logistic regression analyses of the relationships between CFB in each DAS28 score and ACR20/50/70 responses with random inter-trial variability (in the intercept) were conducted and the sample size for each trial was used for weighting
**Results:** The observed and model-estimated relationships between DAS28 and ACR20/50/70 are presented in Figure 1. For a CFB in DAS28 CRP of -1 point, the point estimate [90% prediction interval (PI)] for ACR20, ACR50 and ACR70 responders is 33% [25% to 43%], 13% [8% to 22%] and 4% [2% to 7%], respectively. For a treatment that increases the CFB in DAS28 CRP from -1.0 to -2.0 points, the increase in ACR20, ACR50 and ACR70 responders is estimated to be 26% [24% to 26%], 19% [13% to 24%] and 9% [6% to 14%], respectively. For a treatment that increases the CFB in DAS28 CRP from -2.0 to -3.0 points, the increase in ACR20, ACR50 and ACR70 responders is estimated to be 22% [18% to 25%], 27% [24% to 28%] and 22% [16% to 28%], respectively. The relationship between the ACR scores and DAS28 was estimated to be slightly shallower and more variable for DAS28 ESR than DAS28 CRP.
Figure 1: The relationship between DAS28 continuous scores (DAS28 CRP, DAS28 ESR and unspecified DAS28) and the proportion of responders based on the ACR criteria. The solid lines and the shaded areas depict the median and 90% prediction interval for the proportion of responders at the end of treatment (EOT) for ACR20 (red), ACR50 (green) and ACR70 (blue) responders. The symbols represent the observed relationships for the analyzed trials with the symbol size weighted by the arm sample size.

**Conclusions:** A quantitative relationship between the continuous DAS28 score and proportion of subjects achieving ACR response has been established. The relationship between the DAS28 scores and ACR responders is estimated to be non-linear, most prominently for the deeper ACR responses. DAS28 CRP was better correlated with the ACR scores than DAS28 ESR based on the lower heterogeneity estimated in the relationship

## THU0039 MORE THAN ONE IN THREE PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AT THE ULTRASOUND EXAMINATION OF THEIR HANDS ARE MISCLASSIFIED AS BEING IN REMISSION BY THEIR CLINICIANS: RESULTS FROM A LARGE COHORT STUDY

A. Gill[1], S. Nihtyanova[1], S. Hussain[2], P. Sivakumaran[2], J. Manson[3], C. Ciurtin[3]. *[1]Rheumatology, Royal Free Hospital; [2]University College London Medical School; [3]Rheumatology, University College Hospital, London, United Kingdom*

**Background:** Assessment of active synovitis in rheumatoid arthritis (RA) is complex but essential for diagnosis and ongoing management. Clinical assessment is supported by serum laboratory analysis of inflammatory markers, high sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR). Musculoskeletal power Doppler ultrasonography (PDUS) has recently demonstrated greater sensitivity over clinical assessment and serum inflammatory markers in detecting active synovitis.
**Objectives:** To investigate the association between findings on PDUS, clinical assessment, serum hsCRP and ESR in the assessment of active synovitis in RA.
**Methods:** This cross-sectional study evaluated 218 consecutive RA patients (82% female) referred to ultrasound (US) clinic. Two assessors performed US examination using a 22 hand joint protocol, assessing wrists, metacarpophalangeal and proximal interphalangeal joints bilaterally (OMERACT scoring system). HsCRP and ESR were measured within 1 month of US scan. Patients with ≥3 swollen (SJ) and ≥3 tender joints (TJ) in hands were considered to have significant clinical synovitis (active or chronic).
**Results:** Of 218 patients with RA, 100 (46%) had positive PDUS signal in at least one joint. Raised hsCRP was found in 25% and raised ESR in 45%. Seventy-two of 202 patients (36%) had ≥3 TJ and ≥3SJ (clinically active synovitis). Whilst tender joint count was not correlated with positive PDUS (OR 1.01, p=0.334), swollen joint count (SJC) demonstrated strong association, with >30% increase in odds for positive PDUS for increase in SJC by one (OR 1.3, p<0.001). Of 96 patients with positive PDUS, 46 (48%) had ≥3TJ and ≥3SJ. Of 105 patients with negative PDUS, 26 (25%) had ≥3TJ and ≥3SJ (p=0.001).
Of 196 patients with ESR and PDUS data available, 44 (47%) of PDUS positive

and 45 (44%) of PDUS negative patients had raised ESR, showing no significant association (p=0.667). There was no difference in proportion of patients with raised CRP (25%) in PDUS positive vs. negative groups (p=0.748).
ESR and SJC were only very weakly correlated (Spearman's rho =0.16, p=0.03). Of 138 patients with either clinical or serological evidence of disease activity, 73 (53%) had positive PDUS. Among asymptomatic patients with normal hsCRP and ESR, 21 (38%) were PDUS positive (p=0.058).
**Conclusions:** Both hsCRP and ESR correlated poorly with clinical examination and PDUS detection of active synovitis. This should raise awareness among clinicians that hsCRP, ESR and clinical examination are misleading in appreciating the risk of ongoing inflammation in some patients with RA, as 38% of active RA patients in our study fell into this category. Further research into establishing the appropriate hsCRP cut-off value to distinguish between a subclinical inflammatory state and disease remission might yield better understanding of the role of hsCRP in monitoring disease activity in RA.

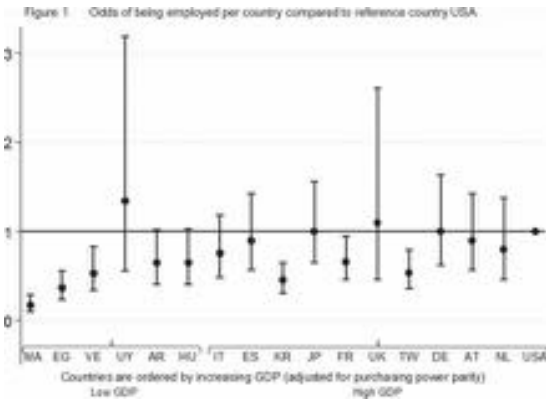
## THU0040 IMPACT OF BASELINE CONVENTIONAL DISEASE ACTIVITY VARIABLES, IMAGING ASSESSMENT OF RA ACTIVITY (JOINT US AND MRI SYNOVITIS SCORES), MMP-3 AND CALPROTECTIN LEVELS ON ACHIEVEMENT OF ACR70 RESPONSE IN RA PATIENTS AFTER ETANERCEPT TREATMENT

A. Pchelintseva[1], E. Panasyuk[1], N. Ionichenok[1], A. Zhornyak[1], A. Ilyina[1], I. Andrianova[1], M. Cherkasova[2], M. Severinova[3], A. Volkov[3], A. Smirnov[4], L. Denisov[1]. *[1]Department of Clinical Trials; [2]Laboratory of Immunology and Molecular Biology of the Rheumatic Diseases; [3]Diagnostic Department; [4]Department of Radiology, Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

**Background:** Monitoring of RA activity is important in daily practice and clinical trials, in particular for subjects receiving biologics. As a result, new imaging tools and more objective biomarkers of synovial inflammation and joint destruction have been developed.
**Objectives:** To evaluate role of imaging methods (joint MRI, US), biomarkers (calprotectin-CP and MMP-3) and RA activity parameters in achievement of ACR70 response after Etanercept (ETN) therapy
**Methods:** 25 pts (mean age 49,4±13,7 yrs) with active RA despite stable doses of cDMARDs (DAS28 6,12±0,97) had received ETN 50 mg weekly sc for 24 weeks. RA duration was 6,38±5,9 yrs, 92% were women, 64%>RF+. Clinical and laboratory evaluation was done at weeks 0 and 25. US exam was performed before start of ETN treatment and after 6 month of ETN therapy by the same independent sonographer. 7-joint score (grade 0–3) included wrist, intercarpal, 2–3 MCP, 2–3 PIP joints of the clinically dominant hand and knee was used. MRI was done at baseline and after end of ETN treatment. Assessment of 2–5 MCP joints of the clinically dominant hand (0-no synovitis, 1–10-severity of synovitis) was done by the same independent radiologist.CP and MMP-3 serum levels (ELISA) were measured at the same time points. Changes of all parameters since baseline were assessed. Predictive factors of achievement ACR70 responce were explored.
**Results:** All clinical, laboratory, MRI and US parameters of RA activity had significantly improved during ETN therapy (p<0,05).We detected statistically significant difference only in baseline MRI synovitis score between responders and non-responders according ACR70 (p=0,0074). (table 1)

Table 1. The difference in baseline variables between ACR70 responders and non-responders



| Baseline parameters | Responders | Non-responders | p |
|---|---|---|---|
| SJC/66, Me [$Q_{25}$–$Q_{75}$] | 13 [10–16] | 10 [8–13] | 0.156 |
| ESR, mm/h, M±SD | 45±29 | 41±23 | 0.977 |
| CRP, mg/ml, Me [$Q_{25}$–$Q_{75}$] | 9.8 [8.2–51.9] | 16.4 [7–34.5] | 0.886 |
| DAS28 | 6.23 [5.84–6.62] | 5.96 [5.43–6.72] | 0.587 |
| CDAI, Me [$Q_{25}$–$Q_{75}$] | 35.6 [32.1–39.1] | 31 [26.7–39.7] | 0.139 |
| SDAI, Me [$Q_{25}$–$Q_{75}$] | 38 [33–42.8] | 32.9 [30.3–41.3] | 0.287 |
| CP, μg/ml, Me [$Q_{25}$–$Q_{75}$] | 4.54 [2.13–8.83] | 3.53 [1.88–12.01] | 0.977 |
| MMP-3, ng/ml, Me [$Q_{25}$–$Q_{75}$] | 1.14 [0.36–2.44] | 0.85 [0.44–1.23] | 0.51 |
| BM, Me [$Q_{25}$–$Q_{75}$] | 5.5 [2–10] | 8 [3–11] | 0.627 |
| PD, Me [$Q_{25}$–$Q_{75}$] | 1 [0.5–3] | 1 [1–2] | 0.797 |
| MRI, Me [$Q_{25}$–$Q_{75}$] | 1.5 [0–2] | 3 [3–4] | **0.0074** |

We did not find any significant difference between groups in MeΔ at weeks 0–12 of ESR, CRP, CP and MMP-3, whereas MeΔ of SJC distinguished in ACR70 responders and non-responders (p=0,0494).
**Conclusions:** 1. US and MRI synovitis sum scores decreased significantly in parallel with CP and MMP-3 serum levels and RA activity variables during ETN therapy. 2. Low baseline MRI synovitis sum score is more useful in comparison with baseline US, CP, MMP-3 and conventional RA activity factors as predictive tool of good responce in RA during anti-TNF therapy. 3. Decrease of ESR, CRP, CP and MMP-3 at week 12 had not impact on ACR70 response at week 25.

## THU0041 LARGE COUNTRY DIFFERENCES IN WORK OUTCOMES IN PATIENTS WITH RA – AN ANALYSIS IN THE MULTINATIONAL STUDY COMORA

A. Van Der Zee-Neuen[1,2], P. Putrik[1,2], S. Ramiro[3], A. Keszei[4], I. Hmamouchi[5], M. Dougados[6], A. Boonen[2,7]. *[1]Maastricht University; [2]CAPHRI School for Public Health and Primary Care, Maastricht; [3]Leiden University Medical Center, Leiden, Netherlands; [4]Uniklinik RWTH Aachen University, Aachen, Germany; [5]Université Mohamed-V Souissi, Rabat, Morocco; [6]Paris-Descartes University, Paris, France; [7]Maastricht University Medical Center, Maastricht, Netherlands*

**Background:** Better insight into country- or system related differences in work outcomes is important when trying to take country specific measures aiming to improve short- and long-term work outcomes of patients with rheumatoid arthritis (RA).
**Objectives:** We aimed to explore whether country of residence and specific country characteristics are associated with work outcomes in patients with RA.
**Methods:** Data from the cross-sectional multinational study COMORA (17 countries) were used. Work outcomes were measured by the Work Productivity and Activity Impairment Questionnaire (WPAI) assessing employment (yes/no), absenteeism (% of time) and presenteeism (% of normal productivity). The contribution of country of residence, gross domestic product (GDP), human development index (HDI), unemployment rate, social protection expenditures (SPE) and world region to the work outcomes was investigated in logistic or ordinal logistic regression models after adjusting for clinical and sociodemographic factors.
**Results:** The study sample consisted of 3,920 patients of whom the mean age was 56 (SD 13), 3,191 (82%) were female and 1,197 (31%) were employed. Large country differences were found for all work outcomes. The country with the best work outcome was used as reference. Morocco showed the lowest adjusted employment compared to the USA (OR 0.17; [95%CI 0.10; 0.30]) followed by Egypt (OR 0.37 [95% CI 0.24; 0.56]), Korea (OR 0.45 [95% CI 0.31; 0.65]), Venezuela (OR 0.53 [95% CI 0.34; 0.84]), Taiwan (OR 0.54 [95% CI 0.36; 0.80] and France (OR 0.66 [95% CI 0.46; 0.95]) (figure 1). Compared to Japan, absenteeism was highest in Morocco (OR 12.63 [4.45; 35.89]) followed by Hungary (OR 6.49 [95%CI 2.45; 17.23]) and Argentina (OR 3.25 [95%CI 1.25; 8.45]). Compared to Venezuela, presenteeism was highest in Taiwan (OR 13.81 [5.95; 32.04]) followed by Korea (OR 10.59 [95%CI 4.77; 25.13]) and Italy (OR 8.96 [95%CI 3.53; 22.76]). All country indices except SPE were significantly associated with the outcomes. Low GDP countries had lower odds of employment (OR 0.66; [0.54; 0.80]), higher odds of absenteeism (OR 2.68 [1.91; 3.76]), but a lower odds of presenteeism (OR 0.45 [0.32; 0.62]) compared to high GDP countries.

**Conclusions:** Substantial differences in work outcomes among RA patients were observed between countries. Lower economic and human welfare were associated with worse employment, higher absenteeism but paradoxically also with lower presenteeism.

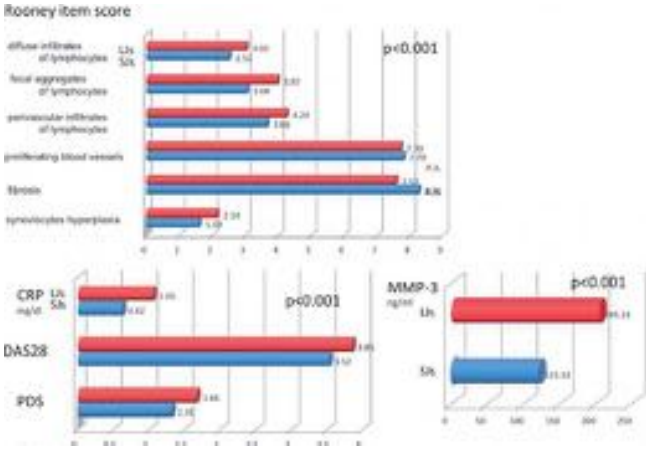
## THU0042 EVALUATION OF SYNOVITIS AT THE LARGE JOINT USING ULTRASONOGRAPHY AND HISTOLOGICAL FINDINGS FOR RA PATIENTS



A. Abe[1], H. Ishikawa[1], K. Wakaki[2], A. Murasawa[1]. *[1]Rheumatology, Niigata Rheumatic Center; [2]Pathology, Niigata Prefectural Shibata Hospital, Shibata, Niigata, Japan*

**Background:** After starting to use biological DMARDs (bDMARD), the number of small joint (SJ) arthroplasty increased as compared with large joint (LJ) at our rheumatic center. Additionally, ultrasonography (US) for the examination of the affected joints widely utilized and it became a tool by which the rheumatologist should learn to diagnose RA and to evaluate disease activity.
**Objectives:** To clarify relationship among systemic disease activity, local disease

activity using US and synovial histopathological evaluation, we examined serum CRP, MMP-3 and DAS28, and US at the surgical site before surgery. After surgery, histopathological examination of the gathered synovium at the surgical site was performed.

**Methods:** Between March, 2011 and September, 2015, 668 joints underwent surgical treatment and synovial biopsies were performed. There were 152 LJs including 8 shoulders, 60 elbows and 84 knees, and 516 SJs including185 fingers, 118 toes, 192 wrists and 21 ankles. Male: female ratio was 1:7. The bDMARD (IFX20, ETN62, ADA17, TCZ44, ABT16, CZP4, GLM13) was used in 176 cases. Maximum power Doppler (PD) signal grade of US was determined ranging from 0 to 3. They were compared with serum CRP, MMP-3, DAS28 and local disease activity using histopathological evaluation using Rooney score (RS).

**Results:** Systemic disease activity correlated with local PD signal intensity both in LJs and SJs. Also, total RS and its item score excepting "proliferating blood vessels" correlated well with PD signal intensity. Systemic disease activity, local synovial proliferation and lymphocyte infiltration were more severe in LJs than in SJs. Though sensitivity of synovitis at LJs lower than at SJs, there was not a significant difference in PD signal intensity and RS between at LJs and at SJs. RS reflected systemic disease activity more in LJs than in SJs.

**Conclusions:** US is an excellent tool to reflect local synovitis as well as systemic disease activity both in LJs and SJs.

## THU0043 MINIMAL IMPORTANT DIFFERENCE IN HAQ: A VALIDATION FROM HEALTH ECONOMIC PERSPECTIVES IN PATIENT WITH RHEUMATOID ARTHRITIS USING REAL-WORLD DATA FROM ADELPHI DATABASE

C. Han, N. Li, S. Peterson. *Janssen Global Services LLC, Spring House, United States*

**Background:** A change of 0.25 in HAQ score has been considered as clinically meaningful.

**Objectives:** This study is to evaluate the clinical meaningfulness of the HAQ change from health economic perspectives in patients with rheumatoid arthritis using real-world data.

**Methods:** This is a retrospective cross-sectional study using data in ADELPHI Disease-Specific Program collected in 2014 (EU5 and US). Patients with clinically diagnosed RA (N=1032) were enrolled and completed self-reported outcomes measures including physical function by Health Assessment Questionnaire-disability index (HAQ-DI), employment status, work productivity by Work Productivity and Activity Impairment Questionnaire-General Health (WPAI-GH) and general health status by EQ visual analogue scale (EQ VAS). Clinical characteristics include disease activity defined by DAS28. Correlations between HAQ-DI score and other outcomes were analyzed using univariate or multiple regression analysis.

**Results:** The majority of patients were female (72.1%) with average age of 55 years old and disease duration of about 9 years. The mean (SD) HAQ-DI score was 0.76 (0.69) with 42.2% having a HAQ-DI score $\geq$1, indicating moderate to severe physical disability. 58% of patients were currently unemployed. Patients with a HAQ-DI score of $>$1.0, 77% were unemployed with a EQ VAS of 54.2, while patients with normal HAQ score of $\leq$0.5, 40% were unemployed with a EQ VAS of 75.6. HAQ-DI score was significantly correlated with the unemployed in multivariate logistic regression model ($p<0.001$), and correlated with time lost from work ($p<0.001$) and general health status by EQ VAS ($p<0.001$) by multivariate linear regression model. After adjustment for demographic characteristics including age, gender, and disease duration, an 0.25 increase in HAQ-DI score was associated with a 30% increase in likelihood for unemployed status (OR=1.30, 95% CI=1.22, 1.39).

**Conclusions:** Physical function measured by HAQ-DI is a valid measure to predict employment status and general health status in patients with RA.

## THU0044 EFFICACY OF TREAT-TO-TARGET BIOLOGIC THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARED TO DELAYED INITIATION OF BIOLOGICS: A REAL WORLD STUDY

C.E. Lampropoulos[1], P. Orfanos[2], M. Manoussakis[1], A. Tzioufas[1], H.M. Moutsopoulos[1], P.G. Vlachoyiannopoulos[1]. *[1]Department of Pathophysiology; [2]Department of Hygiene, Epidemiology and Medical Statistics, Medical School, National University of Athens, Athens, Greece*

**Background:** Rheumatoid arthritis (RA) is a chronic, devastating disease with involvement of small and large joints. Treat-to-target strategy aims to improve the outcome of patients with RA and rapidly reduce disease activity by using properly and aggressively all the therapeutic options[1].

**Objectives:** To estimate the efficacy of the first bDMARD, overall and by specific bDMARD, in RA patients, when administered according to international recommendations[2], compared to delayed initiation of bDMARDs (usual care) in an outpatient clinic.

**Methods:** Disease activity was regularly measured by DAS-28 until the end of treatment with the first bDMARD. Good response to treatment was considered when remission or low disease activity was achieved. Cox proportional-hazards analyses and Kaplan-Meier (KM) plots were performed to assess the likelihood (hazard ratio, HR) of achieving a good response.

**Results:** There were 113 patients in T2T and 250 patients in usual care group (study-sample characteristics, Table 1). Efficacy of treatment was measured at 3, 12, 24, 36 months and at the end of treatment (Table 2), with significant advantage of the T2T group ($p<0.001$). The IR for T2T group was 37.16 (95% CI 30.29–45.58) and for usual care group 17.26 (95% CI 14.54–20.50). The IRR between the 2 groups was 2.15.

The KM plots (Figure 1) depicted that the likelihood for a good response was significantly higher among patients of the T2T group ($p<0.001$), with comparable efficacy of the 3 classical bDMARDs: infliximab (p=0.008), adalimumab (p=0.018) and etanercept ($p<0.001$) (Figure 2). The HR of the likelihood of achieving good response was 1.71 (95% CI 1.18–2.47, p=0.004) in favor of the T2T group. Etanercept and the newer bDMARDs seemed to be more effective than infliximab or adalimumab whereas total steroid dose $>$500mg and swollen joint count (6–10) were found to be negative predictive factors for a good response.

**Conclusions:** Treat-to-target treatment with bDMARDs offers a rapid and better long-term outcome to patients with RA, compared to delayed initiation of biologic treatment[3,4,5].

## THU0045 14-3-3ETA POSITIVITY IS ASSOCIATED WITH RADIOGRAPHIC PROGRESSION DESPITE PATIENTS ACHIEVING CLINICAL REMISSION

D. van Schaardenburg[1], S. Turk[1], W.P. Maksymowych[2], A. Marotta[3]. *[1]Reade, Amsterdam, Netherlands; [2]University of Alberta, Edmonton; [3]Augurex Life Sciences Corp., Vancouver, Canada*

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease characterized by synovial inflammation which may lead to irreversible joint damage, reduced mobility and decreased quality of life. Although clinical remission can often be achieved with DMARD therapy, remission is often not observed on imaging and the presence of bone edema on MRI is the current best predictor of radiographic progression. Another marker associated with radiographic outcomes is 14–3-3$\eta$, which is a joint-derived protein whose serological expression is independent of CRP[1], modifiable over time[2], and linked with the upregulation of factors that drive the joint damage process[3].

**Objectives:** Examine whether patients who achieve clinical remission at year 1 (Yr1) but remain 14–3-3$\eta$ positive have worse radiographic outcomes by year 3 (Yr3).

**Methods:** Baseline (BL) and Yr1 plasma 14–3-3η protein titres were measured in a cohort of 360 early RA patients from the Reade Institute; all patients were treatment naïve at BL. 14–3-3η positivity was based on the cut-off ≥0.19 ng/ml. Mean (SD) patient age was 55 (12) years and 74% were female. Radiographic progression at Yr3, across the whole cohort and in those patients that achieved Yr1 DAS28 ESR remission (<2.6), was assessed as well as ΔSHS of ≥1, 3 and 5 points from Yr1 to Yr3. Mann-Whitney and Fisher Exact testing was performed to determine the significance (p≤0.05) of group differences and the association with marker positivity, respectively.

**Results:** At BL and Yr1, 245 (68%) and 210 (58%) of patients were 14–3-3η positive. Patients who were positive at baseline or Yr1 had significantly worse radiographic progression by Yr3 than 14–3-3η negative patients; BL 14–3-3η positivity (+ve vs.-ve): [2.0 (0.0–7.5) vs. 0.0 (0.0–4.0), p=0.019] and Yr1 14–3-3η positivity (+ve vs. -ve): [2.0 (0.0–8.0) vs. 0.0 (0.0–4.0), p=0.0012]. A total of 109 (30%) patients achieved Yr1 DAS28 remission. Patients who achieved remission yet were 14–3-3η positive at Yr1 experienced significantly worse radiographic progression by Yr3 than negative patients [1.0 (0.0 -5.0) vs. 0.0 (0.0–2.0), p=0.016]. A similar and significant trend for radiographic progression was observed in patients who did not achieve clinical remission and were 14–3-3η positive at Yr1 versus those who were 14–3-3η negative [2.0 (0.0–11.0) vs. 1.0 (0.0–5.0), p=0.029]. The table below demonstrates that positivity for 14–3-3η at both BL and Yr1, across the whole cohort as well as in those achieving clinical remission, is associated with radiographic progression. Yr1 positivity was more strongly associated with ΔSHS ≥5 than BL.

| Yr1 to Yr3 | ΔSHS≥1 | | ΔSHS≥3 | | ΔSHS≥5 | |
|---|---|---|---|---|---|---|
| | OR (95%CI) | p-value | OR (95%CI) | p-value | OR (95%CI) | p-value |
| Whole Cohort, n=360 | | | | | | |
| BL Pos, n=245 | 1.6 (1.0-2.5) | 0.024 | 1.6 (1.0-2.5) | 0.034 | 1.5 (0.9-2.5) | 0.076 |
| Yr1 Pos, n=210 | 1.8 (1.2-2.8) | 0.004 | 1.8 (1.2-2.8) | 0.005 | 1.9 (1.2-3.1) | 0.005 |
| Non-Remitters, n=251 | | | | | | |
| BL Pos, n=174 | 1.6 (0.9-2.8) | 0.062 | 1.6 (0.9-2.7) | 0.074 | 1.4 (0.8-2.5) | 0.150 |
| Yr1 Pos, n=151 | 1.6 (1.0-2.7) | 0.050 | 1.6 (1.0-2.7) | 0.050 | 1.4 (0.8-2.5) | 0.117 |
| Remitters, n=109 | | | | | | |
| BL Pos, n=71 | 1.6 (0.7-3.5) | 0.179 | 1.6 (0.6-3.8) | 0.234 | 1.6 (0.5-4.9) | 0.280 |
| Yr1 Pos, n=59 | 2.3 (1.0-4.9) | 0.029 | 2.4 (1.0-5.7) | 0.038 | 5.8 (1.6-21.4) | 0.003 |

**Conclusions:** Patients who achieve DAS28 remission at Yr1 but remain 14–3-3η positive are at risk of future radiographic progression. As expected with a modifiable biomarker such as 14–3-3η, serial assessment is more informative than baseline assessment.

## THU0046 A 3-YEAR STUDY OF WORK IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON THE IORRA COHORT

E. Tanaka, E. Inoue, R. Yamaguchi, Y. Shimizu, N. Sugimoto, D. Hoshi, K. Shidara, E. Sato, Y. Seto, A. Nakajima, S. Momohara, A. Taniguchi, H. Yamanaka. *Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

**Background:** Indirect costs of rheumatoid arthritis (RA) due to losses such as reduced productivity are an important social issue in addition to rapidly increasing direct costs; however, work disability in patients with RA have not been thoroughly assessed in Japan. With the recent changes in socioeconomic structure, the number of female paid workers has been increasing; thus, the impact of RA on the work impairment of Japanese patients has been rapidly increasing. In addition, work status is strongly influenced by cultural differences among races. Furthermore, with the recent improvement of RA treatment strategy, it has not been evaluated whether work disability in patients with RA improved or not in a real world settings. Hence, we evaluated longitudinally work impairment in patients with RA in daily practice using a large cohort database.

**Objectives:** To study how the magnitude of work impairment in Japanese patients with rheumatoid arthritis (RA) has changed over the past 3 years in routine clinical practice.

**Methods:** Patients with RA who participated in both of the IORRA studies conducted in April 2012 and April 2013 and those who worked for pay on both surveys and were aged 55 years or younger at baseline were identified. Changes over the 3 years in the absenteeism (AB), presenteeism (PR) and overall work impairment (OWI) scores as determined by the Work Productivity and Activity Impairment (WPAI) were evaluated in those patients. In addition, patients with work impairment, defined as AB >0% or PR ≥30%, at baseline were classified according to whether or not they still had work impairment at 3 years to identify differences in their characteristics.

**Results:** Among 4,214 patients with RA who participated in both of the IORRA studies, 1,310 patients were selected in this study cohort (mean age, 51.5 years; females, 80.1%; Japanese version of the HAQ [J-HAQ], 0.37). The AB, PR, OWI scores in the 1310 patients were 1.8%, 16.4% and 17.3%, respectively, at baseline, which remained unchanged at 3 years (2.1%, 16.4% and 17.6%, respectively). At baseline, 206 patients (15.7%) had work impairment, of whom 117 patients (56.8%) (mean age, 43.8 years; females, 85.5%; DAS28, 3.1 [2.8 at 3 years]; J-HAQ, 0.80 [0.75 at 3 years]; 73.5% [76.9% at 3 years] of patients received methotrexate; 36.8% [38.5% at 3 years] received biologics) continued to have it at 3 years, and 89 patients (43.2%) (mean age, 44.2 years; females, 84.3%; DAS28, 3.2 [2.1 at 3 years]; J-HAQ, 0.54 [0.25 at 3 years]; 77.5% [82.0% at 3 years] of patients received methotrexate; 24.7% [39.3% at 3 years] received biologics) were free from work impairment.

**Conclusions:** In the overall population of Japanese patients with RA, work impairment has not been improved over the past 3 years; however, as many as 43.2% of patients with work impairment at baseline have experienced improved work productivity. In these patients, more intensive RA therapy has resulted in a greater reduction in disease activity or functional impairment.

## THU0047 ARTHROSCOPIC MACRO-ASSESSMENT OF SYNOVIA IN RHEUMATOID ARTHRITIS PATIENTS HIGH ANTI-CCP

E.B. Komarova[1], B.A. Rebrov[1], A. Blagodarenko[1], I. Pokryshka[2]. [1]*Internal Medcine, SI "Lugansk State Medical University";* [2]*Rheumatology, Regional Clinical Hospital, Lugansk, Ukraine*

**Background:** Antibodies to cyclic citrullinated peptide (anti-CCP) are valuable immunological marker for early diagnostic of rheumatoid arthritis (RA). They are highly sensitive and highly specific in RA. In addition, anti-CCP used as prognostic marker of severe RA. Arthroscopy is a minimally invasive technique, safe and efficient for visualization and biopsy of synovia (S) in rheumatology. Changes and structure of S are different for stages of RA. Detailed study of S changes features depending on the RA clinical course is an actual problem in rheumatology, as it allows early diagnostic of the disease, clinical course prognosis and individual therapy prescription.

**Objectives:** to define a peculiarities of S macro-assessment on arthroscopy in RA patients depending on the blood level of anti-CCP

**Methods:** knee arthroscopy was performed in 33 patients with RA (diagnosis is verified according to the criteria ACR/EULAR, 2010). Patients were divided into two groups depending on the blood level of anti-CCP. The first group ("–" anti-CCP), with negative or low positive level, included 13 patients (40%) (anti-CCP level was ≤40 IU/ml). The second group ("+" anti-CCP) positive and highly positive - 20 patients (60%) (anti-CCP level was >40 IU/ml). The patients of the two groups were not statistically different for clinical and demographic indicators.

All arthroscopy was performed in the same sterile operating room via arthroscope (Karl Storz GmbH, Tuttlingen, Germany) of 2.4 mm with an angle of 30°. Arthroscopy was performed in accordance with Helsinki Declaration. All chambers of the joint were inspected. The joint lavage for visualization was perfomed throughout the procedure, but minimized (usually it is about 500 to 1000 ml). All the arthroscopy procedure was recorded on video for the further evaluation of the macroscopic picture of the knee joint changes. Parameters of the changes were estimated: the type of S hyperplasia, S vascularization, atrophic changes in S, presence of pannus and fibrin, shape of S villi

**Results:** Indices of inflammatory and of villous S hyperplasia were equally often (62% and 76%, 69% and 75%, respectively) in the patients of the two examined groups. S hyperemia and expressed vascular pattern predominated in "+" anti-CCP group of the patients - 76% of cases, compared with the group "–" anti-CCP - 36% ($\chi^2$=4.17, p=0.04). Growth of S with clavate villi tended to increase in the patients of "+" anti-CCP group. Presence of pannus significantly prevalent in patients with "+" anti-CCP group (75%) when compared with "–" anti-CCP groups - 31% ($\chi^2$=4.63, p=0.03). The presence of fibrin tended to increase in incidence in patients of "+" anti-CCP, but it was not statistically significant. The percentage of patients with atrophic changes of S was practically the same in the compared groups.

**Conclusions:** RA patients with anti-CCP blood level of >40 IU/ml have S hyperemia with increased vascular pattern twice more often, and the presence of pannus on S arthroscopy was 2.5 times more often in them. The data shows the intensity of inflammation and angiogenesis in S of high anti-CCP blood level patients. This contributes to an aggressive course of RA in these patients with the rapid development of cartillage-bone destruction

**Disclosure of Interest:** None declared

## THU0048 TESTING OF 14-3-3ETA IN EARLY UNDIFFERENTIATED POLYARTHRITIS CAN ASSIST WITH PRIORITIZING REFERRALS OF HIGH JOINT DAMAGE RISK PATIENTS TO RHEUMATOLOGISTS

G. Boire[1], N. Carrier[2], A.J. de Brum Fernandes[1], P. Liang[1], A. Masetto[1], Y. Gui[3], J. Savill[3], S. Michienzi[3], H.A. Menard[4], W.P. Maksymowych[5], A. Marotta[3]. *[1]University of Sherbrooke; [2]Centre hospitalier universitaire de Sherbrooke, Sherbrooke; [3]Augurex Life Sciences Corp., Vancouver; [4]MSK Research Axis, McGill University Health Center Research Institute, Montreal; [5]University of Alberta, Edmonton, Canada*

**Background:** Achievement of radiographic remission in RA is dependent on early patient identification and effective triaging to enable prompt referral to enable tight control treatment strategies. Assessment within 12 weeks of symptom onset i.e. the "window of opportunity" is reportedly associated with less joint destruction and a higher likelihood of achieving remission. Based on RF or anti-CCP2 testing at the primary care level, approximately one half of early RA patients may test negative and not be referred. Further, since referral times can often be lengthy, rheumatologists in consult with GPs require more sensitive, disease specific tools to prioritize the referral of patients who are at greatest risk for radiographic progression. 14–3-3η is a soluble diagnostic RA marker that is involved in the pathophysiology of the disease and informs joint damage progression.
**Objectives:** The aim of this study was to examine the combined benefit of 14–3-3η and anti-CCP2 testing in early undifferentiated polyarthritis to inform radiographic progression rate.
**Methods:** Serum 14–3–3η levels were measured at baseline in 331 patients with recent onset polyarthritis (Sherbrooke EUPA), for which a follow up of at least 60 months was completed. Mean (SD) age was 60 years, 62% were female, and median (IQR) duration of symptoms was 4 (1.7–5.7) months. Radiographic progression was defined as a change in Sharp/van der Heijde score, $\Delta SHS \geq 1$ at 18, 30, 42, and 60 months. Differences in mean ΔSHS based on 14 -3-3η positivity was assessed using the Mann-Whitney U-test at the diagnostic cut-off of ≥0.19 ng/ml. ANOVA analysis was performed to assess the significance of 14–3-3η and anti-CCP2 co-expression with radiographic progression over 60 months.
**Results:** At baseline, 46% and 40% of patients were positive for 14–3-3η and anti-CCP2, respectively. Together, 14–3-3η or anti-CCP2 captured 55% of patients. Of these, 58% were positive for both markers whereas 42% were positive for one or the other. Over the course of 60 months, mean (SD) radiographic progression from baseline was significantly higher in 14–3-3η seropositive patients when compared with seronegative patients, 10.0 (15.6) vs. 6.3 (13.40) p=0.022. Radiographic progression based on biomarker co-expression analysis shows that patients who were positive for both anti-CCP2 and 14–3-3η had the most significant changes in radiographic outcomes over 60 months.

| Timepoint | Group | n | Mean ΔSHS ± SD | p-value |
|---|---|---|---|---|
| Baseline to 60 months | Both negative | 144 | 6.22±13.91 | 0.024 |
| | Only 14–3–3η positive | 47 | 6.43±12.09 | |
| | Only anti-CCP2 positive | 25 | 6.40±10.01 | |
| | Both positive | 100 | 11.66±16.76 | |

**Conclusions:** Early undifferentiated polyarthritis patients who are positive for 14–3-3η and anti-CCP2 have more radiographic progression over 60 months. 14–3-3η positive status can assist with prioritization of high joint damage risk patient referrals to rheumatologists.

## THU0049 IS PATIENT GLOBAL ASSESSMENT IN BOOLEAN-BASED REMISSION IN RHEUMATOID ARTHRITIS REALLY REQUIRED INSTEAD OF PHYSICIAN GLOBAL ASSESSMENT? A COMPARATIVE STUDY WITH ULTRASOUND

G. Ozen, A.U. Unal, A. Topcu, P. Atagunduz, H. Direskeneli, N. Inanc. *Rheumatology, Marmara University School of Medicine, Istanbul, Turkey*

**Background:** Patient global assessment (PtGA) is included in all the current remission definitions for RA despite the fact that PtGA is not exclusively related to disease activity.
**Objectives:** In this study in order to objectively identify whether patient's assessment is better than physician's (Ph) or not, we compared disease activities assessed with ultrasound (US) of Boolean remission patients with PtGA and with PhGA.
**Methods:** RA patients in clinical remission (DAS28 ESR<2.6) for at least 3 months were included. Boolean based remission definition and modified version by substitution of PtGA with PhGA were determined. A standard gray scale (GS) and power Doppler (PD) US examination of 28 joints (included in DAS28) for the presence of synovitis was performed by an experienced sonographer (NI) blinded to clinical data. US synovitis GS and PD signals were semiquantitatively graded from 0 to 3 and were recorded as sum scores of PD and GS, respectively.
**Results:** A total of 88 out of 389 RA patients (22.6%) in DAS28 remission were enrolled (F/M=55/33, mean age 53.4±12.0, disease duration 10.5±6.3 years, bDMARDs 44.3%, RF/Anti-CCP positivity 72%). Of 88 patients, 33 (37.5%) fulfilled the Boolean remission criteria. When PtGA was substituted with PhGA, Boolean remission rate increased to 61.4% (n=54) ($P$<0.001). Regarding US disease activity no PD, no GS and no PD+GS signals were observed in 13 (39.4%) vs 16 (29.6%), 10 (30.3%) vs 11 (20.4%) and 9 (27.3%) vs 10 (18.5%) patients in Boolean remission with PtGA and PhGA, respectively (Table 1). When PD and GS signals > grade 1 were taken into account, % of patients without PD, GS or both signals were also similar Table 1). US disease activity parameters of Boolean PtGA and Boolean PhGA remission and their counterpart nonremission patients were compared as well, Boolean remission either with PtGA or PhGA had significantly lower PD scores compared to Boolean nonremission groups with PtGA or PhGA (1 [0–4] vs 3 [1–7], $P$=0.016 and 1.5 [0–4] vs 4 [0.75–7], $P$=0.027, respectively).

**Table 1. US disease activity parameters of remission patients according to Boolean based criteria with PtGA and PhGA***

| | Boolean REM with PtGA (n=33) | Boolean REM with PhGA (n=54) | *P* value |
|---|---|---|---|
| PD synovitis sum score (0-84) | 1 (0-4) | 1.5 (0-4) | 0.43 |
| PD synovitis sum score (without counting grade 1 signals) | 0 (0-3) | 0 (0-4) | 0.58 |
| GS synovitis sum score (0-84) | 3 (0-8.5) | 3 (1-8) | 0.58 |
| GS synovitis sum score (without counting grade 1 signals) | 2 (0-4) | 2 (0-6) | 0.58 |
| US joint count with PD signal (0-28) | 1 (0-2.5) | 1 (0-3) | 0.44 |
| US joint count with PD signal (without counting grade 1 signals) | 0 (0-1.5) | 0 (0-2) | 0.58 |
| US joint count with GS signal (0-28) | 1 (0-4) | 2 (1-4) | 0.43 |
| US joint count with GS signal (without counting grade 1 signals) | 1 (0-2) | 1 (0-3) | 0.58 |
| PD≥1 | 21 (63.6) | 31 (57.4) | 0.61 |
| GS≥1 | 16 (48.5) | 24 (44.4) | 0.71 |
| PD≥1 and GS≥1 | 14 (42.5) | 22 (40.7) | 0.68 |
| US JC with GS≥1 | 14 (42.5) | 24 (44.4) | 0.71 |
| ESR, mm/h | 18 (11-26) | 17 (10-28) | 0.43 |
| CRP, mg/L | 3.2 (2.1-3.9) | 3.2 (2.7-3.8) | 0.83 |
| Tender joint count, median (min-max) | 0 (0-1) | 0 (0-1) | 0.58 |
| PD sum score in the tender joints, median (min-max) | 0 (0-0) | 0 (0-0) | 0.50 |

*The values were presented as median (IQR). †The values were presented as n (%).

**Conclusions:** RA patients in Boolean remission with PhGA do not have higher disease activity that is verified by US, compared to patients in Boolean remission with PtGA. Furthermore Boolean remission with PhGA differentiates patients with US evinced inflammation, especially PD scores, as good as PtGA. These data suggest that PtGA might be substituted with PhGA in Boolean criteria with higher remission achievement rates. Prospective follow up and recruitment of more patients will clarify the consistency of these results over time and impact of this substitution on functionality.

## THU0050 ORTHOPEDIC SURGICAL INTERVENTION AIMING AT HIGHER LEVEL OF QUALITY OF LIFE AND MENTAL WELLNESS FOR THE PATIENTS WITH RHEUMATOID ARTHRITIS. A PROSPECTIVE COHORT STUDY OF 276 SURGICALLY-TREATED PATIENTS

H. Ishikawa[1], A. Abe[1], A. Murasawa[1], T. Kojima[2], M. Kojima[3], N. Ishiguro[2], S. Ito[1], K. Nakazono[1], T. Nemoto[1], H. Lee[1], D. Kobayashi[1], C. Takai[1]. *[1]Rheumatology, Niigata Rheumatic Center, Shibata; [2]Orthopedic Surgery, Nagoya University Hospital; [3]Medical Education, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan*

**Background:** By the biologic treatment of rheumatoid arthritis (RA), uncontrollable synovitis in the past has been well comtrolled. However, some patients with established RA are still difficult to reach comprehensive disease control, thus surgical reconstruction for the damaged joint is required. Recently, patients desired to achieve functional remission aiming at the higher level of quality of life (QOL) and the mental wellness.
**Objectives:** The objective of this study was to clarify the effect of orthopedic surgical intervention for the disabled patients with RA using the assessment of patient-reported outcome (PRO) and disease activity.

**Methods:** Surgical reconstruction of the damaged joint was scheduled on 276 sites in 276 patients (male: 34, female: 242) with RA between October 2012 and September 2014. The average age was 64 (19–89) years old and the average duration of the disease was 16 (1–60) years. The surgical site was shoulder in 6 patients, elbow in 26, wrist in 74, hand in 63 (combined with wrist in 18), hip in 13, knee in 50, ankle in 12, and forefoot in 50. The procedure included alloarthroplasty (shoulder: 5, elbow: 22, hand: 36, hip: 13, knee: 47), arthroplasty without prosthesis (wrist: 30, hand: 10, forefoot: 67), arthrodesis (wrist: 37, hand: 33, ankle: 11, forefoot: 5), and synovectomy (shoulder: 1, elbow: 4, wrist: 15, hand: 6, knee: 3, ankle: 1). MTX was used in 176 patients (64%) with the average dose of 7.7mg/w, and PSL was used in 175 patients (63%) with the average dose of 4.0mg/d. Biologics was used in 69 patients (25%) including ETN: 20, TCZ: 17, IFX: 11, GLM:9, ADA: 8 patients. PRO was assessed by Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), Beck Depression Inventory-II (BDI-II), and patient's general health using visual analogue scale of 100mm (Pt-GH). Disease activity was assessed by 28-joint Disease Activity Score using C reactive protein (DAS28-CRP). They were measured just before surgery (baseline), at 6 and 12 months after surgery.
**Results:** As a whole, physical function (HAQ-DI), QOL (HAQ-DI, EQ-5D, Pt-GH) and mental wellness (BDI-II, Pt-GH), disease activity (DAS28-CRP) significantly improved at 6 and 12 months after surgery compared to those at baseline ($p<0.01$) (Table1, Figure1). The rate of clinical remission in DAS28-CRP (<2.3) at baseline, 6 and 12 months after surgery was 23%, 55% and 53%, respectively. The rate of functional remission in HAQ-DI (<0.5) was 25%, 31% and 30%, respectively. The rate of minimal depression in BDI-II (≤13) was 58%, 64% and 65%, respectively.

Table 1. Change in patient-reported outcome and disease activity (n=276)

| | HAQ-DI | EQ-5D | BDI-II | Pt-GH | DAS28-CRP |
|---|---|---|---|---|---|
| Baseline | 1.1 ± 0.7 | 0.69 ± 0.11 | 13.0 ± 8.8 | 39 ± 25 | 3.1 ± 1.0 |
| 6mos.after surgery | 1.0 ± 0.8* | 0.74 ± 0.14* | 11.7 ± 8.2* | 26 ± 21* | 2.4 ± 1.5* |
| 12mos.after surgery | 1.0 ± 0.8* | 0.75 ± 0.14* | 11.6 ± 8.5* | 27 ± 21* | 2.4 ± 0.8* |

mean ± SD, *:p<0.001 compared to baseline

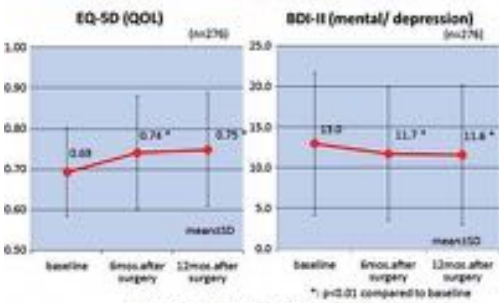

Figure 1: Change in EQ-5D and BDI-II

**Conclusions:** Favorable effects of orthopedic surgical intervention on QOL and mental wellness as well as physical function were confirmed in the disabled patients with RA. To improve QOL and mental wellness, surgical treatment for the damaged joint should be considered in combination with tight medical control. It also had an ameliorating effect on disease activity.

## THU0051 THE LEVELS OF SERUM PENTRAXIN 3, IL 6, FETUIN A AND INSULIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

I. Tekeoğlu[1], A. Kamanlı[1], S. Sağ[1], M.S. Sağ[1], H. Harman[2], K. Nas[1], M. Altındiş[3]. *[1]Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Sakarya University, Sakarya; [2]Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Bolu İzzet Baysal University, Bolu; [3]Department of Microbiology, Faculty of Medicine, Sakarya University, Sakarya, Turkey*

**Background:** The pathogenesis of RA is not well understood, but genetic, environmental and immunologic factors are known to be involved in the development of the disease. The long pentraxin, pentraxin-3 (PTX-3), is an inflammatory marker and a member of pentraxin superfamily which contains CRP and serum amyloid P. There are some published studies showing the relationship between RA and PTX-3. (1–3). We investigated that PTX3, IL 6, fetuin- A, insulin and HOMA-IR might also have a role in the pathogenesis of RA.
**Objectives:** The aim of this study was to evaluate the relationship between disease severity and biochemical parameters such as pentraxin-3, fetuin-A, IL-6,insulin and HOMA-IR levels in patients with rheumatoid arthritis.
**Methods:** This study included 60 patients with RA and 20 healthy controls. Serum pentraxin-3, fetuin-A, IL-6 and insulin concentrations were determined. Also, HOMA-IR values were calculated. Disease activity was assessed with Disease Activity Score (DAS28). Quality of life was evaluated by the use of the Health Assessment Questionnaire disability index.
**Results:** The serum values for ESR, CRP, pentraxin-3 and fetuin-A in patients with RA were elevated than control subjects (p values=0.001, 0.001, 0.000, 0.000, 0.01, 0.02, respectively) A positive correlation was evident between the DAS 28 score and IL6 levels (r =0.263, p=0.045). We found no correlation between the DAS28 score and HOMA-IR, the levels of pentraxin 3, fetuin A, insulin ($p<0.05$). Fetuin A levels was positively correlated with cumulative steroid dose (r=0.382, p=0.035). A statistically significant correlation was evident between presence of cardiovascular disease and HOMA-IR values in RA patients (r=0.437, p=0.032). In addition, DAS-28 score values were not in correlation with insulin, fetuin-A, HOMA-IR, IL-6 and pentraxin-3 levels ($p>0.05$).
**Conclusions:** Elevated levels of pentraxin-3, fetuin-A, CRP, ESR might play a role in the pathogenesis of RA. Levels of IL-6, fetuin-A, insulin HOMA-IR, pentraxin -3, CRP, ESR concentrations were not associated with clinical severity of the RA.

## THU0052 ASSOCIATION BETWEEN ANTIPHOSPHOLIPID ANTIBODIES AND ARTERIAL THROMBOTIC EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

K.-J. Kim[1], I.-W. Baek[2], Y.-J. Park[1], K.-S. Park[1], C.-S. Cho[3]. *[1]Internal Medicine, St. Vincent's Hospital, The Catholic University of Korea, Suwon; [2]Internal Medicine, Yeouido St. Mary's Hospital, The Catholic University of Korea; [3]Internal Medicine, Yeoudo St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of*

**Background:** Antiphospholipid antibodies (aPL) were reported to be found by variable range from 5 to 75% in patients with rheumatoid arthritis (RA) but their clinical significance remains undetermined.
**Objectives:** The aim of this study is to investigate the association of the presence of aPL with thrombotic events in patients with RA.
**Methods:** aPL profile, including lupus anticoagulant (LAC), anti-cardiolipin antibodies (aCL), and anti-$\beta_2$ glycoprotein I antibodies (a$\beta_2$GPI), was evaluated in 360 patients with RA according to the standard guideline. Clinical and radiographic data were collected retrospectively.
**Results:** aPL were identified in 36 patients (10.0%). LAC was the most common type (n=23, 6.4%) and aCL and a$\beta_2$GPI were detected in 5 and 12 patients (1.4 and 3.4%), respectively. Compared to aPL-negative group, aPL-positive group included more male patients (16 (44.4%) vs. 51 (15.7%), $P<0.001$) and had higher rate of ever-smoker (14 (38.9%) vs. 51 (15.7%), $P=0.005$) while there was no difference between two groups in the age, disease duration, and body mass index as well as in the rate of diabetes, hypertension, and dyslipidemia. There was also no significant difference in the positive rate of rheumatoid factor and anti-cyclic citrullinated peptide antibody, values of inflammatory indices and radiographic scores of hand x-ray between two groups. Of note, arterial thrombotic events more commonly developed in aPL-positive group than aPL-negative (5 (13.9%) vs. 7 (2.2%), $P=0.004$) while venous thrombosis did not differ between two groups (0 (0.0%) vs. 3 (0.9%), $P=1.000$). In multivariate regression analysis, the presence of aPL, old age, hypertension, and high value of baseline C-reactive protein were independently associated with arterial thrombotic events ($P<0.05$).
**Conclusions:** A proportion of RA patients was aPL-positive, and the presence of aPL was independently associated with arterial thrombosis. This result suggests that aPL might be contributable to increased risk for arterial thrombosis in patients with RA.

## THU0053 NO EXCESS MORTALITY IN A POPULATION-BASED DANISH RHEUMATOID ARTHRITIS COHORT FROM THE LATE PRE-BIOLOGIC ERA

J.K. Pedersen[1,2,3], R. Holst[3], J. Primdahl[2,3], A.J. Svendsen[4], K. Hørslev-Petersen[2,3]. [1]*Department of Rheumatology C, Odense University Hospital, Odense;* [2]*Research Unit, King Christian X Hospital for Rheumatic Diseases, Graasten;* [3]*Institute of Regional Health Research;* [4]*Institute of Public Health, University of Southern Denmark, Odense, Denmark*

**Background:** Patients with rheumatoid arthritis (RA) from hospital-based series have an increased mortality, in particular from cardiovascular diseases. Estimates of standardized mortality ratios (SMR) from population-based inception cohorts have been inconsistent and mortality in RA patients may be modified by treatment and preventive strategies. Furthermore, human senescence in the general population has been delayed since 1950.(1) We therefore wanted to investigate the all-cause SMR in a Danish population-based inception RA cohort from the late pre-biologic era seen at a regional hospital with documented focus on intention-to-treat (2, 3) and cardiovascular screening (4).
**Objectives:** To investigate SMR in an unselected inception cohort of Danish RA patients from 1995 to 2002.
**Methods:** The case base was the population of the County of South Jutland according to the Danish Civil Registration System (CVR). Incident RA cases were identified at the referral center for rheumatic diseases in the County where the observed completeness of registrations from the case base was 97%.(5) The registry was scrutinized for all RA patients fulfilling the 1987 American College of Rheumatology criteria for RA from 1995 to 2002. Linkage of cases to CVR and the Danish Register of Causes of Death was based on unique personal identification numbers. Cases were followed from inclusion until emigration, death or end of follow-up (31.12.2013). Statistics Denmark provided mortality rates for the total Danish population from 1995 to 2013.
**Results:** A total of 509 cases were identified (Females 68%; mean age 61 years; rheumatoid factor positive 77%; erosive 23%). During 6079 person-years (py) of follow-up 200 (39%) patients had died (Females 32%; males 55%). The main causes of death are seen in table 1. There were no statistically significant differences in the causes of death according to sex (Chi-squared test=12.2, degrees of freedom: 7, p=0.092). The median follow-up time was 13 years and the average mortality rate 33/1000 py (Females 26/1000 py; males 50/1000 py). The overall SMR was 1.04 (95%>confidence interval (CI): 0.91–1.19), in females 0.96 (95%>CI: 0.79–1.43) and in males 1.16 (95%>CI: 0.95–1.43).

Table 1. Main causes of death in 200 Danish patients with RA (numbers (%)

| Diseases (ICD-10 codes) | n (%) |
|---|---|
| Cardiovascular (I00-I99) | 68 (34) |
| Neoplasms (C00-D48) | 52 (26) |
| Pulmonary (J00-J99) | 23 (12) |
| Skin, bone connective tissue (L00-M99) | 10 (5) |
| Gastrointestinal (E00-E90) | 8 (4) |
| Metabolic (E00-E90) | 8 (4) |
| Infectious (A00-B99) | 5 (3) |
| Other (other codes) | 26 (13) |

**Conclusions:** In this population-based study there were no significant excess mortality compared to the general population. The predominant causes of death were cardiovascular-, neoplastic- and pulmonary disease.

## THU0054 GLYCATED ALBUMIN INCREASES WITH DISEASE ACTIVITY IN RHEUMATOID FACTOR POSITIVE RHEUMATOID ARTHRITIS PATIENTS WITH NORMAL FASTING GLUCOSE AND HBA1C

J.-S. Park[1], C.-H. Lee[1], J.J. Song[2], Y.-B. Park[2], S.-K. Lee[2], S.-W. Lee[2]. [1]*Internal medicine, NHIS Ilsan hospital, Goyang-si;* [2]*Internal medicine, Severance Hospital, seoul, Korea, Republic Of*

**Background:** Rheumatoid arthritis (RA) is a prototypical autoimmune disease, characterized by the symmetric inflammation in multiple joints, leading to progressive destruction of joints. Glycated albumin (GA) is a newly suggested parameter for the glycemic status. GA was reported to be correlated with inflammatory burdens such as (C-reactive protein) CRP and inflammatory cytokines levels [1,2].
**Methods:** We consecutively screened 250 RA patients in this study, and finally analyzed data of 205 RA patients. We collected 12 hourfasting blood samples and performed laboratory tests. In this study, we used disease activity score (DAS) 28 using both erythrocyte sedimentation rate (ESR) (DAS28-ESR) and CRP (DAS28-CRP), and we defined DAS28 >3.2 as active RA.
**Results:** Patients with active RA showed significantly higher GA level than those with inactive RA (13.8 ± 1.8 vs. 12.8 ± 1.4%, P<0.001 (DAS28-ESR) and 14.4 ± 1.7 vs. 13.0 ± 1.5%, P<0.001 (DAS28-CRP)). Patients with active RA had significantly higher alkaline phosphatase (ALP) level than those with inactive RA (P=0.003 (DAS28-ESR) and P=0.033 (DAS28-CRP)). On multivariate logistic regression analysis, GA ≥12.95%, CRP ≥1.65 mg/L and ALP ≥60.5 IU/L were independent predictors of active RA based on DAS28-ESR (OR 4.881, P<0.001, OR 12.972, P<0.001, and OR 3.573, P=0.001). Also GA ≥13.95% could independently predict active RA based on DAS28-CRP better than ESR ≥43.5 mm/hr (OR 6.399, P<0.001 vs. OR 4.509, P<0.001), but ALP ≥60.5 IU/L could not.
**Conclusions:** GA level increased with disease activity in rheumatoid factor positive RA patients with normal laboratory results, who had no medical history. GA level showed the potential to predict active RA, comparable with ESR and CRP.

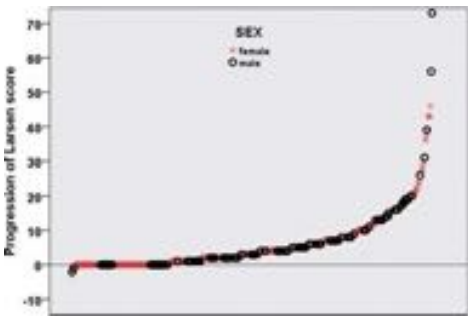
## THU0055 BONE RESORPTION WAS CORRELATED WITH RADIOLOGIC PROGRESSION IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

J. Huang[1], S. Cui[2], J. Jiang[3], Y. Xie[1], L. Zhang[1]. [1]*Rheumatology;* [2]*Clinical Biochemistry Department;* [3]*Radiology, The University of Hong Kong-Shenzhen Hospital, Shenzhen, China*



**Background:** Rheumatoid arthritis (RA) itself is associated with osteoporosis that may be localized or generalized. Joint inflammation in RA induces local periarticular osteoporosis. And the bone loss in the hands and generalized osteoporosis was reported to be correlated.
**Objectives:** To determine the levels of bone turnover markers in patients with rheumatoid arthritis (RA) and the correlation with disease activity index, bone mineral density (BMD) and radiographic progression.
**Methods:** Sixty-eight postmenopausal women with RA were recruited in our study. Serologic measurement including erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), rheumatoid factor (RF) and anti-cyclic citrullinated peptid (anti-CCP) were analyzed. Calcium, vitamin D, bone alkaline phosphatase (BAP) β-crosslaps were also detected. Bone mineral density (BMD, g/cm$^2$) was measured at the lumbar spine and the left femoral neck by dual-energy X-ray absorptiometry (DXA). DAS28 and Sharp score were separately calculated for disease activity and radiographic progression evaluation. Spearman correlation analysis was conducted between clinical biomarkers and disease indexes.
**Results:** The overall rate of patient with abnormal BMD was 94.12%, with osteopenia 29.41% (20/68) and osteoporosis 64.71% (44/68), respectively. ESR, CRP and DAS28 was significantly correlated with each other showing consistent disease activity (p<0.05). Serum β-crosslaps level (452.87±202.40 ug/l) was not correlated with any of disease acidity markers (p all >0.05) and positively correlated with Sharp score (150.76±59.71) in postmenopausal women with RA (r=0.776, p=1×10–6).
**Conclusions:** Osteopenia and osteoporosis was predominant in RA which might be related to disease activity and/or structural damage. β-crosslaps implies radiographic progression instead of disease activity.

## THU0056 WOMEN, MEN, AND RHEUMATOID ARTHRITIS: RADIOGRAPHIC PROGRESSION OVER TEN YEARS IN THE CURRENT MILLENNIUM

J. Asikainen[1], T. Rannio[1], H. Kautiainen[2], P. Hannonen[1], T. Sokka[1]. *[1]KSSHP, Jyväskylä; [2]Helsinki Univ Hospital, Helsinki, Finland*

**Background:** Radiographs of hands and feet represent an objective outcome measure of rheumatoid arthritis (RA). Joint damage is a result of cumulative disease activity over years. Unlike other clinical measures, radiographic damage is caused mainly by disease inflammatory activity. Therefore, radiographs are a proper measure to analyze whether RA behaves differently in women and men over time.
**Objectives:** To compare radiographic progression in women and men over 10 years after diagnosis of early RA.
**Methods:** All 1046 patients who were diagnosed with RA in 1997 – 2005 at a single rheumatology center were scheduled for a 10 year follow-up with radiographs of hands and feet at years 0, 2, 5, and 10. Larsen score (0 - 100) was employed including MCPs, wrists and 2–5 MTP joints. Radiographic progression over 10 years was calculated and compared between women and men.
**Results:** Among 1046 patients (66% women, mean age 58, 60% seropositive, 13% with erosions at baseline), 5-year radiographs were available in 85% and 10-year radiographs in 71% of patients. A 5-year radiographic progression was similar between women and men: among 539 seropositive patients the median (IQR) Larsen score was 2 (0, 6) in 359 women and 2 (0, 7) in 180 men. In 346 seronegative patients the figures were 0 (0, 2) and 0 (0, 2) in 245 women and 101 men, respectively. Overall, 50% of seropositive women and 52% of seropositive men showed erosions and in seronegative patients the respective proportions were 17% and 23%. Also the 10-year radiographic progression was similar between women and men (Figure 1). Among 480 seropositive patients, the median (IQR) Larsen score was 4 (0, 10) in 333 women and 4 (1, 9) in 147 men. In 263 seronegative patients the figures were 0 (0, 2) and 0 (0, 3) in 187 women and 76 men, respectively. Overall, 59% of seropositive women and 63% of men showed erosions and in seronegative patients the proportions were 21% and 28%, respectively. Among seropositive women vs men similar proportion had been treated with various anti rheumatic medications including 90% vs 87% MTX, 22% vs 29% subcutaneous MTX, 75% vs 84% SSZ, 76% vs 71% HCQ, 17% vs 16% LEF, 14% vs 12% im gold, 78% vs 77% Pred, and 22% vs 20% biologic agents. Mortality (a total of 15% of women and 30% of men died over 10 years) was the main reason for missing data.

**Conclusions:** Radiographic progression is similar in women and men who are treated for RA in the current millennium.
**Disclosure of Interest:** None declared

## THU0057 VALIDATION OF THE BASELINE ADAMTS5 MRNA LEVELS AS A PREDICTION BIOMARKER FOR THE EFFICACY OF INFLIXIMAB; A MULTICENTER CLINICAL TRIAL

K. Tsuzaka[1,2], M. Nagata[1], K. Amano[3], T. Mimura[4], S. Kagami[5], Y. Miwa[6], K. Ikeda[7], T. Mitsuka[8], H. Kanai[9], I. Sekigawa[7]. *[1]Iruma Heart Hospital, Iruma; [2]Tokyo Kenko Clinic, Tokyo; [3]Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama; [4]Saitama Medical University, Moroyama, Saitama; [5]Asahi General Hospital, Asahi, Chiba; [6]Showa University School of Medicine, Tokyo; [7]Juntendo University Urayasu Hospital, Urayasu, Chiba; [8]Mitsuka Rheumatism Clinic, Narashino, Chiba; [9]Kanai Medical Clinic, Chiba, Chiba, Japan*

**Background:** A disintegrin and metalloproteinase with thrombospondin motifs 5 (ADAMTS5) has been reported to play a key role in aggrecan degradation in cartilage. Lower level of the baseline blood ADAMTS5 mRNA level has been also reported to predict the better response to infliximab (IFX) in RA patients using a single-center study.
**Objectives:** In this study, we performed a prospective, multicenter, and observational study to derive and validate the baseline blood ADAMTS5 mRNA that would be predictive of the efficacy of IFX in RA patients.
**Methods:** Forty-one RA patients (Age, 54.1±12.3 y/o; Disease duration, 4.5±7.1 years; DAS28_ESR, 5.07±1.07; SDAI 23.5±1.03; Bio naïve, 91.7%) were enrolled and treated with IFX. Peripheral blood samples were collected at baseline and ADAMTS5 mRNA was quantified using real-time PCR as the ratio of b-actin mRNA (Index as BiologicMate®).
**Results:** Five patients dropped out of this study while 44.1%, 14.7%, 29.4%, 41.1%, 23.5%, and 23.5% of the remaining patients achieved good responder, none responder, DAS_ESR remission, DAS_CRP remission, SDAI remission, and Boolean remission at 14 weeks' treatment with IFX, respectively. Baseline ADAMTS5 mRNA levels in the SDAI remission group was significantly ($p=0.049$) lower than that in the non-SDAI remission group at 14 weeks' treatment with IFX. Area under curve (AUC) of the ROC curve for predicting the SDAI remission (SDAI $\leq$3.3) using the baseline ADAMTS5 mRNA at 14 weeks was 0.67, and the cut-off value of ADAMTS5 mRNA was calculated as 2.1 Index. There observed no difference in the general patient backgrounds (average age, disease duration, dose of MTX, dose of steroid, baseline SDAI, etc) between Low-ADAMTS5 ($<$2.1 Index) group and High-ADAMTS5d group. However, DAS28, CDAI, and SDAI at 14 weeks after treatment were significantly ($p=0.031$) lower in Low-ADAMTS5 group than those in High-ADAMTS5 group. The accuracy, positive predictive value (PPV), and negative predictive value (NPV) of the baseline Low-ADAMTS5 ($<$2.1 Index) for predicting the SDAI remission (SDAI $\leq$3.3) at 14 weeks after treatment with IFX were 76.5%, 66.7%, and 85.7%, respectively. Interestingly, we observed positive correlation between baseline ADAMTS5 mRNA and SDAI score at 14 weeks after treatment with IFX.
**Conclusions:** The baseline blood ADAMTS5 mRNA level was validated as a biomarker for the prediction of the response to IFX in RA patients using the multicenter clinical trial.

## THU0058 PREDICTION OF SUCCESSFUL DOSE REDUCTION OR DISCONTINUATION OF BIOLOGICS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW

L. Tweehuysen, C. van den Ende, F. Beeren, E. Been, F. van den Hoogen, A. den Broeder. *Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

**Background:** Tapering of biologics has been shown feasible, effective and safe in rheumatoid arthritis (RA) patients with stable low disease activity. Tapering of biologics is done using a trial-and-error disease activity guided strategy, because it is not known in advance which patient can successfully taper. Prediction of successful dose reduction or discontinuation of a biologic could prevent flares and would save time and drug exposition. In the last years, several studies have investigated biomarkers for predicting successful tapering. However, these results have not yet been systematically summarised.
**Objectives:** To systematically review studies that address prediction of successful dose reduction or discontinuation of biologics in RA patients.
**Methods:** A literature search was performed in PubMed, EMBASE and Cochrane Library (November 2015). Clinical (un)controlled trials were included if they investigated the predictive value of clinical patient characteristics, biochemical tests or imaging measures assessed prior to protocolised dose reduction or discontinuation of a biologic (abatacept, adalimumab, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab) in RA patients with a low disease activity state. Two review authors independently selected studies, extracted data and assessed risk of bias. Qualitative best-evidence synthesis was separately performed for the prediction of successful dose reduction and successful discontinuation. A biomarker was classified as potential predictor if the univariate association was either strong (odds ratio (OR) or hazard ratio (HR) $>$2.0 or $<$0.5) and/or significant ($p<0.05$). If no univariate OR or HR was provided, other univariate association measures, multivariate results or textual conclusions were used. Potential predictors that were studied multiple times and were consistently ($\geq$75% of findings in same direction) associated with successful dose reduction or discontinuation of a biologic were regarded as predictors.
**Results:** Out of 3029 non-duplicate articles, 16 articles on 15 cohorts were included. A total of 17/55 and 33/65 biomarkers were studied in more than one cohort for the prediction of successful dose reduction and successful discontinuation of a biologic. Three predictors were identified: higher adalimumab trough level for successful dose reduction; and lower Sharp/van der Heijde erosion score and shorter symptom duration at the start of a biologic for successful discontinuation. Noteworthy, all three biomarkers were only studied twice, meaning that more frequently investigated biomarkers yielded no consistent predictors. In addition, 13/38 and 8/32 biomarkers studied in only one cohort were classified as potential predictor for successful dose reduction and discontinuation, respectively.
**Conclusions:** The predictive value of a wide variety of biomarkers for successful dose reduction or discontinuation of a biologic has been investigated, but we have found only three biomarkers that were predictive in just two studies. The strength of the evidence is limited by the low quality of included studies and the likelihood

of publication bias and multiple testing. Therefore, validation of the found potential predictors in well-designed predictive studies is needed.
**Disclosure of Interest:** None declared

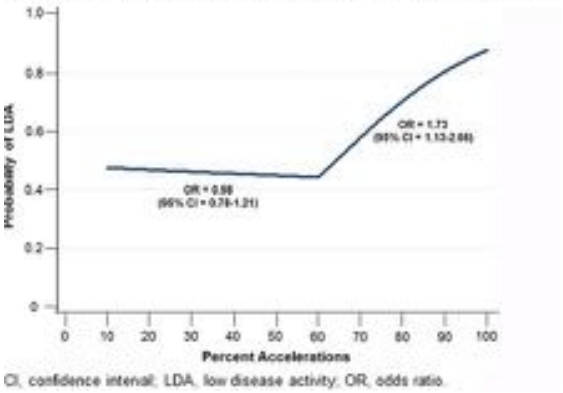
## THU0059 TRENDS IN THE ACHIEVEMENT OF LOW DISEASE ACTIVITY AMONG A US NATIONAL SAMPLE OF RHEUMATOID ARTHRITIS PATIENTS INITIATING BIOLOGICS

L.R. Harrold[1], J.L. Palmer[2], J.R. Curtis[3], J.D. Greenberg[4], D.A. Pappas[5], J.M. Kremer[6]. *[1]UMass Medical School, Worcester, MA; [2]Corrona Research Foundation, Albany, NY; [3]University of Alabama at Birmingham, Birmingham, AL; [4]NYU School of Medicine; [5]Columbia University, New York, NY; [6]Albany Medical College and The Center for Rheumatology, Albany, NY, United States*

**Background:** There is a growing emphasis on treating patients to a target level of low disease activity (LDA) or remission in order to improve outcomes associated with rheumatoid arthritis (RA).
**Objectives:** Our objective was to examine trends in the achievement of LDA over the past decade among RA patients receiving their first, second and third or more biologic agent.
**Methods:** Using the Corrona registry, we identified initiators of biologic therapy (stratified by prior experience: 1st, 2nd, ≥3rd) in distinct periods of calendar time over the last decade (2002–2004, 2005–2007, 2008–2010, 2011–2013) with moderate or high disease activity at the time of the initiation based on the Clinical Disease Activity Index (CDAI >10), and a follow-up CDAI measured at 1 year (±3 months). The primary outcome was achievement of LDA (CDAI ≤10) at 12 months. Trends over time between the groups were examined using Chi square tests. Multivariable logistic regression models were performed adjusting for baseline covariate.
**Results:** We identified 6,534 biologic initiators (1st: 2,769, 2nd: 2181, ≥3rd: 1584) who met inclusion criteria. Between 2011 and 2013, LDA occurred in 51%, 42% and 35% of those initiating their 1st, 2nd and ≥3rd biologic respectively. There was a significant trend over time in achievement of LDA in those initiating their first biologic. In adjusted models, treatment in the earlier time periods for those who initiated their 1st or ≥3rd biologic was associated with a reduced likelihood of achieving LDA (Table).

| Achievement of LDA | Year category | | | | P value for trend |
|---|---|---|---|---|---|
| | 2002–2004 | 2005–2007 | 2008–2010 | 2011–2013 | |
| 1st Biologic | N=282 | N=615 | N=684 | N=1188 | |
| Unadjusted (%) | 43 | 53 | 58 | 51 | 0.0003 |
| Adjusted* OR (95% CI) | 0.68 (0.51–0.90) | 0.93 (0.75–1.15) | 1.21 (0.99–1.49) | 1 | |
| 2nd Biologic | N=127 | N=419 | N=657 | N=978 | |
| Unadjusted (%) | 40 | 38 | 42 | 42 | 0.55 |
| Adjusted* OR (95% CI) | 0.85 (0.50–1.43) | 0.84 (0.65–1.09) | 1.00 (0.81–1.25) | 1 | |
| ≥3rd Biologic | N=55 | N=170 | N=460 | N=899 | |
| Unadjusted (%) | 20 | 32 | 37 | 35 | 0.09 |
| Adjusted* OR (95% CI) | 0.44 (0.22–0.89) | 0.95 (0.66–1.37) | 1.13 (0.88–1.44) | 1 | |

*Adjusted for age, gender, body mass index, disease duration, baseline CDAI, patient pain, functional status and insurance.



**Conclusions:** In the latest time period, achievement of LDA was influenced by biologic experience (50% in 1st biologic vs. 35% ≥3rd biologic initiation). Patients who initiated their 1st or ≥3rd biologic in earlier time periods had a reduced likelihood of achieving LDA (Table). Additional investigation is needed to understand the factors contributing to the trend in improved disease as well as the barriers in order to inform efforts to further increase the proportion of patients who achieve LDA.

## THU0060 THE RELATIONSHIP BETWEEN ADHERENCE TO A TREAT-TO-TARGET APPROACH FOR CLINICAL CARE OF US PATIENTS WITH RHEUMATOID ARTHRITIS AND ACHIEVEMENT OF LOW DISEASE ACTIVITY

L.R. Harrold[1,2], G.W. Reed[1,2], A. John[3], C.J. Barr[2], K.C. Saunders[2], K. Soe[2], R. Magner[1], J.D. Greenberg[2,4], J.M. Kremer[2,5]. *[1]University of Massachusetts Medical School, Worcester; [2]Corrona, LLC, Southborough; [3]Genentech, Inc, South San Francisco; [4]NYU School of Medicine, New York; [5]Albany Medical College and The Center for Rheumatology, Albany, United States*

**Background:** Little is known about the relationship between adherence to the treat-to-target (T2T) paradigm and clinical outcomes in US patients with rheumatoid arthritis (RA).
**Objectives:** To evaluate the relationship between adherence to T2T care and achievement of low disease activity (LDA) using a post hoc analysis of a cluster-randomized behavioral intervention trial evaluating a T2T implementation approach vs usual care (UC) in patients with RA.
**Methods:** Twenty-eight rheumatology practices from the Corrona network recruited patients with RA between July 29, 2011, and July 30, 2013. Eligible patients with moderate or high disease activity (Clinical Disease Activity Index [CDAI >10]) were followed for 12 months. Regardless of randomization in the trial (T2T vs UC), sites were categorized based on rate of acceleration (e.g., initiation or dose increase of cDMARD or biologic at visits with CDAI >10 and no treatment acceleration in the prior 3 months). Sites that accelerated therapy at ≥60% of eligible visits (top tertile) were considered high acceleration (HA) sites; sites with <60% acceleration rates were deemed low acceleration (LA) sites. The primary endpoint was achievement of LDA (CDAI ≤10) at 12 months. Baseline characteristics of the groups were compared using standardized differences. An intent-to-treat analysis was performed with logistic regression models adjusting for clustering by site and covariates associated with |standardized differences| >0.10.
As a sensitivity analysis, logistic regression models were fitted using acceleration rates as a linear association. The first model was as a continuous covariate (1 unit representing a 10% change in acceleration). The second model allowed for a threshold effect and used a linear spline with a knot at 60% acceleration.
**Results:** Overall, there were 10 HA sites (195 patients) and 18 LA sites (337 patients). The groups were similar in terms of sex, race, ethnicity and baseline disease activity. However, HA site patients were younger (mean age, 56 vs 58 years) and had shorter disease duration (mean, 6 vs 9 years). Over the study period, 17% of HA site patients (34/195) and 18% of LA site patients (62/337) dropped out ($P$=0.832). The rates of achievement of LDA at the last visit were 60.5% in the HA group vs 52.5% in the LA group (odds ratio [OR] 1.78; 95% CI 0.96–3.27) in multivariable models adjusting for demographics and disease characteristics. In the sensitivity analyses, use of acceleration rate as a continuous covariate was associated with an OR of 1.15 (95% CI 0.99–1.24). In the model with the spline (Figure), acceleration rates <60% were associated with an OR of 0.98 (95% CI 0.78–1.21), while rates ≥60% had an OR of 1.73 (95% CI 1.13–2.66).

**Figure.** Association of treatment acceleration rate with the probability of achieving LDA

CI, confidence interval; LDA, low disease activity; OR, odds ratio

**Conclusions:** Increased site adherence to a T2T approach was associated with a greater likelihood of achieving LDA. Evidence suggests there may be a threshold effect, indicating a lack of benefit with inconsistent adherence to the T2T approach.

## THU0061 PATIENTS' PERCEPTIONS OF RISK, RISK COMMUNICATION AND PREDICTIVE TESTING FOR RHEUMATOID ARTHRITIS

M. Falahee[1], G. Simons[1], R.J. Stack[1,2], K. Raza[1]. *[1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham; [2]School of Social Sciences, Nottingham Trent University, Nottingham, United Kingdom*

**Background:** Early treatment of rheumatoid arthritis (RA) is associated with improved clinical outcomes. There is a growing research interest in the identification of biomarkers to predict the development of RA in order to facilitate early treatment and preventive interventions. First degree relatives of individuals with a diagnosis of RA are at an increased risk of developing RA and are therefore likely candidates for predictive/preventive approaches. However access to this group is currently dependent on the cooperation of existing RA patients.
**Objectives:** To understand patients' perceptions of risk and predictive testing for RA, and their likelihood of communicating with their relatives about the risk of developing RA in the future.
**Methods:** Twenty-one RA patients (15 females and 6 males; aged 35 – 80 years) took part in semi-structured interviews. The interviews explored perceptions of risk of RA, family communication about risk, predictive testing, and risk reduction strategies. Interviews were audio-recorded, transcribed verbatim and analysed using thematic analysis.
**Results:** Many patients were aware of genetic risk factors for RA and identified one or more relatives who they felt were at risk of developing RA in the future. Some patients described feelings of responsibility or guilt for their relatives' increased risk of developing RA. Environmental risk factors such as infection and psychosocial stress were also suggested, though few patients mentioned that smoking is associated with an elevated risk of RA. Patients described a lack of public awareness about RA and the causes of RA. They also referred to a lack of understanding, by their relatives as well as by the general public, of the negative impact that this condition has on their quality of life.
Many patients held positive views of predictive testing for RA and were of the opinion that prediction would typically be associated with timely and positive preventive intervention. Those with negative views attributed these to their uncertainty about the accuracy of predictive tests, the availability of approaches (including therapeutic ones) to reduce RA risk and the potential for risk knowledge to cause unnecessary worry.
Patients generally expressed willingness to communicate with their relatives about their risk of RA. However many patients identified relatives that they were not in contact with, or communicated with infrequently. Some mentioned that they would not pass on information to particular relatives who they did not get on with. Patients referred to choosing which relatives to communicate with, and described likely variation amongst relatives in their receptivity to risk information, and their likelihood of acting on such information. Reasons suggested for this included relatives being too busy, being in denial of their susceptibility, preferring to deal with things when they happen, being likely to worry, and feeling that RA is not serious enough to warrant action.
**Conclusions:** Accurate information about risk factors for RA, and the potential impact of RA on quality of life, is needed to support family communication about RA risk. Strategies for the management of RA that target relatives of existing patients need to take into account that communication of risk information via patients is likely to be restricted and/or selective.

## THU0062 PROGNOSIS OF EARLY RHEUMATOID ARTHRITIS PATIENTS WITH EROSIVE DISEASE AT BASELINE

N. Konijn[1], L. van Tuyl[1], M. Boers[1,2], D. den Uijl[1], M. ter Wee[1,2], P. Kerstens[3,4], A. Voskuyl[1], D. van Schaardenburg[4,5], M. Nurmohamed[1,4], W. Lems[1,4]. *[1]Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical Center; [2]Epidemiology & Biostatistics, VU University Medical Center, Amsterdam; [3]Rheumatology, Westfriesgasthuis, Hoorn; [4]Rheumatology, Amsterdam Rheumatology and immunology Center, Reade; [5]Rheumatology, Amsterdam Rheumatology and immunology Center, Academic Medical Center, Amsterdam, Netherlands*

**Background:** In 2013, a new EULAR definition of erosive disease for use in the 2010 ACR/EULAR rheumatoid arthritis (RA) classification criteria was published [1]. We were interested in the characteristics of early RA patients with erosive disease according to this new definition, including their propensity to reach ACR/EULAR Boolean remission [2].
**Objectives:** To characterize the clinical course of early RA patients with erosive disease participating in a clinical trial, at baseline and after a 4-year follow-up period.
**Methods:** The presence of erosive disease was assessed at the baseline visit of early RA patients who were treated in the context of the COBRA-light trial [3,4]. After 52 weeks, treatment was continued without protocol. Erosive disease was defined as: "an erosion (defined as a cortical break) seen in at least three separate joints at any of the following sites: the proximal interphalangeal, the metacarpophalangeal, the wrist (counted as one joint) and the metatarsophalangeal joints on radiographs of both hands and feet" [1]. Radiographs were scored by two independent trained assessors according to the Sharp/van der Heijde (SHS) method. ACR/EULAR Boolean remission was assessed at 3, 6, 9 months; and 1, 1.5, 2 and 4 years after trial initiation.
**Results:** Only 8 (5%) of the 162 trial patients had erosive disease at baseline; these were somewhat older than patients without erosive disease at baseline (p=0.10). No differences in rheumatoid factor and ACPA status were found between erosive and non-erosive patients at baseline. After the 52 weeks trial period, 43% COBRA vs. 42% COBRA-light patients used prednisolone for ≥90 days, 34% vs. 44% patients switched to other DMARDs, and 39% vs. 28% used biologicals during the follow-up period. After a mean follow-up period of 4 years (data of 149 patients available), patients with erosive disease reported significantly higher disease activity (p=0.04) and pain (p=0.03) than patients without erosive disease, and a trend for more functional limitations (p=0.05) (Table 1). Likewise, the physician reported significantly higher disease activity (p=0.03); and both the SHS at 4 year (p<0.01) as well as SHS progression since baseline were higher for patients with erosive disease than patients without erosive disease (p=0.09). None of the erosive patients reached Boolean remission at any visit during the 4-year follow up-period, whereas 45% of the non-erosive patients did (p=0.01).

Table 1. Characteristics of RA patients with and without erosive disease

| | Baseline visit (n=162) | | 4 year visit (n=149) | |
|---|---|---|---|---|
| | Erosive (n=8) | Not erosive (n=154) | Erosive (n=8) | Not erosive (n=141) |
| Female, n (%) | 3 (38) | 107 (70) | 3 (38) | 97 (69) |
| Age in years | 59 (11) | 52 (13)* | 64 (11) | 56 (12)* |
| DAS | 4.5 [3.5;4.8] | 4.0 [3.4;4.4] | 2.1 [1.2;2.5] | 1.5 [1.0;2.3] |
| Tender joint count in 53 joints | 19 [16;22] | 14 [9;19] | 4 [0;10] | 2 [0;7] |
| Swollen joint count in 44 joints | 14 [9;19] | 12 [9;16] | 0 [0;2] | 1 [0;3] |
| HAQ | 1.5 [1.3;2.3] | 1.3 [0.9;1.6] | 1.1 [0.5;2.0] | 0.5 [0;1.1]* |
| Change in HAQ (Δ baseline - 4 year) | - | - | -0.5 [-1.2;0.2] | -0.6 [-1.1;-0.2] |
| SHS | 17 [14;21] | 0 [0;14]* | 19 [15;35] | 1.0 [0;3.5]* |
| SHS progression (Δ baseline - 4 year) | - | - | 2.0 [0.5;18.5] | 0.5 [0;2.3]* |
| CRP in mg/l | 22 [5;63] | 13 [4;37] | 4 [2;6] | 3 [2;5] |
| Patient assessment of disease activity | 64 [43;80] | 66 [50;79] | 33 [17;67] | 14 [4;37]* |
| Patient assessment of pain | 72 [23;87] | 62 [41;77] | 42 [26;59] | 18 [5;43]* |
| Patient global assessment | 63 [23;94] | 66 [45;76] | 38 [32;55] | 22 [7;51]* |
| Physician assessment of disease activity | 52 [45;63] | 48 [40;60] | 41 [21;51] | 18 [7;39]* |

* Significant difference between patients with erosive vs. non-erosive disease (p<0.05)
† Trend for significant difference between patients with erosive vs. non-erosive disease (p<0.10)

**Conclusions:** In this exploratory study of early RA, erosive disease at baseline appeared to be rare. However, such disease is associated with a poor prognosis: more active disease, no remission, and worse 4-year outcomes despite a treat-to-target regime aimed at clinical remission.

## THU0063 OUTCOMES OF TREAT-TO-TARGET STRATEGY IN ESTABLISHED RHEUMATOID ARTHRITIS: A LONG-TERM PROSPECTIVE COHORT STUDY

N.P.B.D. Andrade, R.M.D.S. Chakr, R.M. Xavier, D. Viecceli, R. Correa, C.M. Oliveira Filho, C.V. Brenol. *Rheumatology Department, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

**Background:** Treating rheumatoid arthritis (RA) to a target has become a landmark strategy to be pursued in every patient. Compared to usual care, treat to target (T2T) has decreased radiographic progression and improved quality of life and physical function[1]. Nonetheless, few studies have addressed the true long-term impact of a T2T strategy in a real-world setting with established RA patients[2,3].
**Objectives:** To examine the long-term effectiveness of a treat-to-target strategy in patients with established rheumatoid arthritis in daily practice.
**Methods:** Rheumatoid arthritis patients previously treated under usual care condition were started on a T2T strategy between March 2005 and February 2007 and followed through December 2014. Participants were seen every 3 months until remission/low disease activity was reached and every 6 months afterwards. After DMARD change, participants were assessed monthly for three consecutive months. Treatment escalation followed a step-up strategy, according

to national recommendations. Disease activity was measured by DAS28 and CDAI, and physical function by HAQ. Data were extracted by standardized chart and research forms review. Change in disease activity and physical function was compared using Wilcoxon's test and Generalized estimate equations.

**Results:** Significant improvements were seen in both composite scores during follow-up period. There was a significant reduction in DAS28 (4.6±0.1 vs. 3.1±0.1; $p<0.001$) and in CDAI (21.2±1.0 vs. 7.9±0.7; $p<0.001$). Physical function also improved, as demonstrated by reduction in HAQ-DI (1.3±0.05 vs 1.0±0.1; $p<0.001$). The reduction in DAS28, CDAI and HAQ-DI was nonlinear. The percentage of participants in remission increased significantly from 11% to 35% by DAS28 and from 6% to 19% by CDAI ($p<0.001$). Likewise, there was an improvement in LDA from 10% to 28% by DAS28 and from 22% to 52% by CDAI ($p\leq0.001$). At the end of follow up, 62% of the cohort achieved the target by DAS28 and 71% by CDAI. As well as 30% of participants reached HAQ$\leq$0.5 and DAS$\leq$3.2.

**Conclusions:** Treat-to-target strategy aiming for remission or low activity disease is effective in patients with established RA. The access to biologic DMARDs might have contributed to achieve disease activity control in a substantial proportion of the patients.

## THU0064 SHORT AND SUSTAINED PERIODS OF ACR/EULAR REMISSION PREDICT GOOD FUNCTIONAL OUTCOME, BUT NOT STABLE RADIOGRAPHIC OUTCOME IN EARLY RHEUMATOID ARTHRITIS

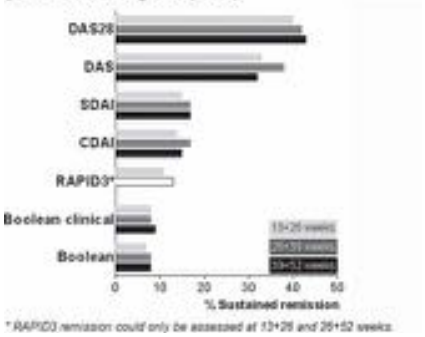
N. Konijn[1], L. van Tuyl[1], M. Boers[1,2], D. Den Uijl[1], M. ter Wee[1,2], P. Kerstens[3,4], A. Voskuyl[1], D. van Schaardenburg[3,5], M. Nurmohamed[1,3], W. Lems[1,3].

*[1]Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical Center; [2]Epidemiology & Biostatistics, VU University Medical Center; [3]Rheumatology, Amsterdam Rheumatology and immunology Center, Reade, Amsterdam; [4]Rheumatology, Westfriesgasthuis, Hoorn; [5]Rheumatology, Amsterdam Rheumatology and immunology Center, Academic Medical Center, Amsterdam, Netherlands*

**Background:** The ACR/EULAR remission criteria were validated against their potential to predict future prognosis of rheumatoid arthritis (RA) [1]. Sustained remission was not studied, but is likely to be an even stronger predictor of RA prognosis. Furthermore, the patients in the validation study mainly had established RA, whereas results might be different for early RA patients.

**Objectives:** To investigate whether remission at single and consecutive visits predicts good outcome in early RA.

**Methods:** The presence of remission according to ACR/EULAR and other criteria (Boolean clinical, CDAI, DAS, DAS28, RAPID3) was assessed in early RA patients during the first year of the COBRA-light trial [2,3]. Likelihood ratios were used to assess whether meeting the remission criteria at single visits (13, 26, 39 or 52 weeks) and consecutive visits (13+26, 26+39 or 39+52 weeks) predicted good outcome in the second year (52–104 weeks). Good outcome was defined for function (HAQ consistently $\leq$0.5 and no deterioration), radiographic damage progression (no deterioration in Sharp-Van der Heijde scores) and both ("overall good outcome").



**Results:** Of the original 164 trial patients, 144 had evaluable data. In the second year, good functional outcome was observed in 35%, good radiographic outcome in 79%, and both in 28% of the patients. Highest sustained remission rates at 13+26, 26+39, and 39+52 weeks were observed for DAS28, followed by DAS, SDAI, CDAI, RAPID3, Boolean clinical and Boolean criteria (Figure 1). Almost all criteria predicted good functional and good overall outcome, at both single and consecutive visits; only single DAS remission did not significantly predict good overall outcome (p=0.07). Sustained remission periods resulted in higher likelihood ratios than remission at single visits (Table 1). None of the criteria predicted good radiographic outcome.

Table 1. Predictive value of remission at single and consecutive visits (n=144)

| | LR+ of remission at single visits | | | LR+ of remission at consecutive visits | | |
|---|---|---|---|---|---|---|
| | Good functional outcome | Good radiographic outcome | Good overall outcome | Good functional outcome | Good radiographic outcome | Good overall outcome |
| Boolean | 3.6* | 1.3 | 2.8* | 29.2* | 0.6 | 4.8* |
| Boolean clinical | 3.3* | 1.2 | 2.6* | 31.0* | 0.7 | 5.2* |
| CDAI | 2.3* | 1.2 | 2.0* | 6.8* | 0.8 | 3.1* |
| SDAI | 2.3* | 1.3 | 2.1* | 7.0* | 0.7 | 3.3* |
| DAS | 1.4* | 1.0 | 1.2* | 2.4* | 1.0 | 2.1* |
| DAS28 | 1.4* | 1.1 | 1.3* | 1.8* | 1.3 | 1.8* |
| RAPID3† | 3.5* | 0.9 | 2.7* | 12.8* | 1.0 | 5.2* |

*Indicates significant predictor ($p<0.05$); †RAPID3 remission could only be assessed at 13, 26 and 52 weeks, not at week 39; LR+ = Positive likelihood ratio.

Figure 1. Sustained remission in early RA patients during the first year of the COBRA-light trial (n=144)

* RAPID3 remission could only be assessed at 13+26 and 26+52 weeks.

**Conclusions:** Early RA patients who reach remission according to ACR/EULAR and other criteria during short or sustained periods are likely to retain good physical function in the subsequent months. Sustained remission periods are a stronger predictor than remission at single visits. However, in the setting of low overall damage progression, (sustained) remission was not predictive of good radiographic outcome.

## THU0065 POTENTIAL PREDICTORS FOR ACHIEVING AND/OR MAINTAINING LOW DISEASE ACTIVITY OR REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Akkoc[1], C.A. Zerbini[2], D. Karateev[3], R. Pedersen[4], B. Vlahos[4], L. Marshall[4], C. Bao[5], M. Al-Maini[6], Q. Shen[4]. *[1]Dokuz Eylül University, Izmir, Turkey; [2]Centro Paulista de Investigacao Clinica, Sao Paulo, Brazil; [3]Institute of Rheumatology, Moscow, Russian Federation; [4]Pfizer, Collegeville, United States; [5]Ren Ji Hospital, Shanghai, China; [6]Mafraq Hospital, Abu Dhabi, United Arab Emirates*

**Background:** Treatment with tumor necrosis factor inhibitors (TNFi) such as etanercept (ETN) is effective in patients with rheumatoid arthritis (RA). However, not all patients respond to treatment. Physicians would be able to better provide the best treatment to their patients if there were criteria that identified potential good responders to TNFi therapy.

**Objectives:** To evaluate criteria at baseline for their predictive value for (1) initial response to ETN treatment at week 24, and (2) for maintaining low disease activity (LDA) or remission at week 52 using data from the T2T trial (NCT01981473).

**Methods:** Patients with moderate-to-severe RA were treated with 50 mg ETN (ETN50) on a background of methotrexate ± disease-modifying anti-rheumatic drugs (DMARDs) for 24 weeks (open-label, Period 1 (P1)). Patients achieving LDA (Disease Activity Score-28 joints (DAS28)–erythrocyte sedimentation rate (ESR)<3.2) at week 24 were randomized to continue ETN50 or switched to placebo (PBO) for another 28 weeks (Period 2 (P2)). Baseline variables were analyzed for the probability of patients achieving DAS28-ESR or Clinical Disease Activity Index (CDAI) LDA (<3.2) at the end of P1 and to determine whether patients in remission maintained it at the end of P2. All data were evaluated using logistic regression analysis.

**Results:** Evaluable data were available for 473 of the 491 patients enrolled in P1. After 24 weeks of ETN treatment (end of P1), only being female (p=0.031) and using DMARDs (p=0.029) were predictive of patients being able to achieve DAS28-ESR LDA (<3.2). Younger patients and patients with lower DAS28-ESR, ESR, and Health Assessment Questionnaire–Disability Index (HAQ-DI) showed a statistically significant greater probability to achieve remission (DAS28-ESR<2.6) at the end of P1. Patients with lower DAS28-ESR, DAS28-C-reactive protein (CRP), CDAI, Simplified Disease Activity Index (SDAI), HAQ-DI, and shorter time to LDA in P1 at week 24 prior to entering P2 showed a statistically significant greater probability to maintain DAS28-ESR LDA or remission at week 52 for both patients who continued on ETN or were switched to PBO during P2. Younger patients (p=0.006) and patients with shorter disease duration (p=0.008) showed

a statistically greater probability to achieve CDAI remission at week 24. Lower DAS28-ESR, DAS28-CRP, CDAI, SDAI, HAQ-DI, and shorter time to LDA in P1 at week 24 prior to entering P2 showed a statistically significant greater probability to maintain CDAI LDA or remission at week 52 for both patients who continued on ETN or were switched to PBO during P2. The proportion of patients who maintained LDA or remission was consistently greater in the ETN arm compared with the PBO arm. None of the other baseline variables were predictive of patients being able to achieve LDA or remission.

**Conclusions:** In this post-hoc analysis, younger patients and patients with lower disease activity at baseline or shorter time to achieve LDA were more likely to achieve and maintain LDA or remission.

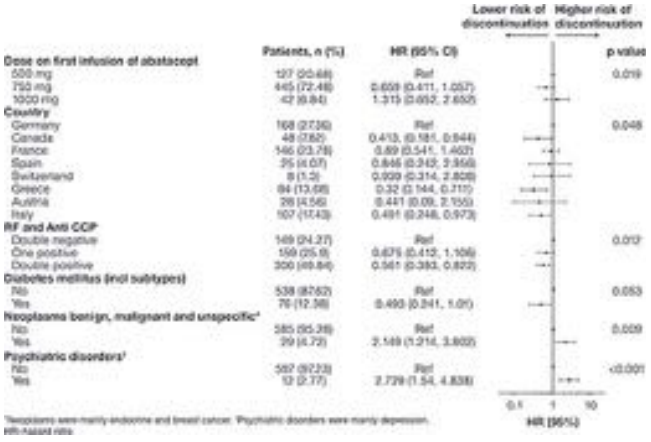
## THU0066 DO PREDICTORS OF IV ABATACEPT RETENTION DEPEND ON THE LINE OF RHEUMATOID ARTHRITIS TREATMENT: 12-MONTH INTERIM ANALYSIS OF THE OBSERVATIONAL, PROSPECTIVE ACTION STUDY



R. Alten[1], H. Nüßlein[2], M. Galeazzi[3], H.M. Lorenz[4], X. Mariette[5], A. Cantagrel[6], M. Chartier[7], Y. Elbez[8], C. Rauch[9], M. Le Bars[10].
*[1]Schlosspark-Klinik University Medicine, Berlin; [2]University of Erlangen-Nuremberg, Nuremberg, Germany; [3]University of Siena, Siena, Italy; [4]University Hospital, Heidelberg, Germany; [5]Université Paris-Sud, Paris; [6]Hôpital Purpan, Toulouse; [7]Chiltern International, Neuilly; [8]Excelya, Boulogne-Billancourt, France; [9]Bristol-Myers Squibb, Munich, Germany; [10]Bristol-Myers Squibb, Rueil-Malmaison, France*

**Background:** ACTION (NCT02109666) is an ongoing study to provide prospective, real-world data on IV abatacept (ABA) retention in RA. Prognostic factors for IV ABA retention were previously identified in a 12-month interim analysis of patients (pts) enrolled May 2008–Jan 2011 who failed ≥1 prior biologic DMARD.[1]

**Objectives:** To compare rates and identify predictors of IV ABA retention by treatment line (biologic naïve vs biologic failure) in a 12-month interim analysis.

**Methods:** ACTION is a 2-year, observational study of pts with moderate-to-severe RA who initiated IV ABA in Europe and Canada. Enrolment periods: May 2008–Dec 2010 (biologic naïve/failed prior biologics); Sept 2010–Dec 2013 (biologic naïve); Oct 2011–Dec 2013 (failed prior biologics). Data cut-off was May 2015. Crude retention rates were estimated by Kaplan–Meier analysis and compared using a log-rank test. Known risk factors and factors with significance in univariate models ($p \leq 0.20$) and no collinearity were entered into a multivariate Cox proportional hazards regression model. Factors with $p \leq 0.10$ after backward selection were retained. Efficacy assessments at 12 months included EULAR response and DAS28 (CRP) score.
